### Example

```
NOC-NX9500(config-profile-testNX9000)#critical-resource test monitor direct any
19.234.160.5 arp-only vlan 1
```

```

NOC-NX9500(config-profile-testNX9000)#show context include-factory | include cri
tical-resource
critical-resource monitor interval 30
service critical-resource port-mode-source-ip 0.0.0.0
critical-resource test monitor direct any 19.234.160.5 arp-only vlan 1
critical-resource retry-count 3
NOC-NX9500(config-profile-testNX9000)#

```

## crypto

[Profile Config Commands](#) on page 862

Use the `crypto` command to define a system-level local ID for Internet Security Association and Key Management Protocol (ISAKMP) negotiation and to enter the ISAKMP policy, ISAKMP client, or ISAKMP peer command set.

The following table summarizes `crypto` configuration mode commands:

| Command                                                        | Description                                                                      |
|----------------------------------------------------------------|----------------------------------------------------------------------------------|
| <a href="#">crypto</a> on page 931                             | Invokes commands used to configure ISAKMP policy, ISAKMP client, and ISAKMP peer |
| <a href="#">crypto-auto-ipsec-tunnel commands</a> on page 937  | Creates an auto IPsec VPN tunnel and enters its configuration mode               |
| <a href="#">crypto-ikev1/ikev2-policy commands</a> on page 943 | Creates a crypto IKEv1/IKEv2 policy and enters its configuration mode            |
| <a href="#">crypto-ikev1/ikev2-peer commands</a> on page 949   | Creates a IKEv1/IKEv2 peer and enters its configuration mode                     |
| <a href="#">crypto-map-config-commands</a> on page 955         | Creates a crypto map and enters its configuration mode                           |
| <a href="#">crypto-remote-vpn-client commands</a> on page 974  | Creates a remote VPN client and enters its configuration mode                    |

## crypto

[crypto](#) on page 931

Use the `crypto` command to define a system-level local ID for ISAKMP negotiation and enter the ISAKMP policy, ISAKMP client, or ISAKMP peer configuration mode.

A crypto map entry is a single policy that describes how certain traffic is secured. There are two types of crypto map entries: `ipsec-manual` and `ipsec-ike` entries. Each entry is given an index (used to sort the ordered list).

When a non-secured packet arrives on an interface, the crypto map associated with that interface is processed (in order). If a crypto map entry matches the non-secured traffic, the traffic is discarded.

When a packet is transmitted on an interface, the crypto map associated with that interface is processed. The first crypto map entry that matches the packet is used to secure the packet. If a suitable

Security Association (SA) exists, it is used for transmission. Otherwise, IKE is used to establish a SA with the peer. If no SA exists (and the crypto map entry is “respond only”), the packet is discarded.

When a secured packet arrives on an interface, its Security Parameter Index (SPI) is used to look up a SA. If a SA does not exist (or if the packet fails any of the security checks), it is discarded. If all checks pass, the packet is forwarded normally.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

```
crypto [auto-ipsec-secure|enable-ike-uniqueids|ike-version|ikev1|ikev2|ipsec|load-management|map|pki|plain-text-deny-acl-scope|remote-vpn-client]
```

```
crypto [auto-ipsec-secure|enable-ike-uniqueids|load-management]
```

```
crypto ike-version [ikev1-only|ikev2-only]
```

```
crypto ikev1 [dpd-keepalive <10-3600>|dpd-retries <1-100>|nat-keepalive <10-3600>|peer <IKEV1-PEER>|policy <IKEV1-POLICY-NAME>|remote-vpn]
```

```
crypto ikev2 [cookie-challenge-threshold <1-100>|dpd-keepalive <10-3600>|dpd-retries <1-100>|nat-keepalive <10-3600>|peer <IKEV2-PEER>|policy <IKEV2-POLICY-NAME>|remote-vpn]
```

```
crypto ipsec [df-bit|security-association|transform-set]
```

```
crypto ipsec df-bit [clear|copy|set]
```

```
crypto ipsec security-association lifetime [kilobytes <500-2147483646>|seconds <120-86400>]
```

```
crypto ipsec transform-set <TRANSFORM-SET-TAG> [esp-3des|esp-aes|esp-aes-192|esp-aes-256|esp-des|esp-null] [esp-aes-xcbc-mac|esp-md5-hmac|esp-sha-hmac|esp-sha256-hmac]
```

```
crypto map <CRYPTO-MAP-TAG> <1-1000> [ipsec-isakmp {dynamic}|ipsec-manual]
```

```
crypto pki import crl <TRUSTPOINT-NAME> URL <1-168>
```

```
crypto plain-text-deny-acl-scope [global|interface]
```

```
crypto remote-vpn-client
```

Parameters

```
crypto [auto-ipsec-secure|enable-ike-uniqueids|load-management]
```

|                             |                                                                                                                                                                       |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>auto-ipsec-secure</b>    | Configures the Auto IPsec Secure parameter settings. For Auto IPsec tunnel configuration commands, see <a href="#">crypto-auto-ipsec-tunnel commands</a> on page 937. |
| <b>enable-ike-uniqueids</b> | Enables Internet Key Exchange (IKE) unique ID check. For more information on IKE unique IDs, see <a href="#">remotegw</a> on page 941.                                |
| <b>load-management</b>      | Configures load management for platforms using software cryptography                                                                                                  |

```
crypto ike-version [ikev1-only|ikev2-only]
```

|                                                      |                                                                                                                                                                                                      |
|------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ike-version</b><br><b>[ikev1-only ikev2-only]</b> | Selects and starts the IKE daemon <ul style="list-style-type: none"> <li>ikev1-only – Enables support for IKEv1 tunnels only</li> <li>ikev2-only – Enables support for IKEv2 tunnels only</li> </ul> |
|------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
crypto ikev1 [dpd-keepalive <10-3600>|dpd-retries <1-100>|nat-keepalive <10-3600>|peer <IKEV1-PEER>|policy <IKEV1-POLICY-NAME>|remote-vpn]
```

|                                         |                                                                                                                                                                                                                                                                                       |
|-----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ikev1</b>                            | Configures the IKE version 1 parameters                                                                                                                                                                                                                                               |
| <b>dpd-keepalive &lt;10-3600&gt;</b>    | Sets the global Dead Peer Detection (DPD) keep alive interval from 10 - 3600 seconds. This is the interval between successive IKE keep alive messages sent to detect if a peer is dead or alive. The default is 30 seconds.                                                           |
| <b>dpd-retries &lt;1-1000&gt;</b>       | Sets the global DPD retries count from 1 - 1000. This is the number of keep alive messages sent to a peer before the tunnel connection is declared as dead. The default is 5.                                                                                                         |
| <b>nat-keepalive &lt;10-3600&gt;</b>    | Sets the global NAT keep alive interval from 10 - 3600 seconds. This is the interval between successive NAT keep alive messages sent to detect if a peer is dead or alive. The default is 20 seconds.                                                                                 |
| <b>peer &lt;IKEV1-PEER&gt;</b>          | Specify the name/Identifier for the IKEv1 peer. For IKEv1 peer configuration commands, see <a href="#">crypto-ikev1/ikev2-peer commands</a> on page 949.                                                                                                                              |
| <b>policy &lt;IKEV1-POLICY-NAME&gt;</b> | Configures an ISKAMP policy. Specify the name of the policy. The local IKE policy and the peer IKE policy must have matching group settings for successful negotiations. For IKEv1 policy configuration commands, see <a href="#">crypto-ikev1/ikev2-policy commands</a> on page 943. |
| <b>remote-vpn</b>                       | Specifies the IKEv1 remote-VPN server configuration (responder only)                                                                                                                                                                                                                  |

```
crypto ikev2 [cookie-challenge-threshold <1-100>|dpd-keepalive <10-3600>|dpd-retries <1-100>|nat-keepalive <10-3600>|peer <IKEV2-PEER>|policy <IKEV2-POLICY-NAME>|remote-vpn]
```

|                                                 |                                                                                                                                                            |
|-------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ikev2</b>                                    | Configures the IKE version 2 parameters                                                                                                                    |
| <b>cookie-challenge-threshold &lt;1-100&gt;</b> | Starts the cookie challenge mechanism after the number of half open IKE SAs exceeds the specified limit. Specify the limit from 1 - 100. The default is 5. |
| <b>dpd-keepalive &lt;10-3600&gt;</b>            | Sets the global DPD keepalive interval from 10 - 3600 seconds. The default is 30 seconds.                                                                  |
| <b>dpd-retries &lt;1-100&gt;</b>                | Sets the global DPD retries count from 1 - 100. The default is 5.                                                                                          |

|                                                |                                                                                                                                                                   |
|------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nat-keepalive</b><br><b>&lt;10-3600&gt;</b> | Sets the global NAT keepalive interval from 10 - 3600 seconds. The default is 20 seconds.                                                                         |
| <b>peer &lt;IKEV2-PEER&gt;</b>                 | Specify the name/Identifier for the IKEv2 peer                                                                                                                    |
| <b>policy &lt;IKEV2-POLICY-NAME&gt;</b>        | Configures an ISKAMP policy. Specify the policy name. The local IKE policy and the peer IKE policy must have matching group settings for successful negotiations. |
| <b>remote-vpn</b>                              | Specifies an IKEv2 remote-VPN server configuration (responder only)                                                                                               |

crypto ipsec df-bit [clear|copy|set]

|                                |                                                                                                                                                                                                                                                                                                                                                                                           |

### crypto-auto-ipsec-tunnel commands

**crypto** on page 931

Creates an auto IPSec VPN tunnel and changes the mode to auto-ipsec-secure mode for further configuration

Auto IPSec tunneling provides a secure tunnel between two networked peer controllers or service platforms and associated access points that are within a range of valid IP addresses. You can define which packets are sent within the tunnel, and how they are protected. When a tunneled peer sees a sensitive packet, it creates a secure tunnel and sends the packet through the tunnel to its remote peer destination or associated access point.

Tunnels are sets of SA between two peers. SAs define the protocols and algorithms applied to sensitive packets and specify the keying mechanisms used by tunneled peers. SAs are unidirectional and exist in both the inbound and outbound direction. SAs are established per the rules and conditions of defined security protocols (AH or ESP).

The IKE protocol is a key management protocol used in conjunction with IPsec. IKE enhances IPsec by providing additional features, flexibility, and configuration simplicity for the IPsec standard. IKE enables secure communications without time consuming manual pre-configuration for auto IPsec tunneling.

```

nx9500-6C8809(config-profile-default-rfs4000)#crypto auto-ipsec-secure
nx9500-6C8809(config-profile-default-rfs4000-crypto-auto-ipsec-secure)#?

nx9500-6C8809(config-profile-default-rfs4000-crypto-auto-ipsec-secure)#

```

The following table summarizes the crypto IPsec auto tunnel configuration mode commands:

| Command                                  | Description                                                                                                  |
|------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| <a href="#">groupid</a> on page 938      | Specifies the identity string used for IKE authentication                                                    |
| <a href="#">ip</a> on page 939           | Enables the controller or service platform to uniquely identify APs and the hosts present in the AP's subnet |
| <a href="#">ike-lifetime</a> on page 940 | Configures the IKE SA's key lifetime in seconds                                                              |
| <a href="#">ikev2</a> on page 941        | Enables the forced re-authentication of IKEv2 peer                                                           |
| <a href="#">remotegw</a> on page 941     | Defines the IKE version used for an auto IPsec tunnel using secure gateways                                  |
| <a href="#">no</a> on page 942           | Removes or reverts the crypto auto IPsec tunnel settings                                                     |

groupid

[crypto-auto-ipsec-tunnel commands](#) on page 937

Specifies the identity string used for IKE authentication

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

```
groupid <WORD> [psk|rsa]
groupid <WORD> [psk [0 <WORD>|2 <WORD>|<WORD>]|rsa]
```

#### Parameters

```
groupid <WORD> [psk [0 <WORD>|2 <WORD>|<WORD>]|rsa]
```

|                                                              |                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>&lt;WORD&gt;</b>                                          | Specify a string not exceeding 64 characters. This is the group identity used for IKE exchange for auto IPsec secure peers. After providing a group ID, specify the authentication method used to authenticate peers on the auto IPsec secure tunnel. The options are: psk and rsa.                                                                             |
| <b>psk [0 &lt;WORD&gt;   2 &lt;WORD&gt;   &lt;WORD&gt; ]</b> | Configures the pre-shared key (PSK) as the authentication type for secure peer authentication on the auto IPsec secure tunnel <ul style="list-style-type: none"> <li>• 0 &lt;WORD&gt; - Configures a clear text key</li> <li>• 2 &lt;WORD&gt; - Configures an encrypted key</li> <li>• &lt;WORD&gt; - Specify a string value from 8 - 21 characters.</li> </ul> |
| <b>rsa</b>                                                   | Configures the Rivest-Shamir-Adleman (RSA) key. RSA is an algorithm for public key cryptography. It is the first algorithm known to be suitable for signing, as well as encryption. This is the default setting.                                                                                                                                                |

#### Note

Only one group ID is supported on the controller or service platform. All APs, controllers, and service platform must use the same group ID.

#### Example

```
nx9500-6C8809(config-profile-default-rfs4000-crypto-auto-ipsec-secure)#groupid
testgroup@123 rsa

nx9500-6C8809(config-profile-default-rfs4000-crypto-auto-ipsec-secure)#show context
crypto auto-ipsec-secure
groupid testgroup@123 rsa
nx9500-6C8809(config-profile-default-rfs4000-crypto-auto-ipsec-secure)#
```

ip

[crypto-auto-ipsec-tunnel commands](#) on page 937

Enables the controller to uniquely identify APs and the hosts present in the AP's subnet. This allows the controller to correctly identify the destination host and create a dynamic site-to-site VPN tunnel between the host and the private network behind the controller.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

## Syntax

`ip nat crypto`

## Parameters

`ip nat crypto`

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ip nat crypto</b> | Enables unique identification of APs and the hosts present in each AP's subnet. Providing a unique ID enables the access point, wireless controller, or service platform to uniquely identify the destination device. This is essential in networks where there are multiple APs behind a router, or when two (or more) APs behind two (or more) different routers have the same IP address. Further, the same subnet exists behind these APs. For example, let us consider a scenario where there are two APs (A and B) behind two routers (1 and 2). AP 'A' is behind router '1'. And AP 'B' is behind router '2'. Both these APs have the same IP address (192.168.13.8). The subnet behind APs A and B is also the same (100.1.1.0/24). In such a scenario the controller fails to uniquely identify the hosts present in either AP's subnet. For more information, see <a href="#">remotegw</a> on page 941 and <a href="#">crypto</a> on page 931. |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Example

```
rfs4000-229D58config-profile-testRFS4000-crypto-auto-ipsec-secure)#ip nat crypto

rfs4000-229D58config-profile-testRFS4000-crypto-auto-ipsec-secure)#show context
crypto auto-ipsec-secure
 remotegw ike-version ikev2 uniqueid
 ip nat crypto
rfs4000-229D58config-profile-testRFS4000-crypto-auto-ipsec-secure)#
```

ike-lifetime

[crypto-auto-ipsec-tunnel commands](#) on page 937

Configures the IKE SA's key lifetime in seconds

The lifetime defines how long a connection (encryption/authentication keys) should last, from successful key negotiation to expiration. Two peers need not exactly agree on the lifetime, though if they do not, there is some clutter for a superseded connection on the peer defining the lifetime as longer.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

## Syntax

`ike-lifetime <600-86400>`

## Parameters

`ike-lifetime <600-86400>`

|                                                 |                                                                                                                                                                                        |
|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ike-lifetime</b><br><b>&lt;600-86400&gt;</b> | Sets the IKE SA's key lifetime in seconds <ul style="list-style-type: none"><li>• &lt;600-86400&gt; – Specify a value from 600 - 86400 seconds. The default is 8600 seconds.</li></ul> |
|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Example

```
rfs4000-229D58(config-profile-testRFS4000-crypto-auto-ipsec-secure)#ike-lifetime 800

rfs4000-229D58(config-profile-testRFS4000-crypto-auto-ipsec-secure)#show context crypto
auto-ipsec-secure
 ike-lifetime 800
rfs4000-229D58(config-profile-testRFS4000-crypto-auto-ipsec-secure)#
```

ikev2

[crypto-auto-ipsec-tunnel commands](#) on page 937

Enables the forced IKEv2 peer re-authentication. This option is disabled by default.

In most IPsec tunnel configurations, the lifetime of IKE SAs between peers is limited. Once the IKE SA key expires it is renegotiated. In such a scenario, the IKEv2 tunnel peers may or may not re-authenticate themselves. When enabled, IKE tunnel peers have to re-authenticate each time the IKE SA is renegotiated.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
ikev2 peer reauth
```

### Parameters

```
ikev2 peer reauth
```

|                          |                                                                                                                                           |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ikev2 peer reauth</b> | Enables IKEv2 peer re-authentication. When enabled, IKE tunnel peers are forced to re-authenticate each time the IKE key is renegotiated. |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|

### Example

```
rfs4000-229D58(config-profile-testRFS4000-crypto-auto-ipsec-secure)#ikev2 peer reauth
```

remotegw

[crypto-auto-ipsec-tunnel commands](#) on page 937

Defines the IKE version used for auto IPSEC tunnel negotiation with the IPsec remote gateway other than the controller

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
remotegw ike-version [ikev1-aggr|ikev1-main|ikev2] {uniqueid}
```

### Parameters

```
remotegw ike-version [ikev1-aggr|ikev1-main|ikev2] {uniqueid}
```

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>remotegw ike-version</b> | Configures the IKE version used for initiating auto IPsec tunnel with secure gateways other than the controller                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>ikev1-aggr</b>           | Aggregation mode is used by the auto IPsec tunnel initiator to set up the connection                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>ikev1-main</b>           | Main mode is used by the auto IPsec tunnel initiator to establish the connection                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>ikev2</b>                | IKEv2 is the preferred method when wireless controller/AP only is used                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>uniqueid</b>             | <p>This keyword is common to all of the above parameters.</p> <ul style="list-style-type: none"> <li>• <b>uniqueid</b> – Optional. Enables the assigning of a unique ID to APs (using this profile) behind a router by prefixing the MAC address to the group ID</li> </ul> <p>Providing a unique ID enables the access point, wireless controller, or service platform to uniquely identify the destination device. This is essential in networks where there are multiple APs behind a router, or when two (or more) APs behind two (or more) different routers have the same IP address. For example, let us consider a scenario where there are two APs (A and B) behind two routers (1 and 2). AP 'A' is behind router '1'. And AP 'B' is behind router '2'. Both these APs have the same IP address (192.168.13.8). In such a scenario, the controller fails to establish an Auto IPsec VPN tunnel to either APs, because it is unable to uniquely identify them.</p> <p>After enabling unique ID assignment, enable IKE unique ID check. For more information, see <a href="#">crypto</a> on page 931.</p> |

#### Example

```
nx9500-6C8809(config-profile-default-rfs4000-crypto-auto-ipsec-secure)#remotegw
ike-version ikev2 uniqueid
```

```
nx9500-6C8809(config-profile-default-rfs4000-crypto-auto-ipsec-secure)#show context
```

```
crypto auto-ipsec-secure
remotegw ike-version ikev2 uniqueid
nx9500-6C8809(config-profile-default-rfs4000-crypto-auto-ipsec-secure)#
```

no

[crypto-auto-ipsec-tunnel commands](#) on page 937

Removes or resets this auto IPsec tunnel settings

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

```
no [groupid|ike-lifetime|ikev2 peer reauth|ip nat crypto]
```

#### Parameters

```
no <PARAMETERS>
```

|                                        |                                                                                    |
|----------------------------------------|------------------------------------------------------------------------------------|
| <b>no</b><br><b>&lt;PARAMETERS&gt;</b> | Removes or resets this auto IPsec tunnel's settings based on the parameters passed |
|----------------------------------------|------------------------------------------------------------------------------------|

#### Example

The following example shows the Auto IPsec VLAN bridge settings before the 'no' command is executed:

```
nx9500-6C8809(config-profile-default-rfs4000-crypto-auto-ipsec-secure)#show context
crypto auto-ipsec-secure
 groupid testpassword@123 rsa
nx9500-6C8809(config-profile-default-rfs4000-crypto-auto-ipsec-secure)#
```

```
nx9500-6C8809(config-profile-default-rfs4000-crypto-auto-ipsec-secure)#no groupid
```

The following example shows the Auto IPsec VLAN bridge settings after the 'no' command is executed:

```
nx9500-6C8809(config-profile-default-rfs4000-crypto-auto-ipsec-secure)#show context
crypto auto-ipsec-secure
nx9500-6C8809(config-profile-default-rfs4000-crypto-auto-ipsec-secure)#
```

## crypto-ikev1/ikev2-policy commands

[crypto](#) on page 931

Defines crypto-IKEv1/IKEv2 commands in detail

IKE protocol is a key management protocol standard used in conjunction with IPsec. IKE enhances IPsec by providing additional features, flexibility, and configuration simplicity for the IPsec standard. IKE automatically negotiates IPsec SAs and enables secure communications without time consuming manual pre-configuration.

Use the (config) instance to configure IKEv1/IKEv2 policy configuration commands.

To navigate to the IKEv1/IKEv2 policy config instance, use the following commands:

```
<DEVICE>(config)#profile <DEVICE-TYPE> <PROFILE-NAME>
<DEVICE>(config-profile-<PROFILE-NAME>)#crypto ikev1/ikev2 policy <IKEV1/IKEV2-POLICY-NAME>
```

```
nx9500-6C8809(config-profile-default-rfs4000)#crypto ikev1 policy ikev1-testpolicy
rfs7000-37FABE(config-profile-default-rfs4000-ikev1-policy-ikev1-testpolicy)#?
```

Crypto IKEv1 Policy Configuration commands:

|                 |                                                   |
|-----------------|---------------------------------------------------|
| dpd-keepalive   | Set Dead Peer Detection interval in seconds       |
| dpd-retries     | Set Dead Peer Detection retries count             |
| isakmp-proposal | Configure ISAKMP Proposals                        |
| lifetime        | Set lifetime for ISAKMP security association      |
| mode            | IKEv1 mode (main/aggressive)                      |
| no              | Negate a command or set its defaults              |
| clrscr          | Clears the display screen                         |
| commit          | Commit all changes made in this session           |
| end             | End current mode and change to EXEC mode          |
| exit            | End current mode and down to previous mode        |
| help            | Description of the interactive help system        |
| revert          | Revert changes                                    |
| service         | Service Commands                                  |
| show            | Show running system information                   |
| write           | Write running configuration to memory or terminal |

```
nx9500-6C8809(config-profile-default-rfs4000-ikev1-policy-ikev1-testpolicy)#
```

```
nx9500-6C8809(config-profile-test-ikev2-policy-ikev2-testpolicy)#?
```

Crypto IKEv2 Policy Configuration commands:

|                 |                                                            |
|-----------------|------------------------------------------------------------|
| dpd-keepalive   | Set Dead Peer Detection interval in seconds                |
| isakmp-proposal | Configure ISAKMP Proposals                                 |
| lifetime        | Set lifetime for ISAKMP security association               |
| no              | Negate a command or set its defaults                       |
| sa-per-acl      | Setup single SA for all rules in the ACL (ONLY APPLICABLE) |

FOR SITE-TO-SITE VPN)

```
clrscr Clears the display screen
commit Commit all changes made in this session
do Run commands from Exec mode
end End current mode and change to EXEC mode
exit End current mode and down to previous mode
help Description of the interactive help system
revert Revert changes
service Service Commands
show Show running system information
write Write running configuration to memory or terminal
```

```
nx9500-6C8809(config-profile-test-ikev2-policy-ikev2-testpolicy)#
```

#### Note

IKEv2 being an improved version of the original IKEv1 design, is recommended in most deployments. IKEv2 provides enhanced cryptographic mechanisms, NAT and firewall traversal, attack resistance, etc.

The following table summarizes crypto IKEv1/iKEv2 configuration mode commands:

| Command                                     | Description                                                                                                  |
|---------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| <a href="#">dpd-keepalive</a> on page 944   | Sets DPD keep alive packet interval                                                                          |
| <a href="#">dpd-retries</a> on page 945     | Sets the maximum number of attempts for sending DPD keep alive packets (applicable only to the IKEv1 policy) |
| <a href="#">isakmp-proposal</a> on page 945 | Configures ISAKMP proposals                                                                                  |
| <a href="#">lifetime</a> on page 946        | Specifies how long an IKE SA is valid before it expires                                                      |
| <a href="#">mode</a> on page 947            | Sets the mode of the tunnels (applicable only to the IKEv1 policy)                                           |
| <a href="#">no</a> on page 948              | Removes or reverts IKEv1/IKEv2 policy settings                                                               |

#### dpd-keepalive

[crypto-ikev1/ikev2-policy commands](#) on page 943

Sets the DPD keep-alive packet interval

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

```
dpd-keepalive <10-3600>
```

Parameters

```
dpd-keepalive <10-3600>
```

**<10-3600>**

Specifies the interval, in seconds, between successive DPD keep alive packets. The IKE keep alive message is used to detect a dead peer on the remote end of the IPsec VPN tunnel. Specify the time from 10 - 3600 seconds. The default is 30 seconds.

#### Example

```
nx9500-6C8809(config-profile-default-rfs4000-ikev1-policy-ikev1-testpolicy)#dpd-keepalive 11
```

```
nx9500-6C8809(config-profile-default-rfs4000-ikev1-policy-testpolicy)#show context
crypto ikev1 policy testpolicy
 dpd-keepalive 11
 isakmp-proposal default encryption aes-256 group 2 hash sha
nx9500-6C8809(config-profile-default-rfs4000-ikev1-policy-testpolicy)#
```

dpd-retries

[crypto-ikev1/ikev2-policy commands](#) on page 943

Sets the maximum number of times DPD keep-alive packets are sent to a peer. Once this value is exceeded, without a response from the peer, the VPN tunnel connection is declared dead. This option is available only for the IKEv1 policy.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

```
dpd-retries <1-100>
```

#### Parameters

```
dpd-retries <1-100>
```

**<1-100>**

Declares a peer dead after the specified number of retries. Specify a value from 1 - 100. The default is 5.

#### Example

```
nx9500-6C8809(config-profile-default-rfs4000-ikev1-policy-ikev1-testpolicy)#dpd-retries 10
```

```
nx9500-6C8809(config-profile-default-rfs4000-ikev1-policy-ikev1-testpolicy)#show context
crypto ikev1 policy testpolicy
 dpd-keepalive 11
 dpd-retries 10
 isakmp-proposal default encryption aes-256 group 2 hash sha
nx9500-6C8809(config-profile-default-rfs4000-ikev1-policy-ikev1-testpolicy)#
```

isakmp-proposal

[crypto-ikev1/ikev2-policy commands](#) on page 943

Configures ISAKMP proposals and their parameters

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000

- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

```
isakmp-proposal <WORD> encryption [3des|aes|aes-192|aes-256] group [14|2|5] hash [aes-xcbc-mac|md5|sha|sha256]
```

#### Parameters

```
isakmp-proposal <WORD> encryption [3des|aes|aes-192|aes-256] group [14|2|5] hash [aes-xcbc-mac|md5|sha|sha256]
```

|                                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>&lt;WORD&gt;</b>                          | Assigns the target peer (tunnel destination) a 32 character maximum name to distinguish it from others with a similar configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>encryption [3des aes aes-192 aes-256]</b> | Configures the encryption method used by the tunneled peers to securely inter-operate <ul style="list-style-type: none"> <li>• 3des - Configures triple data encryption standard</li> <li>• aes - Configures AES (128 bit keys)</li> <li>• aes-192 - Configures AES (192 bit keys)</li> <li>• aes-256 - Configures AES (256 bit keys). This is the default setting.</li> </ul>                                                                                                                                                                                                           |
| <b>group [14 2 5]</b>                        | Specifies the Diffie-Hellman (DH) group identifier used by VPN peers to derive a shared secret password without having to transmit. DH groups determine the strength of the key used in key exchanges. The higher the group number, the stronger and more secure the key. Options include 2, 5 and 14. <ul style="list-style-type: none"> <li>• 14 - Configures DH group 14</li> <li>• 2 - Configures DH group 2. This is the default setting.</li> <li>• 5 - Configures DH group 5</li> </ul>                                                                                           |
| <b>hash [aes-xcbc-mac md5 sha sha256]</b>    | Specifies the hash algorithm used to authenticate data transmitted over the IKE SA. The hash algorithm specified here is used by VPN peers to exchange credential information. <ul style="list-style-type: none"> <li>• aes-xcbc-mac - Uses AES XCBC Auth hash algorithm. This option is applicable only to the IKEv2 policy configuration context.</li> <li>• md5 - Uses Message Digest 5 (MD5) hash algorithm</li> <li>• sha - Uses Secure Hash Authentication (SHA) hash algorithm. This is the default setting.</li> <li>• sha256 - Uses Secure Hash Standard 2 algorithm</li> </ul> |

#### Example

```
nx9500-6C8809(config-profile-default-rfs4000-ikev1-policy-ikev1-testpolicy)#isakmp-proposal testproposal encryption aes group 2 hash sha
```

```
nx9500-6C8809(config-profile-default-rfs4000-ikev1-policy-ikev1-testpolicy)#show context
crypto ikev1 policy testpolicy
 dpd-keepalive 11
 dpd-retries 10
 isakmp-proposal default encryption aes-256 group 2 hash sha
 isakmp-proposal testpraposal encryption aes group 2 hash sha
nx9500-6C8809(config-profile-default-rfs4000-ikev1-policy-ikev1-testpolicy)#
```

lifetime

[crypto-ikev1/ikev2-policy commands](#) on page 943

Specifies how long an IKE SA (encryption/authentication keys) is valid. The value specified is the validity period of the IKE SA from successful key negotiation to expiration.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

**lifetime** <600-86400>

#### Parameters

lifetime <600-86400>

|                                             |                                                                                                                                                                                                                                                          |
|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>lifetime</b><br><b>&lt;600-86400&gt;</b> | Specifies how many seconds an IKE SA lasts before it expires. Set a time stamp from 600 - 86400 seconds. <ul style="list-style-type: none"> <li>• &lt;600-86400&gt; - Specify a value from 600 - 86400 seconds. The default is 86400 seconds.</li> </ul> |
|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

#### Example

```

nx9500-6C8809(config-profile-default-rfs4000-ikev1-policy-ikev1-testpolicy)#lifetime 655

nx9500-6C8809(config-profile-default-rfs4000-ikev1-policy-ikev1-testpolicy)#show context
crypto ikev1 policy testpolicy
 dpd-keepalive 11
 dpd-retries 10
 lifetime 655
 isakmp-proposal default encryption aes-256 group 2 hash sha
 isakmp-proposal testproposal encryption aes group 2 hash sha
nx9500-6C8809(config-profile-default-rfs4000-ikev1-policy-ikev1-testpolicy)#

```

mode

[crypto-ikev1/ikev2-policy commands](#) on page 943

Configures the IPSec mode of operation for the IKEv1 policy. This option is not available for IKEv2 policy.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

**mode** [aggressive|main]

#### Parameters

mode [aggressive|main]

|                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>mode</b><br><b>[aggressive </b><br><b>main]</b> | Sets the mode of the tunnels <ul style="list-style-type: none"> <li>• aggressive - Initiates the aggressive mode</li> <li>• main - Initiates the main mode</li> </ul> <p>If configuring the IKEv1 IPSec policy, define the IKE mode as either main or aggressive. In the aggressive mode, 3 messages are exchanged between the IPSec peers to setup the SA. On the other hand, in the main mode, 6 messages are exchanged. The default setting is main.</p> |
|----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Example

```
nx9500-6C8809(config-profile-default-rfs4000-ikev1-policy-ikev1-testpolicy)#mode aggressive

nx9500-6C8809(config-profile-default-rfs4000-ikev1-policy-ikev1-testpolicy)#show context
crypto ikev1 policy testpolicy
 dpd-keepalive 11
 dpd-retries 10
 lifetime 655
 isakmp-proposal default encryption aes-256 group 2 hash sha
 isakmp-proposal testpraposal encryption aes group 2 hash sha
 mode aggressive
nx9500-6C8809(config-profile-default-rfs4000-ikev1-policy-ikev1-testpolicy)#
```

no

[crypto-ikev1/ikev2-policy commands](#) on page 943

Removes or reverts IKEv1/IKEv2 policy settings

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

## Syntax

```
no [dpd-keepalive|dpd-retries|isakmp-proposal <WORD>|lifetime|mode]
```

## Parameters

```
no <PARAMETERS>
```

|                                                                                                             |
|-------------------------------------------------------------------------------------------------------------|
| <b>no &lt;PARAMETERS&gt;</b> Removes or reverts this IKEv1/IKEv2 policy settings based on parameters passed |
|-------------------------------------------------------------------------------------------------------------|

## Example

The following example shows the IKEV1 Policy settings before the 'no' commands are executed:

```
nx9500-6C8809(config-profile-default-rfs4000-ikev1-policy-ikev1-testpolicy)#show context
crypto ikev1 policy testpolicy
 dpd-keepalive 11
 dpd-retries 10
 lifetime 655
 isakmp-proposal default encryption aes-256 group 2 hash sha
 isakmp-proposal testpraposal encryption aes group 2 hash sha
 mode aggressive
nx9500-6C8809(config-profile-default-rfs4000-ikev1-policy-ikev1-testpolicy)#

nx9500-6C8809(config-profile-default-rfs4000-ikev1-policy-ikev1-testpolicy)#no mode
nx9500-6C8809(config-profile-default-rfs4000-ikev1-policy-ikev1-testpolicy)#no dpd-keepalive
nx9500-6C8809(config-profile-default-rfs4000-ikev1-policy-ikev1-testpolicy)#no dpd-retries
```

The following example shows the IKEV1 Policy settings after the 'no' commands are executed:

```
nx9500-6C8809(config-profile-default-rfs4000-ikev1-policy-ikev1-testpolicy)# show context
crypto ikev1 policy testpolicy
 lifetime 655
 isakmp-proposal default encryption aes-256 group 2 hash sha
 isakmp-proposal testpraposal encryption aes group 2 hash sha
nx9500-6C8809(config-profile-default-rfs4000-ikev1-policy-ikev1-testpolicy)#
```

## crypto-ikev1/ikev2-peer commands

[crypto](#) on page 931

Use the (config) instance to configure IKEv1/IKEv2 peer configuration commands. To navigate to the IKEv1/IKEv2 peer config instance, use the following commands:

```
<DEVICE>(config)#profile <DEVICE-TYPE> <PROFILE-NAME>
<DEVICE>(config-profile-<PROFILE-NAME>)#crypto ikev1/ikev2 peer <IKEV1/IKEV2-PEER-NAME>
```

```
nx9500-6C8809(config-profile-default-rfs4000)#crypto ikev1 peer peer1
nx9500-6C8809(config-profile-default-rfs4000-ikev1-peer-peer1)#?
```

Crypto IKEV1 Peer Configuration commands:

```
authentication Configure Authentication credentials
ip Configure peer address/fqdn
localid Set local identity
no Negate a command or set its defaults
remoteid Configure remote peer identity
use Set setting to use

clrscr Clears the display screen
commit Commit all changes made in this session
end End current mode and change to EXEC mode
exit End current mode and down to previous mode
help Description of the interactive help system
revert Revert changes
service Service Commands
show Show running system information
write Write running configuration to memory or terminal
```

```
nx9500-6C8809(config-profile-default-rfs4000-ikev1-peer-peer1)#
```

```
nx9500-6C8809(config-profile-default-rfs4000)#crypto ikev2 peer peer1
nx9500-6C8809(config-profile-default-rfs4000-ikev2-peer-peer1)#?
```

Crypto IKEV2 Peer Configuration commands:

```
authentication Configure Authentication credentials
ip Configure peer address/fqdn
localid Set local identity
no Negate a command or set its defaults
remoteid Configure remote peer identity
use Set setting to use

clrscr Clears the display screen
commit Commit all changes made in this session
do Run commands from Exec mode
end End current mode and change to EXEC mode
exit End current mode and down to previous mode
help Description of the interactive help system
revert Revert changes
service Service Commands
show Show running system information
write Write running configuration to memory or terminal
```

```
nx9500-6C8809(config-profile-default-rfs4000-ikev2-peer-peer1)#
```

The following table summarizes crypto IPsec IKEv1/IKEv2 peer configuration mode commands:

| Command                                    | Description                                                    |
|--------------------------------------------|----------------------------------------------------------------|
| <a href="#">authentication</a> on page 950 | Configures a peer's authentication mode and the pre-shared key |
| <a href="#">ip</a> on page 951             | Configures the peer's IP address                               |

| Command                           | Description                                                                                                                                                              |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>localid</code> on page 951  | Configures a peer's local identity details                                                                                                                               |
| <code>remoteid</code> on page 952 | Configures a remote peer's identity details                                                                                                                              |
| <code>use</code> on page 953      | Associates an IKEv1 policy and IKEv2 policy with the IKEv1 and IKEv2 peer respectively                                                                                   |
| <code>no</code> on page 954       | Negates a command or reverts settings to their default. The <code>no</code> command, when used in the ISAKMP policy mode, defaults the ISAKMP protection suite settings. |

authentication

`crypto-ikev1/ikev2-peer commands` on page 949

Configures IKEv1/IKEv2 peer's authentication mode and the pre-shared key

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

```
authentication [psk|rsa]
```

```
authentication psk [0 <WORD>|2 <WORD>|<WORD>] {local|remote}
```

```
authentication rsa
```

Parameters

```
authentication psk [0 <WORD>|2 <WORD>|<WORD>] {local|remote}
```

|                                                                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <pre>psk [0 &lt;WORD&gt;  2 &lt;WORD&gt;  &lt;WORD&gt;] {local remote}</pre> | <p>Configures the authentication mode as pre-shared key (PSK). The PSK is a string, 8 - 12 characters long. It is shared by both ends of the VPN tunnel connection. If using IKEv2, both a local and remote string must be specified for handshake validation at both ends (local and remote) of the VPN connection.</p> <ul style="list-style-type: none"> <li>• 0 &lt;WORD&gt; - Configures a clear text key</li> <li>• 2 &lt;WORD&gt; - Configures an encrypted key</li> <li>• &lt;WORD&gt; - Configures the pre-shared key</li> </ul> <p>The following keywords are available only in the IKEv2 peer configuration mode:</p> <ul style="list-style-type: none"> <li>• local - Optional. Uses the specified key for local peer authentication only</li> <li>• remote - Optional. Uses the specified key for remote peer authentication only</li> </ul> <p><b>Note:</b> In case the peer type is not specified, this string is used for authenticating both local and remote peers.</p> |
|------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
authentication rsa
```

|            |                                                                                                                                                                                                                                                                                                                                                                      |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>rsa</b> | Configures the authentication mode as Rivest, Shamir, and Adleman (RSA) This is the default setting (for both IKEv1 and IKEv2). RSA is the first known public-key cryptography algorithm designed signing and encryption. If configuring the IKEv2 peer, the 'rsa' option allows you to enable authentication at both ends of the VPN connection (local and remote). |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

#### Example

```

nx9500-6C8809(config-profile-default-rfs4000-ikev1-peer-peer1)#authentication rsa

nx9500-6C8809(config-profile-default-rfs4000-ikev2-peer-peer1)#authentication
psk 0 key@123456

nx9500-6C8809(config-profile-default-rfs4000-ikev2-peer-peer1)#show context
crypto ikev2 peer peer1
 authentication psk 0 key@123456 local
 authentication psk 0 key@123456 remote
nx9500-6C8809(config-profile-default-rfs4000-ikev2-peer-peer1)#

```

ip

[crypto-ikev1/ikev2-peer commands](#) on page 949

Sets the IP address or Fully Qualified Domain Name (FQDN) of the IPSec VPN peer used in the tunnel setup

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

```
ip [address <IP>|fqdn <WORD>]
```

#### Parameters

```
ip [address <IP>|fqdn <WORD>]
```

|                           |                                          |
|---------------------------|------------------------------------------|
| <b>address &lt;IP&gt;</b> | Specify the peer device's IP address.    |
| <b>fqdn &lt;WORD&gt;</b>  | Specify the peer device's FQDN hostname. |

#### Example

```

nx9500-6C8809(config-profile-default-rfs4000-ikev1-peer-peer1)#ip address 172.16.10.12

nx9500-6C8809(config-profile-default-rfs4000-ikev1-peer-peer1)#show context
crypto ikev1 peer peer1
 ip address 172.16.10.12
nx9500-6C8809(config-profile-default-rfs4000-ikev1-peer-peer1)#

nx9500-6C8809(config-profile-default-rfs4000-ikev2-peer-peer1)#ip address 192.168.10.6

nx9500-6C8809(config-profile-default-rfs4000-ikev2-peer-peer1)#show context
crypto ikev2 peer peer1
 ip address 192.168.10.6
 authentication psk 0 test@123456 local
 authentication psk 0 test@123456 remote
nx9500-6C8809(config-profile-default-rfs4000-ikev2-peer-peer1)#

```

localid

[crypto-ikev1/ikev2-peer commands](#) on page 949

Sets a IKEv1/IKEv2 peer's local identity. This local identifier is used with this peer configuration for an IKE exchange with the target VPN IPsec peer.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

```
localid [address | autogen-uniqueid | dn | email | fqdn | string]
```

```
localid [address <IP> | autogen-uniqueid <WORD> | dn <WORD> | email <WORD> | fqdn <WORD> | string <WORD>]
```

Parameters

```
localid [address <IP> | dn <WORD> | email <WORD> | fqdn <WORD> | string <WORD>]
```

|                                      |                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>address &lt;IP&gt;</b>            | Configures the peer's IP address. The IP address is used as local identity.                                                                                                                                                                                                                                                                                                                                  |
| <b>autogen-uniqueid &lt;WORD&gt;</b> | Generates a localid using the device's unique identity. The system prefixes the device's unique identity to the string provided here. The device's unique identity should be existing and configured. For more information on configuring a device's unique identity, see <a href="#">autogen-uniqueid</a> on page 883. <ul style="list-style-type: none"><li>• &lt;WORD&gt; - Provide the string.</li></ul> |
| <b>dn &lt;WORD&gt;</b>               | Configures the peer's distinguished name. (for example, "C=us ST=<state> L=<location> O=<organization> OU=<org unit>". The maximum length is 128 characters.                                                                                                                                                                                                                                                 |
| <b>email &lt;WORD&gt;</b>            | Configures the peer's e-mail address. The maximum length is 128 characters.                                                                                                                                                                                                                                                                                                                                  |
| <b>fqdn &lt;WORD&gt;</b>             | Configures the peer's FQDN. The maximum length is 128 characters.                                                                                                                                                                                                                                                                                                                                            |
| <b>string &lt;WORD&gt;</b>           | Configures the peer's identity string. The maximum length is 128 characters. This is the default setting.                                                                                                                                                                                                                                                                                                    |

Example

```
nx9500-6C8809(config-profile-default-rfs4000-ikev1-peer-peer1)#localid email bob@examplecompany.com
```

```
nx9500-6C8809(config-profile-default-rfs4000-ikev1-peer-peer1)#show context crypto ikev1 peer peer1 ip address 172.16.10.12 localid email bob@examplecompany.com nx9500-6C8809(config-profile-default-rfs4000-ikev1-peer-peer1)#
```

remoteid

[crypto-ikev1/ikev2-peer commands](#) on page 949

Configures a IKEv1/IKEv2 peer's remote identity. This remote identifier is used with this peer configuration for an IKE exchange with the target VPN IPsec peer.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

```
remoteid [address <IP>|dn <WORD>|email <WORD>|fqdn <WORD>|string <WORD>]
```

#### Parameters

```
remoteid [address <IP>|dn <WORD>|email <WORD>|fqdn <WORD>|string <WORD>]
```

|                            |                                                                                                                                                                    |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>address &lt;IP&gt;</b>  | Configures the remote IKEv1/IKEv2 peer's IP address. The IP address is used as the peer's remote identity.                                                         |
| <b>dn &lt;WORD&gt;</b>     | Configures the remote peer's distinguished name. For example, "C=us ST=<state> L=<location> O=<organization> OU=<org unit>". The maximum length is 128 characters. |
| <b>email &lt;WORD&gt;</b>  | Configures the remote peer's e-mail address. The maximum length is 128 characters.                                                                                 |
| <b>fqdn &lt;WORD&gt;</b>   | Configures a peer's FQDN. The maximum length is 128 characters.                                                                                                    |
| <b>string &lt;WORD&gt;</b> | Configures a peer's identity string. The maximum length is 128 characters.                                                                                         |

#### Example

```
nx9500-6C8809(config-profile-default-rfs4000-ikev1-peer-peer1)#remoteid dn SanJose
```

```
nx9500-6C8809(config-profile-default-rfs4000-ikev1-peer-peer1)#show context
```

```
crypto ikev1 peer peer1
 ip address 172.16.10.12

```

```
crypto ikev2 peer peer1
 remoteid address 157.235.209.63
```

```
nx9500-6C8809(config-profile-default-rfs4000-ikev2-peer-peer1)#
```

use

[crypto-ikev1/ikev2-peer commands](#) on page 949

Associates IKEv1/IKEv2 policy with the IKEv1/IKEv2 peer respectively

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

```
use ikev1-policy <IKEV1-POLICY-NAME>
```

```
use ikev2-policy <IKEV2-POLICY-NAME>
```

## Parameters

use ikev1-policy <IKEV1-POLICY-NAME>

|                                                   |                                                                                                                                                   |
|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>use ikev1-policy &lt;IKEV1-POLICY-NAME&gt;</b> | Specify the IKEv1 policy name.<br>The local IKEv1 policy and the peer IKEv1 policy must have matching group settings for successful negotiations. |
|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|

use ikev2-policy <IKEV2-POLICY-NAME>

|                                                   |                                                                                                                                                   |
|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>use ikev2-policy &lt;IKEV2-POLICY-NAME&gt;</b> | Specify the IKEv2 policy name.<br>The local IKEv2 policy and the peer IKEv2 policy must have matching group settings for successful negotiations. |
|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|

## Example

```
nx9500-6C8809(config-profile-default-rfs4000-ikev1-peer-peer1)#use ikev1-policy test-ikev1policy
```

```
nx9500-6C8809(config-profile-default-rfs4000-ikev1-peer-peer1)#show context
crypto ikev1 peer peer1
 ip address 172.16.10.12
 remoteid dn SanJose
 localid email bob@examplecompany.com
 use ikev1-policy test-ikev1policy
nx9500-6C8809(config-profile-default-rfs4000-ikev1-peer-peer1)#
```

```
nx9500-6C8809(config-profile-default-rfs4000-ikev2-peer-peer1)#use ikev2-policy test-ikev2policy
```

```
nx9500-6C8809(config-profile-default-rfs4000-ikev2-peer-peer1)#show context
crypto ikev2 peer peer1
 remoteid address 157.235.209.63
 use ikev2-policy test-ikev2policy
nx9500-6C8809(config-profile-default-rfs4000-ikev2-peer-peer1)#
```

no

[crypto-ikev1/ikev2-peer commands](#) on page 949

Removes or reverts IKEv1/IKEv2 peer settings

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

## Syntax

```
no [authentication|ip|localid|remoteid|use <IKEv1/IKEv2-POLICY-NAME>]
```

## Parameters

no <PARAMETERS>

|                              |                                                                             |
|------------------------------|-----------------------------------------------------------------------------|
| <b>no &lt;PARAMETERS&gt;</b> | Removes or reverts IKEv1/IKEv2 peer settings based on the parameters passed |
|------------------------------|-----------------------------------------------------------------------------|

## Example

The following example shows the Crypto IKEV1 peer1 settings before the 'no' commands are executed:

```
nx9500-6C8809(config-profile-default-rfs4000-ikev1-peer-peer1)#show context
crypto ikev1 peer peer1
 ip address 172.16.10.12
 remoteid dn SanJose
 localid email bob@examplecompany.com
 use ikev1-policy test-ikev1policy
nx9500-6C8809(config-profile-default-rfs4000-ikev1-peer-peer1)#

nx9500-6C8809(config-profile-default-rfs4000-ikev1-peer-peer1)#no localid
nx9500-6C8809(config-profile-default-rfs4000-ikev1-peer-peer1)#no remoteid
```

The following example shows the Crypto IKEV1 peer1 settings after the 'no' commands are executed:

```
nx9500-6C8809(config-profile-default-rfs4000-ikev1-peer-peer1)#show context
crypto ikev1 peer peer1
 ip address 172.16.10.12
 use ikev1-policy test-ikev1policy
nx9500-6C8809(config-profile-default-rfs4000-ikev1-peer-peer1)#
```

The following example shows the Crypto IKEV2 peer1 settings before the 'no' commands are executed:

```
nx9500-6C8809(config-profile-default-rfs4000-ikev2-peer-peer1)#show context
crypto ikev2 peer peer1
 remoteid address 157.235.209.63
 use ikev2-policy test
nx9500-6C8809(config-profile-default-rfs4000-ikev2-peer-peer1)#
```

The following example shows the Crypto IKEV2 peer1 settings after the 'no' commands are executed:

```
nx9500-6C8809(config-profile-default-rfs4000-ikev2-peer-peer1)#no use ikev2-policy

nx9500-6C8809(config-profile-default-rfs4000-ikev2-peer-peer1)#show context
crypto ikev2 peer peer1
 remoteid address 157.235.209.63
nx9500-6C8809(config-profile-default-rfs4000-ikev2-peer-peer1)#
```

## crypto-map-config-commands

[crypto](#) on page 931

This section explains crypto map configuration mode commands in detail.

A crypto map entry is a single policy that describes how certain traffic is secured. There are two types of crypto map entries: ipsec-manual and ipsec-ike. Each entry is given an index (used to sort the ordered list).

IPSec VPN provides a secure tunnel between two networked peers. Administrators can define which packets are sent within the tunnel, and how they're protected. When a tunneled peer sees a sensitive packet, it creates a secure tunnel and sends the packet through the tunnel to its remote peer destination.

Tunnels are sets of SA between two peers. SAs define the protocols and algorithms applied to sensitive packets and specify the keying mechanisms used by tunneled peers. SAs are unidirectional and exist in both the inbound and outbound direction. SAs are established per the rules and conditions of defined security protocols (AH or ESP).

IKE is a key management protocol standard used in conjunction with IPSec. IKE enhances IPSec by providing additional features, flexibility, and configuration simplicity for the IPSec standard. IKE

automatically negotiates IPsec SAs, and enables secure communications without time consuming manual pre-configuration.

Use crypto maps to configure IPsec VPN SAs. Crypto maps combine the elements comprising IPsec SAs. Crypto maps also include transform sets. A transform set is a combination of security protocols, algorithms and other settings applied to IPsec protected traffic. One crypto map is utilized for each IPsec peer, however for remote VPN deployments one crypto map is used for all the remote IPsec peers.

Use the (config) instance to enter the crypto map configuration mode. To navigate to the crypto-map configuration instance, use the following commands:

In the device-config mode:

```
<DEVICE>(config-device-<DEVICE-MAC>)#crypto map <CRYPTO-MAP-TAG> <1-1000> [ipsec-isakmp {dynamic}|ipsec-manual]
```

In the profile-config mode:

```
<DEVICE>(config-profile-<PROFILE-NAME>)#crypto map <CRYPTO-MAP-TAG> <1-1000> [ipsec-isakmp {dynamic}|ipsec-manual]
```

There are three different configurations defined for each listed crypto map: site-to-site manual (ipsec-manual), site-to-site-auto tunnel (ipsec-isakmp), and remote VPN client (ipsec-isakmp dynamic). With site-to-site deployments, an IPsec tunnel is deployed between two gateways, each at the edge of two different remote networks. With remote VPN, an access point located at remote branch defines a tunnel with a security gateway. This facilitates the end points in the branch office to communicate with the destination endpoints (behind the security gateway) in a secure manner.

Each crypto map entry is given an index (used to sort the ordered list).

```
nx9500-6C8809(config-profile-default-rfs4000)#crypto map map1 1 ipsec-manual
nx9500-6C8809(config-profile-default-rfs4000-cryptomap-map1#1)#?
```

Manual Crypto Map Configuration commands:

|                      |                                                                                                    |
|----------------------|----------------------------------------------------------------------------------------------------|
| local-endpoint-ip    | Use this IP as local tunnel endpoint address, instead of the interface IP (Advanced Configuration) |
| mode                 | Set the tunnel mode                                                                                |
| no                   | Negate a command or set its defaults                                                               |
| peer                 | Set peer                                                                                           |
| security-association | Set security association parameters                                                                |
| session-key          | Set security session key parameters                                                                |
| use                  | Set setting to use                                                                                 |
| clearscr             | Clears the display screen                                                                          |
| commit               | Commit all changes made in this session                                                            |
| do                   | Run commands from Exec mode                                                                        |
| end                  | End current mode and change to EXEC mode                                                           |
| exit                 | End current mode and down to previous mode                                                         |
| help                 | Description of the interactive help system                                                         |
| revert               | Revert changes                                                                                     |
| service              | Service Commands                                                                                   |
| show                 | Show running system information                                                                    |
| write                | Write running configuration to memory or terminal                                                  |

```
nx9500-6C8809(config-profile-default-rfs4000-cryptomap-map1#1)#
```

The following table summarizes crypto map configuration mode commands:

| Command                                                                           | Description                                              |
|-----------------------------------------------------------------------------------|----------------------------------------------------------|
| <a href="#">crypto-map auto-vpn-tunnel/remote-vpn-client instance</a> on page 957 | Configures an auto site-to-site VPN or remote VPN client |
| <a href="#">crypto-map-ipsec-manual-instance</a> on page 968                      | Configures a manual site-to-site VPN                     |

crypto-map auto-vpn-tunnel/remote-vpn-client instance

[crypto-map-config-commands](#) on page 955

To navigate to the auto site-to-site VPN tunnel configuration instance, use the following command:

In the device-config mode:

```
<DEVICE>(config-device-<DEVICE-MAC>)#crypto map <CRYPTO-MAP-TAG> <1-1000> ipsec-isakmp
```

In the profile-config mode:

```
<DEVICE>(config-profile-<PROFILE-NAME>)#crypto map <CRYPTO-MAP-TAG> <1-1000> ipsec-isakmp
```

```
rfs4000-229D58(config-device-00-23-68-22-9D-58)#crypto map test 1 ipsec-isakmp
```

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#?
```

Site to Site Crypto Map Configuration commands:

```
ip Internet Protocol config commands
local-endpoint-ip Use this IP as local tunnel endpoint address, instead
of the interface IP (Advanced Configuration)
no Negate a command or set its defaults
peer Add a remote peer
pfs Specify Perfect Forward Secrecy
security-association Security association parameters
transform-set Specify IPSec transform to use
use Set setting to use

clrscr Clears the display screen
commit Commit all changes made in this session
do Run commands from Exec mode
end End current mode and change to EXEC mode
exit End current mode and down to previous mode
help Description of the interactive help system
revert Revert changes
service Service Commands
show Show running system information
write Write running configuration to memory or terminal
```

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#
```

To navigate to the remote VPN client configuration instance, use the following command:

In the device-config mode:

```
<DEVICE>(config-device-<DEVICE-MAC>)#crypto map <CRYPTO-MAP-TAG> <1-1000> ipsec-isakmp
{dynamic}
```

In the profile-config mode:

```
<DEVICE>(config-profile-<PROFILE-NAME>)#crypto map <CRYPTO-MAP-TAG> <1-1000> ipsec-isakmp
{dynamic}
```

```
rfs4000-229D58(config-device-00-23-68-22-9D-58)#crypto map test 2 ipsec-isakmp dynamic
```

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#2)#?
```

Dynamic Crypto Map Configuration commands:

```
local-endpoint-ip Use this IP as local tunnel endpoint address, instead
```

```

of the interface IP (Advanced Configuration)
modeconfig Set the mode config method
no Negate a command or set its defaults
peer Add a remote peer
pfs Specify Perfect Forward Secrecy
remote-type Set the remote VPN client type
security-association Security association parameters
transform-set Specify IPSec transform to use
use Set setting to use

clrscr Clears the display screen
commit Commit all changes made in this session
do Run commands from Exec mode
end End current mode and change to EXEC mode
exit End current mode and down to previous mode
help Description of the interactive help system
revert Revert changes
service Service Commands
show Show running system information
write Write running configuration to memory or terminal

```

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#2)#
```

The following table lists the IPSec-Auto-VPN/Remote-VPN tunnel configuration commands:

| Command                                          | Description                                                                                                                                                            |
|--------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">ip</a> on page 958                   | Enables this setting to utilize IP/Port NAT on the VPN tunnel. This command is applicable only to the site-to-site VPN tunnel.                                         |
| <a href="#">local-endpoint-ip</a> on page 959    | Uses the configured IP as local tunnel endpoint address, instead of the interface IP. This command is applicable to the site-to-site VPN tunnel and remote VPN client. |
| <a href="#">modeconfig</a> on page 960           | Configures the mode config method (pull or push) associated with the remote VPN client. This command is applicable only to the remote VPN client.                      |
| <a href="#">peer</a> on page 960                 | Configures the IKEv1 or IKEv2 peer for the VPN tunnel. This command is applicable to the site-to-site VPN tunnel and remote VPN client.                                |
| <a href="#">pfs</a> on page 961                  | Configures the Perfect Forward Secrecy (PFS) for the VPN tunnel. This command is applicable to the site-to-site VPN tunnel and remote VPN client.                      |
| <a href="#">remote-type</a> on page 962          | Configures the remote VPN client type as either None or XAuth. This command is applicable only to the remote VPN client.                                               |
| <a href="#">security-association</a> on page 963 | Defines this automatic VPN tunnel's IPSec SA settings. This command is applicable to the site-to-site VPN tunnel and remote VPN client.                                |
| <a href="#">transform-set</a> on page 964        | Applies a transform set (encryption and hash algorithms) to the VPN tunnel. This command is applicable to the site-to-site VPN tunnel and remote VPN client.           |
| <a href="#">use</a> on page 965                  | Applies an existing and configured IP access list to the VPN tunnel. This command is applicable to the site-to-site VPN tunnel and remote VPN client.                  |
| <a href="#">no</a> on page 966                   | Removes or reverts site-to-site VPN tunnel or remote VPN client settings                                                                                               |

[ip](#)

[crypto-map auto-vpn-tunnel/remote-vpn-client instance](#) on page 957

Enables this setting to utilize IP/Port NAT on this auto site-to-site VPN tunnel. This option is disabled by default.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

```
ip nat crypto
```

Parameters

```
ip nat crypto
```

|                      |                                                                                                                  |
|----------------------|------------------------------------------------------------------------------------------------------------------|
| <b>ip nat crypto</b> | Enables this setting to utilize IP/Port NAT on the site-to-site VPN tunnel. This setting is disabled by default. |
|----------------------|------------------------------------------------------------------------------------------------------------------|

Example

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#ip nat crypto
```

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#show context
crypto map test 1 ipsec-isakmp
ip nat crypto
```

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#
```

local-endpoint-ip

[crypto-map auto-vpn-tunnel/remote-vpn-client instance](#) on page 957

Uses the configured IP as local tunnel endpoint address, instead of the interface IP

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

```
local-endpoint-ip <IP>
```

Parameters

```
local-endpoint-ip <IP>
```

|                                     |                                                                                                                                                                                                                                                          |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>local-endpoint-ip &lt;IP&gt;</b> | Configures the local VPN tunnel's (site-to-site VPN tunnel or remote VPN client) endpoint IP address <ul style="list-style-type: none"><li>• &lt;IP&gt; - Specify the IP address. The specified IP address must be available on the interface.</li></ul> |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Example

Site-to-site VPN tunnel:

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#local-endpoint-ip
192.168.13.10

rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#2)#
modeconfig

```

[crypto-map auto-vpn-tunnel/remote-vpn-client instance](#) on page 957

Configures the mode config method (pull or push) associated with the remote VPN client

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

```
modeconfig [pull|push]
```

Parameters

```
modeconfig [pull|push]
```

|                                         |                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>modeconfig</b><br><b>[pull push]</b> | Configures the mode config method associated with a remote VPN client. The options are: pull and push.<br>The mode (pull or push) defines the method used to assign a virtual IP. This setting is relevant for IKEv1 only, since IKEv2 always uses the configuration payload in pull mode. The default setting is push. |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Example

```

Remote VPN client:

rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#2)#modeconfig pull

rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#2)#show context
crypto map test 2 ipsec-isakmp dynamic
modeconfig pull
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#2)
peer

```

[crypto-map auto-vpn-tunnel/remote-vpn-client instance](#) on page 957

Configures the IKEv1 or IKEv2 peer for the auto site-to-site VPN tunnel or remote VPN client. The peer device can be specified either by its hostname or by its IP address. A maximum of three peers can be configured.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

```
peer <1-3> [ikev1|ikev2] <IKEv1/IKEv2-PEER-NAME>
```

#### Parameters

```
peer <1-3> [ikev1|ikev2] <IKEv1/IKEv2-PEER-NAME>
```

|                                      |                                                                                                                                       |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <b>peer &lt;1-3&gt;</b>              | Creates a new peer and configures the peer's priority level. Peer '1' is the primary peer, and peer '3' is redundant.                 |
| <b>ikev1 &lt;IKEv1-PEER-NAME&gt;</b> | Configures an IKEv1 peer <ul style="list-style-type: none"> <li>• &lt;IKEv1-PEER-NAME&gt; - Specify the IKEv1 peer's name.</li> </ul> |
| <b>ikev2&lt;IKEv2-PEER-NAME&gt;</b>  | Configures an IKEv2 peer <ul style="list-style-type: none"> <li>• &lt;IKEv2-PEER-NAME&gt; - Specify the IKEv2 peer's name.</li> </ul> |

#### Example

Site-to-site tunnel:

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#peer 1 ikev2 ikev2Peer1
```

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#show context
crypto map test 1 ipsec-isakmp
peer 1 ikev2 ikev2Peer1
local-endpoint-ip 192.168.13.10
ip nat crypto
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#
```

Remote VPN client:

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#2)#peer 1 ikev1 Re
moteIKEv1Peer1

rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#2)#show context
crypto map test 2 ipsec-isakmp dynamic
peer 1 ikev1 RemoteIKEv1Peer1
local-endpoint-ip 157.235.204.62
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#2)#
```

pfs

[crypto-map auto-vpn-tunnel/remote-vpn-client instance](#) on page 957

Configures Perfect Forward Secrecy (PFS) for the auto site-to-site VPN tunnel or remote VPN client

PFS is the key-establishment protocol, used to secure VPN communications. If one encryption key is compromised, only data encrypted by that specific key is compromised. For PFS to exist, the key used to protect data transmissions must not be used to derive any additional keys. Options include 2, 5 and 14. This option is disabled by default.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000

- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

**pfs** [14|2|5]

Parameters

**pfs** [14|2|5]

|                     |                                                                                                                                                                                                                                 |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>pfs</b> [14 2 5] | <p>Configures PFS</p> <ul style="list-style-type: none"> <li>• 14 – Configures D-H Group14 (2048-bit modp)</li> <li>• 2 – Configures D-H Group2 (1024-bit modp)</li> <li>• 5 – Configures D-H Group5 (1536-bit modp)</li> </ul> |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Example

Site-to-site VPN tunnel:

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#pfs 5

rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#show context
crypto map test 1 ipsec-isakmp
 peer 1 ikev2 ikev2Peer1
 local-endpoint-ip 192.168.13.10
 pfs 5
 ip nat crypto
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#
```

Remote VPN client:

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#2)#pfs 14

rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#2)#show context
crypto map test 2 ipsec-isakmp dynamic
 peer 1 ikev1 RemoteIKEv1Peer1
 local-endpoint-ip 157.235.204.62
 pfs 14
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#2)#
```

remote-type

[crypto-map auto-vpn-tunnel/remote-vpn-client instance](#) on page 957

Configures the remote VPN client type as either None or XAuth

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

**remote-type** [none|xauth]

Parameters

**remote-type** [none|xauth]

|                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>remote-type</b><br><b>[none   xauth]</b> | <p>Specify the remote VPN's client type</p> <ul style="list-style-type: none"> <li>• none – Configures remote VPN client with No XAUTH</li> <li>• xauth – Configures remote VPN client as using XAUTH (applicable only for IKEv1). This is the default setting.</li> </ul> <p>XAuth (extended authentication) provides additional authentication validation by permitting an edge device to request extended authentication information from an IPSec host. This forces the host to respond with additional authentication credentials. The edge device respond with a failed or passed message.</p> |
|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Example

Remote VPN client:

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#2)#remote-type none

rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#2)#show context
crypto map test 2 ipsec-isakmp dynamic
peer 1 ikev1 RemoteIKEv1Peer1
local-endpoint-ip 157.235.204.62
pfs 14
remote-type none
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#2)#
```

security-association

[crypto-map auto-vpn-tunnel/remote-vpn-client instance](#) on page 957

Defines the IPSec SA's (created by this auto site-to-site VPN tunnel or remote VPN client) settings

Supported in the following platforms:

- Access Points – AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers – RFS4000
- Service Platforms – NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

```
security-association [inactivity-timeout | level | lifetime]
```

```
security-association [inactivity-timeout <120-86400> | level perhost]
security-association lifetime [kilobytes <500-2147483646> | seconds <120-86400>]
```

Parameters

```
security-association [inactivity-timeout <120-86400> | level perhost]
```

|                                                       |                                                                                                                                                                                                                                                                                       |
|-------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>inactivity-timeout</b><br><b>&lt;120-86400&gt;</b> | <p>Specifies an inactivity period, in seconds, for this IPSec VPN SA. Once the set value is exceeded, the association is timed out.</p> <ul style="list-style-type: none"> <li>• &lt;120-86400&gt; – Specify a value from 120 - 86400 seconds. The default is 900 seconds.</li> </ul> |

| <b>lifetime</b><br><b>[kilobytes</b><br><b>&lt;500-2147483646</b><br><b>&gt;  seconds</b><br><b>&lt;120-86400&gt;]</b> | Defines the IPsec SA's lifetime (in kilobytes and/or seconds). Values can be entered in both kilobytes and seconds. Which ever limit is reached first, ends the security association. <ul style="list-style-type: none"> <li>• kilobytes &lt;500-2147483646&gt; – Defines volume based key duration. Specify a value from 500 - 2147483646 kilobytes. Select this option to define a connection volume lifetime (in kilobytes) for the duration of the IPsec VPN SA. Once the set volume is exceeded, the association is timed out. This option is disabled by default.</li> <li>• seconds &lt;120-86400&gt; – Defines time based key duration. Specify the time frame from 120 - 86400 seconds. Select this option to define a lifetime (in seconds) for the duration of the IPsec VPN SA. Once the set value is exceeded, the association is timed out. This option is disabled by default.</li> </ul> |
|------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Example

Site-to-site tunnel:

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#security-association
inactivity-timeout 200
```

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#security-association
level perhost
```

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#security-association
lifetime kilobytes 250000
```

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#show context
crypto map test 1 ipsec-isakmp
 security-association level perhost
 peer 1 ikev2 ikev2Peer1
 local-endpoint-ip 192.168.13.10
 pfs 5
 security-association lifetime kilobytes 250000
 security-association inactivity-timeout 200
 ip nat crypto
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#
```

Remote VPN client:

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#2)#security-association
lifetime seconds 10000
```

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#2)#show context
crypto map test 2 ipsec-isakmp dynamic

transform-set

[crypto-map auto-vpn-tunnel/remote-vpn-client instance](#) on page 957

Applies a transform set (encryption and hash algorithms) to site-to-site VPN tunnel or remote VPN client. This command allows you to provide customized data protection for each crypto map can be customized with its own data protection and peer authentication schemes.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

```
transform-set <TRANSFORM-SET-TAG> {<TRANSFORM-SET-TAG>}
```

#### Parameters

```
transform-set <TRANSFORM-SET-TAG> {<TRANSFORM-SET-TAG>}
```

|                                  |                                                                                                                                                                                                                                                                   |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>transform-set</b>             | Applies a transform set. The transform set should be existing and configured.                                                                                                                                                                                     |
| <b>&lt;TRANSFORM-SET-TAG&gt;</b> | <ul style="list-style-type: none"> <li>• &lt;TRANSFORM-SET-TAG&gt; - Specify the transform set's name.</li> <li>• &lt;TRANSFORM-SET-TAG&gt; - Optional. Specify a second transform set. You can provide multiple, space-separated, transform set tags.</li> </ul> |

#### Example

Site-to-site VPN tunnel:

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#transform-set AutoVPN
```

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#show context
crypto map test 1 ipsec-isakmp
 security-association level perhost
 peer 1 ikev2 ikev2Peer1
 local-endpoint-ip 192.168.13.10
 pfs 5
 security-association lifetime kilobytes 250000
 security-association inactivity-timeout 200
 transform-set AutoVPN
 ip nat crypto
```

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#
```

Remote VPN client:

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#2)#transform-set RemoteVPN
```

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#2)#show context
crypto map test 2 ipsec-isakmp dynamic
 peer 1 ikev1 RemoteIKEv1Peer1
 local-endpoint-ip 157.235.204.62
 pfs 14
 security-association lifetime seconds 10000
 transform-set RemoteVPN
 remote-type none
```

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#2)#
```

use

[crypto-map auto-vpn-tunnel/remote-vpn-client instance](#) on page 957

Applies an existing and configured IP access list to the auto site-to-site VPN tunnel or remote VPN client. Based on the IP access list's settings traffic is permitted or denied across the VPN tunnel.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000, RFS6000

- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

```
use ip-access-list <IP-ACCESS-LIST-NAME>
```

#### Parameters

```
use ip-access-list <IP-ACCESS-LIST-NAME>
```

**ip-access-list** Specify the IP access list name.  
**<IP-ACCESS-LIST-NAME>**

#### Example

Site-to-site VPN tunnel:

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#use ip-access-list test
```

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#show context
crypto map test 1 ipsec-isakmp
 use ip-access-list test
 security-association level perhost
 peer 1 ikev2 ikev2Peer1
 local-endpoint-ip 192.168.13.10
 pfs 5
 security-association lifetime kilobytes 250000
 security-association inactivity-timeout 200
 transform-set AutoVPN
 ip nat crypto
```

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#
```

Remote VPN client:

```
rrfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#2)#use ip-access-list test1
```

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#2)#show context
' crypto map test 2 ipsec-isakmp dynamic
 use ip-access-list test1
 peer 1 ikev1 RemoteIKEv1Peer1
 local-endpoint-ip 157.235.204.62
 pfs 14
 security-association lifetime seconds 10000
 transform-set RemoteVPN
 remote-type none
```

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#2)#
```

no

[crypto-map auto-vpn-tunnel/remote-vpn-client instance](#) on page 957

Removes or reverts the auto site-to-site VPN tunnel or remote VPN client settings

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

```
no [ip|local-endpoint-ip|modeconfig|peer|pfs|remote-type|security-association| transform-set|use]
```

Parameters

no <PARAMETERS>

|                           |                                                                                      |
|---------------------------|--------------------------------------------------------------------------------------|
| <b>no</b>                 | Removes or resets this auto site-to-site/remote VPN settings based on the parameters |
| <b>&lt;PARAMETERS&gt;</b> | passed                                                                               |

Example

The following example shows the IPSec site-to-site VPN tunnel 'test' settings before the 'no' commands are executed:

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#show context
crypto map test 1 ipsec-isakmp
 use ip-access-list test
 security-association level perhost
 peer 1 ikev2 ikev2Peer1
 local-endpoint-ip 192.168.13.10
 pfs 5
 security-association lifetime kilobytes 250000
 security-association inactivity-timeout 200
 transform-set AutVPN
 ip nat crypto
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#
```

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#no use ip-access-list
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#no security-association
level perhost
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#no ip nat crypto
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#no pfs
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#no local-endpoint-ip
```

The following example shows the IPSec site-to-site VPN tunnel 'test' settings after the 'no' commands are executed:

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#show context
crypto map test 1 ipsec-isakmp
 peer 1 ikev2 ikev2Peer1
 security-association lifetime kilobytes 250000
 security-association inactivity-timeout 200
 transform-set AutoVPN
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#1)#
```

The following example shows the IPSec remote VPN client 'test' settings before the 'no' commands are executed:

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#2)#show context
crypto map test 2 ipsec-isakmp dynamic
 use ip-access-list test2
 peer 1 ikev1 RemoteIKEv1Peer1
 local-endpoint-ip 157.235.204.62
 pfs 14
 security-association lifetime seconds 10000
 transform-set RemoteVPN
 remote-type none
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#2)#
```

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#2)#no use ip-access-list
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#2)#no peer 1
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#2)#no transform-set
```

The following example shows the IPsec remote VPN client 'test' settings after the 'no' commands are executed:

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#2)#show context
crypto map test 2 ipsec-isakmp dynamic
 local-endpoint-ip 157.235.204.62
 pfs 14
 security-association lifetime seconds 10000
 remote-type none
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#2)#
crypto-map-ipsec-manual-instance
```

[crypto-map-config-commands](#) on page 955

To navigate to the automatic IPsec manual VPN tunnel configuration instance, use the following command:

In the device-config mode:

```
<DEVICE>(config-device-<DEVICE-MAC>)#crypto map <CRYPTO-MAP-TAG> <1-1000> ipsec-manual
```

In the profile-config mode:

```
<DEVICE>(config-profile-<PROFILE-NAME>)#crypto map <CRYPTO-MAP-TAG> <1-1000> ipsec-manual
```

```
rfs4000-229D58(config-device-00-23-68-22-9D-58)#crypto map test 3 ipsec-manual
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#3)#?
```

Manual Crypto Map Configuration commands:

|                                   |                                                                                                    |
|-----------------------------------|----------------------------------------------------------------------------------------------------|
| <code>local-endpoint-ip</code>    | Use this IP as local tunnel endpoint address, instead of the interface IP (Advanced Configuration) |
| <code>mode</code>                 | Set the tunnel mode                                                                                |
| <code>no</code>                   | Negate a command or set its defaults                                                               |
| <code>peer</code>                 | Set peer                                                                                           |
| <code>security-association</code> | Set security association parameters                                                                |
| <code>session-key</code>          | Set security session key parameters                                                                |
| <code>use</code>                  | Set setting to use                                                                                 |
| <code>clearscr</code>             | Clears the display screen                                                                          |
| <code>commit</code>               | Commit all changes made in this session                                                            |
| <code>do</code>                   | Run commands from Exec mode                                                                        |
| <code>end</code>                  | End current mode and change to EXEC mode                                                           |
| <code>exit</code>                 | End current mode and down to previous mode                                                         |
| <code>help</code>                 | Description of the interactive help system                                                         |
| <code>revert</code>               | Revert changes                                                                                     |
| <code>service</code>              | Service Commands                                                                                   |
| <code>show</code>                 | Show running system information                                                                    |
| <code>write</code>                | Write running configuration to memory or terminal                                                  |

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-cryptomap-test#3)#
```

The following table summarizes IPsec manual VPN tunnel configuration mode commands:

| Command                                       | Description                                                                                                   |
|-----------------------------------------------|---------------------------------------------------------------------------------------------------------------|
| <code>local-endpoint-ip</code> on page 969    | Uses the configured IP as local tunnel endpoint address, instead of the interface IP (Advanced Configuration) |
| <code>mode</code> on page 969                 | Sets the tunnel mode                                                                                          |
| <code>peer</code> on page 970                 | Sets the peer device's IP address                                                                             |
| <code>security-association</code> on page 970 | Defines the lifetime (in kilobytes and/or seconds) of IPsec SAs created by a crypto map                       |

| Command                                 | Description                                                 |
|-----------------------------------------|-------------------------------------------------------------|
| <a href="#">session-key</a> on page 971 | Defines encryption and authentication keys for a crypto map |
| <a href="#">use</a> on page 973         | Uses the configured IP access list                          |
| <a href="#">no</a> on page 973          | Removes or reverts crypto map IPsec manual settings         |

## local-endpoint-ip

[crypto-map-ipsec-manual-instance](#) on page 968

Uses the configured IP as local tunnel endpoint address, instead of the interface IP (Advanced Configuration)

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

**local-endpoint-ip** <IP>

Parameters

**local-endpoint-ip** <IP>

|                               |                                                                                                                                                                                                                        |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>local-endpoint-ip</b> <IP> | <p>Uses the configured IP as local tunnel's endpoint address</p> <ul style="list-style-type: none"> <li>• &lt;IP&gt; - Specify the IP address. The specified IP address must be available on the interface.</li> </ul> |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Example

```
nx9500-6C8809(config-profile-default-rfs4000-cryptomap-map1#1)#local-endpoint-ip 172.16.10.3
```

mode

[crypto-map-ipsec-manual-instance](#) on page 968

Sets the crypto map tunnel mode

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

**mode** [transport|tunnel]

Parameters

**mode** [transport|tunnel]

|                                  |                                                                                                                                                                                                   |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>mode [transport   tunnel]</b> | Sets the mode of the tunnel for this crypto map <ul style="list-style-type: none"><li>• transport – Initiates transport mode</li><li>• tunnel – Initiates tunnel mode (default setting)</li></ul> |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

#### Example

```
nx9500-6C8809(config-profile-default-rfs4000-cryptomap-map1#1)#mode transport
```

```
nx9500-6C8809(config-profile-default-rfs4000-cryptomap-map1#1)#show context
crypto map map1 1 ipsec-manual
mode transport
```

```
nx9500-6C8809(config-profile-default-rfs4000-cryptomap-map1#1)#
```

peer

[crypto-map-ipsec-manual-instance](#) on page 968

Sets the peer device's IP address. This can be set for multiple remote peers. The remote peer can be an IP address.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

```
peer <IP>
```

#### Parameters

```
peer <IP>
```

|                        |                                                                                        |
|------------------------|----------------------------------------------------------------------------------------|
| <b>peer &lt;IP&gt;</b> | Enter the peer device's IP address. If not configured, it implies respond to any peer. |
|------------------------|----------------------------------------------------------------------------------------|

#### Example

```
nx9500-6C8809(config-profile-default-rfs4000-cryptomap-map1#1)#peer 172.16.10.12
```

```
nx9500-6C8809(config-profile-default-rfs4000-cryptomap-map1#1)#show context
crypto map map1 1 ipsec-manual
peer 172.16.10.12
```

```
nx9500-6C8809(config-profile-default-rfs4000-cryptomap-map1#1)#
```

security-association

[crypto-map-ipsec-manual-instance](#) on page 968

Defines the lifetime (in kilobytes and/or seconds) of IPSec SAs created by this crypto map

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

```
security-association lifetime [kilobytes <500-2147483646>|seconds
<120-86400>]
```

#### Parameters

```
security-association lifetime [kilobytes <500-2147483646>|seconds <120-86400>]
```

|                           |                                                                                                                        |
|---------------------------|------------------------------------------------------------------------------------------------------------------------|
| <b>lifetime</b>           | Values can be entered in both kilobytes and seconds. Which ever limit is reached first, ends the security association. |
| <b>[kilobytes</b>         |                                                                                                                        |
| <b>&lt;500-2147483646</b> | • kilobytes <500-2147483646> - Defines volume based key duration. Specify a value                                      |
| <b>&gt;  seconds</b>      | from 500 - 2147483646 bytes.                                                                                           |
| <b>&lt;120-86400&gt;]</b> | • seconds <120-86400> - Defines time based key duration. Specify the time frame                                        |
|                           | from 120 - 86400 seconds.                                                                                              |

#### Note

This command is not applicable to the ipsec-manual crypto map.

#### Example

```
nx9500-6C8809(config-profile-default-rfs4000-cryptomap-map2#2)#security-association
lifetime seconds 123
```

```
nx9500-6C8809(config-profile-default-rfs4000-cryptomap-map2#2)#show context
Command not applicable to this crypto map
```

```
nx9500-6C8809(config-profile-default-rfs4000-cryptomap-map2#2)#
```

session-key

[crypto-map-ipsec-manual-instance](#) on page 968

Defines encryption and authentication keys for this crypto map

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

```
session-key [inbound|outbound] [ah|esp] <256-4294967295>
```

```
session-key [inbound|outbound] ah <256-4294967295> [0|2|authenticator
[md5|sha]] <WORD>
```

```
session-key [inbound|outbound] esp <256-4294967295> [0|2|cipher [3des|
aes|aes-192| aes-256|des|esp-null]] <WORD> authenticator [md5|sha] <WORD>
```

#### Parameters

```
session-key [inbound|outbound] ah <256-4294967295> [0|2|authenticator [md5|sha]] <WORD>
```

|                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>session-key</b><br>[ inbound  <br>outbound ]         | Defines the manual inbound and outbound security association key parameters                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>esp</b><br><256-4294967295><br>5>                                               | Configures Encapsulating Security Payloads (ESP) as the security protocol for the security session. This is the default setting. <ul style="list-style-type: none"> <li>&lt;256-4294967295&gt; - Sets the SPI for the security association from 256 - 4294967295</li> </ul> <p>The SPI (in combination with the destination IP address and security protocol) identifies the security association.</p>                                                                                                                                                                                                                                                                                                                                                                                                         |
| [ 0   2   cipher<br>[ 3des   aes  <br>aes-192  <br>aes-256   des  <br>esp-null ] ] | <ul style="list-style-type: none"> <li>0 - Sets a clear text key</li> <li>2 - Sets an encrypted key</li> <li>cipher - Sets encryption/decryption key details <ul style="list-style-type: none"> <li>3des - ESP with 3DES encryption</li> <li>aes - ESP with AES encryption</li> <li>aes-192 - ESP with AES-192 encryption</li> <li>aes-256 - ESP with AES-256 encryption</li> <li>des - ESP with DES encryption</li> <li>esp-null - ESP with no encryption</li> </ul> </li> </ul> <p>authenticator - Specify ESP authenticator details<br/>md5 &lt;WORD&gt; - ESP with MD5 authentication<br/>sha &lt;WORD&gt; - ESP with SHA authentication</p> <p>&lt;WORD&gt; - Sets security association key value. The following key lengths (in hex characters) are required (w/o leading 0x).AH-MD5: 32, AH-SHA: 40</p> |

#### Example

```
nx9500-6C8809(config-profile-default-rfs4000-cryptomap-map1#1)#session-key inbound esp 273
cipher esp-null authenticator sha 58768979
```

```
nx9500-6C8809(config-profile-default-rfs4000-cryptomap-map1#1)#show context
crypto map map1 1 ipsec-manual
peer 172.16.10.2
mode transport
session-key inbound esp 273 0 cipher esp-null authenticator sha 58768979
nx9500-6C8809(config-profile-default-rfs4000-cryptomap-map1#1)#
```

use

[crypto-map-ipsec-manual-instance](#) on page 968

Associates an existing IP access list with this crypto map. The ACL protects the VPN traffic.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

```
use ip-access-list <IP-ACCESS-LIST-NAME>
```

Parameters

```
use ip-access-list <IP-ACCESS-LIST-NAME>
```

|                                                                                                      |
|------------------------------------------------------------------------------------------------------|
| <p><b>ip-access-list</b> Specify the IP access list name.<br/><b>&lt;IP-ACCESS-LIST-NAME&gt;</b></p> |
|------------------------------------------------------------------------------------------------------|

Example

```
nx9500-6C8809(config-profile-default-rfs4000-cryptomap-map1#1)#use ip-access-list test

nx9500-6C8809(config-profile-default-rfs4000-cryptomap-map1#1)#show context
crypto map map1 1 ipsec-manual
use ip-access-list test
peer 172.16.10.12
mode transport
session-key inbound esp 273 0 cipher esp-null authenticator sha 5876897
nx9500-6C8809(config-profile-default-rfs4000-cryptomap-map1#1)#
```

no

[crypto-map-ipsec-manual-instance](#) on page 968

Removes or resets this crypto map's settings

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

```
no [local-endpoint-ip|mode|peer|security-association|session-key|use]
```

## Parameters

no <PARAMETERS>

|                                        |                                                                           |
|----------------------------------------|---------------------------------------------------------------------------|
| <b>no</b><br><b>&lt;PARAMETERS&gt;</b> | Removes or resets this crypto map settings based on the parameters passed |
|----------------------------------------|---------------------------------------------------------------------------|

## Example

```
nx9500-6C8809(config-profile-default-rfs4000-cryptomap-map1#)#show context
crypto map map1 1 ipsec-manual
 use ip-access-list test
 peer 172.16.10.12
 mode transport
 session-key inbound esp 273 0 cipher esp-null authenticator sha 5876897
nx9500-6C8809(config-profile-default-rfs4000-cryptomap-map1#)#
```

```
nx9500-6C8809(config-profile-default-rfs4000-cryptomap-map1#)#no use ip-access-list
nx9500-6C8809(config-profile-default-rfs4000-cryptomap-map1#)#no peer
nx9500-6C8809(config-profile-default-rfs4000-cryptomap-map1#)#no mode
```

```

```

## crypto-remote-vpn-client commands

[crypto](#) on page 931

This section documents the IKEV2 remote VPN client configuration settings. Use this command to define the server resources used to secure (authenticate) a remote VPN connection with a target peer.

Use the profile-config instance to configure remote VPN client settings. To navigate to the remote-vpn-client configuration instance, use the following commands:

```
<DEVICE>(config)#profile <DEVICE-TYPE> <PROFILE-NAME>
<DEVICE>(config-profile-<PROFILE-NAME>)#crypto remote-vpn-client
<DEVICE>(config-profile-<PROFILE-NAME>-crypto-ikev2-remote-vpn-client)#
```

### Note

To configure remote VPN client settings on a device, on the device's configuration mode, use the `crypto > remote-vpn-client` command. For example: `rfs4000-229D58(config-device-00-23-68-22-9D-58)#crypto remote-vpn-client`

The following configuration enables a access point to adopt to a controller over the remote VPN link:

- On a profile: `rfs4000-229D58(config-profile-testRFS4000)#controller host <HOST-IP> remote-vpn-client`
- On a device: `rfs4000-229D58(config-00-23-68-22-9D-58)#controller host <HOST-IP> remote-vpn-client`  
`rfs4000-229D58(config)#profile rfs4000 testRFS4000`  
`rfs4000-229D58(config-profile-testRFS4000)#`

```
rfs4000-229D58(config-profile-testRFS4000)#crypto remote-vpn-client
rfs4000-229D58(config-profile-testRFS4000-crypto-ikev2-remote-vpn-client)#?
Crypto IKEV2 Remote Vpn Client Config commands:
dhcp-peer Configure parameters for peers received via DHCP option
no Negate a command or set its defaults
peer Add a remote peer
shutdown Disable remote vpn client
transform-set Specify IPSec transform to use

clrscr Clears the display screen
commit Commit all changes made in this session
do Run commands from Exec mode
end End current mode and change to EXEC mode
exit End current mode and down to previous mode
help Description of the interactive help system
revert Revert changes
service Service Commands
show Show running system information
write Write running configuration to memory or terminal

rfs4000-229D58(config-profile-testRFS4000-crypto-ikev2-remote-vpn-client)#
```

The following table summarizes `crypto remote VPN client` configuration mode commands:

| Command                                | Description                                                            |
|----------------------------------------|------------------------------------------------------------------------|
| <code>dhcp-peer</code> on page 976     | Configures DHCP peer's local ID and authentication settings            |
| <code>peer</code> on page 976          | Adds a remote IKEv2 peer                                               |
| <code>shutdown</code> on page 977      | Disables the remote VPN client                                         |
| <code>transform-set</code> on page 978 | Associates an existing IPSec transform set with this remote VPN client |
| <code>no</code> on page 978            | Removes the remote VPN client settings                                 |

## dhcp-peer

[crypto-remote-vpn-client commands](#) on page 974

Configures DHCP peer's local ID and authentication settings

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

```
dhcp-peer [authentication|localid]
```

```
dhcp-peer authentication [psk [0 <WORD>|2 <WORD>|<WORD>]|rsa]
```

```
dhcp-peer localid [autogen-uniqueid <WORD>|string <WORD>]
```

Parameters

```
dhcp-peer authentication [psk [0 <WORD>|2 <WORD>|<WORD>]|rsa]
```

|                                                                                        |                                                                                                                                                                                                                                                                                                                                                |
|----------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>dhcp-peer authentication [psk [0 &lt;WORD&gt; 2 &lt;WORD&gt; &lt;WORD&gt;] rsa]</b> | Configures the DHCP peer's authentication type as PSK <ul style="list-style-type: none"><li>• 0 &lt;WORD&gt; - Configures a clear text authentication key</li><li>• 2 &lt;WORD&gt; - Configures an encrypted authentication key</li><li>• &lt;WORD&gt; - Provide a 8 - 21 character shared key password for DHCP peer authentication</li></ul> |
| <b>dhcp-peer authentication rsa</b>                                                    | Configures the DHCP peer's authentication type as RSA. This is the default setting.                                                                                                                                                                                                                                                            |

```
dhcp-peer localid [autogen-uniqueid <WORD>|string <WORD>]
```

|                                                                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>dhcp-peer localid [autogen-uniqueid &lt;WORD&gt; string &lt;WORD&gt;]</b> | Configures the DHCP peer's localid using one of the following options: <ul style="list-style-type: none"><li>• autogen-uniqueid - Generates a localid using the device's unique identity. The system prefixes the device's unique identity to the string provided here. The device's unique identity should be existing and configured. For more information on configuring a device's unique identity, see <a href="#">autogen-uniqueid</a> on page 883.<ul style="list-style-type: none"><li>• &lt;WORD&gt; - Provide the string.</li></ul></li><li>• string - Uses the value provided here as the DHCP peer's localid.<ul style="list-style-type: none"><li>• &lt;WORD&gt; - Provide the string.</li></ul></li></ul> |
|------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Example

```
rfs4000-229D58(config-profile-testRFS4000-crypto-ikev2-remote-vpn-client)#dhcp-peer authentication psk 0 @123testing
```

```
rfs4000-229D58(config-profile-testRFS4000-crypto-ikev2-remote-vpn-client)#show context crypto remote-vpn-client
 dhcp-peer authentication psk 0 @123testing
rfs4000-229D58(config-profile-testRFS4000-crypto-ikev2-remote-vpn-client)#
```

peer

[crypto-remote-vpn-client commands](#) on page 974

Configures IKEv2 peers and assigns them priorities for utilization with remote VPN client connections. A maximum of three (3) peers can be added to support redundancy.

IKEv2 uses an initial handshake in which VPN peers negotiate cryptographic algorithms, mutually authenticate, and establish a session key, creating an IKE-SA. Additionally, a first IPSec SA is established during the initial SA creation. All IKEv2 messages are request/response pairs. It is the responsibility of the side sending the request to retransmit if it does not receive a timely response.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

```
peer <1-3> ikev2 <IKEV2-PEER-NAME>
```

Parameters

```
peer <1-3> ikev2 <IKEV2-PEER-NAME>
```

|                                      |                                                                                                                                                                                                                                                    |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>peer &lt;1-3&gt;</b>              | Adds a IKEv2 peer. You can add maximum of three (3) peers to achieve redundancy. <ul style="list-style-type: none"><li>• &lt;1-3&gt; - Specify a priority level for the peer from 1 - 3 (1 = primary, 2 = secondary, and 3 = redundant).</li></ul> |
| <b>ikev2 &lt;IKEV2-PEER-NAME&gt;</b> | Specify the IKEv2 peer's name.<br><b>Note:</b> The peer should be existing and configured. To configure an IKEv2 peer use the <code>crypto &gt; ikev2 &gt; peer &gt; &lt;IKEV2-PEER-NAME&gt;</code> command.                                       |

Example

```
rfs4000-229D58(config-profile-testRFS4000-crypto-ikev2-remote-vpn-client)#peer 1 ikev2 ikev2Peer1
```

```
rfs4000-229D58(config-profile-testRFS4000-crypto-ikev2-remote-vpn-client)#peer 2 ikev2 ikev2Peer2
```

```
rfs4000-229D58(config-profile-testRFS4000-crypto-ikev2-remote-vpn-client)#show context crypto remote-vpn-client peer 1 ikev2 ikev2Peer1 peer 2 ikev2 ikev2Peer2
```

```
rfs4000-229D58(config-profile-testRFS4000-crypto-ikev2-remote-vpn-client)#
```

shutdown

[crypto-remote-vpn-client commands](#) on page 974

Disables remote-vpn-client on this profile or device. Remote VPN client feature is enabled by default.

To enable a disabled remote VPN client execute the `no > shutdown` command.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

**shutdown**

Parameters

None

Example

```
rfs4000-229D58(config-profile-testRFS4000-crypto-ikev2-remote-vpn-client)#
shutdown
rfs4000-229D58(config-profile-testRFS4000-crypto-ikev2-remote-vpn-client)#
```

transform-set

[crypto-remote-vpn-client commands](#) on page 974

Specifies the IPSec Transform set to use with this remote VPN client. A transform set is a combination of security protocols, algorithms, and other settings applied to IPSec protected client traffic.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

**transform-set** <IPSEC-XFORM-TAG> {<IPSEC-XFORM-TAG>}

Parameters

**transform-set** <IPSEC-XFORM-TAG> {<IPSEC-XFORM-TAG>}

|                                                                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p><b>transform-set</b><br/><b>&lt;IPSEC-XFORM-TAG&gt;</b> &lt;IPSEC-XFORM-TAG&gt;</p> | <p>Associates an IPSec Transform (should be existing and configured) set with this remote VPN client. You can optionally associate more than one transform set with this remote VPN client configuration. List the transform set tags separated by a space.</p> <p><b>Note:</b> To configure a transform-set, use the <code>crypto &gt; ipsec &gt; transform-set</code> command in the profile or device configuration mode.</p> |
|----------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Example

```
rfs4000-229D58(config-profile-testRFS4000-crypto-ikev2-remote-vpn-client)#transform-set
TransformSet1
```

```
rfs4000-229D58(config-profile-testRFS4000-crypto-ikev2-remote-vpn-client)#show
context
crypto remote-vpn-client
peer 1 ikev2 ikev2Peer1
transform-set TransformSet1
rfs4000-229D58(config-profile-testRFS4000-crypto-ikev2-remote-vpn-client)#
```

no

[crypto-remote-vpn-client commands](#) on page 974

Removes the remote VPN client settings

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

```
no [dhcp-peer|peer <1-3>|shutdown|transform-set]
```

```
no dhcp-peer [authentication|localid]
```

```
no peer <1-3>
```

```
no shutdown
```

```
no transform-set
```

Parameters

```
no <PARAMETERS>
```

|                                        |                                                                                  |
|----------------------------------------|----------------------------------------------------------------------------------|
| <b>no</b><br><b>&lt;PARAMETERS&gt;</b> | Removes or resets this remote VPN client settings based on the parameters passed |
|----------------------------------------|----------------------------------------------------------------------------------|

Example

```
rfs4000-229D58(config-profile-testRFS4000-crypto-ikev2-remote-vpn-client)#show context
crypto remote-vpn-client
peer 1 ikev2 peer5
rfs4000-229D58(config-profile-testRFS4000-crypto-ikev2-remote-vpn-client)#

rfs4000-229D58(config-profile-testRFS4000-crypto-ikev2-remote-vpn-client)#no peer 1

rfs4000-229D58(config-profile-testRFS4000-crypto-ikev2-remote-vpn-client)#show context
crypto remote-vpn-client
rfs4000-229D58(config-profile-testRFS4000-crypto-ikev2-remote-vpn-client)#
```

*database*

[Profile Config Commands](#) on page 862

Backs up captive-portal and/or NSight database to a specified location and file. When applied to devices, this profile will enable the back up of the specified database. This command also enables you to configure a low-disk-space threshold value.

These parameters can also be configured in the device configuration context of an NX95XX series service platform.

**Supported in the following platforms:**

- Service Platforms — NX9500, NX9510, NX9600, VX9000

**Syntax**

```
database [backup|low-disk-space-threshold]
```

```
database backup database [captive-portal|nsight] <URL>
```

```
database low-disk-space-threshold <10-50>
```

### Parameters

```
database backup database [captive-portal|nsight] <URL>
```

### *device-onboard*

[Profile Config Commands](#) on page 862

Configures the logo image file name and title displayed on the EGuest device-onboarding portal. The EGuest UI can be accessed only by vendor-admin users.

#### Note

Vendor admin users are configured in the Management policy context. For more information, see [user \(management-policy\)](#) on page 1544.

### Supported in the following platforms:

- Service Platforms — NX9500, NX9510, NX9600, VX9000

## Syntax

```
device-onboard [logo|title] <WORD>
```

## Parameters

```
device-onboard [logo|title] <WORD>
```

|                                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## *device-upgrade*

[Profile Config Commands](#) on page 862

Configures device firmware upgrade settings on this profile

Administrators can customize profiles with unique device configuration file and firmware upgrade support. In a clustered environment, operations performed on one device are propagated to each member of the cluster and then onwards to devices managed by each cluster member. The number of concurrent device upgrades and their start times can be customized to ensure a sufficient number of devices remain in duty while upgrades are administered to others.

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
device-upgrade [add-auto|auto|count|persist-images]
```

```
device-upgrade add-auto [(ap6522|ap6562|ap71xx|ap7502|ap7522|ap7532|ap7562|ap7602|ap7612|ap7622|ap7632|ap7662|ap81xx|ap8432|ap8533|rfs4000|nx5500|nx75xx|nx9000|nx9600)]
```

```
device-upgrade auto {(ap6522|ap6562|ap71xx|ap7502|ap7522|ap7532|ap7562|ap7602|ap7612|ap7622|ap7632|ap7662|ap81xx|ap8432|ap8533|rfs4000|nx5500|nx75xx|nx9000|nx9600)}
```

```
device-upgrade count <1-128>
```

```
device-upgrade persist-images
```

### Parameters

```
device-upgrade add-auto[(ap6522|ap6562|ap71xx|ap7502|ap7522|ap7532|ap7562|ap7602|ap7612|ap7622|ap7632|ap7662|ap81xx|ap8432|ap8533|rfs4000|nx5500|nx75xx|nx9000|nx9600)]
```

|                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>device-upgrade</b><br><b>add-auto</b> | Configures a list of device types for automatic firmware upgrade. This command specifies the types of devices that can be automatically upgraded (if enabled). To enable automatic device firmware upgrade, use the 'auto' command. When enabled, access points, wireless controllers, and service platforms, using this profile, will automatically upgrade firmware on adopted devices that match the specified device types. |
| <b>[ &lt;DEVICE-TYPE&gt; ]</b>           | Specifies the type of devices to be upgraded. Select the device type. The options are: AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533, RFS4000, NX5500, NX75XX, NX95XX, NX96XX, VX9000.<br><br><b>Note:</b> Multiple device types can be added to the add-auto list.                                                                                    |

```
device-upgrade auto {(ap6522|ap6562|ap71xx|ap7502|ap7522|ap7532|ap7562|ap7602|ap7612|ap7622|ap7632|ap7662|ap81xx|ap8432|ap8533|rfs4000|nx5500|nx75xx|nx9000|nx9600)}
```

|                            |                                                                                                                                                                                                                                                                                                                                                          |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>device-upgrade auto</b> | Enables automatic firmware upgrade on specified device types. When used along with the add-auto command, the auto command allows access points, wireless controllers, and service platforms to automatically upgrade firmware on adopted devices matching the specified device types.                                                                    |
| <b>&lt;DEVICE-TYPE&gt;</b> | Optional. Specifies the type of device to be lined up for automatic firmware upgrade. The options are: AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533, RFS4000, NX5500, NX75XX, NX95XX, NX9600, VX9000.<br><br><b>Note:</b> Multiple device types can be added to the auto list. |

device-upgrade count <1-128>

|                                           |                                                                                                                                                                                    |
|-------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>device-upgrade count &lt;1-128&gt;</b> | Configures the maximum number of concurrent upgrades possible <ul style="list-style-type: none"> <li>• &lt;1-128&gt; - specify a value from 1 - 128. The default is 10.</li> </ul> |
|-------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

device-upgrade persist-images

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>device-upgrade</b> | Configures parameters for automatic firmware upgrade of adopted devices. Use this command to select the device types and the maximum number of concurrent upgrades.                                                                                                                                                                                                                                                                                                     |
| <b>persist-images</b> | Enables RF Domain manager to retain AP firmware image after upgrade, subject to availability of space. This option is enabled by default.<br>This option is enabled for all controllers and service platforms RF Domain managers with the flash memory capacity to store firmware images for the selected access point models they provision. This feature is disabled for access point RF Domain managers that do not typically have the flash memory capacity needed. |

### Example

```
rfs4000-229D58(config-profile-default-rfs4000)#device-upgrade auto ap7lxx

*diag*

[Profile Config Commands](#) on page 862

Enables looped packet logging. When enabled, devices, using this profile, start logging looped packets to a separate queue. This option is disabled by default.

Looped packet logging can also be enabled in the device configuration context.

#### Note

To view logged looped packets, execute the **service > show > diag > pkts** command. For more information, see [service](#) on page 647.

#### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

#### *dot1x*

[Profile Config Commands](#) on page 862

Configures 802.1x standard authentication controls

Dot1x (or 802.1x) is an IEEE standard for network authentication. It enables media-level (layer 2) access control, providing the capability to permit or deny connectivity based on user or device identity. Dot1x allows port-based access using authentication. An dot1x enabled port can be dynamically enabled or disabled depending on user identity or device connection.

Devices supporting dot1x allow the automatic provision and connection to the wireless network without launching a Web browser at login. When within range of a dot1x network, a device automatically connects and authenticates without needing to manually login.

Before authentication, the endpoint is unknown, and traffic is blocked. Upon authentication, the endpoint is known and traffic is allowed. The controller or service platform uses source MAC filtering to ensure only the authenticated endpoint is allowed to send traffic.

Dot1x authentication capabilities is supported on the following platforms:

**Supported in the following platforms:**

- Access Points — AP6522, AP6562, AP7502, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500

Dot1x supplicant capabilities is supported on the following platforms:

**Supported in the following platforms:**

- Access Points — AP6522, AP6562, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500

**Syntax**

```
dot1x [guest-vlan | holdtime | system-auth-control | use]
```

```
dot1x holdtime <0-600>
dot1x system-auth-control
dot1x guest-vlan supplicant
dot1x use aaa-policy <AAA-POLICY-NAME>
```

**Parameters**

```
dot1x system-auth-control
```

|                            |                                                                                                                            |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <b>system-auth-control</b> | Enables system auth control. Enables dot1x authorization globally for the controller. This feature is disabled by default. |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------|

```
dot1x holdtime <0-600>
```

|                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>holdtime<br/>&lt;0-600&gt;</b> | Configures a holdtime value. This is the interval after which an authentication attempt is ignored or failed. <ul style="list-style-type: none"><li>• &lt;0-600&gt; – Specify a value from 0 - 600 seconds. A value of '0' indicates no holdtime. The default is 600 seconds or 10 minutes.</li></ul> Adding a hold time at startup allows time for the network to converge before receiving or transmitting 802.1x authentication packets. |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
dot1x guest-vlan supplicant
```

|                   |                                                                                                                               |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <b>guest-vlan</b> | Configures guest VLAN and supplicant behavior. This feature is disabled by default.                                           |
| <b>supplicant</b> | Allows 802.1x capable supplicant to enter guest VLAN. When enabled, this is the VLAN that supplicant's traffic is bridged on. |

```
dot1x use aaa-policy <AAA-POLICY-NAME>
```

|                                                         |                                                                                                                                                                                                                                                                                                  |
|---------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>use aaa-policy</b><br><b>&lt;AAA-POLICY-NAME&gt;</b> | Associates a specified 802.1x AAA policy (for MAC authentication) with this access point profile <ul style="list-style-type: none"> <li>• <b>&lt;AAA-POLICY-NAME&gt;</b> - Specify the AAA policy name. Once specified, this AAA policy is utilized for authenticating user requests.</li> </ul> |
|---------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

*dpi*

[Profile Config Commands](#) on page 862

Enables Deep Packet Inspection (DPI) on this profile. DPI is an advanced packet analysis technique, which analyzes packet and packet content headers to determine the nature of network traffic. When enabled, DPI inspects packets of all flows to identify applications (such as, Netflix, Twitter, Facebook,

etc.) and extract metadata (such as, host name, server name, TCP-RTT, etc.) for further use by the WiNG firewall.

This command is also available in the device configuration mode.

#### Supported in the following platforms:

- Access Points — AP7522, AP7532, AP7602, AP7612, AP7622, AP7632, AP7662
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600

#### Syntax

```
dpi {custom-app/logging/metadata}
```

```
dpi {custom-app <CUSTOM-APP-NAME>}
```

```
dpi {logging [level [<0-7>|alerts|critical|debugging|emergencies|errors|informational|notifications|warnings]|on]}
```

```
dpi {metadata [http/ssl/tcp-rtt/voice-video]}
```

```
dpi {metadata [http/ssl/voice-video]}
```

```
dpi {metadata tcp-rtt {app-group <APPLICATION-GROUP-NAME>}}
```

#### Parameters

```
dpi {custom-app <CUSTOM-APP-NAME>}
```

|                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                    |

### *dscp-mapping*

[Profile Config Commands](#) on page 862

Configures IP Differentiated Services Code Point (DSCP) to 802.1p priority mapping for untagged frames

#### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

```
dscp-mapping <WORD> priority <0-7>
```

#### Parameters

```
dscp-mapping <word> priority <0-7>
```

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>&lt;WORD&gt;</b>         | Specifies the DSCP value of a received IP packet. This could be a single value or a list. For example, 10-20, 25, 30-35.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>priority &lt;0-7&gt;</b> | <p>Specifies the 802.1p priority to use for a packet if untagged. The priority is set on a scale of 0 - 7. The priority values are:</p> <ul style="list-style-type: none"> <li>• 0 - Best effort</li> <li>• 1 - Background</li> <li>• 2 - Spare</li> <li>• 3 - Excellent effort</li> <li>• 4 - Controlled load</li> <li>• 5 - Video</li> <li>• 6 - Voice</li> <li>• 7 - Network control</li> </ul> <p><b>Note:</b> The specified 802.1p priority value is added as a 3-bit IP precedence value in the Type of Service (ToS) field of the IP header used to set the priority. Up to 64 entries are permitted.</p> |

### Example

```
nx9500-6C8809(config-profile-default-rfs4000)#dscp-mapping 20 priority 7
```

```
nx9500-6C8809(config-profile-default-rfs4000)#show context

*eguest-server (VX9000 only)*

[Profile Config Commands](#) on page 862

Enables the ExtremeGuest (EGuest) server

The WiNG EGuest solution is an independently installable VM/Server that provides integrated guest management and analytics. Use this command to enable the EGuest daemon on the EGuest server.

#### Note

EGuest being a licensed feature, ensure that the EGUEST-DEV license is applied on the EGuest server's self context. For more information, see [license](#) on page 1267.

---

### Supported in the following platforms:

- Service Platforms — VX9000

#### Note

For more information on configuring an EGuest captive-portal deployment, see [configuring ExtremeGuest captive portal](#) on page 332.

---

### Syntax

```
eguest-server
```

### Parameters

```
eguest-server
```

|                      |                                                                                                                                                                                                         |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>eguest-server</b> | <b>Note:</b> Execute this command, without the 'host' option, on the EGuest server. When executed, the EGuest daemon is enabled on the host.<br><br>EGuest server can be hosted only a VX9000 platform. |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Example

On the EGuest server, execute the command without the 'host' option to enable the EGuest daemon.

```
EG-Server(config-device-02-EE-1A-7E-AE-5B)#eguest-server
```

```
EG-Server(config-device-02-EE-1A-7E-AE-5B)#show context include-factory | include eguest-server
eguest-server
EG-Server(config-device-02-EE-1A-7E-AE-5B)#
```

#### *email-notification*

[Profile Config Commands](#) on page 862

Configures e-mail notification settings. When a system event occurs e-mail notifications are sent (provided message logging is enabled) based on the settings configured here. Use this option to configure the outgoing SMTP server settings.

#### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
email-notification [host|recipient]
```

```
email-notification recipient <RECIPIENT-NAME>
```

```
email-notification host <SMTP-SERVER-IP/HOSTNAME> sender <SENDER-EMAIL>
[port|security|username]
```

```
email-notification host <SMTP-SERVER-IP/HOSTNAME> sender <SENDER-EMAIL>
[(port <1-65535>, security [none|ssl|starttls], username <SMTP-USERNAME>
password [2 <WORD>|<WORD>])]
```

### Parameters

```
email-notification recipient <RECIPIENT-EMAIL>
```

|                                                    |                                                                                                                                                                                                                                                                           |
|----------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>recipient</b><br><b>&lt;RECIPIENT-EMAIL&gt;</b> | <p>Defines the recipient's e-mail address. A maximum of 6 (six) e-mail addresses can be configured.</p> <ul style="list-style-type: none"> <li>• &lt;RECIPIENT-EMAIL&gt; - Specify the recipient's e-mail address (should not exceed 64 characters in length).</li> </ul> |
|----------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
email-notification host <SMTP-SERVER-IP/HOSTNAME> sender <SENDER-EMAIL> [(port <1-65535>,
security [none|ssl|starttls], username <SMTP-USERNAME> password [2 <WORD>|<WORD>])]
```

|                                             |                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

*enforce-version*

[Profile Config Commands](#) on page 862

Enables checking of a device's firmware version before attempting adoption or clustering

**Supported in the following platforms:**

- Access Points — AP6522, AP6562, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

## Syntax

```
enforce-version [adoption|cluster] [full|major|minor|none|strict]
```

## Parameters

```
enforce-version [adoption|cluster] [full|major|minor|none|strict]
```

|                 |                                                                                                                                                                            |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>adoption</b> | Verifies firmware versions before adopting. This option is enabled by default.                                                                                             |
| <b>cluster</b>  | Verifies firmware versions before clustering. This option is enabled by default.                                                                                           |
| <b>full</b>     | Allows adoption or clustering when the first four octets of the firmware versions match (for example 5.8.6.0)                                                              |
| <b>major</b>    | Allows adoption or clustering when the first two octets of the firmware versions match (for example 5.8)                                                                   |
| <b>minor</b>    | Allows adoption or clustering when the first three octets of the firmware versions match (for example 5.8.6)                                                               |
| <b>none</b>     | Allows adoption or clustering between any firmware versions                                                                                                                |
| <b>strict</b>   | Allows adoption or clustering only when firmware versions exactly match (for example 5.8.6.0-008B). This is the default setting for both 'adoption' and 'cluster' options. |

## Example

```
nx9500-6C8809(config-profile-test-nx5500)#enforce-version cluster full
nx9500-6C8809(config-profile-test-nx5500)#enforce-version adoption major
```

```
nx9500-6C8809(config-profile-test-nx5500)#show context
profile nx5500 test-nx5500
 no autoinstall configuration
 no autoinstall firmware
 crypto ikev1 policy ikev1-default
 isakmp-proposal default encryption aes-256 group 2 hash sha

interface pppoel
 use firewall-policy default
 enforce-version adoption major
 enforce-version cluster full
 service pm sys-restart
 router ospf
 router bgp
 dot1x system-auth-control
 dot1x use aaa-policy OnBoarding
nx9500-6C8809(config-profile-test-nx5500)#
```

*environmental-sensor*

[Profile Config Commands](#) on page 862

Configures the environmental sensor settings

An AP8132 sensor module is a USB environmental sensor extension to an AP8132 model access point. It provides a variety of sensing mechanisms, allowing the monitoring and reporting of the AP8132's radio coverage area.

**Supported in the following platforms:**

- Access Points – AP8132

**Syntax**

```
environmental-sensor [humidity|light|motion|polling-interval|temperature]
```

```
environmental-sensor [humidity|motion|polling-interval <1-100>|
temperature]
```

```
environmental-sensor light {holdtime|radio-shutdown|threshold}
```

```
environmental-sensor light {holdtime <10-201>|radio-shutdown [all|
radio-1|radio-2]}
```

```
environmental-sensor light {threshold [high <100-10000>|low <0-1000>]}
```

**Parameters**

```
environmental-sensor [humidity|motion|polling-interval <1-100>|temperature]
```

|                                       |                                                                                                                                                                                                                                                                                                                                  |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>environmental-sensor</b>           | Configures environmental sensor settings on this profile                                                                                                                                                                                                                                                                         |
| <b>humidity</b>                       | Enables (turns on) humidity sensors. This setting is enabled by default.                                                                                                                                                                                                                                                         |
| <b>motion</b>                         | Enables (turns on) motion sensors. This setting is enabled by default.                                                                                                                                                                                                                                                           |
| <b>polling-interval &lt;1-100&gt;</b> | Configures polling interval, in seconds, on all sensors. This is the interval after which the sensor module polls its environment to assess the various parameters, such as light intensity. <ul style="list-style-type: none"> <li>• &lt;1-100&gt; – Specify a value from 1 - 100 seconds. The default is 5 seconds.</li> </ul> |
| <b>temperature</b>                    | Enables (turns on) temperature sensors. This setting is enabled by default.                                                                                                                                                                                                                                                      |

```
environmental-sensor light {holdtime <10-201>|radio-shutdown [all|radio-1|radio-2]}
```

|                             |                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>environmental-sensor</b> | Configures environmental sensor settings on this profile                                                                                                                                                                                                                                                                                                                                   |
| <b>light</b>                | Enables (turns on) light sensors and specifies its settings<br>When enabled, the sensor module polls the environment to determine the light intensity. Based on the reading, the system determines whether the AP8132's deployment location has lights on or off. Light intensity also helps determine whether the access point's deployment location is currently populated with clients. |

|                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>holdtime</b><br><b>&lt;10-201&gt;</b>                | Optional. Configures a holdtime, in seconds, for the light sensor <ul style="list-style-type: none"> <li>• &lt;10-201&gt; - Specify a value from 10 - 201 seconds. The default value is 11 seconds.</li> </ul>                                                                                                                                                                                                                                                               |
| <b>radio-shutdown</b><br><b>[all   radio1   radio2]</b> | Optional. Shuts down the sensor's radios <ul style="list-style-type: none"> <li>• all - Shuts down all radios. This is the default setting.</li> <li>• radio1 - Shuts down radio 1</li> <li>• radio2 - Shuts down radio 2</li> </ul> <p>AP8132's using this profile have their radios shut down, when the radio's power falls below the specified threshold. Use the environmental-sensor &gt; light &gt; threshold &gt; [high low] command to set the threshold values.</p> |

```
environmental-sensor light {threshold [high <100-10000>|low <0-1000>]}
```

|                                         |                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>environmental-sensor</b>             | Configures environmental sensor settings on this profile                                                                                                                                                                                                                                                                                         |
| <b>light</b>                            | Enables (turns on) light sensors and specifies its settings                                                                                                                                                                                                                                                                                      |
| <b>threshold</b>                        | Optional. Configures the upper and lower thresholds for the amount of light in the environment                                                                                                                                                                                                                                                   |
| <b>high</b><br><b>&lt;100-10000&gt;</b> | Specifies the upper threshold from 100 - 10000 lux. This value determines whether lighting is on in the AP8132's deployment location. The radios are turned off if the average reading value is lower than the value set here. The default is 400 lux.<br>The light sensor triggers an event if the amount of light exceeds the specified value. |
| <b>low</b> <b>&lt;0-1000&gt;</b>        | Specifies the lower threshold from 0 - 1000 lux. This value determines whether lighting is off in the AP8132's deployment location. The radios are turned on when the average value is higher than the value set here. The default is 200 lux.<br>The light sensor triggers an event if the amount of light drops below the specified value.     |

## events

[Profile Config Commands](#) on page 862

Displays system event messages

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
events [forward on|on]
```

### Parameters

```
events [forward on|on]
```

|                   |                                                                                                                                                                                                                                 |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>forward on</b> | Forwards system event messages to the wireless controller, service platform, or cluster members. This feature is enabled by default. <ul style="list-style-type: none"><li>• on – Enables forwarding of system events</li></ul> |
| <b>on</b>         | Generates system events. This feature is enabled by default.                                                                                                                                                                    |

### Example

```
nx9500-6C8809(config-profile-default-rfs4000)#events forward on
nx9500-6C8809(config-profile-default-rfs4000)#
```

## export

[Profile Config Commands](#) on page 862

Enables export of startup.log file after every boot

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
export startup-log [max-retries|retry-interval|url]
export startup-log [max-retries <2-65535>|retry-interval <30-86400>|url
<URL>]
```

## Parameters

`export startup-log [max-retries <2-65535>|retry-interval <30-86400>|url <URL>]`

|                                        |                                                                                                                                                                                                          |
|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>export startup-log</b>              | Enables export of the startup.log file after every boot. This option is disabled by default.                                                                                                             |
| <b>max-retries &lt;2-65535&gt;</b>     | Configures the maximum number of retries in case the export process fails <ul style="list-style-type: none"><li>• &lt;2-65535&gt; - Specify a value from 2 - 65535.</li></ul>                            |
| <b>retry-interval &lt;30-86400&gt;</b> | Configures the interval between two consecutive retries <ul style="list-style-type: none"><li>• &lt;30-86400&gt; - Specify a value from 30 - 86400 seconds.</li></ul>                                    |
| <b>url &lt;URL&gt;</b>                 | Configures the destination URL in the following format:<br>tftp://<hostname IP>[:port]/path/file<br>ftp://<user>:<passwd>@<hostname IP>[:port]/path/file<br>sftp://<user>@<hostname IP>[:port]/path/file |

## Example

## *file-sync*

[Profile Config Commands](#) on page 862

Configures parameters enabling auto syncing of trustpoint/wireless-bridge certificate between the staging-controller and its adopted access points

This command is applicable to the access point's profile as well as device configuration modes.

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000

- Service Platforms — NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600

### Syntax

```
file-sync [auto|count <1-20>]
```

### Parameters

```
file-sync [auto|count <1-20>]
```

|                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>file-sync</b><br><b>[auto count</b><br><b>&lt;1-20&gt;]</b> | <p>Configures the following file-synching parameters:</p> <ul style="list-style-type: none"> <li>• auto - Enables the staging controller to autoinstall trustpoint/wireless-bridge certificate on an access point when it comes up for the first time and adopts to the controller.</li> </ul> <p>Prior to enabling file syncing, ensure that the wireless-bridge certificate is present on the staging controller. To upload the certificate on the controller, in the user or privilege executable modes, execute the following command:<br/>file-sync &gt; load-file &gt; &lt;URL&gt;.</p> <ul style="list-style-type: none"> <li>• count &lt;1-20&gt; - Configures the maximum number of access points that can be concurrently auto-installed. <ul style="list-style-type: none"> <li>• &lt;1-20&gt; - Specify a value from 1 - 20. The default is 10 access points.</li> </ul> </li> </ul> <p><b>Note:</b> For the NX95XX service platforms the count-range is from 1 - 128.</p> |

*floor*

[Profile Config Commands](#) on page 862

Sets the floor name where the target device (access point, wireless controller, or service platform using this profile) is physically located. Assigning a building floor name helps in grouping devices within the same general coverage area.

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
floor <WORD> {<1-4094>}
```

### Parameters

```
floor <WORD> {<1-4094>}
```

|                                                      |                                                                                                                                                                                                                                                                                               |

*gre*

[Profile Config Commands](#) on page 862

The following table summarizes commands that allow you to enter the GRE configuration mode:

| Command                                          | Description                                                                                                                                                                        |
|--------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">gre</a> on page 1002                 | Enables GRE tunneling on a profile/device. This command also creates a GRE tunnel and enters its configuration mode. Use this command to modify an existing GRE tunnel's settings. |
| <a href="#">gre-config-instance</a> on page 1003 | Summarizes GRE tunnel configuration mode commands                                                                                                                                  |

## gre

gre on page 1001

Enables Generic Routing Encapsulation (GRE) tunneling on this profile, and creates a new GRE tunnel or modifies an existing GRE tunnel.

The GRE protocol allows encapsulation of one protocol over another. It is a tunneling protocol that transports any layer 3 protocol over an IP network. When enabled, a payload packet is first encapsulated in the GRE protocol. The GRE encapsulated payload is then encapsulated in another IP packet before being forwarded to the destination.

GRE tunneling can be configured to bridge Ethernet packets between WLANs and a remote WLAN gateway over an IPv4 GRE tunnel. The tunneling of 802.3 packets using GRE is an alternative to MiNT or L2TPv3. Related features like ACLs for extended VLANs are still available using layer 2 tunneling over GRE.

Using GRE, access points map one or more VLANs to a tunnel. The remote end point is a user-configured WLAN gateway IP address, with an optional secondary IP address should connectivity to the primary GRE peer be lost. VLAN traffic is expected in both directions in the GRE tunnel. A WLAN mapped to these VLANs can be either open or secure. Secure WLANs require authentication to a remote RADIUS server available within your deployment using standard RADIUS protocols. Access Points can reach both the GRE peer as well as the RADIUS server using IPv4.

The WiNG software now supports for both IPv4 or IPv6 tunnel endpoints. However, a tunnel needs to contain either IPv4 or IPv6 formatted device addresses and cannot be mixed. With the new IPv6 tunnel implementation, all outbound packets are encapsulated with the GRE header, then the IPv6 header. The header source IP address is the local address of the IPv6 address of tunnel interface, and the destination address peer address of the tunnel. All inbound packets are de-capsulated by removing the IPv6 and GRE header before sending it over to the IP stack.

### Note

Only one GRE tunnel can be created for every profile.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7622, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

```
gre tunnel <GRE-TUNNEL-NAME>
```

Parameters

```
gre tunnel <GRE-TUNNEL-NAME>
```

dscp

[gre-config-instance](#) on page 1003

Sets the GRE tunnel's DSCP / 802.1q priority value from encapsulated packets to the outer packet IPv4 header.

This option is disabled by default.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7622, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

**dscp** [**<0-63>** | **reflect**]

Parameters

**dscp** [**<0-63>** | **reflect**]

|                                 |                                                                                           |
|---------------------------------|-------------------------------------------------------------------------------------------|
| <b>dscp</b> <b>&lt;0-63&gt;</b> | Specifies the DSCP 802.1q priority value for outer packets from 0 - 63. The default is 1. |
| <b>dscp</b> <b>reflect</b>      | Copies the DSCP 802.1q value from inner packets                                           |

Example

```
rfs4000-229D58(config-device 00-23-68-22-9D-58-gre-tunnel-testGREtunnel)#dscp 20

rfs4000-229D58(config-device 00-23-68-22-9D-58-gre-tunnel-testGREtunnel)#show context
 gre tunnel testGREtunnel
 dscp 20
rfs4000-229D58(config-device 00-23-68-22-9D-58-gre-tunnel-testGREtunnel)#
```

establishment-criteria

[gre-config-instance](#) on page 1003

Configures the GRE tunnel establishment criteria

In a multi-controller RF domain, it is always the master node that establishes the tunnel. The tunnel is created only if the tunnel device is designated as one of the following: vrrp-master, cluster-master, or rf-domain-manager.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7622, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

```
establishment-criteria [always | cluster-master | rf-domain-manager | vrrp-master <1-255>]
```

Parameters

```
establishment-criteria [always | cluster-master | rf-domain-manager | vrrp-master <1-255>]
```

|                                                                                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>establishment-criteria</b><br><b>[always   cluster-master   rf-domain-manager   vrrp-master &lt;1-255&gt;]</b> | Configures the GRE tunnel establishment criteria. The options are: <ul style="list-style-type: none"><li>• always – Always automatically establishes tunnel (default setting). The tunnel device need not be a cluster master, RF Domain manager, or VRRP master to establish the GRE tunnel. This is the default setting.</li><li>• cluster-master – Establishes tunnel only if the tunnel device is designated as the cluster master</li><li>• rf-domain-manager – Establishes tunnel only if the tunnel device is designated as the RF Domain manager</li><li>• vrrp-master &lt;1-255&gt; – Establishes tunnel only if the tunnel device is designated as the Virtual Router Redundancy (VRRP) master<ul style="list-style-type: none"><li>• &lt;1-255&gt; – Configures the VRRP group ID from 1 - 255. A VRRP group enables the creation of a group of routers as a default gateway for redundancy. Clients can point to the IP address of the VRRP virtual router as their default gateway and utilize a different group member if a master becomes unavailable.</li></ul></li></ul> |

failover

[gre-config-instance](#) on page 1003

Enables periodic pinging of the primary gateway to assess its availability. When enabled, the system continues pinging, an unreachable gateway, for a specified number of times and at the specified interval.

This option is disabled by default.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7622, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

```
failover interval <1-250> retry <1-10>
```

Parameters

```
failover interval <1-250> retry <1-10>
```

|                                                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>failover interval</b><br><b>&lt;1-250&gt; retry</b><br><b>&lt;1-10&gt;</b> | Specifies the interval, in seconds, between two successive pings to the primary gateway. If the primary gateway is unreachable, the system pings it at intervals specified here. <ul style="list-style-type: none"><li>• &lt;1-250&gt; - Specify a value from 1 - 250 seconds.</li><li>• retry - Specifies the maximum number attempts made to ping the primary gateway before the session is terminated.<ul style="list-style-type: none"><li>&lt;1-10&gt; - Specify a value from 1 - 10.</li></ul></li></ul> |
|-------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Example

```
rfs4000-229D58(config-device 00-23-68-22-9D-58-gre-tunnel-testGRE Tunnel)#failover interval 200 retry 5
```

```
rfs4000-229D58(config-device 00-23-68-22-9D-58-gre-tunnel-testGRE Tunnel)#show context gre tunnel testGRE Tunnel
dscp 20
failover interval 200 retry 5
rfs4000-229D58(config-device 00-23-68-22-9D-58-gre-tunnel-testGRE Tunnel)#
```

mtu

[gre-config-instance](#) on page 1003

Configures the MTU for IPv4/IPv6 L2GRE tunnel endpoints

The MTU is the largest physical packet size (in bytes) transmittable within the tunnel. Any messages larger than the configured MTU are divided into smaller packets before transmission. Larger the MTU greater is the efficiency because each packet carries more user data, while protocol overheads, such as headers or underlying per-packet delays remain fixed; the resulting higher efficiency means a slight improvement in bulk protocol throughput. A larger MTU results in the processing of fewer packets for the same amount of data.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7622, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000

- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

```
mtu [ipv4 <900-1476>|ipv6 <1236-1456>]
```

#### Parameters

```
mtu [ipv4 <900-1476>|ipv6 <1236-1456>]
```

|                                                           |                                                                                                                                                               |

|---------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>native tagged</b>                        | <p>Enables native VLAN tagging</p> <p>The IEEE 802.1Q specification is supported for tagging frames and coordinating VLANs between devices. IEEE 802.1Q adds four bytes to each frame identifying the VLAN ID for upstream devices that the frame belongs to. If the upstream Ethernet device does not support IEEE 802.1Q tagging, it does not interpret the tagged frames. When VLAN tagging is required between devices, both devices must support tagging and be configured to accept tagged VLANs. When a frame is tagged, the 12 bit frame VLAN ID is added to the 802.1Q header so upstream Ethernet devices know which VLAN ID the frame belongs to. The device reads the 12 bit VLAN ID and forwards the frame to the appropriate VLAN. When a frame is received with no 802.1Q header, the upstream device classifies the frame using the default or native VLAN assigned to the Trunk port. The native VLAN allows an Ethernet device to associate untagged frames to a VLAN when no 802.1Q frame is included in the frame. This feature is disabled by default.</p> |
| <b>native vlan</b><br><b>&lt;1-4094&gt;</b> | <p>Specifies a numerical VLAN ID (1 - 4094) for the native VLAN</p> <p>The native VLAN allows an Ethernet device to associate untagged frames to a VLAN, when no 802.1q frame is included in the frame. Additionally, the native VLAN is the VLAN untagged traffic is directed over when using a port in trunk mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

### Example

```

nx9500-6C8809(config-profile testNX9500-gre-tunnel-testGREtunnel)#native tagged

nx9500-6C8809(config-profile testNX9500-gre-tunnel-testGREtunnel)#native vlan 20

nx9500-6C8809(config-profile testNX9500-gre-tunnel-testGREtunnel)#show context
gre tunnel testGREtunnel
 native vlan 20
 native tagged
 mtu ipv4 1200
 mtu ipv6 1300
 establishment-criteria rf-domain-manager
nx9500-6C8809(config-profile testNX9500-gre-tunnel-testGREtunnel)#

```

no

[gre-config-instance](#) on page 1003

Removes or resets the GRE tunnel settings based on the parameters passed

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7622, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
no [dscp|establishment-criteria|failover|mtu|native|peer|tunneled-vlan]
```

```
no [dscp|establishment-criteria|failover|tunneled-vlan]
```

```
no mtu [ipv4|ipv6]
```

```
no native [tagged|vlan]
```

```
no peer <1-2>
```

Parameters

```
no <PARAMETERS>
```

|                                                                                                         |
|---------------------------------------------------------------------------------------------------------|
| <b>no &lt;PARAMETERS&gt;</b> Removes or resets the GRE tunnel's settings based on the parameters passed |
|---------------------------------------------------------------------------------------------------------|

Example

The following example shows the GRE tunnel 'testGREtunnel' settings before the no commands are executed:

```
rfs4000-229D58(config-device 00-23-68-22-9D-58-gre-tunnel-testGREtunnel)#show context
gre tunnel testGREtunnel
 peer 1 ip 192.168.13.6
 native vlan 1
 tunneled-vlan 1,10
 native tagged
 dscp 20
 failover interval 200 retry 5
rfs4000-229D58(config-device 00-23-68-22-9D-58-gre-tunnel-testGREtunnel)#
```

```
rfs4000-229D58(config-device 00-23-68-22-9D-58-gre-tunnel-testGREtunnel)#no dscp
rfs4000-229D58(config-device 00-23-68-22-9D-58-gre-tunnel-testGREtunnel)#no native vlan
rfs4000-229D58(config-device 00-23-68-22-9D-58-gre-tunnel-testGREtunnel)#no tunneled-vlan
rfs4000-229D58(config-device 00-23-68-22-9D-58-gre-tunnel-testGREtunnel)#no failover
```

The following example shows the GRE tunnel 'testGREtunnel' settings after the no commands are executed:

```
rfs4000-229D58(config-device 00-23-68-22-9D-58-gre-tunnel-testGREtunnel)#show context
gre tunnel testGREtunnel
 peer 1 ip 192.168.13.6
 native tagged
rfs4000-229D58(config-device 00-23-68-22-9D-58-gre-tunnel-testGREtunnel)#
```

peer

[gre-config-instance](#) on page 1003

Adds the GRE tunnel's end-point peers. A maximum of two peers, representing the tunnel's end points, can be added for each GRE tunnel.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7622, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

```
peer <1-2> ip <IPv4/IPv6>
```

Parameters

```
peer <1-2> ip <IPv4/IPv6>
```

|                                              |                                                                                                                                                                                                                                                                                                                                                                                            |

#### tunneled-vlan

[gre-config-instance](#) on page 1003

Defines the VLAN that connected clients use to route GRE tunneled traffic within their respective WLANs

Supported in the following platforms:

- Access Points – AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7622, AP8163, AP8432, AP8533
- Wireless Controllers – RFS4000
- Service Platforms – NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

**tunneled-vlan <VLAN-ID>**

#### Parameters

**tunneled-vlan <VLAN-ID>**

|                                      |                                                                                                                                                                                                                                                      |
|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>tunneled-vlan &lt;VLAN-ID&gt;</b> | <p>Specifies the VLANs associated with this GRE tunnel</p> <ul style="list-style-type: none"> <li>• &lt;VLAN-ID&gt; – Specify the VLAN IDs. Specify a comma-separated list of IDs, to specify multiple VLANs. For example, 1,10,12,16-20.</li> </ul> |
|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

#### Example

```
rfs4000-229D58(config-device 00-23-68-22-9D-58-gre-tunnel-testGREtunnel)# tunneled-vlan 10
```

```
rfs4000-229D58(config-device 00-23-68-22-9D-58-gre-tunnel-testGREtunnel)#show context
gre tunnel testGREtunnel
 peer 1 ip 192.168.13.6
 native vlan 1
 tunneled-vlan 1,10
 native tagged
```

```
dscp 20
failover interval 200 retry 5
rfs4000-229D58(config-device 00-23-68-22-9D-58-gre-tunnel-testGRE Tunnel)#
```

### *http-analyze*

[Profile Config Commands](#) on page 862

Enables forwarding of HTTP request related data to the HTTP analytics engine

Wireless clients (MUs) connect to APs and route their HTTP requests through the APs. These APs extract and forward HTTP request packets, through MiNT, to the NX series controller. The NX series controller uses a new analytic daemon to cache, format, and forward information to the analytics engine. Currently the analytics daemon is supported only on the NX series service platform. Therefore, it is essential that all APs should use an NX series service platform as controller.

In a hierarchically organized network, HTTP analytics data forwarding is a simple and transparent process. The site controllers receive the HTTP data from adopted APs adopted. This data is compressed and forwarded to the Network Operations Center (NOC) controller. There is no need for a separate configuration to enable this feature.

Use this command to configure the mode and interval at which data is sent to the controller and the external analytics engine. This command also configures the external engine's details, such as URL, credentials, etc.

---

#### Note

The Analytics module helps gather data about customer behavior such as web sites visited, search terms used, mobile device types, number of new users vs. repeat users. This data provides a better understanding of pricing strategies and promotions being run by competitors.

---

#### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

```
http-analyze [compress|external-server|update-interval <1-3600>]
```

```
http-analyze [compress|update-interval <1-3600>
```

```
http-analyze external-server [password <WORD>|proxy <URL>|update-interval <1-3600>|url <URL>|username <WORD>|validate-server-certificate]
```

## Parameters

`http-analyze [compress|update-interval <1-3600>]`

|                                       |                                                                                                                                                                                                                                       |
|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>http-analyze</b>                   | Configures HTTP analysis related parameters                                                                                                                                                                                           |
| <b>compress</b>                       | Compresses update files before forwarding to the controller. This option is disabled by default.                                                                                                                                      |
| <b>update-interval &lt;1-3600&gt;</b> | Configures the interval, in seconds, at which buffered packets are pushed to the controller <ul style="list-style-type: none"><li>• &lt;1-3600&gt; - Specify the interval from 1 - 3600 seconds. The default is 60 seconds.</li></ul> |

`http-analyze external-server [password <WORD>|proxy <URL>|update-interval | url|username|validate-server-certificate]`

|                                       |                                                                                                                                                                                                                                                                                                              |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>http-analyze external-server</b>   | Configures the external HTTP analytics engine's parameters                                                                                                                                                                                                                                                   |
| <b>password &lt;WORD&gt;</b>          | Configures the external analytics engine's password <ul style="list-style-type: none"><li>• &lt;WORD&gt; - Provide the login password. This is the password associated with the user name needed to access the external analytics engine.</li></ul>                                                          |
| <b>proxy &lt;URL&gt;</b>              | Configures the proxy server's uniform resource locator (URL) <ul style="list-style-type: none"><li>• &lt;URL&gt; - Specify the proxy server's URL in the following format: <code>http://username:password@proxy-server:port</code>. For example, <code>http://mot:sym@wwwgate0.mot.com:1080</code></li></ul> |
| <b>update-interval &lt;1-3600&gt;</b> | Configures the interval, in seconds, at which buffered packets are pushed to the external analytics engine <ul style="list-style-type: none"><li>• &lt;1-3600&gt; - Specify the interval from 1 - 3600 seconds. The default is 60 seconds.</li></ul>                                                         |
| <b>url &lt;URL&gt;</b>                | Configures the external analytics engine's IP address or URL <ul style="list-style-type: none"><li>• &lt;URL&gt; - Provide the IP address or URL.</li></ul>                                                                                                                                                  |
| <b>username &lt;WORD&gt;</b>          | Configures the user name needed to access the external analytics engine <ul style="list-style-type: none"><li>• &lt;WORD&gt; - Provide the user name.</li></ul>                                                                                                                                              |
| <b>validate-server-certificate</b>    | Validates the external analytics engine's certificate, if it is using HTTPS as the mode of access                                                                                                                                                                                                            |

## interface

[interface](#) on page 1013

Selects an interface to configure

A profile's interface configuration can be defined to support separate physical Ethernet configurations both unique and specific to RFS4000 controllers and NX7500 and NX95XX series service platforms. Ports vary depending on the platform, but controller or service platform models do have some of the same physical interfaces.

A controller or service platform requires its virtual interface be configured for layer 3 (IP) access or layer 3 service on a VLAN. A virtual interface defines which IP address is associated with each VLAN ID the controller or service platform is connected to.

If the profile is configured to support an access point radio, an additional radio interface is available, unique to the access point's radio configuration.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax Service Platforms

```
interface [<INTERFACE-NAME>|fe <1-4>|ge <1-24>|me1|port-channel <1-4>|
pppoe1| radio [1|2|3]|serial <1-4>|tle1 <1-4>|up <1-2>|vlan <1-4094>|
wwan1|xge <1-4>]
```

Syntax Access Points and Wireless Controllers

```
interface [<INTERFACE-NAME>|bluetooth <1-1>|fe <1-4>|ge <1-8>|me1|port-
channel <1-4>|pppoe1|radio [1|2|3]|up1|vlan <1-4094>|wwan1|xge <1-4>]
```

#### Parameters

```
interface [<INTERFACE-NAME>|bluetooth <1-1>|fe <1-4>|ge <1-8>|me1|port-channel <1-4>|radio
[1|2|3]|serial <1-4>|tle1 <1-4>|up <1-2>|vlan <1-4094>|wwan1|xge <1-4>]
```

|                                 |                                                                                                                                                                                                                                                                                                                    |

| <b>xge &lt;1-4&gt;</b>          | Selects a TenGigabitEthernet interface <ul style="list-style-type: none"> <li>• &lt;1-2&gt; - Specify the interface index from 1 - 4.</li> </ul>                                                                                                                                                                   |

#### Usage Guidelines

The ports available on a device vary depending on the model. For example, the following ports are available on RFS4000 and RFS7000 model wireless controllers:

- RFS4000 - ge1, ge2, ge3, ge4, ge5, up1
- GE ports on are RJ-45 supporting 10/100/1000Mbps

ME ports are out-of-band management ports used to manage the controller via CLI or Web UI, even when the other ports on the controller are unreachable.

The ports available on service platforms also vary depending on the model. For example, the following ports are available on NX series service platforms:

- NX7500 - ge1-ge10, xge1-xge2
- NX95XX series - ge1, ge2, xge1-xge4
- EX3500 - ge1-1 to ge1-24
- EX3548 - ge1-1 to ge1-48

GE ports are available on devices, such as RFS4000 controllers. GE ports are RJ-45 supporting 10/100/1000Mbps.

An UP port is used to connect to the backbone network. An UP port supports either RJ-45 or fiber. The UP port is the preferred means to connect to the backbone as it has a non-blocking 1gbps connection unlike the GE ports.

- The following ports are available on access points:
- AP6522 - GE1/POE (LAN)
- AP6562 - GE1/POE
- AP7161 - GE1/POE (LAN), GE2 (WAN)
- AP7502 - GE1 (THRU), fe1, fe2, fe3,
- AP7522 - GE1/POE (LAN)
- AP7532 - GE1/POE (LAN)
- AP8163 - GE1/POE (LAN), GE2 (WAN)

#### Note

For a NX7500 model service platform, there are options for either a 2 port or 4 port network management card. Either card can be managed using WiNG. If the 4 port card is used, ports ge7-ge10 are available. If the 2 port card is used, ports xge1-xge2 are available.

#### Example

```
nx9500-6C8809(config-profile-default-rfs4000-if-vlan44)#
nx9500-6C8809(config-profile-default-rfs4000-if-vlan44)#?

### Interface-config-ge-instance

`interface` on page 1013

This section documents the GigabitEthernet configuration commands.

GE port placement and quantity varies depending on the controller, service platform, or access point model. Configure the GE interface either in the device's profile-config context or directly on a device.

The following example uses the config-profile-nx9500-6C8809 instance to configure a GigabitEthernet interface:

```
nx9500-6C8809(config-profile-testNX9000-if-ge2)#?
Interface configuration commands:
 captive-portal-enforcement Enable captive-portal enforcement on this port
 cdp Cisco Discovery Protocol
 channel-group Channel group commands
 description Interface specific description
 dot1x 802.1X
 duplex Set duplex to interface
 ip Internet Protocol (IP)
 ipv6 Internet Protocol version 6 (IPv6)
 lacp LACP commands
 lacp-channel-group LACP channel commands
 lldp Link Local Discovery Protocol
 mac-auth Enable mac-auth for this port
 no Negate a command or set its defaults
 power PoE Command
 qos Quality of service
 remove-override Remove configuration item override from the
 device (so profile value takes effect)
 shutdown Shutdown the selected interface
 spanning-tree Spanning tree commands
 speed Configure speed
 switchport Set switching mode characteristics
 use Set setting to use

 clrscr Clears the display screen
 commit Commit all changes made in this session
 do Run commands from Exec mode
 end End current mode and change to EXEC mode
 exit End current mode and down to previous mode
 help Description of the interactive help system
 revert Revert changes
 service Service Commands
 show Show running system information
 write Write running configuration to memory or
 terminal
```

```
nx9500-6C8809(config-profile-testNX9000-if-ge2)#
```

The following table summarizes the interface configuration commands:

| Command                                                 | Description                                                                                    |

| <a href="#">use</a> on page 1043                        | Associates IPv4, IPv6, and/or MAC ACL with the selected Ethernet port                          |

## captive-portal-enforcement

[interface-config-ge-instance](#) on page 1017

Enables application of captive portal access permission rules to data transmitted over this specific Ethernet port. This setting is disabled by default.

Captive portal enforcement allows users on the wired network to pass traffic through the captive portal without being redirected to an authentication page. Authentication instead takes place when the

RADIUS server is queried against the wired user's MAC address. If the MAC address is in the RADIUS server's user database, the user can pass traffic on the captive portal.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

```
captive-portal-enforcement {fall-back}
```

Parameters

```
captive-portal-enforcement {fall-back}
```

|                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

cdp

[interface-config-ge-instance](#) on page 1017

Enables CDP on the selected GE port

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

```
cdp [receive|transmit]
```

Parameters

```
cdp [receive|transmit]
```

|                 |                                                                                                                                                                                                                  |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>receive</b>  | Enables CDP packet snooping on this interface. When enabled, the port receives periodic interface updates from a multicast address. This option is enabled by default.                                           |
| <b>transmit</b> | Enables CDP packet transmission on this interface. When enabled, the port sends out periodic interface updates to a multicast address to advertise its presence to neighbors. This option is enabled by default. |

#### Example

```
nx9500-6C8809(config-profile-default-rfs4000-if-ge1)#cdp transmit
```

#### Related Commands

| <b>no</b> on page 1033 | Disables CDP packet snooping on the controller or service platform's selected GE ports |
|------------------------|----------------------------------------------------------------------------------------|

### channel-group

[interface-config-ge-instance](#) on page 1017

Assigns this Ethernet port to a channel group. Ethernet ports can be aggregated to form a channel group. For example, an RFS7000 has four (4) Ethernet ports (1, 2, 3, & 4). These can be aggregated to form a minimum of one and maximum of two channel groups. A port can be a member of only one channel group at a time.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

```
channel-group <1-4>
```

#### Parameters

```
channel-group <1-4>
```

|                    |                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>&lt;1-4&gt;</b> | <p>Specifies a channel group number from 1 - 4. The number of channel groups supported varies with the device type. For example:</p> <ul style="list-style-type: none"> <li>• NX5500 - Supports three channel groups</li> <li>• NX75XX - Supports four channel groups</li> <li>• NX95XX - Supports two channel groups</li> </ul> <p><b>Note:</b> RFS4000 - Supports three channel groups.</p> |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

#### Example

```
nx9500-6C8809(config-profile-default-rfs4000-if-ge1)#channel-group 1
```

```
nx9500-6C8809(config-profile-default-rfs4000-if-ge1)#show context
interface ge1
 ip dhcp trust
 qos trust dscp
 qos trust 802.1p
 channel-group 1
nx9500-6C8809(config-profile-default-rfs4000-if-ge1)#
```

#### Related Commands

`no` on page 1033      Removes the channel group to which this port belongs

description

[interface-config-ge-instance](#) on page 1017

Configures a description for this Ethernet port

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

`description [ <LINE> | <WORD> ]`

Parameters

`description [ <LINE> | <WORD> ]`

|                     |                                                                                                                                     |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <b>&lt;LINE&gt;</b> | Configures the maximum length (number of characters) of the interface description                                                   |
| <b>&lt;WORD&gt;</b> | Configures a unique description for this interface. The description should not exceed the length specified by the <LINE> parameter. |

Example

```
nx9500-6C8809(config-profile-default-rfs4000-if-ge1)#description "This is GigabitEthernet interface for Royal King"
```

```
nx9500-6C8809(config-profile-default-rfs4000-if-ge1)#show context
interface ge1
 description "This is GigabitEthernet interface for Royal King"
 ip dhcp trust
 qos trust dscp
 qos trust 802.1p
 channel-group 1
nx9500-6C8809(config-profile-default-rfs4000-if-ge1)#
```

`no` on page 1033      Removes the interface description

dot1x (authenticator)

[interface-config-ge-instance](#) on page 1017

Configures 802.1X authenticator settings

Dot1x (or 802.1x) is an IEEE standard for network authentication. It enables media-level (layer 2) access control, providing the capability to permit or deny connectivity based on user or device identity. Dot1x allows port-based access using authentication. An dot1x enabled port can be dynamically enabled or disabled depending on user identity or device connection.

Devices supporting dot1x allow the automatic provision and connection to the wireless network without launching a Web browser at login. When within range of a dot1x network, a device automatically connects and authenticates without needing to manually login.

Before authentication, the endpoint is unknown, and traffic is blocked. Upon authentication, the endpoint is known and traffic is allowed. The controller or service platform uses source MAC filtering to ensure only the authenticated endpoint is allowed to send traffic.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP8163, AP8432
- Wireless Controllers — RFS4000, NX5500, NX7500

Syntax

```
dot1x authenticator [guest-vlan | host-mode | max-reauth-req | port-control |
reauthenticate | timeout]
```

```
dot1x authenticator [guest-vlan <1-4094> | host-mode [multi-host | single-
host] | max-reauth-req <1-10> | port-control [auto | force-authorized | force-
unauthorized] | reauthenticate | timeout [quiet-period | reauth-period]
<1-65535>]
```

#### Note

The dot1x (802.1x) supplicant settings are documented in the next section.

Parameters

```
dot1x authenticator [guest-vlan <1-4094> | host-mode [multi-host | single-host] | max-reauth-
req <1-10> | port-control [auto | force-authorized | force-unauthorized] | reauthenticate | timeout
[quiet-period | reauth-period]]
```

|                                                                    |                                                                                                                                                                                                                                                                                                     |

| <b>reauthenticate</b>                                                             | Enables re-authentication for this port. When enabled, clients are forced to re-authenticate on this port. The setting is disabled by default. Therefore, clients are not required to re-authenticate for connection over this port until this setting is enabled.                                                                                                                                                                                                                                                                                                                |
| <b>timeout</b><br><b>[quiet-period   reauth-period]</b><br><b>&lt;1-65535&gt;</b> | <p>Configures timeout settings for this interface</p> <ul style="list-style-type: none"> <li>quiet-period – Configures the quiet period timeout in seconds. This is the interval, in seconds, between successive client authentication attempts.</li> <li>reauth-period – Configures the time after which re-authentication is initiated</li> </ul> <p>The following option is common to ‘quiet-period’ and ‘reauth-period’ keywords:</p> <ul style="list-style-type: none"> <li>&lt;1-65535&gt; – Specify a ‘quiet-period’ or ‘reauth-period’ from 1 - 65535 seconds.</li> </ul> |

### Example

```
rfs4000-229D58(config-profile-testRFS4000-if-gel)#dot1x authenticator guest-vlan 2

rfs4000-229D58(config-profile-testRFS4000-if-gel)#dot1x authenticator host-mode multi-host

rfs4000-229D58(config-profile-testRFS4000-if-gel)#dot1x authenticator max-reauth-req 6

rfs4000-229D58(config-profile-testRFS4000-if-gel)#dot1x authenticator reauthenticate

rfs4000-229D58(config-profile-testRFS4000-if-gel)#show context
interface gel
 dot1x authenticator host-mode multi-host
 dot1x authenticator guest-vlan 2
 dot1x authenticator reauthenticate
 dot1x authenticator max-reauth-count 6
 ip dhcp trust
 qos trust dscp
 qos trust 802.1p
rfs4000-229D58(config-profile-testRFS4000-if-gel)#
```

The following examples show the configurations made on an RFS4000 to enable it as a dot1X authenticator:

- 1 Configure AAA policy on the authenticator, and identify the authentication server as onboard (self):

```
rfs4000-229D58(config-aaa-policy-aaa-wireddot1x)#show context
aaa-policy aaa-wireddot1x
authentication server 1 onboard controller
rfs4000-229D58(config-aaa-policy-aaa-wireddot1x)#
```

This AAA policy is used in the authenticator’s self configuration mode as shown in the last step.

- 2 Configure RADIUS user policy on the authenticator:

```
rfs4000-229D58(config-radius-user-pool-wired-dot1x-users)#show con
radius-user-pool-policy wired-dot1x-users
user bob password 0 bob1234
rfs4000-229D58(config-radius-user-pool-wired-dot1x-users)#
```

The user name and password configured here should match that of the supplicant. For more information, see the examples provided in the [dot1x \(supplicant\)](#) on page 1024 section.

- 3 Configure RADIUS server policy on the authenticator, and associate the RADIUS user policy created in the previous step:

```
rfs4000-229D58(config-radius-server-policy-for-wired-dot1x)#show con
radius-server-policy for-wired-dot1x
use radius-user-pool-policy wired-dot1x-users
rfs4000-229D58(config-radius-server-policy-for-wired-dot1x)#
```

- 4 In the authenticator's self configuration mode, associate the RADIUS server policy, created in the previous step, and configure other parameters (in bold) as shown in the following example:  

```
rfs4000-229D58(config-device-00-15-70-81-73-79)#use radius-server-policy for-wired-dot1x
```
- 5 In the authenticator's interface > ge configuration mode, configure the following parameters:  

```
rfs4000-229D58(config-device-00-15-70-81-73-79-if-ge2)#dot1x authenticator host-mode single-host
rfs6000-817379(config-device-00-15-70-81-73-79-if-ge2)#dot1x authenticator port-control auto
```
- 6 In the authenticator's self configuration mode, configure the following parameters:  

```
rfs4000-229D58(config-device-00-15-70-81-73-79)#dot1x system-auth-control
rfs4000-229D58(config-device-00-15-70-81-73-79)#dot1x use aaa-policy aaa-wireddot1x
```

Following example displays the above configured parameters:

```
rfs4000-229D58(config-device-00-15-70-81-73-79)#show context
use profile default-rfs4000
use rf-domain default
hostname rfs4000-229D58
 use radius-server-policy for-wired-dot1x
interface mel
 ip address 192.168.0.1/24
interface ge2
 dot1x authenticator host-mode single-host
 dot1x authenticator port-control auto
interface vlan1
 ip address dhcp
 ip dhcp client request options all
logging on
logging console debugging
dot1x system-auth-control
dot1x use aaa-policy aaa-wireddot1x
--More--
rfs4000-229D58(config-device-00-15-70-81-73-79)#
```

| <b>username<br/>&lt;USERNAME&gt;</b>                                         | Sets the username for authentication <ul style="list-style-type: none"> <li>• &lt;USERNAME&gt; - Specify the supplicant's username.</li> </ul>                                                                                                                                                               |
| <b>password [0<br/>&lt;WORD&gt;   2<br/>&lt;WORD&gt;  <br/>&lt;WORD&gt;]</b> | Sets the password associated with the supplicant's username. Select any one of the following options: <ul style="list-style-type: none"> <li>• 0 &lt;WORD&gt; - Sets a clear text password</li> <li>• 2 &lt;WORD&gt; - Sets an encrypted password</li> <li>• &lt;WORD&gt; - Specify the password.</li> </ul> |

### Example

```
rfs4000-229D58(config-profile-testRFS4000-if-ge1)#dot1x supplicant username bob
password 0 test@123
```

```
rfs4000-229D58(config-profile-testRFS4000-if-ge1)#show context
interface ge1
 dot1x supplicant username bob password 0 test@123
 dot1x authenticator host-mode multi-host
 dot1x authenticator guest-vlan 2
 dot1x authenticator reauthenticate
 dot1x authenticator max-reauth-count 6
 ip dhcp trust
 qos trust dscp
 qos trust 802.1p
rfs4000-229D58(config-profile-testRFS4000-if-ge1)#
```

The following example shows the configuration made on an AP7522 to enable it as a dot1X supplicant:

```
ap7522-85B19C(config-device-84-24-8D-85-B1-9C-if-ge2)#dot1x supplicant username bob
password 0 bob1234
ap7522-85B19C(config-device-84-24-8D-85-B1-9C)#show context
use profile default-ap7522
use rf-domain default
hostname ap7522-85B19C
no adoption-mode
interface ge1
 switchport mode access
 switchport access vlan 1
 dot1x supplicant username bob password 0 bob1234
logging on
logging console debugging
--More--
ap7522-85B19C(config-device-84-24-8D-85-B1-9C
```

### duplex

[interface-config-ge-instance](#) on page 1017

Configures duplex mode (for the flow of packets) on this Ethernet port

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

`duplex [auto|half|full]`

Parameters

`duplex [auto|half|full]`

|             |                                                                                                                                                                                                                                     |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>auto</b> | Enables automatic duplexity on an interface port. The port automatically detects whether it should run in full or half-duplex mode. (default setting)                                                                               |
| <b>half</b> | Sets the port to half-duplex mode. Allows communication in one direction only at any given time. When selected, data is sent over the port, then immediately data is received from the direction in which the data was transmitted. |
| <b>full</b> | Sets the port to full-duplex mode. Allows communication in both directions simultaneously. When selected, the port can send data while receiving data as well.                                                                      |

Example

```

nx9500-6C8809(config-profile-default-rfs4000-if-ge1)#duplex full

nx9500-6C8809(config-profile-default-rfs4000-if-ge1)#show context
interface ge1
 description "This is GigabitEthernet interface for Royal King"
 duplex full
 dot1x supplicant username Bob password 0 test@123
 ip dhcp trust
 qos trust dscp
 qos trust 802.1p
 channel-group 1
nx9500-6C8809(config-profile-default-rfs4000-if-ge1)#

```

#### ipv6

[interface-config-ge-instance](#) on page 1017

Sets the DHCPv6 and ICMPv6 neighbor discovery (ND) components for this interface

The ICMPv6 ND protocol uses ICMP messages and solicited multicast addresses to track neighboring devices on the same local network. These messages are used to discover a neighbor's link layer address and to verify if a neighboring device is reachable.

The ICMP messages are neighbor solicitation (NS) and neighbor advertisement (NA) messages. When a destination host receives an NS message from a neighbor, it replies back with a NA. The NA contains the following information:

- Source address – This is the IPv6 address of the device sending the NA
- Destination address – This is the IPv6 address of the device from whom the NS message is received
- Data portion – Includes the link layer address of the device sending the NA

NS messages are used to verify a neighbor's (whose link layer address is known) reachability. To confirm a neighbor's reachability a node sends an NS message in which the neighbor's unicast address is specified as the destination address. If the neighbor sends back an acknowledgment on receipt of the NS message it is considered reachable.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

```
ipv6 [dhcpv6|nd]
```

```
ipv6 dhcpv6 trust
```

```
ipv6 nd [header-mismatch-validation|raguard|trust]
```

#### Parameters

```
ipv6 dhcpv6 trust
```

|                          |                                                                                                                                                                                                                                                  |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ipv6 dhcpv6 trust</b> | Enables trust state for DHCPv6 responses on this interface. When enabled, all DHCPv6 responses received on this port are trusted and forwarded. This option is enabled by default.<br>A DHCPv6 server can be connected to a DHCPv6 trusted port. |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
ipv6 nd [header-mismatch-validation|raguard|trust]
```

|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ipv6 nd</b>                    | Configures IPv6 ND settings                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>header-mismatch-validation</b> | Enables matching of source MAC address in the ICMPv6 ND and Ethernet headers (link layer option) to check for mismatch. This option is disabled by default.                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>raguard</b>                    | Allows redirection of router advertisements (RAs) and ICMPv6 packets originating on this interface. When selected, RAs are periodically sent to hosts or sent in response to neighbor solicitation requests. The advertisement includes IPv6 prefixes and other subnet and host information. This option is enabled by default.                                                                                                                                                                                                                   |
| <b>trust</b>                      | Enables trust state for IPv6 ND requests received on this interface. When enabled, IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the neighbor discovery protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to the request with a router advertisement packet containing Internet Layer configuration parameters. This option is disabled by default. |

#### Example

```
nx9500-6C8809(config-device-B4-C7-99-6D-CD-4B-if-gel)#ipv6 dhcpv6 trust

```

```
nx9500-6C8809(config-device-B4-C7-99-6D-CD-4B-if-gel)#
```

#### Related Commands

`no` on page 1033 Removes or reverts IPv6 settings on this interface

lACP

[interface-config-ge-instance](#) on page 1017

Configures the selected GE port's Link Aggregation Control Protocol (LACP) port-priority value. If LACP is enabled, and the selected port is a member of a link aggregation group (LAG), use this command to configure the port's priority within the LAG.

As per the IEEE 802.3ad standard, LACP enables aggregation of multiple physical links to form a single logical channel. Each aggregated group of physical links is a LAG. When enabled, LACP dynamically determines if link aggregation is possible between two peers, and automatically configures the aggregation. LACP also allows the switch to dynamically reconfigure the LAGs. The LAG is enabled only when LACP detects that the remote device is also using LACP and is able to join the LAG.

Enabling LACP provides automatic recovery in case one or more of the aggregated physical links fail.

#### Note

Use the [lACP-channel-group](#) on page 1029 command to configure this port as a LAG member.

Supported in the following platforms:

- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

```
lACP port-priority <1-65535>
```

Parameters

```
lACP port-priority <1-65535>
```

**lACP port-priority <1-65535>**

Configures the selected GE port's port-priority value. The selected port's actual priority within the LAG is determined by the port-priority value specified here along with the port's number. Higher the value, lower is the priority. Use this option to manipulate a port's priority. For example, in a LAG having five physical ports, four active and one standby, manually increasing the standby port's priority ensures that if one of the active port fails, the standby port is included in the LAG during re-negotiation.

- <1-65535> - Specify a value from 1 - 65535. The default value is 32768.

Example

```
nx9500-6C8809(config-profile-testnx9000-if-ge1)#lACP port-priority 2
```

```
nx9500-6C8809(config-profile-testnx9000-if-ge1)#show context
 interface ge1
 lACP port-priority 2
nx9500-6C8809(config-profile-testnx9000-if-ge1)#
```

Related Commands

`no` on page 1033 Removes the selected GE port's configured port-priority value

lACP-channel-group

[interface-config-ge-instance](#) on page 1017

Configures the selected GE port as a member of a port channel group (also referred as LAG)

As per the IEEE 802.3ad standard, LACP enables the aggregation of multiple physical links (ethernet ports) to form a single logical channel. When enabled, LACP dynamically determines if link aggregation is possible and then automatically configures the aggregation. LACP also allows the switch to dynamically reconfigure the LAGs. The LAG is enabled only when LACP detects that the remote device is also using LACP and is able to join the LAG.

#### Note

Successful aggregation of two or more physical links is feasible only if the aggregating physical links are configured identically. To ensure uniformity in configuration across LAG members, implement configuration changes (such as changes in the switching mode, speed, etc.) on the logical port (the port-channel) and not on the physical port. Changes made on the port-channel will cascade down to each member of the LAG thereby retaining uniformity.

Supported in the following platforms:

- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

```
lACP-channel-group <1-4> mode [active|passive]
```

#### Parameters

```
lACP-channel-group <1-4> mode [active|passive]
```

| <b>mode [active passive]</b>          | <p>After configuring the selected port as a LAG member, specify whether the port is an active or passive member within the group. An active member initiates and participates in LACP negotiations.</p> <ul style="list-style-type: none"><li>• active – Configures the port as an active member. When set to active, the port always transmits LACPDU irrespective of the remote device's port mode.</li><li>• passive – Configures the port as passive member. When set to passive, the port will only respond to LACPDU received from its corresponding Active port.</li></ul> <p>At least one port within a LAG, on either of the two negotiating peers, should be in the active mode. LACP negotiations are not initiated if all LAG member ports are passive. Further, the peer-to-peer LACP negotiations are always initiated by the peer with the lower system-priority value. For more information on configuring the system-priority, see <a href="#">lACP</a> on page 1265.</p> |

#### Example

```
nx9500-6C8809(config-profile-testnx9000-if-ge1)#lACP-channel-group 2 mode active
```

```
nx9500-6C8809(config-profile-test2nx9000-if-ge1)#show context
interface ge1
 lACP-channel-group 2 mode active
 lACP port-priority 2
nx9500-6C8809(config-profile-test2nx900-if-ge1)#
```

To enable dynamic link aggregation on a device (service platform), execute the following steps:

- 1 Create a port-channel group on the device. Enter the port-channel configuration mode.

```
nx9500-6C8809(config-device-B4-C7-99-6C-88-09)#interface port-channel 1
```

Set the switching mode to access or trunk as per requirement. In this example, the mode is set to 'access'.

```
nx9500-6C8809(config-device-B4-C7-99-6C-88-09-if-port-channel1)#switchport mode access
```

Specify the VLAN to switch, commit changes and exit.

```
nx9500-6C8809(config-device-B4-C7-99-6C-88-09-if-port-channel1)#switchport access vlan 1
nx9500-6C8809(config-device-B4-C7-99-6C-88-09-if-port-channel1)#commit
nx9500-6C8809(config-device-B4-C7-99-6C-88-09-if-port-channel1)#exit
```

- 2 Enable dynamic link aggregation on the device's physical port. Enter the GE port's configuration mode.

```
nx9500-6C8809(config-device-B4-C7-99-6C-88-09)#interface ge 2
```

Enable link aggregation and associate the port with the port-channel group created in step 1.

```
nx9500-6C8809(config-device-B4-C7-99-6C-88-09-if-ge2)#lacp-channel-group 1 mode active
```

Note, the mode can be set to passive. However, at least one of the aggregated GE ports in the port-channel group should be active in order to initiate link aggregation negotiations with other LACP-enabled peers.

Specify the GE port's priority value.

```
nx9500-6C8809(config-device-B4-C7-99-6C-88-09-if-ge2)#lacp port-priority 2
```

#### lldp

[interface-config-ge-instance](#) on page 1017

Configures Link Local Discovery Protocol (LLDP) parameters on this Ethernet port

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

```
lldp [receive|transmit]
```

Parameters

```
lldp [receive|transmit]
```

|                 |                                                                                                                                                                                                       |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>receive</b>  | Enables LLDP Protocol Data Units (PDUs) snooping. When enabled, the port receives periodic updates from a multicast address informing about presence of neighbors. This option is enabled by default. |
| <b>transmit</b> | Enables LLDP PDU transmission. When enabled, the port sends out periodic interface updates to a multicast address to advertise its presence to neighbors. This option is enabled by default.          |

#### Example

```
nx9500-6C8809(config-profile-default-rfs4000-if-ge1)#lldp transmit
```

## mac-auth

[interface-config-ge-instance](#) on page 1017

Enables authentication of MAC addresses on the selected wired port. When enabled, this feature authenticates the MAC address of a device, connecting to this interface, with a RADIUS server. When successfully authenticated, packets from the source are processed. Since only one MAC address is supported per wired port, packets from all other sources are dropped.

For more information on enabling this feature, see [mac-auth](#) on page 1183.

Enable port MAC authentication in conjunction with Wired 802.1x settings to configure a MAC authentication AAA policy.

This option is also available in the device configuration mode.

Supported in the following platforms:

- Access Points — AP6522 AP6562, AP7161, AP7502, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

**mac-auth**

#### Parameters

None

#### Example

```
rfs4000-229D58(config-profile-testRFS4000-if-ge1)#mac-auth

Usage Guidelines

The no command negates any command associated with it. Wherever required, use the same parameters associated with the command getting negated.

Example

```
nx9500-6C8809(config-profile-default-rfs4000-if-ge1)#no cdp
```

```
nx9500-6C8809(config-profile-default-rfs4000-if-ge1)#no duplex
power
```

[interface-config-ge-instance](#) on page 1017

Configures Power over Ethernet (PoE) settings on this interface

When configured, this option allows the selected port to use Power over Ethernet. When enabled, the controller supports 802.3af PoE on each of its GE ports. PoE allows users to monitor port power consumption and configure power usage limits and priorities for each GE port.

Supported in the following platforms:

- Wireless Controllers – RFS4000

Syntax

```
power {best-effort|limit <0-40>|priority [critical|high|low]}
```

Parameters

```
power {best-effort|limit <0-40>|priority [critical|high|low]}
```

|                                     |                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>power</b>                        | Configures power related thresholds for this interface                                                                                                                                                                                                                                                                                                                                               |
| <b>best-effort</b>                  | Optional. Enables power when the device is not operating from an 802.3at class 4 power source                                                                                                                                                                                                                                                                                                        |
| <b>limit &lt;0-40&gt;</b>           | Optional. Configures the PoE power limit from 0 - 40 Watts. The default is 30 Watts.                                                                                                                                                                                                                                                                                                                 |
| <b>priority [critical high low]</b> | Optional. Configures the PoE power priority on this interface. This is the priority assigned to this port versus the power requirements of the other ports available on the controller. <ul style="list-style-type: none"><li>• critical - Sets PoE priority as critical</li><li>• high - Sets PoE priority as high</li><li>• low - Sets PoE priority as low. This is the default setting.</li></ul> |

Example

```
rfs4000-229D58(config-profile-testRFS4000-if-ge1)#power limit 30
```

```

rfs4000-229D58(config-profile-testRFS4000-if-gel)#power priority critical

rfs4000-229D58(config-profile-testRFS4000-if-gel)#show context
interface gel
 ip dhcp trust
 qos trust dscp
 qos trust 802.1p
 power limit 30
 power priority critical
rfs4000-229D58(config-profile-testRFS4000-if-gel)#

```

## shutdown

[interface-config-ge-instance](#) on page 1017

Shuts down (disables) an interface. The interface is administratively enabled unless explicitly disabled using this command.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

**shutdown**

### Parameters

None

### Example

```
nx9500-6C8809(config-profile-default-rfs4000-if-ge1)#shutdown
```

## spanning-tree

[interface-config-ge-instance](#) on page 1017

Configures spanning tree parameters

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
spanning-tree [bpdufilter|bpduguard|force-version|guard|link-type|mst|
port-cisco-interopability|portfast]
```

```
spanning-tree [force-version <0-3>|guard root|portfast]
```

```
spanning-tree [bpdufilter|bpduguard] [default|disable|enable]
```

```
spanning-tree link-type [point-to-point|shared]
```

```
spanning-tree mst <0-15> [cost <1-200000000>|port-priority <0-240>]
```

```
spanning-tree port-cisco-interoperability [disable|enable]
```

#### Parameters

```
spanning-tree [force-version <0-3>|guard root|portfast]
```

|                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>force-version</b><br><b>&lt;0-3&gt;</b> | Specifies the spanning tree force version. A version identifier of less than 2 enforces the spanning tree protocol. Select one of the following versions: <ul style="list-style-type: none"><li>• 0 - Spanning Tree Protocol (STP)</li><li>• 1 - Not supported</li><li>• 2 - Rapid Spanning tree Protocol (RSTP)</li><li>• 3 - Multiple Spanning Tree Protocol (MSTP). This is the default setting</li></ul>                                                                                                                           |
| <b>guard root</b>                          | Enables Root Guard for the port<br>The Root Guard disables superior Bridge Protocol Data Unit (BPDU) reception. The Root Guard ensures the enabled port is a designated port. If the Root Guard enabled port receives a superior BPDU, it moves to a discarding state (root-inconsistent STP state). This state is equivalent to a listening state, and data is not forwarded across the port. Therefore, enabling the guard root enforces the root bridge position. Use the no parameter with this command to disable the Root Guard. |
| <b>portfast</b>                            | Enables rapid transitions. Enabling PortFast allows the port to bypass the listening and learning states.                                                                                                                                                                                                                                                                                                                                                                                                                              |

```
spanning-tree [bpdupfilter|bpduguard] [default|disable|enable]
```

|                                                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>bpdupfilter</b><br><b>[default  </b><br><b>disable  </b><br><b>enable]</b> | Sets a PortFast BPDU filter for the port<br>Use the no parameter with this command to revert the port BPDU filter to its default.<br>The spanning tree protocol sends BPDUs from all ports. Enabling the BPDU filter ensures PortFast enabled ports do not transmit or receive BPDUs.                                                                                                                                                                                     |
| <b>bpduguard</b><br><b>[default  </b><br><b>disable  </b><br><b>enable]</b>   | Enables BPDU guard on a port<br>Use the no parameter with this command to set BPDU guard to its default.<br>When the BPDU guard is set for a bridge, all PortFast-enabled ports that have the BPDU guard set to default shut down upon receiving a BPDU. If this occurs, the BPDU is not processed. The port can be brought back either manually (using the no shutdown command), or by configuring the errdisable-timeout to enable the port after a specified interval. |

| <b>mst &lt;0-15&gt;</b>                | Configures MST on a spanning tree                                                                                                                                                                                                                                                                                                   |
| <b>cost<br/>&lt;1-200000000&gt;</b>    | Defines path cost for a port from 1 - 200000000. The default path cost depends on the speed of the port. The cost helps determine the role of the port in the MSTP network. The designated cost is the cost for a packet to travel from this port to the root in the MSTP configuration. The slower the media, the higher the cost. |
| <b>port-priority<br/>&lt;0-240&gt;</b> | Defines port priority for a bridge from 1 - 240. Lower the priority greater is the likelihood of the port becoming a designated port. Applying a higher value impacts the port's likelihood of becoming a designated port.                                                                                                          |

speed

[interface-config-ge-instance](#) on page 1017

Specifies the speed of a FastEthernet (10/100) or GigabitEthernet (10/100/1000) port. This is the speed at which the port can receive and transmit the data.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000

- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

`speed [10|100|1000|auto]`

#### Parameters

`speed [10|100|1000|auto]`

|             |                                                                                                                                                                                                                                                                                                                                                                   |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>10</b>   | Forces 10 Mbps operation                                                                                                                                                                                                                                                                                                                                          |
| <b>100</b>  | Forces 100 Mbps operation                                                                                                                                                                                                                                                                                                                                         |
| <b>1000</b> | Forces 1000 Mbps operation                                                                                                                                                                                                                                                                                                                                        |
| <b>auto</b> | Port automatically detects its operational speed based on the port at the other end of the link. Select this option to enable the port to automatically exchange information about data transmission speed and duplex capabilities. Auto negotiation is helpful when in an environment where different devices are connected and disconnected on a regular basis. |

#### Usage Guidelines

Set the interface speed to auto detect and use the fastest speed available. Speed detection is based on connected network hardware.

#### Example

```
nx9500-6C8809(config-profile-default-rfs4000-if-ge1)#speed 10

nx9500-6C8809(config-profile-default-rfs4000-if-ge1)#show context
interface ge1
 description "This is GigabitEthernet interface for Royal King"
 speed 10
 duplex full
 spanning-tree bpduguard enable
 spanning-tree bpdufilter disable
 spanning-tree force-version 1
 spanning-tree guard root
 spanning-tree mst 2 port-priority 10
 dot1x supplicant username Bob password 0 test@123
 ip dhcp trust
 ip arp header-mismatch-validation
 qos trust dscp
 qos trust 802.1p
 channel-group 1
nx9500-6C8809(config-profile-default-rfs4000-if-ge1)#
```

#### switchport

[interface-config-ge-instance](#) on page 1017

Sets switching mode characteristics for the selected interface

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

```
switchport [access|mode|trunk]
```

```
switchport access vlan [<1-4094>|<VLAN-ALIAS-NAME>]
```

```
switchport mode [access|trunk]
```

```
switchport trunk [allowed|fabric-attach|native]
```

```
switchport trunk allowed vlan [<VLAN-ID>|add <VLAN-ID>|none|remove <VLAN-ID>]
```

```
switchport trunk fabric-attach vlan [<1-4094>|<VLAN-ALIAS-NAME>] isid <1-16777214>
```

```
switchport trunk native [tagged|vlan [<1-4094>|<VLAN-ALIAS-NAME>]]
```

Parameters

```
switchport access vlan [<1-4094>|<VLAN-ALIAS-NAME>]
```

| trunk         | Sets trunking mode characteristics of this Ethernet port                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| fabric-attach | <p>Enables FA (Fabric Attach) client operation on this Ethernet port. Use this option to enable non-SPB WiNG devices (access points and controllers) as FA Clients. FA enabled switches, in the FC network, send out LLDP messages with TLV extensions of Organization-specific TLV with OUI, to discover FA clients and advertise capabilities.</p> <p>The FA-enabled client associates with the FA Server (FAS), and obtains provisioning information (management VLAN interface details, and whether the interface is tagged or not) that allows the client to be configured with parameters that allow traffic to flow through the Fabric to the WLAN controller. This initial FA Client to WLC communication uses the Fabric’s default VLAN to I-SID mapping. Use this command to configure the I-SID (Individual Service Identifier) to VLAN mapping that the FA Client uses to negotiate with the FAS.</p> <p><b>Note:</b> You can configure FA Client capability on a device’s profile as well as device contexts.</p> <p><b>Note:</b> This option is enabled only when the switching mode is set to trunk.</p> |

| <pre><b>native [tagged vlan [&lt;1-4094&gt; &lt;VLAN-ALIAS-NAME&gt;]]</b></pre> | <p>Configures the native VLAN ID for the trunk-mode port</p> <p>The native VLAN allows an Ethernet device to associate untagged frames to a VLAN when no 802.1Q frame is included in the frame. Additionally, the native VLAN is the VLAN untagged traffic is directed over when using a port in trunk mode.</p> <ul style="list-style-type: none"> <li>• tagged - Tags the native VLAN. When a frame is tagged, the 12 bit frame VLAN ID is added to the 802.1Q header enabling upstream Ethernet devices to know which VLAN ID the frame belongs to. The device reads the 12 bit VLAN ID and forwards the frame to the appropriate VLAN. When a frame is received with no 802.1Q header, the upstream device classifies the frame using the default or native VLAN assigned to the Trunk port. A native VLAN allows an Ethernet device to associate untagged frames to a VLAN when no 802.1Q frame is included in the frame.</li> <li>• vlan [&lt;1-4094&gt; &lt;VLAN-ALIAS-NAME&gt;] - Sets the native VLAN for classifying untagged traffic when the interface is in trunking mode. <ul style="list-style-type: none"> <li>• &lt;1-4094&gt; - Specify a value from 1 - 4094.</li> <li>• &lt;VLAN-ALIAS-NAME&gt; - Specify the VLAN alias name used to identify the VLANs. The VLAN alias should be existing and configured.</li> </ul> </li> </ul> |

#### Usage Guidelines

Interfaces ge1 - ge4 can be configured as trunk or in access mode. An interface configured as “trunk” allows packets (from the given list of VLANs) to be added to the trunk. An interface configured as “access” allows packets only from native VLANs.

Use the [no] `switchport (access|mode|trunk)` to undo switchport configurations.

#### Example

```
nx9500-6C8809(config-profile-default-rfs4000-if-ge1)#switchport trunk native tagged
```

```

nx9500-6C8809(config-profile-default-rfs4000-if-ge1)#switchport access vlan 1

nx9500-6C8809(config-profile-default-rfs4000-if-ge1)#show context
interface ge1
 description "This is GigabitEthernet interface for Royal King"
 speed 10
 duplex full
 switchport mode access
 switchport access vlan 1
 spanning-tree bpduguard enable
 spanning-tree bpdufilter disable
 --More--
nx9500-6C8809(config-profile-default-rfs4000-if-ge1)#

```

The following is the basic configuration required to enable a device as a FA Client, with tagged native VLAN traffic:

```

ap8432-070235(config-device-74-67-F7-07-02-35-if-ge1)#switchport mode trunk
ap8432-070235(config-device-74-67-F7-07-02-35-if-ge1)#switchport trunk
fabric-attach vlan 1 isid 1
ap8432-070235(config-device-74-67-F7-07-02-35-if-ge1)#switchport trunk
fabric-attach vlan 2 isid 200
ap8432-070235(config-device-74-67-F7-07-02-35-if-ge1)#switchport trunk
fabric-attach vlan 100 isid 1000
ap8432-070235(config-device-74-67-F7-07-02-35-if-ge1)#switchport trunk
allowed vlan 1-2,100
ap8432-070235(config-device-74-67-F7-07-02-35-if-ge1)#switchport trunk
native tagged

use

[interface-config-ge-instance](#) on page 1017

Specifies the IP (IPv4 and IPv6) access list and MAC access list used with this Ethernet port. The associated ACL firewall inspects IP and MAC traffic flows and detects attacks typically not visible to traditional wired firewall appliances.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

```
use [ip-access-list in <IPv4-ACCESS-LIST-NAME>|ipv6-access-list <IPv6-ACCESS-LIST-NAME>|mac-access-list in <MAC-ACCESS-LIST-NAME>]
```

#### Parameters

```
use [ip-access-list in <IPv4-ACCESS-LIST-NAME>|ipv6-access-list <IPv6-ACCESS-LIST-NAME>|mac-access-list in <MAC-ACCESS-LIST-NAME>]
```

|                                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ip-access-list in &lt;IPv4-ACCESS-LIST-NAME&gt;</b>   | Associates an IPv4 access list with this Ethernet port. IPv4 is a connectionless protocol for packet switched networking. IPv4 operates as a best effort delivery method, as it does not guarantee delivery, and does not ensure proper sequencing or duplicate delivery (unlike (TCP). IPv4 hosts can use link local addressing to provide local connectivity. <ul style="list-style-type: none"><li>• in - Applies the IPv4 ACL on incoming packets<ul style="list-style-type: none"><li>• &lt;IPv4-ACCESS-LIST-NAME&gt; - Specify the IPv4 access list name (it should be an existing and configured).</li></ul></li></ul> |
| <b>ipv6-access-list in &lt;IPv6-ACCESS-LIST-NAME&gt;</b> | Associates an IPv6 access list with this Ethernet port. IPv6 is the latest revision of the IP designed to replace IPv4. IPv6 provides enhanced identification and location information for computers on networks routing traffic across the Internet. IPv6 addresses are composed of eight groups of four hexadecimal digits separated by colons. <ul style="list-style-type: none"><li>• in - Applies the IPv6 ACL on incoming packets<ul style="list-style-type: none"><li>• &lt;IPv6-ACCESS-LIST-NAME&gt; - Specify the IPv6 access list name (it should be an existing and configured).</li></ul></li></ul>               |
| <b>mac-access-list in &lt;MAC-ACCESS-LIST-NAME&gt;</b>   | Associates a MAC access list with this Ethernet port. MAC ACLs filter/mark packets based on the MAC address from which they arrive, as opposed to filtering packets on layer 2 ports. <ul style="list-style-type: none"><li>• in - Applies the MAC ACL on incoming packets<ul style="list-style-type: none"><li>• &lt;MAC-ACCESS-LIST-NAME&gt; - Specify the MAC access list name (it should be an existing and configured).</li></ul></li></ul>                                                                                                                                                                              |

## interface-config-vlan-instance

[interface](#) on page 1013

Use the config-profile-<DEVICE-PROFILE-NAME> mode to configure Ethernet, VLAN and tunnel settings.

To switch to this mode, use the following commands:

```
<DEVICE>(config-profile-default-<DEVICE-TYPE>)#interface [<INTERFACE-NAME>| fe <1-4>|ge <1-24>|me1|port-channel <1-4>|pppoe1|radio [1|2|3]|up1|vlan <1-4094>| wwan1|xge <1-24>]
```

The following example uses the config-profile-nx9500-6C8809 instance to configure a VLAN interface:

```
nx9500-6C8809(config-profile-default-rfs4000)#interface vlan 8
nx9500-6C8809(config-profile-default-rfs4000-if-vlan8)#
```

```
nx9500-6C8809(config-profile-default-rfs4000-if-vlan8)#?
```

SVI configuration commands:

|                     |                                                                                 |

## crypto

[interface-config-vlan-instance](#) on page 1045

Associates an existing and configured VPN crypto map with this VLAN interface.

Crypto map entries are sets of configuration parameters for encrypting packets that pass through the VPN tunnel. For more information on crypto maps, see [crypto-map-config-commands](#) on page 955.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
crypto map <CRYPTO-MAP-NAME>
```

### Parameters

```
crypto map <CRYPTO-MAP-NAME>
```

|                                    |                                                                                                                                                                                                                    |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>map &lt;CRYPTO-MAP-NAME&gt;</b> | Attaches a crypto map to the selected VLAN interface. The crypto map should be existing and configured. <ul style="list-style-type: none"> <li>• &lt;CRYPTO-MAP-NAME&gt; - Specify the crypto map name.</li> </ul> |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Example

```
nx9500-6C8809(config-profile-default-rfs4000-if-vlan8)#crypto map map1

nx9500-6C8809(config-profile-default-rfs4000-if-vlan8)#show context
interface vlan8
crypto map map1
nx9500-6C8809(config-profile-default-rfs4000-if-vlan8)#
```

## description

[interface-config-vlan-instance](#) on page 1045

Defines this VLAN interface's description. Use this command to provide additional information about the VLAN.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

**description** <WORD>

#### Parameters

description <WORD>

|                                           |                                                                                                                                                                                                                                                                                                           |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>description</b><br><b>&lt;WORD&gt;</b> | Configures a description for this VLAN interface (should not exceed 64 characters in length) <ul style="list-style-type: none"> <li>• &lt;WORD&gt; - Specify a description unique to the VLAN's specific configuration, to help differentiate it from other VLANs with similar configurations.</li> </ul> |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

#### Example

```
nx9500-6C8809(config-profile-default-rfs4000-if-vlan8)#description "This VLAN interface is configured for the Sales Team"
```

```
nx9500-6C8809(config-profile-default-rfs4000-if-vlan8)#show context
interface vlan8
description "This VLAN interface is configured for the Sales Team"
crypto map map1
nx9500-6C8809(config-profile-default-rfs4000-if-vlan8)#
```

#### Related Commands

|                        |                                        |
|------------------------|----------------------------------------|
| <b>no</b> on page 1056 | Removes the VLAN interface description |
|------------------------|----------------------------------------|

## dhcp

[interface-config-vlan-instance](#) on page 1045

Enables inclusion of optional fields (client identifier) in DHCP client requests. This option is disabled by default.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

**dhcp client include client-identifier**

#### Parameters

dhcp client include client-identifier

|                                                                   |                                                                |
|-------------------------------------------------------------------|----------------------------------------------------------------|
| <b>dhcp client</b><br><b>include client-</b><br><b>identifier</b> | Enables inclusion of client identifier in DHCP client requests |
|-------------------------------------------------------------------|----------------------------------------------------------------|

### Example

```
nx9500-6C8809(config-profile-default-rfs4000-if-vlan8)#dhcp client include client-identifier
```

```
nx9500-6C8809(config-profile-default-rfs4000-if-vlan8)#show context
interface vlan8
 dhcp client include client-identifier
nx9500-6C8809(config-profile-default-rfs4000-if-vlan8)#
```

### Related Commands

|---------------------------------|-----------------------------------------------------------------|
| <a href="#">no</a> on page 1056 | Disables inclusion of client identifier in DHCP client requests |
|---------------------------------|-----------------------------------------------------------------|

## dhcp-relay-incoming

[interface-config-vlan-instance](#) on page 1045

Allows an onboard DHCP server to respond to relayed DHCP packets. This option is disabled by default.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

**dhcp-relay-incoming**

### Parameters

None

### Example

```
nx9500-6C8809(config-profile-default-rfs4000-if-vlan8)#dhcp-relay-incoming
```

```
nx9500-6C8809(config-profile-default-rfs4000-if-vlan8)#show context
interface vlan8
 description "This VLAN interface is configured for the Sales Team"
 crypto map map1
 dhcp-relay-incoming
nx9500-6C8809(config-profile-default-rfs4000-if-vlan8)#
```

## ip

[interface-config-vlan-instance](#) on page 1045

Configures the VLAN interface's IP settings

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000

- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

```
ip [address|dhcp|helper-address|nat|ospf]
```

```
ip helper-address <IP>
```

```
ip address [<IP/M>|<NETWORK-ALIAS-NAME>|dhcp|zeroconf]
```

```
ip address [<IP/M>|<NETWORK-ALIAS-NAME>|zeroconf] {secondary}
```

```
ip address dhcp
```

```
ip dhcp client request options all
```

```
ip nat [inside|outside]
```

```
ip ospf [authentication|authentication-key|bandwidth|cost|message-digest-key|priority]
```

```
ip ospf authentication [message-digest|null|simple-password]
```

```
ip ospf authentication-key simple-password [0 <WORD>|2 <WORD>]
```

```
ip ospf [bandwidth <1-10000000>|cost <1-65535>|priority <0-255>]
```

```
ip ospf message-digest-key key-id <1-255> md5 [0 <WORD>|2 <WORD>]
```

Parameters

```
ip helper-address <IP>
```

ipv6

[interface-config-vlan-instance](#) on page 1045

Configures the VLAN interface's IPv6 settings

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

```
ipv6 [accept | address | dhcp | enable | enforce-dad | mtu | redirects | request-dhcpv6-options | router-advertisements]
```

```
ipv6 accept ra {(no-default-router|no-hop-limit|no-mtu)}
```

```
ipv6 address [<IPv6/M> | autoconfig | eui-64 | link-local | prefix-from-provider]
```

```
ipv6 address [<IPv6/M> | autoconfig]
```

```
ipv6 address eui-64 [<IPv6/M> | prefix-from-provider <WORD> <IPv6-PREFIX/PREFIX-LENGTH>]
```

```
ipv6 address prefix-from-provider <WORD> <HOST-PORITION/LENGTH>
```

```
ipv6 address link-local <LINK-LOCAL-ADD>
```

```
ipv6 dhcp [client [information | prefix-from-provider <WORD>] | relay destination <DEST-IPv6-ADD>]
```

```
ipv6 [enable | enforce-dad | mtu <1280-1500> | redirects | request-dhcpv6-options]
```

```
ipv6 router-advertisements [prefix <IPv6-PREFIX> | prefix-from-provider <WORD>] {no-autoconfig | off-link | site-prefix | valid-lifetime}
```

Parameters

```
ipv6 accept ra {(no-default-router|no-hop-limit|no-mtu)}
```

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ipv6 accept ra</b>    | Enables processing of router advertisements (RAs) on this VLAN interface. This option is enabled by default.<br>When enabled, IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the neighbor discovery protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to the request with a router advertisement packet containing Internet layer configuration parameters. |
| <b>no-default-router</b> | Optional. Disables inclusion of routers on this interface in the default router selection process. This option is disabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>no-hop-limit</b>      | Optional. Disables the use of RA advertised hop-count value on this interface. This option is disabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>no-mtu</b>            | Optional. Disables the use of RA advertised MTU value on this interface. This option is disabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                             |

```
ipv6 address [<IPv6/M> | autoconfig]
```

|                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>relay destination &lt;DEST-IPv6-ADD&gt;</b>                          | <p>Enables DHCPv6 packet forwarding on this VLAN interface</p> <ul style="list-style-type: none"> <li>• destination - Forwards DHCPv6 packets to a specified DHCPv6 relay <ul style="list-style-type: none"> <li>• &lt;DEST-IPv6-ADD&gt; - Specify the destination DHCPv6 relay’s address.</li> </ul> </li> </ul> <p>DHCPv6 relay enhances an extended DHCP relay agent by providing support in IPv6. DHCP relays exchange messages between a DHCPv6 server and client. A client and relay agent exist on the same link. When a DHCP request is received from the client, the relay agent creates a relay forward message and sends it to a specified server address. If no addresses are specified, the relay agent forwards the message to all DHCP server relay multicast addresses. The server creates a relay reply and sends it back to the relay agent. The relay agent then sends back the response to the client.</p> |

no

[interface-config-vlan-instance](#) on page 1045

Negates a command or reverts to defaults. The no command, when used in the Config Interface VLAN mode, negates VLAN interface settings or reverts them to their default.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

```
no [crypto|description|dhcp|dhcp-relay-incoming|ip|ipv6|shutdown|use]
```

```
no dhcp client include client-identifier
```

```
no [crypto map|description|dhcp-relay-incoming|shutdown]
```

```

```

```
no ip [helper-address <IP>|nat]
```

```
no ip address {<IP/M> {secondary}|<NETWORK-ALIAS-NAME> {secondary}}/dhcp/
zeroconf {secondary}}
```

```
no ip dhcp client request options all
```

```
no ip ospf [authentication|authentication-key|bandwidth|cost|message-
digest-key| priority]
```

```
no ipv6 [accept|address|dhcp|enable|enforce-dad|mtu|redirects|request-
dhcpv6-options|router-advertisement]
```

```
no ipv6 [accept ra|enable|enforce-dad|mtu|redirects|request-dhcpv6-
options]
```

```
no ipv6 address [<IPv6/M>|autoconfig|eui-64|link-local|prefix-from-
provider]
```

```
no ipv6 dhcp [client|relay]
```

```
no ipv6 router-advertisement [prefix <WORD>|prefix-from-provider <WORD>]
```

```
no use [bonjour-gw-discovery-policy>|ip-access-list in|ipv6-access-list
in|ipv6-router-advertisement-policy|url-filter]
```

#### Parameters

```
no <PARAMETERS>
```

|                                        |                                                                                  |
|----------------------------------------|----------------------------------------------------------------------------------|
| <b>no</b><br><b>&lt;PARAMETERS&gt;</b> | Removes or reverts this VLAN interface's settings based on the parameters passed |
|----------------------------------------|----------------------------------------------------------------------------------|

## Example

The following example shows the VLAN interface settings before the 'no' commands are executed:

```
nx9500-6C8809(config-profile-default-rfs4000-if-vlan8)#show context
interface vlan8
description "This VLAN interface is configured for the Sales Team"
ip address 10.0.0.1/8
ip dhcp client request options all
ip helper-address 172.16.10.3
ip nat inside
crypto map map1
dhcp-relay-incoming
nx9500-6C8809(config-profile-default-rfs4000-if-vlan8)#

nx9500-6C8809(config-profile-default-rfs4000-if-vlan8)#no crypto map
nx9500-6C8809(config-profile-default-rfs4000-if-vlan8)#no description
nx9500-6C8809(config-profile-default-rfs4000-if-vlan8)#no dhcp-relay-incoming
nx9500-6C8809(config-profile-default-rfs4000-if-vlan8)#no ip dhcp client request options
all
```

The following example shows the VLAN interface settings after the 'no' commands are executed:

```
nx9500-6C8809(config-profile-default-rfs4000-if-vlan8)#show context
interface vlan8
ip address 10.0.0.1/8
ip helper-address 172.16.10.3
ip nat inside
nx9500-6C8809(config-profile-default-rfs4000-if-vlan8)#
```

## shutdown

[interface-config-vlan-instance](#) on page 1045

Shuts down the selected interface. Use the no shutdown command to enable an interface.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

## Syntax

**shutdown**

## Parameters

None

## Example

```
nx9500-6C8809(config-profile-default-rfs4000-if-vlan8)#shutdown

nx9500-6C8809(config-profile-default-rfs4000-if-vlan8)#show context
interface vlan8
ip address 10.0.0.1/8
ip helper-address 172.16.10.3
```

```
shutdown
nx9500-6c8809(config-profile-default-rfs4000-if-vlan8)#
```

## interface-config-port-channel-instance

[interface](#) on page 1013

Profiles can utilize customized port channel configurations as part of their interface settings. Existing port channel profile configurations can be overridden as they become obsolete for specific device deployments.

The following example uses the config-profile-testNX9000 instance to configure a port-channel interface:

```
nx9500-6C8809(config-profile-testNX9000)#interface port-channel 1
nx9500-6C8809(config-profile-testNX9000-if-port-channell)# Port Channel Mode commands:
```

```
description Port description
duplex Set duplex to interface
ip Internet Protocol (IP)
ipv6 Internet Protocol version 6 (IPv6)
no Negate a command or set its defaults
port-channel Portchannel commands
qos Quality of service
remove-override Remove configuration item override from the device (so
 profile value takes effect)
shutdown Shutdown the selected interface
spanning-tree Spanning tree commands
speed Configure speed
switchport Set switching mode characteristics
use Set setting to use
```

```
clrscr Clears the display screen
commit Commit all changes made in this session
do Run commands from Exec mode
end End current mode and change to EXEC mode
exit End current mode and down to previous mode
help Description of the interactive help system
revert Revert changes
service Service Commands
```

show Show running system information  
 write Write running configuration to memory or terminal

## duplex

[interface-config-port-channel-instance](#) on page 1059

Configures the duplex-mode (that is the data transmission mode) for this port channel interface

Supported in the following platforms:

- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
duplex [auto|half|full]
```

### Parameters

```
duplex [auto|half|full]
```

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>duplex [auto half full]</b> | Configures the mode of data transmission as auto, full, or half                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                                | <ul style="list-style-type: none"><li>• auto – Select this option to enable the controller, service platform, or access point to dynamically duplex as port channel performance needs dictate. This is the default setting.</li><li>• full – Select this option to simultaneously transmit data to and from the port channel.</li><li>• half – Select this option to send data over the port channel, then immediately receive data from the same direction in which the data was transmitted.</li></ul> |

### Example

```
nx9500-6C8809(config-profile-testNX9000-if-port-channel1)#duplex full

nx9500-6C8809(config-profile-testNX9000-if-port-channel1)#show context
interface port-channel1
 description "This port-channel is for enabling dynamic LACP."
 duplex full
nx9500-6C8809(config-profile-testNX9000-if-port-channel1)#
```

## ip

[interface-config-port-channel-instance](#) on page 1059

Configures ARP and DHCP related security parameters on this port-channel interface

Supported in the following platforms:

- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
ip [arp|dhcp]
```

```
ip arp [header-mismatch-validation|trust]
```

```
ip dhcp trust
```

Parameters

```
ip arp [header-mismatch-validation|trust]
```

|                                                                                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ip arp</b><br><b>[header-</b><br><b>mismatch-</b><br><b>validation</b><br><b> </b><br><b>trust]</b> | Configures ARP related parameters on this port-channel interface <ul style="list-style-type: none"><li>• header-mismatch-validation – Enables a source MAC mismatch check in both the ARP and ethernet headers. This option is enabled by default.</li><li>• trust – Enables ARP trust on this port channel. If enabled, ARP packets received on this port are considered trusted, and information from these packets is used to identify rogue devices. This option is disabled by default.</li></ul> |
|--------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
ip dhcp trust
```

|                      |                                                                                                                                                                                                        |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ip dhcp trust</b> | Enables DHCP trust. If enabled, only DHCP responses are trusted and forwarded on this port channel, and a DHCP server can be connected only to a DHCP trusted port. This option is enabled by default. |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Example

```
nx9500-6C8809(config-profile-testNX9000-if-port-channel1)#ip arp trust
```

```
nx9500-6C8809(config-profile-testNX9000-if-port-channel1)#show context
```

```
interface port-channel1
 description "This port-channel is for enabling dynamic LACP."
 duplex full
 ip arp trust
```

```
nx9500-6C8809(config-profile-testNX9000-if-port-channel1)#
```

ipv6

[interface-config-port-channel-instance](#) on page 1059

Configures IPv6 related parameters on this port-channel interface

Supported in the following platforms:

- Wireless Controllers – RFS4000
- Service Platforms – NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

```
ipv6 [dhcpv6|nd]
```

```
ipv6 dhcpv6 trust
```

```
ipv6 nd [header-mismatch-validation|raguard|trust]
```

Parameters

```
ipv6 dhcpv6 trust
```

|                          |                                                                                                                                                                                                         |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ipv6 dhcpv6 trust</b> | Enables DHCPv6 trust. If enabled, only DHCPv6 responses are trusted and forwarded on this port channel, and a DHCPv6 server can be connected only to a trusted port. This option is enabled by default. |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
ipv6 nd [header-mismatch-validation|raguard|trust]
```

|                                                           |                                                                                                                                                                                                                                                                 |
|-----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ipv6 nd [header-mismatch-validation raguard trust]</b> | Configures IPv6 neighbor discovery (ND) parameters <ul style="list-style-type: none"> <li>header-mismatch-validation – Enables a mismatch check for the source MAC in both the ND header and link layer options. This option is disabled by default.</li> </ul> |
|-----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                |                                                                                                                                                                                                                                                                                           |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>raguard</b> | Enables router advertisements or IPv6 redirects from this port. Router advertisements are periodically sent to hosts or are sent in response to solicitation requests. The advertisement includes IPv6 prefixes and other subnet and host information. This option is enabled by default. |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|              |                                                                                                                                                                                                         |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>trust</b> | Enables DHCPv6 trust. If enabled, only DHCPv6 responses are trusted and forwarded on this port channel, and a DHCPv6 server can be connected only to a trusted port. This option is enabled by default. |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

#### Example

```

## qos

[interface-config-port-channel-instance](#) on page 1059

Configures Quality of Service (QoS) related parameters on this port-channel interface

Supported in the following platforms:

- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

```
qos trust [802.1p | dscp]
```

#### Parameters

```
qos trust [802.1p | dscp]
```

|                                  |                                                                                                                                                                                                                                                                                                                                                      |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>qos trust [802.1p   dscp]</b> | <p>Configures the following QoS related parameters:</p> <ul style="list-style-type: none"> <li>• 802.1p - Trusts 802.1p class of service (COS) values ingressing on this port channel. This option is enabled by default.</li> <li>• dscp - Trusts IP DSCP QOS values ingressing on this port channel. This option is enabled by default.</li> </ul> |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

#### Example

```
nx9500-6C8809(config-profile-testNX9000-if-port-channel1)#qos trust dscp
nx9500-6C8809(config-profile-testNX9000-if-port-channel1)#show context
```

no

[interface-config-port-channel-instance](#) on page 1059

Removes or reverts to default this port-channel interface's settings

Supported in the following platforms:

- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

```
no beacon [description|duplex|ip|ipv6|port-channel|qos|shutdown|spanning-tree| speed|switchport|use]
```

Parameters

```
no <PARAMETERS>
```

|                                        |                                                                                                                                                                                                     |

| <b>no</b><br><b>&lt;PARAMETERS&gt;</b> | Removes or reverts to default this port-channels interface's settings based on the parameters passed <ul style="list-style-type: none"><li>• &lt;PARAMETERS&gt; - Specify the parameters.</li></ul> |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Example

The following example shows the port-channel interface's interface settings before the 'no' commands are executed:

```
nx9500-6C8809(config-profile-testNX9000-if-port-channell)#show context
description "This port-channel is for enabling dynamic LACP."
 speed 100
 duplex full
 switchport mode trunk
 switchport trunk native vlan 1
 no switchport trunk native tagged
 switchport trunk allowed vlan 1
 use ip-access-list in BROADCAST-MULTICAST-CONTROL
 ipv6 nd trust
 ipv6 nd header-mismatch-validation
 spanning-tree portfast
 spanning-tree bpduguard enable
 spanning-tree bpdufilter enable
 spanning-tree mst 1 port-priority 1
 spanning-tree mst 1 cost 20000
 ip arp trust
 port-channel load-balance src-dst-mac
nx9500-6C8809(config-profile-testNX9000-if-port-channell)#
```

```
nx9500-6C8809(config-profile-testNX9000-if-port-channell)#no duplex
nx9500-6C8809(config-profile-testNX9000-if-port-channell)#no ip arp trust
nx9500-6C8809(config-profile-testNX9000-if-port-channell)#no ipv6 nd trust
nx9500-6C8809(config-profile-testNX9000-if-port-channell)#no port-channel load-balance
```

The following example shows the port-channel interface's interface settings after the 'no' commands are executed:

```
nx9500-6C8809(config-profile-testNX9000-if-port-channell)#show context
interface port-channell
 description "This port-channel is for enabling dynamic LACP."
 speed 100
 switchport mode trunk
```

```

switchport trunk native vlan 1
no switchport trunk native tagged
switchport trunk allowed vlan 1
use ip-access-list in BROADCAST-MULTICAST-CONTROL
ipv6 nd header-mismatch-validation
spanning-tree portfast
spanning-tree bpduguard enable
spanning-tree bpdufilter enable
spanning-tree mst 1 port-priority 1
spanning-tree mst 1 cost 20000
no qos trust dscp
nx9500-6C8809(config-profile-testNX9000-if-port-channel1)#

```

shutdown

[interface-config-port-channel-instance](#) on page 1059

Shutsdown this port-channel interface

Supported in the following platforms:

- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

Syntax

```
shutdown
```

Parameters

None

Example

```
nx9500-6C8809(config-profile-testNX9000-if-port-channel1)#shutdown
```

speed

[interface-config-port-channel-instance](#) on page 1059

Configures the speed at which this port-channel interface receives and transmits data

Supported in the following platforms:

- Wireless Controllers – RFS4000

- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

```
speed [10|100|1000|auto]]]
```

#### Parameters

```
speed [10|100|1000|auto]
```

**speed [10|100|1000| auto]** Configure the data receive-transmit speed for this port channel. The options are:

- 10 - 10 Mbps
- 100 - 100 mbps
- 1000 - 1000 Mbps
- auto - Enables the system to auto select the speed. This is the default setting.

Select either of these options to establish a 10, 100 or 1000 Mbps data transfer rate for the selected half duplex or full duplex transmission over the port. The auto option enables the port-channel to automatically exchange information about data transmission speed and duplex capabilities. Auto negotiation is helpful in an environment where different devices are connected and disconnected on a regular basis.

#### Example

```
nx9500-6C8809(config-profile-testNX9000-if-port-channel1)#speed 100

#### switchport

[interface-config-port-channel-instance](#) on page 1059

Configures the VLAN switching parameters for this port-channel interface

Supported in the following platforms:

- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

```
switchport [access|mode|trunk]
```

```

switchport access vlan [<1-4094>|<VLAN-ALIAS-NAME>]
switchport mode [access|trunk]
switchport trunk [allowed|native]
switchport trunk allowed vlan [<VLAN-ID>|add <VLAN-ID>|none|remove <VLAN-
ID>]
switchport trunk native [tagged|vlan [<1-4094>|<VLAN-ALIAS-NAME>]]

```

#### Parameters

```
switchport access vlan [<1-4094>|<VLAN-ALIAS-NAME>]
```

|                                                            |                                                                                                                                                                                                                                                                                                                                       |

use

[interface-config-port-channel-instance](#) on page 1059

Configures access controls on this port-channel interface

Supported in the following platforms:

- Wireless Controllers – RFS4000
- Service Platforms – NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

## Syntax

```
use [ip-access-list|ipv6-access-list|mac-access-list] in <IP/IPv6/MAC-ACCESS-LIST-NAME>]]
```

## Parameters

```
use [ip-access-list|ipv6-access-list|mac-access-list] in <IP/IPv6/MAC-ACCESS-LIST-NAME>]
```

|                                                                                                                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## interface-config-radio-instance

[interface](#) on page 1013

This section documents radio interface configuration parameters applicable only to the access point profiles.

The access point radio interface can be radio1, radio2, or radio3. The AP7662 model is a dual radio access point. Whereas, AP8533 is a triple radio access point.

To enter the AP profile > radio interface context, use the following commands:

```
<DEVICE>(config)#profile <AP-TYPE> <PROFILE-NAME>
```

```
nx9500-6C8809(config)#profile ap7532 test7532
nx9500-6C8809(config-profile-test7532)#
```

```
nx9500-6C8809(config-profile-test7532)#interface radio 2
nx9500-6C8809(config-profile-test7532-if-radio2)#
```

```
nx9500-6C8809(config-profile-test7532-if-radio2)#?
```

Radio Mode commands:

|----------------------------|-------------------------------------------------------------------------------------------------------------------------|
| adaptivity                 | Adaptivity                                                                                                              |
| aer scout                  | Aer scout Multicast MAC/Enable                                                                                          |
| aggregation                | Configure 802.11n aggregation related parameters                                                                        |
| airtime-fairness           | Enable fair access to medium for clients based on their usage of airtime                                                |
| antenna-diversity          | Transmit antenna diversity for non-11n transmit rates                                                                   |
| antenna-downtilt           | Enable ADEPT antenna mode                                                                                               |
| antenna-elevation          | Specifies the antenna elevation gain                                                                                    |
| antenna-gain               | Specifies the antenna gain of this radio                                                                                |
| antenna-mode               | Configure the antenna mode (number of transmit and receive antennas) on the radio                                       |
| assoc-response             | Configure transmission parameters for Association Response frames                                                       |
| association-list           | Configure the association list for the radio                                                                            |
| beacon                     | Configure beacon parameters                                                                                             |
| bridge                     | Bridge rf-mode related configuration                                                                                    |
| channel                    | Configure the channel of operation for this radio                                                                       |
| data-rates                 | Specify the 802.11 rates to be supported on this radio                                                                  |
| description                | Configure a description for this radio                                                                                  |
| dfs-rehome                 | Revert to configured home channel once dfs evacuation period expires                                                    |
| dynamic-chain-selection    | Automatic antenna-mode selection (antenna for non-11n transmit rates)                                                   |
| ekahau                     | Ekahau Multicast MAC/Enable                                                                                             |
| extended-range             | Configure extended range                                                                                                |
| fallback-channel           | Configure the channel to be used for falling back in the event of radar being detected on the current operating channel |
| guard-interval             | Configure the 802.11n guard interval                                                                                    |
| ldpc                       | Configure support for Low Density Parity Check Code                                                                     |
| lock-rf-mode               | Retain user configured rf-mode setting for this radio                                                                   |
| max-clients                | Maximum number of wireless clients allowed to associate subject to AP limit                                             |
| mesh                       | Configure radio mesh parameters                                                                                         |
| meshpoint                  | Enable meshpoints on this radio                                                                                         |
| mu-mimo                    | Enable multi user MIMO on this radio (selected platforms only)                                                          |
| no                         | Negate a command or set its defaults                                                                                    |
| non-unicast                | Configure handling of non-unicast frames                                                                                |
| off-channel-scan           | Enable off-channel scanning on the radio                                                                                |
| placement                  | Configure the location where this radio is operating                                                                    |
| power                      | Configure the transmit power of the radio                                                                               |
| preamble-short             | Use short preambles on this radio                                                                                       |
| probe-response             | Configure transmission parameters for Probe Response frames                                                             |
| radio-resource-measurement | Configure support for 802.11k Radio Resource Measurement                                                                |

```

radio-share-mode Configure the radio-share mode of operation for
 this radio
rate-selection Default or Opportunistic rate relection
rf-mode Configure the rf-mode of operation for this
 radio
rifs Configure Reduced Interframe Spacing (RIFS)
 parameters
rts-threshold Configure the RTS threshold
shutdown Shutdown the selected radio interface
smart-rf Configure radio specific smart-rf settings
sniffer-redirect Capture packets and redirect to an IP address
 running a packet capture/analysis tool
stbc Configure Space-Time Block Coding (STBC)
 parameters
transmit-beamforming Enable Transmit Beamforming
use Set setting to use
wips Wireless intrusion prevention related
 configuration
wireless-client Configure wireless client related parameters
wlan Enable wlans on this radio

clrscr Clears the display screen
commit Commit all changes made in this session
do Run commands from Exec mode
end End current mode and change to EXEC mode
exit End current mode and down to previous mode

```

The following table summarizes the radio interface configuration commands:

| Commands                                       | Description                                                                                                                      |
|------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">adaptivity</a> on page 1076        | Configures an adaptivity timeout value, in minutes, for avoidance of channels detected with radar or high levels of interference |
| <a href="#">aeroscout</a> on page 1077         | Enables Aeroscout multicast packet forwarding                                                                                    |
| <a href="#">aggregation</a> on page 1078       | Configures 802.11n aggregation parameters                                                                                        |
| <a href="#">airtime-fairness</a> on page 1081  | Enables fair access for clients based on airtime usage                                                                           |
| <a href="#">antenna-diversity</a> on page 1081 | Transmits antenna diversity for non-11n transmit rates                                                                           |
| <a href="#">antenna-downtilt</a> on page 1082  | Enables Advanced Element Panel Technology (ADEPT) antenna mode                                                                   |
| <a href="#">antenna-elevation</a> on page 1082 | Configures the antenna's elevation gain. This command is applicable only to the AP7562 model access point.                       |
| <a href="#">antenna-gain</a> on page 1084      | Specifies the antenna gain for the selected radio                                                                                |

| Commands                                             | Description                                                                                                                                                                            |
|------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">antenna-mode</a> on page 1085            | Configures the radio antenna mode                                                                                                                                                      |
| <a href="#">assoc-response</a> on page 1086          | Enables an access point to ignore or respond to an association/authorization request based on the configured Received Signal Strength Index (RSSI) threshold and deny-threshold values |
| <a href="#">association-list</a> on page 1086        | Associates an existing global association list with this radio interface                                                                                                               |
| <a href="#">beacon</a> on page 1087                  | Configures beacon parameters                                                                                                                                                           |
| <a href="#">bridge</a> on page 1088                  | Configures client-bridge related parameters, if the selected radio's RF mode is set to bridge                                                                                          |
| <a href="#">channel</a> on page 1098                 | Configures a radio's channel of operation                                                                                                                                              |
| <a href="#">data-rates</a> on page 1099              | Specifies the 802.11 rates supported on a radio                                                                                                                                        |
| <a href="#">description</a> on page 1103             | Configures the selected radio's description                                                                                                                                            |
| <a href="#">dfs-rehome</a> on page 1104              | Reverts to configured home channel once Dynamic Frequency Selection (DFS) evacuation period expires                                                                                    |
| <a href="#">dynamic-chain-selection</a> on page 1105 | Enables automatic antenna mode selection                                                                                                                                               |
| <a href="#">ekahau</a> on page 1105                  | Enables Ekahau multicast packet forwarding                                                                                                                                             |
| <a href="#">extended-range</a> on page 1106          | Configures extended range                                                                                                                                                              |
| <a href="#">fallback-channel</a> on page 1107        | Configures the channel to which the radio switches in case of radar detection on the current channel                                                                                   |
| <a href="#">guard-interval</a> on page 1108          | Configures the 802.11n guard interval                                                                                                                                                  |
| <a href="#">ldpc</a> on page 1109                    | Enables support for Low Density Parity Check (LDPC) on the radio interface                                                                                                             |
| <a href="#">lock-rf-mode</a> on page 1110            | Retains user configured RF mode settings for the selected radio                                                                                                                        |
| <a href="#">max-clients</a> on page 1111             | Configures the maximum number of wireless clients allowed to associate with this radio                                                                                                 |
| <a href="#">mesh</a> on page 1112                    | Configures radio mesh parameters                                                                                                                                                       |
| <a href="#">meshpoint</a> on page 1113               | Maps an existing meshpoint to this radio interface                                                                                                                                     |
| <a href="#">mu-mimo</a> on page 1113                 | Enables multi-user multiple input multiple output (MU-MIMO) support on a radio                                                                                                         |
| <a href="#">no</a> on page 1114                      | Negates or resets radio interface settings configured on a profile or a device                                                                                                         |
| <a href="#">non-unicast</a> on page 1117             | Configures the handling of non unicast frames on this radio                                                                                                                            |
| <a href="#">off-channel-scan</a> on page 1119        | Enables selected radio's off channel scanning parameters                                                                                                                               |

| Commands                                                | Description                                                                                                                       |
|---------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|

| <a href="#">stbc</a> on page 1133                       | Configures radio's Space Time Block Coding (STBC) mode                                                                            |
| <a href="#">transmit-beamforming</a> on page 1134       | Enables transmit beamforming on the selected radio interface                                                                      |
| <a href="#">use</a> on page 1135                        | Enables use of an association ACL policy and a radio QoS policy by selected radio interface                                       |
| <a href="#">wips</a> on page 1136                       | Enables access point to change its channel of operation in order to terminate rogue devices                                       |
| <a href="#">wireless-client</a> on page 1137            | Configures wireless client parameters on selected radio                                                                           |
| <a href="#">wlan</a> on page 1138                       | Enables a WLAN on selected radio                                                                                                  |

adaptivity

[interface-config-radio-instance](#) on page 1072

Configures the duration, in minutes, for which channels detected with high levels of interference are avoided by the AP

As per the ETSI's (European Telecommunications Standards Institute) EN 300 328 V1.8.1/ ETSI EN 301 893 V1.7.1 requirements, access points have to monitor interference levels on operating channels, and stop functioning on channels with interference levels exceeding ETSI-specified threshold values.

This command configures the duration for which a channel is avoided on detection of interference, and is applicable only if the channel selection mode is set to ACS, Random, or Fixed.

#### Note

If you want to configure your radio to use a SMART RF policy for channel selection (i.e., the radio's channel selection mode is set to Smart), in the Smart-RF policy config mode, use the **avoidance-time > [adaptivity|dfs] > <30-3600>** command to specify the interval for which a channel is avoided on detection of high levels of interference or radar. For more information, see [avoidance-time](#) on page 1633 (smart-rf policy config mode).

When configured, this feature ensures recovery by switching the radio to a new operating channel. Once adaptivity is triggered, the evacuated channel becomes inaccessible and is available again only after the adaptivity timeout, specified here, expires. In case of fixed channel, the radio switches back to the original channel of operation after the adaptivity timeout expires. On the other hand, ACS-enabled radios continue operating on the new channel even after the adaptivity timeout period expires.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

#### Syntax

```
adaptivity [recovery|timeout <30-3600>]
```

#### Parameters

```
adaptivity [recovery|timeout <30-3600>]
```

|                                          |                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>adaptivity</b>                        | Configures adaptivity parameters on the radio. These parameters are: recovery and timeout.                                                                                                                                                                                                                                                                                                                  |
| <b>recovery</b>                          | Enables switching of channels when an access point's radio is in the adaptivity mode. In the adaptivity mode, an access point monitors interference on its set channel and stops functioning when the radio's defined interference tolerance level is exceeded. When the defined adaptivity timeout is exceeded, the radio resumes functionality on a different channel. This option is enabled by default. |
| <b>timeout</b><br><b>&lt;30-3600&gt;</b> | Configures an adaptivity timeout <ul style="list-style-type: none"><li>• &lt;30-3600&gt; – Specify a value from 30 - 3600 minutes. The default is 90 minutes.</li></ul>                                                                                                                                                                                                                                     |

#### Example

```
nx9500-6C8809(config-profile-testAP7532-if-radiol)#adaptivity timeout 200
```

```
nx9500-6C8809(config-profile-testAP7532-if-radiol)#show context
 interface radiol
 adaptivity timeout 200
nx9500-6C8809(config-profile-testAP7532-if-radiol)#
```

aeroscout

[interface-config-radio-instance](#) on page 1072

Enables Aeroscout multicast packet forwarding. This feature is disabled by default.

Supported in the following platforms:

- Access Points — AP7502, AP7522

Syntax

```
aeroscout [forward ip <IP> port <0-65535>|mac <MAC>]
```

Parameters

```
aeroscout [forward ip <IP> port <0-65535>|mac <MAC>]
```

|                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>aeroscout</b>                                          | Enables Aeroscout packet forwarding and configures the packet forwarding parameters                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

aggregation

[interface-config-radio-instance](#) on page 1072

Configures 802.11n frame aggregation parameters. Frame aggregation increases throughput by sending two or more data frames in a single transmission. There are two types of frame aggregation: MAC Service Data Unit (MSDU) aggregation and MAC Protocol Data Unit (MPDU) aggregation. Both modes group several data frames into one large data frame.

Supported in the following platforms:

- Access Points — AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

Syntax

```
aggregation [ampdu|amsdu]
```

```
aggregation ampdu [rx-only|tx-only|tx-rx|none|max-aggr-size|min-spacing]
```

```
aggregation ampdu [rx-only|tx-only|tx-rx|none]
```

```
aggregation ampdu max-aggr-size [rx|tx]
```

```
aggregation ampdu max-aggr-size rx [8191|16383|32767|65535]
```

```
aggregation ampdu max-aggr-size tx <2000-65535>
```

```
aggregation ampdu min-spacing [0|1|2|4|8|16]
```

```
aggregation amsdu [rx-only|tx-rx]
```

Parameters

```
aggregation ampdu [rx-only|tx-only|tx-rx|none]
```

|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>aggregation</b> | Configures 802.11n frame aggregation parameters                                                                                                                                                                                                                                                                                                                                                               |
| <b>ampdu</b>       | Configures Aggregate MAC Protocol Data Unit (AMPDU) frame aggregation parameters. AMPDU aggregation collects Ethernet frames addressed to a single destination. It wraps each frame in an 802.11n MAC header. This aggregation mode is less efficient, but more reliable in environments with high error rates. It enables the acknowledgement and retransmission of each aggregated data frame individually. |
| <b>tx-only</b>     | Supports the transmission of AMPDU aggregated frames only                                                                                                                                                                                                                                                                                                                                                     |
| <b>rx-only</b>     | Supports the receipt of AMPDU aggregated frames only                                                                                                                                                                                                                                                                                                                                                          |

## airtime-fairness

[interface-config-radio-instance](#) on page 1072

Enables fair access to the medium for wireless clients based on their airtime usage, regardless of whether the client is a high-throughput (802.11n) or legacy client. This option is enabled by default.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

Syntax

```
airtime-fairness {prefer-ht} {weight <1-10>}
```

Parameters

```
airtime-fairness {prefer-ht} {weight <1-10>}
```

|                            |                                                                                                                                                                                                      |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>airtime-fairness</b>    | Enables fair access to the medium for wireless clients based on their airtime usage                                                                                                                  |
| <b>prefer-ht</b>           | Optional. Prioritizes high throughput (802.11n) clients over clients with slower throughput (802.11 a/b/g) and legacy clients                                                                        |
| <b>weight &lt;1-10&gt;</b> | Optional. Configures the relative weightage for 11n clients over legacy clients. <ul style="list-style-type: none"><li>• &lt;1-10&gt; - Sets a weightage ratio for 11n clients from 1 - 10</li></ul> |

Example

```
nx9500-6C8809(config-profile-7lxxTestProfile-if-radio1)#airtime-fairness prefer-ht weight 6
```

```
nx9500-6C8809(config-profile-7lxxTestProfile-if-radio1)#show context
interface radio1
 aggregation ampdu tx-only
 aeroscout forward
 airtime-fairness prefer-ht weight 6
nx9500-6C8809(config-profile-7lxxTestProfile-if-radio1)#
```

## antenna-diversity

[interface-config-radio-instance](#) on page 1072

Enables antenna diversity for transmit frames at non-11n transmit rates

Antenna diversity uses two or more antennas to increase signal quality and strength. This option is disabled by default.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

Syntax

```
antenna-diversity
```

Parameters

None

#### Example

```
nx9500-6C8809(config-profile-7lxxTestProfile-if-radio1)#antenna-diversity
```

```
nx9500-6C8809(config-profile-7lxxTestProfile-if-radio1)#show context
 interface radio1

### antenna-downtilt

[interface-config-radio-instance](#) on page 1072

Enables the Advanced Element Panel Technology (ADEPT) antenna mode. The ADEPT mode increases the probability of parallel data paths enabling multiple spatial data streams. This option is disabled by default.

Supported in the following platforms:

- Access Point — AP7161

#### Syntax

```
antenna-downtilt
```

#### Parameters

None

#### Example

```
nx9500-6C8809(config-profile-7lxxTestProfile-if-radio1)#antenna-downtilt
```

```
nx9500-6C8809(config-profile-7lxxTestProfile-if-radio1)#show context

| <a href="#">no</a> on page 1114 | Disables the ADEPT antenna mode |
|---------------------------------|---------------------------------|

### antenna-elevation

[interface-config-radio-instance](#) on page 1072

Configures an antenna's elevation gain. Antenna gain is the ratio of an antenna's radiation intensity in a given direction to the intensity produced by a no-loss, isotropic antenna radiating equally in all directions. An antenna's gain along the horizon and at an elevation of 30 degree may vary. The elevation

gain is defined as the maximum antenna gain at 30 to 150 degrees above the horizon. If elevation gain is configured, the transmit (TX) power calculations maximize the allowable TX power for an elevation below 30 degree.

Access points must conform to U.S. Federal Communications Commission's (FCC) limitations. FCC has now stipulated a 21dBm Effective Isotropic Radiated Power (EIRP) limit for power directed 30 degrees above the horizon.

For Extreme Networks -supplied antennas, compatible with 5.0 GHz on the AP7562 access point, refer to the Antenna Guide for "Elevation Gain" information. If using a third-party antenna, it is required that you obtain the antenna-elevation gain information from the antenna manufacturer.

The elevation gain should be configured if the access point:

- Is deployed outdoors, and
- Is used with a dipole antenna (panel antenna and polarized antenna are for point to point only, and are excluded from this requirement), and
- Is transmitting in the 5.15 - 5.25 GHz Unlicensed National Information Infrastructure-1 (UNII-1) band.

Professional installers must complete the following steps to ensure compliance with the FCC rule:

- 1 Configure the antenna type. For example:  
`ap7562-80C2AC(config-device-84-24-8D-80-C2-AC-if-radio2)#service antenna-type dipole`
- 2 Configure the antenna peak gain. For example:  
`ap7562-80C2AC(config-device-84-24-8D-80-C2-AC-if-radio2)#antenna-gain 7.0`
- 3 Configure the antenna placement. For example:  
`ap7562-80C2AC(config-device-84-24-8D-80-C2-AC-if-radio2)#placement outdoor`
- 4 Configure the antenna elevation gain. For example:  
`ap7562-80C2AC(config-device-84-24-8D-80-C2-AC-if-radio2)#antenna-elevation 5.0`

After the professional installer enters the antenna type, gain, placement, and elevation gain using the CLI as outlined above, the firmware will use this information and hardcoded maximum limits determined during testing (See Annex C in FCC Report #FR4D0448AB) to limit the EIRP below 21dBm for outdoor use in UNII-1 band. The antenna information is provided in the Installation guide and antenna guide.

Supported in the following platforms:

- Access Points — AP7562

Syntax

`antenna-elevation <-30.0-36.0>`

#### Note

The antenna elevation gain feature is supported only on the AP7562 model access point.

Parameters

`antenna-elevation <-30.0-36.0>`

|                                                       |                                                                                                                                                                       |
|-------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>antenna-elevation</b><br><b>&lt;-30.0-36.0&gt;</b> | Configures the antenna elevation gain from -30.0 - 36.0 dB. Refer to the antenna specifications for antenna-elevation gain information.<br>The default value is 0 dB. |
|-------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Example

```
ap7562-80C2AC(config-device-84-24-8D-80-C2-AC-if-radio2)#antenna-elevation 5.0

ap7562-80C2AC(config-device-84-24-8D-80-C2-AC-if-radio2)#show context
interface radio2
 antenna-elevation 5.0

|---------------------------------|-------------------------------------------------|

## antenna-gain

[interface-config-radio-instance](#) on page 1072

Configures the antenna gain for the selected radio

Antenna gain is the ability of an antenna to convert power into radio waves and vice versa. The access point or wireless controller's Power Management Antenna Configuration File (PMACF) automatically configures the access point or wireless controller's radio transmit power based on the antenna type, its antenna gain (provided here) and the deployed country's regulatory domain restrictions. Once provided, the access point or wireless controller calculates the power range. Antenna gain relates the intensity of an antenna in a given direction to the intensity that would be produced ideally by an antenna that radiates equally in all directions (isotropically), and has no losses. Although the gain of an antenna is directly related to its directivity, its gain is a measure that takes into account the efficiency of the antenna as well as its directional capabilities. It is recommended that only a professional installer set the antenna gain.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

## Syntax

```
antenna-gain <0.0-15.0>
```

## Parameters

```
antenna-gain <0.0-15.0>
```

|                                                |                                                                     |
|------------------------------------------------|---------------------------------------------------------------------|
| <b>antenna-gain</b><br><b>&lt;0.0-15.0&gt;</b> | Sets the antenna gain from 0.0 - 15.0 dBi. The default is 0.00 dBi. |
|------------------------------------------------|---------------------------------------------------------------------|

## Example

```
nx9500-6C8809(config-profile-71xxTestProfile-if-radio1)#antenna-gain 12.0

nx9500-6C8809(config-profile-71xxTestProfile-if-radio1)#show context
interface radio1
 antenna-gain 12.0
 aggregation ampdu tx-only
 aeroscout forward
 antenna-diversity
 airtime-fairness prefer-ht weight 6
 antenna-downtilt
nx9500-6C8809(config-profile-71xxTestProfile-if-radio1)#
```

## Related Commands

[no](#) on page 1114

Resets the radio's antenna gain parameter

## antenna-mode

[interface-config-radio-instance](#) on page 1072

Configures the antenna mode (the number of transmit and receive antennas) on the access point

This command sets the number of transmit and receive antennas on the access point. The 1x1 mode is used for transmissions over just the single -A- antenna, 1xALL is used for transmissions over the -A- antenna and all three antennas for receiving. The 2x2 mode is used for transmissions and receipts over two antennas for dual antenna models. 3x3x3 is used for transmissions and receipts over three antennas for AP8163 models. The default setting is dynamic based on the access point model deployed and its transmit power settings.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

### Syntax

```
antenna-mode [1*1|1*ALL|2*2|3*3|default]
```

### Parameters

```
antenna-mode [1*1|1*ALL|2*2|default]
```

|                     |                                                             |
|---------------------|-------------------------------------------------------------|
| <b>antenna-mode</b> | Configures the antenna mode                                 |
| <b>1*1</b>          | Uses only antenna A to receive and transmit                 |
| <b>1*ALL</b>        | Uses antenna A to transmit and receives on all antennas     |
| <b>2*2</b>          | Uses antennas A and C for both transmit and receive         |
| <b>3*3</b>          | Uses antenna A, B, and C for both transmit and receive      |
| <b>default</b>      | Uses default antenna settings. This is the default setting. |

### Usage Guidelines

To support STBC feature on AP7161 profile, the antenna-mode should not be configured to 1\*1.

### Example

```
nx9500-6C8809(config-profile-71xxTestProfile-if-radio1)#antenna-mode 2x2
```

```
nx9500-6C8809(config-profile-71xxTestProfile-if-radio1)#show context
```

```
interface radio1
 antenna-gain 12.0
 aggregation ampdu tx-only
 aeroscout forward
 antenna-mode 2x2
 antenna-diversity
 airtime-fairness prefer-ht weight 6
 antenna-downtilt
```

```
nx9500-6C8809(config-profile-71xxTestProfile-if-radio1)#
```

### Related Commands

[no](#) on page 1114

Resets the radio antenna mode (the number of transmit and receive antennas) to its default

assoc-response

[interface-config-radio-instance](#) on page 1072

Configures the parameters determining whether the access point ignores or responds to an association/authorization request

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

Syntax

```
assoc-response [deny-threshold <1-12>|rssi-threshold <-128--40>]
```

Parameters

```
assoc-response [deny-threshold <1-12>|rssi-threshold <-128--40>]
```

|                                                  |                                                                                                                                                                                                                                                                                                                                                                                             |

association-list

[interface-config-radio-instance](#) on page 1072

Associates an existing global association list with this radio interface

An association ACL is a policy-based access control list (ACL) that either prevents or allows wireless clients from connecting to a managed access point radio. An ACL is a sequential collection of permit and deny rules that apply to incoming and outgoing packets. When a packet is received on an interface, the controller, service platform, or access point compares the fields in the packet against the applied

ACLs to verify the packet has the required permissions to be forwarded. If a packet does not meet any of the criteria specified in the ACL, it is dropped.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

Syntax

```
association-list global <GLOBAL-ASSOC-LIST-NAME>
```

Parameters

```
association-list global <GLOBAL-ASSOC-LIST-NAME>
```

|                                                                                                                         |                                                                          |

beacon

[interface-config-radio-instance](#) on page 1072

Configures radio beacon parameters

A beacon is a packet broadcasted by adopted radios to keep the network synchronized. Included in a beacon is information, such as the WLAN service area, the radio address, the broadcast destination addresses, a time stamp, and indicators about traffic and delivery such as a Delivery Traffic Indication Message (DTIM). Increase the DTIM/beacon settings (lengthening the time) to let nodes sleep longer and preserve battery life. Decrease these settings (shortening the time) to support streaming-multicast audio and video applications that are jitter sensitive.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

Syntax

```
beacon [dtim-period|period]
```

```
beacon dtim-period [<1-50>|bss]
```

```
beacon dtim-period [<1-50>|bss <1-16> <1-50>]
```

beacon period [50|100|200]

Parameters

beacon dtim-period [<1-50>|bss <1-8> <1-50>]

|                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>beacon</b>                                  | Configures radio beacon parameters                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>dtim-period</b>                             | Configures the radio DTIM interval. A DTIM is a message that informs wireless clients about the presence of buffered multicast or broadcast data. These are simple data frames that require no acknowledgement, so nodes sometimes miss them. Increase the DTIM/ beacon settings (lengthening the time) to let nodes sleep longer and preserve their battery life. Decrease these settings (shortening the time) to support streaming multicast audio and video applications that are jitter-sensitive. |
| <b>&lt;1-50&gt;</b>                            | Configures a single value to use on the radio. Specify a value between 1 and 50.                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>bss &lt;1-16&gt;</b><br><b>&lt;1-50&gt;</b> | Configures a separate DTIM for a Basic Service Set (BSS) on this radio interface <ul style="list-style-type: none"><li>• &lt;1-16&gt; - Sets the BSS number from 1 - 16</li><li>• &lt;1-50&gt; - Sets the BSS DTIM from 1 - 50. The default is 2.</li></ul>                                                                                                                                                                                                                                             |

beacon period [50|100|200]

|                            |                                                                                                                                                                                                                                                                                                                            |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>period [50 100 200]</b> | Configures the beacon period (the interval between consecutive radio beacons) <ul style="list-style-type: none"><li>• 50 - Configures 50 K-uSec interval between beacons</li><li>• 100 - Configures 100 K-uSec interval between beacons (default)</li><li>• 200 - Configures 200 K-uSec interval between beacons</li></ul> |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Example

```
nx9500-6C8809(config-profile-7lxxTestProfile-if-radiol)#beacon dtim-period bss 2 20
nx9500-6C8809(config-profile-7lxxTestProfile-if-radiol)#beacon period 50
```

```
nx9500-6C8809(config-profile-7lxxTestProfile-if-radiol)#show context
interface radiol
 beacon period 50
 beacon dtim-period bss 1 2
 beacon dtim-period bss 2 20
 beacon dtim-period bss 3 2
 --More--
nx9500-6C8809(config-profile-7lxxTestProfile-if-radiol)#
```

bridge

[interface-config-radio-instance](#) on page 1072

Configures the CB (client-bridge) parameters for radios with rf-mode set to bridge. When configured as a client bridge, the radio can authenticate and associate to the WLAN hosted on the infrastructure access point. After successfully associating with the infrastructure WLAN, the CB access point switches frames between its bridge radio and wired/wireless client(s) connected either to its GE port(s) or to the other radio, there by providing the clients access to the infrastructure WLAN resources.

---

This command configures settings that define the authentication-type and encryption-type used by the CB AP to associate and communicate with the infrastructure AP. It also configures other parameters, such as channel-dwell time, wlan ssid, etc.

#### Note

The radio interface configured to form the client-bridge will not be able to service wireless clients as its RF mode is set to bridge and not 2.4 GHz or 5.0 GHz.

---

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7522, AP7532, AP7622, AP7622, AP7632, AP7602, AP7622

Syntax

```
bridge [authentication-type | channel-dwell-time | channel-list | connect-through-bridges | eap | encryption-type | inactivity-timeout | keepalive | max-clients | on-link-loss | on-link-up | roam-criteria | ssid | wpa-wpa2]
```

The following *EAP authentication commands* have been documented in the first five Parameter tables:

```
bridge [authentication-type [eap|none]]
```

```
bridge eap [password|trustpoint|type|username]
```

```
bridge eap type [peap-mschapv2|tls]
```

```
bridge eap password <PASSWORD>
```

```
bridge eap username <USERNAME>
```

```
bridge eap trustpoint [ca|client] <TRUSTPOINT-NAME>
```

```
bridge eap trustpoint on-cert-expiry [continue|discontinue]
```

The following *CB related parameters* have been documented in the last Parameter table:

```
bridge channel-dwell-time <50-2000>
```

```
bridge channel-list [2.4GHz|5GHz] <LIST>
```

```
bridge connect-through-bridges
```

```
bridge encryption-type [ccmp|none|tkip]
```

```
bridge inactivity-timeout <0-864000>
```

```
bridge keepalive [frame-type [null-data|wnmp]]|interval <0-36000>]
```

```
bridge max-clients <1-64>
```

```
bridge on-link-loss shutdown-other-radio <1-1800>
```

```
bridge on-link-up refresh-vlan-interface
```

```
bridge roam-criteria [missed-beacon <1-60>|rssi-threshold <-128--40>]
```

```
bridge ssid <SSID>
```

```
bridge wpa-wpa2 psk <LINE>
```

Parameters

```
bridge [authentication-type [eap|none]]
```

| <b>bridge</b>         | Configures client-bridge related parameters on the selected radio<br><br><b>Note:</b> Prior to configuring the client-bridge parameters, set the radio's rf-mode to bridge.                                                                                                                                                                                                                                                                          |
| <b>eap trustpoint</b> | If EAP authentication type is set to EAP-TLS, use this command to configure TP (trustpoint) details.<br>In EAP-TLS authentication, the CB AP and RADIUS server host authenticate each other using TPs. A TP contains the <i>CA certificate</i> and the <i>CA-signed certificate authenticating</i> the device. To enable TP-based authentication, both the CB AP and the RADIUS server host <b>must</b> use the same CA as the certifying authority. |

**client**  
**<TRUSTPOINT-**  
**NAME>**

Configures the *Client-TP* name (this is the TP installed on the CB AP). When configured, the certificate installed on the CB AP is sent across a TLS tunnel and matched for authentication at the RADIUS server host.

- <TRUSTPOINT-NAME> – Specify the TP name. This configuration is mandatory for enabling TP-based authentication of CB AP.

**Note:** To view TP name, use the **show > crypto > pki > trustpoint** command on the CB AP.

**Note:** On the self of the RADIUS server host, execute the following commands:

**trustpoint > radius-server> <TUSTPOINT-NAME>** - This is the RADIUS server TP name.

**trustpoint > radius-ca > <TUSTPOINT-NAME>** - This is the RADIUS server TP name.

For more information, see [trustpoint \(device-config-mode\)](#) on page 1282.

**ca <TRUSTPOINT-**  
**NAME>**

This configuration is applicable to both the EAP-TLS and PEAP-MSCHAPv2 authentication types. Configure this option only if you want to enable RADIUS server certificate validation at the client end. This configuration is not mandatory for enabling TP-based authentication of CB AP.

- <TRUSTPOINT-NAME> – Specify the TP name (it is the TP installed on the RADIUS server host).

```
bridge eap trustpoint on-cert-expiry [continue|discontinue]]
```

**bridge**

Configures client-bridge related parameters on the selected radio

**Note:** Prior to configuring the client-bridge parameters, set the radio's rf-mode to bridge.

**eap trustpoint**  
**on-cert-expiry**  
**[continue |**  
**discontinue]**

If EAP authentication type is set to EAP-TLS, a CA-signed certificate is used to authenticate the CB AP and RADIUS server host to establish the wireless CB. Use this command to specify whether the wireless CB is to be continued or terminated on expiration of this certificate.

- continue – Enables continuation of the CB even after the certificate (CA/client) has expired. When configured, this option enables automatic CA certificate deployment as and when new CA certificates are available.
- discontinue – Terminates the CB once the certificate (CA/client) has expired.

**Note:** Configure this parameter only if the CB AP and the RADIUS server host are using a crypto CMP policy for automatic certificate renewal. For more information, see [CRYPTO-CMP-POLICY](#) on page 1831.

This is the time for which the CB AP waits for, after missing a beacon from the associated infrastructure AP, before roaming to another infrastructure AP. For example, if the missed-beacon time is set to 30 seconds, and if more than 30 seconds have passed since the last received beacon, the CB AP resumes scanning for another infrastructure AP. The default value is 20 seconds. <ul style="list-style-type: none"> <li>&lt;1-60&gt; – Specify a value from 1 - 60 seconds. The default is 20 seconds.</li> </ul> </li> <li>rssi-threshold &lt;-128--40&gt; – Configures the minimum signal strength, received from target AP, for the bridge connection to be maintained before roaming <ul style="list-style-type: none"> <li>&lt;-128--40&gt; – Specify a value from -128 - -40 dBm. If the RSSI value of infrastructure access point radio signals falls below the specified value, the CB AP resumes scanning for another infrastructure access point. The default is -75 dBm.</li> </ul> </li> </ul> |
| <b>ssid &lt;SSID&gt;</b>                                                             | <p>Configures the infrastructure WLAN SSID the client bridge connects to</p> <ul style="list-style-type: none"> <li>&lt;SSID&gt; – Specify the SSID.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>wpa-wpa2 psk &lt;LINE&gt;</b>                                                     | <p>Configures the encryption PSK to use with the infrastructure WLAN</p> <ul style="list-style-type: none"> <li>&lt;LINE&gt; – Enter the key</li> </ul> <p><b>Note:</b> Pre-shared keys are valid only when the authentication-type is set to none and the encryption-type is set to tkip or ccmp.<br/>The PSK should be 8 - 32 characters in length.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

#### Usage Guidelines EAP Authentication

Use the following commands to view client-bridge configuration:

1 show > wireless > bridge > config

Shows the current client bridge configuration.

2 show > wireless > bridge > candidate-ap

Shows the available infrastructure WLAN candidates that are found during the last scan.

3 show > wireless > bridge > host

Shows the wired/wireless clients that are being bridged.

- 4 show > wireless > bridge > statistics > rf

Shows the client bridge RF statistics.

- 5 show > wireless > bridge > statistics > traffic

Shows the client bridge traffic statistics.

- 6 show > wireless > bridge > certificate > status

Shows the client bridge authentication certificate status.

Use the following command on the CB AP and the RADIUS server host to view installed TP details:

- 1 show > crypto > pki > trustpoints

### Example - CB with authentication 'none' and encryption 'ccmp'

The following example shows the basic parameters that need to be configured on the Infrastructure and the CB APs in order to enable the CB AP to associate with the Infrastructure WLAN. Note, in this example, the authentication mode is set to 'none' and the encryption-type is set to 'ccmp'. The authentication and encryption modes used will vary as per requirement.

- 1 Configure the Infrastructure WLAN:

```
InfrastrNOC(config)#show running-config wlan cb-psk
wlan cb-psk
ssid cb-psk
bridging-mode local
encryption-type ccmp
authentication-type none
wpa-wpa2 psk 0 extreme@123
```

```
InfrastrNOC(config)#
```

- 2 Associate the 'cb-psk' WLAN to the Infrastructure AP.

```
InfrastrAP(config-device-B4-C7-99-5F-50-78-if-radio2)#wlan cb-psk
```

- 3 Confirm the Infrastructure AP's radio interface status.

```
InfrastrAP(config)#show wireless radio

RADIO RADIO-MAC RF-MODE STATE CHANNEL POWER
#CLIENT

InfrastrAP:R1 B4-C7-99-5E-51-40 2.4GHz-wlan Off N/A (smt) 0 (smt) 0
InfrastrAP:R2 B4-C7-99-5E-1A-40 5GHz-Wlan On 165 (165) 17 (smt) 2

Total number of radios displayed: 2
InfrastrAP(config)#
```

- 4 Configure following radio parameters on the CB AP:

```
ClientBridgeAP(config-device-84-24-8D-85-B2-74-if-radio2)#rf-mode bridge
```

```
ClientBridgeAP(config-device-84-24-8D-85-B2-74-if-radio2)#bridge ssid cb-psk
```

```
ClientBridgeAP(config-device-84-24-8D-85-B2-74-if-radio2)#bridge encryption-type ccmp
```

```
ClientBridgeAP(config-device-84-24-8D-85-B2-74-if-radio2)#bridge authentication-type none
```

```
ClientBridgeAP(config-device-84-24-8D-85-B2-74-if-radio2)#bridge wpa-wpa2 psk
extreme@123
```

```
ClientBridgeAP(config-device-84-24-8D-85-B2-74-if-radio2)#show context
interface radio2
 rf-mode bridge
 bridge ssid cb-psk
 bridge encryption-type ccmp
 bridge wpa-wpa2 psk 0 extreme@123
ClientBridgeAP(config-device-84-24-8D-85-B2-74-if-radio2)#
```

Note, bridge SSID, encryption-type, and authentication mode are the same as that of the Infrastructure WLAN.

- 5 Confirm the CB AP's radio interface status.

```
ClientBridgeAP#show wireless radio

RADIO RADIO-MAC RF-MODE STATE CHANNEL POWER
#CLIENT

ClientBridgeAP:R1 84-24-8D-AC-2D-B0 2.4GHz-wlan Off N/A (smt) 0
(smt) 0
ClientBridgeAP:R2 84-24-8D-AC-CC-10 bridge On 165 (smt) 20
(smt) 0

Total number of radios displayed: 2
=====
ClientBridgeAP(config-device-84-24-8D-85-B2-74)#
```

- 6 View the candidate-ap (connected Infrastructure AP's) details on the CB AP.

```
ClientBridgeAP(config-device-84-24-8D-85-B2-74)#show wireless bridge candidate-ap
84-24-8D-AC-CC-10 Client Bridge Candidate APs:
 AP-MAC BAND CHANNEL SIGNAL(dbm) STATUS
 B4-C7-99-5E-1A-40 5 GHz 165 -21 selected
Total number of candidates displayed: 1
Total number of client bridges displayed: 1
=====
ClientBridgeAP(config-device-84-24-8D-85-B2-74)#
```

- 7 View the bridge host details on the CB AP.

```
ClientBridgeAP(config-device-84-24-8D-85-B2-74)#show wireless bridge hosts

Total number of hosts displayed: 1
ClientBridgeAP(config-device-84-24-8D-85-B2-74)#
```

### Example - CB with encryption 'CCMP' and authentication 'EAP-TLS' using Trustpoint Client.

- 1 On the Infrastructure AP,
  - a Configure WLAN as shown below.

```
InfrastrAP7532(config)#show running-config wlan cb-tp
wlan cb-tp
 ssid cb-tp
 bridging-mode local
 encryption-type ccmp
```

```
authentication-type eap
InfraStrAP7532(config)#
```

- b Associate WLAN to the infrastructure AP radio.

```
InfraStrAP(config-device-B4-C7-99-5F-50-78-if-radio2)#show context
interface radio2
 wlan cb-tp bss 1 primary
InfraStrAP(config-device-B4-C7-99-5F-50-78-if-radio2)#
```

- c Confirm infrastructure AP's radio interface status.

```
InfraStrAP(config)#show wireless radio
```

```

RADIO RADIO-MAC RF-MODE STATE CHANNEL
POWER #CLIENT

InfraStrAP:R1 B4-C7-99-5E-51-40 2.4GHz-wlan Off N/A (smt) 0 (smt)
0
InfraStrAP:R2 B4-C7-99-5E-1A-40 5GHz-Wlan On 165 (165) 17 (smt)
2

```

```
Total number of radios displayed: 2
InfraStrAP(config)#
```

- 2 On the RADIUS server host,

- a Configure the RADIUS user policy as shown below:

```
RADServer(config-radius-user-pool-cb-tp)#show context
radius-user-pool-policy cb-tp
 user admin password 0 extreme@123
RADServer(config-radius-user-pool-cb-tp)#
```

#### Note

In case of EAP-TLS authentication, the username configured here should be the "common name" on the client certificate.

- b Use this RADIUS user policy in the RADIUS server policy.

```
RADServer(config-radius-server-policy-cb-tp)#show context
radius-server-policy cb-tp
 use radius-user-pool-policy cb-tp
RADServer(config-radius-server-policy-cb-tp)#
```

- c On the self of the RADIUS server host,

- Apply the RADIUS server policy.  

```
RADServer(config-device-74-67-F7-07-02-35)#use radius-server-policy cb-tp
```
- Configure the trustpoint to be used to authenticate the RADIUS server host and RADIUS server CA.  

```
RADServer(config-device-74-67-F7-07-02-35)#trustpoint radius-server serverTP
RADServer(config-device-74-67-F7-07-02-35)#trustpoint radius-ca serverTP
```

#### Note

Ensure that the trustpoint is existing and installed on the RADIUS server. Also ensure that the RADIUS server host and CB AP are using the same CA for certification.

- 3 On the CB AP,

- a Configure the mandatory parameters as shown below:

```
clientbriAP(config-device-84-24-8D-DF-9A-4C-if-radio2)#show context
interface radio2
 rf-mode bridge
```

```

channel smart
power smart
data-rates default
no preamble-short
bridge ssid cb-tp
bridge encryption-type ccmp
bridge authentication-type eap
bridge eap username admin
bridge eap trustpoint client clientTP
bridge eap type tls
clientbriAP(config-device-84-24-8D-DF-9A-4C-if-radio2)#

```

#### Note

In case of EAP-TLS authentication, the username configured here should be the “common name” on the client certificate.

#### Note

Ensure that the CB AP and RADIUS server host are using the same CA for certification.

- b If you want to enable RADIUS server certificate validation at the client end, execute the following command:

```
clientbriAP(config-device-84-24-8D-DF-9A-4C-if-radio2)#trustpoint radius-ca clientTP
```

#### Note

This is an optional parameter that provides additional security and is applicable for EAP-TLS and PEAP-MSCHAPv2 authentication modes.

### channel

[interface-config-radio-instance](#) on page 1072

Configures a radio’s channel of operation

Only a trained installation professional should define the radio channel. Select Smart for the radio to scan non-overlapping channels listening for beacons from other access points. After the channels are scanned, the radio selects the channel with the fewest access points. In case of multiple access points on the same channel, it selects the channel with the lowest average power level.

#### Note

Channels with a “w” appended to them are unique to the 40 MHz band. Channels with a “ww” appended to them are 802.11ac specific, and appear only when using an and are unique to the 80 MHz band.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

Syntax

```
channel [smart | acs | random | 1 | 2 | 3 | 4 | -----]
```

## Parameters

channel [smart|acs|random|1|2|3|4|-----]

|                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## data-rates

[interface-config-radio-instance](#) on page 1072

Configures the 802.11 data rates on this radio

This command sets the rate options depending on the 802.11 protocol and the radio band selected. If 2.4 GHz is selected as the radio band, select separate 802.11b, 802.11g and 802.11n rates and define how they are used in combination. If 5.0 GHz is selected as the radio band, select separate 802.11a and 802.11n rates then define how they are used together.

If dedicating the radio to either 2.4 or 5.0 GHz support, use the custom keyword to set a 802.11n modulation and coding scheme (MCS) in respect to the radio's channel width and guard interval. A MCS defines (based on RF channel conditions) an optimal combination of rates, bonded channels, multiple spatial streams, different guard intervals and modulation types. Clients can associate as long as they support basic MCS (as well as non-11n basic rates).

Data rates are fixed and not user configurable for radios functioning as sensors.

#### Note

Use the `rf-mode` command to configure a radio's mode of operation.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

description

[interface-config-radio-instance](#) on page 1072

Configures the selected radio's description that helps differentiate it from other radios with similar configurations

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

#### Syntax

**description** <WORD>

#### Parameters

**description** <WORD>

|                                           |                                                                                           |
|-------------------------------------------|-------------------------------------------------------------------------------------------|
| <b>description</b><br><b>&lt;WORD&gt;</b> | Provide a description for the selected radio (should not exceed 64 characters in length). |
|-------------------------------------------|-------------------------------------------------------------------------------------------|

#### Example

```
nx9500-6C8809(config-profile-71xxTestProfile-if-radiol)#description "Primary radio to use"
```

```
nx9500-6C8809(config-profile-71xxTestProfile-if-radiol)#show context
interface radiol
 description "Primary radio to use"

#### dfs-rehome

[interface-config-radio-instance](#) on page 1072

Reverts to configured home channel once the Dynamic Frequency Selection (DFS) evacuation period expires

#### Note

This option is applicable only if the radio's RF mode is set to '5GHz-wlan'.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

#### Syntax

```
dfs-rehome {holdtime <30-3600>}
```

#### Parameters

```
dfs-rehome {holdtime <30-3600>}
```

|                                                                  |                                                                                                                                                                                                                                                                                                                                                       |

### dynamic-chain-selection

[interface-config-radio-instance](#) on page 1072

Enables automatic antenna mode selection. When enabled, the radio can dynamically change the number of transmit chains used (uses a single chain/antenna for frames at non-11n transmit rates). This option is enabled by default.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

#### Syntax

```
dynamic-chain-selection
```

#### Parameters

None

#### Example

```
nx9500-6C8809(config-profile-7lxxTestProfile-if-radiol)#dynamic-chain-selection
nx9500-6C8809(config-profile-7lxxTestProfile-if-radiol)#
```

### ekahau

[interface-config-radio-instance](#) on page 1072

Enables Ekahau multicast packet forwarding. When enabled, Ekahau small, battery powered Wi-Fi tags are attached to tracked assets or assets carried by people. Ekahau processes locations, rules, messages, and environmental data and turns the information into locating maps, alerts and reports.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

Syntax

```
ekahau [forward ip <IP> port <0-65535>|mac <MAC>]
```

Parameters

```
ekahau [forward ip <IP> port <0-65535>|mac <MAC>]
```

guard-interval

[interface-config-radio-instance](#) on page 1072

Configures the 802.11n guard interval. A guard interval ensures distinct transmissions do not interfere with one another. It provides immunity to propagation delays, echoes and reflection of radio signals.

The guard interval is the space between transmitted characters. The guard interval eliminates inter symbol interference (ISI). ISI which occurs when echoes or reflections from one symbol interferes with another. Adding time between transmissions allows echoes and reflections to settle before the next symbol is transmitted. A shorter guard interval results in shorter symbol times, which reduces overhead and increases data rates by up to 10%.

Supported in the following platforms:

- Access Points – AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

Syntax

```
guard-interval [any|long]
```

Parameters

```
guard-interval [any|long]
```

|                       |                                                                                |
|-----------------------|--------------------------------------------------------------------------------|
| <b>guard-interval</b> | Configures the 802.11n guard interval                                          |
| <b>any</b>            | Enables the radio to use any short (400nSec) or long (800nSec) guard interval  |
| <b>long</b>           | Enables the use of long guard interval (800nSec). This is the default setting. |

### Example

```
nx9500-6C8809(config-profile-7lxxTestProfile-if-radiol)#guard-interval long

### ldpc

[interface-config-radio-instance](#) on page 1072

Enables support for Low Density Parity Check (LDPC) codes on the radio interface

LDPC consists of forward error correcting codes that enable error control in data transmission. This option is disabled by default.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

Syntax

`ldpc`

Parameters

None

### Example

```
rfs4000-229D58(config-profile-Test81XX-if-radiol)#ldpc

#### Related Commands

mesh

[interface-config-radio-instance](#) on page 1072

Use this command to configure radio mesh parameters. A Wireless Mesh Network (WMN) is a network of radio nodes organized in a mesh topology. It consists of mesh clients, mesh routers, and gateways.

Each radio setting can have a unique mesh mode and link configuration. This provides a customizable set of connections to other mesh supported radios within the same radio coverage area.

Supported in the following platforms:

- Access Points – AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP8163, AP8432, AP8533

Syntax

```
mesh [client|links|portal|preferred-peer|psk]
```

```
mesh [client|links <1-6>|portal|preferred-peer <1-6> <MAC>|psk [0 <LINE>|2 <LINE>| <LINE>]]
```

Parameters

```
mesh [client|links <1-6>|portal|preferred-peer <1-6> <MAC>|psk [0 <LINE>|2 <LINE>|<LINE>]]
```

|                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## meshpoint

[interface-config-radio-instance](#) on page 1072

Maps an existing meshpoint to this radio

Use this command to assign each WLAN its own BSSID. If using a single-radio access point, there are 8 BSSIDs available. If using a dual-radio access point there are 8 BSSIDs for the 802.11b/g/n radio and 8 BSSIDs for the 802.11a/n radio.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP8163, AP8432, AP8533

### Syntax

```
meshpoint <MESHPOINT-NAME> {bss <1-16>}
```

### Parameters

```
meshpoint <MESHPOINT-NAME> {bss <1-16>}
```

|                                                   |                                                                                                                                                                         |
|---------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>meshpoint</b><br><b>&lt;MESHPOINT-NAME&gt;</b> | Maps a meshpoint to this radio. Specify the meshpoint name.                                                                                                             |
| <b>bss &lt;1-16&gt;</b>                           | Optional. Specifies the radio's BSS where this meshpoint is mapped <ul style="list-style-type: none"><li>• &lt;1-16&gt; - Specify the BSS number from 1 - 16.</li></ul> |

### Example

```
nx9500-6C8809(config-profile-ap71xxTest-if-radiol)#meshpoint test bss 7
nx9500-6C8809(config-profile-ap71xxTest-if-radiol)#show context
interface radiol
 meshpoint test bss 7
nx9500-6C8809(config-profile-ap71xxTest-radiol)#
```

## mu-mimo

[interface-config-radio-instance](#) on page 1072

Enables multi-user multiple input multiple output (MU-MIMO) support on the selected radio. When enabled, multiple users are able to simultaneously access the same channel using the spatial degrees of freedom offered by MIMO.

Supported in the following platforms:

- Access Points — AP7532, AP7562, AP8163, AP8432, AP8533

Syntax

```
mu-mimo
```

Parameters

None

Example

```
nx9500-6C8809(config-profile-TestAP81xx-if-radio1)#mu-mimo
nx9500-6C8809(config-profile-TestAP81xx-if-radio1)#show context include-factory | include

no

[interface-config-radio-instance](#) on page 1072

Negates a command or resets settings to their default. When used in the profile/device > radio interface configuration mode, the no command disables or resets radio interface settings.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

Syntax

```
no <PARAMETERS>
```

Parameters

```
no <PARAMETERS>
```

|                                        |                                                                                   |
|----------------------------------------|-----------------------------------------------------------------------------------|
| <b>no</b><br><b>&lt;PARAMETERS&gt;</b> | Removes or reverts this radio interface's settings based on the parameters passed |
|----------------------------------------|-----------------------------------------------------------------------------------|

Usage Guidelines

The no command negates any command associated with it. Wherever required, use the same parameters associated with the command getting negated.

## Example

```
nx9500-6C8809(config-profile-ap71xxTest-if-radiol)#no ?
 adaptivity Adaptivity
 aeroscout Use Default Aeroscout Multicast MAC Address
 aggregation Configure 802.11n aggregation related parameters
 airtime-fairness Disable fair access to medium for clients,
 provide access in a round-robin mode
 antenna-diversity Use single antenna for non-11n transmit rates
 antenna-downtilt Reset ADEPT antenna mode
 antenna-elevation Reset the antenna elevation of this radio to
 default
 antenna-gain Reset the antenna gain of this radio to default
 antenna-mode Reset the antenna mode (number of transmit and
 receive antennas) on the radio to its default
 assoc-response Configure transmission parameters for
 Association Response frames
 association-list Configure the association list for the radio
 beacon Configure beacon parameters
 bridge Bridge rf-mode related configuration
 channel Reset the channel of operation of this radio to
 default
 data-rates Reset radio data rate configuration to default
 description Reset the description of the radio to its
 default
 dfs-rehome Stay on dfs elected channel after evacuation
 period expires
 dynamic-chain-selection Use the configured transmit antenna mode for all
 clients
 ekahau Use Default Ekahau Multicast MAC Address
 extended-range Reset extended range to default
 fallback-channel Clear the DFS fallback channel for this radio
 guard-interval Configure default value of 802.11n guard
 interval (long: 800nSec)
 ldpc Configure support for Low Density Parity Check
 Code
 lock-rf-mode Allow smart-rf to change rf-mode setting for
 this radio
 max-clients Maximum number of wireless clients allowed to
 associate
 mesh Disable mesh mode operation of the radio
 meshpoint Disable a meshpoint from this radio
 mu-mimo Disable multi user MIMO on this radio (selected
 platforms only)
 non-unicast Configure handling of non-unicast frames
 off-channel-scan Disable off-channel scanning on the radio
 placement Reset the placement of the radio to its default
 power Reset the transmit power of this radio to
 default
 preamble-short Disable the use of short-preamble on this radio
 probe-response Configure transmission parameters for Probe
 Response frames
 radio-resource-measurement Configure support for 802.11k Radio Resource
 Measurement
 radio-share-mode Configure the radio-share mode of operation for
 this radio
 rate-selection Monotonic rate selection
 rf-mode Reset the RF mode of operation for this radio to
 default (2.4GHz on radiol, 5GHz on radio2,
 sensor on radio3)
 rifs Configure Reduced Interframe Spacing (RIFS)
 parameters
 rts-threshold Reset the RTS threshold to its default (65536)
 shutdown Re-enable the selected interface
 smart-rf Reset smart-rf related configuration to default
```

nx9500-6C8809(config-profile-71xxTestProfile-if-radiol)#
non-unicast

```

[interface-config-radio-instance](#) on page 1072

Configures support for forwarding of non-unicast (multicast and broadcast) frames on this radio

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

Syntax

```
non-unicast [forwarding|queue|tx-rate]
```

```
non-unicast forwarding [follow-dtim|power-save-aware]
```

```
non-unicast queue [<1-200>|bss]
```

```
non-unicast queue [<1-200>|bss <1-16> <1-200>]
```

```
non-unicast tx-rate [bss <1-16>|dynamic-all|dynamic-basic|highest-basic|lowest-basic]
```

```
non-unicast tx-rate bss <1-16> [dynamic-all|dynamic-basic|highest-basic|lowest-basic]
```

Parameters

```
non-unicast forwarding [follow-dtim|power-save-aware]
```

|                               |                                                                                                                                                                                                                        |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>non-unicast forwarding</b> | Enables non-unicast frame forwarding on this radio. Once enabled, select one of the available options to specify whether these frames should always follow DTIM, or only follow DTIM when using power save aware mode. |
| <b>follow-dtim</b>            | Specifies frames always wait for the DTIM interval to time out. The DTIM interval is configured using the beacon command. This is the default setting.                                                                 |
| <b>power-save-aware</b>       | Enables immediate forwarding of frames only if all associated wireless clients are in the power save mode                                                                                                              |

```
non-unicast queue [<1-200>|bss <1-16> <1-200>]
```

|                                           |                                                                                                                                                                                                                                                             |
|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>non-unicast queue</b>                  | Enables non-unicast frame forwarding on this radio. Once enabled, specify the number of broadcast packets queued per BSS on this radio. This option is enabled by default. This command also enables you to override the default on a specific BSS.         |
| <b>&lt;1-200&gt;</b>                      | Specify a number from 1 - 200. This value applies to all BSSs. The default is 50 frames per BSS.                                                                                                                                                            |
| <b>bss &lt;1-16&gt;<br/>&lt;1-200&gt;</b> | Overrides the default on a specified BSS <ul style="list-style-type: none"> <li>• &lt;1-16&gt; - Select the BSS number from 1 - 16.</li> <li>• &lt;1-200&gt; - Specify the number of broadcast packets queued for the selected BSS from 1 - 200.</li> </ul> |

non-unicast tx-rate [bss <1-16>|dynamic-all|dynamic-basic|highest-basic| lowest-basic]

|                            |                                                                                                                                                                                                                                                                                                        |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>non-unicast tx-rate</b> | Enables non-unicast frame forwarding on this radio. Once enabled, use one of the available options to configure the rate at which these frames are transmitted.                                                                                                                                        |
| <b>bss &lt;1-16&gt;</b>    | Overrides the default on a specified BSS <ul style="list-style-type: none"> <li>• &lt;1-16&gt; - Select the BSS number from 1 - 16. The transmit rate selected is applied only to the BSS specified here. The tx-rate options are: dynamic-all, dynamic-basic, highest-basic, lowest-basic.</li> </ul> |
| <b>dynamic-all</b>         | Dynamically selects a rate from all supported rates based on current traffic conditions                                                                                                                                                                                                                |
| <b>dynamic-basic</b>       | Dynamically selects a rate from all supported basic rates based on current traffic conditions                                                                                                                                                                                                          |
| <b>highest-basic</b>       | Uses the highest configured basic rate. This is the default setting.                                                                                                                                                                                                                                   |
| <b>lowest-basic</b>        | Uses the lowest configured basic rate                                                                                                                                                                                                                                                                  |

#### off-channel-scan

[interface-config-radio-instance](#) on page 1072

Enables off channel scanning on this radio. This option is disabled by default.

Channel scanning uses the access point's resources and is time consuming. Therefore, enable this option only if the radio has the bandwidth to support channel scan without negatively impacting client support.

Supported in the following platforms:

- Access Points – AP6522, AP6562, AP7161, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

#### Syntax

```
off-channel-scan {channel-list|max-multicast|scan-interval|sniffer-redirect}
```

```
off-channel-scan {channel-list [2.4Ghz|5Ghz]} {<CHANNEL-LIST>}
```

```
off-channel-scan {max-multicast <0-100>|scan-interval <2-100>}
```

```
off-channel-scan {sniffer-redirect tzsp <IP>}
```

#### Parameters

```
off-channel-scan {channel-list [2.4Ghz|5Ghz]} {<CHANNEL-LIST>}
```

|                                     |                                                                                                                                                                                                                                                                                                                        |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>off-channel-scan</b>             | Enables off-channel scanning and configures related parameters. These parameters are optional, and the system configures default settings if no values are specified.                                                                                                                                                  |
| <b>channel-list [2.4GHz   5GHz]</b> | Optional. Selects the 2.4GHz or 5GHz access point radio band. Restricting off channel scans to specific channels frees bandwidth otherwise utilized for scanning across all channels. <ul style="list-style-type: none"> <li>• 2.4GHz – Selects the 2.4 GHz band</li> <li>• 5GHz – Selects the 5.0 GHz band</li> </ul> |
| <b>&lt;CHANNEL-LIST&gt;</b>         | Optional. Specifies a list of 20 MHz, 40 MHz, or 80 MHz channels for the selected band (the channels are separated by commas or hyphens)                                                                                                                                                                               |

```
off-channel-scan {max-multicast <0-100>|scan-interval <2-100>}
```

|                                              |                                                                                                                                                                                                       |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>off-channel-scan</b>                      | Enables off-channel scanning and configures related parameters. These parameters are optional, and the system configures default settings if no values are specified.                                 |
| <b>max-multicast</b><br><b>&lt;0-100&gt;</b> | Optional. Configures the maximum multicast/broadcast messages used to perform OCS <ul style="list-style-type: none"> <li>• &lt;0-100&gt; - Specify a value from 0 - 100. The default is 4.</li> </ul> |
| <b>scan-interval</b><br><b>&lt;2-100&gt;</b> | Optional. Configures the scan interval in dtims <ul style="list-style-type: none"> <li>• &lt;2-100&gt; - Specify a value from 2 - 100. The default is 20 dtims.</li> </ul>                            |

```
off-channel-scan {sniffer-redirect tzsp <IP>}

placement

[interface-config-radio-instance](#) on page 1072

Defines the radio's location (whether the radio is deployed indoors or outdoors). The radio's placement should depend on the country of operation selected and its regulatory domain requirements for radio emissions.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

Syntax

`placement [ indoor|outdoor ]`

Parameters

`placement [ indoor|outdoor ]`

|                  |                                                                                        |
|------------------|----------------------------------------------------------------------------------------|

power

`interface-config-radio-instance` on page 1072

Configures the radio's transmit power setting

The transmit power control (TPC) mechanism automatically reduces the used transmission output power when other networks are within range. Reduced power results in reduced interference issues and increased battery capacity.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

Syntax

```
power [<1-30>|smart]
```

Parameters

```
power [<1-30>|smart]
```

|                     |                                                                                                                                                                                                                                                                     |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>power</b>        | Configures a radio's transmit power                                                                                                                                                                                                                                 |
| <b>&lt;1-30&gt;</b> | Configures the transmit power from 1 - 30 dBm (actual power could be lower based on regulatory restrictions)<br>For APs with dual or three radios, each radio should be configured with a unique transmit power in respect to its intended client support function. |
| <b>smart</b>        | Enables Smart RF to determine the optimum transmit power needed. By default APs use Smart RF to determine transmit power.                                                                                                                                           |

Example

```

[preamble-short](#)

[interface-config-radio-instance](#) on page 1072

Enables short preamble on this radio. If using an 802.11bg radio, enable short preamble. Short preambles improve throughput. However, some devices (SpectralLink phones) require long preambles. This option is disabled by default.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7622, AP8163, AP8432, AP8533

Syntax

`preamble-short`

Parameters

None

Example

```
nx9500-6C8809(config-profile-71xxTestProfile-if-radiol)#preamble-short
```

```
nx9500-6C8809(config-profile-71xxTestProfile-if-radiol)#show context

probe-response

[interface-config-radio-instance](#) on page 1072

Configures transmission parameters for probe response frames

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

Syntax

```
probe-response [rate|retry|rssi-threshold]
```

```
probe-response retry
```

```
probe-response rate [follow-probe-request|highest-basic|lowest-basic]
```

```
probe-response rssi-threshold <-128--40>
```

Parameters

```
probe-response retry
```

|                                 |                                                                                                                                       |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <b>probe-response<br/>retry</b> | Enables retransmission of probe-response frames if no acknowledgement is received from the client. This option is enabled by default. |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|

```
probe-response rate [follow-probe-request|highest-basic|lowest-basic]
```

|                                  |                                                                                                                                                                                                   |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>probe-response<br/>rate</b>   | Configures the rates used for transmission of probe response frames. The tx-rate options available for transmitting probe response frames are: follow-probe-request, highest-basic, lowest-basic. |
| <b>follow-probe-<br/>request</b> | Transmits probe responses at the same rate as the received request (default setting)                                                                                                              |
| <b>highest-basic</b>             | Uses the highest configured basic rate                                                                                                                                                            |
| <b>lowest-basic</b>              | Uses the lowest configured basic rate                                                                                                                                                             |

```
probe-response rssi-threshold <-128--40>
```

|                                                               |                                                                                                                                                                   |
|---------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>probe-response<br/>rssi-threshold<br/>&lt;-128--40&gt;</b> | Ignores probe request from client if the received signal strength is less than the RSSI threshold specified here<br><-128--40> - Specify a value from -128 - -40. |
|---------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Example

```
nx9500-6C8809(config-profile-testAP7161-if-radio1)#probe-response rate highest-basic
```

```
nx9500-6C8809(config-profile-testAP7161-if-radio1)#probe-response retry
```

```
nx9500-6C8809(config-profile-testAP7161-if-radio1)#probe-response rssi-threshold -60
```

```
nx9500-6C8809(config-profile-testAP7161-if-radio1)#show context
```

```
interface radio1
```

```
 probe-response rate highest-basic
```

```
 probe-response rssi-threshold -60
```

```
nx9500-6C8809(config-profile-testAP7161-if-radio1)#
```

radio-resource-measurement

[interface-config-radio-instance](#) on page 1072

Enables 802.11k radio resource measurement. When enabled, the radio station sends channel and neighbor reports.

The IEEE 802.11 Task Group k defined a set of specifications regarding radio resource measurements. These specifications specify the radio resources to be measured and the mechanism used to communicate measurement requests and results.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

Syntax

```
radio-resource-measurement [attenuation-threshold <1-199>|max-entries <1-12>]
```

Parameters

```
radio-resource-measurement [attenuation-threshold <1-199>|max-entries <1-12>]
```

|                                            |                                                                                                                                                                                                                                            |
|--------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>radio-resource-measurement</b>          | Enables 802.11k radio resource measurement on the radio                                                                                                                                                                                    |
| <b>attenuation-threshold &lt;1-199&gt;</b> | Configures the neighbor attenuation threshold, considered when generating channel and neighbor reports <ul style="list-style-type: none"><li>• &lt;1-199&gt; - Specify the attenuation threshold from 1 -199. The default is 90.</li></ul> |
| <b>max-entries &lt;1-12&gt;</b>            | Configures the maximum number of entries to include in channel and neighbor reports <ul style="list-style-type: none"><li>• &lt;1-12&gt; - Specify a value from 1 - 12. The default is 6.</li></ul>                                        |

Example

```
rfs4000-229D58(config-device-00-23-68-22-9D-58-if-radiol)#radio-resource-measurement attenuation-threshold 20
```

```

radio-share-mode

[interface-config-radio-instance](#) on page 1072

Configures the radio's mode of operation as radio share. A radio operating in the radio share mode services clients and also performs sensor functions (defined by the radio's AirDefense Services Platform (ADSP) licenses and profiles).

**Note**

The sensor capabilities of the radio are restricted to the channel and WLANs defined on the radio.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7622, AP8163, AP8432, AP8533

Syntax

`radio-share-mode [inline|off|promiscuous]`

Parameters

`radio-share-mode [inline|off|promiscuous]`

|                         |                                                                                                                                                                                                                                                                                                     |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>radio-share-mode</b> | Enables sharing of packets, switched by this radio, with the WIPS sensor module. There are two radio-share modes, these are: inline and promiscuous                                                                                                                                                 |
| <b>inline</b>           | Enables sharing of all WLAN packets (matching the BSSID of the radio) serviced by the radio with the WIPS sensor module.                                                                                                                                                                            |
| <b>off</b>              | Disables radio share (no packets shared with the WIPS sensor module)                                                                                                                                                                                                                                |
| <b>promiscuous</b>      | Enables the promiscuous radio share mode. In this mode the radio is configured to receive all packets on the channel irrespective of whether the destination address is the radio or not, and shares these packets with the WIPS sensor module for analysis (i.e. without filtering based on BSSI). |

Example

```
nx9500-6C8809(config-profile-71xxTestProfile-if-radiol)#radio-share-mode promiscuous
```

```
nx9500-6C8809(config-profile-71xxTestProfile-if-radiol)#show context

| <b>rate-selection</b> | Sets the rate selection mode to standard or opportunistic                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>standard</b>       | Configures the monotonic rate selection mode. This is the default setting.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>opportunistic</b>  | Configures the opportunistic radio link adaptation (ORLA) rate selection mode. The ORLA algorithm is designed to select data rates that provide best throughput. Instead of using local conditions to decide whether a data rate is acceptable or not, ORLA pro-actively probes other rates to determine if greater throughput is available. If these other rates do provide improved throughput, ORLA intelligently adjusts its selection tables to favour higher performance. ORLA provides improvements both on the client side of a mesh network as well as in the backhaul capabilities.<br><br><b>Note:</b> The ORLA rate selection mode is supported only on the AP7161 and AP8163 model access points. |

Example

```
nx9500-6C8809(config-profile-testAP7161-if-radiol)#rate-selection opportunistic
```

```
nx9500-6C8809(config-profile-testAP7161-if-radiol)#show context
interface radiol
 rate-selection opportunistic
nx9500-6C8809(config-profile-testAP7161-if-radiol)#
```

rf-mode

[interface-config-radio-instance](#) on page 1072

Configures the radio's RF mode of operation

This command sets the mode to either 2.4 GHz WLAN or 5.0 GHz WLAN support depending on the radio's intended client support. If you are currently licensed to use 4.9 GHz, configure the 4.9 GHz-WLAN option.

Set the mode to sensor if using the radio for rogue device detection. The radio cannot support rogue detection when one of the other radios is functioning as a WIPS sensor. To set a radio as a detector, disable sensor support on the other access point radios.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

Syntax

```
rf-mode [2.4GHz-wlan | 4.9GHz-wlan | 5GHz-wlan | bridge | scan-ahead | sensor]
```

Parameters

```
rf-mode [2.4GHz-wlan | 4.9GHz-wlan | 5GHz-wlan | bridge | scan-ahead | sensor]
```

| <b>2.4GHz-wlan</b> | Provides WLAN service in the 2.4 GHz bandwidth                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>4.9GHz-wlan</b> | Provides WLAN service in the 4.9 GHz bandwidth                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>5GHz-wlan</b>   | Provides WLAN service in the 5.0 GHz bandwidth                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>bridge</b>      | <p>Enables this radio to operate as client bridge that can authenticate and associate to a defined infrastructure Wireless LAN (WLAN) access point</p> <p><b>Note:</b> This option is applicable only on the AP6522, AP6562, AP7522, AP7532, and AP7562 model access points. Enable this option only if the access point is to provide client-bridge support. Once enabled, configure the client-bridge parameters. For more information, see <a href="#">bridge</a> on page 1088.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>scan-ahead</b>  | <p>Enables this radio to operate as a scan-ahead radio</p> <p>A radio functioning in the scan-ahead mode is used for forward scanning only. The radio does not support WLAN or mesh services.</p> <p>The scan ahead feature is used in Dynamic Frequency Selection (DFS) aware countries for infrastructure devices, static, and vehicular mounted modems (VMMs). It enables a secondary radio to scan ahead for an active channel for backhaul transmission, in the event of a radar trigger on the primary radio. The device then switches radios allowing transmission to continue. This is required in environments where handoff is required and DFS triggers are common.</p> <p>With a secondary radio dedicated for forward scanning, the primary radio, in case of radar hit, hands over the channel availability check (CAC) function to the secondary radio. This avoids a break in data communication, which would have resulted if the primary radio was to do CAC itself.</p> <p>The secondary radio periodically does a scan of the configured channel list, searching for the other available meshpoint roots. When configured on the root meshpoint, the scan-ahead feature also scans for cleaner channels.</p> |
| <b>sensor</b>      | Operates as a sensor radio. Configures this radio to function as a scanner, providing scanning services on both 2.4 GHz and 5.0 GHz bands. The radio does not provide WLAN services.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

rifs

[interface-config-radio-instance](#) on page 1072

Configures Reduced Interframe Spacing (RIFS) parameters on this radio

This value determines whether interframe spacing is applied to access point transmitted or received packets, both, or none. Inter-frame spacing is the interval between two consecutive Ethernet frames that enable a brief recovery between packets and allow target devices to prepare for the reception of the next packet.

Supported in the following platforms:

- Access Points – AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

Syntax

```
rifs [none|rx-only|tx-only|tx-rx]
```

Parameters

```
rifs [none|rx-only|tx-only|tx-rx]
```

|                |                                                                                                                 |
|----------------|-----------------------------------------------------------------------------------------------------------------|
| <b>rifs</b>    | Configures RIFS parameters                                                                                      |
| <b>none</b>    | Disables support for RIFS. Consider setting the value to None for high-priority traffic to reduce packet delay. |
| <b>rx-only</b> | Supports RIFS possession only                                                                                   |
| <b>tx-only</b> | Supports RIFS transmission only                                                                                 |
| <b>tx-rx</b>   | Supports both RIFS transmission and possession (default setting)                                                |

Example

```
nx9500-6C8809(config-profile-71xxTestProfile-if-radiol)#rifs tx-only
```

```
nx9500-6C8809(config-profile-71xxTestProfile-if-radiol)#show context

rts-threshold

[interface-config-radio-instance](#) on page 1072

Configures the Request to Send (RTS) threshold value on this radio

RTS is a transmitting station's signal that requests a Clear To Send (CTS) response from a receiving client. This RTS/CTS procedure clears the air where clients are contending for transmission time. Benefits include fewer data collisions and better communication with nodes that are hard to find (or hidden) because of other active nodes in the transmission path.

The RTS threshold controls RTS/CTS by initiating an RTS/CTS exchange for data frames larger than the threshold, and sends (without RTS/CTS) any data frames smaller than the threshold.

Consider the trade-offs when setting an appropriate RTS threshold for the WLAN's access point radios. A lower RTS threshold causes more frequent RTS/CTS exchanges. This consumes more bandwidth because of additional latency (RTS/CTS exchanges) before transmissions can commence. A disadvantage is the reduction in data-frame throughput. An advantage is quicker system recovery from electromagnetic interference and data collisions. Environments with more wireless traffic and contention for transmission make the best use of a lower RTS threshold.

A higher RTS threshold minimizes RTS/CTS exchanges, consuming less bandwidth for data transmissions. A disadvantage is less help to nodes that encounter interference and collisions. An advantage is faster data-frame throughput. Environments with less wireless traffic and contention for transmission make the best use of a higher RTS threshold.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

Syntax

```
rts-threshold <0-65536>
```

Parameters

```
rts-threshold <0-65536>
```

|                                                |                                                                                   |
|------------------------------------------------|-----------------------------------------------------------------------------------|
| <b>rts-threshold</b><br><b>&lt;0-65536&gt;</b> | Specify the RTS threshold value from 0 - 65536 bytes. The default is 65536 bytes. |
|------------------------------------------------|-----------------------------------------------------------------------------------|

Example

```
nx9500-6C8809(config-profile-71xxTestProfile-if-radio1)#rts-threshold 100
```

```
nx9500-6C8809(config-profile-71xxTestProfile-if-radio1)#show context
```

```
interface radio1
 rf-mode sensor
 placement outdoor
 mesh client
 rts-threshold 100
 off-channel-scan channel-list 2.4GHz 1
 guard-interval long
 aggregation ampdu tx-only
```

--More--

```
nx9500-6C8809(config-profile-71xxTestProfile-if-radio1)#

service

[interface-config-radio-instance](#) on page 1072

Enables dynamic control function. This dynamic function controls performance of the radio receiver's low noise amplifiers (LNAs).

When enabled, the control function, in the presence of very strong received signals, improves the receiver's performance on radio 1. Strong signals are caused if the distance between the WiFi client and the AP is within two (2) meters. When disabled, the control function is a useful debug tool in case the uplink throughput is less than expected and the AP-to-client separation is greater than two (2) meters. Disabling the control function does not affect the receive sensitivity of the radio.

Supported in the following platforms:

- Access Points — AP6522, AP6562

Syntax

```
service radio-lna [agc|ms]
```

Parameters

```
service radio-lna [agc|ms]
```

|                                   |                                                                                                                                                                                 |

## sniffer-redirect

[interface-config-radio-instance](#) on page 1072

Captures and redirects packets to an IP address running a packet capture/analysis tool

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

Syntax

```
sniffer-redirect [omnipeek|tzsp] <IP> channel [1 | 10 | 100 | 100w -----]
{snap <1-65535> (append descriptor)}
```

Parameters

```
sniffer-redirect [omnipeek|tzsp] <IP> channel [1 | 10 | 100 | 100w -----] {snap <1-65535>
(append descriptor)}
```

|                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

stbc

[interface-config-radio-instance](#) on page 1072

Configures the radio's Space Time Block Coding (STBC) mode. STBC is a pre-transmission encoding scheme providing an improved SNR ratio (even at a single RF receiver). STBC transmits multiple data stream copies across multiple antennas. The receiver combines the copies into one to retrieve data from the signal. These transmitted data versions provide redundancy to increase the odds of receiving data streams with a good data decode (especially in noisy environments).

#### Note

STBC requires the radio has at least two antennas with the capability to transmit two streams. If the antenna mode is configured to 1x1 (or falls back to 1x1 for some reason), STBC support is automatically disabled.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

Syntax

```
stbc [auto|none|tx-only]
```

Parameters

```
stbc [auto|none|tx-only]
```

|                |                                                                                                                       |
|----------------|-----------------------------------------------------------------------------------------------------------------------|
| <b>stbc</b>    | Configures the radio's STBC mode                                                                                      |
| <b>auto</b>    | Autoselects STBC settings based on the platform type and other radio interface settings. This is the default setting. |
| <b>none</b>    | Disables STBC support                                                                                                 |
| <b>tx-only</b> | Configures the AP radio to format and broadcast the special stream (enables STBC support for transmit only)           |

Example

```
nx9500-6C8809(config-profile-81xxTestProfile-if-radio1)#stbc tx-only

rfs6000-37FABE(config-profile-81xxTestProfile-if-radio1)#show context

transmit-beamforming

[interface-config-radio-instance](#) on page 1072

Enables transmit beamforming on this radio interface. This option is disabled by default.

When enabled, this option steers signals to peers in a specific direction to enhance signal strength and improve throughput amongst meshed devices (not clients). Each access point radio supports up to 16 beamforming capable mesh peers. When enabled, a beamformer steers its wireless signals to its peers. A beamformee device assists the beamformer with channel estimation by providing a feedback matrix. The feedback matrix is a set of values sent by the beamformee to assist the beamformer in computing a steering matrix. A steering matrix is an additional set of values used to steer wireless signals at the beamformer so constructive signals arrive at the beamformee for better SNR and throughput. Any

beamforming capable mesh peer connecting to a radio whose capacity is exhausted cannot enable beamforming itself.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP8122, AP8132, AP8163, AP8432, AP8533

Syntax

**transmit-beamforming**

Parameters

None

Example

```
nx9500-6c8809(config-profile-testAP8163-if-radio1)#transmit-beamforming
```

Related Commands

use

[interface-config-radio-instance](#) on page 1072

Applies an association ACL policy and a radio QoS policy on this radio interface

An association ACL is a policy-based Access Control List (ACL) that either prevents or allows wireless clients from connecting to a controller managed access point radio. An ACL is a sequential collection of permit and deny conditions that apply to controller packets. When a packet is received on an interface, the controller compares the fields in the packet against any applied ACLs to verify the packet has the required permissions to be forwarded, based on the criteria specified in the access lists. If a packet does not meet any of the criteria specified in the ACL, the packet is dropped.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

Syntax

```
use [association-acl-policy|radio-qos-policy]
```

```
use [association-acl-policy <ASSOC-ACL-POLICY-NAME>|radio-qos-policy <RADIO-QOS-POLICY-NAME>]
```

Parameters

```
use [association-acl-policy <ASSOC-ACL-POLICY-NAME>|radio-qos-policy <RADIO-QOS-POLICY-NAME>]
```

|                               |                                                                                                                                                                                                                                        |

## wips

[interface-config-radio-instance](#) on page 1072

Enables access point to change its channel of operation in order to terminate rogue devices. The radio should be configured to provide WLAN service.

This option is enabled by default.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

### Note

AP7522 and AP7532 access points use Smart RF to perform off-channel scans. Therefore, ensure that a Smart RF policy is configured and applied to AP7522 and AP7532 access points RF Domains to enable them perform rogue detection and termination.

## Syntax

```
wips airtime-termination allow-channel-change
```

## Parameters

```
wips airtime-termination allow-channel-change
```

|                                                      |                                                                                                                              |
|------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| <b>wips airtime-termination allow-channel-change</b> | Enables access point to change its channel of operation (to that of the rogue device) in order to terminate the rogue device |
|------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------|

## Example

```
nx9500-6C8809(config-profile-testAP8163-if-radiol)#wips air-termination allow-channel-change
```

## Related Commands

no on page 1114

Disables access point to change its channel of operation in order to terminate rogue devices

wireless-client

[interface-config-radio-instance](#) on page 1072

Configures wireless client parameters on this radio

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

Syntax

```
wireless-client tx-power [<0-20>|mode]
```

```
wireless-client <0-20>
```

```
wireless-client tx-power mode [802.11d {wing-ie}/wing-ie {802.11d}]
```

Parameters

```
wireless-client tx-power <0-20>
```

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

wlan

[interface-config-radio-instance](#) on page 1072

Enables a WLAN on this radio

Use this command to configure WLAN/BSS mappings for an existing access point deployment. Administrators can assign each WLAN its own BSSID. If using a single-radio access point, there are 8 BSSIDs available. If using a dual-radio access point there are 8 BSSIDs for the 802.11b/g/n radio and 8 BSSIDs for the 802.11a/n radio.

Supported in the following platforms:

- Access Points – AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

#### Syntax

```
wlan <WLAN-NAME> {bss/primary}
```

```
wlan <WLAN-NAME> {bss <1-16>} {primary}
```

#### Parameters

```
wlan <WLAN-NAME> {bss <1-16>} {primary}
```

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## interface-config-wwan-instance

[interface](#) on page 1013

A Wireless Wide Area Network (WWAN) card is a specialized network interface card that allows a device to connect, transmit and receive data over a Cellular Wide Area Network. The RFS4000 and RFS6000 each have a PCI Express card slot that supports 3G WWAN cards. The WWAN card uses point to point protocol (PPP) to connect to the Internet Service Provider (ISP) and gain access to the Internet. PPP is the protocol used for establishing Internet links over dial-up modems, DSL connections, and many other types of point-to-point communications. PPP packages your system's TCP/IP packets and forwards them to the serial device where they can be put on the network. PPP is a full-duplex protocol that can be used on various physical media, including twisted pair or fiber optic lines or satellite transmission. It uses a variation of High Speed Data Link Control (HDLC) for packet encapsulation.

To switch to the WWAN Interface configuration mode, use the following command:

```
<DEVICE>(config)#profile <DEVICE-TYPE> <DEVICE-PROFILE-NAME>
```

```
<DEVICE>(config-profile-<DEVICE-PROFILE-NAME>)#interface wwan1
```

```
<DEVICE>(config-profile-<DEVICE-PROFILE-NAME>)#?
```

Interface configuration commands:

|             |                                                              |
|-------------|--------------------------------------------------------------|
| apn         | Enter the access point name provided by the service provider |

apn

[interface-config-wwan-instance](#) on page 1139

Configures the cellular data provider's name. This setting is needed in areas with multiple cellular data providers using the same protocols, such as Europe and Asia.

Supported in the following platforms:

- Access Point — AP7161, AP8163
- Wireless Controllers — RFS4000

Syntax

**apn** <WORD>

Parameters

apn <WORD>

|                   |                                                         |
|-------------------|---------------------------------------------------------|
| <b>apn</b> <WORD> | Specify the name of the cellular data service provider. |
|-------------------|---------------------------------------------------------|

Example

```
nx9500-6C8809(config-profile-testRFS4000-if-wwan1)#apn AT&T

nx9500-6C8809(config-profile-testRFS4000-if-wwan1)#show context
 interface wwan1
 apn AT&T
nx9500-6C8809(config-profile-testRFS4000-if-wwan1)#
```

Related Commands

|                                 |                                           |
|---------------------------------|-------------------------------------------|
| <a href="#">no</a> on page 1143 | Removes the configured access point name. |
|---------------------------------|-------------------------------------------|

auth-type

[interface-config-wwan-instance](#) on page 1139

Configures the authentication type used by the cellular data provider

Supported in the following platforms:

- Access Point — AP7161, AP8163
- Wireless Controllers — RFS4000

#### Syntax

```
auth-type [chap | mschap | mschap-v2 | pap]
```

#### Parameters

```
auth-type [chap | mschap | mschap-v2 | pap]
```

|                  |                                                                                                                  |
|------------------|------------------------------------------------------------------------------------------------------------------|
| <b>auth-type</b> | Configures the authentication protocol used on this interface. The options are: PAP, CHAP, MSCHAP, and MSCHAP-v2 |
| <b>chap</b>      | Configures Challenge-Handshake Authentication Protocol (CHAP). This is the default value.                        |
| <b>mschap</b>    | Configures Microsoft Challenge-Handshake Authentication Protocol (MSCHAP)                                        |
| <b>mschapv2</b>  | Configures Microsoft Challenge-Handshake Authentication Protocol (MSCHAP) version 2                              |
| <b>pap</b>       | Configures Password Authentication Protocol (PAP)                                                                |

#### Example

```
nx9500-6C8809(config-profile-testRFS4000-if-wwan1)#auth-type mschap-v2

nx9500-6C8809(config-profile-testRFS4000-if-wwan1)#show context
interface wwan1
 apn AT&T
 auth-type mschap-v2
nx9500-6C8809(config-profile-testRFS4000-if-wwan1)#
```

## crypto

[interface-config-wwan-instance](#) on page 1139

Associates a crypto map with this interface

Supported in the following platforms:

- Access Point — AP7161, AP8163
- Wireless Controllers — RFS4000

#### Syntax

```
crypto map <CRYPTO-MAP-NAME>
```

#### Parameters

```
crypto map <CRYPTO-MAP-NAME>
```

|                                                     |                                                                                                                                                                                            |
|-----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>crypto map</b><br><b>&lt;CRYPTO-MAP-NAME&gt;</b> | Associates a crypto map with this interface <ul style="list-style-type: none"> <li>• &lt;CRYPTO-MAP-NAME&gt; - Specify the crypto map name (should be existing and configured).</li> </ul> |
|-----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

#### Example

```
nx9500-6C8809(config-profile-testRFS4000-if-wwan1)#crypto map test

nx9500-6C8809(config-profile-testRFS4000-if-wwan1)#show context
```

```

interface wwan1
 apn AT&T
 auth-type mschap-v2
 crypto map test
nx9500-6C8809(config-profile-testRFS4000-if-wwan1)#

```

#### Related Commands

ip

[interface-config-wwan-instance](#) on page 1139

Configures IP related settings on this interface

Supported in the following platforms:

- Access Point – AP7161, AP8163
- Wireless Controllers – RFS4000

Syntax

```
ip [default-gateway|nat]
```

```
ip default-gateway priority <1-8000>
```

```
ip nat [inside|outside]
```

Parameters

```
ip default-gateway priority <1-8000>
```

|                                                |                                                                                                                                                                                                   |
|------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ip</b>                                      | Configures IP related settings on this interface                                                                                                                                                  |
| <b>default-gateway priority &lt;1-8000&gt;</b> | Configures the default-gateway's (learned by the wireless WAN) priority. <ul style="list-style-type: none"> <li>• &lt;1-8000&gt; – Specify a value from 1 - 8000. The default is 3000.</li> </ul> |

```
ip nat [inside|outside]
```

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ip</b>                   | Configures IP related settings on this interface                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>nat [inside outside]</b> | Configures the NAT settings. This option is disabled by default. <ul style="list-style-type: none"> <li>• inside – Marks this WWAN interface as NAT inside. The inside network is transmitting data over the network to its intended destination. On the way out, the source IP address is changed in the header and replaced by the (public) IP address.</li> <li>• outside – Marks this WWAN interface as NAT outside. Packets passing through the NAT on the way back to the controller or service platform managed LAN are matched against the records kept by the NAT engine. There, the destination IP address is changed back to the specific internal private class IP address in order to reach the LAN over the network.</li> </ul> |

Example

```
nx9500-6C8809(config-profile-testRFS4000-if-wwan1)#ip default-gateway priority 1
```

```
nx9500-6C8809(config-profile-testRFS4000-if-wwan1)#ip nat inside
```

```
nx9500-6C8809(config-profile-testRFS4000-if-wwan1)#show context
```

```

interface wwan1
 apn AT&T
 auth-type mschap-v2
 crypto map test
 ip nat inside
 ip default-gateway priority 1
nx9500-6C8809(config-profile-testRFS4000-if-wwan1)#

```

|------------------------------|-----------------------------------------------|
| <code>no</code> on page 1143 | Removes IP related settings on this interface |
|------------------------------|-----------------------------------------------|

no

[interface-config-wwan-instance](#) on page 1139

Removes or reverts the WWAN interface settings

Supported in the following platforms:

- Access Point — AP7161, AP8163
- Wireless Controllers — RFS4000

#### Syntax

```
no [all | apn | auth-type | crypto | description | ip | password | shutdown | use |
username]
```

```
no [all | apn | auth-type | description | password | shutdown | username]
```

```
no crypto map
```

```
no ip [default-gateway priority | nat]
```

```
no use ip-access-list in
```

#### Parameters

```
no <PARAMETERS>
```

|                                        |                                                                                  |
|----------------------------------------|----------------------------------------------------------------------------------|
| <b>no</b><br><b>&lt;PARAMETERS&gt;</b> | Removes or reverts this WWAN interface's settings based on the parameters passed |
|----------------------------------------|----------------------------------------------------------------------------------|

#### Usage Guidelines

The no command negates any command associated with it. Wherever required, use the same parameters associated with the command getting negated.

#### Example

The following example displays the WWAN interface settings before the 'no' commands are executed:

```

nx9500-6C8809(config-profile-testRFS4000-if-wwan1)#show context
interface wwan1
 apn AT&T
 auth-type mschap-v2
 crypto map test
 ip nat inside
 ip default-gateway priority 1
nx9500-6C8809(config-profile-testRFS4000-if-wwan1)#

```

```
nx9500-6C8809(config-profile-testRFS4000-if-wwan1)#no apn
nx9500-6C8809(config-profile-testRFS4000-if-wwan1)#no auth-type
```

The following example displays the WWAN interface settings after the 'no' commands are executed:

```
nx9500-6C8809(config-profile-testRFS4000-if-wwan1)#show context
interface wwan1
 crypto map test
 ip nat inside
 ip default-gateway priority 1
nx9500-6C8809(config-profile-testRFS4000-if-wwan1)#
password
```

[interface-config-wwan-instance](#) on page 1139

Configures a password for this WWAN interface. The configured value is used for authentication support by the cellular data carrier.

Supported in the following platforms:

- Access Point — AP7161, AP8163
- Wireless Controllers — RFS4000

Syntax

```
password [2 <WORD> | <WORD>]
```

Parameters

```
password [2 <WORD> | <WORD>]
```

|                       |                                                                                                       |
|-----------------------|-------------------------------------------------------------------------------------------------------|
| <b>password</b>       | Configures a password for this WWAN interface                                                         |
| <b>2 &lt;WORD&gt;</b> | Configures an encrypted password. Use this option when copy pasting the password from another device. |
| <b>&lt;WORD&gt;</b>   | Enter the password string (should not exceed 32 characters in length).                                |

Example

```
nx9500-6C8809(config-profile-testRFS4000-if-wwan1)#password 2 TechPubsTesting@123

nx9500-6C8809(config-profile-testRFS4000-if-wwan1)#show context
interface wwan1
 password TechPubsTesting@123
 crypto map test
 ip nat inside
 ip default-gateway priority 1
nx9500-6C8809(config-profile-testRFS4000-if-wwan1)#
```

Related Commands

|                        |                                 |
|------------------------|---------------------------------|
| <b>no</b> on page 1143 | Removes the configured password |

shutdown

[interface-config-wwan-instance](#) on page 1139

Shuts down this WWAN interface. Use the no > shutdown command to re-start the WWAN interface.

Supported in the following platforms:

- Access Point — AP7161, AP8163
- Wireless Controllers — RFS4000

## Syntax

**shutdown**

## Parameters

None

## Example

```
nx9500-6C8809(config-profile-testRFS4000-if-wwan1)#shutdown

nx9500-6C8809(config-profile-testRFS4000-if-wwan1)#show context
 interface wwan1
 shutdown
nx9500-6C8809(config-profile-testRFS4000-if-wwan1)#
```

## Related Commands

|---------------------------------|------------------------------|
| <a href="#">no</a> on page 1143 | Re-starts the WWAN interface |
|---------------------------------|------------------------------|

use

[interface-config-wwan-instance](#) on page 1139

Associates an IP ACL with this interface. The ACL should be existing and configured.

The ACL applies an IP based firewall to all incoming packets. The ACL identifies a single IP or a range of IPs that are to be allowed or denied access on this interface.

Supported in the following platforms:

- Access Point — AP7161, AP8163
- Wireless Controllers — RFS4000

## Syntax

**use ip-access-list in <ACCESS-LIST-NAME>**

## Parameters

**use ip-access-list in <ACCESS-LIST-NAME>**

|                                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>use ip-access-list in &lt;ACCESS-LIST-NAME&gt;</b> | Associates an inbound IPv4 ACL with this interface. This setting applies to IPv4 inbound traffic only and not IPv6 traffic. IPv4 operates as a best effort delivery method, as it does not guarantee delivery, and does not ensure proper sequencing or duplicate delivery (unlike TCP). IPv4 hosts can use link local addressing to provide local connectivity. <ul style="list-style-type: none"><li>• &lt;ACCESS-LIST-NAME&gt; - Specify the IP ACL name.</li></ul> |
|-------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Example

```
nx9500-6C8809(config-profile-testRFS4000-if-wwan1)#use ip-access-list in test

nx9500-6C8809(config-profile-testRFS4000-if-wwan1)#show context
 interface wwan1
 password TechPubsTesting@123
 crypto map test
 ip nat inside
 use ip-access-list in test
 ip default-gateway priority 1
nx9500-6C8809(config-profile-testRFS4000-if-wwan1)#
```

## Related Commands

---

`no` on page 1143      Removes the IP ACL associated with this interface

## interface-config-bluetooth-instance

[interface](#) on page 1013

AP8432 and AP8533 model access points utilize a built-in Bluetooth chip for specific Bluetooth functional behaviors in a WiNG managed network. AP8432 and AP8533 models support both Bluetooth classic and Bluetooth low energy (BLE) technology. These platforms use their Bluetooth classic enabled radio to sense other Bluetooth enabled devices and report device data (MAC address, RSSI and device calls) to an ADSP server for intrusion detection. If the device presence varies in an unexpected manner, ADSP can raise an alarm.

### Note

AP8132 model access points support an external USB Bluetooth radio providing ADSP Bluetooth classic sensing functionality only, not the BLE beaconing functionality available for AP8432 and AP8533 model access points described in this section.

AP8432 and AP8533 model access points support Bluetooth beaconing to emit either iBeacon or Eddystone-URL beacons. The access point's Bluetooth radio sends non-connectable, undirected low-energy (LE) advertisement packets periodically. These advertisement packets are short and sent on Bluetooth advertising channels that conform to already-established iBeacon and Eddystone-URL standards. However, portions of the advertising packet are customizable via the Bluetooth radio interface configuration context.

To switch to this mode, use the following commands:

```
<DEVICE>(config)#profile <ap8432/ap8533> <PROFILE-NAME>

<DEVICE>(config-profile-default-ap8432)#interface bluetooth ?
 <1-1> Bluetooth interface index?
```

The following example uses the default-ap8432 profile instance to configure the Bluetooth radio interface:

```
nx9500-6C8809(config-profile-default-ap8432)#interface bluetooth 1
nx9500-6C8809(config-profile-default-ap8432-if-bluetooth1)# Bluetooth Radio Mode commands:
 beacon Configure low-energy beacon operation parameters
 description Configure a description for this bluetooth radio
 eddystone Configure eddystone beacon payload parameters
 ibeacon Configure iBeacon beacon payload parameters
 mode Set the bluetooth operation mode
 no Negate a command or set its defaults
 shutdown Shutdown the selected bluetooth radio interface

beacon

[interface-config-bluetooth-instance](#) on page 1146

Configures the Bluetooth radio's beacon's emitted transmission pattern for Bluetooth radios functioning in the low energy beacon (le-beacon) mode. This option is applicable only if the Bluetooth radio's operational mode is set to le-beacon.

Supported in the following platforms:

- Access Points - AP8432, AP8533

Syntax

```
beacon [pattern|period|txpower]
```

```
beacon pattern [eddytone-url1|eddytone-ulr2|ibeacon]
```

```
beacon period <100-10000>
```

```
beacon txpower <-15-6>
```

Parameters

```
beacon pattern [eddytone-url1|eddytone-ulr2|ibeacon]
```

|                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>beacon pattern</b><br><b>[eddytone-<br/>url1  <br/>eddytone-<br/>ulr2   ibeacon]</b> | <p>When the beacon mode is set to 'le-beacon', use this command to configure the Bluetooth radio's beacon's emitted transmission pattern. Select one of the following beacon patterns:</p> <ul style="list-style-type: none"><li>• eddytone-url1 - Transmits an Eddystone-URL beacon using URL 1. This is the default setting.</li><li>• eddytone-ulr2 - Transmits an Eddystone-URL beacon using URL 2</li></ul> <p>An Eddystone-URL frame broadcasts a URL using a compressed encoding scheme to better fit within a limited advertisement packet. Once decoded, the URL can be used by a client for Internet access. If an Eddystone-URL beacon broadcasts https:anysite, clients receiving the packet can access that URL. If setting the transmission pattern as 'eddytone-url1' or 'eddytone-ulr2', use the 'eddytone' keyword to configure Eddystone beacon payload parameters. For more information, see <a href="#">eddytone</a> on page 1150.</p> <ul style="list-style-type: none"><li>• ibeacon - Transmits an ibeacon beacon. iBeacon was created by Apple for use in iPhone OS (iOS) devices (beginning with iOS version 7.0). There are three data fields Apple has made available to iOS applications, a Universally Unique Identifier (UUID) for device identification, a Major value for device class and a Minor value for more refined information like product category. If setting the transmission pattern as 'ibeacon', use the 'ibeacon' keyword to configure ibeacon beacon payload parameters. For more information, see <a href="#">ibeacon</a> on page 1151.</li></ul> <p>For more information on configuring the Bluetooth radio's operational mode, see <a href="#">mode</a> on page 1152.</p> |

|--------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>beacon period</b><br><b>&lt;100-10000&gt;</b> | <p>Configures the Bluetooth radio's beacon transmission period, in milliseconds, from 100 - 10000. As the defined period increases, so does the CPU processing time and the number of packets incrementally transmitted (typically one per minute).</p> <ul style="list-style-type: none"><li>• &lt;100-10000&gt; - Specify a value from 100 - 10000 milliseconds. The default value is 1000 milliseconds.</li></ul> |
|--------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
beacon txpower <-15-6>
```

```
beacon txpower <-15-6>
```

Configures the Bluetooth radio's le-beacon transmit power. This determines how far a beacon can transmit data.

- <-15-6> - Specify a value from -15 - -6 dBm. The default value is -10 dBm.

#### Example

```
nx9500-6C8809(config-profile-default-ap8432-if-bluetooth1)#beacon pattern eddystone-url2
```

```
nx9500-6C8809(config-profile-default-ap8432-if-bluetooth1)#beacon period 900
```

```
nx9500-6C8809(config-profile-default-ap8432-if-bluetooth1)#show context
interface bluetooth1
 shutdown
 description AP8432-BLE-Radiol
 mode le-beacon
 beacon pattern eddystone-url2
 beacon period 900
```

```
nx9500-6C8809(config-profile-default-ap8432-if-bluetooth1)#
```

#### Related Commands

[no](#) on page 1153

Removes or reverts to default this Bluetooth radio's beacon-related configurations

#### description

[interface-config-bluetooth-instance](#) on page 1146

Configures a description for the Bluetooth radio interface, differentiating it from other Bluetooth supported radio's within the same RF Domain

Supported in the following platforms:

- Access Points - AP7602, AP7612, AP7622, AP7632, AP7662, AP8432, AP8533

#### Syntax

```
description <WORD>
```

#### Parameters

```
description <WORD>
```

**description**  
**<WORD>**

Configures a description for the AP8432/AP8533 access point's Bluetooth radio's description

- <WORD> - Provide a description that uniquely identifies this radio interface from other similar Bluetooth supported radios (should not exceed 64 characters) within an RF Domain.

#### Example

```
nx9500-6C8809(config-profile-default-ap8432-if-bluetooth1)#description AP8432-BLE-Radiol
```

```
nx9500-6C8809(config-profile-default-ap8432-if-bluetooth1)#show context
interface bluetooth1
 shutdown
 description AP8432-BLE-Radiol
```

```
nx9500-6C8809(config-profile-default-ap8432-if-bluetooth1)#
```

#### Related Commands

no on page 1153

Removes this Bluetooth radio interface's description

eddystone

[interface-config-bluetooth-instance](#) on page 1146

Configures Eddystone beacon payload parameters. Configure these parameters only if the Bluetooth radio interface's operational mode is set to 'le-beacon', and the beacon's emitted transmission pattern is set to either 'eddystone-url1' or 'eddystone-url2'.

Supported in the following platforms:

- Access Points - AP7602, AP7612, AP7622, AP7632, AP7662, AP8432, AP8533

Syntax

```
eddystone [calibration-rssi <-127-127>|url [1|2] <WORD>]
```

Parameters

```
eddystone [calibration-rssi|url [1|2] <WORD>]
```

```
eddystone
[calibration-
rss
<-127-127>|
url [1|2]
<WORD>]
```

If the Beacon transmission pattern has been set to either 'eddystone-url1' or 'eddystone-url2', configure the following Eddystone parameters:

- calibration-rssi - Configures the Eddystone beacon measured calibration signal strength, from -127 to 127 dBm, at 0 meters. Mobile devices can approximate their distance to beacons based on received signal strength. However, distance readings can fluctuate since they depend on several external factors. The closer you are to a beacon, the more accurate the reported distance. This setting is the projected calibration signal strength at 0 meters.
  - <-127-127> - Specify a value from -127 - 127 dBm. The default value is -19 dBm.
- url [1|2] <WORD> - Configures the Eddystone URL as URL1 OR URL2
  - 1 - Selects the Eddystone URL number 1
  - 2 - Selects the Eddystone URL number 2

The following keyword is common to the 'eddystone-url1' and 'eddystone-url2' keywords:

- <WORD> - Enter a 64 character maximum eddystone-URL1/eddystone-URL2. The URL must be 18 characters or less once auto-encoding is applied. URL encoding is used when placing text in a query string to avoid confusion with the URL itself. It is typically used when a browser sends data to a Web server.

Example

```
nx9500-6C8809(config-profile-default-ap8432-if-bluetooth1)#eddystone calibration-rssi -120
```

```
nx9500-6C8809(config-profile-default-ap8432-if-bluetooth1)#show context
interface bluetooth1
shutdown
description AP8432-BLE-Radiol
mode le-beacon
beacon pattern eddystone-url2
beacon period 900
eddystone calibration-rssi -120
```

```
nx9500-6C8809(config-profile-default-ap8432-if-bluetooth1)#
```

Related Commands

Removes or reverts to default this Bluetooth radio's Eddystone beacon payload configurations

## ibeacon

[interface-config-bluetooth-instance](#) on page 1146

Configures iBeacon beacon payload parameters. Configure these parameters only if the Bluetooth radio interface's operational mode is set to 'le-beacon', and the beacon's emitted transmission pattern is set to 'ibeacon'.

Supported in the following platforms:

- Access Points - AP7602, AP7612, AP7622, AP7632, AP7662, AP8432, AP8533

Syntax

```
ibeacon [calibration-rssi <-127-127>|major <0-65535>|minor <0-65535>|uuid <WORD>]
```

```
ibeacon [calibration-rssi <-127-127>|uuid <WORD>]
```

```
ibeacon [major|minor] <0-65535>
```

Parameters

```
ibeacon [calibration-rssi <-127-127>|major <0-65535>|minor <0-65535>|uuid <WORD>]
```

|                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ibeacon</b>                           | Configures following iBeacon beacon payload parameters: calibration-rssi, major, minor, and uuid                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>calibration-rssi &lt;-127-127&gt;</b> | Configures the iBeacon measured calibration signal strength, from -127 to 127 dBm, at 1 meter. Mobile devices can approximate their distance to beacons based on received signal strength. However, distance readings can fluctuate since they depend on several external factors. The closer you are to a beacon, the more accurate the reported distance. This setting is the projected calibration signal strength at 1 meter. <ul style="list-style-type: none"><li>• &lt;-127-127&gt; - Specify a value from -127 - 127 dBm. The default value is -60 dBm.</li></ul> |
| <b>major &lt;0-65535&gt;</b>             | Configures the iBeacon Major value from 0 - 65535. Major values identify and distinguish groups. For example, each beacon on a specific floor in a building could be assigned a unique major value. <ul style="list-style-type: none"><li>• &lt;0-65535&gt; - Specify a value from 0 - 65535. The default value is 1111.</li></ul>                                                                                                                                                                                                                                        |
| <b>minor &lt;0-65535&gt;</b>             | Configures the iBeacon Minor value from 0 - 65535. Minor values identify and distinguish individual beacons. Minor values help identify individual beacons within a group of beacons assigned a major value. The default setting is 2,222. <ul style="list-style-type: none"><li>• &lt;0-65535&gt; - Specify a value from 0 - 65535. The default value is 2222.</li></ul>                                                                                                                                                                                                 |
| <b>uuid &lt;WORD&gt;</b>                 | Configures a 32 hex character maximum UUID. The UUID classification contains 32 hexadecimal digits, split into 5 groups, separated by dashes. For example, f2468da65fa82e841134bc5b71e0893e. The UUID distinguishes iBeacons in the network from all other beacons in networks outside of your direct administration. <ul style="list-style-type: none"><li>• &lt;WORD&gt; - Specify the UUID (should not exceed 32 hexadecimal characters). The default value is 01F101F101F101F101F101F101F101F1.</li></ul>                                                             |

#### mode

[interface-config-bluetooth-instance](#) on page 1146

Configures the Bluetooth radio's mode of operation as bt-sensor, le-beacon, or le-sensor.

Supported in the following platforms:

- Access Points - AP7602, AP7612, AP7622, AP7632, AP7662, AP8432, AP8533

#### Syntax

```
mode [bt-sensor | le-beacon | le-sensor]
```

#### Parameters

```
mode [bt-sensor | le-beacon | le-sensor]
```

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>mode</b> | <p>Configures the Bluetooth radio's mode of operation. The options are:</p> <ul style="list-style-type: none"> <li>• <b>bt-sensor</b> - Select this option to enable the radio as a bt-sensor. Bt-sensors are Bluetooth classic sensors providing robust wireless connections for legacy devices. Typically these connections are not ideally suited for the newer BLE (Bluetooth low energy) technology supported devices. This is the default setting.</li> <li>• <b>le-beacon</b> - Select this option to provide Bluetooth support for newer BLE technology supported devices. le-beacons are newer Bluetooth low energy beacons ideal for applications requiring intermittent or periodic transfers of small amounts of data. le-beacons are not designed as replacements for classic beacon sensors. If selecting this option, use the <a href="#">beacon</a> on page 1147 keyword to configure the Beacon transmission period and Beacon transmission pattern.</li> <li>• <b>le-sensor</b> - Select this option to provide Bluetooth support for LE (low energy) asset tracking. When enabled, it uses the AP's Bluetooth radio to detect BLE 'asset tags' within the managed network. This information is reported to a back-end server (for example, the NSight server).</li> </ul> |

#### Example

```

nx9500-6C8809(config-profile-default-ap8432-if-bluetooth1)#mode le-beacon

nx9500-6C8809(config-profile-default-ap8432-if-bluetooth1)#show context
interface bluetooth1
 shutdown
 mode le-beacon

```

```
beacon pattern ibeacon
ibeacon calibration-rssi -70
ibeacon major 1110
ibeacon minor 2210
ibeacon uuid f2468da65fa82e841134bc5b71e0893e
nx9500-6C8809(config-profile-default-ap8432-if-bluetooth1)#
```

#### Related Commands

- [no](#) on page 1153 Reverts this Bluetooth radio's mode of operation to le-beacon

## shutdown

[interface-config-bluetooth-instance](#) on page 1146

Shutsdown the selected AP8432/AP8533 Bluetooth radio interface

Supported in the following platforms:

- Access Points - AP7602, AP7612, AP7622, AP7632, AP7662, AP8432, AP8533

#### Syntax

**shutdown**

#### Parameters

None

#### Example

```
nx9500-6C8809(config-profile-default-ap8432-if-bluetooth1)#shutdown

nx9500-6C8809(config-profile-default-ap8432-if-bluetooth1)#show context
interface bluetooth1
 shutdown
 mode le-beacon
 beacon pattern ibeacon
 ibeacon calibration-rssi -70
 ibeacon major 1110
 ibeacon minor 2210
 ibeacon uuid f2468da65fa82e841134bc5b71e0893e

```

#### Related Commands

- [no](#) on page 1153 Reverses shutdown

## no

[interface-config-bluetooth-instance](#) on page 1146

Removes or reverts to default this AP8432/AP8533 Bluetooth radio interface's settings

Supported in the following platforms:

- Access Points - AP7602, AP7612, AP7622, AP7632, AP7662, AP8432, AP8533

#### Syntax

**no** [beacon | description | eddystone | ibeacon | mode | shutdown]

**no** beacon [pattern | period]

**no** description

```

no eddystone [calibration-rssi|url [1|2]
no ibeacon [calibration-rssi|major|minor|uuid]
no mode
no shutdown

```

Parameters  
no <PARAMETERS>

|                                        |                                                                                                                                                                                                         |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>no</b><br><b>&lt;PARAMETERS&gt;</b> | Removes or reverts to default this Bluetooth radio interface's settings based on the parameters passed <ul style="list-style-type: none"> <li>• &lt;PARAMETERS&gt; - Specify the parameters.</li> </ul> |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Example

The following example shows the AP8432 default profile's Bluetooth radio interface settings:

```

nx9500-6C8809(config-profile-default-ap8432-if-bluetooth1)#show context
interface bluetooth1
 shutdown
 mode le-beacon
 beacon pattern ibeacon
 ibeacon calibration-rssi -70
 ibeacon major 1110
 ibeacon minor 2210
 ibeacon uuid f2468da65fa82e841134bc5b71e0893e
nx9500-6C8809(config-profile-default-ap8432-if-bluetooth1)#

```

```

nx9500-6C8809(config-profile-default-ap8432-if-bluetooth1)#no shutdown
nx9500-6C8809(config-profile-default-ap8432-if-bluetooth1)#no ibeacon minor
nx9500-6C8809(config-profile-default-ap8432-if-bluetooth1)#no ibeacon calibration-rssi

```

The following example shows the AP8432 default profile's Bluetooth radio interface settings after the 'no' commands are executed:

```

nx9500-6C8809(config-profile-default-ap8432-if-bluetooth1)#show context
interface bluetooth1
 no shutdown
 mode le-beacon
 beacon pattern ibeacon
 ibeacon major 1110
 ibeacon uuid f2468da65fa82e841134bc5b71e0893e
nx9500-6C8809(config-profile-default-ap8432-if-bluetooth1)#

```

*ip*

[Profile Config Commands](#) on page 862

The following table summarizes NAT pool configuration commands:

| Command                                               | Description                                                                                                                       |
|-------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">ip</a> on page 1155                       | Configures IP components, such as default gateway, DHCP, DNS server forwarding, name server, domain name, routing standards, etc. |
| <a href="#">nat-pool-config-instance</a> on page 1160 | Invokes NAT pool configuration parameters                                                                                         |

## ip

[ip](#) on page 1154

Configures IPv4 routing components, such as default gateway, DHCP, DNS server forwarding, name server, domain name, routing standards, etc.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600

Syntax

```
ip [default-gateway|dhcp|dns-server-forward|domain-lookup|domain-name|igmp|name-server|nat|route|routing]
```

```
ip default-gateway [<IP>|<HOST-ALIAS-NAME>|failover|priority [dhcp-client <1-1800>|static-route <1-1800>]]
```

```
ip [dns-server-forward|domain-lookup|domain-name <DOMAIN-NAME>|name-server <IP>| routing]
```

```
ip dhcp client [hostname|persistent-lease]
```

```
ip igmp snooping {fast-leave|forward-unknown-multicast|querier}
ip igmp snooping {fast-leave|forward-unknown-multicast}
ip igmp snooping {querier} {max-response-time <1-25>|query-interval <1-18000>|robustness-variable <1-7>|timer expiry <60-300>|version <1-3>}
```

### Note

The command 'ip igmp snooping' can be configured under bridge VLAN context also. For example: rfs7000-37FABE(config-device 00-15-70-37-FA-BE-bridge-vlan-1)#ip igmp snooping forward-unknown-multicast

```
ip nat [crypto|inside|outside|pool]
```

```
ip nat [crypto source pool|pool] <NAT-POOL-NAME>
```

```
ip nat [inside|outside] [destination|source]
```

```
ip nat [inside|outside] destination static <ACTUAL-IP> <1-65535> [tcp|udp] [(<NATTED-IP> {<1-65535>})]
```

```
ip nat [inside|outside] source [list|static]
```

```
ip nat [inside|outside] source static <ACTUAL-IP> <1-65535> [tcp|udp] [(<NATTED-IP> {<1-65535>})]
```

```
ip nat [inside|outside] source list <IP-ACCESS-LIST-NAME> interface
[<INTERFACE-NAME>|pppoe1|vlan <1-4094>|wwan1] [(address <IP>|interface
<L3-IF-NAME>|overload|pool <NAT-POOL-NAME>)]
```

```
ip route <IP/M> [<IP>|<HOST-ALIAS-NAME>]
```

Parameters

```
ip default-gateway [<IP>|<HOST-ALIAS-NAME>|failover|priority [dhcp-client <1-1800>|static-
route <1-1800>]]
```

## nat-pool-config-instance

**ip** on page 1154

Use the config-profile-<DEVICE-PROFILE-NAME> instance to configure Network Address Translation (NAT) pool settings.

The following example uses the config-profile-nx9500-6C8809 instance to configure NAT pool settings:

```
nx9500-6C8809(config-profile-default-rfs4000)#ip nat pool pool1
nx9500-6C8809(config-profile-default-rfs4000-nat-pool-pool1)#
```

```
nx9500-6C8809(config-profile-default-rfs4000-nat-pool-pool1)#?
```

Nat Policy Mode commands:

```
address Specify addresses for the nat pool
no Negate a command or set its defaults

clrscr Clears the display screen
commit Commit all changes made in this session
do Run commands from Exec mode
end End current mode and change to EXEC mode
exit End current mode and down to previous mode
help Description of the interactive help system
revert Revert changes
service Service Commands
```

```
show Show running system information
write Write running configuration to memory or terminal
```

```
nx9500-6C8809(config-profile-default-rfs4000-nat-pool-pool1)
```

The following table summarizes NAT pool configuration commands:

| Command                              | Description                           |
|--------------------------------------|---------------------------------------|
| <a href="#">address</a> on page 1161 | Configures NAT pool addresses         |
| <a href="#">no</a> on page 1162      | Negates a command or sets its default |

## address

[nat-pool-config-instance](#) on page 1160

Configures NAT pool of IP addresses

Define a range of IP addresses hidden from the public Internet. NAT modifies network address information in the defined IP range while in transit across a traffic routing device. NAT only provides IP address translation and does not provide a firewall. A branch deployment with NAT by itself will not block traffic from being potentially routed through a NAT device. Consequently, NAT should be deployed with a stateful firewall.

Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600

### Syntax

```
address [<IP> | range <START-IP> <END-IP>]
```

### Parameters

```
address [<IP> | range <START-IP> <END-IP>]
```

|                                              |                                                                                                                                                                                                                                        |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>address &lt;IP&gt;</b>                    | Adds a single IP address to the NAT pool                                                                                                                                                                                               |
| <b>range &lt;START-IP&gt; &lt;END-IP&gt;</b> | Adds a range of IP addresses to the NAT pool <ul style="list-style-type: none"><li>• &lt;START-IP&gt; - Specify the starting IP address of the range.</li><li>• &lt;END-IP&gt; - Specify the ending IP address of the range.</li></ul> |

### Example

```
nx9500-6C8809(config-profile-default-rfs4000-nat-pool-pool1)#address range 172.16.10.2 172.16.10.8
```

```
nx9500-6C8809(config-profile-default-rfs4000-nat-pool-pool1)#show context
ip nat pool pool1
address range 172.16.10.2 172.16.10.8
nx9500-6C8809(config-profile-default-rfs4000-nat-pool-pool1)#
```

|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Usage Guidelines

The no command negates any command associated with it. Wherever required, use the same parameters associated with the command getting negated.

Example

```
nx9500-6C8809(config-profile-default-rfs4000-nat-pool-pool1)#show context
 ip nat pool pool1
 address range 172.16.10.2 172.16.10.8
nx9500-6C8809(config-profile-default-rfs4000-nat-pool-pool1)#

nx9500-6C8809(config-profile-default-rfs4000-nat-pool-pool1)#no address range 1
72.16.10.2 172.16.10.8

nx9500-6C8809(config-profile-default-rfs4000-nat-pool-pool1)#show context
 ip nat pool pool1
nx9500-6C8809(config-profile-default-rfs4000-nat-pool-pool1)#
```

*ipv6*

[Profile Config Commands](#) on page 862

Configures IPv6 routing components, such as default gateway, DNS server forwarding, name server, routing standards, etc.

These IPv6 settings are applied to all devices using this profile.

You can also configure IPv6 settings on a device, using the device's configuration mode.

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600

#### Note

The IPv6 settings configured at the profile/device level are global configuration settings and not interface-specific.

### Syntax

```
ipv6 [default-gateway|dns-server-forward|hop-limit|mld|name-server|nd-reachable-time|neighbor|ns-interval|ra-convert|route|ula-reject-route|unicast-routing]
```

```
ipv6 [default-gateway <IPv6> {vlan <VLAN-ID>}/dns-server-forward|hop-limit <1-255>|name-server <IPv6>|nd-reachable-time <5000-3600000>|ns-interval <1000-3600000>|ula-reject-route|unicast-routing]
```

```
ipv6 ra-convert {throttle interval <3-1800> max-RAs <1-256>}
```

```
ipv6 mld snooping {forward-unknown-multicast|querier}
ipv6 mld snooping {forward-unknown-multicast}
ipv6 mld snooping {querier} {max-response-time <1-25000>|query-interval <1-18000>|robustness-variable <1-7>|timer expiry <60-300>|version <1-2>}
```

```
ipv6 neighbor [<IPv6>|timeout]
```

```
ipv6 neighbor <IPv6> <MAC> [<INTF-NAME>|pppoe1|vlan <1-4094>|wwan1]
{dhcp-server| router}
ipv6 neighbor timeout <15-86400>
```

```
ipv6 route <DEST-IPv6-PREFIX/PREFIX-LENGTH> <IPv6-GATEWAY-ADDRESS> {vlan <VLAN-ID>}
```

### Parameters

```
ipv6 [default-gateway <IPv6> {vlan <VLAN-ID>}|dns-server-forward|hop-limit <1-255>|name-server <IPv6>|nd-reachable-time <5000-3600000>|ns-interval <1000-3600000>|ula-reject-route|unicast-routing]
```

|                                                            |                                                                                                                                                                                                                                  |
|------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ipv6</b>                                                | Configures IPv6 routing components                                                                                                                                                                                               |
| <b>default-gateway &lt;IPv6&gt; {vlan &lt;VLAN-ID&gt;}</b> | Configures IPv6 default gateway's address in the ::/0 format <ul style="list-style-type: none"><li>• vlan &lt;VLAN-ID&gt; - Optional. Specify the VLAN interface's ID through which the default gateway is accessible.</li></ul> |
| <b>dns-server-forward</b>                                  | Enables DNS server forwarding. This command enables the forwarding of DNS queries to DNS servers outside of the network. This feature is disabled by default.                                                                    |

|                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>hop-limit</b><br><b>&lt;1-255&gt;</b>                | Configures the IPv6 hop count limit <ul style="list-style-type: none"> <li>• &lt;1-255&gt; – Specify a value between 1 - 255. The default is 64.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>name-server</b><br><b>&lt;IPv6&gt;</b>               | Configures the IPv6 name server's address <ul style="list-style-type: none"> <li>• &lt;IPv6&gt; – Specify the address of the IPv6 name server.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>nd-reachable-time</b><br><b>&lt;5000-3600000&gt;</b> | Configures the time, in milliseconds, that a neighbor is assumed to be reachable after having received neighbor discovery (ND) confirmation for their reachability <ul style="list-style-type: none"> <li>• &lt;5000-3600000&gt; – Specify a value from 5000 - 3600000 milliseconds. The default is 30,000 milliseconds.</li> </ul>                                                                                                                                                                                                                                                                                               |
| <b>ns-interval</b><br><b>&lt;1000-3600000&gt;</b>       | Configures the interval, in milliseconds, between two consecutive retransmitted neighbor solicitation (NS) messages. NS messages are sent by a node to determine the link layer address of a neighbor, or verify a neighbor is still reachable via a cached link-layer address. <ul style="list-style-type: none"> <li>• &lt;1000-3600000&gt; – Specify a value from 1000 - 3600000. The default is 1000 milliseconds.</li> </ul>                                                                                                                                                                                                 |
| <b>ula-reject-route</b>                                 | Installs a "reject" route for Unique Local Address (ULA) prefixes. This ensures that site-border routers and firewalls do not forward packets with ULA source or destination addresses outside of the site, unless explicitly configured with routing information about specific /48 or longer Local IPv6 prefixes. This option is disabled by default. The ULA is an IPv6 address used in private networks for local communication within a site (for example a company, campus, or within a set of branch office networks). These site local addresses are IPv6 addresses that fall in the block fc00::/7, defined in RFC 4193. |
| <b>unicast-routing</b>                                  | Enables IPv6 unicast routing. This feature is enabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

```
ipv6 ra-convert {throttle interval <3-1800> max-RAs <1-256>}
```

|                                                                                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>mld snooping forward-unknown-multicast</b> | <p>Enables multicast listener discovery (MLD) protocol snooping. This feature is disabled by default.</p> <p>When enabled, IPv6 devices (access point, wireless controller, or service platform) can examine MLD messages exchanged between hosts and multicast routers to discern which hosts are receiving multicast group traffic. Based on the information gathered these devices forward multicast traffic only to those interfaces connected to interested receivers instead of flooding traffic to all interfaces. This prevents VLANs from getting flooded with IPv6 multicast traffic.</p> |

### *l2tpv3*

[Profile Config Commands](#) on page 862

Defines the L2TPV3 settings for tunneling layer 2 payloads using VPNs

L2TPv3 is an IETF standard that defines the control and encapsulation protocol settings for tunneling layer 2 frames in an IP network (and access point profile) between two IP nodes. Use L2TPv3 to create tunnels for transporting layer 2 frames. L2TPv3 enables WiNG supported controllers and access points to create tunnels for transporting Ethernet frames to and from bridge VLANs and physical ports. L2TPv3 tunnels can be defined between WiNG devices and other vendor devices supporting the L2TPv3 protocol.

#### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600

#### Syntax

```
l2tpv3 [hostname <HOSTNAME> | inter-tunnel-bridging | logging | manual-session |
router-id [<1-4294967295> | <IP>] | tunnel | udp-listen-port <1024-65535>]
```

```
l2tpv3 logging ip-address [<IP> | any] hostname [<HOSTNAME> | any] router-id
[<IP> | <WORD> | any]
```

#### Parameters

```
l2tpv3 [hostname <HOSTNAME> | inter-tunnel-bridging | manual-session | router-id [<1-4294967295> |
<IP>] | tunnel | udp-listen-port <1024-65535>]
```

## *l3e-lite-table*

[Profile Config Commands](#) on page 862

Configures L3e lite table aging time

The L3e Lite table stores information about destinations and their location within a specific IPsec tunnel. This enables quicker packet transmissions. The table is updated as nodes transmit packets.

### **Supported in the following platforms:**

- Wireless Controllers — RFS4000
- Service Platforms — NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600

### **Syntax**

```
l3e-lite-table aging-time <10-1000000>
```

### **Parameters**

```
l3e-lite-table aging-time <10-1000000>
```

|                           |                                                                                                                                                                                                             |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>l3e-lite-table</b>     | Configures the aging time in seconds. The aging time defines the duration a learned L3e entry (IP, VLAN) remains in the L3e Lite table before deletion due to lack of activity. The default is 300 seconds. |
| <b>aging-time</b>         |                                                                                                                                                                                                             |
| <b>&lt;10-1000000&gt;</b> |                                                                                                                                                                                                             |

### **Example**

```
nx9500-6C8809(config-profile-default-rfs4000)#l3e-lite-table aging-time 1000
```

### *led-timeout*

[Profile Config Commands](#) on page 862

Configures the LED-timeout timer in the device or profile configuration mode

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600

## Syntax

```
led-timeout [<15-1440>|shutdown]
```

## Parameters

```
led-timeout [<15-1440>|shutdown]
```

**led-time**  
**[<15-1440>|**  
**shutdown]**

Sets the LED-timeout timer. The value provided here determines the interval (time to lapse) for which a device's LEDs are turned off after the last radio state change. For example, if set at 15 minutes, the LEDs are turned off for 15 minutes after the last radio state change.

- <15-1440> – Specify a value from 15 - 1400 minutes. The default is 30 minutes.
- shutdown – Shuts down the LED-timeout timer. The device LEDs are not turned off.

## Example

```
nx9500-6C8809(config-device-B4-C7-99-6C-88-09)#led-timeout 25
```

```

[Profile Config Commands](#) on page 862

Enables LLDP on this profile and configures LLDP settings

LLDP or IEEE 802.1AB is a vendor-neutral Data Link Layer protocol used by network devices for advertising of (announcing) identity, capabilities, and interconnections on a IEEE 802 LAN network. The protocol is formally referred to by the IEEE as Station and Media Access Control Connectivity Discovery. Both LLDP snooping and ability to generate and transmit LLDP packets is provided.

Information obtained via CDP and LLDP snooping is available in the UI. Information obtained using LLDP is provided during the adoption process, so the layer 2 device detected by the access point can be used as a criteria in the provisioning policy.

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
lldp [holdtime | med-tlv-select | run | timer]
```

```
lldp [holdtime <10-1800> | run | timer <5-900>]
```

```
lldp med-tlv-select [inventory-management | power-management {auto}]
```

### Parameters

```
lldp [holdtime <10-1800> | run | timer <5-900>]
```

### load-balancing

[Profile Config Commands](#) on page 862

Configures load balancing parameters

#### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

```

load-balancing [advanced-params | balance-ap-loads | balance-band-loads |
balance-channel-loads | band-control-startegy | band-ratio | group-id | neighbor-
selection-strategy]

```

```
load-balancing advanced-params [2.4GHz-load|5GHz-load|ap-load|equality-
margin| hiwater-threshold|max-neighbors|max-preferred-band-load|min-
common-clients|min-neighbor-rssi|min-probe-rssi]
```

```
load-balancing advanced-params [2.4GHz-load|5GHz-load|ap-load] [client-
weightage|throughput-weightage] <0-100>
```

```
load-balancing advanced-params equality-margin [2.4GHz|5GHz|ap|band]
<0-100>
```

```
load-balancing advanced-params hiwater-threshold [ap|channel-2.4GHz|
channel-5GHz]<0-100>
```

```
load-balancing advanced-params max-preferred-band-load [2.4GHz|5GHz]
<0-100>
```

```
load-balancing advanced-params [max-neighbors <0-16>|min-common-clients
<0-256>| min-neighbor-rssi <-100-30>|min-probe-rssi <-100-30>]
```

```
load-balancing [balance-ap-loads|balance-band-loads|balance-channel-loads
[2.4GHz|5GHz]]
```

```
load-balancing band-control-strategy [distribute-by-ratio|prefer-2.4GHz|
prefer-5GHz]
```

```
load-balancing band-ratio [2.4GHz|5GHz] [0|<1-10>]
```

```
load-balancing group-id <GROUP-ID>
```

```
load-balancing neighbor-selection-strategy [use-common-clients|use-roam-
notification|use-smart-rf]
```

### Parameters

```
load-balancing advanced-params [2.4GHz-load|5GHz-load|ap-load] [client-weightage|
throughput-weightage] <0-100>
```

Specify a value from -100 - 30 dBm. The default is -65 dBm.</li> </ul>                                   |
| <b>min-probe-rssi &lt;-100-30&gt;</b>    | Configures the minimum received probe signal strength required to qualify the sender as a common client <ul style="list-style-type: none"> <li>• &lt;0-100&gt; – Sets the signal strength in dBm. Specify a value from -100 - 30 dBm. The default is -100 dBm.</li> </ul> |

load-balancing [balance-ap-loads|balance-band-loads|balance-channel-loads [2.4GHz|5GHz]]

|                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>load-balancing</b>                      | Configures the following load balancing parameters: ap-loads, band-loads, and channel-loads.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>balance-ap-loads</b>                    | Enables neighbor AP load balancing. This option distributes the access point's radio load amongst other controller managed access point radios. This option is disabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>balance-band-loads</b>                  | Enables balancing of the total band load amongst neighbors. This option balances the access point's radio load by assigning a ratio to both the 2.4 GHz and 5.0 GHz bands. Balancing radio load by band ratio allows an administrator to assign a greater weight to radio traffic on either the 2.4 GHz or 5.0 GHz band. This option is disabled by default.                                                                                                                                                                                                                                                                                        |
| <b>balance-channel-loads [2.4GHz 5GHz]</b> | Enables the following: <ul style="list-style-type: none"> <li>• 2.4GHz – Channel load balancing on 2.4 GHz band. This option is disabled by default. Balances the access point's 2.4 GHz radio load across channels supported within the country of deployment. This can prevent congestion on the 2.4 GHz radio if a channel is over utilized.</li> <li>• 5GHz – Channel load balancing on 5.0 GHz band. This option is disabled by default. Balances the access point's 5.0 GHz radio load across channels supported within the country of deployment. This can prevent congestion on the 5.0 GHz radio if a channel is over utilized.</li> </ul> |

load-balancing band-control-strategy [distribute-by-ratio|prefer-2.4GHz|prefer-5GHz]

|                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>load-balancing band-control-strategy</b> | Configures a band control strategy<br>By default, this option steers 5.0 GHz-capable clients to the 5.0 GHz band. When an access point hears a request from a client to associate on both the 2.4 GHz and 5.0 GHz bands, it knows the client is capable of operation in 5.0 GHz. Band steering steers the client by responding only to the 5.0 GHz association request and not the 2.4 GHz request. Consequently, the client only associates in the 5.0 GHz band. |
| <b>distribute-by-ratio</b>                  | Distributes clients to either band according to the band-ratio                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>prefer-2.4GHz</b>                        | Nudges all dual-band clients to 2.4 GHz band                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>prefer-5GHz</b>                          | Nudges all dual-band clients to 5.0 GHz band. This is the default setting.                                                                                                                                                                                                                                                                                                                                                                                        |

load-balancing band-ratio [2.4GHz|5GHz] [0|<1-10>]

|                                  |                                                                                                                                                                                                                                                                                                                                   |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>load-balancing band-ratio</b> | Configures the relative loading of 2.4 GHz band and 5.0 GHz band. This allows an administrator to weight client traffic load if wishing to prioritize client traffic load on the 2.4 GHz or the radio band. The higher the value set, the greater the weight assigned to radio traffic load on the 2.4 GHz or 5.0 GHz radio band. |
| <b>2.4GHz [0   &lt;1-10&gt;]</b> | Configures the relative loading of 2.4 GHz band <ul style="list-style-type: none"> <li>• 0 - Selecting '0' steers all dual-band clients preferentially to the other band</li> <li>• &lt;0-10&gt; - Configures a relative load as a number from 0 - 10. The default is 0.</li> </ul>                                               |
| <b>5ghz [0   &lt;1-10&gt;]</b>   | Configures the relative loading of 5.0 GHz band <ul style="list-style-type: none"> <li>• 0 - Selecting '0' steers all dual-band clients preferentially to the other band</li> <li>• &lt;0-10&gt; - Configures a relative load as a number from 0 - 10. The default is 1.</li> </ul>                                               |

load-balancing group-id <GROUP-ID>

|                                                 |                                                                                                                                                                                                          |
|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>load-balancing group-id &lt;GROUP-ID&gt;</b> | Configures group ID to facilitate load balancing <ul style="list-style-type: none"> <li>• &lt;GROUP-ID&gt; - Specify the group ID. This option is enabled only when a group ID is configured.</li> </ul> |
|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

load-balancing neighbor-selection-strategy [use-common-clients|use-roam-notification|use-smart-rf]

|                                                   |                                                                                                                        |
|---------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| <b>load-balancing neighbor-selection-strategy</b> | Configures a neighbor selection strategy. The options are: use-common-clients, use-roam-notification, and use-smart-rf |
| <b>use-common-clients</b>                         | Selects neighbors based on probes from clients common to neighbors. This option is enabled by default.                 |
| <b>use-roam-notification</b>                      | Selects neighbors based on roam notifications from roamed clients. This option is enabled by default.                  |
| <b>use-smart-rf</b>                               | Selects neighbors detected by Smart RF. This option is enabled by default.                                             |

### Example

```

### *logging*

[Profile Config Commands](#) on page 862

Enables message logging and configures logging settings. When enabled, the profile logs individual system events to a user-defined log file or a syslog server. Message logging is disabled by default.

Enabling message logging is recommended, because system event logs can be analyzed to determine an overall pattern that may be negatively impacting performance.

This command can also be executed in the device configuration mode.

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
logging [aggregation-time | buffered | console | facility | forward | host | on |
syslog]
```

```
logging [aggregation-time <1-60> | host [<IPv4> | <IPv6>] {port <1-65535>} |
on]
```

```
logging [buffered | console | syslog | forward] [<0-7> | emergencies | alerts |
critical | errors | warnings | notifications | informational | debugging]
```

```
logging facility [local0 | local1 | local2 | local3 | local4 | local5 | local6 |
local7]
```

### Parameters

```
logging [aggregation-time <1-60> | host [<IPv4> | <IPv6>] {port <1-65535>} | on]
```

## *mac-address-table*

[Profile Config Commands](#) on page 862

Configures the MAC address table. Use this command to create MAC address table entries by assigning a static address to the MAC address table.

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
mac-address-table [aging-time|detect-gateways|static]
mac-address-table aging-time [0|<10-1000000>]
mac-address-table detect-gateways
mac-address-table static <MAC> vlan <1-4094> interface [<L2-INTERFACE>|ge
<1-4>| port-channel <1-2>]
```

### Parameters

```
mac-address-table aging-time [0|<10-1000000>]
```

|                                                            |                                                                                                                                                                                                                                                                                     |
|------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### mac-auth

[Profile Config Commands](#) on page 862

Enables authentication of a client's MAC address on wired ports. When configured, MAC authentication will be enabled on devices using this profile.

To enable MAC address authentication on a device, enter the device's configuration mode and execute the mac-auth command.

When enabled, the source MAC address of a device, connected to the specified wired port, is authenticated with the RADIUS server. Once authenticated the device is permitted access to the managed network and packets from the authenticated source are processed. If not authenticated the

device is either denied access or provided guest access through the guest VLAN (provided guest VLAN access is configured on the port).

Enabling MAC authentication requires you to first configure a AAA policy specifying the RADIUS server. Configure the client's MAC address on the specified RADIUS server. Attach this AAA policy to a profile or a device. Finally, enable MAC authentication on the desired wired port of the device or device-profile.

Only one MAC address is supported for every wired port. Consequently, when one source MAC address is authenticated, packets from all other sources are dropped.

To enable client MAC authentication on a wired port:

- 1 Configure the user on the RADIUS server. The following examples create a RADIUS server user entry.

```
<DEVICE>(config)#radius-group <RAD-GROUP-NAME>
<DEVICE>(config-radius-group-<RAD-GROUP-NAME>)#policy vlan <VLAN-ID>

<DEVICE>(config)#radius-user-pool-policy <RAD-USER-POOL-NAME>
<DEVICE>(config-radius-user-pool-<RAD-USER-POOL-NAME>)#user <USER-NAME> password
<PASSWORD> group <RAD-GROUP-OF-STEP-A>
```

Note: The <USER-NAME> and <PASSWORD> should be the client's MAC address. This address will be matched against the MAC address of incoming traffic at the specified wired port.

```
<DEVICE>(config)#radius-server-policy <RAD-SERVER-POL-NAME>
<DEVICE>(config-radius-server-policy-<RAD-SERVER-POL-NAME>)#use radius-user-pool-policy
<RAD-USER-POOL-OF-STEP-B>
```

- 2 Configure a AAA policy exclusively for wired MAC authentication and specify the authentication (RADIUS) server settings. The following example creates a AAA policy 'macauth' and enters its configuration mode:

```
<DEVICE-A>(config)#aaa-policy macauth
<DEVICE-A>(config-aaa-policy-macauth)#...
```

Specify the RADIUS server details.

```
<DEVICE-A>(config)#aaa-policy macauth
<DEVICE-A>(config-aaa-policy-macauth)#authentication server <1-6> [host <IP>|onboard]
```

- 3 Attach the AAA policy to the device or profile. When attached to a profile, the AAA policy is applied to all devices using this profile.

```
<DEVICE>(config-device-aa-bb-cc-dd-ee)#mac-auth use aaa-policy macauth
<DEVICE>(config-profile-<DEVICE-PROFILE-NAME>)#mac-auth use aaa-policy macauth
```

- 4 Enable mac-auth on the device's desired GE port. When enabled on a profile, MAC address authentication is enabled, on the specified GE port, of all devices using this profile.

```
<DEVICE>(config-device-aa-bb-cc-dd-ee)#interface ge x
<DEVICE>(config-device-aa-bb-cc-dd-ee-gex)#mac-auth
```

```
<DEVICE>(config-profile-<PROFILE-NAME>)#interface ge x
<DEVICE>(config-profile-<PROFILE-NAME>)#mac-auth
```

#### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000

- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

## Syntax

```
mac-auth use aaa-policy <AAA-POLICY-NAME>
```

## Parameters

```
mac-auth use aaa-policy <AAA-POLICY-NAME>
```

|                                               |                                                                                                                                                                                           |
|-----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>mac-auth</b>                               | Enables 802.1X authentication of MAC addresses on this profile. Use the device configuration mode to enable this feature on a device.                                                     |
| <b>use aaa-policy &lt;AAA-POLICY-NAME&gt;</b> | Associates an existing AAA policy with this profile (or device) <AAA-POLICY NAME> - Specify the AAA policy name. The AAA policy used should be created especially for MAC authentication. |

## Example

The following examples demonstrate the configuration of authentication of MAC addresses on wired ports:

```
rfs4000-229D58(config-aaa-policy-mac-auth)#authentication server 1 onboard controller
```

```
rfs4000-229D58(config-aaa-policy-mac-auth)#show context
aaa-policy mac-auth
 authentication server 1 onboard controller
rfs4000-229D58(config-aaa-policy-mac-auth)#
```

```
rfs4000-229D58(config)#radius-group RG
rfs4000-229D58(config-radius-group-RG)#policy vlan 11
```

```
rfs4000-229D58(config-radius-group-RG)#show context
radius-group RF
 policy vlan 11
rfs4000-229D58(config-radius-group-RG)#
```

```
rfs4000-229D58(config)#radius-user-pool-policy RUG
rfs4000-229D58(config-radius-user-pool-RUG)#user 00-16-41-55-F8-5D password 0

### *management-server*

[Profile Config Commands](#) on page 862

Configures a management server with this profile. This command is also applicable to the device configuration context.

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
management-server <HOST-NAME> port <1-65535>
```

### Parameters

```
management-server <HOST-NAME> port <1-65535>
```

**management-server** <HOST-NAME> port <1-65535>

Configures a management server with this profile. Use this command to identify the management server.

- <HOST-NAME> - Specify the management server's host name.
- port <1-65535> - Specify the port where the management server is reachable. The default setting is port 443.

**Note:** If the adoption-mode, on this profile, is set to 'cloud', ensure that the management-server configuration points to the ExtremeCloud Web address. If the adoption-mode is set to 'ws-controller', provide the ESE controller's IP address or hostname as the management server. For information on configuring the adoption-mode, see [adoption-mode](#) on page 868.

### Example

```
nx9500-6C8809(config-profile-testRFS4000)#management-server nx9500-6C8809 port 300

nx9500-6C8809(config-profile-testRFS4000)#show context include-factory | include
management-server
 management-server nx9500-6C8809 port 300
nx9500-6C8809(config-profile-testRFS4000)#
```

### *meshpoint-device*

[Profile Config Commands](#) on page 862

Configures meshpoint device parameters. This feature is configurable in the profile and device configuration modes.

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
meshpoint-device <MESHPOINT-NAME>
```

### Parameters

```
meshpoint-device <MESHPOINT-NAME>
```

**meshpoint-device** <MESHPOINT-NAME>

Configures meshpoint device parameters

- <MESHPOINT-NAME> - Specify meshpoint name.

## Usage Guidelines

For VMM (Vehicular Mounted Modem) access points or other mobile devices, set the path selection method as mobile-snr-leaf in the config-meshpoint-device mode. For more information, see [path-method \(meshpoint-device-config\)](#) on page 1796.

```
nx9500-6C8809(config-profile-testAP7161)#meshpoint-device test

nx9500-6C8809(config-profile-testAP7161-meshpoint-test)#?
Mesh Point Device Mode commands:
 acs Configure auto channel selection parameters
 exclude Exclude neighboring Mesh Devices
 hysteresis Configure path selection SNR hysteresis values
 monitor Event Monitoring
 no Negate a command or set its defaults
 path-method Path selection method used to find a root node
 preferred Configure preferred path parameters
 root Set this meshpoint as root
 root-select Root selection method parameters

For more information on the meshpoint-device configuration parameters, see [MESHPOINT](#) on page 1760.

### *meshpoint-monitor-interval*

[Profile Config Commands](#) on page 862

Configures the meshpoint monitoring interval. This is the interval, in seconds, at which the meshpoint status is checked.

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

## Syntax

```
meshpoint-monitor-interval <1-65535>
```

## Parameters

```
meshpoint-monitor-interval <1-65535>
```

|                                                             |                                                                                                                                                                                                     |

*mint*

[Profile Config Commands](#) on page 862

Configures MiNT protocol parameters required for MiNT creation and adoption

MiNT links are required for adoption of a device (APs, wireless controller, and service platform) to a controller. The MiNT link is created on both the adoptee and the adopter. WiNG provides several commands to configure MiNT links and establish adoption for both IPv4 and IPv6 addresses.

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
mint [dis|inter-tunnel-bridging|level|link|mlcp|rate-limit|spf-latency|
tunnel-across-extended-vlan|tunnel-controller-load-balancing]
```

```
mint dis [priority-adjustment <-255-255>|strict-evis-reachability]
```

```
mint inter-tunnel-bridging
```

```
mint level 1 area-id [<1-16777215>|<NUMBER-ALIAS-NAME>]
```

```
mint link [force|ip|listen|vlan]
```

```
mint link force ip [<IPv4>|<IPv6>] [<1-65535> level 2|level 2]
{adjacency-hold-time <2-600>|cost <1-10000>|hello-interval <1-120>|ipsec-
secure {gw [<IP>|<HOST-NAME>]}}
```

```
mint link [listen ip [<IPv4>|<IPv6>|<HOST-ALIAS-NAME>]|vlan <1-4094>]
{adjacency-hold-time <2-600>|cost <1-10000>|hello-interval <1-120>|ipsec-
security {gw [<IP>|<HOST-NAME>]}}|level [1|2]}
```

```
mint link ip [<IPv4>|<IPv6>|<HOST-ALIAS-NAME>] {<1-65535>/adjacency-hold-
time <2-600>/cost <1-10000>/hello-interval <1-120>/ipsec-security {gw
[<IP>|<HOST-NAME>]}/level [1/2]}
```

```
mint mlcp [ip|ipv6|vlan]
```

```
mint rate-limit level2 [link|mlcp]
```

```
mint rate-limit level2 [link [ip [<IPv4>|<IPv6>] <1-65535>|vlan
<1-4094>]|mlcp [ip|ipv6|vlan]] rate <50-1000000> max-burst-size <2-1024>

| <b>link listen ip</b><br>[<IPv4> <IPv6> <br><HOST-ALIAS-<br>NAME>] | <p>Creates a MiNT routing link</p> <ul style="list-style-type: none"> <li>listen – Creates a MiNT listening link</li> <li>ip – Creates a MiNT listening link over UDP/IP or IPv6 <ul style="list-style-type: none"> <li>&lt;IPv4&gt; – Specify the IPv4 address of the listening UDP/IP link.</li> <li>&lt;IPv6&gt; – Specify the IPv6 address of the listening UDP/IP link.</li> <li>&lt;HOST-ALIAS-NAME&gt; – Specify the host alias identifying the MiNT link address. The host alias should existing and configured.</li> </ul> </li> </ul> <p>UDP/IP links can be created by configuring a matching pair of links, one on each end point. However, that is error prone and does not scale. So UDP/IP links can also listen (in the TCP sense), and dynamically create connected UDP/IP links when contacted. The typical configuration is to have a listening UDP/IP link on the IP address S.S.S.S, and for all the APs to have a regular UDP/IP link to S.S.S.S.</p> |

| <b>mint rate-limit level2</b>                                            | <p>Applies rate limits on extended VLAN traffic</p> <p>Excessive traffic can cause performance issues on an extended VLAN. Excessive traffic can be caused by numerous sources including network loops, faulty devices, or malicious software.</p> <p>Rate limiting reduces the maximum rate sent or received per wireless client. It prevents any single user from overwhelming the wireless network, and also provides differential service for service providers. Uplink and downlink rate limits are usually configured on a RADIUS server using vendor specific attributes. Rate limits are extracted from the RADIUS server's response. When such attributes are not present, the settings defined on the controller, service platform or access point are applied. You can set separate QoS rate limit configurations for data types transmitted from the network (upstream) and data transmitted from a wireless clients back to associated radios (downstream).</p> |
| <b>link [ip &lt;IPv4/IPv6&gt; &lt;1-65535&gt;   vlan &lt;1-4094&gt;]</b> | <p>Configures rate limit parameters applicable for all statically configured MiNT links on level2. Traffic exceeding the defined rate is dropped and a log message is generated. The default setting is 5000 Kbps.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|                                                                                                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>max-burst-size</b><br><b>&lt;2-1024&gt;</b>                                                                        | Configures the maximum burst size from 0 - 1024 Kbytes<br>Smaller the burst size, lesser is the probability of the upstream packet transmission resulting in congestion for the WLAN's client destinations. By trending the typical number of ARP, broadcast, multicast and unknown unicast packets over a period of time, the average rate for each access category can be obtained. Once a baseline is obtained, add a 10% margin (minimally) to allow for traffic bursts. The default burst size is 320 Kbytes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>red-threshold</b><br><b>[background  </b><br><b>best-effort  </b><br><b>video   voice]</b><br><b>&lt;0-100&gt;</b> | Optional. Configures the random early detection (RED) threshold (as a percentage) for the following traffic types: <ul style="list-style-type: none"> <li>• background – Configures the RED threshold for low priority background traffic. Background packets are dropped and a log message generated if the rate exceeds the set value. Background traffic consumes the least bandwidth of any access category, so this value can be set to a lower value once a general upstream rate is known by the network administrator (using a time trend analysis). The default setting is 50%.</li> <li>• best-effort – Configures the RED threshold for low priority best-effort traffic. Best-effort packets are dropped and a log message generated if the rate exceeds the set value. Best effort traffic consumes little bandwidth, so this value can be set to a lower value once a general upstream rate is known by the network administrator (using a time trend analysis).The default setting is 50%.</li> <li>• video – Configures the RED threshold for high priority video traffic. Video packets are dropped and a log message generated if the rate exceeds the set value. Video traffic consumes significant bandwidth, so this value can be set to a higher value once a general upstream rate is known by the network administrator (using a time trend analysis).The default setting is 25%.</li> <li>• voice – Configures the RED threshold for high priority voice traffic. Voice packets are dropped and a log message generated if the rate exceeds the set value. Voice applications consume significant bandwidth, so this value can be set to a higher value once a general upstream rate is known by the network administrator (using a time trend analysis).The default setting is 0%. <ul style="list-style-type: none"> <li>• &lt;0-100&gt; – After selecting the traffic type, specify the RED threshold from 0 - 100%.</li> </ul> </li> </ul> |

*misconfiguration-recovery-time*

[Profile Config Commands](#) on page 862

Verifies connectivity after a configuration is received

#### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

## Syntax

```
misconfiguration-recovery-time [0|<60-300>]
```

## Parameters

```
misconfiguration-recovery-time [0|<60-300>]
```

|                       |                                                                       |
|-----------------------|-----------------------------------------------------------------------|
| <b>&lt;60-300&gt;</b> | Sets the recovery time from 60 - 300 seconds (default is 180 seconds) |
| <b>0</b>              | Disables recovery from misconfiguration                               |

## Example

```
NOC-NX9500(config-profile-testNX9000)#misconfiguration-recovery-time 65
```

```
NOC-NX9500(config-profile-testNX9000)#show context include-factory | include mis
configuration-recovery-time
 misconfiguration-recovery-time 65
 min-misconfiguration-recovery-time 500
NOC-NX9500(config-profile-testNX9000)#
```

[Profile Config Commands](#) on page 862

Configures neighbor inactivity timeout

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

## Syntax

```
neighbor-inactivity-timeout <1-1000>
```

## Parameters

```
neighbor-inactivity-timeout <1-1000>
```

|                       |                                                                                                                                                                       |

### *neighbor-info-interval*

[Profile Config Commands](#) on page 862

Configures the neighbor information exchange interval

#### **Supported in the following platforms:**

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### **Syntax**

```
neighbor-info-interval <1-100>
```

#### **Parameters**

```
neighbor-info-interval <1-100>
```

|                      |                                                                |
|----------------------|----------------------------------------------------------------|
| <b>&lt;1-100&gt;</b> | Sets interval from 1 - 100 seconds. The default is 10 seconds. |
|----------------------|----------------------------------------------------------------|

#### **Example**

```
nx9500-6C8809(config-profile-default-rfs4000)#neighbor-info-interval 6

*noc*

[Profile Config Commands](#) on page 862

Configures Network Operations Center (NOC) statistics update interval. This is the interval at which statistical updates are sent by the RF Domain manager to its adopting controller (the NOC controller).

**Supported in the following platforms:**

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

**Syntax**

```
noc update-interval [<5-3600>|auto]
```

**Parameters**

```
noc update-interval [<5-3600>|auto]
```

|                                                   |                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>noc update-interval</b><br>[<5-3600> <br>auto] | <p>Configures NOC statistics update interval</p> <ul style="list-style-type: none"> <li>• &lt;5-3600&gt; - Specify the update interval from 5 - 3600 seconds.</li> <li>• auto - The NOC statistics update interval is automatically adjusted by the wireless controller or service platform based on load. *nsight*

[Profile Config Commands](#) on page 862

Configures NSight database related parameters. Use this command to configure the data-update periodicity, number of applications posted to the NSight server for a wireless client, and the duration for which data is stored in the NSight database's buckets. These parameters impact the amount of data stored in the NSight DB and interval at which data is aggregated and expired within the NSight DB. For more information on data aggregation and expiration, see [Usage Guidelines\(Data Aggregation and Expiration\)](#) on page 1205.

Configure these parameters in the NSight server's profile configuration mode. These parameters are also configurable on the NSight server's device configuration mode.

#### Supported in the following platforms:

- Service Platforms — NX9500, NX9510, NX9600, VX9000

#### Syntax

```
nsight database [statistics|summary]
```

```
nsight database statistics [avc-update-interval|max-apps-per-client|max-http-usage-metadata|max-http-visits-metadata|max-ssl-usage-metadata|max-ssl-visits-metadata|update-interval|wireless-clients-update-interval]
```

```
nsight database statistics [avc-update-interval|update-interval|wireless-clients-update-interval] [120|30|300|60|600]
```

```
nsight database statistics max-apps-per-client <1-1000>
```

```
nsight database statistics [max-http-usage-metadata|max-http-visits-metadata|max-ssl-usage-metadata|max-ssl-visits-metadata] <1-1000>
```

```
nsight database summary duration <1-24> <1-168> <1-2160> <24-26280>
```

#### Parameters

```
nsight database statistics [avc-update-interval|update-interval|wireless-clients-update-interval] [120|30|300|60|600]
```

|                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nsight database statistics</b> | Configures NSight database statistics related parameters                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>avc-update-interval</b>        | Configures the interval, in seconds, at which Application Visibility and Control (AVC) statistics is updated to the NSight database. This interval represents the rate at which AVC-related data is inserted in the NSight database's first bucket. This first bucket data is referred to as the RAW records. A bucket is a database collection that holds statistical data on a per RF Domain basis. For more information, see <a href="#">Usage Guidelines (Data Aggregation and Expiration)</a> on page 1274.<br>When configured, RF Domain managers posting AVC-related data to the NSight server receive a reply from the NSight server intimating the next update time. The NSight server calculates the 'next update time' based on the avc-update-interval configured here. |

|                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>update-interval</b>                  | Configures the interval, in seconds, at which data is updated to the NSight server. This interval represents the rate at which data (excluding AVC and wireless-clients related statistics) is inserted in the NSight database's first bucket. This first bucket data is referred to as the RAW records. A bucket is a database collection that holds statistical data on a per RF Domain basis. For more information, see <a href="#">Usage Guidelines (Data Aggregation and Expiration)</a> on page 1274.                                                                                                                                                                                                                                                                                          |
| <b>contd..</b>                          | When configured, RF Domain managers posting data to the NSight server receive a reply from the NSight server intimating the next update time. The NSight server calculates the 'next update time' based on the update-interval configured here.<br><br><b>Note:</b> Use the 'avc-update-interval' and 'wireless-clients-update-interval' keywords to configure update interval for AVC-related and wireless-clients related information respectively.                                                                                                                                                                                                                                                                                                                                                |
| <b>wireless-clients-update-interval</b> | Configures the interval, in seconds, at which wireless-client statistics is updated to the NSight server. This interval represents the rate at which wireless-clients related statistics is inserted in the NSight database's first bucket. This first bucket data is referred to as the RAW records. A bucket is a database collection that holds statistical data on a per RF Domain basis. For more information, see <a href="#">Usage Guidelines (Data Aggregation and Expiration)</a> on page 1274.<br>When configured, RF Domain managers posting wireless-client related data to the NSight server receive a reply from the NSight server intimating the next update time. The NSight server calculates the 'next update time' based on the wireless-clients-update-interval configured here. |

The default is 7 days (168 hours).</li> <li>&lt;24-26280&gt; – Specify the bucket 4 duration from 24 - 26280 hours (i.e. 1 day to 3 years). The default is 365 days (1 year).</li> </ul> <p>A bucket is a database collection that holds statistical data for each RF Domain within the network. (Note, only those RF Domain’s that are using an NSight policy with the NSight server host configured will post data to the NSight server. (For more information, see <a href="#">use (rf-domain-config-mode)</a> on page 524 in the RF Domain configuration mode.) NSight database has four (4) buckets. The data from each bucket is aggregated and pushed to the next bucket once the data storage duration, specified for the bucket, has exceeded. For more information on data aggregation, see <a href="#">Usage Guidelines (Data Aggregation and Expiration)</a> on page 1274.</p> |

### Usage Guidelines(Data Aggregation and Expiration)

Data Aggregation:

The NSight functionality, a data analytics tool, analyzes data that is generated periodically by the nodes within the managed wireless LAN. For large WLAN networks, generating significantly large amount of data, storing data forever is neither feasible nor beneficial. Therefore, older statistics are summarized into aggregated (averaged) records. All records, for a fixed time period in past, are summarized into one record by taking an average of them. Although this causes a loss in the data’s granularity, average numbers for any given time period is still available.

---

Statistical data periodically posted by RF Domain managers to the NSight server are stored in buckets (database collections) within the NSight database. There are four buckets in total. These are:

- First bucket (termed as the RAW bucket) - B1
- Second bucket - B2
- Third bucket - B3
- Fourth bucket - B4

On completion of the data storage duration, records from a bucket are aggregated (at a fixed rate) and inserted into the next bucket. The rate at which records are aggregated into the next bucket becomes the next bucket's granularity. For example, the B1 records (that have exceeded the data storage duration configured for B1) are aggregated (at the rate specified) and inserted into B2. Similarly, data from B2 are aggregated into B3, and from B3 to B4. The fixed rate of aggregation (or granularity) AND default storage duration for each bucket is as follows:

- B1: storage duration 8 hours
- B2: granularity 10 minutes / storage duration 24 hours
- B3: granularity 1 hour / storage duration 7 days
- B4: granularity 1 day / storage duration 1 year

Let us consider (with default update-interval settings) the growth of any one of the statistical buckets.

- Since B1's default data storage duration is 8 hours, B1 will hold a maximum of 960 records per RF Domain after 8 hours (updated at the rate of 30 seconds).
- Since B2's granularity is 10 minutes, every 10 minutes 20 records from the B1 will be aggregated into a single record and inserted into B2.
- Since B2's default storage duration is 24 hours, it will contain a maximum of 144 records per RF Domain after 24 hours.
- Since B3's granularity is 1 hour, every hour 6 records from B2 will be aggregated into a single record and inserted into B3.
- Since B3's default storage duration is 7 days, it will contain a maximum of 168 records per RF Domain after 7 days.
- Since B4's granularity is 1 day, every day 24 records from B3 will be aggregated into a single record and inserted into B4.
- Since B4's default storage duration is 365 days, it will contain a maximum of 365 records per RF Domain after 1 year.

Data Expiration:

The expiration of older records (also referred to as purging or deleting of records) occurs along with data aggregation for each bucket.

Let us consider (with default data storage-duration settings) the expiration of data for any one of the statistical buckets.

- As stated earlier, at the end of 8 hours B1 will have 960 records per RF Domain. After a period of 8 hours and 10 minutes, all 960 records are aggregated into 144 records and inserted into B2. To enable B1 to hold exactly 8 hours worth of data, 20 of the oldest records (corresponding to the first

10 minutes) are purged from B1 at the end of 8 hours and 10 minutes. This expiration cycle is triggered every 10 minutes.

- At the end of 24 hours B2 will have 144 records per RF Domain. After a period of 24 hours and 10 minutes, one of the oldest record (corresponding to the first 10 minutes) is purged from B2. This expiration cycle is triggered every 10 minutes to enable B2 to maintain exactly 24 hours worth of data.
- At the end of 7 days B3 will have 168 records per RF Domain. After a period of 7 days and one hour one of the oldest record (corresponding to the first hour) is purged from B3. This expiration cycle is triggered every 1 hour to enable B3 to maintain exactly 7 days worth of data.
- At the end of 365 days B4 will have 365 records per RF Domain. After 365 days, the oldest records (corresponding to the first day) are purged from B4. This expiration cycle is triggered every 1 day to enable B4 to maintain exactly 365 days worth of data.

### Example

```
nx9500-6C8809(config-profile-testNX9500)#nsight database statistics avc-update-interval
120

nx9500-6C8809(config-profile-testNX9500)#nsight database statistics update-interval 30

nx9500-6C8809(config-profile-testNX9500)#nsight database statistics wireless-clients-
update-interval 600

nx9500-6C8809(config-profile-testNX9500)#nsight database statistics max-apps-per-client 20

nx9500-6C8809(config-profile-testNX9500)#nsight database summary duration 12 30 200 500

nx9500-6C8809(config-profile-testNX9500)#show context include-factory | include nsight
use nsight-policy nsight-noc
nsight database statistics update-interval 30
nsight database statistics wireless-clients-update-interval 600
nsight database summary duration 12 30 200 500
nsight database statistics avc-update-interval 120
nsight database statistics max-apps-per-mu 20

[Profile Config Commands](#) on page 862

Configures the Network Time Protocol (NTP) server settings

NTP manages time and/or network clock synchronization within the network. NTP is a client/server implementation. Controllers, service platforms, and access points (NTP clients) periodically synchronize their clock with a master clock (an NTP server). For example, a controller resets its clock to 07:04:59 upon reading a time of 07:04:59 from its designated NTP server.

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000

- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
ntp server <PEER-IP/HOSTNAME> {autokey|key|maxpoll|minpoll|prefer|version}
```

```
ntp server <PEER-IP/HOSTNAME> {autokey}
```

```
ntp server <PEER-IP/HOSTNAME> {maxpoll [1024|2048|4096|8192]}
```

```
ntp server <PEER-IP/HOSTNAME> {minpoll [1024|128|256|512|64]}
```

```
ntp server <PEER-IP> {key <1-65534> md5 [0 <WORD>|2<WORD>|<WORD>]}
```

```
ntp server <PEER-IP/HOSTNAME> {prefer version <1-4>|version <1-4> prefer}
```

### Parameters

```
ntp server <PEER-IP/HOSTNAME> {autokey} {prefer version <1-4>|version <1-4>}
```

|                                            |                                                                                                                                                                                                                                                                       |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ntp server &lt;PEER-IP/HOSTNAME&gt;</b> | Configures NTP server resources that are used to obtain system time <ul style="list-style-type: none"> <li>• &lt;PEER-IP/HOSTNAME&gt; - Identifies the NTP server resource by its IP address or hostname. Enables support for OmniTrail Location Server (OTLS) beacon identification

OmniTrail (offered by OmniTrail technologies) is a Wi-Fi based locationing protocol used in positioning and tracking location solutions. Access points supporting OTLS beacon identification lock their radios to scan channels for beacons with OTLS tags. Beacons received by the access point are matched for the OTLS signature, and in case of a match, the beacons are forwarded to the OTLS server as UDP payload.

Use this command to configure OTLS server details on the AP and enable OTLS data forwarding. Alternately, OTLS parameters can be configured in the AP's profile on the controller or service platform, and pushed to adopted access points. When configured, APs establish connection with the OTLS server and forward OTLS locationing feeds to the server.

### Supported in the following platforms:

- Access Points — AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8432, AP8533

### Syntax

```
otls [apid|control-port|data-port|forward|server-ip]
```

```
otls apid <WORD>
```

```
otls control-port <0-65535>
```

```
otls data-port [2.4GHz|5GHz] <0-65535>
```

```
otls forward [2.4GHz|5GHz] [disable|enable]
```

```
otls server-ip <OTLS-SERVER-IP>
```

### Parameters

```
otls apid <WORD>
```

|                                   |                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>otls apid<br/>&lt;WORD&gt;</b> | Configures a unique identification for the OTLS-enabled access point. The access point identifier (APID) enables the OTLS server to identify the AP forwarding the OTLS tag. <ul style="list-style-type: none"><li>• &lt;WORD&gt; - Specify an ID for the AP.</li></ul> To ensure that OTLS-enabled APs have unique OTLS ID, it is recommended that the APID is configured in the device context of each AP. |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
otls control-port <0-65535>
```

|                                          |                                                                                                                                                                                                            |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>otls control-port &lt;0-65535&gt;</b> | Configures the port used by the AP to establish and maintain connection with the OTLS server <ul style="list-style-type: none"><li>• &lt;0-65535&gt; - Specify the control port from 0 - 655635.</li></ul> |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
otls data-port [2.4GHz|5GHz] <0-65535>
```

|                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>otls data-port [2.4GHz 5GHz] &lt;0-65535&gt;</b> | Configures the port used by the AP to forward OTLS beacons to the OTLS server. However, OTLS data forwarding has to be enabled on the APs. Use the <code>otls &gt; forward &gt; [2.4GHz 5GHz] &gt; [disable enable]</code> command to enable data forwarding. <ul style="list-style-type: none"><li>• 2.4GHz - Configures the port used to forward OTLS beacons received on the 2.4 GHz band</li><li>• 5.0GHz - Configures the port used to forward OTLS beacons received on the 5.0 GHz band</li></ul> The following keyword is common to the above parameters: <ul style="list-style-type: none"><li>• &lt;0-65535&gt; - Specify a data-forwarding port from 0 - 65535.</li></ul> |
|-----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
otls forward [2.4GHz|5GHz] [disable|enable]
```

|                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>otls forward [2.4GHz 5GHz] [disable enable]</b> | Enables or disables OTLS tag forwarding <ul style="list-style-type: none"><li>• 2.4GHz - Enables or disables forwarding of OTLS beacons received on the 2.4 GHz band</li><li>• 5GHz - Enables or disables forwarding of OTLS beacons received on the 5.0 GHz band</li></ul> The following keywords are common to the above parameters: <ul style="list-style-type: none"><li>• disable - Disables OTLS tag forwarding. By default OTLS beacon forwarding is disabled for both 2.4 GHz and 5.0 GHz bands.</li><li>• enable - Enables OTLS tag forwarding</li></ul> |
|----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
otls server-ip <OTLS-SERVER-IP>
```

|                                              |                                                                                                                                                          |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>otls server-ip &lt;OTLS-SERVER-IP&gt;</b> | Configures the OTLS server's IP address <ul style="list-style-type: none"><li>• &lt;OTLS-SERVER-IP&gt; - Specify the OTLS server's IP address.</li></ul> |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|

## Example

```
ap8533-84A224(config-device-84-24-8D-84-A2-24)#otls apid 112233
ap8533-84A224(config-device-84-24-8D-84-A2-24)#otls forward 2.4GHz enable
ap8533-84A224(config-device-84-24-8D-84-A2-24)#otls forward 5GHz enable
ap8533-84A224(config-device-84-24-8D-84-A2-24)#otls control-port 8890
ap8533-84A224(config-device-84-24-8D-84-A2-24)#otls data-port 2.4GHz 8888
ap8533-84A224(config-device-84-24-8D-84-A2-24)#otls data-port 5GHz 8889
ap8533-84A224(config-device-84-24-8D-84-A2-24)#otls server-ip 192.168.13.10

ap8533-84A224(config-device-84-24-8D-84-A2-24)#show context include-factory | include otls
otls forward 5GHz enable
otls forward 2.4GHz enable
otls server-ip 192.168.13.10
otls control-port 8890
otls data-port 2.4GHz 8888
otls data-port 5GHz 8889
otls apid 112233
ap8533-84A224(config-device-84-24-8D-84-A2-24)
```

The following example displays OTLS parameters configured on an AP8533 profile:

```
nx9500-6C8809(config-profile-testAP8533)#show context include-factory | include otls
otls forward 5GHz enable
otls forward 2.4GHz enable
otls server-ip 192.168.13.10
otls control-port 8890
otls data-port 2.4GHz 8888
otls data-port 5GHz 8889
otls apid 12345
nx9500-6C8809(config-profile-testAP8533)#
```

### *offline-duration*

[Profile Config Commands](#) on page 862

Sets the duration, in minutes, for which a device remains unadopted before it generates offline event

This command is also supported on the device configuration mode.

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
offline-duration <5-43200>
```

### Parameters

```
offline-duration <5-43200>
```

|                                                   |                                                                    |
|---------------------------------------------------|--------------------------------------------------------------------|
| <b>offline-duration</b><br><b>&lt;5-43200&gt;</b> | Specify a value from 5 - 43200 minutes. The default is 10 minutes. |
|---------------------------------------------------|--------------------------------------------------------------------|

### Example

```
rfs4000-229D58(config-profile-test)#offline-duration 200

rfs4000-229D58(config-profile-test)#show context
profile rfs4000 test
no autoinstall configuration
no autoinstall firmware
crypto ikev1 policy ikev1-default
 isakmp-proposal default encryption aes-256 group 2 hash sha
.....
interface wwan1
interface pppoe1
use firewall-policy default
service pm sys-restart
```

```
router ospf
offline-duration 200
rfs4000-229D58(config-profile-test)#
```

### Related Commands

|------------------------------|-----------------------------------------------------|
| <code>no</code> on page 1200 | Resets the offline-duration to default (10 minutes) |
|------------------------------|-----------------------------------------------------|

### *power-config*

[Profile Config Commands](#) on page 862

Configures the power option mode. Use this command in the profile configuration mode to configure the transmit output power of access point radios. This command is also available in the device-config mode.

Single radio model access points always operate using a full power configuration. The power management configurations described in this section do not apply to single radio models. When an access point is powered on for the first time, the system determines the power budget available to the access point. If 802.3af is selected, the access point assumes 12.95 watts is available. If the mode is changed, the access point requires a reset to implement the change. If 802.3at is selected, the access point assumes 23 - 26 watts is available.

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
power-config [af-option|at-option|mode]
```

```
power-config [af-option|at-option] [range|throughput]
```

```
power-config mode [auto|3af]
```

### Parameters

```
power-config [af-option|at-option] [range|throughput]
```

|                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>power-config</b>                                       | Configures the power option mode                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>af-option</b><br><b>[range  </b><br><b>throughput]</b> | <p>Configures the 802.3.af power mode option. The options are:</p> <ul style="list-style-type: none"> <li>range – Configures the af power range mode. This mode provides higher power but fewer transmission (tx) chains.</li> </ul> <p>Select range when range is preferred over performance for broadcast/multicast (group) traffic. The data rates used for range are the lowest defined basic rates.</p> <ul style="list-style-type: none"> <li>throughput – Configures the af power throughput mode. |------------------------------|-----------------------------------------------------------|

### *preferred-controller-group*

[Profile Config Commands](#) on page 862

Specifies the controller group preferred for adoption

At adoption, an access point solicits and receives multiple adoption responses from controllers and service platforms available on the network. These adoption responses contain loading policy information the access point uses to select the optimum controller or service platform for adoption. After selecting the controller or service platform, the access point associates with it and optionally obtains an image upgrade and configuration. By default, an auto provisioning policy generally distributes AP adoption evenly amongst available controllers and service platforms. Use this command to specify the controller or service platform preferred for adoption. Once configured, the access point adopts to the specified preferred controller or service platform.

#### **Supported in the following platforms:**

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

#### **Syntax**

```
preferred-controller-group <WORD>
```

#### **Parameters**

```
preferred-controller-group <WORD>
```

|                     |                                                                                                                                                                                                       |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>&lt;WORD&gt;</b> | Specify the name of the controller (wireless controller or service platform) group preferred for adoption. Devices using this profile are added, on adoption, to the controller group specified here. |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

#### **Example**

```
NOC-NX9500(config-profile-testNX9000)#preferred-controller-group testGroup
```

```
NOC-NX9500(config-profile-testNX9000)#show context include-factory | include preferred-controller-group
 preferred-controller-group testGroup
NOC-NX9500(config-profile-testNX9000)#
```

### *preferred-tunnel-controller*

[Profile Config Commands](#) on page 862

Configures the tunnel controller's name preferred for tunneling extended VLAN traffic. Devices using this profile will prefer to route their extended VLAN traffic through the specified tunnel controller (wireless controller or service platform).

**Supported in the following platforms:**

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

**Syntax**

```
preferred-tunnel-controller <NAME>
```

**Parameters**

```
preferred-tunnel-controller <NAME>
```

|                                                       |                                      |
|-------------------------------------------------------|--------------------------------------|
| <code>preferred-tunnel-controller &lt;NAME&gt;</code> | Configures the preferred tunnel name |
|-------------------------------------------------------|--------------------------------------|

**Example**

```

## *rf-domain-manager*

[Profile Config Commands](#) on page 862

Configures the RF Domain manager election criteria

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
rf-domain-manager [capable|priority <1-255>]
```

### Parameters

```
rf-domain-manager [capable|priority <1-255>]
```

|                               |                                                                                                                                                                                                                                                                                                                    |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>rf-domain-manager</b>      | Configures the RF Domain manager election criteria                                                                                                                                                                                                                                                                 |
| <b>capable</b>                | Enables devices using this profile capable of being elected as the RF Domain manager. The RF Domain manager stores and provisions configuration and firmware images for other members of the RF Domain. It also updates state changes, if any, to RF Domain members. This option is enabled by default.            |
| <b>priority &lt;1-255&gt;</b> | Assigns a priority value for devices using this profile in the RF Domain manager election process. The higher the number set, higher is the device's priority in the RF Domain manager election process. <ul style="list-style-type: none"> <li>• &lt;1-255&gt; – Select a priority value from 1 - 255.</li> </ul> |

### Example

```
NOC-NX9500(config-profile-testNX9000)#rf-domain-manager capable
```

```
NOC-NX9500(config-profile-testNX9000)#rf-domain-manager capable
```

```
NOC-NX9500(config-profile-testNX9000)#show context include-factory | include rf-
domain-manager
 rf-domain-manager capable
 rf-domain-manager priority 1
NOC-NX9500(config-profile-testNX9000)#
```

## router

[Profile Config Commands](#) on page 862

Enables dynamic routing (BGP and/or OSPF) and enters the routing protocol configuration mode

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Note

BGP is supported only on RFS4000, NX75XX, and NX 95XX model controllers and service platforms.

The NX 95XX service platforms do not support OSPF routing.

The access points only support OSPF routing.

### Syntax

```
router [bgp|ospf]
```

## Parameters

router [bgp|ospf]

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>router</b> | Enables dynamic routing and enters the routing protocol configuration mode                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>bgp</b>    | <p>Enables BGP dynamic routing and configures relevant settings</p> <p>BGP is an inter-ISP routing protocol, which establishes routing between ISPs. ISPs use BGP to exchange routing and reachability information between Autonomous Systems (AS) on the Internet. BGP uses TCP as its transport protocol, eliminating the need to implement explicit update fragmentation, retransmission, acknowledgement, and sequencing. Routing information exchanged through BGP supports destination based forwarding only. It assumes a router forwards packets based on the destination address carried in the IP header of the packet.</p> <p>An AS is a set of routers under the same administration that use Interior Gateway Protocol (IGP) and common metrics to define how to route packets within the AS.</p> <p>For more information on dynamic BGP routing configurations, see <a href="#">BORDER GATEWAY PROTOCOL</a> on page 1852.</p> |
| <b>ospf</b>   | <p>Enables OSPF dynamic routing and configures relevant settings. Changes configuration mode to router mode</p> <p>OSPF is a link-state IGP. OSPF routes IP packets within a single routing domain (autonomous system), like an enterprise LAN. OSPF gathers link state information from neighbor routers and constructs a network topology. The topology determines the routing table presented to the Internet Layer which makes routing decisions based solely on the destination IP address found in IP packets.</p> <p>For more information on dynamic OSPF routing configurations, see <a href="#">ROUTER-MODE</a> on page 1722.</p>                                                                                                                                                                                                                                                                                                  |

## Example

```
nx9500-6C8809(config-profile-default-rfs4000)#router ospf
```

```
nx9500-6C8809(config-profile default-rfs4000-router-ospf)#?
```

```
Router OSPF Mode commands:
```

```
area OSPF area
auto-cost OSPF auto-cost
default-information Distribution of default information
ip Internet Protocol (IP)
network OSPF network
no Negate a command or set its defaults
ospf Ospf
passive Make OSPF Interface as passive
redistribute Route types redistributed by OSPF
route-limit Limit for number of routes handled OSPF process
router-id Router ID

clrscr Clears the display screen
commit Commit all changes made in this session
do Run commands from Exec mode
end End current mode and change to EXEC mode
exit End current mode and down to previous mode
help Description of the interactive help system
revert Revert changes
service Service Commands
show Show running system information
write Write running configuration to memory or terminal
```

```
nx9500-6C8809(config-profile default-rfs4000-router-ospf)#
```

*spanning-tree*

[Profile Config Commands](#) on page 862

Enables spanning tree commands. Use these commands to configure the errdisable, multiple spanning tree and portfast settings.

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
spanning-tree [errdisable|mst|portfast]
```

```
spanning-tree errdisable recovery [cause bpduguard|interval <10-1000000>]
```

```
spanning-tree mst [<0-15>|cisco-interoperability|enable|forward-time|
hello-time|instance|max-age|max-hops|region|revision]
```

```
spanning-tree mst [<0-15> priority <0-61440>|cisco-interoperability
[enable|disable]|enable|forward-time <4-30>|hello-time <1-10>|instance
<1-15>| max-age <6-40>|max-hops <7-127>|region <LINE>|revision <0-255>]
```

```
spanning-tree portfast [bpdufilter|bpduguard] default
```

### Parameters

```
spanning-tree errdisable recovery [cause bpduguard|interval <10-1000000>]
```

|                                              |                                                                                                                                                                                                    |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>spanning-tree</b>                         | Configures spanning-tree related parameters                                                                                                                                                        |
| <b>errdisable</b>                            | Disables or shuts down ports where traffic is looping, or ports with traffic in one direction                                                                                                      |
| <b>recovery</b>                              | Enables the timeout mechanism for a port to be recovered. This option is disabled by default.                                                                                                      |
| <b>cause</b><br><b>bpduguard</b>             | Specifies the reason for errdisable <ul style="list-style-type: none"><li>• bpduguard - Recovers from errdisable due to bpduguard</li></ul>                                                        |
| <b>interval</b><br><b>&lt;10-1000000&gt;</b> | Specifies the interval after which a port is enabled <ul style="list-style-type: none"><li>• &lt;10-1000000&gt; - Specify a value from 10 - 1000000 seconds. The default is 300 seconds.</li></ul> |

```
spanning-tree mst [<0-15> priority <0-61440>|cisco-interoperability [enable|disable]|

### Usage Guidelines

If a bridge does not hear BPDUs from the root bridge within the specified interval, assume the network has changed and recomputed the spanning-tree topology.

Generally, spanning tree configuration settings in the config mode define the configuration for bridge and bridge instances.

MSTP is based on instances. An instance is a group of VLANs with a common spanning tree. A single VLAN cannot be associated with multiple instances.

Wireless Controllers or service platforms with the same instance, VLAN mapping, revision number and region names define a unique region. Wireless Controllers or service platforms in the same region exchange BPDUs with instance record information within.

### Example

```

nx9500-6C8809(config-profile-default-rfs4000)#spanning-tree errdisable recovery cause
bpduguard

nx9500-6C8809(config-profile-default-rfs4000)#spanning-tree mst 2 priority 4096

### *traffic-class-mapping*

[Profile Config Commands](#) on page 862

Maps the IPv6 traffic class value of incoming IPv6 untagged packets to 802.1p priority. This mapping is required to provide priority of service to some packets over others. For example, VoIP packets get higher priority than data packets to provide a better quality of service for high priority voice traffic. Devices use the traffic class field in the IPv6 header to set this priority. This command allows you to assign a priority for different IPv6 traffic types.

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
traffic-class-mapping <IPv6-TRAFFIC-CLASS-VALUE> priority <0-7>
```

### Parameters

```
traffic-class-mapping <IPv6-TRAFFIC-CLASS-VALUE> priority <0-7>
```

### *traffic-shape*

[Profile Config Commands](#) on page 862

Enables traffic shaping and configures traffic shaping parameters. This command is applicable to both the profile and device configuration modes.

Traffic shaping is a means of regulating data transfers and ensuring a specific level of performance within a network. Traffic shaping does the following:

- Controls flow of packets based on their priority value. Prioritized traffic streams are given priority over less important traffic.
- Controls traffic on an interface to match its flow to the speed of a remote target's interface and ensure traffic conforms to applied policies
- Shapes traffic to meet downstream requirements and eliminate network congestion when data rates are in conflict.

Use this option to apply traffic shaping to specific applications or application categories. Note, in scenarios where a traffic class is matched against an application, application-category, and ACL rule, the application rule will be applied first, followed by the application-category, and finally the ACL. Further, using traffic shaping, an application takes precedence over an application category.

To enable traffic shaping, configure QoS values on the basis of which priority of service is provided to some packets over others. For example, VoIP packets get higher priority than data packets to provide a better quality of service for high priority voice traffic. For configuring IPv6 traffic class mappings, see [traffic-class-mapping](#) on page 1223. And for configuring DSCP traffic class mappings, see [dscp-mapping](#) on page 989.

---

**Supported in the following platforms:**

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530

**Syntax**

```
traffic-shape [activation-criteria|app-category|application|class|enable|priority-map|total-bandwidth]
```

```
traffic-shape activation-criteria [always|cluster-master|rf-domain-manager|vrrp-master <1-255>]
```

```
traffic-shape app-category <APP-CATEGORY-NAME> class <1-4>
```

```
traffic-shape application <APPLICATION-NAME> class <1-4>
```

```
traffic-shape class <1-4> [max-buffers|max-latency|rate]
```

```
traffic-shape class <1-4> max-buffers <1-400> {red-level <1-400>/red-percent <1-100>}
```

```
traffic-shape class <1-4> max-latency <1-1000000> [msec|usec]
```

```
traffic-shape class <1-4> rate [<1-250000> [Kbps|Mbps]]|total-bandwidth-percent <1-100>]
```

**Note**

The available range for the 'rate' field will vary depending on the unit selected. It is 250 - 250000 for Kbps and 1 - 250 for Mbps.

---

```
traffic-shape priority-map <0-7>
```

```
traffic-shape total-bandwidth <1-1000000> [Kbps|Mbps]
```

**Note**

The available range for the 'total-bandwidth' field will vary depending on the unit selected. It is 250 - 1000000 for Kbps and 1 - 1000 for Mbps.

---

```
traffic-shape enable
```

**Parameters**

```
traffic-shape activation-criteria [always|cluster-master|rf-domain-manager|vrrp-master <1-255>]
```

This is the default setting.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>cluster-master</b>                    | Invokes traffic shaping when the device is the cluster master. The solitary cluster master (elected using a priority assignment scheme) is a cluster member that provides management configuration and Smart RF data to other members within the cluster. Cluster requests go through the elected master before dissemination to other cluster members.                                                                                                                                       |
| <b>rf-domain-manager</b>                 | Invokes traffic shaping when the device is the RF Domain manager. The RF Domain manager is the elected member capable of storing and provisioning configuration and firmware images for other members of the RF Domain.                                                                                                                                                                                                                                                                       |
| <b>vrrp-master &lt;1-255&gt;</b>         | Invokes traffic shaping when the device is the VRRP master. As the VRRP master, the device responds to ARP requests, forwards packets with a destination link MAC layer address equal to the virtual router MAC layer address, rejects packets addressed to the IP associated with the virtual router and accepts packets addressed to the IP associated with the virtual router. <ul style="list-style-type: none"> <li>• &lt;1-255&gt; - Specify the VRRP group ID from 1 - 255.</li> </ul> |

```
traffic-shape app-category <APP-CATEGORY-NAME> class <1-4>
```

|                                                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>traffic-shape class &lt;1-4&gt; rate</b>  | <p>Configures traffic rate, in either Kbps, Mbps or percentage, for the different traffic shaper class. Specify rates for different traffic shaper class to control the maximum traffic rate sent or received on an interface. Consider this form of rate limiting on interfaces at the edge of a network to limit traffic into or out of the network. Traffic within the set limit is sent and traffic exceeding the set limit is dropped or sent with a different priority.</p> <ul style="list-style-type: none"> <li>class &lt;1-4&gt; – Specify the traffic-shaper class from 1 - 4.</li> </ul> |
| <b>&lt;1-250000&gt; [Kbps   Mbps]</b>        | <p>Configures the traffic rate, in Kbps, Mbps, for the class specified in the previous step</p> <ul style="list-style-type: none"> <li>&lt;1-250000&gt; – Specify the rate from 1 - 250000.</li> <li>[Kbps Mbps] – Configures the unit for measuring bandwidth as Kbps or Mbps. The default setting is Kbps.</li> </ul> <p><b>Note:</b> The range varies depending on the unit selected. traffic-shape enable

|                             |                                                                                                                                                                               |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>traffic-shape enable</b> | <p>Enables traffic shaping using the defined bandwidth, rate and class mappings configured using this command</p> <p><b>Note:</b> Traffic shaping is disabled by default.</p> |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Usage Guidelines

Following are the default max-buffers set for the traffic shaper classes:

```
traffic-shape class 1 max-buffers 35 35 35 30 25 20 15 10 red-level 27 27 27 23 25 20 15 10
traffic-shape class 2 max-buffers 35 35 35 30 25 20 15 10 red-level 27 27 27 23 25 20 15 10
traffic-shape class 3 max-buffers 35 35 35 30 25 20 15 10 red-level 27 27 27 23 25 20 15 10
traffic-shape class 4 max-buffers 35 35 35 30 25 20 15 10 red-level 27 27 27 23 25 20 15 10
```

Following is the default priority-map settings:

```
traffic-shape priority-map 2 0 1 3 4 5 6 7
```

### Example

*trustpoint* (profile-config-mode)

[Profile Config Commands](#) on page 862

Configures the trustpoint assigned for validating a CMP auth Operator

A certificate links identity information with a public key enclosed in the certificate.

A CA is a network authority that issues and manages security credentials and public keys for message encryption. The CA signs all digital certificates it issues with its own private key. The corresponding public key is contained within the certificate and is called a CA certificate. A browser must contain the CA certificate in its Trusted Root Library so it can trust certificates signed by the CA's private key.

Depending on the public key infrastructure, the digital certificate includes the owner's public key, the certificate expiration date, the owner's name and other public key owner information.

Each certificate is digitally signed by a trustpoint. The trustpoint signing the certificate can be a certificate authority, corporation or individual. A trustpoint represents a CA/identity pair containing the identity of the CA, CA-specific configuration parameters, and an association with an enrolled identity certificate.

#### Note

Certificates/trustpoints used in this command should be verifiable as existing on the device. For information on configuring trustpoints on a device, see [trustpoint \(device-config-mode\)](#) on page 1282.

#### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

```
trustpoint [cmp-auth-operator|https|radius-ca|radius-server] <TRUSTPOINT-NAME>
```

#### Parameters

```
trustpoint [cmp-auth-operator|https|radius-ca|radius-server] <TRUSTPOINT-NAME>
```

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>https</b>             | Assigns an existing trustpoint to validate HTTPS requests                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>cmp-auth-operator</b> | Assigns an existing trustpoint to validate CMP auth operator Once validated, CMP is used to obtain and manage digital certificates in a PKI network. Digital certificates link identity information with a public key enclosed within the certificate, and are issued by the CA. Use this command to specify the CMP-assigned trustpoint. When specified, devices send a certificate request to the CMP supported CA server, and download the certificate directly from the CA server. CMP supports multiple request options through for device communicating to a CMP supported CA server. The device can initiate a request for getting the certificates from the server. It can also auto update the certificates which are about to expire. |
| <b>radius-ca</b>         | Assigns an existing trustpoint to validate client certificates in EAP                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|                                |                                                                                                                                                                                                                                                                   |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>radius-server</b>           | Assigns an existing trustpoint to validate RADIUS server certificate                                                                                                                                                                                              |
| <b>&lt;TRUSTPOINT-NAME&gt;</b> | The following keyword is common to all of the above parameters: <ul style="list-style-type: none"> <li>• &lt;TRUSTPOINT-NAME&gt; – After selecting the service to validate, specify the trustpoint name (should be existing and stored on the device).</li> </ul> |

### Example

```
nx9500-6C8809(config-profile-testNX9500)#trustpoint cmp-auth-operator test
```

```
nx9500-6C8809(config-profile-testNX9500)#show context
profile nx9000 testNX9500
 no autoinstall configuration
 no autoinstall firmware
 crypto ikev1 policy ikev1-default
 isakmp-proposal default encryption aes-256 group 2 hash sha

 service pm sys-restart
 router bgp
 trustpoint cmp-auth-operator test
nx9500-6C8809(config-profile-testNX9500)#
```

## tunnel-controller

[Profile Config Commands](#) on page 862

Configures the tunneled WLAN (extended VLAN) wireless controller or service platform's name

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
tunnel-controller <NAME>
```

### Parameters

```
tunnel-controller <NAME>
```

|                                                 |                                                                                                                                                                                  |
|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>tunnel-controller</b><br><b>&lt;NAME&gt;</b> | Configures the tunneled WLAN (extended VLAN) wireless controller or service platform's name <ul style="list-style-type: none"> <li>• &lt;NAME&gt; – Specify the name.</li> </ul> |
|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Example

```
rfs7000-37FABE(config-profile-default-rfs4000)#tunnel-controller testgroup
```

[Profile Config Commands](#) on page 862

Configures VRRP group settings

A default gateway is a critical resource for connectivity. However, it is prone to a single point of failure. Thus, redundancy for the default gateway is required. If WAN backhaul is available, and a router failure occurs, then the controller should act as a router and forward traffic on to its WAN link.

Define an external VRRP configuration when router redundancy is required in a network requiring high availability.

Central to VRRP configuration is the election of a VRRP master. A VRRP master (once elected) performs the following functions:

- Responds to ARP requests
- Forwards packets with a destination link layer MAC address equal to the virtual router's MAC address

- Rejects packets addressed to the IP address associated with the virtual router, if it is not the IP address owner
- Accepts packets addressed to the IP address associated with the virtual router, if it is the IP address owner or accept mode is true.

The nodes that lose the election process enter a backup state. In the backup state they monitor the master for any failures, and in case of a failure one of the backups, in turn, becomes the master and assumes the management of the designated virtual IPs. A backup does not respond to an ARP request, and discards packets destined for a virtual IP resource.

#### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7622, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

```
vrrp [<1-255>|version]
```

```
vrrp <1-255> [delta-priority|description|interface|ip|monitor|preempt|priority| sync-group|timers]
```

```
vrrp <1-255> [delta-priority <1-253>|description <LINE>|ip <IP> {<IP>}|preempt {delay <1-65535>}|priority <1-254>|sync-group]
```

```
vrrp <1-255> interface vlan <1-4094>
```

```
vrrp <1-255> monitor [<IF-NAME>|critical-resource|pppoe1|vlan|wwan1]
```

```
vrrp <1-255> monitor [<IF-NAME>|pppoe1|vlan <1-4094>|wwan1] {(<IF-NAME>|critical-resource|pppoe1|vlan|wwan1)}
```

```
vrrp <1-255> monitor critical-resource <CRM-NAME1> <CRM-NAME2> <CRM-NAME3> <CRM-NAME4> (action [decrement-priority|increment-priority] {<IF-NAME>|pppoe1| vlan|wwan1})
```

```
vrrp <1-255> timers advertise [<1-255>|centiseconds <25-4095>|msec <250-999>]
```

```
vrrp version [2|3]
```

#### Parameters

```
vrrp <1-255> [delta-priority <1-253>|description <LINE>|vrrp ip <IP> {<IP>}| preempt {delay <1-65535>}|priority <1-254>|sync-group]
```

|                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>vrrp &lt;1-255&gt;</b>              | Configures the virtual router ID from 1- 255. Identifies the virtual router the packet is reporting status for.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>delta-priority &lt;1-253&gt;</b>    | Configures the priority to decrement (local link monitoring and critical resource monitoring) or increment (critical resource monitoring). When the monitored interface is down, the configured priority decrements by a value defined by the delta-priority option. When monitoring critical resources, the value increments by the delta-priority option. <ul style="list-style-type: none"> <li>• &lt;1-253&gt; - Specify the delta priority level from 1- 253.</li> </ul>                                                                                      |
| <b>description &lt;LINE&gt;</b>        | Configures a text description for the virtual router to further distinguish it from other routers with similar configuration <ul style="list-style-type: none"> <li>• &lt;LINE&gt; - Provide a description (a string from 1- 64 characters in length)</li> </ul>                                                                                                                                                                                                                                                                                                   |
| <b>ip &lt;IP-ADDRESSES&gt;</b>         | Identifies the IP address(es) backed by the virtual router. These are IP addresses of Ethernet switches, routers, and security appliances defined as virtual router resources. <ul style="list-style-type: none"> <li>• &lt;IP-ADDRESSES&gt; - Specify the IP address(es) in the A.B.C.D format.</li> </ul> <p>This configuration triggers VRRP operation.</p>                                                                                                                                                                                                     |
| <b>preempt {delay &lt;1-65535&gt;}</b> | Controls whether a high priority backup router preempts a lower priority master. This field determines if a node with higher priority can takeover all virtual IPs from a node with lower priority. This feature is disabled by default. <ul style="list-style-type: none"> <li>• delay - Optional. Configures the pre-emption delay timer from 1 - 65535 seconds (default is 0 seconds). This option can be used to delay sending out the master advertisement or, in case of monitored link coming up, adjusting the VRRP priority by priority delta.</li> </ul> |
| <b>priority &lt;1-254&gt;</b>          | Configures the priority level of the router within a VRRP group. This value determines which node is elected as the Master. Higher values imply higher priority, value 254 has the highest precedence (default is 100).                                                                                                                                                                                                                                                                                                                                            |
| <b>sync-group</b>                      | Adds this VRRP group to a synchronized group. To trigger VRRP failover, it is essential all individual groups within a synchronized group have failover. VRRP failover is triggered if an advertisement is not received from the virtual masters that are part of this VRRP sync group. This feature is disabled by default.                                                                                                                                                                                                                                       |

```
vrrp <1-255> interface vlan <1-4094>
```

### *vrp-state-check*

[Profile Config Commands](#) on page 862

Publishes interface via OSPF or BGP based on Virtual Router Redundancy Protocol (VRRP) status

VRRP allows automatic assignment of available IP routers to participating hosts. This increases the availability and reliability of routing paths via automatic default gateway selections on an IP subnetwork. This option is enabled by default.

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7622, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
vrp-state-check
```

### Parameters

None

### Example

```

## virtual-controller

[Profile Config Commands](#) on page 862

Enables an access point as a virtual-controller (VC) or a dynamic virtual controller (DVC)

When configured without the 'auto' option, this command manually enables an AP as a VC. The 'auto' option allows dynamic enabling of APs as VCs. When DVC is enabled on an AP's device or profile context, the AP is dynamically enabled as the VC on being elected as the RF-Domain manager.

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Note

The DVC feature is supported only on the AP7522, AP7532, AP7562, AP8432, and AP8533 model access points.

### Syntax

```
virtual-controller {auto|management-interface}
```

```
virtual-controller auto
```

```
virtual-controller {management-interface [ip address <IP/M>|vlan <1-4094>]}
```

### Parameters

```
virtual-controller auto
```

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>virtual-controller auto</b> | <p>Enables an AP as a virtual-controller</p> <ul style="list-style-type: none"><li>• auto – Enables AP as a DVC. When enabled, the AP on being elected as the RF Domain manager takes on the role of the virtual controller. In an RF-Domain, DVC can be enabled on multiple access points. However, only the current RF-Domain manager AP has a running instance of the DVC. This option is applicable only if enabling DVC.</li></ul> <p><b>Note:</b> MLCP discovery does not function on APs enabled as VC or DVCs. Do an explicit “mint link vlan X” on the AP's device/profile context, or “control-vlan X” in the AP's RF-Domain context, to establish MiNT links between the VC and its adopted APs.</p> |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
virtual-controller {management-interface [ip address <IP/M>|vlan <1-4094>]}
```

```

virtual-

controller

{management-

interface [ip

address <IP/M> |

vlan <1-4094>]}

```

**Note:** Enables an AP as a virtual-controller. If enabling DVC, use this option to configure management interface details.

- management-interface - Configures the management interface for the DVC. Configuring the management interface ensures failover in case the RF Domain manager is unreachable.
- ip address <IP/M> - Specify the management interface IP address. Due to the random nature of DVC, specifying an explicit management interface IP address makes it easier to manage VCs. In case of fail over, this IP address is installed as the secondary IP address on the new VC.
- vlan <1-4094> - Optional. Specifies the VLAN from 1 - 4094 on which the management interface IP address is configured.

For DVC, configuring management-interface ip address is mandatory. However, VLAN configuration is optional. If you configure the ip address without specifying the VLAN, the system configures the specified ip address as secondary ip on VLAN 1.

### Example

```

ap8533-9A1529(config-device-74-67-F7-9A-15-29)#virtual-controller auto

ap8533-9A1529(config-device-74-67-F7-9A-15-29)#virtual-controller management-interface ip
address 110.110.110.120/24

ap8533-9A1529(config-device-74-67-F7-9A-15-29)#virtual-controller management-interface
vlan 100

ap8533-9A1529(config-device-74-67-F7-9A-15-29)#show context | include virtual-controller
virtual-controller auto
virtual-controller management-interface ip address 110.110.110.120/24
virtual-controller management-interface vlan 100
ap8533-9A1529(config-device-74-67-F7-9A-15-29)#

```

The following example shows the management interface VLAN IP address being configured as the secondary IP address.

```

ap8533-9A1529(config-device-74-67-F7-9A-15-29)#show ip interface brief

INTERFACE IP-ADDRESS/MASK TYPE STATUS PROTOCOL

vlan1 10.1.1.11/24 primary UP up
vlan100 110.110.110.110/24 primary UP up
vlan100 110.110.110.120/24 secondary UP up

```

### wep-shared-key-auth

[Profile Config Commands](#) on page 862

Enables support for 802.11 WEP shared key authentication

When enabled, devices, using this profile, use a WEP key to access the network. The controller or service platform use the key algorithm to convert an ASCII string to the same hexadecimal number. Clients without the recommended adapters need to use WEP keys manually configured as hexadecimal numbers. This option is disabled by default.

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

```
service memory kernel decrease
```

|                                       |                                                                                                                                                                                                                                |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>service memory kernel decrease</b> | Enables reduction in kernel memory usage. When enabled, firewall flows are reduced by 75% resulting in reduced kernel memory usage. A reboot is required for the option to take effect.<br>This option is disabled by default. |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
service meshpoint loop-prevention-port [<L2-INTERFACE-NAME>|ge <1-4>| port-channel <1-2>]
```

|                                       |                                                                                                                                                                                                            |
|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>meshpoint loop-prevention-port</b> | Limits meshpoint loop prevention to a single port                                                                                                                                                          |
| <b>&lt;L2-INTERFACE-NAME&gt;</b>      | Limits meshpoint loop prevention on a specified Ethernet interface <ul style="list-style-type: none"> <li>• &lt;L2-INTERFACE-NAME&gt; - Specify the layer 2 Ethernet interface name.</li> </ul>            |
| <b>ge &lt;1-4&gt;</b>                 | Limits meshpoint loop prevention on a specified GigabitEthernet interface <ul style="list-style-type: none"> <li>• ge &lt;1-4&gt; - Specify the GigabitEthernet interface index from 1 - 4.</li> </ul>     |
| <b>port-channel &lt;1-2&gt;</b>       | Limits meshpoint loop prevention on a specified port-channel interface <ul style="list-style-type: none"> <li>• port-channel &lt;1-2&gt; - Specify the port-channel interface index from 1 - 2.</li> </ul> |

```
service pm sys-restart
```

|                       |                                                                                                                 |
|-----------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>pm sys-restart</b> | Enables the process monitor (PM) to restart the system when a process fails. This option is enabled by default. |
|-----------------------|-----------------------------------------------------------------------------------------------------------------|

```
service power-config [3af-out|force-3at]
```

|                               |                                                                                                       |
|-------------------------------|-------------------------------------------------------------------------------------------------------|
| <b>power-config 3af-out</b>   | Enables LLDP power negotiation, but uses 3af power. This option is disabled by default.               |
| <b>power-config force-3at</b> | Disables LLDP negotiation and forces 802.3at power configuration. This option is disabled by default. |

```
service radius dynamic-authorization additional-port <1-65535>
```

|                                                                     |                                                                                                                                                                                                                                                                                                     |
|---------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>radius dynamic-authorization additional-port &lt;1-65535&gt;</b> | Configures an additional UDP port used by the device to listen for dynamic authorization messages <ul style="list-style-type: none"> <li>• &lt;1-65535&gt; - Specify a value from 1 - 65535. The default is 3799.</li> </ul> <p>The Cisco Identity Services Engine (ISE) server uses port 1700.</p> |
|---------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
service remote-config apply-delay <0-600>
```

|                                                |                                                                                                                                                                                                                                    |
|------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>remote-config apply-delay &lt;0-600&gt;</b> | Delays configuration of a remote device (after it becomes active) by the specified time period <ul style="list-style-type: none"> <li>• &lt;0-600&gt; - Specify a value from 0 - 600 seconds. The default is 0 seconds.</li> </ul> |
|------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
service rss-timeout <0-86400>
```

|                                    |                                                                                                                                                                                                                                                                                                     |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>rss-timeout &lt;0-86400&gt;</b> | Configures the duration, in seconds, for which an adopted access point will continue to provide wireless functions even after losing controller adoption. <ul style="list-style-type: none"> <li>• &lt;0-86400&gt; - Specify a value from 0 - 86400 seconds. The default is 300 seconds.</li> </ul> |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
service watchdog
```

|                 |                                                                                                                                                                                                                                            |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>watchdog</b> | Enables the watchdog. This feature is enabled by default. Enabling the watchdog option implements heartbeat messages to ensure other associated devices are up and running and capable of effectively inter-operating with the controller. |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
service wireless anqp-frag-always
```

|                                  |                                                                                |
|----------------------------------|--------------------------------------------------------------------------------|
| <b>wireless anqp-frag-always</b> | Enables fragmentation of all ANQP packets. This option is disabled by default. |
|----------------------------------|--------------------------------------------------------------------------------|

```
service wireless anqp-frag-size <100-1500>
```

|                                                 |                                                                                                                                                                       |
|-------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>wireless anqp-frag-size &lt;100-1500&gt;</b> | Configures the ANQP packet fragment size <ul style="list-style-type: none"> <li>• &lt;100-1500&gt; - Specify a value from 100 - 1500. The default is 1200.</li> </ul> |
|-------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
service wireless client tx-deauth on-radar-detection
```

|                                     |                                                                                                                                   |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <b>wireless client</b>              | Configures wireless client and stations related settings                                                                          |
| <b>tx-deauth on-radar-detection</b> | Enables access points to transmit deauth to clients when changing channels on radar detection. This option is enabled by default. |

```
service wireless cred-cache-sync [full|interval <30-864000>|never|partial]
```

|                                             |                                                                                                                                                                                                                             |
|---------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>wireless cred-cache-sync</b>             | Configures the credential cache's synchronization parameters. The parameters are: full, interval, never, and partial.                                                                                                       |
| <b>full</b>                                 | Enables synchronization of all credential cache entries                                                                                                                                                                     |
| <b>interval</b><br><b>&lt;30-864000&gt;</b> | Sets the interval, in seconds, at which the credential cache is synchronized <ul style="list-style-type: none"> <li>• &lt;30-864000&gt; - Specify a value from 30 - 864000 seconds. The default is 1200 seconds.</li> </ul> |
| <b>never</b>                                | Disables credential cache entry synchronization for all associated clients other than roaming clients. This is the default setting.                                                                                         |
| <b>partial</b>                              | Enables partial synchronization of parameters for associated clients, with credential cache close to aging out                                                                                                              |

```
service wireless inter-ap-key [0 <WORD> | 2 <WORD> | <WORD>]
```

|                                                         |                                                                                                   |
|---------------------------------------------------------|---------------------------------------------------------------------------------------------------|
| <b>wireless inter-ap-key</b>                            | Configure encryption key used for securing inter-ap messages. This option is disabled by default. |
| <b>[ 0&lt;WORD&gt;   2&lt;WORD&gt;   &lt;WORD&gt; ]</b> | Specify a clear text or encrypted key.                                                            |

```
service wireless noise-immunity
```

|                                |                                                                                                      |
|--------------------------------|------------------------------------------------------------------------------------------------------|
| <b>wireless noise-immunity</b> | Polls for status and reconfigures radio in case of receive stall. This option is enabled by default. |
|--------------------------------|------------------------------------------------------------------------------------------------------|

```
service wireless reconfig-on-rx-stall
```

|                                      |                                     |
|--------------------------------------|-------------------------------------|
| <b>wireless reconfig-on-rx-stall</b> | Enables noise immunity on the radio |
|--------------------------------------|-------------------------------------|

```
service wireless test [max-rate|min-rate] [1,2,5.5,6,11,12,18,24,36,48,54,mcs0,mcs1,.....mcs23]
```

|                            |                                                                                                                                             |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <b>wireless test</b>       | Configures the serviceability parameters used for testing                                                                                   |
| <b>[max-rate min-rate]</b> | Configures the maximum and minimum data rates for clients using rate-scaling. The 'max-rate' and min-rate' options are disabled by default. |
| <b>[1,2,5.5,...mcs23]</b>  | Select the maximum and minimum data rates applicable.                                                                                       |

```
service wireless test max-retries <0-15>
```

|                                 |                                                                                    |
|---------------------------------|------------------------------------------------------------------------------------|
| <b>wireless test</b>            | Configures the serviceability parameters used for testing                          |
| <b>max-retries &lt;0-15&gt;</b> | Configures the maximum number of retries per packet from 0 - 15. The default is 0. |

```
service wireless wispe-controller-port <1-65535>
```

|                                                        |                                                                                                                                                                                                                                                  |
|--------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>wispe-controller-port</b><br><b>&lt;1-65535&gt;</b> | Resets the Wireless Switch Protocol Enhanced (WISPe) controller port. This is the UDP port used to listen for WISPe. <ul style="list-style-type: none"> <li>• &lt;1-65535&gt; - Specify a value from 1 - 65535. The default is 24756.</li> </ul> |

zone

[Profile Config Commands](#) on page 862

Configures the zone for devices using this profile. The zone can also be configured on the device's self context.

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
zone <NAME>
```

### Parameters

```
zone <NAME>
```

|                          |                                                                                                                                 |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>zone &lt;NAME&gt;</b> | Configures the device's zone/area <ul style="list-style-type: none"> <li>• &lt;NAME&gt; - Specify the zone/areaname.</li> </ul> |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------|

### Example

```
nx9500-6C8809(config-profile-testNX9000)#szone Ecospace

nx9500-6C8809(config-profile-testNX9000)#show context include-factory | include
zone
zone Ecospace
nx9500-6C8809(config-profile-testNX9000)#
```

### Related Commands

|                        |                                                       |
|------------------------|-------------------------------------------------------|
| <b>no</b> on page 1200 | Removes the zone configured on this profile or device |
|------------------------|-------------------------------------------------------|

## Device Config Commands

**PROFILES** on page 857

Use the (config) instance to configure device specific parameters

To navigate to this instance, use the following commands:

```
<DEVICE>(config)#<DEVICE-TYPE> <MAC>
<DEVICE>(config-device-<MAC>)#?
```

Device Mode commands:

|                                         |                                                                             |
|-----------------------------------------|-----------------------------------------------------------------------------|
| adopter-auto-provisioning-policy-lookup | Use centralized auto-provisioning policy when adopted by another controller |
| adoption                                | Adoption configuration                                                      |
| adoption-mode                           | Configure the adoption mode for the access-points in this RF-Domain         |
| adoption-site                           | Set system's adoption site                                                  |
| alias                                   | Alias                                                                       |
| application-policy                      | Application Policy configuration                                            |
| area                                    | Set name of area where the system is located?                               |
| arp                                     | Address Resolution Protocol (ARP)                                           |
| auto-learn                              | Auto learning                                                               |
| autogen-uniqueid                        | Autogenerate a unique id                                                    |
| autoinstall                             | Autoinstall settings                                                        |
| bridge                                  | Ethernet bridge                                                             |
| captive-portal                          | Captive portal                                                              |
| cdp                                     | Cisco Discovery Protocol                                                    |
| channel-list                            | Configure channel list to be advertised to wireless clients                 |
| cluster                                 | Cluster configuration                                                       |
| configuration-persistence               | Enable persistence of configuration across reloads (startup config file)    |
| contact                                 | Configure the contact                                                       |
| controller                              | WLAN controller configuration                                               |
| country-code                            | Configure the country of operation                                          |
| critical-resource                       | Critical Resource                                                           |
| crypto                                  | Encryption related commands                                                 |
| database                                | Database command                                                            |
| device-upgrade                          | Device firmware upgrade                                                     |
| device-onboard                          | Device-onboarding configuration                                             |
| dot1x                                   | 802.1X                                                                      |

|                                    |                                                                                 |
|------------------------------------|---------------------------------------------------------------------------------|
| dpi                                | Enable Deep-Packet-Inspection (Application Assurance)                           |
| dscp-mapping                       | Configure IP DSCP to 802.1p priority mapping for untagged                       |
| eguest-server                      | Enable EGuest Server functionality frames                                       |
| email-notification                 | Email notification configuration                                                |
| enforce-version                    | Check the firmware versions of devices before interoperating                    |
| environmental-sensor               | Environmental Sensors Configuration                                             |
| events                             | System event messages                                                           |
| export                             | Export a file                                                                   |
| file-sync                          | File sync between controller and adoptees                                       |
| floor                              | Set the floor within a area where the system is located                         |
| geo-coordinates                    | Configure geo coordinates for this device                                       |
| gre                                | GRE protocol                                                                    |
| hostname                           | Set system's network name                                                       |
| http-analyze                       | Specify HTTP-Analysis configuration                                             |
| interface                          | Select an interface to configure                                                |
| ip                                 | Internet Protocol (IP)                                                          |
| ipv6                               | Internet Protocol version 6 (IPv6)                                              |
| l2tpv3                             | L2tpv3 protocol                                                                 |
| l3e-lite-table                     | L3e lite Table                                                                  |
| lACP                               | LACP commands                                                                   |
| layout-coordinates                 | Configure layout coordinates for this device                                    |
| led                                | Turn LEDs on/off on the device                                                  |
| led-timeout                        | Configure the time for the led to turn off after the last radio state change    |
| legacy-auto-downgrade              | Enable device firmware to auto downgrade when other legacy devices are detected |
| legacy-auto-update                 | Auto upgrade of legacy devices                                                  |
| license                            | License management command                                                      |
| lldp                               | Link Layer Discovery Protocol                                                   |
| load-balancing                     | Configure load balancing parameter                                              |
| location                           | Configure the location                                                          |
| logging                            | Modify message logging facilities                                               |
| mac-address-table                  | MAC Address Table                                                               |
| mac-auth                           | 802.1X                                                                          |
| mac-name                           | Configure MAC address to name mappingss                                         |
| management-server                  | Configure management server address                                             |
| memory-profile                     | Memory profile to be used on the device                                         |
| meshpoint-device                   | Configure meshpoint device parameters                                           |
| meshpoint-monitor-interval         | Configure meshpoint monitoring interval                                         |
| min-misconfiguration-recovery-time | Check controller connectivity after configuration is received                   |
| mint                               | MinT protocol                                                                   |
| mirror                             | Mirroring                                                                       |
| misconfiguration-recovery-time     | Check controller connectivity after configuration is received                   |
| mpact-server                       | MPACT server configuration                                                      |
| neighbor-inactivity-timeout        | Configure neighbor inactivity timeout                                           |
| neighbor-info-interval             | Configure neighbor information exchange interval                                |

|                             |                                                                                     |
|-----------------------------|-------------------------------------------------------------------------------------|
| no                          | Negate a command or set its defaults                                                |
| noc                         | Configure the noc related setting                                                   |
| nsight                      | NSight                                                                              |
| nsight-sensor               | Enable sensor for Nsight                                                            |
| ntp                         | Ntp server A.B.C.D                                                                  |
| offline-duration            | Set duration for which a device remains unadopted before it generates offline event |
| otls                        | Omnitrail Location Server                                                           |
| override-wlan               | Configure RF Domain level overrides for wlan                                        |
| power-config                | Configure power mode                                                                |
| preferred-controller-group  | Controller group this system will prefer for adoption                               |
| preferred-tunnel-controller | Tunnel Controller Name this system will prefer for tunneling extended vlan traffic  |
| radius                      | Configure device-level radius authentication parameters                             |
| raid                        | RAID                                                                                |
| remove-override             | Remove configuration item override from the device (so profile value takes effect)  |
| rf-domain-manager           | RF Domain Manager                                                                   |
| router                      | Dynamic routing                                                                     |
| rsa-key                     | Assign a RSA key to a service                                                       |
| sensor-server               | AirDefense sensor server configuration                                              |
| slot                        | PCI expansion Slot                                                                  |
| spanning-tree               | Spanning tree                                                                       |
| timezone                    | Configure the timezone                                                              |
| traffic-class-mapping       | Configure IPv6 traffic class to 802.1p priority mapping for untagged frames         |
| traffic-shape               | Traffic shaping                                                                     |
| trustpoint                  | Assign a trustpoint to a service                                                    |
| tunnel-controller           | Tunnel Controller group this controller belongs to                                  |
| use                         | Set setting to use                                                                  |
| vrrp                        | VRRP configuration                                                                  |
| vrrp-state-check            | Publish interface via OSPF/BGP only if the interface VRRP state is not BACKUP       |
| wep-shared-key-auth         | Enable support for 802.11 WEP shared key authentication                             |
| zone                        | Configure Zone name                                                                 |
| clrscr                      | Clears the display screen                                                           |
| commit                      | Commit all changes made in this session                                             |
| do                          | Run commands from Exec mode                                                         |
| end                         | End current mode and change to EXEC mode                                            |
| exit                        | End current mode and down to previous mode                                          |
| help                        | Description of the interactive help system                                          |
| revert                      | Revert changes                                                                      |
| service                     | Service Commands                                                                    |
| show                        | Show running system information                                                     |
| write                       | Write running configuration to memory or terminal                                   |

<DEVICE>(config-device-<MAC>)#

The following table summarizes device configuration mode commands:

| Command                                                             | Description                                                                                                                                                                                                            |
|---------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">adopter-auto-provisioning-policy-lookup</a> on page 866 | Enables the use of a centralized auto provisioning policy on this device                                                                                                                                               |
| <a href="#">adoption</a> on page 867                                | Configures a minimum and maximum delay time in the initiation of the device adoption process                                                                                                                           |
| <a href="#">adoption-site</a> on page 1258                          | Sets the device's adoption site name                                                                                                                                                                                   |
| <a href="#">alias</a> on page 870                                   | Configures network, VLAN, and service aliases on a device                                                                                                                                                              |
| <a href="#">application-policy</a> on page 878                      | Associates a RADIUS server provided application policy with this device. When associated, the application policy allows wireless clients (MUs) to always find the RADIUS-supplied application policy in the dataplane. |
| <a href="#">area</a> on page 1259                                   | Sets the name of area where the system is deployed                                                                                                                                                                     |
| <a href="#">arp</a> on page 880                                     | Configures ARP parameters                                                                                                                                                                                              |
| <a href="#">auto-learn</a> on page 882                              | Enables controllers or service platforms to maintain a local configuration record of devices requesting adoption and provisioning. The command also enables learning of a device's host name via DHCP options.         |
| <a href="#">autogen-uniqueid</a> on page 883                        | When executed in the device configuration mode, this command generates a unique ID for the logged device                                                                                                               |
| <a href="#">autoinstall</a> on page 884                             | Autoinstalls firmware image and configuration setup parameters                                                                                                                                                         |
| <a href="#">bridge</a> on page 885                                  | Configures Ethernet Bridging parameters                                                                                                                                                                                |
| <a href="#">captive-portal</a> on page 913                          | Configures captive portal advanced Web page upload on this profile                                                                                                                                                     |
| <a href="#">cdp</a> on page 914                                     | Operates CDP on the device                                                                                                                                                                                             |
| <a href="#">channel-list</a> on page 1260                           | Configures channel list advertised to wireless clients                                                                                                                                                                 |
| <a href="#">cluster</a> on page 915                                 | Sets cluster configuration                                                                                                                                                                                             |
| <a href="#">configuration-persistence</a> on page 917               | Enables configuration persistence across reloads                                                                                                                                                                       |
| <a href="#">contact</a> on page 1261                                | Sets contact information                                                                                                                                                                                               |
| <a href="#">controller</a> on page 918                              | Configures a WLAN's wireless controller or service platform                                                                                                                                                            |
| <a href="#">country-code</a> on page 1261                           | Configures wireless controller or service platform's country code                                                                                                                                                      |
| <a href="#">critical-resource</a> on page 923                       | Monitors user configured IP addresses and logs their status                                                                                                                                                            |
| <a href="#">crypto</a> on page 931                                  | Configures data encryption protocols and settings                                                                                                                                                                      |
| <a href="#">database</a> on page 979                                | Backs up captive-portal and/or NSight database to a specified location and file and configures a low-disk-space threshold value                                                                                        |

| Command                                                 | Description                                                                                                                                                   |
|---------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">device-upgrade</a> on page 981              | Configures device firmware upgrade settings on this device                                                                                                    |
| <a href="#">diag</a> on page 983                        | Enables looped packet logging                                                                                                                                 |
| <a href="#">dot1x</a> on page 984                       | Configures 802.1x standard authentication controls                                                                                                            |
| <a href="#">dpi</a> on page 986                         | Enables Deep Packet Inspection (DPI) on this device                                                                                                           |
| <a href="#">dscp-mapping</a> on page 989                | Configures IP Differentiated Services Code Point (DSCP) to 802.1p priority mapping for untagged frames                                                        |
| <a href="#">eguest-server (VX9000 only)</a> on page 990 | Enables the EGuest daemon when executed without the 'host' option                                                                                             |
| <a href="#">eguest-server (NOC Only)</a> on page 991    | Points to the EGuest server, when executed along with the 'host' option                                                                                       |
| <a href="#">email-notification</a> on page 992          | Configures e-mail notification settings                                                                                                                       |
| <a href="#">enforce-version</a> on page 994             | Checks the device firmware version before attempting connection                                                                                               |
| <a href="#">environmental-sensor</a> on page 995        | Configures the environmental sensor device settings. If the device is an environmental sensor, use this command to configure its settings.                    |
| <a href="#">events</a> on page 998                      | Enables system event message generation and forwarding                                                                                                        |
| <a href="#">export</a> on page 998                      | Enables export of startup.log file after every boot                                                                                                           |
| <a href="#">file-sync</a> on page 999                   | Configures parameters enabling syncing of trustpoint/wireless-bridge certificate between the staging-controller and its adopted access points                 |
| <a href="#">floor</a> on page 1262                      | Sets the floor name where the system is located                                                                                                               |

| <a href="#">router</a> on page 1218                          | Configures dynamic router protocol settings.                                                                              |
| <a href="#">rsa-key</a> on page 1280                         | Assigns a RSA key to SSH                                                                                                  |
| <a href="#">sensor-server</a> on page 1281                   | Configures an AirDefense sensor server                                                                                    |
| <a href="#">spanning-tree</a> on page 1220                   | Enables spanning tree commands on the logged device                                                                       |
| <a href="#">traffic-class-mapping</a> on page 1223           | Maps the IPv6 traffic class value of incoming IPv6 untagged packets to 802.1p priority                                    |
| <a href="#">traffic-shape</a> on page 1224                   | Enables traffic shaping and configures traffic shaping parameters on this device                                          |
| <a href="#">trustpoint (device-config-mode)</a> on page 1282 | Assigns trustpoints to validate various services, such as HTTPS, RADIUS CA, RADIUS server, external LDAP server, etc.     |
| <a href="#">timezone</a> on page 1282                        | Configures wireless controller or service platform's time zone settings                                                   |
| <a href="#">tunnel-controller</a> on page 1231               | Configures the tunneled WLAN (extended VLAN) wireless controller or service platform's name                               |
| <a href="#">use</a> on page 1232                             | Associates different policies and settings with this device                                                               |
| <a href="#">vrrp</a> on page 1238                            | Configures VRRP group settings                                                                                            |
| <a href="#">vrrp-state-check</a> on page 1242                | Publishes interface via OSPF or BGP based on Virtual Router Redundancy Protocol (VRRP) status                             |
| <a href="#">wep-shared-key-auth</a> on page 1244             | Enables support for 802.11 WEP shared key authentication                                                                  |
| <a href="#">raid</a> on page 1284                            | Enables alarm on the array. This command is supported only on the NX9500 series service platform.                         |

### *adoption-site*

[Device Config Commands](#) on page 1252

Sets the device's adoption site name

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
adoption-site <SITE-NAME>
```

### Parameters

```
adoption-site <SITE-NAME>
```

|                                                                                       |
|---------------------------------------------------------------------------------------|
| <b>adoption-site</b> Sets the device's adoption site name<br><b>&lt;SITE-NAME&gt;</b> |
|---------------------------------------------------------------------------------------|

### Example

```
rfs4000-229D58(config-device-00-23-68-22-9D-58)#adoption-site SanJoseMainOffice
```

### Related Commands

|                                                                           |
|---------------------------------------------------------------------------|
| <b>no</b> on page 1271      Disables or reverts settings to their default |
|---------------------------------------------------------------------------|

*area*

[Device Config Commands](#) on page 1252

Sets the physical area where the device (controller, service platform, or access point) is deployed. This can be a building, region, campus or other area that describes the deployment location of the device. Assigning an area name is helpful when grouping devices in RF Domains and profiles, as devices in the same physical deployment location may need to share specific configuration parameters in respect to radio transmission and interference requirements specific to that location.

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
area <AREA-NAME>
```

### Parameters

```
area <AREA-NAME>
```

|                                                                                                                                                                                         |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>area &lt;AREA-NAME&gt;</b> Sets the physical area where the device is deployed<br><b>&lt;AREA-NAME&gt;</b> <AREA-NAME> - Specify the area name (should not 64 characters in length). |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Example

```
nx9500-6C8809(config-device-00-04-96-4A-A7-08)#area RMZEcoSpace

nx9500-6C8809(config-device-00-04-96-4A-A7-08)#show context
ap71xx 00-04-96-4A-A7-08
 use profile default-ap71xx
 use rf-domain default
 hostname ap71361-4AA708
 area RMZEcospace
nx9500-6C8809(config-device-00-04-96-4A-A7-08)#
```

## Related Commands

|                              |                                               |
|------------------------------|-----------------------------------------------|
| <code>no</code> on page 1271 | Disables or reverts settings to their default |
|------------------------------|-----------------------------------------------|

### *channel-list*

[Device Config Commands](#) on page 1252

Configures the channel list advertised to wireless clients

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
channel-list [2.4GHz | 5GHz | dynamic]
channel-list [2.4GHz <CHANNEL-LIST> | 5GHz <CHANNEL-LIST> | dynamic]
```

### Parameters

```
channel-list [2.4GHz <CHANNEL-LIST> | 5GHz <CHANNEL-LIST> | dynamic]
```

|                                              |                                                                                                                                                                                                           |
|----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>channel-list</b>                          | Configures the channel list advertised to wireless clients                                                                                                                                                |
| <b>2.4GHz</b><br><b>&lt;CHANNEL-LIST&gt;</b> | Configures the channel list advertised by radios operating in 2.4 GHz <ul style="list-style-type: none"><li>• &lt;CHANNEL-LIST&gt; - Specify a list of channels separated by commas or hyphens.</li></ul> |
| <b>5GHz &lt;CHANNEL-LIST&gt;</b>             | Configures the channel list advertised by radios operating in 5.0 GHz <ul style="list-style-type: none"><li>• &lt;CHANNEL-LIST&gt; - Specify a list of channels separated by commas or hyphens.</li></ul> |
| <b>dynamic</b>                               | Enables dynamic (neighboring access point based) update of configured channel list                                                                                                                        |

### Example

```
nx9500-6C8809(config-device-00-04-96-4A-A7-08)#channel-list 2.4GHz 1,2

nx9500-6C8809(config-device-00-04-96-4A-A7-08)#show context
ap71xx 00-04-96-4A-A7-08
 use profile default-ap71xx
 use rf-domain default
 hostname ap7161-4AA708
 area RMZEcospace
```

```
channel-list 2.4GHz 1,2
nx9500-6C8809(config-device-00-04-96-4A-A7-08)#
```

### *contact*

[Device Config Commands](#) on page 1252

Defines an administrative contact for a deployed device (controller, service platform, or access point)

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
contact <WORD>
```

### Parameters

```
contact <WORD>
```

|                       |                                                                                     |
|-----------------------|-------------------------------------------------------------------------------------|
| <b>contact</b> <WORD> | Specify the administrative contact name (should not exceed 64 characters in length) |
|-----------------------|-------------------------------------------------------------------------------------|

### Example

```
rfs7000-37FABE(config-device-00-04-96-4A-A7-08)#contact Bob+1-631-738-5200
```

```
rfs7000-37FABE(config-device-00-04-96-4A-A7-08)#show context
ap71xx 00-04-96-4A-A7-08
 use profile default-ap71xx
 use rf-domain default
 hostname ap7131-4AA708
 area RMZEospace
 contact Bob+1-631-738-5200
 channel-list 2.4GHz 1,2
rfs7000-37FABE(config-device-00-04-96-4A-A7-08)#
```

### Related Commands

| <a href="#">no</a> on page 1271 | Resets the administrative contact name |
|---------------------------------|----------------------------------------|

### *country-code*

[Device Config Commands](#) on page 1252

Defines the two digit country code for legal device deployment

Configuring the correct country is central to legal operation. Each country has its own regulatory restrictions concerning electromagnetic emissions and the maximum RF signal strength that can be transmitted.

**Supported in the following platforms:**

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

**Syntax**

country-code <WORD>

**Parameters**

country-code <COUNTRY-CODE>

|                                                    |                                                                                                                                    |
|----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b>country-code</b><br><b>&lt;COUNTRY-CODE&gt;</b> | Defines the two digit country code for legal device deployment<br>• <COUNTRY-CODE> - Specify the two letter ISO-3166 country code. |
|----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|

**Example**

```
nx9500-6C8809(config-device-00-04-96-4A-A7-08)#country-code us

nx9500-6C8809(config-device-00-04-96-4A-A7-08)#show context
ap71xx 00-04-96-4A-A7-08
 use profile default-ap71xx
 use rf-domain default
 hostname ap7161-4AA708
 area RMZEcospace
 contact Bob+1-631-738-5200
 country-code us
 channel-list 2.4GHz 1,2
nx9500-6C8809(config-device-00-04-96-4A-A7-08)#
```

**Related Commands**

|                                 |                                     |
|---------------------------------|-------------------------------------|
| <a href="#">no</a> on page 1271 | Removes the configured country code |
|---------------------------------|-------------------------------------|

*floor*

[Device Config Commands](#) on page 1252

Sets the building floor name representative of the location within the area or building the device (controller, service platform, or access point) is physically deployed. Assigning a building floor name is helpful when grouping devices in RF Domains and profiles, as devices on the same physical building floor may need to share specific configuration parameters in respect to radio transmission and interference requirements specific to that location.

**Supported in the following platforms:**

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533

- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
floor <FLOOR-NAME> <1-4094>
```

### Parameters

```
floor <FLOOR-NAME> <1-4094>
```

|                                                       |                                                                                                                                                                                                                                                                                                            |
|-------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p><b>floor &lt;FLOOR-NAME&gt; &lt;1-4094&gt;</b></p> | <p>Sets the building floor name where the device is deployed</p> <ul style="list-style-type: none"> <li>• &lt;1-4094&gt; - Sets a numerical floor designation in respect to the floor's actual location within a building. Specify a value from 1 - 4094. The default setting is the 1st floor.</li> </ul> |
|-------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Example

```
nx9500-6C8809(config-device-00-04-96-4A-A7-08)#floor 5thfloor
```

```
nx9500-6C8809(config-device-00-04-96-4A-A7-08)#show context
```

```
ap71xx 00-04-96-4A-A7-08
 use profile default-ap71xx
 use rf-domain default
 hostname ap7161-4AA708
 area RMZEcospace
 floor 5thfloor
 contact Bob+1-631-738-5200
 country-code us
 channel-list 2.4GHz 1,2
nx9500-6C8809(config-device-00-04-96-4A-A7-08)#
```

### Related Commands

### *geo-coordinates*

[Device Config Commands](#) on page 1252

Configures the geographic coordinates for this device. Specifies the exact location of this device in terms of latitude and longitude coordinates.

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
geographic coordinates <-90.0000-90.0000> <-180.0000-180.0000>
```

## Parameters

geographic coordinates <-90.0000-90.0000> <-180.0000-180.0000>

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>geographic coordinates</b> | <p>Configures the geographic coordinates for this device</p> <ul style="list-style-type: none"><li>• &lt;-90.0000-90.0000&gt; - Specify the device's latitude coordinate from -90.0000 to 90.0000. When looking at a floor map, latitude lines specify the east-west position of a point on the Earth's surface.</li><li>• &lt;-180.0000-180.0000&gt; - Specify the device's longitude coordinate from -180.0000 to 180.0000. When looking at a floor map, longitude lines specify the north-south position of a point on the Earth's surface.</li></ul> |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Example

```
rfs4000-229D58(config-device-00-23-68-22-9D-58)#geo-coordinates -90.0000 166.0000

rfs4000-229D58(config-device-00-23-68-22-9D-58)#show context

*hostname*

[Device Config Commands](#) on page 1252

Sets the system's network name

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

## Syntax

hostname <WORD>

## Parameters

hostname <WORD>

|                                                                                                                                                                           |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>hostname &lt;WORD&gt;</b> Sets the name of the managing wireless controller, service platform, or access point. This name is displayed when accessed from any network. |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Example

```
nx9500-6C8809(config-device-00-04-96-4A-A7-08)#hostname TechPubAP7161
```

The hostname has changed from 'ap7131-4AA708' to 'TechPubAP7161'

```
nx9500-6C8809(config-device-00-04-96-4A-A7-08)#show context
ap71xx 00-04-96-4A-A7-08
 use profile default-ap71xx
 use rf-domain default
 hostname TechPubAP7161
 area RMZEcospace
 floor 5thfloor
 contact Bob+1-631-738-5200
 country-code us
 channel-list 2.4GHz 1,2
nx9500-6C8809(config-device-00-04-96-4A-A7-08)#
```

## Related Commands

|                        |                           |
|------------------------|---------------------------|
| <b>no</b> on page 1271 | Removes device's hostname |
|------------------------|---------------------------|

*lACP*

[Device Config Commands](#) on page 1252

Configures an LACP-enabled peer's system priority value. LACP uses this system priority value along with the peer's MAC address to form the system ID. In a LAG, the peer with the lower system ID initiates LACP negotiations with another peer. In scenarios, where both peers have the same system-priority value assigned, the peer with the lower MAC gets precedence.

### Note

For more information on enabling link aggregation, see [lACP](#) on page 1029 and [lACP-channel-group](#) on page 1029.

## Supported in the following platforms:

- Service Platforms — NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600

## Syntax

lACP system-priority <1-65535>

## Parameters

lACP system-priority <1-65535>

**lACP system-priority**  
**<1-65535>**

Configures the LACP system priority value

- <1-65535> - Specify a value from 1 - 65535. Lower the value, higher is the priority. Therefore, '1' and '65535' indicate highest and lowest system-priority values respectively. The default value is 32768.

### Example

```
nx9500-6C8809(config-device-B4-C7-99-6C-88-09)#lACP system-priority 1
```

```
nx9500-6C8809(config-device-B4-C7-99-6C-88-09)#show context include-factory | include lACP
lACP system-priority 1
lACP channel-group 1 mode active
lACP port-priority 2
lACP channel-group 1 mode active
lACP port-priority 2
nx9500-6C8809(config-device-B4-C7-99-6C-88-09)#
```

### Related Commands

**no** on page 1271

Removes this device's configured system-priority value

*layout-coordinates*

[Device Config Commands](#) on page 1252

Configures X and Y layout coordinates for the device

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
layout-coordinates <-4096.0-4096.0> <-4096.0-4096.0>
```

### Parameters

```
layout-coordinates <-4096.0-4096.0> <-4096.0-4096.0>
```

**layout-coordinates**

Configures X and Y layout coordinates for the device

**<-4096.0-4096.0>** Specify the X coordinate from -4096 - 4096.0  
>

**<-4096.0-4096.0>** Specify the Y coordinate from -4096 - 4096.0  
>

### Example

```
nx9500-6C8809(config-device-00-04-96-4A-A7-08)#layout-coordinates 1.0 2.0
```

```
nx9500-6C8809(config-device-00-04-96-4A-A7-08)#show context
ap71xx 00-04-96-4A-A7-08
```

```
use profile default-ap71xx
use rf-domain default
hostname TechPubAP7161
area RMZEcospace
floor 5thfloor
layout-coordinates 1.0 2.0
contact Bob+1-631-738-5200
country-code us
channel-list 2.4GHz 1,2

### *license*

[Device Config Commands](#) on page 1252

Adds a license pack on the device for the specified feature (AP/AAP/ADSEC/HTANLT/WEBF/NSIGHT/NSIGHT-PER/EGUEST-DEV)

The WiNG HM network defines a three-tier structure, consisting of multiple wireless sites managed by a single Network Operations Center (NOC) controller, The NOC controller constitutes the first and the site controllers constitute the second tier of the hierarchy. The site controllers may or may not be grouped to form clusters. The site controllers in turn adopt and manage access points that form the third tier of the hierarchy.

The NOC controllers and/or site controllers can both have license packs installed. Adoption of APs by the NOC and site controllers depends on the number of licenses available on each of these controllers.

The NOC controllers and/or site controllers can both have license packs installed. When a AP is adopted by a site controller, the site controller pushes a license on to the AP. The various possible scenarios are:

- AP licenses installed only on NOC controller:

The NOC controller provides the site controllers with AP licenses, ensuring that per platform limits are not exceeded.

- AP licenses installed on site controller:

The site controller uses its installed licenses, and then asks the NOC controller for additional licenses in case of a shortage.

In a hierarchical and centrally managed network, the NOC controller can pull unused AP licenses from site controllers and relocate to other site controllers when required.

- AP licenses installed on any member of a site cluster:

The site controller shares installed and borrowed (from the NOC) licenses with other controllers within a site cluster.

### **Supported in the following platforms:**

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000

- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

license <WORD> <LICENSE-KEY>

### Parameters

license <WORD> <LICENSE-KEY>

| <b>&lt;WORD&gt;</b>        | <p>Specify the feature name (AP/AAP/ADSEC/HTANLT/WEBF/NSIGHT/NSIGHT-PER/EGUEST-DEV) for which license is added.</p> <ul style="list-style-type: none"> <li>• AP License: This is the license key required for AP adoptions. The number of APs that can be adopted depends on the installed license count. If the installed license count is 10 APs and the number of AP adoptions is 5, 5 additional APs can still be adopted under the terms of the license.</li> <li>• AAP License: This is the license key required for AAP adoptions. The number of AAPs that can be adopted depends on the installed license count. If the installed license count is 10 APs and the number of AAP adoptions is 5, 5 additional AAPs can still be adopted under the terms of the license.</li> <li>• ADSEC License: This is the license key required to install the Role Based Firewall feature and increase the number of IPSec VPN tunnels. The number of IPSec tunnels varies by platform.</li> <li>• HTANLT: This is the license key required to install Analytics (an enhanced statistical management tool) for NX95XX series service platforms.</li> <li>• WEBF License: This is the license key required to install the Web filtering feature. Web filtering is used to restrict access to specific resources on the Internet.</li> <li>• NSIGHT/NSIGHT-PER Licenses: This is the license key required to install NSight on a supported service platform. The NSight UI displays a comprehensive, day-to-day overview of the network in a graphical, visually interactive, and easy-to-use format. However, NSight being a licensed service, on expiration of the first 120 days grace period, the NSight server's NSight UI can be launched only on the application of the NSight or NSight-Per (NSight Perpetual) license.</li> </ul> <p>The difference between the NSight and NSight-Per licenses is that the first one has an expiration date, whereas the latter doesn't have an expiration date. Once purchased and applied, the NSight-Per license is active forever, and is therefore ideally suited for a Replica-set, NSight deployment, where it is essential that the license is perpetually active and synched across the NSight servers and their primary and secondary databases.</p> <p><b>Note:</b> NSight is supported only on NX9500, NX9510, NX9600 model service platforms, and the VX9000 virtual controller.</p> <ul style="list-style-type: none"> <li>• EGUEST-DEV License - This is the per-device license key installed on the EGuest server. Once installed the EGuest feature is activated. The EGuest-DEV license defines the number of APs supported by each EGuest server. The maximum limit for per-device license is 100,000.</li> </ul> <p>The EGuest server is supported only on the VX9000 platform.</p> |
| <b>&lt;LICENSE-KEY&gt;</b> | Specify the license key.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## location

[Device Config Commands](#) on page 1252

Sets the location where a managed device (controller, service platform, or access point) is deployed. This is the location of the device with respect to the RF Domain it belongs.

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
location <WORD>
```

### Parameters

```
location <WORD>
```

**<WORD>**

Specify the managed device's location as part of its RF Domain configuration

### Example

```

nx9500-6C8809(config-device-00-04-96-4A-A7-08)#location SanJose

nx9500-6C8809(config-device-00-04-96-4A-A7-08)#show context
ap71xx 00-04-96-4A-A7-08

```

```

use profile default-ap7lxx
use rf-domain default
hostname TechPubAP7161
area RMZEcospace
floor 5thfloor
layout-coordinates 1.0 2.0
location SanJose

### *mac-name*

[Device Config Commands](#) on page 1252

Configures a client name to MAC address mapping. Use this command to assign a user-friendly name to the device (controller, service platform, or access point) and map it to the device's MAC address.

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
mac-name <MAC> <NAME>
```

### Parameters

```
mac-name <MAC> <NAME>
```

|                             |                                                                                                                                                                                                                                                    |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>mac-name &lt;MAC&gt;</b> | Maps a user-friendly name to the device's MAC address                                                                                                                                                                                              |
| <b>&lt;NAME&gt;</b>         | <ul style="list-style-type: none"> <li>• &lt;MAC&gt; – Specify the device's MAC address.</li> <li>• &lt;NAME&gt; – Specify the 'friendly' name used for the specified MAC address. This is the name used in events and statistics logs.</li> </ul> |

### Example

```
nx9500-6C8809(config-device-00-04-96-4A-A7-08)#mac-name 00-04-96-4A-A7-08 5.8TestAP
```

```

```

|                        |                                                                               |
|------------------------|-------------------------------------------------------------------------------|
| <b>no</b> <PARAMETERS> | Removes or resets the logged device's settings based on the parameters passed |
|------------------------|-------------------------------------------------------------------------------|

### Usage Guidelines

The `no` command negates any command associated with it. Wherever required, use the same parameters associated with the command getting negated

## Example

```
rfs7000-37FABE(config-device-00-04-96-4A-A7-08)#no area
rfs7000-37FABE(config-device-00-04-96-4A-A7-08)#no contact
```

*nsight*

[Device Config Commands](#) on page 1252

Configures NSight database related parameters. Use this command to configure the data-update periodicity, number of applications posted to the NSight server for a wireless client, and the duration for which data is stored in the NSight database's buckets. These parameters impact the amount of data stored in the NSight DB and interval at which data is aggregated and expired within the NSight DB. For more information on data aggregation and expiration, see [Usage Guidelines \(Data Aggregation and Expiration\)](#) on page 1274.

Configure these parameters in the NSight server's device configuration mode.

### Supported in the following platforms:

- Service Platforms — NX9500, NX9510, NX9600, VX9000

### Syntax

```
nsight database [statistics|summary]
```

```
nsight database statistics [avc-update-interval|max-apps-per-client|
update-interval|wireless-clients-update-interval]
```

```
nsight database statistics [avc-update-interval|update-interval|wireless-
clients-update-interval] [120|30|300|60|600]
```

```
nsight database statistics max-apps-per-client <1-1000>
```

```
nsight database summary duration <1-24> <1-168> <1-2160> <24-26280>
```

### Parameters

```
nsight database statistics [avc-update-interval|update-interval|wireless-clients-update-
interval] [120|30|300|60|600]
```

| <b>statistics</b>          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>avc-update-interval</b> | Configures the interval, in seconds, at which Application Visibility and Control (AVC) statistics is updated to the NSight database. This interval represents the rate at which AVC-related data is inserted in the NSight database's first bucket. This first bucket data is referred to as the RAW records. A bucket is a database collection that holds statistical data on a per RF Domain basis. For more information, see <a href="#">Usage Guidelines (Data Aggregation and Expiration)</a> on page 1274.<br>When configured, RF Domain managers posting AVC-related data to the NSight server receive a reply from the NSight server intimating the next update time. The NSight server calculates the 'next update time' based on the avc-update-interval configured here. |

|                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>&lt;24-26280&gt;</b>        | <ul style="list-style-type: none"> <li>• &lt;1-2160&gt; – Specify the bucket 3 duration from 1 - 2160 hours (i.e. 1 hour to 90 days). The default is 7 days (168 hours).</li> <li>• &lt;24-26280&gt; – Specify the bucket 4 duration from 24 - 26280 hours (i.e. 1 day to 3 years). The default is 365 days (1 year).</li> </ul> <p><b>Note:</b> A bucket is a database collection that holds statistical data for each RF Domain within the network. (Note, only those RF Domain's that are using an NSight policy with the NSight server host configured will post data to the NSight server. For more information, see <a href="#">use (rf-domain-config-mode)</a> on page 524 in the RF Domain configuration mode.) NSight database has four (4) buckets. The data from each bucket is aggregated and pushed to the next bucket once the data storage duration, specified for the bucket, has exceeded. For more information on data aggregation, see <a href="#">Usage Guidelines (Data Aggregation and Expiration)</a>.</p> |

### Usage Guidelines (Data Aggregation and Expiration)

Data Aggregation:

The NSight functionality, a data analytics tool, analyzes data that is generated periodically by the nodes within the managed wireless LAN. For large WLAN networks, generating significantly large amount of data, storing data forever is neither feasible nor beneficial. Therefore, older statistics are summarized into aggregated (averaged) records. All records, for a fixed time period in past, are summarized into one record by taking an average of them. Although this causes a loss in the data's granularity, average numbers for any given time period is still available.

Statistical data periodically posted by RF Domain managers to the NSight server are stored in buckets (database collections) within the NSight database. There are four buckets in total. These are:

- First bucket (termed as the RAW bucket) - B1
- Second bucket - B2
- Third bucket - B3
- Fourth bucket - B4

On completion of the data storage duration, records from a bucket are aggregated (at a fixed rate) and inserted into the next bucket. The rate at which records are aggregated into the next bucket becomes the next bucket's granularity. For example, the B1 records (that have exceeded the data storage duration configured for B1) are aggregated (at the rate specified) and inserted into B2. Similarly, data from B2 are aggregated into B3, and from B3 to B4. The fixed rate of aggregation (or granularity) AND default storage duration for each bucket is as follows:

- B1: storage duration 8 hours
- B2: granularity 10 minutes / storage duration 24 hours
- B3: granularity 1 hour / storage duration 7 days
- B4: granularity 1 day / storage duration 1 year

Let us consider (with default update-interval settings) the growth of any one of the statistical buckets.

- Since B1's default data storage duration is 8 hours, B1 will hold a maximum of 960 records per RF Domain after 8 hours (updated at the rate of 30 seconds).
- Since B2's granularity is 10 minutes, every 10 minutes 20 records from the B1 will be aggregated into a single record and inserted into B2.
- Since B2's default storage duration is 24 hours, it will contain a maximum of 144 records per RF Domain after 24 hours.
- Since B3's granularity is 1 hour, every hour 6 records from B2 will be aggregated into a single record and inserted into B3.
- Since B3's default storage duration is 7 days, it will contain a maximum of 168 records per RF Domain after 7 days.
- Since B4's granularity is 1 day, every day 24 records from B3 will be aggregated into a single record and inserted into B4.
- Since B4's default storage duration is 365 days, it will contain a maximum of 365 records per RF Domain after 1 year.

Data Expiration:

The expiration of older records (also referred to as purging or deleting of records) occurs along with data aggregation for each bucket.

Let us consider (with default data storage-duration settings) the expiration of data for any one of the statistical buckets.

- As stated earlier, at the end of 8 hours B1 will have 960 records per RF Domain. After a period of 8 hours and 10 minutes, all 960 records are aggregated into 144 records and inserted into B2. To enable B1 to hold exactly 8 hours worth of data, 20 of the oldest records (corresponding to the first 10 minutes) are purged from B1 at the end of 8 hours and 10 minutes. This expiration cycle is triggered every 10 minutes.
- At the end of 24 hours B2 will have 144 records per RF Domain. After a period of 24 hours and 10 minutes, one of the oldest record (corresponding to the first 10 minutes) is purged from B2. This expiration cycle is triggered every 10 minutes to enable B2 to maintain exactly 24 hours worth of data.
- At the end of 7 days B3 will have 168 records per RF Domain. After a period of 7 days and one hour one of the oldest record (corresponding to the first hour) is purged from B3. This expiration cycle is triggered every 1 hour to enable B3 to maintain exactly 7 days worth of data.
- At the end of 365 days B4 will have 365 records per RF Domain. After 365 days, the oldest records (corresponding to the first day) are purged from B4. This expiration cycle is triggered every 1 day to enable B4 to maintain exactly 365 days worth of data.

### Example

```
nx9500-6C8809(config-device-B4-C7-99-6C-88-09)#nsight database statistics avc-update-interval 120
```

```
nx9500-6C8809(config-device-B4-C7-99-6C-88-09)#nsight database statistics update-interval 30
```

```
nx9500-6C8809(config-device-B4-C7-99-6C-88-09)#nsight database statistics wireless-clients-update-interval 600
```

```

*override-wlan*

[Device Config Commands](#) on page 1252

Configures WLAN's RF Domain level overrides

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
override-wlan <WLAN> [shutdown|ssid|vlan-pool|wep128|wpa-wpa2-psk]
```

```
override-wlan <WLAN> [shutdown|ssid <SSID>|vlan-pool <1-4094> {limit <0-8192>}]| wpa-wpa2-psk <WORD>]
```

```
override-wlan <WLAN> wep128 [key <1-4> hex [0<WORD>|2 <WORD>]]|transmit-key <1-4>]
```

### Parameters

```
override-wlan <WLAN> [shutdown|ssid <SSID>|vlan-pool <1-4094> {limit <0-8192>}]| wpa-wpa2-psk <WORD>]
```

|                          |                                                                                                                                          |

| <b>wep128 [key</b><br><b>&lt;1-4&gt; hex</b><br><b>[0&lt;WORD&gt;  2</b><br><b>&lt;WORD&gt;] </b><br><b>transmit-key</b><br><b>&lt;1-4&gt;</b> | Configures the WEP128 key for this WLAN, and also enables key transmission<br>Wired Equivalent Privacy (WEP) is a security protocol specified in the IEEE Wireless Fidelity (Wi-Fi) standard. WEP 128 uses a 104 bit key, which is concatenated with a 24-bit initialization vector (IV) to form the RC4 traffic key. This results in a level of security and privacy comparable to that of a wired LAN.                                                                                                                                                                                                                                                                                                                                      |
|                                                                                                                                                | <ul style="list-style-type: none"> <li>• key &lt;1-4&gt; hex - Configures a hexadecimal key (clear text or encrypted) and specifies the key's index. <ul style="list-style-type: none"> <li>• 0 &lt;WORD&gt; - Configures a clear text key. Specify a 4 - 32 character pass key.</li> <li>• 2 &lt;WORD&gt; - Configures an encrypted key. Specify a 4 - 32 character pass key.</li> </ul> </li> <li>• transmit-key &lt;1-4&gt; - Enables transmission of key index. Specify the key index.</li> </ul> <p>Wireless devices and their connected clients use the algorithm to convert an ASCII string to the same hexadecimal number. Clients without the required adapters need to use WEP keys manually configured as hexadecimal numbers.</p> |

### Example

```
rfs7000-37FABE(config-device-00-04-96-4A-A7-08)#override-wlan test vlan-pool 8
```

```
rfs7000-37FABE(config-device-00-04-96-4A-A7-08)#show context
```

```
ap71xx 00-04-96-4A-A7-08
 use profile default-ap71xx

## remove-override

[Device Config Commands](#) on page 1252

Removes device overrides in order to enable profile settings to take effect

### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

### Syntax

```
remove-override <PARAMETERS>
```

### Parameters

```
remove-override <PARAMETERS>
```

|                                                     |                                                                                                                                                                                       |
|-----------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>remove-override</b><br><b>&lt;PARAMETERS&gt;</b> | Removes settings configured at the device level based on the parameters passed. The profile (applied to the device) settings take effect once the device-level overrides are removed. |
|-----------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Example

```
rfs4000-229D58(config-device-00-23-68-22-9D-58)#remove-override ?
 adopter-auto-provisioning-policy-lookup Use centralized auto-provisioning
 policy when adopted by another
 controller
 adoption Adoption configuration
 adoption-mode Configure the adoption mode for the
 access-points in this RF-Domain
 alias Alias
 all Remove all overrides for the device

rfs4000-229D58(config-device-00-23-68-22-9D-58)#

[Device Config Commands](#) on page 1252

Assigns an SSH RSA key

SSH keys are a pair of cryptographic keys used to authenticate users instead of, or in addition to, a username/password. One key is private and the other is public key. Secure Shell (SSH) public key authentication can be used by a requesting client to access resources, if properly configured. The RSA key pair must be generated on the client. The public portion of the key pair resides with the controller, service platform, or access point locally, while the private portion remains on a secure area of the client.

#### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

```
rsa-key ssh <RSA-KEY-NAME>
```

#### Parameters

```
rsa-key ssh <RSA-KEY-NAME>
```

[Device Config Commands](#) on page 1252

Configures an AirDefense sensor server resource for client terminations and WIPS event logging. This is the server that supports WIPS events on behalf of the controller or service platform.

**Supported in the following platforms:**

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

**Syntax**

```
sensor-server <1-3> ip <IP/HOSTNAME> {port [443|<1-65535>]}
```

**Parameters**

```
sensor-server <1-3> ip <IP/HOSTNAME> {port [443|<1-65535>]}
```

|                                            |                                                                                                                                                                                                                                                                                        |
|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>sensor-server</b><br><b>&lt;1-3&gt;</b> | Sets a numerical index to differentiate this AirDefense sensor server from other servers. A maximum of 3 (three) sensor server resources can be defined.                                                                                                                               |
| <b>ip &lt;IP/<br/>HOSTNAME&gt;</b>         | Configures the AirDefense sensor server's IP address or hostname <ul style="list-style-type: none"><li>• &lt;IP/HOSTNAME&gt; - Specify the IP address.</li></ul>                                                                                                                       |
| <b>port [443  <br/>&lt;1-65535&gt;]</b>    | Optional. Configures the port. The options are: <ul style="list-style-type: none"><li>• 443 - The default port used by the AirDefense server. This is the default setting.</li><li>• &lt;1-65535&gt; - Manually sets the port number of the AirDefense server from 1 - 65535</li></ul> |

**Example**

```
nx9500-6C8809(config-device-00-04-96-4A-A7-08)#sensor-server 1 ip 172.16.10.7

*trustpoint (device-config-mode)*

[Device Config Commands](#) on page 1252

Assigns trustpoints to validate various services, such as HTTPS, RADIUS CA, RADIUS server, external LDAP server, etc.

For more information on digital certificates and certificate authorities, see [trustpoint \(profile-config-mode\)](#) on page 1229.

#### Note

Certificates/trustpoints used in this command should be verifiable as existing on the device.

#### Supported in the following platforms:

- Access Points — AP6522, AP6562, AP7161, AP7502, AP7522, AP7532, AP7562, AP7602, AP7612, AP7622, AP7632, AP7662, AP8163, AP8432, AP8533
- Wireless Controllers — RFS4000
- Service Platforms — NX5500, NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600, VX9000

#### Syntax

```
trustpoint [cloud-client | cmp-auth-operator | https | radius-ca | radius-ca-ldaps | radius-server | radius-server-ldaps] <TRUSTPOINT-NAME>
```

#### Parameters

```
trustpoint [cloud-client | cmp-auth-operator | https | radius-ca | radius-ca-ldaps | radius-server | radius-server-ldaps] <TRUSTPOINT-NAME>
```

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>trustpoint</b>        | Assigns trustpoints to validate various services. The assigned trustpoint is used as the CA for validating the services.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>cloud-client</b>      | Assigns trustpoint to validate cloud client. The trustpoint should be existing and installed on the device.<br>Use this option on cloud-enabled access points and cloud-adopted, to secure the communication between the cloud AP and cloud client. The trustpoint should be existing and installed on the AP. The cloud-enabled access points are AP7502, AP7522, AP7532, and AP7562. For local-controller adopted APs, this configuration is not required.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>cmp-auth-operator</b> | Assigns an existing trustpoint to validate CMP auth operator. Once validated, CMP is used to obtain and manage digital certificates in a PKI network. Digital certificates link identity information with a public key enclosed within the certificate, and are issued by the CA.<br>Use this command to specify the CMP-assigned trustpoint. When specified, devices send a certificate request to the CMP supported CA server, and download the certificate directly from the CA server. CMP supports multiple request options through for device communicating to a CMP supported CA server. The device can initiate a request for getting the certificates from the server. It can also auto update the certificates which are about to expire.<br><br><b>Note:</b> When configured, this cmp-auth-operator trustpoint setting overrides the profile-level configuration. |
| <b>https</b>             | Assigns an existing trustpoint to validate HTTPS                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>radius-ca</b>         | Assigns an existing trustpoint to validate client certificates in EAP                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>radius-ca-ldaps</b>   | Assigns an existing trustpoint to validate external LDAP server                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>radius-server</b>     | Assigns an existing trustpoint to validate RADIUS server certificate                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>radius-server-ldaps</b>     | Assigns an existing trustpoint to RADIUS server certificate to validate LDAP server                                                                                                                                                                                                                                                                                                                                          |
| <b>&lt;TRUSTPOINT-NAME&gt;</b> | <p>The following keyword is common to all of the above parameters:</p> <ul style="list-style-type: none"> <li>• &lt;TRUSTPOINT-NAME&gt; – After selecting the service to validate, specify the trustpoint name (should be existing and stored on the device).</li> </ul> <p><b>Note:</b> By default, the system assigns the default-trustpoint to validate the following: https, radius-server, and radius-server-ldaps.</p> |

### Example

A device's default HTTPS, RADIUS, and CMP certificate/trustpoint configuration is as follows:

```
nx9500-6C8809(config-device-B4-C7-99-6C-88-09)#show context include-factory | include trustpoint
trustpoint https default-trustpoint
no trustpoint radius-ca
trustpoint radius-server default-trustpoint
no trustpoint radius-ca-ldaps
trustpoint radius-server-ldaps default-trustpoint
no trustpoint cmp-auth-operator
nx9500-6C8809(config-device-B4-C7-99-6C-88-09)#
```

```
nx9500-6C8809(config-device-B4-C7-99-6C-88-09)#trustpoint https test
```

```
nx9500-6C8809(config-device-B4-C7-99-6C-88-09)#show context include-factory | include trustpoint
trustpoint https test
no trustpoint radius-ca
trustpoint radius-server default-trustpoint
no trustpoint radius-ca-ldaps
trustpoint radius-server-ldaps default-trustpoint
no trustpoint cmp-auth-operator
nx9500-6C8809(config-device-B4-C7-99-6C-88-09)#
```

*raid*

[Device Config Commands](#) on page 1252

Enables chassis alarm that sounds when events are detected that degrade RAID support (drive content mirroring) on a service platform

The NX95XX (NX9500 and NX9510) series service platforms include a single Intel MegaRAID controller (virtual drive) with RAID-1 mirroring support enabled. The online virtual drive supports up to two physical drives that could require hot spare substitution if a drive were to fail. The WiNG software allows you to manage the RAID controller event alarm and syslogs supporting the array hardware from the service platform user interface without rebooting the service platform BIOS.

Although RAID controller drive arrays are available only on the NX95XX series service platforms, they can be administrated on behalf of a NX95XX profile by a different model service platform or wireless controller.

#### Supported in the following platforms:

- Service Platforms — NX7530, NX9500, NX9510, NX9600

## Syntax

```
raid alarm enable
```

## Parameters

```
raid alarm enable
```

|                     |                                                                                                                                                                                                 |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>alarm enable</b> | Enables audible alarm, which is triggered a RAID drives fails. When triggered the alarm can be disabled by executing the <code>raid &gt; silence</code> command in the device's Priv Exec mode. |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Example

```
nx9500-6C8809(config-device-B4-C7-99-6C-88-09)#raid alarm enable
```

```
nx9500-6C8809(config-device-B4-C7-99-6C-88-09)#show context
```

```
nx9000 B4-C7-99-6C-88-09
 use profile default-nx9000
 use rf-domain default
 hostname nx9500-6C8809
 ip default-gateway 192.168.13.2
 interface gel
 switchport mode access
 switchport access vlan 1
 interface vlan1
 ip address 192.168.13.13/24
 logging on
 logging console warnings
 logging buffered warnings
 raid alarm enable
nx9500-6C8809(config-device-B4-C7-99-6C-88-09)#
```

## T5 Profile Config Commands

[PROFILES](#) on page 857

A T5 controller uses the IPX operating system to manage its connected radio devices, as opposed to the WiNG operating used by RFS wireless controllers and NX service platforms. However, a T5 controller, once enabled as a supported external device, can provide data to WiNG to assist in a T5's management within a WiNG supported subnet populated by both types of devices. The Customer Premises Equipment (CPEs) are the T5 controller managed radio devices using the IPX operating system. These CPEs use a DSL as their high speed Internet access mechanism using the CPE's physical wallplate connection and phone jack.

To navigate to this instance, use the following commands:

```
<DEVICE>(config-profile-<PROFILE-NAME>)#?
T5 Profile Mode commands:
 cpe T5 CPE configuration
 interface Select an interface to configure
 ip Internet Protocol (IP)
 no Negate a command or set its defaults
 ntp Configure NTP
 override-wlan Configure RF Domain level overrides for wlan
```

```

t5 T5 configuration
t5-logging Modify message logging facilities
use Set setting to use

clrscr Clears the display screen
commit Commit all changes made in this session
do Run commands from Exec mode
end End current mode and change to EXEC mode
exit End current mode and down to previous mode
help Description of the interactive help system
revert Revert changes
service Service Commands
show Show running system information
write Write running configuration to memory or terminal

```

<DEVICE>(config-profile-<PROFILE-NAME>)#

The following table summarizes T5 profile configuration mode commands:

| Command                                    | Description                                                                                                         |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| <a href="#">cpe</a> on page 1286           | Configures T5 CPE related settings (IP address range and VLAN)                                                      |
| <a href="#">interface</a> on page 1288     | Configures the T5 controller's interfaces                                                                           |
| <a href="#">ip</a> on page 1290            | Configures the default gateway's IP address                                                                         |
| <a href="#">no</a> on page 1291            | Removes or reverts this T5 controller profile settings                                                              |

| <a href="#">use</a> on page 1295           | Defines this T5 profile's management settings                                                                       |

## *cpe*

[T5 Profile Config Commands](#) on page 1285

Configures T5 CPE related settings. This command is available both in the T5 profile and T5 device contexts

### **Supported in the following platforms:**

- Wireless Controllers — RFS4000
- Service Platforms — NX9500, NX9510

### **Syntax T5 Profile & T5 Device Context**

```
cpe [address led]
```

```
cpe address vlan <1-4094> <START-IP> <END-IP>
```

```
cpe led cpe <cpe1-24>
```

The following commands are specific to the T5 device context:

```
cpe [boot|reload|upgrade]
```

```
cpe boot system <cpe1-24> <primary|secondary>
```

```
cpe reload <cpe1-24>
```

```
cpe <cpe1-24> upgrade <IMAGE-LOCATION>
```

### Parameters

```
cpe address vlan <1-4094> <START-IP> <END-IP>
```

|                                            |                                                                                                                                                                                                                                                                                          |
|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>cpe address</b>                         | Configures the range of addresses that can be assigned to adopted CPEs                                                                                                                                                                                                                   |
| <b>vlan &lt;1-4094&gt;</b>                 | Configures the VLAN assigned to the CPEs managed by this T5 controller                                                                                                                                                                                                                   |

### Example

```
nx9500-6C8809(config-profile-T5TestProfile)#cpe address vlan 200 192.168.13.26
192.168.13.30
```

```
nx9500-6C8809(config-profile-T5TestProfile)#show context
profile t5 T5TestProfile
no autoinstall configuration
no autoinstall firmware
interface vlan1
interface vlan4090
interface fe 5 2
.....
interface radio 11 1
interface fe 9 2
interface radio 18 1
interface fe 9 1
use firewall-policy default
service pm sys-restart
cpe address vlan 200 192.168.13.26 192.168.13.30
nx9500-6C8809(config-profile-T5TestProfile)#
```

### interface

[T5 Profile Config Commands](#) on page 1285

Configures the T5 controller's interfaces

### Supported in the following platforms:

- Wireless Controllers — RFS4000
- Service Platforms — NX9500, NX9510

## Syntax

```
interface [<WORD>|dsl|fe|ge|radio|vlan]
```

```
interface [<WORD>|dsl <1-24>|fe <1-24> <1-2>|ge <1-2>|radio <1-24> <1-2>|
vlan <1-4094>]
```

## Parameters

```
interface [<WORD>|dsl <1-24>|fe <1-24> <1-2>|ge <1-2>|radio <1-24> <1-2>|vlan <1-4094>]
```

|                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| <b>dsl &lt;1-24&gt;</b>                   | <p>Configures the specified DSL interface. A T5 controller uses the IPX operating system to manage its connected radio devices, as opposed to the WiNG operating used by controllers and NX service platforms. However, a T5 controller, once enabled as a supported external device, can provide data to WiNG to assist in a T5's management within a WiNG supported subnet populated by both types of devices. The CPEs are the T5 controller managed radio devices using the IPX operating system. These CPEs use DSL as their high speed Internet access mechanism using the CPE's physical wallplate connection and phone jack.</p> <ul style="list-style-type: none"><li>• &lt;1-24&gt; – Specify the DSL port index from 1 - 24.</li></ul>                                                   |
| <b>fe &lt;1-24&gt;<br/>&lt;1-2&gt;</b>    | <p>Configures the specified FastEthernet interface. The T5 controller has the following FastEthernet port designations: fe1-fe2 (fe1-fe2 are for up to 24 CPE devices managed by a T5 controller).</p> <ul style="list-style-type: none"><li>• &lt;1-24&gt; – Specify the DSL port index from 1 - 24.</li><li>• &lt;1-2&gt; – Specify the FastEthernet interface to configure.</li></ul> <p>In the FastEthernet interface configuration mode, specify the interface settings.</p>                                                                                                                                                                                                                                                                                                                   |
| <b>ge &lt;1-2&gt;</b>                     | <p>Configures the specified GigabitEthernet interface. T5 controllers have two Ethernet port designations, These are ge1 and ge2. The GE ports can be RJ-45 or fiber ports supporting 10/100/1000Mbps.</p> <ul style="list-style-type: none"><li>• &lt;1-2&gt; – Specify the interface index from 1 - 2.</li></ul> <p>In the GigabitEthernet interface configuration mode, specify the interface settings.</p>                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>radio &lt;1-24&gt;<br/>&lt;1-2&gt;</b> | <p>Configures the specified radio interface. T5 controller managed CPE device radios can have their radio configurations overridden once their radios have successfully associated and have been provisioned by the adopting controller, service platform, or peer model AP controller access point.</p> <ul style="list-style-type: none"><li>• &lt;1-24&gt; – Specify the radio interface index from 1 - 24.</li><li>• &lt;1-2&gt; – Allows the second radio to be specified as a radio interface. For example, this is “interface radio X Y” where ‘X’ is the DSL line number and ‘Y’ is the radio interface (number).</li></ul>                                                                                                                                                                 |
| <b>vlan &lt;1-4094&gt;</b>                | <p>Configures the specified VLAN interface. Once configured, the VLAN interface provides layer 3 (IP) T5 controller access or provides layer 3 service on a VLAN. The VLAN interface defines which IP address is associated with each VLAN ID a T5 controller is connected to. A VLAN interface is created for the default VLAN (VLAN 1) to enable remote administration. This interface is also used to map VLANs to IP4 and IPv6 formatted IP address ranges. This mapping determines the destination for routing.</p> <ul style="list-style-type: none"><li>• &lt;1-4094&gt; – Specify the VLAN interface index from 1 - 4094.</li></ul> <p>In the VLAN configuration mode, specify the interface's primary IP address in the A.B.C.D/M format. Optionally specify the secondary IP address.</p> |

## Example

```
rfs7000-37FABE(config-profile-t5Profile)#interface dsl 1

rfs7000-37FABE(config-profile-t5Profile-if-dsl1)#?
Interface configuration commands:
 description Port description
 ds-interleaver Enable impulse noise protection in the downstream
 direction
 ds-max-datarate Configure maximum allowed downstream rate for the
 interface
 ds-min-margin Configure the minimum downstream signal-to-noise(SNR)
 ratio margin
 ds-target-margin Configure the desired downstream signal-to-noise (SNR)
 ratio margin
 duplex Set duplex to interface
 flowcontrol Set flowcontrol to interface
 line-power Use the line-power command to apply power to the interface
 no Negate a command or set its defaults
 qos QOS settings
 shutdown Shutdown the selected interface
 speed Configure speed
 switchport Set switching mode characteristics
 us-interleaver Enable impulse noise protection in the upstream direction
 us-max-datarate Configure maximum allowed upstream rate for the interface
 us-min-margin Configure the minimum upstream signal-to-noise (SNR) ratio
 margin
 us-target-margin Configure the desired upstream signal-to-noise (SNR) ratio
 margin

[T5 Profile Config Commands](#) on page 1285

Configures the default gateway's IP address

### Supported in the following platforms:

- Wireless Controllers — RFS4000
- Service Platforms — NX9500, NX9510

### Syntax

```
ip default-gateway <IP>
```

## Parameters

```
ip default-gateway <IP>
```

|                                      |                                                               |
|--------------------------------------|---------------------------------------------------------------|
| <b>ip default-gateway &lt;IP&gt;</b> | Enter the default gateway's IP address in the A.B.C.D format. |
|--------------------------------------|---------------------------------------------------------------|

## Example

```
nx9500-6C8809(config-profile-t5Profile)#ip default-gateway 192.168.13.7
```

```
nx9500-6C8809(config-profile-t5Profile)#show context
profile t5 t5Profile
```

```
 ip default-gateway 192.168.13.7
 no autoinstall configuration
 no autoinstall firmware
 interface vlan1
 interface vlan4090
 interface fe 5 2
 interface ge 2
 interface ge 1
 interface fe 5 1
```

```
--More--
```

```
nx9500-6C8809(config-profile-t5Profile)#
```

*no*

[T5 Profile Config Commands](#) on page 1285

Removes or reverts this T5 controller profile settings

### Supported in the following platforms:

- Wireless Controllers — RFS4000
- Service Platforms — NX9500, NX9510

## Syntax

```
no [cpe|interface|ntp|override-wlan|t5-logging|use]
```

```
no cpe led cpe <1-24>
```

```
no interface vlan <2-4094>
```

```
no ntp server <IP>
```

```
no override-wlan <WLAN-NAME> vlan
```

```
no t5-logging host <IP>
```

```
no use management-policy
```

## Parameters

```
no <PARAMETERS>
```

|                                        |                                                                              |
|----------------------------------------|------------------------------------------------------------------------------|
| <b>no</b><br><b>&lt;PARAMETERS&gt;</b> | Removes or reverts to default the selected T5 profile's or device's settings |
|----------------------------------------|------------------------------------------------------------------------------|

## Example

```
nx9500-6C8809(config-profile-t5Profile)#show context
profile t5 t5Profile
 ip default-gateway 192.168.13.7
 no autoinstall configuration
 no autoinstall firmware
 interface vlan1
 interface vlan4090

 use firewall-policy default

nx9500-6C8809(config-profile-t5Profile)#
```

*ntp*

[T5 Profile Config Commands](#) on page 1285

Configures the NTP server associated with this T5 profile. T5 controllers, using this profile, will obtain their system time from the specified NTP server resources.

### Supported in the following platforms:

- Wireless Controllers — RFS4000
- Service Platforms — NX9500, NX9510

### Syntax

```
ntp server <IP>
```

### Parameters

```
ntp server <IP>
```

|                                        |                                                                                                   |
|----------------------------------------|---------------------------------------------------------------------------------------------------|
| <b>ntp server</b><br><b>&lt;IP&gt;</b> | Specify the NTP server's IP address. You can specify a maximum of 3 (three) NTP server resources. |
|----------------------------------------|---------------------------------------------------------------------------------------------------|

### Example

```
nx9500-6C8809(config-profile-t5Profile)#ntp server 192.168.13.2

nx9500-6C8809(config-profile-t5Profile)#show context
profile t5 t5Profile
 ip default-gateway 192.168.13.7
 no autoinstall configuration
 no autoinstall firmware
 interface dsl 5
```

```

.....
use firewall-policy default
ntp server 192.168.13.2
service pm sys-restart
nx9500-6C8809(config-profile-t5Profile)#

```

### *override-wlan*

[T5 Profile Config Commands](#) on page 1285

Use this option to configure RF Domain level configuration for WLAN. The override configured here are applied to all T5 devices using this T5 profile.

#### Supported in the following platforms:

- Wireless Controllers – RFS4000
- Service Platforms – NX9500, NX9510

#### Syntax

```
override-wlan <WLAN-NAME> vlan <1-4094>
```

#### Parameters

```
override-wlan <WLAN-NAME> vlan <1-4094>
```

|                                        |                                                                                                              |
|----------------------------------------|--------------------------------------------------------------------------------------------------------------|
| <b>override-wlan &lt;WLAN-NAME&gt;</b> | <b>Note:</b> Overrides the specified WLAN's VLAN configuration<br><br><WLAN-NAME> - Specify the WLAN's name. |
| <b>vlan &lt;1-4094&gt;</b>             | Specify the new VLAN option<br>• <1-4094> - Specify the VLAN from 1 - 4094.                                  |

#### Example

The following example displays the WLAN SJOFFWLAN configuration:

```

nx9500-6C8809(config-wlan-SJOFFWLAN)#show context
wlan SJOFFWLAN
description "SJ Office WLAN"
ssid SJOFFWLAN
vlan 468
bridging-mode local
encryption-type ccmp
authentication-type eap-psk
use aaa-policy test
nx9500-6C8809(config-wlan-SJOFFWLAN)#

```

The following example overrides the SJOFFWLAN WLAN's VLAN configuration on the T5 profile:

```

nx9500-6C8809(config-profile-testT5)#override-wlan SJOFFWLAN vlan 30

nx9500-6C8809(config-profile-testT5)#show context include-factory | include override-wlan
override-wlan SJOFFWLAN vlan 30
nx9500-6C8809(config-profile-testT5)#

```

*t5*

[T5 Profile Config Commands](#) on page 1285

Configures this T5 controller's country of operation

### Supported in the following platforms:

- Wireless Controllers — RFS4000
- Service Platforms — NX9500, NX9510

### Syntax

```
t5 country-code <WORD>
```

### Parameters

```
t5 country-code <WORD>
```

|                                            |                                                                      |
|--------------------------------------------|----------------------------------------------------------------------|
| <b>country-code</b><br><b>&lt;WORD&gt;</b> | Configures the 2 letter ISO-3166 country code for this T5 controller |
|--------------------------------------------|----------------------------------------------------------------------|

### Example

```
nx9500-6C8809(config-profile-T5TestProfile)#t5 country-code us
```

```
nx9500-6C8809(config-profile-T5TestProfile)#show context
profile t5 T5TestProfile
 no autoinstall configuration
 no autoinstall firmware
 interface vlan1
 interface vlan4090
 interface fe 5 2

 interface fe 9 1
 use firewall-policy default
 service pm sys-restart
 t5 country-code US
 cpe address vlan 200 192.168.13.26 192.168.13.30
nx9500-6C8809(config-profile-T5TestProfile)#
```

*t5-logging*

[T5 Profile Config Commands](#) on page 1285

Configures a maximum of 5 (five) remote hosts capable of receiving syslog messages from this selected T5 controller

### Supported in the following platforms:

- Wireless Controllers — RFS4000
- Service Platforms — NX9500, NX9510

## Syntax

```
t5-logging host <IP> severity [error|info|notice|trace|warning] facility
[local0|local1|local2|local3|local4|local5|local6|local7]
```

## Parameters

```
t5-logging host <IP> severity [error|info|notice|trace|warning] facility [local0|local1|
local2|local3|local4|local5|local6|local7]
```

|                                                                                                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>t5-logging</b><br><b>host &lt;IP&gt;</b>                                                                                                | Configures syslog message logging settings <ul style="list-style-type: none"><li>host &lt;IP&gt; – Configures the external syslog remote host resource's IP address. This is the host dedicated to receive T5 syslog messages.</li></ul>                                                                                                                                                                                                                                                                                                                              |
| <b>severity</b><br><b>[error info </b><br><b>notice  trace </b><br><b>warning]</b>                                                         | Configures the syslog message filtering severity level. The options are: <ul style="list-style-type: none"><li>Error – Only forwards error and above syslog event messages.</li><li>Info – Only forwards informational and above syslog event messages.</li><li>notice – Only forwards syslog notices relating to general device operational events. These are events that are of more interest than the “info” events.</li><li>trace – Only forwards trace routing event messages</li><li>warning – Only forwards warnings and above syslog event messages</li></ul> |
| <b>facility</b><br><b>[local0 </b><br><b>local1 </b><br><b>local2 local3 </b><br><b>local4 </b><br><b>local5 local6 </b><br><b>local7]</b> | Configures the facility level for log messages sent to the syslog server. The facility level specifies the type of program logging the message. Specifying the facility level allows the configuration file to specify that message handling will vary with varying facility type. The options are: local0, local1, local2, local3, local4, local5, local5, local6, local7. The default value is local7.                                                                                                                                                              |

## Example

```
nx9500-6C8809(config-profile-T5TestProfile)#t5-logging host 192.168.13.10 severity warning
facility local6
```

```
nx9500-6C8809(config-profile-T5TestProfile)#show context
profile t5 T5TestProfile
t5-logging host 192.168.13.10 severity warning facility local6
no autoinstall configuration
.....
no autoinstall firmware
t5 country-code US
cpe address vlan 200 192.168.13.26 192.168.13.30
nx9500-6C8809(config-profile-T5TestProfile)#
```

use

[T5 Profile Config Commands](#) on page 1285

Associates a management policy with this T5 profile. The specified policy is applied to all T5 controllers using this profile.

### Supported in the following platforms:

- Wireless Controllers — RFS4000
- Service Platforms — NX9500, NX9510

### Syntax

```
use management-policy <POLICY-NAME>
```

### Parameters

```
use management-policy <POLICY-NAME>
```

|                            |                                                                                                               |
|----------------------------|---------------------------------------------------------------------------------------------------------------|
| <b>use</b>                 | Associates a management policy with this T5 profile (should be existing and configured)                       |
| <b>management-policy</b>   | <ul style="list-style-type: none"><li>• &lt;POLICY-NAME&gt; - Specify the management policy's name.</li></ul> |
| <b>&lt;POLICY-NAME&gt;</b> |                                                                                                               |

### Example

```
nx9500-6C8809(config-profile-t5Profile)#use management-policy default
Trustpoints HTTPS Server and RSA keys for SSH can be configured with 'trustpoint' and
'rsa-key' commands in device context
nx9500-6C8809(config-profile-t5Profile)#
```

## EX3524 & EX3548 Profile/Device Config Commands

**PROFILES** on page 857

Creates a new EX3524 and EX3548 profile and enters its configuration mode.

To navigate to this instance, use the following commands:

```
<DEVICE>(config)#profile ex35xx <EX35XX-PROFILE-NAME>
```

Where ex35xx can be a EX3524 or a EX3548 device type.

```
<DEVICE>(config-profile-<EX35XX-PROFILE-NAME>)#?
EX35XX Profile Mode commands:
 interface Select an interface to configure
 ip Internet Protocol (IP)
 no Negate a command or set its defaults
 power EX3500 Power over Ethernet Command
 upgrade Configures upgrade option for ex3500 system
 use Set setting to use

 clrscr Clears the display screen
 commit Commit all changes made in this session
 do Run commands from Exec mode
 end End current mode and change to EXEC mode
 exit End current mode and down to previous mode
 help Description of the interactive help system
 revert Revert changes
 service Service Commands
 show Show running system information
 write Write running configuration to memory or terminal
```

```
<DEVICE>(config-profile-<EX35XX-PROFILE-NAME>)#
```

The following table summarizes EX3524 and EX3548 profile/device configuration mode commands:

| Command                                | Description                                                                             |
|----------------------------------------|-----------------------------------------------------------------------------------------|
| <a href="#">interface</a> on page 1297 | Selects an interface type and enters the selected interface's configuration mode        |
| <a href="#">ip</a> on page 1310        | Configures the default gateway through which this EX35XX switch can reach other subnets |
| <a href="#">power</a> on page 1311     | Enables power inline compatibility mode on this EX35XX profile                          |
| <a href="#">upgrade</a> on page 1312   | Configures adopted EX35XX switch upgrade settings                                       |
| <a href="#">use</a> on page 1313       | Applies an EX3500 management policy to this EX35XX profile                              |
| <a href="#">no</a> on page 1314        | Removes or reverts this EX35XX profile's settings                                       |

## *interface*

[EX3524 & EX3548 Profile/Device Config Commands](#) on page 1296

This command selects an interface type and enters the selected interface's configuration mode. The EX35XX switch has GE and VLAN interfaces. Select the interface type and provide the interface ID to enter its configuration mode.

| Command                                                     | Description                                                                      |
|-------------------------------------------------------------|----------------------------------------------------------------------------------|
| <a href="#">interface</a> on page 1297                      | Selects an interface type and enters the selected interface's configuration mode |
| <a href="#">interface-ge-config commands</a> on page 1299   | Summarizes GE interface configuration mode commands                              |
| <a href="#">interface-vlan-config commands</a> on page 1308 | Summarizes VLAN interface configuration mode commands                            |

## **interface**

[interface](#) on page 1297

Selects the EX35XX interface type and enters the selected interface's configuration mode

Supported in the following platforms:

- Switches — EX3524, EX3548
- Wireless Controllers — RFS4000
- Service Platforms — NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600

Syntax

```
interface [ge 1 <1-48>|vlan <1-4094>]
```

Parameters

```
interface [ge 1 <1-48>|vlan <1-4094>]
```

|                            |                                                                                                                                                                                                                                                                                                                                     |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>interface</b>           | Selects the EX35XX interface type and enters its configuration mode. The interface options available are: GE and VLAN                                                                                                                                                                                                               |
| <b>ge 1 &lt;1-48&gt;</b>   | Selects a GE interface to configure <ul style="list-style-type: none"> <li>• 1 - Configures the GE interface unit identifier as 1</li> <li>• &lt;1-48&gt; - Configures the physical port number from 1 - 24/48</li> </ul> <p><b>Note:</b> For the EX3524 model switch the GE port range is 1-24, and for the EX3548 it is 1-48.</p> |
| <b>vlan &lt;1-4094&gt;</b> | Selects a VLAN interface to configure <ul style="list-style-type: none"> <li>• &lt;1-4094&gt; - Specify the VLAN interface ID from 1 - 4094.</li> </ul>                                                                                                                                                                             |

### Example

```

nx4500-5CFA8E(config-profile-testEX35XX)#interface vlan 1

## interface-ge-config commands

[interface](#) on page 1297

The following table lists the EX35XX GE interface configuration mode commands:

| Command                                   | Description                                                                                                                          |
|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">access-group</a> on page 1299 | Binds an EX3500 ACL to the selected port                                                                                             |
| <a href="#">port</a> on page 1300         | Enables port monitoring on the selected port                                                                                         |
| <a href="#">power</a> on page 1302        | Turns power on or off for the selected port                                                                                          |
| <a href="#">shutdown</a> on page 1303     | Shuts down the selected port                                                                                                         |
| <a href="#">speed-duplex</a> on page 1304 | Configures the speed and duplex mode of the selected port when auto-negotiation is disabled. Auto-negotiation is enabled by default. |
| <a href="#">switch-port</a> on page 1304  | Configures the switch mode characteristics of the selected port                                                                      |
| <a href="#">use</a> on page 1306          | Applies a EX3500 QoS policy map with the selected port                                                                               |
| <a href="#">no</a> on page 1307           | Removes or reverts the selected port's settings                                                                                      |

access-group

[interface-ge-config commands](#) on page 1299

Binds an EX3500 ACL to the selected port

When applied to the port, the ACL takes effect. Only one ACL can be bound to a port at a time. In case you bind a new ACL to a port with an existing ACL binding, the old binding is replaced with the new one.

Supported in the following platforms:

- Switches — EX3524, EX3548
- Wireless Controllers — RFS4000
- Service Platforms — NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600

Syntax

```
access-group [ex3500-ext-access-list|ex3500-std-access-list|mac-access-list] <ACL-NAME> in {time-range <TIME-RANGE-NAME>}
```

Parameters

```
access-group [ex3500-ext-access-list|ex3500-std-access-list|mac-access-list] <ACL-NAME> in {time-range <TIME-RANGE-NAME>}
```

|                                                |                                                                                                                                                                                                                                                                                                                                            |
|------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>access-group</b>                            | Binds a EX3500 ACL with this GE port. Select ACL type and specify the ACL name. The ACL should be existing and configured.                                                                                                                                                                                                                 |
| <b>ex3500-ext-access-list &lt;ACL-NAME&gt;</b> | Binds an existing and configured EX3500 extended ACL <ul style="list-style-type: none"> <li>• &lt;ACL-NAME&gt; - Specify the ACL name.</li> </ul>                                                                                                                                                                                          |
| <b>ex3500-std-access-list &lt;ACL-NAME&gt;</b> | Binds an existing and configured EX3500 standard ACL <ul style="list-style-type: none"> <li>• &lt;ACL-NAME&gt; - Specify the ACL name.</li> </ul>                                                                                                                                                                                          |
| <b>mac-access-list &lt;ACL-NAME&gt;</b>        | Binds an existing and configured EX3500 MAC ACL <ul style="list-style-type: none"> <li>• &lt;ACL-NAME&gt; - Specify the MAC ACL name.</li> </ul>                                                                                                                                                                                           |
| <b>in</b>                                      | Applies the specified ACL to all incoming packets                                                                                                                                                                                                                                                                                          |
| <b>time-range &lt;TIME-RANGE-NAME&gt;</b>      | Optional. Associates a EX3500 absolute or periodic time range with this access group. The specified ACL is bound to the port during the time period specified by the associated time range. <ul style="list-style-type: none"> <li>• &lt;TIME-RANGE-NAME&gt; - Specify the time range name (should be existing and configured).</li> </ul> |

#### Example

```
nx9500-6C8809(config-profile-testEX3524-if-ge1-20)#access-group ex3500-ext-access-list EX3500_ACL_EXT_1 in time-range EX3500_TimeRange_01
```

```
nx9500-6C8809(config-profile-testEX3524-if-ge1-20)#show context
interface ge 1 20
access-group ex3500-ext-access-list EX3500_ACL_EXT_1 in time-range EX3500_TimeRange_01
nx9500-6C8809(config-profile-testEX3524-if-ge1-20)#
```

#### Related Commands

|                        |                                        |
|------------------------|----------------------------------------|
| <b>no</b> on page 1307 | Removes the GE port EX3500 ACL binding |
|------------------------|----------------------------------------|

port

[interface-ge-config commands](#) on page 1299

Enables port monitoring on the selected port. This allows the port to monitor specified ports and/or MAC address(es). When enabled, the switch sends a copy of the network packets seen on the specified switch port (or VLAN interface) to the monitoring switch port. These packets are analyzed and debugged to provide vital information, such as network performance, intrusion alerts, etc.

Supported in the following platforms:

- Switches – EX3524, EX3548
- Wireless Controllers – RFS4000
- Service Platforms – NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600

#### Syntax

```
port monitor [ethernet | ex3500-ext-access-list | ex3500-std-access-list | mac-access-list | mac-address | vlan]
```

```
port monitor ethernet 1 <1-52> {both/rx/tx}
```

```
port monitor [ex3500-ext-access-list|ex3500-std-access-list|mac-access-list] <ACL-NAME>
```

```
port monitor mac-address <MAC>
```

```
port monitor vlan <1-4094>
```

Parameters

```
port monitor ethernet 1 <1-52> {both|rx|tx}
```

#### power

[interface-ge-config commands](#) on page 1299

Enables power allocation to the selected port. When enabled, the power is allocated to this port. Use the command to configure the power allocation settings, such as maximum power allocated, priority level of this port in connection with power allocation, and the time range within which these power settings are applied.

This option is enabled by default.

Supported in the following platforms:

- Switches — EX3524, EX3548
- Wireless Controllers — RFS4000
- Service Platforms — NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600

#### Syntax

```
power inline {maximum/priority/time-range}
```

```
power inline {maximum allocation milliwatts <3000-34200>}
```

```
power inline {priority [critical/high/low]}
```

```
power inline {time-range <TIME-RANGE-NAME>}
```

#### Parameters

```
power inline {maximum allocation milliwatts <3000-34200>}
```

|                                                         |                                                                                                                                                                                                                                         |

## speed-duplex

[interface-ge-config commands](#) on page 1299

Configures the speed and duplex mode of the selected port when auto-negotiation is disabled. Auto-negotiation is enabled by default.

This option is disabled by default.

Supported in the following platforms:

- Switches — EX3524, EX3548
- Wireless Controllers — RFS4000
- Service Platforms — NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600

## Syntax

```
speed-duplex [100full | 100half | 10full | 10half]
```

## Parameters

```
speed-duplex [100full | 100half | 10full | 10half]
```

|                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## switch-port

[interface-ge-config commands](#) on page 1299

Configures the switch mode characteristics of the selected port

Supported in the following platforms:

- Switches – EX3524, EX3548
- Wireless Controllers – RFS4000
- Service Platforms – NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600

Syntax

```
switchport [allowed|l2protocol-tunnel|mode|native]
```

```
switchport allowed [add <VLAN-ID>|none|remove <VLAN-ID>]
```

```
switchport l2protocol-tunnel [cdp|lldp|pvst+|spanning-tree|vtp]
```

```
switchport mode [access|hybrid|trunk]
```

```
switchport native
```

Parameters

```
switchport allowed [add <VLAN-ID>|none|remove <VLAN-ID>]
```

use

[interface-ge-config commands](#) on page 1299

Applies a EX3500 QoS policy map with the selected port

Supported in the following platforms:

- Switches – EX3524, EX3548
- Wireless Controllers – RFS4000
- Service Platforms – NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600

#### Syntax

```
use ex3500-policy-map <EX3500-QoS-POLICY-MAP-NAME> in
```

## Parameters

`use ex3500-policy-map <EX3500-QoS-POLICY-MAP-NAME> in`

|                                                                 |                                                                                                             |
|-----------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| <b>use ex3500-policy-map &lt;EX3500-QoS-POLICY-MAP-NAME&gt;</b> | Applies a EX3500 QoS policy map with the selected port                                                      |
|                                                                 | • <EX3500-QoS-POLICY-MAP-NAME> - Specify the EX3500 QoS policy map name (should be existing and configured) |
|                                                                 | • in - Applies the specified policy to traffic ingressing at the selected port.                             |

## Example

```
nx9500-6C8809(config-profile-testEX3524-if-ge1-20)#use ex3500-policy-map in test

nx9500-6C8809(config-profile-testEX3524-if-ge1-20)#show context
interface ge 1 20
 shutdown
 speed-duplex 100half
 switchport mode access

`no`

[interface-ge-config commands](#) on page 1299

Removes or reverts the selected port's settings

Supported in the following platforms:

- Switches – EX3524, EX3548

### Syntax

```
no [access-group | port | power | shutdown | speed-duplex | switchport | use]
```

```
no access-group [ex3500-ext-access-list | ex3500-std-access-list | mac-access-list] <ACL-NAME> in
```

```
no port monitor [ethernet | ex3500-ext-access-list | ex3500-std-access-list | mac-access-list | mac-address | vlan]
```

```
no port monitor ethernet 1 <1-52>
```

```
no port monitor [ex3500-ext-access-list | ex3500-std-access-list | mac-access-list] <ACL-NAME>
```

```
no port monitor mac-address <MAC>
```

```
no port monitor vlan <1-4094>
```

```

no power inline {maximum allocation/priority/time-range}

no shutdown

no speed-duplex

no switchport [l2protocol-tunnel [cdp|lldp|pvst+|spanning-tree|vtp]|
native vlan]

no use ex3500-policy-map in

```

Parameters  
no <PARAMETERS>

|                           |                                                                                |
|---------------------------|--------------------------------------------------------------------------------|
| <b>no</b>                 | Removes or reverts the selected port's settings based on the parameters passed |
| <b>&lt;PARAMETERS&gt;</b> |                                                                                |

### Example

The following example shows the EX3524 profile's GE port 20's settings before the 'no' commands are executed:

```

nx9500-6C8809(config-profile-testEX3524-if-ge1-20)#show context
interface ge 1 20
 shutdown
 speed-duplex 100half
 switchport mode access
 use ex3500-policy-map in test
 power inline maximum allocation milliwatts 30000
 power inline priority critical
 power inline time-range EX3500_TimeRange_01
 access-group ex3500-ext-access-list EX3500_ACL_EXT_1 in time-range EX3500_TimeRange_01
 port monitor vlan 20
nx9500-6C8809(config-profile-testEX3524-if-ge1-20)#

```

```

nx9500-6C8809(config-profile-testEX3524-if-ge1-20)#no shutdown
nx9500-6C8809(config-profile-testEX3524-if-ge1-20)#no power inline maximum allocation
nx9500-6C8809(config-profile-testEX3524-if-ge1-20)#no use ex3500-policy-map in

```

The following example shows the EX3524 profile's GE port 20's settings after the 'no' commands are executed:

```

nx9500-6C8809(config-profile-testEX3524-if-ge1-20)#show context
interface ge 1 20
 speed-duplex 100half
 switchport mode access
 power inline maximum allocation milliwatts 32400
 power inline priority critical
 power inline time-range EX3500_TimeRange_01
 access-group ex3500-ext-access-list EX3500_ACL_EXT_1 in time-range EX3500_TimeRange_01
 port monitor vlan 20
nx9500-6C8809(config-profile-testEX3524-if-ge1-20)#

```

## Interface-vlan-config commands

[interface](#) on page 1297

The following table lists the VLAN interface configuration mode commands:

| Command                      | Description                                                        |
|------------------------------|--------------------------------------------------------------------|
| <code>ip</code> on page 1309 | Configures IP related settings for this VLAN interface             |
| <code>no</code> on page 1310 | Removes the IP related settings configured for this VLAN interface |

ip

[interface-vlan-config commands](#) on page 1308

Configures IP related settings for this VLAN interface

Supported in the following platforms:

- Switches – EX3524, EX3548
- Wireless Controllers – RFS4000
- Service Platforms – NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600

Syntax

```
ip address [<IP/M>|bootp|dhcp]
```

```
ip address <IP/M> {default-gateway <IP>|secondary <IP>}
```

```
ip address [bootp|dhcp]
```

Parameters

```
ip address <IP/M> {default-gateway <IP>|secondary <IP>}
```

|------------------------------|-----------------------------------------------------------|
| <code>no</code> on page 1310 | Removes the IP address configured for this VLAN interface |
|------------------------------|-----------------------------------------------------------|

`no`

[interface-vlan-config commands](#) on page 1308

Removes the IP related settings configured for this VLAN interface

Supported in the following platforms:

- Switches – EX3524, EX3548
- Wireless Controllers – RFS4000
- Service Platforms – NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600

## Syntax

```
no ip address [<IP/M> | bootp | dhcp]
```

## Parameters

```
no <PARAMETERS>
```

|                                                    |                                                                               |
|----------------------------------------------------|-------------------------------------------------------------------------------|
| <code>no</code><br><code>&lt;PARAMETERS&gt;</code> | Removes this EX3500's selected VLAN's settings based on the parameters passed |
|----------------------------------------------------|-------------------------------------------------------------------------------|

## Example

The following example shows the interface VLAN 20 setting before the 'no' command is executed:

```
nx9500-6C8809(config-profile-testEX3524-if-vlan20)#show context
interface vlan 20
 ip address 192.168.13.28/24 default-gateway 192.168.13.13
nx9500-6C8809(config-profile-testEX3524-if-vlan20)#
```

```
nx9500-6C8809(config-profile-testEX3524-if-vlan20)#no ip address 192.168.13.28/24
```

The following example shows the interface VLAN 20 setting after the 'no' command is executed:

```
nx9500-6C8809(config-profile-testEX3524-if-vlan20)#show context
interface vlan 20
nx9500-6C8809(config-profile-testEX3524-if-vlan20)#
```

`ip`

[EX3524 & EX3548 Profile/Device Config Commands](#) on page 1296

Configures the default gateway through which this EX35XX switch can reach other subnets

## Supported in the following platforms:

- Switches – EX3524, EX3548

- Wireless Controllers – RFS4000
- Service Platforms – NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600

### Syntax

```
ip default-gateway <IP>
```

### Parameters

```
ip default-gateway <IP>
```

|                                      |                                                                   |
|--------------------------------------|-------------------------------------------------------------------|
| <b>ip default-gateway &lt;IP&gt;</b> | Configures the default gateway's IP address in the A.B.C.D format |
|                                      | • <IP> – Specify the IP address.                                  |

### Example

```

nx9500-6C8809(config-profile-testEX3524)#
```

## upgrade

[EX3524 & EX3548 Profile/Device Config Commands](#) on page 1296

Configures adopted EX35XX switch upgrade settings

For a EX35XX switch to adopt to and be managed by a WiNG controller, you need to upload two images on the switch. An operation code (opcode) image and an adopted image. The opcode image functions as an operating system that enables the WiNG controller to communicate with the EX35XX switch. This command allows you to configure the EX35XX's opcode image upgrade settings.

### Supported in the following platforms:

- Switches — EX3524, EX3548
- Wireless Controllers — RFS4000
- Service Platforms — NX7500, NX7510, NX7520, NX7530, NX9500, NX9510, NX9600

### Syntax

```
upgrade opcode [auto|path <LINE>|reload]
```

### Parameters

```
upgrade opcode [auto|path <LINE>|reload]
```

|                          |                                                                       |
|--------------------------|-----------------------------------------------------------------------|
| <b>upgrade opcode</b>    | Configures the opcode image upgrade settings                          |
| <b>auto</b>              | Enables automatic upgrade                                             |
| <b>path &lt;LINE&gt;</b> | Configures the location of the opcode image                           |
| <b>reload</b>            | Enables automatic reload after successful loading of the opcode image |

### Example

# AAA POLICY COMMANDS

## AAA-POLICY

---

This chapter summarizes the AAA (Authentication, Authorization, and Accounting) policy commands in the CLI command structure.

A AAA policy enables administrators to define access control settings governing network permissions. External RADIUS and LDAP servers (AAA servers) also provide user database information and user authentication data. Each WLAN maintains its own unique AAA configuration.

AAA provides a modular way of performing the following services:

**Authentication** — Provides a means for identifying users, including login and password dialog, challenge and response, messaging support and (depending on the security protocol), encryption. Authentication is the technique by which a user is identified before allowed access to the network. Configure AAA authentication by defining a list of authentication methods, and then applying the list to various interfaces. The list defines the authentication schemes performed and their sequence. The list must be applied to an interface before the defined authentication technique is conducted.

**Authorization** — Authorization occurs immediately after authentication. Authorization is a method for remote access control, including authorization for services and individual user accounts and profiles. Authorization functions through the assembly of attribute sets describing what the user is authorized to perform. These attributes are compared to information contained in a database for a given user and the result is returned to AAA to determine the user's actual capabilities and restrictions. The database could be located locally or be hosted remotely on a RADIUS server. Remote RADIUS servers authorize users by associating AV (attribute-value) pairs with the appropriate user. Each authorization method must be defined through AAA. When AAA authorization is enabled it's applied equally to all interfaces.

**Accounting** — Collects and sends security server information for billing, auditing, and reporting user data; such as start and stop times, executed commands (such as PPP), number of packets, and number of bytes. Accounting enables wireless network administrators to track the services users are accessing and the network resources they are consuming. When accounting is enabled, the network access server reports user activity to a RADIUS security server in the form of accounting records. Each accounting record is comprised of AV pairs and is stored locally on the access control server. The data can be analyzed for network management, client billing, and/or auditing. Accounting methods must be defined through AAA. When AAA accounting is activated, it is applied equally to all interfaces on the access servers.

Use the (config) instance to configure AAA policy commands. To navigate to the config-aaa-policy instance, use the following commands:

```
nx9500-6C8809(config)#aaa-policy test
nx9500-6C8809(config-aaa-policy-test)#?
AAA Policy Mode commands:
 accounting Configure accounting parameters
 attribute Configure RADIUS attributes in access and accounting
 requests
 authentication Configure authentication parameters
 health-check Configure server health-check parameters
```

```

mac-address-format Configure the format in which the MAC address must be
 filled in the Radius-Request frames
no
proxy-attribute Configure radius attribute behavior when proxying
 through controller or rf-domain-manager
server-pooling-mode Configure the method of selecting a server from the
 pool of configured AAA servers
use Set setting to use

clrscr Clears the display screen
commit Commit all changes made in this session
do Run commands from Exec mode
end End current mode and change to EXEC mode
exit End current mode and down to previous mode
help Description of the interactive help system
revert Revert changes
--More--
nx9500-6C8809(config-aaa-policy-test)#

```

## aaa-policy-commands

The following table summarizes the AAA policy configuration mode commands:

**Table 35: AAA Policy Configuration Commands**

| Command                                          | Description                                                                                                              |
|--------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <a href="#">accounting</a> on page 1318          | Configures accounting parameters                                                                                         |
| <a href="#">attribute</a> on page 1321           | Configure RADIUS attributes in access and accounting requests                                                            |
| <a href="#">authentication</a> on page 1324      | Configures authentication parameters                                                                                     |
| <a href="#">health-check</a> on page 1329        | Configures health check parameters                                                                                       |
| <a href="#">mac-address-format</a> on page 1330  | Configures the MAC address format                                                                                        |
| <a href="#">proxy-attribute</a> on page 1331     | Configures the RADIUS server's attribute behavior when proxying through the wireless controller or the RF Domain manager |
| <a href="#">server-pooling-mode</a> on page 1332 | Defines the method for selecting a server from the pool of configured AAA servers                                        |
| <a href="#">use</a> on page 1333                 | Defines the AAA command settings                                                                                         |
| <a href="#">no</a> on page 1334                  | Negates a command or sets its default                                                                                    |

### Note

For more information on common commands (clrscr, commit, help, revert, service, show, write, and exit), see [COMMON COMMANDS](#) on page 640.

### Note

The input parameter <HOSTNAME>, wherever used in syntaxes across this chapter, cannot include an underscore (\_) character. In other words, the name of a device cannot contain an underscore.

## accounting

Configures the server type and interval at which interim accounting updates are sent to the server. A maximum of 6 accounting servers can be configured.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
accounting [interim|server|type]
accounting interim interval <60-3600>
accounting server [<1-6>|preference]
accounting server preference [auth-server-host|auth-server-number|none]
accounting server <1-6> [dscp|host|nai-routing|onboard|proxy-mode|retry-timeout-factor|
timeout]
accounting server <1-6> [dscp <0-63>|retry-timeout-factor <50-200>]
accounting server <1-6> host <IP/HOSTNAME/HOST-ALIAS> secret [0 <SECRET>|2 <SECRET>|
<SECRET>]
{port <1-65535>}
accounting server <1-6> nai-routing realm-type [prefix|suffix] realm <REALM-TEXT> {strip}
accounting server <1-6> onboard [centralized-controller|self|controller]
accounting server <1-6> proxy-mode [none|through-centralized-controller|through-controller|
through-mint-host <HOSTNAME/MINT-ID>|through-rf-domain-manager]
accounting server <1-6> timeout <1-60> {attempts <1-10>}
accounting type [start-interim-stop|start-stop|stop-only]
```

### Parameters

```
accounting interim interval <60-3600>
```

|                    |                                                                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| interim            | Configures the interim accounting interval. This is the interval at which interim accounting updates are posted to the accounting server. |
| interval <60-3000> | Specify the interim interval from 60 - 3600 seconds. The default is 1800 seconds.                                                         |

```
accounting server preference [auth-server-host|auth-server-number|none]
```

|                    |                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| server             | Configures the RADIUS accounting server's settings                                                                                                                                                                  |
| preference         | Configures the accounting server's preference mode. Authentication requests are forwarded to an accounting server, from the pool, based on the preference mode selected.                                            |
| auth-server-host   | Sets the authentication server as the accounting server. This is the default setting. This parameter indicates the same server is used for authentication and accounting. The server is identified by its hostname. |
| auth-server-number | Sets the authentication server as the accounting server. This parameter indicates the same server is used for authentication and accounting. The server is identified by its index number.                          |
| none               | Indicates the accounting server is independent of the authentication server                                                                                                                                         |

```
accounting server <1-6> [dscp <0-63>|retry-timeout-factor <50-200>]
```

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| server <1-6>                  | Configures an accounting server. Up to 6 accounting servers can be configured.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| dscp <0-63>                   | Sets the DSCP (Differentiated Services Code Point) value for QoS (Quality of Service) monitoring. This value is used in generated RADIUS packets. <ul style="list-style-type: none"> <li>• &lt;0-63&gt; - Sets the DSCP value from 0 - 63. The default value is 34.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                         |
| retry-timeout-factor <50-200> | Sets the scaling factor for retransmission timeouts. The timeout at each attempt is a function of this retry-timeout factor and the attempt number. <ul style="list-style-type: none"> <li>• &lt;50-200&gt; - Specify a value from 50 - 200. The default is 100.</li> </ul> <p>If the scaling factor is 100, the interval between two consecutive retries remains the same, irrespective of the number of retries.</p> <p>If the scaling factor is less than 100, the interval between two consecutive retries reduces with subsequent retries.</p> <p>If this scaling factor is greater than 100, the interval between two consecutive retries increases with subsequent retries.</p> |

```
accounting server <1-6> host <IP/HOSTNAME/HOST-ALIAS> secret [0 <SECRET>|2 <SECRET>|<SECRET>] {port <1-65535>}
```

|                                         |                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| server <1-6>                            | Configures an accounting server. Up to 6 accounting servers can be configured.                                                                                                                                                                                                                                                                                     |
| host <IP/HOSTNAME/HOST-ALIAS>           | Configures the accounting server's hostname IP address, or host-alias<br>The host alias should be existing and configured.                                                                                                                                                                                                                                         |
| secret [0 <SECRET> 2 <SECRET> <SECRET>] | Configures a common secret key used to authenticate with the accounting server <ul style="list-style-type: none"> <li>• 0 &lt;SECRET&gt; - Configures a clear text secret key</li> <li>• 2 &lt;SECRET&gt; - Configures an encrypted secret key</li> <li>• &lt;SECRET&gt; - Specify the secret key. This shared secret should not exceed 127 characters.</li> </ul> |
| port <1-65535>                          | Optional. Configures the accounting server's UDP port (the port used to connect to the accounting server) <ul style="list-style-type: none"> <li>• &lt;1-65535&gt; - Specify the port number from 1 - 65535. The default value is 1813.</li> </ul>                                                                                                                 |

```
accounting server <1-6> nai-routing realm-type [prefix|suffix] realm <REALM-TEXT> {strip}
```

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| server <1-6> | Configures an accounting server. Up to 6 accounting servers can be configured.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| nai-routing  | Enables NAI (Network Access Identifier) routing. This option is disabled by default.<br>The NAI is a character string in the format of an e-mail address as either user or user@realm but it need not be a valid e-mail address or a fully qualified domain name. AAA servers identify clients using the NAI. The NAI can be used either in a specific or generic form. The specific form, which must contain the user portion and may contain the @realm portion, identifies a single user. Using the generic form allows all users to be configured on a single command line, irrespective of whether the users are within a realm or not. Each user still needs a unique security association, but these associations can be stored on a AAA server. The original purpose of the NAI was to support roaming between dial up ISPs. With NAI, an ISP does not have the accounts for all of its roaming partners in a single RADIUS database. RADIUS servers can proxy requests to remote servers as need be. |
| realm-type   | Specifies whether the prefix or suffix of the username is used as the match criteria. For example, if the option selected is prefix, the username's prefix is matched to the realm.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [prefix<br>suffix]        | Select one of the following options: <ul style="list-style-type: none"> <li>prefix - Matches the prefix of the username (For example, username is of type DOMAIN/user1, DOMAIN/user2). This is the default setting.</li> <li>suffix - Matches the suffix of the username (For example, user1@DOMAIN, user2)@DOMAIN)</li> </ul>                                                                                                                                              |
| realm<br><REALM-<br>TEXT> | Configures the text matched against the username. Enter the realm name (should not exceed 50 characters). When the RADIUS accounting server receives a request for a user name, the server references a table of user names. If the user name is known, the server proxies the request to the RADIUS server. <ul style="list-style-type: none"> <li>&lt;REALM-TEXT&gt; - Specifies the matching text including the delimiter (a delimiter is typically " or '@')</li> </ul> |
| strip                     | Optional. When enabled, strips the realm from the username before forwarding the request to the RADIUS server. This option is disabled by default.                                                                                                                                                                                                                                                                                                                          |

```
accounting server <1-6> onboard [centralized-controller|self|controller]
```

|                        |                                                                                                                  |
|------------------------|------------------------------------------------------------------------------------------------------------------|
| server <1-6>           | Configures an accounting server. Up to 6 accounting servers can be configured.                                   |
| onboard                | Selects an onboard server instead of an external host                                                            |
| centralized-controller | Configures the server on the centralized controller managing the network                                         |
| self                   | Configures the onboard server on a AP, wireless controller, or service platform (where the client is associated) |
| controller             | Configures local RADIUS server settings                                                                          |

```
accounting server <1-6> proxy-mode [none|through-centralized-controller|
through-controller|through-mint-host <HOSTNAME/MINT-ID>|through-rf-domain-manager]
```

|                                         |                                                                                                                         |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| server <1-6>                            | Configures an accounting server. Up to 6 accounting servers can be configured.                                          |
| proxy-mode                              | Configures the mode used to proxy requests. The options are: none, through-controller, and through-rf-domain-manager.   |
| none                                    | No proxy required. Sends the request directly using the IP address of the device. This is the default setting.          |
| through-centralized-controller          | Proxies requests through the centralized controller that is configuring and managing the network                        |
| through-controller                      | Proxies requests through the controller (access point, wireless controller, or service platform) configuring the device |
| through-mint-host<br><HOSTNAME/MINT-ID> | Proxies requests through a neighboring MiNT device. Provide the device's MiNT ID or hostname.                           |
| through-rf-domain- manager              | Proxies requests through the local RF Domain Manager                                                                    |

```
accounting server <1-6> timeout <1-60> {attempts <1-10>}
```

|                  |                                                                                                                                                                                                                  |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| server <1-6>     | Configures an accounting server. Up to 6 accounting servers can be configured.                                                                                                                                   |
| timeout <1-60>   | Configures the timeout for each request sent to the RADIUS server <ul style="list-style-type: none"> <li>• &lt;1-60&gt; – Specify a value from 1 - 60 seconds. The default is 5 seconds.</li> </ul>              |
| {attempts<1-10>} | Optional. Specifies the number of attempts made at transmitting a request before being dropped <ul style="list-style-type: none"> <li>• &lt;1-10&gt; – Specify a value from 1 - 10. The default is 3.</li> </ul> |

accounting type [start-interim-stop|start-stop|stop-only]

|                    |                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| type               | Configures the type of RADIUS accounting packets sent. The options are: start-interim-stop, start-stop, and stop-only.                                              |
| start-interim-stop | Sends accounting-start and accounting-stop messages at the start and end of the session. This option also sends interim accounting updates.                         |
| start-stop         | Sends only accounting-start and accounting-stop messages at the start and end of the session. Interim accounting updates are not sent. This is the default setting. |
| stop-only          | Sends only an accounting-stop message at the end of the session                                                                                                     |

### Examples

```

nx9500-6C8809(config-aaa-policy-test)#accounting interim interval 65
nx9500-6C8809(config-aaa-policy-test)#accounting server 2 host 172.16.10.10 secret
test1 port 1
nx9500-6C8809(config-aaa-policy-test)#accounting server 2 timeout 2 attempts 2
nx9500-6C8809(config-aaa-policy-test)#accounting type start-stop
nx9500-6C8809(config-aaa-policy-test)#accounting server preference auth-server-number
nx9500-6C8809(config-aaa-policy-test)#show context
aaa-policy test
 accounting server 2 host 172.16.10.10 secret 0 test1 port 1
 accounting server 2 timeout 2 attempts 2
 accounting interim interval 65
 accounting server preference auth-server-number
nx9500-6C8809(config-aaa-policy-test)#

```

### Related Commands

|    |                                                |
|----|------------------------------------------------|
| no | Removes or resets accounting server parameters |
|----|------------------------------------------------|

### attribute

Configures RADIUS Framed-MTU attribute used in access and accounting requests. The Framed-MTU attribute reduces the EAP (Extensible Authentication Protocol) packet size of the RADIUS server. This command is useful in networks where routers and firewalls do not perform fragmentation.

To ensure network security, some firewall software drop UDP fragments from RADIUS server EAP packets. Consequently, the packets are large. Using Framed MTU (Maximum Transmission Unit) reduces the packet size. EAP authentication uses Framed MTU to notify the RADIUS server about the MTU negotiation with the client. The RADIUS server communications with the client do not include EAP messages that cannot be delivered over the network.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533

- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
attribute [acct-delay-time|acct-multi-session-id|chargeable-user-identity|
cisco-vsa|framed-ip-address|framed-mtu|location-information|nas-ip-address|nas-ipv6-
address|
operator-name|service-type]
attribute acct-delay-time
attribute acct-multi-session-id
attribute chargeable-user-identity
attribute cisco-vsa audit-session-id
attribute framed-ip-address
attribute framed-mtu <100-1500>
attribute location-information [include-always|none|server-requested]
attribute nas-ip-address <WORD>
attribute nas-ipv6-address
attribute operator-name <OPERATOR-NAME>
attribute service-type [framed|login]
```

### Parameters

```
attribute acct-delay-time
```

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| acct-delay-time | Enables support for <i>accounting-delay-time</i> attribute in accounting requests. When enabled, this attribute indicates the number of seconds the client has been trying to send a request to the accounting server. By subtracting this value from the time the packet is received by the server, the system is able to calculate the time of a request-generating event. Note, the network transit time is ignored. This option is disabled by default.<br>Including the acct-delay-time attribute in accounting requests updates the acct-delay-time value whenever the packet is retransmitted, This changes the content of the attributes field, requiring a new identifier and request authenticator. |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
attribute multi-session-id
```

|                       |                                                                                                                                                                                                                                                                                                                                               |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| acct-multi-session-id | Enables support for <i>accounting-multi-session-id</i> attribute. When enabled, it allows linking of multiple related sessions of a roaming client. This option is useful in scenarios where a client roaming between access points sends multiple RADIUS accounting requests to different access points. This option is disabled by default. |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
attribute chargeable-user-identity
```

|                          |                                                                                                    |
|--------------------------|----------------------------------------------------------------------------------------------------|
| chargeable-user-identity | Enables support for <i>chargeable-user-identity</i> attribute. This option is disabled by default. |
|--------------------------|----------------------------------------------------------------------------------------------------|

```
attribute cisco-vsa audit-session-id
```

|                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

`attribute nas-ip-address <WORD>`

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| nas-ip-address <WORD> | <p>Enables configuration of an IP address, which is used as the RADIUS attribute 4, NAS-IP-Address, without changing the source IP address in the IP header of the RADIUS packets. If you are using a cluster of small NASs (network access servers) to simulate a large NAS, use this option to improve scalability. The IP address configured using this option allows the NASs to behave as a single RADIUS client from the perspective of the RADIUS server.</p> <ul style="list-style-type: none"> <li>• &lt;WORD&gt; – Provide the IPv4 address.</li> </ul> |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

`attribute nas-ipv6-address`

|                  |                                                                                                                                                                                                                                                                        |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| nas-ipv6-address | Enables support for NAS IPv6 address. This option is disabled by default. When enabled, IPv6 addresses are assigned to hosts. The length of IPv4 and IPv6 addresses is 32-bit and 128-bit respectively. Consequently, an IPv6 address requires a larger address space. |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

attribute operator-name <OPERATOR-NAME>

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| operator-name <OPERATOR-NAME> | Enables support for RFC5580 operator name attribute. When enabled, the network operator's name is included in all RADIUS authentication and accounting messages and uniquely identifies the access network owner. This option is disabled by default. <ul style="list-style-type: none"> <li>&lt;OPERATOR-NAME&gt; - Specify the network operator's name (should not exceed 63 characters in length).</li> </ul> |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

attribute service-type [framed|login]

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| service-type [framed login] | Configures the <i>service-type</i> (6) attribute value. This attribute identifies the following: the type of service requested and the type of service to be provided. <ul style="list-style-type: none"> <li>framed - Sets <i>service-type to framed</i> (2) in the authentication packets. When enabled, a framed protocol, PPP (Point-to-Point Protocol) or SLIP (Serial Line Internet Protocol), is started for the client. This is the default setting.</li> <li>login - Sets <i>service-type to login</i> (1) in the authentication packets. When enabled, the client is connected to the host.</li> </ul> |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Examples

```

nx9500-6C8809(config-aaa-policy-test)#attribute framed-mtu 110

## authentication

Configures user authentication parameters

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
authentication [eap|protocol|server]
authentication eap wireless-client [attempts <1-10>|identity-request-retry-timeout
<10-5000>|
identity-request-timeout <1-60>|retry-timeout-factor <50-200>|timeout <1-60>]
authentication protocol [chap|mschap|mschapv2|pap]
authentication server <1-6> [dscp|host|nac|nai-routing|onboard|proxy-mode|retry-timeout-
factor|timeout]
authentication server <1-6> dscp <0-63>
authentication server <1-6> host <IP/HOSTNAME/HOST-ALIAS> secret [0 <SECRET>|2 <SECRET>|
<SECRET>]
{port <1-65535>}
authentication server <1-6> nac
authentication server <1-6> nai-routing realm-type [prefix|suffix] realm <REALM-NAME>
{strip}
authentication server <1-6> onboard [centralized-controller|controller|self]
authentication server <1-6> proxy-mode [none|through-centralized-controller|
through-controller|through-mint-host <HOSTNAME/MINT-ID>|through-rf-domain-manager]
authentication server <1-6> retry-timeout-factor <50-200>
authentication server <1-6> timeout <1-60> {attempts <1-10>}
```

## Parameters

```
authentication eap wireless-client [attempts <1-10>|identity-request-retry-timeout
<10-5000>|
identity-request-timeout <1-60>|retry-timeout-factor <50-200>|timeout <1-60>]
```

Up to 6 RADIUS servers can be configured.</p> <ul style="list-style-type: none"> <li>&lt;1-6&gt; – Specify the RADIUS server index from 1 - 6.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                     |
| nac          | <p>Enables NAC (Network Access Control) on the RADIUS authentication server identified by the &lt;1-6&gt; parameter.</p> <p>Using NAC, the controller hardware and software grant access to specific network resources. NAC performs a user and client authorization check for resources that do not have a NAC agent. NAC verifies the client's compliance with the controller's security policy. The controller supports only the EAP/802.1x type of NAC. However, the controller also provides a means to bypass NAC authentication for client's that do not have NAC 802.1x support (printers, phones, PDAs, etc.).</p> |

| nai-routing                      | Enables NAI routing. When enabled, AAA servers identify clients using NAI. This option is disabled by default.<br>The NAI is a character string in the format of an e-mail address as either user or user@realm but it need not be a valid e-mail address or a fully qualified domain name. AAA servers identify clients using the NAI. The NAI can be used either in a specific or generic form. The specific form, which must contain the user portion and may contain the @realm portion, identifies a single user. Using the generic form allows all users to be configured on a single command line, irrespective of whether the users are within a realm or not. Each user still needs a unique security association, but these associations can be stored on a AAA server. The original purpose of the NAI was to support roaming between dial up ISPs. With NAI, an ISP does not have the accounts for all of its roaming partners in a single RADIUS database. RADIUS servers can proxy requests to remote servers as need be. |
| realm-type<br>[prefix<br>suffix] | Configures the realm-type used for NAI authentication <ul style="list-style-type: none"> <li>prefix – Sets the realm prefix. For example, in the realm name 'AC\JohnTalbot', the prefix is 'AC' and the user name 'JohnTalbot'.</li> <li>suffix – Sets the realm suffix. For example, in the realm name 'JohnTalbot@AC.org' the suffix is 'AC.org' and the user name is 'JohnTalbot'.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| realm<br><REALM-<br>NAME>        | Sets the realm information used for RADIUS authentication. The realm name should not exceed 64 characters in length. When the wireless controller or access point's RADIUS server receives a request for a user name the server references a table of usernames. If the user name is known, the server proxies the request to the RADIUS server. <ul style="list-style-type: none"> <li>&lt;REALM-NAME&gt; – Sets the realm used for authentication. This value is matched against the user name provided for RADIUS authentication.</li> </ul> <p>Example:</p> <p>Prefix - AC\JohnTalbot</p> <p>Suffix - JohnTalbot@AC.org</p>                                                                                                                                                                                                                                                                                                                                                                                                         |
| strip                            | Optional. Indicates the realm name must be stripped from the user name before sending it to the RADIUS server for authentication. For example, if the complete username is 'AC\JohnTalbot', then with the <i>strip</i> parameter enabled, only the 'JohnTalbot' part of the complete username is sent for authentication. This option is disabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

### health-check

An AAA server could go offline. When a server goes offline, it is marked as *down*. This command configures the interval after which a server marked as *down* is checked to see if it has come back online and is reachable.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
health-check interval <60-86400>
```

### Parameters

```
health-check interval <60-86400>
```

|                        |                                                                                                                                                                                                                                                     |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| interval<br><60-86400> | Configures an interval (in seconds) after which a down server is checked to see if it is reachable again <ul style="list-style-type: none"> <li>&lt;60-86400&gt; - Specify a value from 60 - 86400 seconds. The default is 3600 seconds.</li> </ul> |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Examples

```

nx9500-6C8809(config-aaa-policy-test)#health-check interval 4000
nx9500-6C8809(config-aaa-policy-test)#show context

### mac-address-format

Configures the format MAC addresses are filled in RADIUS request frames

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```

mac-address-format [middle-hyphen|no-delim|pair-colon|pair-hyphen|quad-dot]
case [lower|upper] attributes [all|username-password]

```

#### Parameters

```

mac-address-format [middle-hyphen|no-delim|pair-colon|pair-hyphen|quad-dot]
case [lower|upper] attributes [all|username-password]

```

|               |                                                                                  |
|---------------|----------------------------------------------------------------------------------|
| middle-hyphen | Configures the MAC address format as AABCCDDEEFF                                 |
| no-delim      | Configures the MAC address format as AABCCDDEEFF (without delimiters)            |
| pair-colon    | Configures the MAC address format as AA:BB:CC:DD:EE:FF                           |
| pair-hyphen   | Configures the MAC address display format as AA-BB-CC-DD-EE-FF (default setting) |
| quad-dot      | Configures the MAC address display format as AABB.CCDD.EEFF                      |

|                                    |                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| case [lower upper]                 | Indicates the case the MAC address is formatted <ul style="list-style-type: none"> <li>• lower - Indicates MAC address is in lower case. For example, aa:bb:cc:dd:ee:ff</li> <li>• upper - Indicates MAC address is in upper case. For example, AA:BB:CC:DD:EE:FF (default setting)</li> </ul>                                                     |
| attributes [all username-password] | Configures RADIUS attributes to which this MAC format is applicable <ul style="list-style-type: none"> <li>• all - Applies to all attributes with MAC addresses such as username, password, calling-station-id, and called-station-id</li> <li>• username-password - Applies only to the username and password fields (default setting)</li> </ul> |

### Examples

```

nx9500-6C8809(config-aaa-policy-test)#mac-address-format quad-dot case upper attributes
username-password
nx9500-6C8809(config-aaa-policy-test)#show context
aaa-policy test
 authentication server 5 host 172.16.10.10 secret 0 test1 port 1
 authentication server 5 timeout 10 attempts 3
 accounting server 2 host 172.16.10.10 secret 0 test1 port 1
 accounting server 2 timeout 2 attempts 2
 mac-address-format quad-dot case upper attributes username-password
 authentication protocol chap
 --More--
nx9500-6C8809(config-aaa-policy-test)#

```

### Related Commands

### *proxy-attribute*

Configures RADIUS server's attribute behavior when proxying through a wireless controller or a RF Domain manager

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```

proxy-attribute [nas-identifier|nas-ip-address]
proxy-attribute [nas-identifier [originator|proxier]]nas-ip-address [none|proxier]]

```

#### Parameters

```

proxy-attribute [nas-identifier [originator|proxier]]nas-ip-address [none|proxier]]

```

|                                        |                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| nas-identifier<br>[originator proxier] | <p>Uses NAS identifier</p> <ul style="list-style-type: none"> <li>• originator – Configures the NAS identifier as the originator of the RADIUS request. The originator could be an AP, or a wireless controller with radio. This is the default setting.</li> <li>• proxier – Configures the proxying device as the NAS identifier. The device could be a controller or a RF Domain manager.</li> </ul> |
| nas-ip-address<br>[none proxier]       | <p>Uses NAS IP address</p> <ul style="list-style-type: none"> <li>• none – NAS IP address attribute is not filled</li> <li>• proxier – NAS IP address is filled by the proxying device. The device could be a controller or a RF Domain manager. This is the default setting.</li> </ul>                                                                                                                |

### Examples

```
nx9500-6C8809(config-aaa-policy-test)#proxy-attribute nas-ip-address proxier
nx9500-6C8809(config-aaa-policy-test)#proxy-attribute nas-identifier originator
```

### Related Commands

|----|--------------------------------------------|
| no | Resets RADIUS server's proxying attributes |
|----|--------------------------------------------|

### *server-pooling-mode*

Configures the mode used to select the server from a pool of AAA servers. The available methods are *failover* and *load-balance*.

In the failover scenario, when a configured AAA server goes down, the server with the next higher index takes over for the failed server.

In the load-balance scenario, when a configured AAA server goes down, the remaining servers distribute the load amongst themselves.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
server-pooling-mode [failover|load-balance]
```

### Parameters

```
server-pooling-mode [failover|load-balance]
```

|              |                                                                                                                                                                                      |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| failover     | Sets the pooling mode to failover. This is the default setting. When a configured AAA server fails, the server with the next higher index takes over the failed server's load.       |
| load-balance | Sets the pooling mode to load balancing. When a configured AAA server fails, all servers in the pool share the failed server's load, transmitting requests in a round-robin fashion. |

## Examples

```
nx9500-6C8809(config-aaa-policy-test)#server-pooling-mode load-balance
nx9500-6C8809(config-aaa-policy-test)#show context
aaa-policy test
 authentication server 5 host 172.16.10.10 secret 0 test2 port 1
 authentication server 5 timeout 10 attempts 3
 accounting server 2 host 172.16.10.10 secret 0 test1 port 1
 server-pooling-mode load-balance
 mac-address-format quad-dot case upper attributes username-password
 accounting server preference auth-server-number
 health-check interval 4000
nx9500-6C8809(config-aaa-policy-test)#
```

## Related Commands

|                                                                                                  |
|--------------------------------------------------------------------------------------------------|

|--------------------------------------------------------------------------------------------------|

## use

Associates a NAC (Network Access Control) list with this AAA policy. When associated only the set of configured devices to allowed use of the configured AAA servers.

For more information on creating a NAC list, see [nac-list](#).

## Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
use nac-list <NAC-LIST-NAME>
```

## Parameters

```
use nac-list <NAC-LIST-NAME>
```

|                                             |                                                                                                                                                                                                  |
|---------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>nac-list &lt;NAC-LIST-NAME&gt;</code> | Associates a NAC list with this AAA policy <ul style="list-style-type: none"><li>• <code>&lt;NAC-LIST-NAME&gt;</code> - Specify the NAC list name (should be existing and configured).</li></ul> |
|---------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Examples

```
nx9500-6C8809(config-aaa-policy-test)#use nac-list test1
nx9500-6C8809(config-aaa-policy-test)#show context
aaa-policy test
 authentication server 5 host 172.16.10.10 secret 0 test1 port 1
 authentication server 5 timeout 10 attempts 3
 accounting server 2 host 172.16.10.10 secret 0 test1 port 1
 server-pooling-mode load-balance
 mac-address-format quad-dot case upper attributes username-password
 accounting server preference auth-server-number
 health-check interval 4000
 use nac-list test1
nx9500-6C8809(config-aaa-policy-test)#
```

## Related Commands

|                       |                                             |
|-----------------------|---------------------------------------------|
| <code>no</code>       | Dissociates a NAC list from this AAA policy |
| <code>nac-list</code> | Creates a NAC list                          |

`no`

Removes this AAA policy settings or reverts them to default values

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
no [accounting|attribute|authentication|health-check|mac-address-format|proxy-attribute|
server-pooling-mode|use]
no accounting interim interval
no accounting server preference
no accounting server <1-6> {dscp/nai-routing/proxy-mode/retry-timeout-factor/timeout}
no accounting type
no attribute [acct-delay-time|acct-multi-session-id|chargeable-user-identity|
cisco-vsa audit-session-id|framed-ip-address|framed-mtu|location-information|nas-ipv6-
address|
operator-name|service-type]
no authentication [eap|protocol|server]
no authentication eap wireless-client [attempts|identity-request-retry-timeout|
identity-request-timeout|retry-timeout-factor|timeout]
no authentication protocol
no authentication server <1-6> {dscp/nac/nai-routing/proxy-mode/retry-timeout-factor/
timeout}
no health-check interval
no mac-address-format
no proxy-attribute [nas-identifier|nas-ip-address]
no server-pooling-mode
no use nac-list
```

### Parameters

`no <PARAMETERS>`

|                                    |                                                                |
|------------------------------------|----------------------------------------------------------------|
| <code>no &lt;PARAMETERS&gt;</code> | Removes or reverts to default the selected AAA policy settings |
|------------------------------------|----------------------------------------------------------------|

### Examples

The following example shows the AAA policy 'test' settings before the 'no' commands are executed:

```
nx9500-6C8809(config-aaa-policy-test)#show context
aaa-policy test
 authentication server 5 host 172.16.10.10 secret 0 test1 port 1
 authentication server 5 timeout 10 attempts 3
 accounting server 2 host 172.16.10.10 secret 0 test1 port 1
 accounting server 2 timeout 2 attempts 2
 mac-address-format quad-dot case upper attributes username-password
 authentication protocol chap
 accounting interim interval 65
 accounting server preference auth-server-number
```

---

```
health-check interval 4000
attribute framed-mtu 110
nx9500-6C8809(config-aaa-policy-test)#
nx9500-6C8809(config-aaa-policy-test)#no accounting server 2 timeout 2
nx9500-6C8809(config-aaa-policy-test)#no accounting interim interval
nx9500-6C8809(config-aaa-policy-test)#no health-check interval
nx9500-6C8809(config-aaa-policy-test)#no attribute framed-mtu
nx9500-6C8809(config-aaa-policy-test)#no authentication protocol
```

The following example shows the AAA policy 'test' settings after the 'no' commands are executed:

```
nx9500-6C8809(config-aaa-policy-test)#show context
aaa-policy test
authentication server 5 host 172.16.10.10 secret 0 test1 port 1
authentication server 5 timeout 10 attempts 3
accounting server 2 host 172.16.10.10 secret 0 test1 port 1
mac-address-format quad-dot case upper attributes username-password
accounting server preference auth-server-number
health-check interval 4000
nx9500-6C8809(config-aaa-policy-test)#
```

# AUTO PROVISIONING POLICY

## AUTO-PROVISIONING-POLICY

---

This topic summarizes the auto provisioning policy commands in the CLI command structure.

Wireless devices can adopt and manage other wireless devices. For example, a wireless controller can adopt multiple access points. When a device is adopted, the device configuration is provisioned by the adopting device. Since multiple configuration policies are supported, an adopting device uses auto provisioning policies to determine which configuration policies are applied to an adoptee based on its properties. For example, a configuration policy could be assigned based on MAC address, IP address, CDP snoop strings, etc.

Auto provisioning or adoption is the process by which an access point discovers controllers in the network, identifies the most desirable controller, associates with the identified controller, and optionally obtains an image upgrade, obtains its configuration and considers itself provisioned.

At adoption, an access point solicits and receives multiple adoption responses from controllers available on the network. These adoption responses contain loading policy information the access point uses to select the optimum controller for adoption. An auto-provisioning policy maps a new AP to a profile and RF Domain based on various parameters related to the AP and where it is connected. By default a new AP will be mapped to the default profile and default RF Domain. Modify existing auto-provisioning policies or create a new one as needed to meet the configuration requirements of a device.

An auto-provisioning policy enables an administrator to define rules for the supported access points capable of being adopted by a controller. The policy determines which configuration policies are applied to an adoptee based on its properties. For example, a configuration policy could be assigned based on MAC address, IP address, CDP (cisco discovery protocol) snoop strings, etc. Once created an auto provisioning policy can be used in profiles or device configuration objects. The policy contains a set of rules (ordered by precedence) that either deny or allow adoption based on potential adoptee properties and a catch-all variable that determines if the adoption should be allowed when none of the rules is matched. All rules (both deny and allow) are evaluated sequentially starting with the rule with the lowest precedence. The evaluation stops as soon as a rule has been matched, no attempt is made to find a better match further down in the set.

For example,

```
rule #1 adopt ap7161 10 profile default vlan 10
rule #2 adopt ap6562 20 profile default vlan 20
rule #3 adopt ap7161 30 profile default serial-number
rule #4 adopt ap7161 40 p d mac aa bb
```

AP 7161 L2 adoption, VLAN 10 - will use rule #1

AP 7161 L2 adoption, VLAN 20 - will not use rule #2 (wrong type), may use rule #3 if the serial number matched, or rule #4

If aa<= MAC <= bb, or else default.

With the implementation of the HM hierarchically managed network, the auto-provisioning policy has been modified to enable controllers to adopt other controllers in addition to access points.

The new WiNG HM network defines a three-tier structure, consisting of multiple wireless sites managed by a single NOC (Network Operations Center) controller, The NOC controller constitutes the first and the site controllers constitute the second tier of the hierarchy. The site controllers in turn adopt and manage access points that form the third tier of the hierarchy.

All adopted devices (access points and second-level controllers) are referred to as the 'adoptee'. The adopting devices are the 'adopters'.

A controller cannot be configured as an adoptee and an adopter simultaneously. In other words, a controller can either be an adopter (adopts another controller) or an adoptee (is adopted by another controller). Therefore, a site controller, which has been adopted by a NOC controller, cannot adopt another controller.

A controller should be configured to specify the device types (APs and/or controllers) that it can adopt. For more information on configuring the adopted-device types for a controller, see [controller](#) on page 918.

---

#### Note

The adoption capabilities of a controller depends on:

- Whether the controller is deployed at the NOC or site
  - A NOC controller can adopt site controllers and access points
  - A site controller can adopt access points only
- The controller device type, which determines the number and type of devices it can adopt

---

Use the (config) instance to configure auto-provisioning-policy. To navigate to the auto-provisioning-policy configuration instance, use the following command:

```
<DEVICE>(config)#auto-provisioning-policy <POLICY-NAME>
nx9500-6C8809(config)#auto-provisioning-policy test
nx9500-6C8809(config-auto-provisioning-policy-test)#?
Auto-Provisioning Policy Mode commands:
 adopt Add rule for device adoption
 auto-create-rfd-template When RF Domain specified by the matching rule
 template does not exist create new RF Domain
 automatically
 default-adoption Adopt devices even when no matching rules are
 found. Assign default profile and default
 rf-domain
 deny Add rule to deny device adoption
 evaluate-always Set the flag to evaluate the policy everytime,
 regardless of previous adoption status
 no Negate a command or set its defaults
 redirect Add rule to redirect device adoption
 upgrade Add rule for device upgrade

 clrscr Clears the display screen
 commit Commit all changes made in this session
 do Run commands from Exec mode
 end End current mode and change to EXEC mode
 exit End current mode and down to previous mode
 help Description of the interactive help system
 revert Revert changes
 service Service Commands
```

```

show Show running system information
write Write running configuration to memory or terminal
nx9500-6C8809(config-auto-provisioning-policy-test)#

```

## auto-provisioning-policy-commands

The following table summarizes auto provisioning policy configuration commands:

*Table: Auto Provisioning Policy Configuration Commands*

| Command                       | Description                                                                                         |
|-------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>adopt</code>            | Adds a permit adoption rule                                                                         |
| <code>default-adoption</code> | Adopts devices even when no matching rules are found. Assigns default profile and default RF Domain |
| <code>deny</code>             | Adds a deny adoption rule                                                                           |
| <code>no</code>               | Negates a command or reverts settings to their default                                              |
| <code>redirect</code>         | Adds a rule redirecting device adoption to a specified controller within the system                 |
| <code>upgrade</code>          | Adds a device upgrade rule to this auto provisioning policy                                         |
| <code>evaluate-always</code>  | Sets the flag value                                                                                 |

### Note

For more information on common commands (clscr, commit, help, revert, service, show, write, and exit), see [COMMON COMMANDS](#) on page 640.

### Note

The input parameter <HOSTNAME>, wherever used in syntaxes across this chapter, cannot include an underscore (\_) character. In other words, the name of a device cannot contain an underscore.

## *adopt*

Adds device adoption rules to the Auto Provisioning Policy

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```

adopt [anyap | ap6522 | ap6562 | ap71xx | ap7502 | ap7522 | ap7532 | ap7562 | ap7602 | ap7612 | ap7622 | ap7632 |

|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| adopt                         | Adds an adopt device rule. The rule applies to the selected device types. Specify the device type and assign a precedence to the rule.<br>The different device types are:<br>AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533, RFS 4000, NX 5500, NX 75XX, NX 95XX, NX 96XX, and VX 9000.                                                                                                                                                                                                                              |
| precedence <1-10000>          | Sets the rule precedence from 1 - 10000. A rule with a lower value has a higher precedence.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| profile <DEVICE-PROFILE-NAME> | Sets the device profile for this provisioning policy. The selected device profile must be appropriate for the device being provisioned. For example, use an AP 7502 device profile for an AP 7502. Using an inappropriate device profile can result in unpredictable results. Provide a device profile name.<br>Provide a device profile name (should be existing and configured). Or a template with appropriate substitution tokens, such as 'campus- $\$$ MODEL[1:6]', 'FQDN[1:4]-indoor'. Refer to <a href="#">Usage Guidelines</a> for the different types of built in tokens available in the system. |

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| rf-domain <RF-DOMAIN-NAME> | <p>Sets the RF Domain for this auto provisioning policy. The provisioning policy is only applicable to devices that try to become a part of the specified RF Domain. Provide the full RF Domain name OR use a string alias to identify the RF Domain.</p> <p>Provide the full RF Domain name or an alias (should be existing and configured). Or a template with appropriate substitution tokens, such as '\$CDP[1:7]', '\$DNS-SUFFIX[1:5]'. Refer to <a href="#">Usage Guidelines</a> for the different types of built in tokens available in the system.</p> <p>Use the built-in string alias or a user-defined string alias. String aliases allow you to configure APs in the same RF Domain as the adopting controller. A string alias maps a name to an arbitrary string value, for example, 'alias string \$DOMAIN test.example_company.com'. In this example, the string-alias \$DOMAIN is mapped to the string: <i>test.example_company.com</i>. For more information, see <a href="#">alias</a>.</p> |
| any                        | Indicates any device. Any device seeking adoption is adopted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| adopt                         | <p>Adds an adopt device rule. The rule applies to the selected device types. Specify the device type and assign a precedence to the rule.</p> <p>The different device types are:<br/>AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533, RFS 4000, NX 5500, NX 75XX, NX 95XX, NX 96XX, and VX 9000.</p> <p><b>Note:</b> Use the 'anyap' option to auto provision any AP regardless of its model type.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| precedence <1-10000>          | Sets the rule precedence. A rule with a lower value has a higher precedence.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| profile <DEVICE-PROFILE-NAME> | <p>Sets the device profile for this provisioning policy. The selected device profile must be appropriate for the device being provisioned. For example, use an AP 7502 device profile for an AP 7502. Using an inappropriate device profile can result in unpredictable results. Provide a device profile name.</p> <p>Provide a device profile name (should be existing and configured). Or a template with appropriate substitution tokens, such as 'campus-\$MODEL[1:6]', 'FQDN[1:4]-indoor'. Refer to <a href="#">Usage Guidelines</a> for the different types of built in tokens available in the system.</p>                                                                                                                                                                                                                                                                                                                                                                                                         |
| rf-domain <RF-DOMAIN-NAME>    | <p>Sets the RF Domain for this auto provisioning policy. The provisioning policy is only applicable to devices that try to become a part of the specified RF Domain. Provide the full RF Domain name OR use a string alias to identify the RF Domain.</p> <p>Provide the full RF Domain name or an alias (should be existing and configured). Or a template with appropriate substitution tokens, such as '\$CDP[1:7]', '\$DNS-SUFFIX[1:5]'. Refer to <a href="#">Usage Guidelines</a> for the different types of built in tokens available in the system.</p> <p><b>Note:</b> Use the built-in string alias or a user-defined string alias. String aliases allow you to configure APs in the same RF Domain as the adopting controller. A string alias maps a name to an arbitrary string value, for example, 'alias string \$DOMAIN test.example_company.com'. In this example, the string-alias \$DOMAIN is mapped to the string: <i>test.example_company.com</i>. For more information, see <a href="#">alias</a>.</p> |
| area <AREA-NAME>              | <p>Matches the area of deployment. This option is not applicable to the 'rf-domain' parameter.</p> <ul style="list-style-type: none"> <li>&lt;AREA-NAME&gt; - Enter a 64 character maximum deployment area name assigned to this policy. Devices with matching area names are adopted.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cdp-match<br><LOCATION-SUBSTRING>       | Matches a substring in a list of CDP snoop strings (case insensitive). For example, if an access point snooped 3 devices: controller1.example.com, controller2.example.com, and controller3.example.com, 'controller1', 'example', 'example.com', are examples of the substrings that will match. <ul style="list-style-type: none"> <li>• &lt;LOCATION-SUBSTRING&gt; – Specify the value to match. Devices matching the specified value are adopted.</li> </ul>                                                                                                                                           |
| dhcp-option<br><DHCP-OPTION>            | Matches the value found in DHCP vendor option 191 (case insensitive). DHCP vendor option 191 can be setup to communicate various configuration parameters to an AP. The value of the option in a string in the form of tag=value separated by a semicolon, for example 'tag1=value1;tag2=value2;tag3=value3'. The access point includes the value of tag 'rf-domain', if present. <ul style="list-style-type: none"> <li>• &lt;DHCP-OPTION&gt; – Specify the DHCP option. Devices matching the specified value are adopted.</li> </ul>                                                                     |
| floor <FLOOR-NAME>                      | Matches the floor name. This option is not applicable to the 'rf-domain' parameter. <ul style="list-style-type: none"> <li>• &lt;FLOOR-NAME&gt; – Enter a 32 character maximum deployment floor name assigned to this policy. Devices with matching floor names are adopted.</li> </ul>                                                                                                                                                                                                                                                                                                                    |
| fqdn <FQDN>                             | Matches a substring to the FQDN (Fully Qualified Domain Name) of a device (case insensitive) FQDN is a domain name that specifies its exact location in the DNS hierarchy. It specifies all domain levels, including its top-level domain and the root domain. This parameter allows a device to adopt based on its FQDN value. <ul style="list-style-type: none"> <li>• &lt;FQDN&gt; – Specify the FQDN name. Devices matching the specified value are adopted.</li> </ul>                                                                                                                                |
| ip [<START-IP><br><END-IP>] <IP/MASK>   | Adopts a device if its IP address matches the specified IPv4 address or is within the specified IP address range. Or if the device is a part of the specified subnet. <ul style="list-style-type: none"> <li>• &lt;START-IP&gt; – Specify the first IPv4 address in the range. <ul style="list-style-type: none"> <li>• &lt;END-IP&gt; – Specify the last IPv4 address in the range.</li> </ul> </li> <li>• &lt;IP/MASK&gt; – Specify the IPv4 subnet and mask to match against the device's IP address.</li> </ul>                                                                                        |
| ipv6 [<START-IP><br><END-IP>] <IP/MASK> | Adopts a device if its IP address matches the specified IPv6 address or is within the specified IP address range. Or if the device is a part of the specified subnet. <ul style="list-style-type: none"> <li>• &lt;START-IP&gt; – Specify the first IPv6 address in the range. <ul style="list-style-type: none"> <li>• &lt;END-IP&gt; – Specify the last IPv6 address in the range.</li> </ul> </li> <li>• &lt;IP/MASK&gt; – Specify the IPv6 subnet and mask to match against the device's IPv6 address.</li> </ul>                                                                                      |
| lldp-match<br><LLDP-STRING>             | Matches a substring in a list of LLDP (Link Layer Discovery Protocol) snoop strings (case insensitive). For example, if an Access Point snooped 3 devices: controller1.example.com, controller2.example.com and controller3.example.com,'controller1', 'example', 'example.com', are substrings match. LLDP is a vendor neutral link layer protocol that advertises a network device's identity, capabilities, and neighbors on a local area network. <ul style="list-style-type: none"> <li>• &lt;LLDP-STRING&gt; – Specify the LLDP string. Devices matching the specified value are adopted.</li> </ul> |
| mac <START-MAC> {<END-MAC>}             | Adopts a device if its MAC address matches the specified MAC address or is within the specified MAC address range <START-MAC> – Specify the first MAC address in the range. Provide this MAC address if you want to match for a single device. <ul style="list-style-type: none"> <li>• &lt;END-MAC&gt; – Optional. Specify the last MAC address in the range.</li> </ul>                                                                                                                                                                                                                                  |
| model-number<br><MODEL-NUMBER>          | Adopts a device if its model number matches <MODEL-NUMBER> <ul style="list-style-type: none"> <li>• &lt;MODEL-NUMBER&gt; – Specify the model number to match.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|                                      |                                                                                                                                                                                 |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| serial-number<br><SERIAL-<br>NUMBER> | Adopts a device if its serial number matches <SERIAL-NUMBER><br><ul style="list-style-type: none"> <li>• &lt;SERIAL-NUMBER&gt; - Specify the serial number to match.</li> </ul> |
| vlan <VLAN-ID>                       | Adopts a device if its VLAN matches <VLAN-ID><br><ul style="list-style-type: none"> <li>• &lt;VLAN-ID&gt; - Specify the VLAN ID.</li> </ul>                                     |

**Usage Guidelines: Built-in Tokens & Alias**

Following are the built-in tokens that can be used to identify the devices to adopt:

- \$FQDN - references FQDN of adopting device
- \$CDP - references CDP Device Id of the wired switch to which adopting device is connected
- \$LLDP - references LLDP System Name of wired switch to which adopting device is connected
- \$DHCP - references DHCP Option Value received by the adopting device
- \$SN - references SERIAL NUMBER of adopting device
- \$MODEL - references MODEL NUMBER of adopting device
- \$DNS-SUFFIX - references FQDN excluding the hostname of the adopting device
- \$CDP-SUFFIX - references CDP excluding the hostname of the adopting device
- \$LLDP-SUFFIX - references LLDP excluding the hostname of the adopting device

Following is the built-in alias that can be used to identify the RF Domain of devices to adopt:

- \$AUTO-RF-DOMAIN - rf-domain of adopting device

**Examples**

```
rfs4000-229D58(config-auto-provisioning-policy-test)#adopt ap8432 precedence 5 profile
default-ap8432 rf-domain TechPubs vlan 1
rfs4000-229D58(config-auto-provisioning-policy-test)#show context
auto-provisioning-policy test
 adopt ap8432 precedence 5 profile default-ap8432 rf-domain TechPubs vlan 1
rfs4000-229D58(config-auto-provisioning-policy-test)#
rfs4000-229D58(config-auto-provisioning-policy-test)#show wireless ap configured

|----|-----------------------------------------------------------------|
| no | Removes an adopt device rule from this Auto Provisioning Policy |
|----|-----------------------------------------------------------------|

*auto-create-rfd-template*

Enables auto creation of an RF Domain:

- when tokens are used to select the RF Domain to apply to devices matching the adoption criteria, and
- the token-specified RF Domain does not exist.

During device adoption, if the token-specified RF Domain (configured using the 'adopt' rule) is not found, the system auto creates a new RF Domain based on an existing RF Domain template specified using this command. This option is disabled by default.

## Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
auto-create-rfd-template <RF-DOMAIN-NAME>
```

## Parameters

```
auto-create-rfd-template <RF-DOMAIN-NAME>
```

|                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| auto-create-rfd-template <RF-DOMAIN-NAME> | <p>Auto creates a new RF Domain based on an existing RF Domain template</p> <ul style="list-style-type: none"><li>• &lt;RF-DOMAIN-NAME&gt; – Specify the RF Domain name (should be existing and configured). The new RF Domain created is saved with the token name specified in the 'adopt' command.</li></ul> <p><b>Note:</b> For more information on configuring tokens, see <a href="#">Usage Guidelines: Built-in Tokens &amp; Alias</a>.</p> |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Examples

The following example configures an adopt rule for adopting any AP7532 and applying an RF Domain matching the token "\$MODEL[1:5]" to the adopted AP:

```
nx9500-6C8809(config-auto-provisioning-policy-test)#adopt ap7532 precedence 20
rf-domain $MODEL[1:5] any
nx9500-6C8809(config-auto-provisioning-policy-test)#show context
auto-provisioning-policy test
 adopt ap7532 precedence 20 rf-domain $MODEL[1:5] any
nx9500-6C8809(config-auto-provisioning-policy-test)#
```

The following example enables auto creation of an RF Domain using an existing RF Domain 'rfd-AP' as template:

- RF Domain name "AP-75": Applicable to any AP 7532

```
nx9500-6C8809(config-auto-provisioning-policy-test)#auto-create-rfd-template AP-75
nx9500-6C8809(config-auto-provisioning-policy-test)#show context
auto-provisioning-policy test
 adopt ap7532 precedence 20 any
 auto-create-rfd-template rfd-AP
nx9500-6C8809(config-auto-provisioning-policy-test)#
```
- As per the above configurations, when an AP 7532 comes up for first-time adoption, the system:
  - Checks for an RF Domain matching the options provided in the 'adopt' rule, and if not found
  - auto creates the RF Domain only if:
    - A token is specified in the 'adopt' rule. For example, \$MODEL[1:5], and
    - the 'auto-create-rfd-template' option is configured
  - Uses the 'RF Domain' specified in the auto-create-rfd-template command as a template. Therefore, the specified RF Domain should be existing and configured.
  - Applies the new RF Domain to the AP.

|---------------------------------------------------------------------------------|
| <code>no</code> Removes a deny adoption rule from this Auto Provisioning Policy |
|---------------------------------------------------------------------------------|

### *evaluate-always*

Sets flag to run this auto-provisioning policy every time an access point is adopted. The access point's previous adoption status is not taken into consideration.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
evaluate-always
```

## Parameters

None

## Examples

```
rfs4000-229D58(config-auto-provisioning-policy-test)#evaluate-always
rfs4000-229D58(config-auto-provisioning-policy-test)#show context

## Related Commands

|           |                                                            |
|-----------|------------------------------------------------------------|
| <b>no</b> | Removes a redirect rule from this Auto Provisioning Policy |
|-----------|------------------------------------------------------------|

## upgrade

Adds a device upgrade rule to this auto provisioning policy. When applied to a controller, the upgrade rule ensures adopted devices, of the specified type, are upgraded automatically.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
upgrade [anyap|ap6522|ap6562|ap71xx|ap7502|ap7522|ap7532|ap7562|ap7602|ap7612|
ap7622|ap7632|ap7662|ap81xx|ap8432|ap8533|rfs4000|nx5500|nx75xx|nx95xx|vx9000|nx96xx]
upgrade [anyap|ap6522|ap6562|ap71xx|ap7502|ap7522|ap7532|ap7562|ap7602|ap7612|
ap7622|ap7632|ap7662|ap81xx|ap8432|ap8533|rfs4000|nx5500|nx75xx|nx95xx|vx9000|nx96xx]
precedence <1-10000> [any|cdp-match|dhcp-option|fqdn|ip|ipv6|lldp-match|mac|model-number|
serial-number|vlan]
upgrade [anyap|ap6522|ap6562|ap71xx|ap7502|ap7522|ap7532|ap7562|ap7602|ap7612|
ap7622|ap7632|ap7662|ap81xx|ap8432|ap8533|rfs4000|nx5500|nx75xx|nx95xx|vx9000|nx96xx]
precedence <1-10000> [cdp-match <LOCATION-SUBSTRING>|dhcp-option <DHCP-OPTION>|fqdn <FQDN>|
ip [<START-IP> <END-IP>|<IP/MASK>]|ipv6 [<START-IP> <END-IP>|<IP/MASK>]|

Rules with lower values get precedence over rules with higher values.                                                                                                                                                                                                                                                                                                                                                                                               |

Devices matching the specified string are upgraded.</li> </ul>                                                                                                                                                                                                                                                         |
| dhcp-option <DHCP-OPTION>          | <p>Configures the DHCP options to match</p> <p>DHCP options identify the vendor and DHCP client functionalities. This information is used by the client to convey to the DHCP server that the client requires extra information in a DHCP response.</p> <ul style="list-style-type: none"> <li>• &lt;DHCP-OPTION&gt; - Specify the DHCP option value. Devices matching the specified value are upgraded.</li> </ul>                                                                           |
| fqdn <FQDN>                        | <p>Configures the FQDN to match.</p> <p>FQDN is a domain name that specifies its exact location in the DNS hierarchy. It specifies all domain levels, including its top-level domain and the root domain.</p> <ul style="list-style-type: none"> <li>• &lt;FQDN&gt; - Specify the FQDN. Devices matching the specified value are upgraded.</li> </ul>                                                                                                                                         |
| ip [<START-IP> <END-IP> <IP/MASK>] | <p>Upgrades if a device's IPv4 address matches the specified IP address or is within the specified IP address range</p> <ul style="list-style-type: none"> <li>• &lt;START-IP&gt; - Specify the first IPv4 address in the range. <ul style="list-style-type: none"> <li>• &lt;END-IP&gt; - Specify the last IPv4 address in the range.</li> </ul> </li> <li>• &lt;IP/MASK&gt; - Specify the IPv4 subnet and mask to match against the device's IP address.</li> </ul>                         |

|                                              |                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ipv6 [<START-IP><br><END-IP>  <IP/<br>MASK>] | Upgrades if a device's IPv6 address matches the specified IP address or is within the specified IP address range <ul style="list-style-type: none"> <li>• &lt;START-IP&gt; – Specify the first IPv6 address in the range.</li> <li>• &lt;END-IP&gt; – Specify the last IPv6 address in the range.</li> <li>• &lt;IP/MASK&gt; – Specify the IPv6 subnet and mask to match against the device's IP address.</li> </ul> |
| lldp-match <LLDP-<br>STRING>                 | Configures the device location to match, based on LLDP snoop strings. LLDP is a vendor neutral link layer protocol used to advertise a network device's identity, capabilities, and neighbors on a local area network. <ul style="list-style-type: none"> <li>• &lt;LLDP-STRING&gt; – Specify the location. Devices matching the specified string are upgraded.</li> </ul>                                           |
| mac <START-MAC><br>{<END-MAC>}               | Configures a single or a range of MAC addresses. Devices matching the specified values are upgraded. <ul style="list-style-type: none"> <li>• &lt;START-MAC&gt; – Specify the first MAC address in the range. Provide only this MAC address to filter a single device.</li> <li>• &lt;END-MAC&gt; – Optional. Specify the last MAC address in the range.</li> </ul>                                                  |
| model-number<br><MODEL-NUMBER>               | Configures the device model number <ul style="list-style-type: none"> <li>• &lt;MODEL-NUMBER&gt; – Specify the model number. Devices matching the specified model number are upgraded.</li> </ul>                                                                                                                                                                                                                    |
| serial-number<br><SERIAL-NUMBER>             | Configures the device's serial number <ul style="list-style-type: none"> <li>• &lt;SERIAL-NUMBER&gt; – Specify the serial number. Device with the specified serial number is upgraded.</li> </ul>                                                                                                                                                                                                                    |
| vlan <VLAN-ID>                               | Configures the VLAN ID <ul style="list-style-type: none"> <li>• &lt;VLAN-ID&gt; – Specify the VLAN ID. Devices assigned to the specified VLAN are upgraded.</li> </ul>                                                                                                                                                                                                                                               |

## Examples

```

rfs4000-229D58(config-auto-provisioning-policy-test1)#upgrade ap8432 precedence 10 any
rfs4000-229D58(config-auto-provisioning-policy-test1)#upgrade ap7522 precedence 11 vlan 1
rfs4000-229D58(config-auto-provisioning-policy-test1)#show context
auto-provisioning-policy test
 default-adoption
 evaluate-always
 deny ap8432 precedence 1 mac 74-67-F7-07-02-35
 deny ap8432 precedence 2 ip 192.168.13.24 102.168.13.26
 adopt ap8432 precedence 5 profile default-ap8432 rf-domain TechPubs vlan 1
 redirect ap81xx precedence 6 controller 192.168.13.10 ip 192.168.13.11 192.168.13.15
 redirect ap7532 precedence 7 controller 192.168.13.10 model-number AP-7532-67030-WR
 upgrade ap8432 precedence 10 any
 upgrade ap7522 precedence 11 vlan 1
rfs4000-229D58(config-auto-provisioning-policy-test1)#

```

## Related Commands

|                                                                      |
|----------------------------------------------------------------------|
| <b>no</b> Removes an upgrade rule from this Auto Provisioning Policy |
|----------------------------------------------------------------------|

*no*

Removes a deny, permit, or redirect rule from the selected auto provisioning policy

## Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
no [adopt|auto-create-rfd-template|default-adoption|deny|evaluate-always|redirect|upgrade]
no adopt precedence <1-10000>
no auto-create-rfd-template
no deny precedence <1-10000>
no evaluate-always
no default-adoption
no redirect precedence <1-10000>
no upgrade precedence <1-10000>
```

## Parameters

```
no <PARAMETERS>
```

|                 |                                                                                      |
|-----------------|--------------------------------------------------------------------------------------|
| no <PARAMETERS> | Removes a deny, permit, or redirect rule from the specified auto provisioning policy |
|-----------------|--------------------------------------------------------------------------------------|

## Examples

The following example shows the auto-provisioning-policy 'test' settings before the 'no' commands are executed:

```
rfs4000-229D58(config-auto-provisioning-policy-test1)#show context
auto-provisioning-policy test
 default-adoption
 evaluate-always
 deny ap8432 precedence 1 mac 74-67-F7-07-02-35
 deny ap8432 precedence 2 ip 192.168.13.24 102.168.13.26
 adopt ap8432 precedence 5 profile default-ap8432 rf-domain TechPubs vlan 1
 redirect ap81xx precedence 6 controller 192.168.13.10 ip 192.168.13.11 192.168.13.15
 redirect ap7532 precedence 7 controller 192.168.13.10 model-number AP-7532-67030-WR
 upgrade ap8432 precedence 10 any
 upgrade ap7522 precedence 11 vlan 1
rfs4000-229D58(config-auto-provisioning-policy-test1)#
rfs4000-229D58(config-auto-provisioning-policy-test)#no default-adoption
rfs4000-229D58(config-auto-provisioning-policy-test)#no deny precedence 1
rfs4000-229D58(config-auto-provisioning-policy-test)#no redirect precedence 6
rfs4000-229D58(config-auto-provisioning-policy-test)#no upgrade precedence 11
```

The following example shows the auto-provisioning-policy 'test' settings after the 'no' commands are executed:

```
rfs4000-229D58(config-auto-provisioning-policy-test)#show context
auto-provisioning-policy test
 deny ap8432 precedence 2 ip 192.168.13.24 102.168.13.26
 adopt ap8432 precedence 5 profile default-ap8432 rf-domain TechPubs vlan 1
 redirect ap7532 precedence 7 controller 192.168.13.10 model-number AP-7532-67030-WR
 upgrade ap8432 precedence 10 any
rfs4000-229D58(config-auto-provisioning-policy-test)#
```

# ASSOCIATION ACL POLICY

## ASSOCIATION-ACL-POLICY

---

This chapter summarizes the association ACL (Access Control List) policy commands in the CLI command structure. An association ACL is a policy-based ACL that either prevents or allows wireless clients from connecting to a controller managed WLAN.

System administrators can use an association ACL to grant or restrict wireless clients access to the WLAN by specifying client MAC addresses or range of MAC addresses to either include or exclude from controller connectivity. Association ACLs are applied to WLANs as an additional access control mechanism.

Use the (config) instance to configure the association ACL policy. To navigate to the association-acl-policy instance, use the following commands:

```
<DEVICE>(config)#association-acl-policy <POLICY-NAME>
nx9500-6C8809(config)#association-acl-policy test
nx9500-6C8809(config-assoc-acl-test)#?
Association ACL Mode commands:
 deny Specify MAC addresses to be denied
 no Negate a command or set its defaults
 permit Specify MAC addresses to be permitted

 clrscr Clears the display screen
 commit Commit all changes made in this session
 do Run commands from Exec mode
 end End current mode and change to EXEC mode
 exit End current mode and down to previous mode
 help Description of the interactive help system
 revert Revert changes
 service Service Commands
 show Show running system information
 write Write running configuration to memory or terminal

nx9500-6C8809(config-assoc-acl-test)#
```

### Note

If creating an new association ACL policy, provide a name specific to its function. Avoid naming it after a WLAN it may support. The name cannot exceed 32 characters.

---

Before defining an association ACL policy and applying it to a WLAN, refer to the following deployment guidelines to ensure the configuration is optimally effective:

- The name and configuration of an association ACL policy should meet the requirements of the WLANs it may map to. However, be careful not to name ACLs after specific WLANs, as individual ACL policies can be used by more than one WLAN.
- You cannot apply more than one MAC based ACL to a layer 2 interface. If a MAC ACL is already configured on a layer 2 interface, and a new MAC ACL is applied to the interface, the new ACL replaces the previously configured one.

## Association-acl-policy-commands

The following table summarizes the association ACL policy configuration commands:

Table: Association ACL Policy Configuration Commands

| Command                          | Description                                                    |
|----------------------------------|----------------------------------------------------------------|
| <code>deny</code> on page 1356   | Specifies a range of MAC addresses denied access to the WLAN   |
| <code>permit</code> on page 1357 | Specifies a range of MAC addresses allowed access to the WLAN  |
| <code>no</code> on page 1359     | Removes a deny or permit rule from this association ACL policy |

### Note

For information on common commands (clear, commit, help, revert, service, show, write, and exit), see [COMMON COMMANDS](#) on page 640.

### Note

The input parameter <HOSTNAME>, wherever used in syntaxes across this chapter, cannot include an underscore ( \_ ) character. In other words, the name of a device cannot contain an underscore.

### *deny*

Creates a list of devices denied access to the managed network. Devices are identified by their MAC address. A single MAC address or a range of MAC addresses can be denied access. This command also sets the precedence on how deny rules are applied. Up to a thousand (1000) deny rules can be defined for every association ACL policy. Each rule has a unique sequential precedence value assigned, and are applied to packets on the basis of this precedence value. Lower the precedence of a rule, higher is its priority. This results in the rule with the lowest precedence being applied first. No two rules can have the same precedence. The default precedence is 1, so be careful to prioritize ACLs accordingly as they are added.

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
deny <STARTING-MAC> [<ENDING-MAC> |precedence]
deny <STARTING-MAC> precedence <1-1000>
deny <STARTING-MAC> <ENDING-MAC> precedence <1-1000>
```

#### Parameters

```
deny <STARTING-MAC> precedence <1-1000>
```

|                     |                                                                                                                                                                                                                   |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| deny                | Adds a single device or a set of devices to the deny list                                                                                                                                                         |
| <STARTING-MAC>      | To add a single device, enter its MAC address in the <STARTING-MAC> parameter.                                                                                                                                    |
| precedence <1-1000> | Sets a precedence value for this rule. Rules are applied in an increasing order of their precedence. <ul style="list-style-type: none"> <li>&lt;1-1000&gt; - Specify a precedence value from 1 - 1000.</li> </ul> |

```
deny <STARTING-MAC> <ENDING-MAC> precedence <1-1000>
```

|                     |                                                                                                                                                                                         |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| deny                | Adds a single device or a set of devices to the deny list. To add a set of devices, provide the range of MAC addresses.                                                                 |
| <STARTING-MAC>      | Specify the first MAC address in the range.                                                                                                                                             |
| <ENDING-MAC>        | Specify the last MAC address in the range.                                                                                                                                              |
| precedence <1-1000> | Sets a precedence rule. Rules are applied in an increasing order of their precedence. <ul style="list-style-type: none"> <li>&lt;1-1000&gt; - Specify a value from 1 - 1000.</li> </ul> |

### Usage Guidelines

Every rule has a unique sequential precedence value. You cannot add two rules with the same precedence. Rules are checked in an increasing order of precedence. That means, the rule with precedence 1 is checked first, then the rule with precedence 2 and so on.

### Examples

```
nx9500-6C8809(config-assoc-acl-test)#deny 11-22-33-44-55-01 11-22-33-44-55-FF precedence
150
nx9500-6C8809(config-assoc-acl-test)#deny 11-22-33-44-56-01 precedence 160
nx9500-6C8809(config-assoc-acl-test)#show context
association-acl-policy test
 deny 11-22-33-44-55-01 11-22-33-44-55-FF precedence 150
 deny 11-22-33-44-56-01 precedence 160
nx9500-6C8809(config-assoc-acl-test)#
```

### Related Commands

|    |                                                      |
|----|------------------------------------------------------|
| no | Removes a deny rule from this Association ACL Policy |
|----|------------------------------------------------------|

### *permit*

Creates a list of devices allowed access to the managed network. Devices are permitted access based on their MAC address. A single MAC address or a range of MAC addresses can be specified. This command also sets the precedence on how permit list rules are applied. Up to a thousand (1000) permit rules can be defined for every association ACL policy. Each rule has a unique sequential precedence value assigned, and are applied to packets on the basis of this precedence value. Lower the precedence of a rule, higher is its priority. This results in the rule with the lowest precedence being applied first. No two rules can have the same precedence. The default precedence is 1, so be careful to prioritize ACLs accordingly as they are added.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533

- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
permit <STARTING-MAC> [<ENDING-MAC> | precedence]
permit <STARTING-MAC> precedence <1-1000>
permit <STARTING-MAC> <ENDING-MAC> precedence <1-1000>
```

### Parameters

```
permit <STARTING-MAC> precedence <1-1000>
```

|                     |                                                                                                                                                                                                      |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| permit              | Adds a single device or a set of devices to the permit list                                                                                                                                          |
| <STARTING-MAC>      | To add a single device, enter its MAC address in the <STARTING-MAC> parameter.                                                                                                                       |
| precedence <1-1000> | Specifies a rule precedence. Rules are applied in an increasing order of their precedence value. <ul style="list-style-type: none"> <li>• &lt;1-1000&gt; – Specify a value from 1 - 1000.</li> </ul> |

```
permit <STARTING-MAC> <ENDING-MAC> precedence <1-1000>
```

|                     |                                                                                                                                                                                                      |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| permit              | Adds a single device or a set of devices to the permit list To add a set of devices, provide the MAC address range.                                                                                  |
| <STARTING-MAC>      | Specify the first MAC address of the range.                                                                                                                                                          |
| <ENDING-MAC>        | Specify the last MAC address of the range.                                                                                                                                                           |
| precedence <1-1000> | Specifies a rule precedence. Rules are applied in an increasing order of their precedence value. <ul style="list-style-type: none"> <li>• &lt;1-1000&gt; – Specify a value from 1 - 1000.</li> </ul> |

### Usage Guidelines

Every rule has a unique sequential precedence value. You cannot add two rules with the same precedence. Rules are checked in an increasing order of precedence. That means, the rule with precedence 1 is checked first, then the rule with precedence 2 and so on.

### Examples

```
nx9500-6C8809(config-assoc-acl-test)# permit 11-22-33-44-66-01 11-22-33-44-66-FF
precedence 170
nx9500-6C8809(config-assoc-acl-test)# permit 11-22-33-44-67-01 precedence 180
nx9500-6C8809(config-assoc-acl-test)#show context
association-acl-policy test
deny 11-22-33-44-55-01 11-22-33-44-55-FF precedence 150
deny 11-22-33-44-56-01 precedence 160
permit 11-22-33-44-66-01 11-22-33-44-66-FF precedence 170
permit 11-22-33-44-67-01 precedence 180
nx9500-6C8809(config-assoc-acl-test)#
```

### Related Commands

|----|--------------------------------------------------------|
| no | Removes a permit rule from this Association ACL Policy |
|----|--------------------------------------------------------|

no

Removes a deny or permit rule from this Association ACL Policy

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
no [deny|permit]
no deny <STARTING-MAC> precedence <1-1000>
no deny <STARTING-MAC> <ENDING-MAC> precedence <1-1000>
no permit <STARTING-MAC> precedence <1-1000>
no permit <STARTING-MAC> <ENDING-MAC> precedence <1-1000>
```

#### Parameters

no <PARAMETERS>

|                 |                                                                |
|-----------------|----------------------------------------------------------------|
| no <PARAMETERS> | Removes a deny or permit rule from this association ACL policy |
|-----------------|----------------------------------------------------------------|

#### Examples

The following example shows the association ACL policy 'test' settings before the 'no' commands is executed:

```
nx9500-6C8809(config-assoc-acl-test)#show context
association-acl-policy test
 deny 11-22-33-44-55-01 11-22-33-44-55-FF precedence 150
 deny 11-22-33-44-56-01 precedence 160
 permit 11-22-33-44-66-01 11-22-33-44-66-FF precedence 170
 permit 11-22-33-44-67-01 precedence 180
nx9500-6C8809(config-assoc-acl-test)#
nx9500-6C8809(config-assoc-acl-test)#no deny 11-22-33-44-56-01 11-22-33-44-56-FF
precedence 150
```

The following example shows the association ACL policy 'test' settings after the 'no' commands is executed:

```
nx9500-6C8809(config-assoc-acl-test)#show context
association-acl-policy test
 deny 11-22-33-44-56-01 precedence 160
 permit 11-22-33-44-66-01 11-22-33-44-66-FF precedence 170
 permit 11-22-33-44-67-01 precedence 180
nx9500-6C8809(config-assoc-acl-test)#
```

# ACCESS LIST

## ACCESS-LIST

---

This chapter summarizes IP and MAC access list commands in the CLI command structure.

Access lists control access to the managed network using a set of rules also known as ACEs (Access Control Entries). Each rule specifies an action taken when a packet matches that rule. If the action is deny, the packet is dropped. If the action is permit, the packet is allowed. A set of deny and/or permit rules based on IP (IPv4 and IPv6) addresses constitutes a IP ACL (Access Control List). Similarly, a set of deny and/or permit rules based on MAC addresses constitutes a MAC ACL.

Within a managed network, IP ACLs are used as firewalls to filter packets and also mark packets. IP based firewall rules are specific to the source and destination IP addresses and have unique precedence orders assigned. Both IP and non-IP traffic on the same layer 2 interface can be filtered by applying an IP ACL. With either IPv4 or IPv6, create access rules for traffic entering a controller, service platform, or access point interface, because if you are going to deny specific types of packets, it's recommended you do it before the controller, service platform, or access point spends time processing them, since access rules are given priority over other types of firewall rules.

MAC ACLs are firewalls that filter or mark packets based on the MAC address which they arrive, as opposed to filtering packets on layer 2 ports. Optionally filter layer 2 traffic on a physical layer 2 interface using MAC addresses. A MAC firewall rule uses source and destination MAC addresses for matching operations, where the result is a typical allow, deny or mark designation to controller managed packet traffic.

Once defined, an IP and/or MAC ACL (consisting of a set of firewall rules) must be applied to an interface to be a functional filtering tool.

Firewall supported devices (access points, wireless controllers, and service platforms) process firewall rules (within an IP/MAC ACL) sequentially, in ascending order of their precedence value. When a packet matches a rule, the firewall applies the action specified in the rule to determine whether the traffic is allowed or denied. Once a match is made, the firewall does not process subsequent rules in the ACL.

The WiNG software enables the configuration of IP SNMP ACLs. These ACLs control access by combining IP ACLs with SNMP server community strings.

The following ACLs are supported:

- [ip-access-list](#) on page 1363
- [ipv6-access-list](#) on page 1403
- [mac-access-list](#) on page 1389
- [ip-snmp-access-list](#) on page 1415
- [ex3500-ext-access-list](#) on page 1417
- [ex3500-std-access-list](#) on page 1424

Use IP and MAC commands under the global configuration to create an access list.

- When the access list is applied on an Ethernet port, it becomes a port ACL

- When the access list is applied on a VLAN interface, it becomes a router ACL

Use the (config) instance to configure a new ACL or modify an existing ACL. To navigate to the (config-access-list) instance, use the following commands:

```
<DEVICE>(config)#ip access-list <IP-ACCESS-LIST-NAME>
<DEVICE>(config)#mac access-list <MAC-ACCESS-LIST-NAME>
<DEVICE>(config)#ipv6 access-list <IPv6-ACCESS-LIST-NAME>
<DEVICE>(config)#ip snmp-access-list <SNMP-ACCESS-LIST-NAME>
<DEVICE>(config)#ex3500-ext-access-list <EX3500-EXT-ACCESS-LIST-NAME>
<DEVICE>(config)#ex3500-std-access-list <EX3500-STD-ACCESS-LIST-NAME>
```

#### Note

If creating a new ACL policy, provide a name that uniquely identifies its purpose. The name cannot exceed 32 characters.

### IPv4 Access List

```
nx9500-6C8809(config)#ip access-list IPv4ACL
nx9500-6C8809(config-ip-acl-IPv4ACL)#?
ACL Configuration commands:
 deny Specify packets to reject
 disable Disable rule if not needed
 insert Insert this rule (instead of overwriting a existing rule)
 no Negate a command or set its defaults
 permit Specify packets to forward

 clrscr Clears the display screen
 commit Commit all changes made in this session
 do Run commands from Exec mode
 end End current mode and change to EXEC mode
 exit End current mode and down to previous mode
 help Description of the interactive help system
 revert Revert changes
 service Service Commands
 show Show running system information
 write Write running configuration to memory or terminal

nx9500-6C8809(config-ip-acl-IPv4ACL)#
```

### IPv6 Access List

```
nx9500-6C8809(config)#ipv6 access-list IPv6ACL
nx9500-6C8809(config-ipv6-acl-IPv6ACL)#?
IPv6 Access Control Mode commands:
 deny Specify packets to reject
 no Negate a command or set its defaults
 permit Specify packets to forward

 clrscr Clears the display screen
 commit Commit all changes made in this session
 do Run commands from Exec mode
 end End current mode and change to EXEC mode
 exit End current mode and down to previous mode
 help Description of the interactive help system
 revert Revert changes
 service Service Commands
 show Show running system information
 write Write running configuration to memory or terminal

nx9500-6C8809(config-ipv6-acl-IPv6ACL)#
```

## MAC Access List

```
nx9500-6C8809(config)#mac access-list MACACL
nx9500-6C8809(config-mac-acl-MACACL)#?
MAC Extended ACL Configuration commands:
 deny Specify packets to reject
 disable Disable rule if not needed
 ex3500 Ex3500 device
 insert Insert this rule (instead of overwriting a existing rule)
 no Negate a command or set its defaults
 permit Specify packets to forward

 clrscr Clears the display screen
 commit Commit all changes made in this session
 do Run commands from Exec mode
 end End current mode and change to EXEC mode
 exit End current mode and down to previous mode
 help Description of the interactive help system
 revert Revert changes
 service Service Commands
 show Show running system information
 write Write running configuration to memory or terminal

nx9500-6C8809(config-mac-acl-MACACL)#
```

## SNMP Access List

```
nx9500-6C8809(config)#ip snmp-access-list SNMPACL
nx9500-6C8809(config-ip-snmp-acl-SNMPACL)#?
SNMP ACL Configuration commands:
 deny Specify packets to reject
 no Negate a command or set its defaults
 permit Specify packets to forward

 clrscr Clears the display screen
 commit Commit all changes made in this session
 do Run commands from Exec mode
 end End current mode and change to EXEC mode
 exit End current mode and down to previous mode
 help Description of the interactive help system
 revert Revert changes
 service Service Commands
 show Show running system information
 write Write running configuration to memory or terminal

nx9500-6C8809(config-ip-snmp-acl-SNMPACL)#
```

The WiNG NOC controller also has the capabilities of adopting and managing EX3500 series switch. These switches are Gigabit Ethernet layer 2 switches with either 24 or 48 10/100/1000-BASE-T ports, and four SFP (Small Form Factor Pluggable) transceiver slots for fiber connectivity. Once adopted to the NOC, various ACLs specifically defined for a EX3500 switch can be used to either prevent or allow specific clients from using it.

The following EX3500 ACLs are supported:

- [EX3500 Extended Access List](#).
- [EX3500 Standard Access List](#).

- **EX3500 (MAC ACL)**. This configures a EX3500 deny or permit rule in a MAC ACL.

#### Note

The input parameter <HOSTNAME>, wherever used in syntaxes across this chapter, cannot include an underscore ( \_ ) character. In other words, the name of a device cannot contain an underscore.

## ip-access-list

The following table summarizes IP Access List configuration commands.

Table: IP-Access-List-Config Commands

| Command                                | Description                                                                                                                                                           |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>deny (ipv4-acl)</b> on page 1363    | Creates a deny access rule or modifies an existing rule. A deny access rule rejects packets from specified address(es) and/or destined for specified address(es).     |
| <b>disable (ipv4-acl)</b> on page 1374 | Disables an existing deny or permit rule without removing it from the ACL                                                                                             |
| <b>insert (ipv4-acl)</b> on page 1376  | Inserts a rule in an IP ACL without overwriting or replacing an existing rule having the same precedence                                                              |
| <b>permit (ipv4-acl)</b> on page 1378  | Creates a permit access rule or modifies an existing rule. A permit access rule accepts packets from specified address(es) and/or destined for specified address(es). |
| <b>no (ipv4-acl)</b> on page 1388      | Removes a deny and/or a permit access rule from a IP ACL                                                                                                              |

#### Note

For more information on common commands (clrscr, commit, help, revert, service, show, write, and exit), see **COMMON COMMANDS** on page 640.

### *deny (ipv4-acl)*

Creates a deny rule that rejects packets received from a specified source IP and/or addressed to a specified destination IP. You can also use this command to modify an existing deny rule.

#### Note

Use a decimal value representation to implement a *permit/deny* designation for a packet. The command set for IP ACLs provides the hexadecimal values for each listed EtherType. Use the decimal equivalent of the EtherType listed for any other EtherType.

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
deny [<NETWORK-SERVICE-ALIAS-NAME>|dns-name|icmp|ip|proto|tcp|udp]
deny <NETWORK-SERVICE-ALIAS-NAME> [<SOURCE-IP/MASK>|<NETWORK-GROUP-ALIAS-NAME>|

|                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| eigrp                              | Identifies the EIGRP (Enhanced Internet Gateway Routing Protocol) protocol (number 88) EIGRP enables routers to maintain copies of neighbors' routing tables. Routers use this information to determine the fastest route to a destination. When a router fails to find a route in its stored route tables, it sends a query to neighbors who in turn query their neighbors till a route is found. EIGRP also enables routers to inform neighbors of changes in their routing tables.                                                |
| gre                                | Identifies the GRE (General Routing Encapsulation) protocol (number 47) GRE is a tunneling protocol that enables transportation of protocols (IP, IPX, DEC net, etc.) over an IP network. GRE encapsulates the packet at the source and removes the encapsulation at the destination.                                                                                                                                                                                                                                                |
| igmp                               | Identifies the IGMP (Internet Group Management Protocol) protocol (number 2) IGMP establishes and maintains multicast group memberships to interested members. Multicasting allows a networked computer to send content to multiple computers who have registered to receive the content. IGMP snooping is for listening to IGMP traffic between an IGMP host and routers in the network to maintain a map of the links that require multicast streams. Multicast traffic is filtered out for those links which do not require them. |
| igp                                | Identifies any private internal gateway (primarily used by CISCO for their IGRP) (number 9) IGP enables exchange of information between hosts and routers within a managed network. The most commonly used IGP (interior gateway protocol) protocols are: RIP (Routing Information Protocol) and OSPF (Open Shortest Path First).                                                                                                                                                                                                    |
| ospf                               | Identifies the OSPF protocol (number 89) OSPF is a link-state IGP. OSPF routes IP packets within a single routing domain (autonomous system), like an enterprise LAN. OSPF gathers link state information from neighbor routers and constructs a network topology. The topology determines the routing table presented to the Internet Layer which makes routing decisions based solely on the destination IP address found in IP packets.                                                                                           |
| vrrp                               | Identifies the VRRP (Virtual Router Redundancy Protocol) protocol (number 112) VRRP allows a pool of routers to be advertised as a single virtual router. This virtual router is configured by hosts as their default gateway. VRRP elects a master router, from this pool, and assigns it a virtual IP address. The master router routes and forwards packets to hosts on the same subnet. When the master router fails, one of the backup routers is elected as the master and its IP address is mapped to the virtual IP address. |
| <SOURCE-IP/<br>MASK>               | Specifies the source IP address and mask (A.B.C.D/M) to match. Packets (EIGRP, GRE, IGMP, IGP, OSPF, or VRRP) received from the specified sources are dropped.                                                                                                                                                                                                                                                                                                                                                                       |
| <NETWORK-<br>GROUP-ALIAS-<br>NAME> | Applies a network-group alias to identify the source IP addresses. Packets (EIGRP, GRE, IGMP, IGP, OSPF, or VRRP) received from the sources defined in the network-group alias are dropped. <ul style="list-style-type: none"> <li>• &lt;NETWORK-GROUP-ALIAS-NAME&gt; - Specify the network-group alias name (should be existing and configured).</li> </ul>                                                                                                                                                                         |
| any                                | Specifies the source as any IP address. Packets (EIGRP, GRE, IGMP, IGP, OSPF, or VRRP) received from any source are dropped.                                                                                                                                                                                                                                                                                                                                                                                                         |
| from-vlan<br><VLAN-ID>             | Specifies a single VLAN or a range of VLANs as the match criteria. Packets (EIGRP, GRE, IGMP, IGP, OSPF, or VRRP) received from the VLANs identified here are dropped. <ul style="list-style-type: none"> <li>• &lt;VLAN-ID&gt; - Specify the VLAN ID. A range of VLANs is represented by the start and end VLAN IDs separated by a hyphen (for example, 12-20).</li> </ul> <p><b>Note:</b> Use this option with WLANs and port ACLs.</p>                                                                                            |

|                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| host <SOURCE-HOST-IP>                            | Identifies a specific host (as the source to match) by its IP address. Packets (EIGRP, GRE, IGMP, IGP, OSPF, or VRRP) received from the specified host are dropped. <ul style="list-style-type: none"> <li>&lt;SOURCE-HOST-IP&gt; – Specify the source host’s exact IP address in the A.B.C.D format.</li> </ul>                                                                                                                                                                                                                                                                                                                                |
| <DEST-IP/MASK>                                   | Specifies the destination IP address and mask (A.B.C.D/M) to match. Packets (EIGRP, GRE, IGMP, IGP, OSPF, or VRRP) addressed to the specified destinations are dropped.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| any                                              | Specifies the destination as any IP address. Packets (EIGRP, GRE, IGMP, IGP, OSPF, or VRRP) addressed to any destination are dropped.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| host <DEST-HOST-IP>                              | Identifies a specific host (as the destination to match) by its IP address. Packets (EIGRP, GRE, IGMP, IGP, OSPF, or VRRP) addresses to the specified host are dropped. <ul style="list-style-type: none"> <li>&lt;SOURCE-HOST-IP&gt; – Specify the destination host’s exact IP address in the A.B.C.D format.</li> </ul>                                                                                                                                                                                                                                                                                                                       |
| <NETWORK-GROUP-ALIAS-NAME>                       | Applies a network-group alias to identify the destination IP addresses. Packets (EIGRP, GRE, IGMP, IGP, OSPF, or VRRP) addressed to the destinations identified in the network-group alias are dropped. <ul style="list-style-type: none"> <li>&lt;NETWORK-ALIAS-NAME&gt; – Specify the network-group alias name (should be existing and configured).</li> </ul> <p><b>Note:</b> After specifying the source and destination IP address(es), specify the action taken in case of a match.</p>                                                                                                                                                   |
| log                                              | Logs all deny events matching this entry. If a source and/or destination IP address is matched (i.e. a packet (EIGRP, GRE, IGMP, IGP, OSPF, or VRRP) is received from a specified IP address and/or is destined for a specified IP address), an event is logged.                                                                                                                                                                                                                                                                                                                                                                                |

### Usage Guidelines

Use this command to deny traffic between networks/hosts based on the protocol type selected in the access list configuration. The following protocols are supported:

- IP
- ICMP
- TCP
- UDP
- PROTO (any Internet protocol other than TCP, UDP, and ICMP)

The last ACE (access control entry) in the access list is an implicit deny statement.

---

Whenever the interface receives the packet, its content is checked against the ACEs in the ACL. It is allowed or denied based on the ACL configuration.

- Filtering TCP/UDP allows you to specify port numbers as filtering criteria.
- Select ICMP as the protocol to allow or deny ICMP packets. Selecting ICMP filters ICMP packets based on ICMP type and code.

#### Note

The log option is functional only for router ACL's. The log option displays an informational logging message about the packet that matches the entry sent to the console

---

### Examples

```
nx9500-6C8809(config-ip-acl-test)#deny proto vrrp any any log rule-precedence 600
nx9500-6C8809(config-ip-acl-test)#deny proto ospf any any log rule-precedence 650
nx9500-6C8809(config-ip-acl-test)#show context
ip access-list test
 deny proto vrrp any any log rule-precedence 600
 deny proto ospf any any log rule-precedence 650
nx9500-6C8809(config-ip-acl-test)#
```

#### Using aliases in IP access list.

The following examples show the usage of network-group aliases:

Example 1.

```
rfs4000-229D58(config-ip-acl-bar)#permit ip $foo any rule-precedence 10
```

Example 2.

```
rfs4000-229D58(config-ip-acl-bar)#permit tcp 192.168.100.0/24 $foobar eq ftp rule-
precedence 20
```

Example 3.

```
rfs4000-229D58(config-ip-acl-bar)#deny ip $guest $lab rule-precedence 30
```

- In example 1, network-group alias \$foo is used as a source.
- In example 2, network-group alias \$foobar is used as a destination.
- In example 3, network-group aliases \$guest and \$lab are used as source and destination respectively.

The following examples show the usage of network-service aliases:

Example 4.

```
rfs4000-229D58(config-ip-acl-bar)# permit $kerberos 10.60.20.0/24 $kerberos-servers log
rule-precedence 40
```

Example 5.

```
rfs4000-229D58(config-ip-acl-bar)#permit $Tandem 10.60.20.0/24 $Tandem-servers log rule-
precedence 50
```

In examples 4, and 5:

- The network-service aliases (\$kerberos and \$Tandem) define the destination protocol-port combinations.
- The source network is 10.60.20.0/24.
- The destination network-address combinations are defined by the network-group aliases (\$kerberos-servers and \$Tandem-servers).

|--------------|---------------------------------------------------------------|
| <b>no</b>    | Removes a specified IP deny access rule                       |
| <b>alias</b> | Creates and configures aliases (network, VLAN, service, etc.) |

### *disable (ipv4-acl)*

Disables an existing deny or permit rule without removing it from the ACL. A disabled rule is inactive and is not used to filter packets.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
disable [deny|insert|permit]
disable [deny|insert [deny|permit]|permit] [<NETWORK-SERVICE-ALIAS-NAME>|dns-name|
icmp|ip|proto|tcp|udp]
disable [deny|insert [deny|permit]|permit] [<NETWORK-SERVICE-ALIAS-NAME>|
dns-name [contains|exact|suffix]|icmp|ip|proto <PROTOCOL-OPTIONS>|tcp|udp]
[<SOURCE-IP/MASK>|<NETWORK-GROUP-ALIAS-NAME>|any|from-vlan <VLAN-ID>|host <SOURCE-HOST-
IP>]
[<DEST-IP/MASK>|<NETWORK-GROUP-ALIAS-NAME>|any|host <DEST-HOST-IP>] (log,mark [8021p <0-7>|
dscp <0-63>],rule-precedence)
```

### Parameters

```
disable [deny|insert [deny|permit]|permit] [<NETWORK-SERVICE-ALIAS-NAME>|
dns-name [contains|exact|suffix]|icmp|ip|proto <PROTOCOL-OPTIONS>|tcp|udp]
[<SOURCE-IP/MASK>|<NETWORK-GROUP-ALIAS-NAME>|any|from-vlan <VLAN-ID>|host <SOURCE-HOST-
IP>]
[<DEST-IP/MASK>|<NETWORK-GROUP-ALIAS-NAME>|any|host <DEST-HOST-IP>] (log,mark [8021p <0-7>|
dscp <0-63>],rule-precedence)
```
