| host <SOURCE-HOST-IP>           | Specify the source host's exact IP address.                                                                                                                                                                                                                                                     |
| <DEST-IP/MASK>                  | Specify the destination IP address and mask in the A.B.C.D/M format.                                                                                                                                                                                                                            |
| <NETWORK-GROUP-ALIAS-NAME>      | Specifies the network-group alias, identified by the <NETWORK-GROUP-ALIAS-NAME> keyword, associated with this deny/permit rule                                                                                                                                                                  |
| any                             | Select 'any' if the rule is applicable to any destination IP address.                                                                                                                                                                                                                           |
| host <DEST-HOST-IP>             | Specify the destination host's exact IP address.                                                                                                                                                                                                                                                |
| log                             | Select log, if the rule has been configured to log records in case of a match.                                                                                                                                                                                                                  |
| mark [8021p <0-7>  dscp <0-63>] | Specifies packets to mark <ul style="list-style-type: none"> <li>8021p &lt;0-7&gt; - Marks packets by modifying 802.1p VLAN user priority</li> <li>dscp &lt;0-63&gt; - Marks packets by modifying DSCP TOS bits in the header</li> </ul>                                                        |
| rule-precedence <1-5000>        | Specify the rule precedence. The deny or permit rule with the specified precedence is disabled.<br><br><b>Note:</b> To enable a disabled rule, enter the rule again without the 'disable' keyword.<br><br><b>Note:</b> The <b>no &gt; disable</b> command removes a disabled rule from the ACL. |

## Examples

The following example shows the 'auto-tunnel-acl' settings before the disable command is executed:

```

nx9500-6C8809(config-ip-acl-auto-tunnel-acl)#show context
ip access-list auto-tunnel-acl
 deny ip host 200.200.200.99 30.30.30.1/24 rule-precedence 2
 permit ip host 200.200.200.99 any rule-precedence 3
nx9500-6C8809(config-ip-acl-auto-tunnel-acl)#
nx9500-6C8809(config-ip-acl-auto-tunnel-acl)#disable permit ip host 200.200.200.99 any
rule-precedence 3

```

The following example shows the 'auto-tunnel-acl' settings after the disable command is executed:

```

nx9500-6C8809(config-ip-acl-auto-tunnel-acl)#show context
ip access-list auto-tunnel-acl
 deny ip host 200.200.200.99 30.30.30.1/24 rule-precedence 2
 disable permit ip host 200.200.200.99 any rule-precedence 3
nx9500-6C8809(config-ip-acl-auto-tunnel-acl)#
rfs4000-229D58(config-ip-acl-test)#deny icmp any any log rule-precedence 1
rfs4000-229D58(config-ip-acl-test)#show context
ip access-list test

```

```

deny icmp any any rule-precedence 1
rfs4000-229D58(config-ip-acl-test)#
rfs4000-229D58(config-ip-acl-test)#disable deny icmp any any rule-precedence 1
rfs4000-229D58(config-ip-acl-test)#show context
ip access-list test
deny tcp from-vlan 1 any any rule-precedence 1
permit icmp any host 192.168.13.7 1 1 rule-precedence 2
rfs4000-229D58(config-ip-acl-test)#
rfs4000-229D58(config-ip-acl-test)#disable insert deny ip any any log rule-precedence 2
rfs4000-229D58(config-ip-acl-test)#show context
ip access-list test
deny tcp from-vlan 1 any any rule-precedence 1
deny ip any any log rule-precedence 2
permit icmp any host 192.168.13.7 1 1 rule-precedence 3
rfs4000-229D58(config-ip-acl-test)#

```

In the following example a disable deny rule has been inserted in the IP ACL “test”:

```

rfs4000-229D58(config-ip-acl-test)#show context
ip access-list test
deny tcp from-vlan 1 any any rule-precedence 1
permit icmp any host 192.168.13.7 1 1 rule-precedence 2
rfs4000-229D58(config-ip-acl-test)#
rfs4000-229D58(config-ip-acl-test)#disable insert deny ip any any log rule-precedence 2
rfs4000-229D58(config-ip-acl-test)#show context
ip access-list test
deny tcp from-vlan 1 any any rule-precedence 1
deny ip any any log rule-precedence 2
permit icmp any host 192.168.13.7 1 1 rule-precedence 3
rfs4000-229D58(config-ip-acl-test)#

```

### Related Commands

|               |                                                                 |
|---------------|-----------------------------------------------------------------|
| <b>no</b>     | Enables a disabled deny or permit rule                          |
| <b>deny</b>   | Creates a new deny access rule or modifies an existing rule     |
| <b>permit</b> | Creates a new permit access rule or modifies an existing rule   |
| <b>alias</b>  | Creates and configures a aliases (network, VLAN, service, etc.) |

### *insert (ipv4-acl)*

Enables the insertion of a rule in an IP ACL without overwriting or replacing an existing rule having the same precedence

The insert option allows a new rule to be inserted within a IP access list. Consider an IP ACL consisting of rules having precedences 1, 2, 3, 4, 5, and 6. You want to insert a new rule with precedence 4, without overwriting the existing precedence 4 rule. Using the insert option inserts the new rule prior to the existing one. The existing precedence 4 rule’s precedence changes to 5, and the change cascades down the list of rules within the ACL. That means rule 5 becomes rule 6, and rule 6 becomes rule 7.

#### Note

NOT using *insert* when creating a new rule having the same precedence as an existing rule overwrites the existing rule.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
insert [deny|permit] <PARAMETERS> (log,mark [8021p <0-7>|dscp <0-63>],rule-precedence <1-5000>)
{(rule-description <LINE>)}
```

## Parameters

```
insert [deny|permit] <PARAMETERS> (log,mark [8021p <0-7>|dscp <0-63>],rule-precedence <1-5000>)
{(rule-description <LINE>)}
```

|                                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [deny permit]                                        | Inserts a deny or a permit rule within an IP ACL                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <PARAMETERS>                                         | Provide the match criteria for this deny/permit rule. Packets will be filtered based on the criteria set here.<br>For more information on the deny rule, see <a href="#">deny</a> .<br>For more information on the permit rule, see <a href="#">permit</a> .                                                                                                                                                                                                                                       |
| log                                                  | After specifying the match criteria, specify the action taken for filtered packets<br>Logs all deny/permit events matching this entry. If a source and/or destination IP address is matched an event is logged.                                                                                                                                                                                                                                                                                    |
| mark [8021p <0-7> <br>dscp <0-63>]                   | Specifies packets to mark <ul style="list-style-type: none"><li>8021p &lt;0-7&gt; - Marks packets by modifying 802.1p VLAN user priority</li><li>dscp &lt;0-63&gt; - Marks packets by modifying DSCP TOS bits in the header</li></ul>                                                                                                                                                                                                                                                              |
| rule-precedence <1-5000> rule-<br>description <LINE> | Assigns a precedence for this deny/permit rule <ul style="list-style-type: none"><li>&lt;1-5000&gt; - Specify a value from 1 - 5000.<br/><b>Note:</b> Lower the precedence higher is the priority. A rule with precedence 3 gets priority over a rule with precedence 10.</li><li>rule-description - Optional. Configures a description for this deny/permit rule. Provide a description that uniquely identifies the purpose of this rule (should not exceed 128 characters in length).</li></ul> |

### Note

The log option is functional only for router ACL's. The log option displays an informational logging message about the packet that matches the entry sent to the console.

## Examples

```
rfs4000-229D58(config-ip-acl-test)#deny tcp from-vlan 1 any any rule-precedence 1
rfs4000-229D58(config-ip-acl-test)#permit icmp any host 192.168.13.7 1 1 rule-precedence 2
rfs4000-229D58(config-ip-acl-test)#show context
ip access-list test
 deny tcp from-vlan 1 any any rule-precedence 1
 permit icmp any host 192.168.13.7 1 1 rule-precedence 2
rfs4000-229D58(config-ip-acl-test)#
```

In the following example a new rule is inserted between the rules having precedences 1 and 2. The precedence of the existing precedence '2' rule changes to precedence 3.

```
rfs4000-229D58(config-ip-acl-test)#insert deny ip any any rule-precedence 2
rfs4000-229D58(config-ip-acl-test)#show context
ip access-list test
 deny tcp from-vlan 1 any any rule-precedence 1
 deny ip any any rule-precedence 2
 permit icmp any host 192.168.13.7 1 1 rule-precedence 3
rfs4000-229D58(config-ip-acl-test)#
```

|--------------|---------------------------------------------------------------|
| <b>alias</b> | Creates and configures aliases (network, VLAN, service, etc.) |
|--------------|---------------------------------------------------------------|

### *permit (ipv4-acl)*

Creates a permit rule that marks packets (from a specified source IP and/or to a specified destination IP) for forwarding. You can also use this command to modify an existing permit rule.

#### Note

Use a decimal value representation to implement a permit/deny designation for a packet. The command set for IP ACLs provides the hexadecimal values for each listed EtherType. Use the decimal equivalent of the EtherType listed for any other EtherType.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
permit [<NETWORK-SERVICE-ALIAS-NAME>|dns-name|icmp|ip|proto|tcp|udp]
permit <NETWORK-SERVICE-ALIAS-NAME> [<SOURCE-IP/MASK>|<NETWORK-GROUP-ALIAS-NAME>|

```
permit icmp [<SOURCE-IP/MASK>|<NETWORK-GROUP-NAME>|any|from-vlan <VLAN-ID>|
host <SOURCE-HOST-IP>] [<DEST-IP/MASK>|<NETWORK-GROUP-NAME>|any|host <DEST-HOST-IP>]
(<ICMP-TYPE> <ICMP-CODE> ,log,rule-precedence <1-5000>) {(rule-description <LINE>)}
```

|                            |                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| icmp                       | Applies this permit rule to ICMP packets only                                                                                                                                                                                                                                                                                                                                                               |
| <SOURCE-IP/MASK>           | Specifies the source IP address and mask (A.B.C.D/M) to match. ICMP packets received from the specified sources are permitted.                                                                                                                                                                                                                                                                              |
| <NETWORK-GROUP-ALIAS-NAME> | Applies a network-group alias to identify the source IP addresses. ICMP packets received from the addresses identified by the network-group alias are permitted. <ul style="list-style-type: none"> <li>• &lt;NETWORK-GROUP-ALIAS-NAME&gt; – Specify the network-group alias name (should be existing and configured).</li> </ul>                                                                           |
| any                        | Specifies the source as any IP address. ICMP packets received from any source are permitted.                                                                                                                                                                                                                                                                                                                |
| from-vlan <VLAN-ID>        | Specifies a single VLAN or a range of VLANs as the match criteria. ICMP packets received from the VLANs identified here are permitted. <ul style="list-style-type: none"> <li>• &lt;VLAN-ID&gt; – Specify the VLAN ID. To configure a range of VLANs, enter the start and end VLAN IDs separated by a hyphen (for example, 12-20).</li> </ul> <p><b>Note:</b> Use this option with WLANs and port ACLs.</p> |
| host <SOURCE-HOST-IP>      | Identifies a specific host (as the source to match) by its IP address. ICMP packets received from the specified host are permitted. <ul style="list-style-type: none"> <li>• &lt;SOURCE-HOST-IP&gt; – Specify the source host's exact IP address in the A.B.C.D format.</li> </ul>                                                                                                                          |
| <DEST-IP/MASK>             | Specifies the destination IP address and mask (A.B.C.D/M) to match. ICMP packets addressed to specified destinations are permitted.                                                                                                                                                                                                                                                                         |
| <NETWORK-GROUP-ALIAS-NAME> | Applies a network-group alias to identify the destination IP addresses. ICMP packets destined for addresses identified by the network-group alias are permitted. <ul style="list-style-type: none"> <li>• &lt;NETWORK-GROUP-ALIAS-NAME&gt; – Specify the network-group alias name (should be existing and configured).</li> </ul>                                                                           |
| any                        | Specifies the destination as any IP address. ICMP packets addressed to any destination are permitted.                                                                                                                                                                                                                                                                                                       |
| host <DEST-HOST-IP>        | Identifies a specific host (as the destination to match) by its IP address. ICMP packets addressed to the specified host are permitted. <ul style="list-style-type: none"> <li>• &lt;DEST-HOST-IP&gt; – Specify the destination host's exact IP address in the A.B.C.D format.</li> </ul>                                                                                                                   |
| <ICMP-TYPE>                | Defines the ICMP packet type<br>For example, an ICMP type 0 indicates it is an ECHO REPLY, and type 8 indicates it is an ECHO.                                                                                                                                                                                                                                                                              |
| <ICMP-CODE>                | Defines the ICMP message type<br>For example, an ICMP code 3 indicates "Destination Unreachable", code 1 indicates "Host Unreachable", and code 3 indicates "Port Unreachable."<br><br><b>Note:</b> After specifying the source and destination IP address(es), the ICMP message type, and the ICMP code, specify the action taken in case of a match.                                                      |

| <PROTOCOL-NAME>   | Filters protocols using their IANA protocol name <ul style="list-style-type: none"> <li>&lt;PROTOCOL-NAME&gt; – Specify the protocol name.</li> </ul>                                                                                                                                                                                                                                                                                                                                              |
| eigrp             | Identifies the EIGRP protocol (number 88)<br>EIGRP enables routers to maintain copies of neighbors' routing tables. Routers use this information to determine the fastest route to a destination. When a router fails to find a route in its stored route tables, it sends a query to neighbors who in turn query their neighbors till a route is found. EIGRP also enables routers to inform neighbors of changes in their routing tables.                                                        |
| gre               | Identifies the GRE protocol (number 47)<br>GRE is a tunneling protocol that enables transportation of protocols (IP, IPX, DEC net, etc.) over an IP network. GRE encapsulates the packet at the source and removes the encapsulation at the destination.                                                                                                                                                                                                                                           |
| igmp              | Identifies the IGMP protocol (number 2)<br>IGMP establishes and maintains multicast group memberships to interested members. Multicasting allows a networked computer to send content to multiple computers who have registered to receive the content. IGMP snooping is for listening to IGMP traffic between an IGMP host and routers in the network to maintain a map of the links that require multicast streams. Multicast traffic is filtered out for those links which do not require them. |
| igp               | Identifies any private internal gateway (primarily used by CISCO for their IGRP) (number 9)<br>IGP enables exchange of information between hosts and routers within a managed network. The most commonly used IGP protocols are: RIP and OSPF                                                                                                                                                                                                                                                      |

|                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ospf                               | Identifies the OSPF protocol (number 89)<br>OSPF is a link-state IGP. OSPF routes IP packets within a single routing domain (autonomous system), like an enterprise LAN. OSPF gathers link state information from neighbor routers and constructs a network topology. The topology determines the routing table presented to the Internet Layer which makes routing decisions based solely on the destination IP address found in IP packets.                                                      |
| vrrp                               | Identifies the VRRP protocol (number 112)<br>VRRP allows a pool of routers to be advertised as a single virtual router. This virtual router is configured by hosts as their default gateway. VRRP elects a master router, from this pool, and assigns it a virtual IP address. The master router routes and forwards packets to hosts on the same subnet. When the master router fails, one of the backup routers is elected as the master and its IP address is mapped to the virtual IP address. |
| <SOURCE-IP/<br>MASK>               | Specifies the source IP address and mask (A.B.C.D/M) to match. Packets (EIGRP, GRE, IGMP, IGP, OSPF, or VRRP) received from the specified sources are permitted.                                                                                                                                                                                                                                                                                                                                   |
| <NETWORK-<br>GROUP-ALIAS-<br>NAME> | Applies a network-group alias to identify the source IP addresses. Packets (EIGRP, GRE, IGMP, IGP, OSPF, or VRRP) received from the sources defined in the network-group alias are permitted. <ul style="list-style-type: none"> <li>• &lt;NETWORK-GROUP-ALIAS-NAME&gt; - Specify the network-group alias name (should be existing and configured).</li> </ul>                                                                                                                                     |
| any                                | Specifies the source as any IP address. Packets (EIGRP, GRE, IGMP, IGP, OSPF, or VRRP) received from any source are permitted.                                                                                                                                                                                                                                                                                                                                                                     |
| from-vlan<br><VLAN-ID>             | Specifies a single VLAN or a range of VLANs as the match criteria. Packets (EIGRP, GRE, IGMP, IGP, OSPF, or VRRP) received from the VLANs identified here are permitted. <ul style="list-style-type: none"> <li>• &lt;VLAN-ID&gt; - Specify the VLAN ID. A range of VLANs is represented by the start and end VLAN IDs separated by a hyphen (for example, 12-20).</li> </ul> <p><b>Note:</b> Use this option with WLANs and port ACLs.</p>                                                        |
| host <SOURCE-<br>HOST-IP>          | Identifies a specific host (as the source to match) by its IP address. Packets (EIGRP, GRE, IGMP, IGP, OSPF, or VRRP) received from the specified host are permitted. <ul style="list-style-type: none"> <li>• &lt;SOURCE-HOST-IP&gt; - Specify the source host's exact IP address in the A.B.C.D format.</li> </ul>                                                                                                                                                                               |
| <DEST-IP/MASK>                     | Specifies the destination IP address and mask (A.B.C.D/M) to match. Packets (EIGRP, GRE, IGMP, IGP, OSPF, or VRRP) addressed to the specified destinations are permitted.                                                                                                                                                                                                                                                                                                                          |
| any                                | Specifies the destination as any destination IP address. Packets (EIGRP, GRE, IGMP, IGP, OSPF, or VRRP) addressed to any destination are permitted.                                                                                                                                                                                                                                                                                                                                                |
| host <DEST-<br>HOST-IP>            | Identifies a specific host (as the destination to match) by its IP address. Packets (EIGRP, GRE, IGMP, IGP, OSPF, or VRRP) addresses to the specified host are permitted. <ul style="list-style-type: none"> <li>• &lt;SOURCE-HOST-IP&gt; - Specify the destination host's exact IP address in the A.B.C.D format.</li> </ul>                                                                                                                                                                      |
| <NETWORK-<br>GROUP-ALIAS-<br>NAME> | Applies a network-group alias to identify the destination IP addresses. Packets (EIGRP, GRE, IGMP, IGP, OSPF, or VRRP) addressed to the destinations identified in the network-group alias are permitted. <ul style="list-style-type: none"> <li>• &lt;NETWORK-ALIAS-NAME&gt; - Specify the network-group alias name (should be existing and configured).</li> </ul> <p>After specifying the source and destination IP address(es), specify the action taken in case of a match.</p>               |

|                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

A rule with precedence 3 gets priority over a rule with precedence 10.</p> <ul style="list-style-type: none"> <li>rule-description – Optional. Configures a description for this permit rule. Provide a description that uniquely identifies the purpose of this rule (should not exceed 128 characters in length).</li> </ul> |

### Usage Guidelines

Use this command to permit traffic between networks/hosts based on the protocol type selected in the access list. The following protocols are supported:

- IP
- ICMP
- ICP
- UDP
- PROTO (any Internet protocol other than TCP, UDP, and ICMP)

The last ACE in the access list is an implicit deny statement.

Whenever the interface receives the packet, its content is checked against all the ACEs in the ACL. The packet is allowed or denied based on the ACL configuration.

- Filtering on TCP or UDP allows you to specify port numbers as filtering criteria.
- Select ICMP to allow/deny packets. Selecting ICMP filters ICMP packets based on ICMP type and code.

#### Note

The log option is functional only for router ACL's. The log option displays an informational logging message about the packet matching the entry sent to the console.

### Examples

```

nx9500-6C8809(config-ip-acl-test)#permit ip 172.16.10.0/24 any log rule-precedence 750
nx9500-6C8809(config-ip-acl-test)#permit tcp 172.16.10.0/24 any log rule-precedence 800
nx9500-6C8809(config-ip-acl-test)#show context
ip access-list test
 permit ip 172.16.10.0/24 any log rule-precedence 750
 permit tcp 172.16.10.0/24 any log rule-precedence 800
nx9500-6C8809(config-ip-acl-test)#

```

|-------|---------------------------------------------------------------|
| no    | Removes a specified IP permit access rule                     |
| alias | Creates and configures aliases (network, VLAN, service, etc.) |

*no (ipv4-acl)*

Removes a deny, permit, or disable rule

**Supported in the following platforms:**

- Access Points — AP 6522, AP 6532, AP 6562, AP 7502, AP 7522, AP 7532, AP 7161, AP 81XX, AP 8232
- Wireless Controllers — RFS 4000, RFS 6000
- Service Platforms — NX 7500, NX 9500, NX 9510

**Syntax**

```
no [deny|disable|permit]
no [deny|permit] [<NETWORK-SERVICE-ALIAS-NAME>|icmp|ip|proto|tcp|udp]
 <RULE-PARAMETERS>
no disable [deny|permit] [<NETWORK-SERVICE-ALIAS-NAME>|icmp|ip|proto|tcp|udp]
 <RULE-PARAMETERS>
```

**Parameters**

```
no [deny|permit] <NETWORK-SERVICE-ALIAS-NAME>icmp|ip|proto|tcp|udp] <RULE-PARAMETERS>
```

| icmp                         | Removes a disabled deny or permit rule applicable to ICMP packets only                                                                                                                                                                                                   |
| ip                           | Removes a disabled deny or permit rule applicable to IP packets only                                                                                                                                                                                                     |
| proto                        | Removes a disabled deny or permit rule applicable to protocols (other than IP, ICMP, TCP, and UDP)                                                                                                                                                                       |
| [tcp udp]                    | Removes a disabled deny or permit rule applicable to TCP/UDP packets                                                                                                                                                                                                     |

|                                                     |                                                                                                                                                                                                                                                                 |
|-----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <RULE-PARAMETERS>                                   | Enter the exact parameters used when configuring the rule.                                                                                                                                                                                                      |
| rule-precedence <1-5000><br>rule-description <LINE> | Specify the precedence assigned to this disabled deny/permit rule. <ul style="list-style-type: none"> <li>rule-description – Optional. Specify the rule description.</li> </ul> <p><b>Note:</b> The system removes the disabled rule from the selected ACL.</p> |

### Usage Guidelines

Provide the rule-precedence value when using the no command.

### Examples

The following example shows the ACL 'test' settings before the 'no' commands are executed:

```
<exsw1>(config-ip-acl-test)#show context
ip access-list test
 deny proto vrrp any any log rule-precedence 600
 deny proto ospf any any log rule-precedence 650
```

```
<exsw1>(config-ip-acl-test)#
<exsw1>(config-ip-acl-test)#no deny proto vrrp any any rule-precedence 600
<exsw1>(config-ip-acl-test)#no deny proto ospf any any rule-precedence 650
```

The following example shows the ACL 'test' settings after the 'no' commands are executed:

```
<exsw1>(config-ip-acl-test)#show context
ip access-list test
<exsw1>(config-ip-acl-test)#
```

### Related Commands

|         |                                                 |
|---------|-------------------------------------------------|
| deny    | Creates a deny access rule                      |
| disable | Disables a deny or permit rule within an IP ACL |
| permit  | Creates a permit access rule                    |

## mac-access-list

The following table summarizes MAC Access list configuration commands:

**Table 36: MAC-Access-List-Config Commands**

| Command | Description                                                                                                     |
|---------|-----------------------------------------------------------------------------------------------------------------|
| deny    | Creates a new deny access rule or modifies an existing rule. A deny access rule marks packets for rejection.    |
| disable | Disables a MAC deny or permit rule without removing it from the ACL                                             |
| ex3500  | Creates a MAC ACL deny and/or permit rule applicable only to the EX3500 switch                                  |
| insert  | Inserts a rule in an MAC ACL without overwriting or replacing an existing rule having the same precedence       |
| no      | Removes a deny and/or a permit access rule from a MAC ACL                                                       |
| permit  | Creates a new permit access rule or modifies an existing rule. A deny access rule marks packets for forwarding. |

## deny (mac-acl)

Creates a deny rule that marks packets (from a specified source MAC and/or to a specified destination MAC) for rejection. You can also use this command to modify an existing deny rule.

### Note

Use a decimal value representation to implement a permit/deny designation for a packet. The command set for MAC ACLs provide the hexadecimal values for each listed EtherType. Use the decimal equivalent of the EtherType listed for any other EtherType.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
deny [<SOURCE-MAC> <SOURCE-MAC-MASK>|any|host <SOURCE-HOST-MAC>]
[<DEST-MAC> <DEST-MAC-MASK>|any|host <DEST-HOST-MAC>] (dot1p <0-7>,type [8021q|<1-65535>|
aarp|appletalk|arp|ip|ipv6|ipx|mint|rarp|wisp],vlan <1-4095>,log,rule-precedence <1-5000>)
{(rule-description <LINE>)}
```

### Parameters

```
deny [<SOURCE-MAC> <SOURCE-MAC-MASK>|any|host <SOURCE-HOST-MAC>]
[<DEST-MAC> <DEST-MAC-MASK>|any|host <DEST-HOST-MAC>] (dot1p <0-7>,type [8021q|<1-65535>|
aarp|appletalk|arp|ip|ipv6|ipx|mint|rarp|wisp],vlan <1-4095>,log,rule-precedence <1-5000>)
{(rule-description <LINE>)}
```

|                                   |                                                                                                                                                                                                                                                                                                                                |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <SOURCE-MAC><br><SOURCE-MAC-MASK> | Configures the source MAC address and mask to match <ul style="list-style-type: none"><li>• &lt;SOURCE-MAC&gt; - Specify the source MAC address to match.</li><li>• &lt;SOURCE-MAC-MASK&gt; - Specify the source MAC address mask.</li></ul> Packets received from the specified MAC addresses are dropped.                    |
| any                               | Identifies all devices as the source to deny access. | vlan <1-4095>                                                             | Configures the VLAN where the traffic is received <ul style="list-style-type: none"> <li>• &lt;1-4095&gt; – Specify the VLAN ID from 1 - 4095.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| log                                                                       | Logs all deny events matching this entry. If a source and/or destination MAC address is matched (i.e., a packet is received from a specified MAC address or is destined for a specified MAC address), an event is logged.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| rule-precedence <1-5000> rule-description <LINE>                          | The following keywords are recursive and common to all of the above parameters: <ul style="list-style-type: none"> <li>• rule-precedence – Assigns a precedence for this deny rule <ul style="list-style-type: none"> <li>• &lt;1-5000&gt; – Specify a value from 1 - 5000.</li> </ul> <p><b>Note:</b> Lower the precedence higher is the priority. A rule with precedence 3 gets priority over a rule with precedence 10.</p> </li> <li>• rule-description – Optional. Configures a description for this deny rule. Provide a description that uniquely identifies the purpose of this rule (should not exceed 128 characters in length).</li> </ul>                                                                                                                                                                                                                                                                                                                                                                |

### Usage Guidelines

The deny command disallows traffic based on layer 2 (data-link layer) data. The MAC access list denies traffic from a particular source MAC address or any MAC address. It can also disallow traffic from a list of MAC addresses based on the source mask.

The MAC access list can disallow traffic based on the VLAN and EtherType.

- ARP
- WISP
- IP
- 802.1q

#### Note

MAC ACLs always takes precedence over IP based ACLs.

The last ACE in the access list is an implicit deny statement. Whenever the interface receives the packet, its content is checked against all the ACEs in the ACL. It is allowed or denied based on the ACL's configuration.

### Examples

```
rfs4000-229D58(config-mac-acl-test)#deny 41-85-45-89-66-77 ff-ff-ff-00-00-00 any
vlan 1 rule-precedence 1
rfs4000-229D58(config-mac-acl-test)#deny host 00-01-ae-00-22-11 any rule-precedence 2
rfs4000-229D58(config-mac-acl-test)#show context
mac access-list test
 deny 41-85-45-89-66-77 FF-FF-FF-00-00-00 any vlan 1 rule-precedence 1
 deny host 00-01-AE-00-22-11 any rule-precedence 2
rfs4000-229D58(config-mac-acl-test)#
```

The MAC ACL (in the example below) denies traffic from any source MAC address to a particular host MAC address:

```
nx9500-6C8809(config-mac-acl-test)#deny any host 00:01:ae:00:22:11 vlan 1 log rule-
precedence 1
```

The following example denies traffic between two hosts based on MAC addresses:

```
nx9500-6C8809(config-mac-acl-test)#deny host 01:02:fe:45:76:89 host 01:02:89:78:78:45 vlan
1 log rule-precedence 1
```

### Related Commands

|           |                                          |
|-----------|------------------------------------------|
| <b>no</b> | Removes a specified MAC deny access rule |
|-----------|------------------------------------------|

### *disable (mac-acl)*

Disables a MAC deny or permit rule without removing it from the ACL. A disabled rule is inactive and is not used to filter packets.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
disable [deny|insert|permit]
disable [deny|permit] [<SOURCE-MAC> <SOURCE-MAC-MASK>|any|host <SOURCE-HOST-MAC>]
[<DEST-MAC> <DEST-MAC-MASK>|any|host <DEST-HOST-MAC>] (dot1p <0-7>|mark [8021p <0-7>|dscp
<0-63>],
type [8021q|<1-65535>|aarp|appletalk|arp|ip|ipv6|ipx|mint|rarp|wisp],vlan <1-4095>) log
(rule-precedence <1-5000>) {(rule-description <LINE>)}
disable insert [deny|permit]
```

### Parameters

```
disable [deny|permit] [<SOURCE-MAC> <SOURCE-MAC-MASK>|any|host <SOURCE-HOST-MAC>]
[<DEST-MAC> <DEST-MAC-MASK>|any|host <DEST-HOST-MAC>] (dot1p <0-7>|mark [8021p <0-7>|dscp
<0-63>],
type [8021q|<1-65535>|aarp|appletalk|arp|ip|ipv6|ipx|mint|rarp|wisp],vlan <1-4095>) log
(rule-precedence <1-5000>) {(rule-description <LINE>)}
```

A rule with precedence 3 gets priority over a rule with precedence 10.</p> </li> <li>rule-description - Optional. Configures a description for this rule. Provide a description that uniquely identifies the purpose of this rule (should not exceed 128 characters in length).</li> </ul> |

## Examples

The following example shows the MAC access list 'test' settings before the 'disable' command is executed:

```
rfs4000-229D58(config-mac-acl-test)#show context
mac access-list test
deny 41-85-45-89-66-77 FF-FF-FF-00-00-00 any vlan 1 rule-precedence 1
```

```
deny host 00-01-AE-00-22-11 any rule-precedence 2
rfs4000-229D58(config-mac-acl-test)#
rfs4000-229D58(config-mac-acl-test)#disable deny host 00-01-AE-00-22-11 any rule-
precedence 2
```

The following example shows the MAC access list 'test' settings after the 'disable' command is executed:

```
rfs4000-229D58(config-mac-acl-test)#show context
mac access-list test
deny 41-85-45-89-66-77 FF-FF-FF-00-00-00 any vlan 1 rule-precedence 1
disable deny host 00-01-AE-00-22-11 any rule-precedence 2
rfs4000-229D58(config-mac-acl-test)#
```

### ex3500 (mac-acl-config-commands)

Creates a MAC ACL deny and/or permit rule, applicable only to the EX3500 switch

Each deny or permit rule consists of a set of match criteria and an associated action, which is deny access for the deny rule and allow access for the permit rule. When applied to layer 2 traffic (between a EX35XX switch and the WiNG managed service platform or a WiNG VM interface) every packet is matched against the configured match criteria and in case of a match the packet is dropped or forwarded depending on the rule type.

EX35XX devices (EX3524 and EX3548) are layer 2 Gigabit Ethernet switches with either 24 or 48 10/100/1000-BASE-T ports, and four SFP transceiver slots for fiber connectivity. Each 10/100/1000 Mbps port supports both the IEEE 802.3af and IEEE 802.3at-2009 PoE standards. An EX35XX switch has an SNMP-based management agent that provides both in-band and out-of-band management access. The EX35XX switch utilizes an embedded HTTP Web agent and CLI, which in spite of being different from that of the WiNG operating system provides WiNG controllers PoE and port management resources.

#### Note

To implement the EX3500 MAC ACL rule, apply the MAC ACL directly to a EX35XXwi device, or to an EX35XX profile. For more information, see [access-group](#) on page 1299.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
ex3500 [deny|permit] [all|tagged-eth2|untagged-eth2]
ex3500 [deny|permit] [all|tagged-eth2|untagged-eth2] [any |host <SOURCE-MAC>|
network <SOURCE-MAC> <SOURCE-MAC-MASK>] [any|host <DEST-MAC>|network <DEST-MAC>
<DEST-MAC-MASK>] [ethertype <0-65535>|ethertype-mask <0-65535>|ex3500-time-range
<TIME-RANGE-NAME>|rule-precedence <1-128>|vlan <1-4094>|vlan-mask <1-4095>]
```

## Parameters

```
ex3500 [deny|permit] [all|tagged-eth2|untagged-eth2] [any |host <SOURCE-MAC>|
network <SOURCE-MAC> <SOURCE-MAC-MASK>] [any|host <DEST-MAC>|network <DEST-MAC>
<DEST-MAC-MASK>] [ethertype <0-65535|ethertype-mask <0-65535>|ex3500-time-range
<TIME-RANGE-NAME>|rule-precedence <1-128>|vlan <1-4094>|vlan-mask <1-4095>]
```

|------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [deny permit]                                                    | <p>Creates a deny or permit MAC ACL rule and configures the rule parameters. Every EX3500 MAC ACL rule provides a set of match criteria against which incoming and outgoing packets (to and from an EX35XX device) are matched. In case of a match, the packet is dropped or forwarded depending on the rule type. The packet is dropped in case of a deny rule, and forwarded for an permit rule.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <a href="#">no (mac-acl)</a> on page 1401 | Removes this EX3500 deny/permit rule from the MAC ACL |
|-------------------------------------------|-------------------------------------------------------|

### *insert (mac-acl)*

Enables the insertion of a rule in an MAC ACL without overwriting or replacing an existing rule having the same precedence

The insert option allows a new rule to be inserted within a MAC ACL. Consider an MAC ACL consisting of rules having precedences 1, 2, 3, 4, 5, and 6. You want to insert a new rule with precedence 4, without overwriting the existing precedence 4 rule. Using the insert option inserts the new rule prior to the

existing one. The existing precedence 4 rule's precedence changes to 5, and the change cascades down the list of rules within the ACL. That means rule 5 becomes rule 6, and rule 6 becomes rule 7.

#### Note

NOT using insert when creating a new rule having the same precedence as an existing rule, overwrites the existing rule.

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
insert [deny|permit] <PARAMETERS> (dot1p <0-7>,mark [8021p <0-7>|dscp <0-63>],
type [8021q|<1-65535>|aarp|appletalk|arp|ip|ipv6|ipx|mint|rarp|wisp],vlan <1-4095>,
log,rule-precedence <1-5000>) {(rule-description <LINE>)}
```

#### Parameters

```
insert [deny|permit] <PARAMETERS> (dot1p <0-7>,mark [8021p <0-7>|dscp <0-63>],
type [8021q|<1-65535>|aarp|appletalk|arp|ip|ipv6|ipx|mint|rarp|wisp],vlan <1-4095>,
log,rule-precedence <1-5000>) {(rule-description <LINE>)}
```

If a source and/or destination MAC address is matched (i.e. a packet is received from a specified MAC address or is destined for a specified MAC address), an event is logged.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| rule-precedence <1-5000> rule-description <LINE>                           | The following keywords are recursive and common to all of the above parameters: <ul style="list-style-type: none"> <li>• rule-precedence - Assigns a precedence for this deny/permit rule</li> <li>• &lt;1-5000&gt; - Specify a value from 1 - 5000.</li> </ul> <p><b>Note:</b> Lower the precedence higher is the priority. A rule with precedence 3 gets priority over a rule with precedence 10.</p> <ul style="list-style-type: none"> <li>• rule-description - Optional. Configures a description for this deny/permit rule. Provide a description that uniquely identifies the purpose of this rule (should not exceed 128 characters in length).</li> </ul>                                                                                                                                                                                                                                                 |

## Examples

```
rfs4000-229D58(config-mac-acl-test1)#deny 11-22-33-44-55-66 11-22-33-44-55-77 any rule-
precedence 1
rfs4000-229D58(config-mac-acl-test1)#deny host B4-C7-99-6D-CD-9B any rule-precedence 2
rfs4000-229D58(config-mac-acl-test1)#show context
mac access-list test1
 deny 11-22-33-44-55-66 11-22-33-44-55-77 any rule-precedence 1
 deny host B4-C7-99-6D-CD-9B any rule-precedence 2
rfs4000-229D58(config-mac-acl-test1)#
```

In the following example a new rule is inserted between the rules having precedences 1 and 2. The precedence of the existing precedence '2' rule changes to precedence 3.

```
rfs4000-229D58(config-mac-acl-test1)#insert permit host B4-C7-99-6D-B5-D6 host B4-C7-99-6D-
CD-9B rule-precedence 2
rfs4000-229D58(config-mac-acl-test1)#show context
mac access-list test1
 deny 11-22-33-44-55-66 11-22-33-44-55-77 any rule-precedence 1
 permit host B4-C7-99-6D-B5-D6 host B4-C7-99-6D-CD-9B rule-precedence 2
 deny host B4-C7-99-6D-CD-9B any rule-precedence 3
rfs4000-229D58(config-mac-acl-test1)#
```

## permit (mac-acl)

Creates a permit rule that marks packets (from a specified source MAC and/or to a specified destination MAC) for forwarding. You can also use this command to modify an existing permit rule.

### Note

Use a decimal value representation to implement a permit/deny designation for a packet. The command set for MAC ACLs provide the hexadecimal values for each listed EtherType. Use the decimal equivalent of the EtherType listed for any other EtherType.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
permit [<SOURCE-MAC> <SOURCE-MAC-MASK>|any|host <SOURCE-HOST-MAC>] [<DEST-MAC> <DEST-MAC-MASK>|any|host <DEST-HOST-MAC>] (dot1p <0-7>,mark [8021p <0-7>,dscp <0-63>],type [8021q|<1-65535>|aarp|appletalk|arp|ip|ipv6|ipx|mint|rarp|wisp],vlan <1-4095>) log (rule-precedence <1-5000>){(rule-description <LINE>)}
```

### Parameters

```
permit [<SOURCE-MAC> <SOURCE-MAC-MASK>|any|host <SOURCE-HOST-MAC>] [<DEST-MAC> <DEST-MAC-MASK>|any|host <DEST-HOST-MAC>] (dot1p <0-7>,mark [8021p <0-7>,dscp <0-63>],type [8021q|<1-65535>|aarp|appletalk|arp|ip|ipv6|ipx|mint|rarp|wisp],vlan <1-4095>) log (rule-precedence <1-5000>){(rule-description <LINE>)}
```

### Usage Guidelines

The permit command in the MAC ACL allows traffic based on layer 2 (data-link layer) information. A MAC access list permits traffic from a source MAC address or any MAC address. It also has an option to allow traffic from a list of MAC addresses (based on the source mask).

The MAC access list can be configured to allow traffic based on VLAN information, or Ethernet type. Common types include:

- ARP
- WISP
- IP
- 802.1q

Layer 2 traffic is not allowed by default. To adopt an Access Point through an interface, configure an ACL to allow an Ethernet WISP.

Use the mark option to specify the ToS (type of service) and priority value. The tos value is marked in the IP header and the 802.1p priority value is marked in the dot1q frame.

Whenever the interface receives the packet, its content is checked against all the ACEs in the ACL. It is marked based on the ACL's configuration.

#### Note

To apply an IP based ACL to an interface, a MAC access list entry is mandatory to allow ARP. A MAC ACL always takes precedence over IP based ACLs.

### Examples

```
nx9500-6C8809(config-mac-acl-test)#permit host 11-22-33-44-55-66 any log mark 8021p 3 rule-
precedence 600
nx9500-6C8809(config-mac-acl-test)#permit host 22-33-44-55-66-77 host 11-22-33-44-55-66
type ip log rule-precedence 610
nx9500-6C8809(config-mac-acl-test)#show context
mac access-list test
 permit host 11-22-33-44-55-66 any log mark 8021p 3 rule-precedence 600
 permit host 22-33-44-55-66-77 host 11-22-33-44-55-66 type ip log rule-precedence 610
nx9500-6C8809(config-mac-acl-test)#
```

|--------|--------------------------|
| deny   | Creates a MAC deny ACL   |
| permit | Creates a MAC permit ACL |

## ipv6-access-list

Configures an IPv6 ACL. IPv6 ACLs define a set of rules that filter IPv6 packets flowing through a port or interface. Each rule specifies the action taken when a packet matches the rule. If the action is deny, the packet is dropped. If the action is permit, the packet is allowed.

The WiNG software supports IPv6 only on VLAN interfaces. Therefore, IPv6 ACLs can be applied only on the VLAN interface.

The following table summarizes IPv6 access list configuration commands:

**Table 37: IPv6 Access List Config Mode Commands**

| Command                                     | Description                                                                                                                                                                |
|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>deny (ipv6-acl)</code> on page 1403   | Creates a deny access rule or modifies an existing rule. A deny access rule rejects IPv6 packets from specified address(es) and/or destined for specified address(es).     |
| <code>permit (ipv6-acl)</code> on page 1409 | Creates a permit access rule or modifies an existing rule. A permit access rule accepts IPv6 packets from specified address(es) and/or destined for specified address(es). |
| <code>no (ipv6-acl)</code> on page 1414     | Removes a deny and/or a access rule from a IPv6 ACL                                                                                                                        |

### *deny (ipv6-acl)*

Creates a deny rule that rejects packets from a specified IPv6 source and/or to a specified IPv6 destination. You can also use this command to modify an existing deny rule.

#### **Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### **Syntax**

```
deny [icmpv6|ipv6|proto|tcp|udp]
deny icmpv6 [<SOURCE-IPv6/MASK>|any|host <SOURCE-HOST-IPv6>] [<DEST-IPv6/MASK>|any|
host <DEST-HOST-IPv6>] [code [eq <ICMPv6-CODE>|range <STARTING-ICMPv6-CODE> <ENDING-ICMPv6-
CODE>]]
type [eq <ICMPv6-TYPE>|range <STARTING-ICMPv6-TYPE> <ENDING-ICMPv6-TYPE>]]
(log,rule-precedence <1-5000>) {(rule-description <LINE>)}
deny ipv6 [<SOURCE-IPv6/MASK>|any|host <SOURCE-HOST-IPv6>] [<DEST-IPv6/MASK>|any|
host <DEST-HOST-IPv6>] (log,rule-precedence <1-5000>) {(rule-description <LINE>)}
deny proto [<PROTOCOL-NUMBER>|<PROTOCOL-NAME>|eigrp|gre|igmp|ospf|vrrp]
[<SOURCE-IPv6/MASK>|any|host <SOURCE-HOST-IPv6>] [<DEST-IPv6/MASK>|any|host <DEST-HOST-
IPv6>]
(log,rule-precedence <1-5000>) {(rule-description <LINE>)}
deny [tcp|udp] [<SOURCE-IPv6/MASK>|any|host <SOURCE-HOST-IPv6>] [<DEST-IPv6/MASK>|any|
eq <SOURCE-PORT>|host <DEST-HOST-IPv6>|range <START-PORT> <END-PORT>] [eq [<1-65535>|<
SERVICE-NAME>|bgp|dns|ftp|ftp-data|gopher|https|ldap|nntp|ntp|pop3|sip|smtp|ssh|telnet|
tftp|www]]
range <START-PORT> <END-PORT>] (log,rule-precedence <1-5000>) {(rule-description <LINE>)}
```

## Parameters

```
deny icmpv6 [<SOURCE-IPv6/MASK>|any|host <SOURCE-HOST-IPv6>] [<DEST-IPv6/MASK>|any|
host <DEST-HOST-IPv6>] [code [eq <ICMPv6-CODE>|range <STARTING-ICMPv6-CODE> <ENDING-ICMPv6-
CODE>]]
type [eq <ICMPv6-TYPE>|range <STARTING-ICMPv6-TYPE> <ENDING-ICMPv6-TYPE>]]
(log,rule-precedence <1-5000>) {(rule-description <LINE>)}
```

|                          |                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| icmpv6                   | Applies this deny rule to ICMPv6 packets only                                                                                                                                                                                                                                                                                                                                   |
| <SOURCE-IPv6/MASK>       | Specifies a range of IPv6 source address (network) to match. ICMPv6 packets received from any source in the specified network are dropped.                                                                                                                                                                                                                                      |
| any                      | Specifies the source as any IPv6 address. ICMPv6 packets received from any source are dropped.                                                                                                                                                                                                                                                                                  |
| host <SOURCE-HOST-IPv6>  | Identifies a specific host (as the source to match) by its IPv6 address. ICMPv6 packets received from the specified host are dropped. <ul style="list-style-type: none"> <li>&lt;SOURCE-HOST-IPv6&gt; - Specify the source host's exact IPv6 address.</li> </ul>                                                                                                                |
| <DEST-IPv6/MASK>         | Specifies a range of IPv6 destination address (network) to match. ICMPv6 packets addressed to any destination within the specified network are dropped.                                                                                                                                                                                                                         |
| any                      | Specifies the destination as any IPv6 address. ICMPv6 packets addressed to any destination are dropped.                                                                                                                                                                                                                                                                         |
| host <DEST-HOST-IPv6>    | Identifies a specific host (as the destination to match) by its IPv6 address. ICMPv6 packets addressed to the specified host are dropped. <ul style="list-style-type: none"> <li>&lt;DEST-HOST-IPv6&gt; - Specify the destination host's exact IPv6 address.</li> </ul>                                                                                                         |
| <ICMPv6-TYPE> [eq range] | Defines the ICMPv6 type field filter <ul style="list-style-type: none"> <li>eq - Configures a specific ICMPv6 type. Specify the ICMPv6 type value.</li> <li>range - Configures a range of ICMPv6 types. Specify the starting and ending ICMPv6 type values.</li> </ul> <p><b>Note:</b> ICMPv6 packets with type field value matching the values specified here are dropped.</p> |
| <ICMPv6-CODE>            | Defines the ICMPv6 code field filter <ul style="list-style-type: none"> <li>eq - Configures a specific ICMPv6 code. Specify the ICMPv6 code value.</li> <li>range - Configures a range of ICMPv6 code. Specify the starting and ending ICMPv6 code values.</li> </ul> <p><b>Note:</b> ICMPv6 packets with code field value matching the values specified here are dropped.</p>  |
| log                      | Logs all deny events matching this entry                                                                                                                                                                                                                                                                                                                                        |

|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <PROTOCOL-NAME>         | Filters protocols using their IANA protocol name <ul style="list-style-type: none"> <li>&lt;PROTOCOL-NAME&gt; – Specify the protocol name.</li> </ul>                                                                                                                                                                                                                                                                                                                                              |
| eigrp                   | Identifies the EIGRP protocol (number 88)<br>EIGRP enables routers to maintain copies of neighbors' routing tables. Routers use this information to determine the fastest route to a destination. When a router fails to find a route in its stored route tables, it sends a query to neighbors who in turn query their neighbors till a route is found. EIGRP also enables routers to inform neighbors of changes in their routing tables.                                                        |
| gre                     | Identifies the GRE protocol (number 47)<br>GRE is a tunneling protocol that enables transportation of protocols (IP, IPX, DEC net, etc.) over an IP network. GRE encapsulates the packet at the source and removes the encapsulation at the destination.                                                                                                                                                                                                                                           |
| igp                     | Identifies any private internal gateway (primarily used by CISCO for their IGRP) (number 9)<br>IGP enables exchange of information between hosts and routers within a managed network. The most commonly used IGP protocols are: RIP and OSPF.                                                                                                                                                                                                                                                     |
| ospf                    | Identifies the OSPF protocol (number 89)<br>OSPF is a link-state IGP. OSPF routes IP packets within a single routing domain (autonomous system), like an enterprise LAN. OSPF gathers link state information from neighbor routers and constructs a network topology. The topology determines the routing table presented to the Internet Layer which makes routing decisions based solely on the destination IP address found in IP packets.                                                      |
| vrrp                    | Identifies the VRRP protocol (number 112)<br>VRRP allows a pool of routers to be advertised as a single virtual router. This virtual router is configured by hosts as their default gateway. VRRP elects a master router, from this pool, and assigns it a virtual IP address. The master router routes and forwards packets to hosts on the same subnet. When the master router fails, one of the backup routers is elected as the master and its IP address is mapped to the virtual IP address. |
| <SOURCE-IPv6/MASK>      | Specifies a range of IPv6 source address (network) to match. Packets (EIGRP, GRE, IGMP, IGP, OSPF, or VRRP) received from any source in the specified network are dropped.                                                                                                                                                                                                                                                                                                                         |
| any                     | Specifies the source as any IPv6 address. Packets (EIGRP, GRE, IGMP, IGP, OSPF, or VRRP) received from any source are dropped.                                                                                                                                                                                                                                                                                                                                                                     |
| host <SOURCE-HOST-IPv6> | Identifies a specific host (as the source to match) by its IPv6 address. Packets (EIGRP, GRE, IGMP, IGP, OSPF, or VRRP) received from the specified host are dropped. <ul style="list-style-type: none"> <li>&lt;SOURCE-HOST-IP&gt; – Specify the source host's exact IPv6 address.</li> </ul>                                                                                                                                                                                                     |
| <DEST-IPv6/MASK>        | Specifies a range of IPv6 destination address (network) to match. Packets (EIGRP, GRE, IGMP, IGP, OSPF, or VRRP) addressed to any destination within the specified network are dropped.                                                                                                                                                                                                                                                                                                            |
| any                     | Specifies the destination as any IPv6 address. Packets (EIGRP, GRE, IGMP, IGP, OSPF, or VRRP) addressed to any destination are dropped.                                                                                                                                                                                                                                                                                                                                                            |
| host <DEST-HOST-IPv6>   | Identifies a specific host (as the destination to match) by its IPv6 address. Packets (EIGRP, GRE, IGMP, IGP, OSPF, or VRRP) addressed to the specified host are dropped. <ul style="list-style-type: none"> <li>&lt;DEST-HOST-IPv6&gt; – Specify the destination host's exact IPv6 address.</li> </ul>                                                                                                                                                                                            |

## permit (ipv6-acl)

Creates a permit rule that accepts packets from a specified IPv6 source and/or addressed to a specified IPv6 destination. You can also use this command to modify an existing permit rule.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
permit [icmpv6|ipv6|proto|tcp|udp]
permit icmpv6 [<SOURCE-IPv6/MASK>|any|host <SOURCE-HOST-IPv6>] [<DEST-IPv6/MASK>|any|
host <DEST-HOST-IPv6>] [code [eq <ICMPv6-CODE>|range <STARTING-ICMPv6-CODE> <ENDING-ICMPv6-
CODE>]]
type [eq <ICMPv6-TYPE>|range <STARTING-ICMPv6-TYPE> <ENDING-ICMPv6-TYPE>]]
(log,rule-precedence <1-5000>) {(rule-description <LINE>)}
permit ipv6 [<SOURCE-IPv6/MASK>|any|host <SOURCE-HOST-IPv6>] [<DEST-IPv6/MASK>|any|
host <DEST-HOST-IPv6>] (log,rule-precedence <1-5000>) {(rule-description <LINE>)}
permit proto [<PROTOCOL-NUMBER>|<PROTOCOL-NAME>|eigrp|gre|igmp|ospf|vrrp]
[<SOURCE-IPv6/MASK>|any|host <SOURCE-HOST-IPv6>] [<DEST-IPv6/MASK>|any|host <DEST-HOST-
IPv6>]
(log,rule-precedence <1-5000>) {(rule-description <LINE>)}
permit [tcp|udp] [<SOURCE-IPv6/MASK>|any|host <SOURCE-HOST-IPv6>] [<DEST-IPv6/MASK>|any|
eq <SOURCE-PORT>|host <DEST-HOST-IPv6>|range <START-PORT> <END-PORT>] [eq [<1-65535>|<
SERVICE-NAME>|bgp|dns|ftp|ftp-data|gopher|https|ldap|nntp|ntp|pop3|sip|smtp|ssh|telnet|
tftp|www]]
range <START-PORT> <END-PORT>] (log,rule-precedence <1-5000>) {(rule-description <LINE>)}
```

### Parameters

```
permit icmpv6 [<SOURCE-IPv6/MASK>|any|host <SOURCE-HOST-IPv6>] [<DEST-IPv6/MASK>|any|
host <DEST-HOST-IPv6>] [code [eq <ICMPv6-CODE>|range <STARTING-ICMPv6-CODE> <ENDING-ICMPv6-
CODE>]]
type [eq <ICMPv6-TYPE>|range <STARTING-ICMPv6-TYPE> <ENDING-ICMPv6-TYPE>]]
(log,rule-precedence <1-5000>) {(rule-description <LINE>)}
```

| <PROTOCOL-NAME>   | Filters protocols using their IANA protocol name <ul style="list-style-type: none"> <li>• &lt;PROTOCOL-NAME&gt; - Specify the protocol name.</li> </ul>                                                                                                                                                                                                                                                                                                                                            |
| eigrp             | Identifies the EIGRP protocol (number 88)<br>EIGRP enables routers to maintain copies of neighbors' routing tables. Routers use this information to determine the fastest route to a destination. When a router fails to find a route in its stored route tables, it sends a query to neighbors who in turn query their neighbors till a route is found. EIGRP also enables routers to inform neighbors of changes in their routing tables.                                                        |
| gre               | Identifies the GRE protocol (number 47)<br>GRE is a tunneling protocol that enables transportation of protocols (IP, IPX, DEC net, etc.) over an IP network. GRE encapsulates the packet at the source and removes the encapsulation at the destination.                                                                                                                                                                                                                                           |
| igp               | Identifies any private internal gateway (primarily used by CISCO for their IGRP) (number 9)<br>IGP enables exchange of information between hosts and routers within a managed network. The most commonly used IGP protocols are: RIP and OSPF.                                                                                                                                                                                                                                                     |
| ospf              | Identifies the OSPF protocol (number 89)<br>OSPF is a link-state IGP. OSPF routes IP packets within a single routing domain (autonomous system), like an enterprise LAN. OSPF gathers link state information from neighbor routers and constructs a network topology. The topology determines the routing table presented to the Internet Layer which makes routing decisions based solely on the destination IP address found in IP packets.                                                      |
| vrrp              | Identifies the VRRP protocol (number 112)<br>VRRP allows a pool of routers to be advertised as a single virtual router. This virtual router is configured by hosts as their default gateway. VRRP elects a master router, from this pool, and assigns it a virtual IP address. The master router routes and forwards packets to hosts on the same subnet. When the master router fails, one of the backup routers is elected as the master and its IP address is mapped to the virtual IP address. |

|                          |                                                                                                                                                                                                                                                                                                           |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <SOURCE-IPv6/MASK>       | Specifies a range of IPv6 source address (network) to match. Packets (EIGRP, GRE, IGMP, IGP, OSPF, or VRRP) received from any source in the specified network are forwarded.                                                                                                                              |
| any                      | Specifies the source as any IPv6 address. Packets (EIGRP, GRE, IGMP, IGP, OSPF, or VRRP) received from any source are forwarded.                                                                                                                                                                          |
| host <SOURCE-HOST-IPv6>  | Identifies a specific host (as the source to match) by its IPv6 address. | <a href="#">no (ipv6-acl)</a> on page 1414 | Removes a specified permit access rule from this IPv6 ACL |
|--------------------------------------------|-----------------------------------------------------------|

### *no (ipv6-acl)*

Removes a deny or permit rule from this IPv6 ACL Policy

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```

no [deny|permit]
no [deny|permit] [icmpv6|ipv6|proto|tcp|udp] <RULE-PARAMETERS> {(rule-description <LINE>)}

```

#### Parameters

no <PARAMETERS>

|                 |                                                                  |
|-----------------|------------------------------------------------------------------|
| no <PARAMETERS> | Removes a deny or permit rule from the selected IPv6 access list |
|-----------------|------------------------------------------------------------------|

### Examples

The following example shows the ACL 'test' settings before the 'no' commands is executed:

```

nx9500-6C8809(config-ipv6-acl-test)#show context
ipv6 access-list test
 deny icmpv6 any any type eq destination-unreachable code eq router-renumbering-command
 log rule-precedence 1

```

```

permit proto gre any any log rule-precedence 2
nx9500-6C8809(config-ipv6-acl-test)#
nx9500-6C8809(config-ipv6-acl-test)#no deny icmpv6 any any type eq 1 log rule-precedence 1
nx9500-6C8809(config-ipv6-acl-test)#show context
ipv6 access-list test
 permit proto gre any any log rule-precedence 2
nx9500-6C8809(config-ipv6-acl-test)#

```

## ip-snmp-access-list

SNMP performs network management functions using a data structure called a MIB (Management Information Base). SNMP is widely implemented but not very secure, since it uses only text community strings for accessing controller or service platform configuration files.

Use SNMP ACLs to help reduce SNMP vulnerabilities, as SNMP traffic can be exploited to produce a DoS (denial of service).

The following table summarizes SNMP access list configuration commands:

**Table 38: SNMP Access List Config Mode Commands**

| Command                                           | Description                                           |
|---------------------------------------------------|-------------------------------------------------------|
| <a href="#">deny (ip-snmp acl)</a> on page 1415   | Creates a deny SNMP MIB object traffic rule           |
| <a href="#">permit (ip-snmp acl)</a> on page 1416 | Creates a permit SNMP MIB object traffic rule         |
| <a href="#">no (ip-snmp acl)</a> on page 1417     | Removes a deny or permit SNMP MIB object traffic rule |

### *deny (ip-snmp acl)*

Creates a deny SNMP MIB object traffic rule. Use this command to specify the match criteria based on which SNMP traffic is denied

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
deny [<IP/M>|any|host <IP>]
```

#### Parameters

```
deny [<IP/M>|any|host <IP>]
```

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| deny [<IP/M> any host <IP>] | <p>Configures the match criteria for this deny rule</p> <ul style="list-style-type: none"> <li>• &lt;IP/M&gt; - Specifies a network address and mask in the A.B.C.D/M format. |-----------------------------------------------|---------------------------------------------|

### *permit (ip-snmp acl)*

Creates a permit SNMP MIB object traffic rule. Use this command to specify the match criteria based on which SNMP traffic is permitted.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
permit [<IP/M>|any|host <IP>]
```

## Parameters

```
permit [<IP/M>|any|host <IP>]
```

|                                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|-----------------------------------------------|-----------------------------------------------|

*no (ip-snmp acl)*

Removes a deny or permit rule from the IP SNMP ACL. Use this command to remove IP SNMP ACL as they become obsolete for filtering network access permissions.

**Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

**Syntax**

```
no [deny|permit] [<IP/M>|any|host <IP>]
```

**Parameters**

```
no <PARAMETERS>
```

|                 |                                                              |
|-----------------|--------------------------------------------------------------|
| no <PARAMETERS> | Removes deny and/or permit access rule from this IP SNMP ACL |
|-----------------|--------------------------------------------------------------|

**Usage Guidelines**

- 

**Examples**

```
nx9500-6C8809(config-ip-snmp-acl-test)#show context
ip snmp-access-list test
 permit host 192.168.13.13
 deny 192.168.13.0/24
nx9500-6C8809(config-ip-snmp-acl-test)#
nx9500-6C8809(config-ip-snmp-acl-test)#no permit host 192.168.13.13
nx9500-6C8809(config-ip-snmp-acl-test)#show context
ip snmp-access-list test
 deny 192.168.13.0/24
nx9500-6C8809(config-ip-snmp-acl-test)#
```

## ex3500-ext-access-list

An IPv4 EX3500 extended ACL is a policy-based ACL that either prevents or allows specific clients from using the EX35XX (EX3524 or EX3548) switch. It allows you to permit or deny client access by specifying that the traffic from a specific host or network and/or the traffic to a specific host or network be either denied or permitted.

An EX3500 extended ACL consists of a set of deny /permit rules that filter packets based on both source and destination IPv4 addresses. Each rule specifies a set of match criteria (the source and destination IP addresses) and has a unique precedence value assigned. These ACL rules are applied sequentially to the traffic at a port, by a firewall-supported device, in an increasing order of their precedence. When a packet matches the criteria specified in a rule the packet is either forwarded or dropped based on the rule type.

The following table summarizes IPv4 EX3500 extended ACL configuration commands:

**Table 39: EX3500 Extended Access List Config Mode Commands**

| Command                                              | Description                                                                                                                                                          |
|------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">deny (ex3500-ext acl)</a> on page 1418   | Creates a deny access rule or modifies an existing rule. A deny access rule rejects packets from specified address(es) and/or destined to specified address(es).     |
| <a href="#">permit (ex3500-ext acl)</a> on page 1420 | Creates a permit access rule or modifies an existing rule. A permit access rule accepts packets from specified address(es) and/or destined to specified address(es). |
| <a href="#">no (ex3500-ext acl)</a> on page 1423     | Removes a deny and/or a permit access rule from this IPv4 EX3500 extended ACL                                                                                        |

**Note**

To implement the EX3500 extended ACL, apply it directly to a EX35XX device, or to an EX35XX profile. For more information, see [access-group](#) on page 1299.

*deny (ex3500-ext acl)*

Creates a deny ACL rule that filters packets based on the source and/or destination IPv4 address, and other specified criteria. You can also use this command to modify an existing deny rule.

**Supported in the following platforms:**

- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

**Syntax**

```
deny [<0-255>|tcp|udp] [<SOURCE-NETWORK-IP/MASK>|any|host <SOURCE-HOST-IP>]
[<DEST-NETWORK-IP/MASK>|any|host <DEST-HOST-IP>] [control-flag <0-63>|
destination-port <0-65535>|destination-port-bitmark <0-65535>|dscp <0-63>|
ex3500-time-range <TIME-RANGE-NAME>|ip-precedence <0-63>|rule-precedence <1-128>|
source-port <0-65535>|source-port-bitmark <0-65535>]
```

**Parameters**

```
deny [<0-255>|tcp|udp] [<SOURCE-NETWORK-IP/MASK>|any|host <SOURCE-HOST-IP>]
[<DEST-NETWORK-IP/MASK>|any|host <DEST-HOST-IP>] [control-flag <0-63>|
destination-port <0-65535>|destination-port-bitmark <0-65535>|dscp <0-63>|
ex3500-time-range <TIME-RANGE-NAME>|ip-precedence <0-63>|rule-precedence <1-128>|
source-port <0-65535>|source-port-bitmark <0-65535>]
```

|                                                      |                                                                                                                                                                                                                                                                                                                                                                                                                        |

| rule-precedence <1-128>       | The following keywords are recursive and common to all of the above parameters: <ul style="list-style-type: none"> <li>rule-precedence - Assigns a precedence to this deny rule <ul style="list-style-type: none"> <li>&lt;1-128&gt; - Specify a value from 1 - 5000.</li> </ul> </li> </ul> <p><b>Note:</b> Lower the precedence higher is the priority. A rule with precedence 3 gets priority over a rule with precedence 4 and is applied first to packets.</p> |

### Usage Guidelines

Use this command to deny traffic between networks/hosts based on the protocol type selected in the access list configuration. The following protocols are supported:

- TCP
- UDP
- <0-255> (any Internet protocol other than TCP, UDP, and ICMP)

Packet content is checked against the ACEs in the ACL, and are allowed or denied access based on the ACL configuration.

- Filtering TCP/UDP allows you to specify port numbers as filtering criteria

### Examples

The following example denies TCP outgoing packets from all sources p within the 192.168.14.0/24 network to a specific host 192.168.13.13:

```
nx9500-6C8809(config-ip-ex3500-ext-acl-test)#deny tcp 192.168.14.0/24 host 192.168.13.13
rule-precedence 1
nx9500-6C8809(config-ip-ex3500-ext-acl-test)#show context
ip ex3500-ext-access-list test
 deny tcp 192.168.14.0/24 host 192.168.13.13 rule-precedence 1
nx9500-6C8809(config-ip-ex3500-ext-acl-test)#
```

|-------------------------------------|-----------------------------------------------------------------------------------|

*permit (ex3500-ext acl)*

Creates a permit ACL rule that filters packets based on the source and/or destination IPv4 address, and other specified criteria. You can also use this command to modify an existing permit rule.

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
permit [<0-255>|tcp|udp] [<SOURCE-NETWORK-IP/MASK>|any|host <SOURCE-HOST-IP>]
[<DEST-NEWORK-IP/MASK>|any|host <DEST-HOST-IP>] [control-flag <0-63>|destination-port
<0-65535>|
destination-port-bitmark <0-65535>|dscp <0-63>|ex3500-time-range <TIME-RANGE-NAME>|
ip-precedence <0-63>|rule-precedence <1-128>|source-port <0-65535>|source-port-bitmark
<0-65535>]
```

## Parameters

```
permit [<0-255>|tcp|udp] [<SOURCE-NETWORK-IP/MASK>|any|host <SOURCE-HOST-IP>]
[<DEST-NEWORK-IP/MASK>|any|host <DEST-HOST-IP>] [control-flag <0-63>|destination-port
<0-65535>|
destination-port-bitmark <0-65535>|dscp <0-63>|ex3500-time-range <TIME-RANGE-NAME>|
ip-precedence <0-63>|rule-precedence <1-128>|source-port <0-65535>|source-port-bitmark
<0-65535>]
```

|                                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| permit [<0-255> tcp udp]                             | Creates a permit rule, and identifies the protocol type. This permit rule is applied only to packets matching the protocol specified here.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| [<SOURCE-NETWORK-IP/MASK> any host <SOURCE-HOST-IP>] | Specifies the source as any, host, or network <ul style="list-style-type: none"><li>&lt;SOURCE-NETWORK-IP/MASK&gt; - Configures a network as the source. Provide the network's IPv4 address along with the mask.</li><li>host &lt;SOURCE-HOST-IP&gt; - Configures a single device as the source. Provide the host device's IPv4 address.</li><li>any - Specifies that the source can be any device</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| [<DEST-NETWORK-IP/MASK> any host <DEST-HOST-IP>]     | Specifies the destination as any, host, or network <ul style="list-style-type: none"><li>&lt;DEST-NETWORK-IP/MASK&gt; - Configures a network as the destination. Provide the network's IPv4 address along with the mask.</li><li>host &lt;DEST-HOST-IP&gt; - Configures a single device as the destination. Provide the host device's IPv4 address.</li><li>any - Specifies that the destination can be any device</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| control-flag <0-63>                                  | Configures the decimal number (representing a bit string) that specifies the control flag bits in byte 14 of the TCP header <ul style="list-style-type: none"><li>&lt;0-63&gt; - Specify a value from 0 - 63.</li></ul> <p><b>Note:</b> Control flags can be used only in ACLs designed to filter TCP traffic.</p> <p>The TCP header contains several one-bit boolean fields known as flags that influence flow of data across a TCP connection. Ignoring the CWR and ECE flags added for congestion notification by RFC 3168, there are six TCP control flags.</p> <ul style="list-style-type: none"><li>URG flag - Marks incoming packet as urgent</li><li>ACK flag - Acknowledges receipt of packet</li><li>PUSH flag - Ensures that the packet is given appropriate priority. Often used at the beginning and end of data transfer.</li><li>RST flag - Resets the connection. Happens when remote host receives a establish connection packet, but does not have a service waiting to answer and sends a reply with reset flag.</li><li>SYN flag - Establishes the 3-way handshake between two hosts</li><li>FIN flag - Tears down the connection established between two hosts via the 3-way SYN process</li></ul> |

|                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| destination-port <0-65535>          | Configures the protocol destination port to match. The destination protocol can be TCP, UDP or any other protocol identified by its number (<0-255>). <ul style="list-style-type: none"> <li>&lt;0-65535&gt; - Specify the destination port from 0 - 65535.</li> </ul>                                                                                                                                                                                                |
| destination-port-bitmark <0-65535>  | Configures the decimal number representing the protocol destination port bits to match <ul style="list-style-type: none"> <li>&lt;0-65535&gt; - Specify the destination port bits from 0 - 65535.</li> </ul>                                                                                                                                                                                                                                                          |
| dscp <0-63>                         | Configures the DSCP priority level <ul style="list-style-type: none"> <li>&lt;0-63&gt; - Specify a value from 0 - 63.</li> </ul> <p><b>Note:</b> If specifying DSCP priority, ip-precedence cannot be specified.</p>                                                                                                                                                                                                                                                  |
| ex3500-time-range <TIME-RANGE-NAME> | Applies a periodic or absolute time range to this rule <ul style="list-style-type: none"> <li>&lt;TIME-RANGE-NAME&gt; - Specify the time range name (should be existing and configured). For information on configuring EX3500 time-range, see <a href="#">ex3500</a>.</li> </ul>                                                                                                                                                                                     |
| ip-precedence <0-7>                 | Configures the IP header precedence <ul style="list-style-type: none"> <li>&lt;0-7&gt; - Specify a value from 0 - 7.</li> </ul>                                                                                                                                                                                                                                                                                                                                       |
| source-port <0-65535>               | Configures the protocol source port to match. The source protocol can be TCP, UDP or any other protocol identified by its number (<0-255>). <ul style="list-style-type: none"> <li>&lt;0-65535&gt; - Specify the source port from 0 - 65535.</li> </ul>                                                                                                                                                                                                               |
| source-port-bitmark <0-65535>       | Configures the decimal number representing the protocol source port bits to match <ul style="list-style-type: none"> <li>&lt;0-65535&gt; - Specify the source port bits from 0 - 65535.</li> </ul>                                                                                                                                                                                                                                                                    |
| rule-precedence <1-128>             | The following keywords are recursive and common to all of the above parameters: <ul style="list-style-type: none"> <li>rule-precedence - Assigns a precedence to this permit rule <ul style="list-style-type: none"> <li>&lt;1-128&gt; - Specify a value from 1 - 5000.</li> </ul> </li> </ul> <p><b>Note:</b> Lower the precedence higher is the priority. A rule with precedence 3 gets priority over a rule with precedence 4 and is applied first to packets.</p> |

### Usage Guidelines

Use this command to permit traffic between networks/hosts based on the protocol type selected in the access list configuration. The following protocols are supported:

- TCP
- UDP
- <0-255> (any Internet protocol other than TCP, UDP, and ICMP)

Packet content is checked against the ACEs in the ACL, and are allowed or denied access based on the ACL configuration.

- Filtering TCP/UDP allows you to specify port numbers as filtering criteria.

## Examples

The following example permits outgoing TCP packets from all sources within the 192.168.14.0 network to any destination, with the TCP control flag set to 16 (acknowledge):

```
nx9500-6C8809(config-ip-ex3500-ext-acl-test)#permit tcp 192.168.14.0/24 any control-flag
16 rule-precedence 2
nx9500-6C8809(config-ip-ex3500-ext-acl-test)#show context
ip ex3500-ext-access-list test
 deny tcp 192.168.14.0/24 host 192.168.13.13 rule-precedence 1
 permit tcp 192.168.14.0/24 any control-flag 16 rule-precedence 2
nx9500-6C8809(config-ip-ex3500-ext-acl-test)#
```

## Related Commands

|                                     |                                                                                     |
|-------------------------------------|-------------------------------------------------------------------------------------|
| <code>no (ex3500-ext acl)</code> on | Removes a specified permit access rule from this IPv4 EX3500 extended ACL page 1423 |
|-------------------------------------|-------------------------------------------------------------------------------------|

*no (ex3500-ext acl)*

Removes a deny or permit access rule from this IPv4 EX3500 extended ACL

## Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
no [deny|permit] [<0-255>|tcp|udp] [<SOURCE-NETWORK-IP/MASK>|any|host <SOURCE-HOST-IP>]
[<DEST-NETWORK-IP/MASK>|any|host <DEST-HOST-IP>] [control-flag <0-63>|destination-port
<0-65535>|
destination-port-bitmark <0-65535>|dscp <0-63>|ex3500-time-range <TIME-RANGE-NAME>|
ip-precedence <0-63>|rule-precedence <1-128>|source-port <0-65535>|source-port-bitmark
<0-65535>]
```

## Parameters

no <PARAMETERS>

|                                    |                                                                     |
|------------------------------------|---------------------------------------------------------------------|
| <code>no &lt;PARAMETERS&gt;</code> | Removes a deny or permit access rule based on the parameters passed |
|------------------------------------|---------------------------------------------------------------------|

## Usage Guidelines

The keyword 'control-flag <0-63>' is only applicable to ACL rules filtering TCP traffic.

## Examples

The following example shows the IPv4 EX3500 extended ACL 'test' settings before the 'no' commands are executed:

```
nx9500-6C8809(config-ip-ex3500-ext-acl-test)#show context
ip ex3500-ext-access-list test
 deny tcp 192.168.14.0/24 host 192.168.13.13 rule-precedence 1
 permit tcp 192.168.14.0/24 any control-flag 16 rule-precedence 2
nx9500-6C8809(config-ip-ex3500-ext-acl-test)#
nx9500-6C8809(config-ip-ex3500-ext-acl-test)#no permit tcp 192.168.14.0/24 any control-
flag 16 rule-precedence 2
```

The following example shows the IPv4 EX3500 extended ACL 'test' settings after the 'no' commands are executed:

```
nx9500-6C8809(config-ip-ex3500-ext-acl-test)#show context
ip ex3500-ext-access-list test
 deny tcp 192.168.14.0/24 host 192.168.13.13 rule-precedence 1
nx9500-6C8809(config-ip-ex3500-ext-acl-test)#
```

## ex3500-std-access-list

An EX3500 standard ACL is a policy-based ACL that contains a set of filter criteria and action that is applied to traffic originating from a specified source.

The following table summarizes IPv4 EX3500 standard ACL configuration commands:

**Table 40: EX3500-Standard-Access-List-Config Commands**

| Command                                              | Description                                                                                                                                                                                                              |
|------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">deny (ex3500-std acl)</a> on page 1424   | Creates a deny rule that rejects packets from a specified source or sources. The source can be a single device or a range of devices within a specified network. Use this command to also edit an existing deny rule.    |
| <a href="#">permit (ex3500-std acl)</a> on page 1425 | Creates a permit rule that allows packets from a specified source or sources. The source can be a single device or a range of devices within a specified network. Use this command to also edit an existing permit rule. |
| <a href="#">no (ex3500-std acl)</a> on page 1426     | Removes a deny and/or a permit access rule from this IPv4 EX3500 extended ACL                                                                                                                                            |

### Note

To implement the EX3500 standard ACL, apply it directly to a EX35XX device, or to an EX35XX profile. For more information, see [access-group](#) on page 1299.

### *deny (ex3500-std acl)*

Creates a deny rule that rejects packets from a specified source or sources. The source can be a single device or a range of devices within a specified network. Use this command to also edit an existing deny rule.

#### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
deny [<SOURCE-NETWORK-IP/MASK>|any|host <SOURCE-HOST-IP>] {ex3500-time-range <TIME-RANGE-NAME>}
```

#### Parameters

```
deny [<SOURCE-NETWORK-IP/MASK>|any|host <SOURCE-HOST-IP>] {ex3500-time-range <TIME-RANGE-NAME>}
```

|                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| deny [<SOURCE-NETWORK-IP/MASK> any host <SOURCE-HOST-IP>] | <p>Creates a deny rule that rejects packets from a specified source or a network. Use one of the following options to specify the source: any, host, or network.</p> <ul style="list-style-type: none"> <li>• &lt;SOURCE-NETWORK-IP/MASK&gt; - Configures a network as the source. Provide the network's IPv4 address along with the mask.</li> <li>• host &lt;SOURCE-HOST-IP&gt; - Configures a single device as the source. Provide the host device's IPv4 address.</li> <li>• any - Specifies that the source can be any device</li> </ul> |
| ex3500-time-range <TIME-RANGE-NAME>                       | <p>Optional. Applies a periodic or absolute time range to this deny rule</p> <ul style="list-style-type: none"> <li>• &lt;TIME-RANGE-NAME&gt; - Specify the time range name (should be existing and configured). The ACL is triggered during the time period configured in the specified EX3500 time range. For information on configuring EX3500 time-range, see <a href="#">ex3500</a>.</li> </ul>                                                                                                                                          |

### Examples

```

nx9500-6C8809(config-ip-ex3500-std-acl-test)#deny 192.168.14.0/24
nx9500-6C8809(config-ip-ex3500-std-acl-test)#show context
ip ex3500-std-access-list test
 deny 192.168.13.0/24
nx9500-6C8809(config-ip-ex3500-std-acl-test)#

```

|--------------------------------------------------|-------------------------------------------------------------------------|

### *permit (ex3500-std acl)*

Creates a permit rule that allows packets from a specified source or sources. The source can be a single device or a range of devices within a specified network. Use this command to also edit an existing permit rule.

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
permit [<SOURCE-NETWORK-IP/MASK>|any|host <SOURCE-HOST-IP>] {ex3500-time-range <TIME-RANGE-NAME>}
```

### Parameters

```
permit [<SOURCE-NETWORK-IP/MASK>|any|host <SOURCE-HOST-IP>] {ex3500-time-range <TIME-RANGE-NAME>}
```

|                                                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

### Examples

The following example shows the IPv4 EX3500 standard ACL ‘test’ settings before the ‘no’ commands are executed:

```
nx9500-6C8809(config-ip-ex3500-std-acl-test)#show context
ip ex3500-std-access-list test
```

---

```
deny 192.168.14.0/24
permit host 192.168.13.13 ex3500-time-range EX3500_TimeRange_01
nx9500-6C8809(config-ip-ex3500-std-acl-test)#
nx9500-6C8809(config-ip-ex3500-std-acl-test)#no deny 192.168.14.0/24
```

The following example shows the IPv4 EX3500 standard ACL 'test' settings after the 'no' commands are executed:

```
nx9500-6C8809(config-ip-ex3500-std-acl-test)#show context
ip ex3500-std-access-list test
permit host 192.168.13.13 ex3500-time-range EX3500_TimeRange_01
nx9500-6C8809(config-ip-ex3500-std-acl-test)#
```

# DHCP POLICY

## DHCP-SERVER-POLICY

---

This chapter summarizes DHCP (Dynamic Host Control Protocol) server policy commands in the CLI command structure.

DHCP automatically assigns network IP addresses to requesting clients to enable them access to network resources. DHCP tracks IP address assignments, their lease times and their availability. Each subnet can be configured with its own address pool. Whenever a DHCP client requests an IP address, the DHCP server assigns an IP address from that subnet's address pool. When the controller's (wireless controller, service platform, or access point) onboard DHCP server allocates an address to a DHCP client, the client is assigned a lease, which expires after a pre-determined interval. Before a lease expires, wireless clients (with assigned leases) are expected to renew them to continue using the addresses. Once the lease expires, the client is no longer permitted to use the leased IP address. The controller's DHCP server policy ensures all IP addresses are unique, and no IP address is assigned to a second client while the first client's assignment is valid (its lease has not expired). IP address management is conducted by a controller's DHCP server and not by an administrator.

The controller's internal DHCP server groups wireless clients based on defined user-class option values. Clients with a defined set of user class values are segregated by class. A DHCP server can associate multiple classes to each pool. Each class in a pool is assigned an exclusive range of IP addresses. DHCP clients are compared against classes. If the client matches one of the classes assigned to the pool, it receives an IP address from the range assigned to the class. If the client doesn't match any of the classes in the pool, it receives an IP address from a default pool range (if defined). Multiple IP addresses for a single VLAN allow the configuration of multiple IP addresses, each belonging to different subnet. Class configuration allows a DHCP client to obtain an address from the first pool to which the class is assigned.

Use the (config) instance to configure DHCP/DHCPv6 server policy parameters. To navigate to the config DHCP server policy instance, use the following commands:

```
<DEVICE> (config)#dhcp-server-policy <POLICY-NAME>
nx9500-6C8809(config)#dhcp-server-policy test
nx9500-6C8809(config-dhcp-server-policy-test)#?
DHCP policy Mode commands:
 bootp BOOTP specific configuration
 dhcp-class Configure DHCP class (for address allocation using DHCP
 user-class options)
 dhcp-pool Configure DHCP server address pool
 dhcp-server Activating dhcp server based on criteria
 no Negate a command or set its defaults
 option Define DHCP server option
 ping Specify ping parameters used by DHCP Server

 clrscr Clears the display screen
 commit Commit all changes made in this session
 do Run commands from Exec mode
 end End current mode and change to EXEC mode
 exit End current mode and down to previous mode
 help Description of the interactive help system
 revert Revert changes
```

```

service Service Commands
show Show running system information
write Write running configuration to memory or terminal

```

```
nx9500-6C8809(config-dhcp-policy-test)#
```

To navigate to the config DHCPv6 server policy instance, use the following commands:

```

<DEVICE>(config)#dhcpv6-server-policy <POLICY-NAME>
nx9500-6C8809(config)#dhcpv6-server-policy test
nx9500-6C8809(config-dhcpv6-server-policy-test)#?

```

DHCPv6 server policy Mode commands:

```

dhcpv6-pool Configure DHCPV6 server address pool
no Negate a command or set its defaults
option Define DHCPV6 server option
restrict-vendor-options Restrict vendor specific options to be sent in
 server reply
server-preference Server preference value sent in the reply, by the
 server to client

clrscr Clears the display screen

do Run commands from Exec mode
end End current mode and change to EXEC mode
exit End current mode and down to previous mode
help Description of the interactive help system
revert Revert changes
service Service Commands
show Show running system information
write Write running configuration to memory or terminal

```

```
nx9500-6C8809(config-dhcpv6-server-policy-test)#
```

This chapter is organized into the following subsections:

- [dhcp-server-policy commands](#) on page 1429.
- [dhcpv6-server-policy commands](#) on page 1471.

## dhcp-server-policy commands

The following table summarizes the DHCP server policy configuration mode commands:

**Table 41: DHCP-Server-Policy Config Mode Commands**

| Command                                                                | Description                                |
|------------------------------------------------------------------------|--------------------------------------------|
| <a href="#">bootp (dhcpv4-server-policy-config)</a> on page 1430       | Configures a BOOTP specific configuration  |
| <a href="#">dhcp-class (dhcpv4-server-policy-config)</a> on page 1431  | Configures a DHCP server class             |
| <a href="#">dhcp-pool (dhcpv4-server-policy-config)</a> on page 1434   | Configures a DHCP server address pool      |
| <a href="#">dhcp-server (dhcpv4-server-policy-config)</a> on page 1469 | Configures DHCP server options             |
| <a href="#">option (dhcpv4-server-policy-config)</a> on page 1468      | Defines the DHCP option used in DHCP pools |

**Table 41: DHCP-Server-Policy Config Mode Commands (continued)**

| Command                                                      | Description                                     |
|--------------------------------------------------------------|-------------------------------------------------|
| <code>ping (dhcpv4-server-policy-config)</code> on page 1468 | Specifies ping parameters used by a DHCP server |
| <code>no (dhcpv4-server-policy-config)</code> on page 1471   |                                                 |

**Note**

For more information on common commands (clrscr, commit, help, revert, service, show, write, and exit), see [COMMON COMMANDS](#) on page 640.

**Note**

The input parameter <HOSTNAME>, wherever used in syntaxes across this chapter, cannot include an underscore (\_) character. In other words, the name of a device cannot contain an underscore.

*bootp (dhcpv4-server-policy-config)*

Configures a BOOTP specific configuration

BOOTP (Bootstrap Protocol) requests are used by UNIX diskless workstations to obtain the location of their boot image and IP address within the managed network. A BOOTP configuration server provides this information and also assigns an IP address from a configured pool of IP addresses. By default, all BOOTP requests are forwarded to the BOOTP configuration server by the controller. When enabled, this feature allows controllers, using this DHCP server policy, to ignore BOOTP requests.

**Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

**Syntax**

`bootp ignore`

**Parameters**

`bootp ignore`

|                           |                                              |
|---------------------------|----------------------------------------------|
| <code>bootp ignore</code> | Enables controllers to ignore BOOTP requests |
|---------------------------|----------------------------------------------|

**Examples**

```
nx9500-6C8809(config-dhcp-policy-test)#bootp ignore
nx9500-6C8809(config-dhcp-policy-test)#show context
dhcp-server-policy test
 bootp ignore
nx9500-6C8809(config-dhcp-policy-test)#
```

## Related Commands

`no (dhcpv4-server-policy-config)` on page 1471

Disables the ignore BOOTP requests option

### *dhcp-class (dhcpv4-server-policy-config)*

Creates a DHCP server class and enters its configuration mode. Use this command to configure or modify user class option values. Once defined, the controller's internal DHCP server uses the configured values to group wireless clients into DHCP classes, such that each user class consists of wireless clients sharing the same set of user class values.

A controller, service platform, or access point's local DHCP server assigns IP addresses to requesting DHCP clients based on user class option names. The DHCP server can assign IP addresses from as many IP address ranges as defined by an administrator. The DHCP user class associates a particular range of IP addresses to a device in such a way that all devices of that type are assigned IP addresses from the defined range.

A DHCP user class applies different DHCP settings to a set of wireless clients. Wireless clients using the same DHCP settings are grouped under one DHCP class. Grouping users into classes facilitates the provision of differentiated service.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
dhcp-class <DHCP-CLASS-NAME>
```

### Parameters

```
dhcp-class <DHCP-CLASS-NAME>
```

|                   |                                                                                                                                                                                                                                                                                                                |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <DHCP-CLASS-NAME> | Creates a DHCP user class <ul style="list-style-type: none"><li>• &lt;DHCP-CLASS-NAME&gt; - Specify a name that appropriately identifies this class of wireless clients. If a class with the specified name does not exist, it is created. The class name should not exceed 32 characters in length.</li></ul> |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Examples

Use the `dhcp-class` command to configure a DHCP user class.

```
nx9500-6C8809(config-dhcp-policy-test)#dhcp-class dhcpclass1
nx9500-6C8809(config-dhcp-policy-test-class-dhcpclass1)#?
DHCP class Mode commands:
 multiple-user-class Enable multiple user class option
 no Negate a command or set its defaults
 option Configure DHCP Server options

 clrscr Clears the display screen
 commit Commit all changes made in this session
 do Run commands from Exec mode
 end End current mode and change to EXEC mode
 exit End current mode and down to previous mode
```

```

help Description of the interactive help system
revert Revert changes
service Service Commands
show Show running system information
write Write running configuration to memory or terminal

```

```
nx9500-6C8809(config-dhcp-policy-test-class-dhcpclass1)#
```

The following table summarizes the DHCP user class configuration commands.

**Table 42: DHCP-User-Class Config Mode Commands**

| Command                                                                                     | Description                                                                    |
|---------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------|
| <code>multiple-user-class (dhcpv4-class-config)</code> on page 1432                         | Enables or disables multiple user class option for this DHCP user class policy |
| <code>option (dhcpv4-class-config)</code> on page 1433                                      | Configures DHCP user class options for this DHCP user class policy             |
| <code>no (dhcpv4-class-config)</code> on page 1433                                          | Removes this DHCP class settings                                               |

### multiple-user-class (dhcpv4-class-config)

Enables multiple user class option for this DHCP user class policy. Enabling this option allows this user class to transmit multiple option values to other DHCP servers also supporting multiple user class options.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
multiple-user-class
```

#### Parameters

None

#### Examples

```

nx9500-6C8809(config-dhcp-policy-test-class-class1)#multiple-user-class
nx9500-6C8809(config-dhcp-policy-test-class-dhcpclass1)#show context
dhcp-class dhcpclass1
 multiple-user-class
nx9500-6C8809(config-dhcp-policy-test-class-dhcpclass1)#

```

#### Related Commands

| <code>no (dhcpv4-class-config)</code> on page 1433 | Disables the multiple user class option for the selected DHCP user class policy |
|----------------------------------------------------|---------------------------------------------------------------------------------|

### option (dhcpv4-class-config)

Configures DHCP user class options for this DHCP user class policy

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

Syntax

```
option user-class <VALUE>
```

Parameters

```
option user-class <VALUE>
```

|                    |                                                                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| user-class <VALUE> | Configures DHCP user class options <ul style="list-style-type: none"><li>• &lt;VALUE&gt; - Specify the DHCP user class option's ASCII value.</li></ul> |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|

Examples

```
nx9500-6C8809(config-dhcp-policy-test-class-class1)#option user-class test
nx9500-6C8809(config-dhcp-policy-test-class-dhcpclass1)#show context
dhcp-class dhcpclass1
 option user-class test
 multiple-user-class
nx9500-6C8809(config-dhcp-policy-test-class-dhcpclass1)#
```

Related Commands

|                                                       |                                               |
|-------------------------------------------------------|-----------------------------------------------|
| <a href="#">no (dhcpv4-class-config)</a> on page 1433 | Removes the configured DHCP user class option |
|-------------------------------------------------------|-----------------------------------------------|

### no (dhcpv4-class-config)

Removes this DHCP user class policy's settings

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

Syntax

```
no [multiple-user-class|option]
no option user-class <VALUE>
```

Parameters

```
no <PARAMETERS>
```

|                 |                                                                     |
|-----------------|---------------------------------------------------------------------|
| no <PARAMETERS> | Disables multiple user class options on this DHCP user class policy |
|-----------------|---------------------------------------------------------------------|

Examples

The following example shows the DHCP class settings before the 'no' commands are executed:

```
nx9500-6C8809(config-dhcp-policy-test-class-dhcpclass1)#show context
dhcp-class dhcpclass1
 option user-class test
```

```

multiple-user-class
nx9500-6C8809(config-dhcp-policy-test-class-dhcpclass1)#
nx9500-6C8809(config-dhcp-policy-test-class-class1)#no multiple-user-class
nx9500-6C8809(config-dhcp-policy-test-class-dhcpclass1)#no option user-class test

```

The following example shows the DHCP class settings after the 'no' commands are executed:

```

nx9500-6C8809(config-dhcp-policy-test-class-dhcpclass1)#show context
dhcp-class dhcpclass1
nx9500-6C8809(config-dhcp-policy-test-class-dhcpclass1)#

```

### *dhcp-pool (dhcpv4-server-policy-config)*

Creates a DHCP server address pool and enters its configuration mode.

The DHCP pool command creates and manages a pool of IP addresses. These IP addresses are assigned to devices using the DHCP protocol. IP addresses have to be unique for each device in the network. Since IP addresses are finite, DHCP ensures that every device, in the network, is issued a unique IP address by tracking the issue, release, and reissue of IP addresses.

The DHCP pool command configures a finite set of IP addresses that can be assigned whenever a device joins a network.

DHCP services are available for specific IP interfaces. A pool (or range) of IP network addresses and DHCP options can be created for each IP interface defined. This range of addresses is available to DHCP enabled wireless devices on either a permanent or leased basis. This enables the reuse of limited IP address resources for deployment in any network. DHCP options are provided to each DHCP client with a DHCP response and provides DHCP clients information required to access network resources (default gateway, domain name, DNS server and WINS server configuration). An option exists to identify the vendor and functionality of a DHCP client. The information is a variable-length string of characters (or octets) with a meaning specified by the vendor of the DHCP client.

#### **Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### **Syntax**

```
dhcp-pool <POOL-NAME>
```

#### **Parameters**

```
dhcp-pool <POOL-NAME>
```

|             |                                                                                                                                                                                                                                                                                                                                                                         |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <POOL-NAME> | <p>Creates a DHCP server address pool</p> <ul style="list-style-type: none"> <li>• &lt;POOL-NAME&gt; - Specify a name that appropriately identifies this DHCP address pool. If a pool with the specified name does not exist, it is created. The pool name cannot be modified as part of the edit process. However, an obsolete address pool can be deleted.</li> </ul> |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

#### **Examples**

Use the `dhcp-pool` command to configure a DHCP user pool.

```

nx9500-6C8809(config-dhcp-policy-test)#dhcp-pool pool1
nx9500-6C8809(config-dhcp-policy-test-pool-pool1)#?

```

DHCP pool Mode commands:

```

address Configure network pool's included addresses
bootfile Boot file name
ddns Dynamic DNS Configuration
default-router Default routers
dns-server DNS Servers
domain-name Configure domain-name
excluded-address Prevent DHCP Server from assigning certain addresses
lease Address lease time
netbios-name-server NetBIOS (WINS) name servers
netbios-node-type NetBIOS node type
network Network on which DHCP server will be deployed
next-server Next server in boot process
no Negate a command or set its defaults
option Raw DHCP options
respond-via-unicast Send DHCP offer and DHCP Ack as unicast messages
static-binding Configure static address bindings
static-route Add static routes to be installed on dhcp clients
update Control the usage of DDNS service

clrscr Clears the display screen

### address (dhcpv4-pool-config)

Adds IP addresses to the DHCP address pool. These IP addresses are assigned to each device joining the network.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
address [<IP> | <HOST-ALIAS-NAME> | range]
address [<IP> | <HOST-ALIAS-NAME> | range [<START-IP> | <START-HOST-ALIAS-NAME>] [<END-IP> | <END-
HOST-ALIAS-NAME>]]
{ class <DHCP-CLASS-NAME> }
```

#### Parameters

```
address [<IP> | <HOST-ALIAS-NAME> | range [<START-IP> | <START-HOST-ALIAS-NAME>] [<END-IP> | <END-
HOST-ALIAS-NAME>]]
{ class <DHCP-CLASS-NAME> }
```

|                   |                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <IP>              | Adds a single IP address to the DHCP address pool                                                                                                                                                                                                                                                                                                                                     |
| <HOST-ALIAS-NAME> | Adds a single host mapped to the specified host alias. The host alias should be existing and configured.<br><br><b>Note:</b> A network host alias maps a name to a single network host. For example, 'alias host \$HOST 1.1.1.100'. In this example the host alias is '\$HOST' and it maps to a single host '1.1.1.100'. For more information, see <a href="#">alias</a> on page 237. |

|                                                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| range [<START-IP> <START-HOST-ALIAS-NAME>] [<END-IP> <END-HOST-ALIAS-NAME>] | <p>Adds a range of IP addresses to the DHCP address pool. Use one of the following options to provide the first IP address in the range:</p> <ul style="list-style-type: none"> <li>• &lt;START-IP&gt; – Specifies the first IP address in the range</li> <li>• &lt;START-HOST-ALIAS-NAME&gt; – Specifies a host alias, mapped to the first IP address in the range</li> </ul> <p>Use one of the following options to provide the last IP address in the range:</p> <ul style="list-style-type: none"> <li>• &lt;END-IP&gt; – Specifies the last IP address in the range</li> <li>• &lt;END-HOST-ALIAS-NAME&gt; – Specifies a host alias, mapped to the last IP address in the range</li> </ul> <p><b>Note:</b> The host aliases should be existing and configured.</p> |
| class <DHCP-CLASS-NAME>                                                     | <p>Optional. Applies additional DHCP options, or a modified set of options to those available to wireless clients. For more information, see <a href="#">dhcp-class (dhcpv4-server-policy-config)</a> on page 1431.</p> <ul style="list-style-type: none"> <li>• &lt;DHCP-CLASS-NAME&gt; – Sets the DHCP class (should be existing and configured)</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                           |

### Examples

```
rfs4000-229D58(config-dhcp-policy-test-pool-testPool)#address 192.168.13.4 class dhcpclass1
rfs4000-229D58(config-dhcp-policy-test-pool-testPool)#show context
dhcp-pool testPool
 address 192.168.13.4 class dhcpclass1
rfs4000-229D58(config-dhcp-policy-test-pool-testPool)#
```

## bootfile (dhcpv4-pool-config)

The Bootfile command provides a diskless node path to the image file while booting up. Only one file can be configured for each DHCP pool.

For more information on the BOOTP protocol with reference to the DHCP policy, see bootp [bootp \(dhcpv4-server-policy-config\)](#) on page 1430.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
bootfile <IMAGE-FILE-PATH>
```

### Parameters

```
bootfile <IMAGE-FILE-PATH>
```

|                   |                                                                                                                                                                  |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <IMAGE-FILE-PATH> | Sets the path to the boot image for BOOTP clients. The file name can contain letters, numbers, dots and hyphens. Consecutive dots and hyphens are not permitted. |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|

#### Examples

```
rfs4000-229D58(config-dhcp-policy-test-pool-testPool)#bootfile test.txt
rfs4000-229D58(config-dhcp-policy-test-pool-testPool)#show context
dhcp-pool testPool
 address 192.168.13.4 class dhcpclass1
 bootfile test.txt
rfs4000-229D58(config-dhcp-policy-test-pool-testPool)#
```

### ddns (dhcpv4-pool-config)

DDNS (Dynamic DNS) parameters. Dynamic DNS provides a way to access an individual device in a DHCP serviced network using a static device name.

Depending on the DHCP server's configuration, the IP address of a device changes periodically. To ensure continuous accessibility to a device (having a dynamic IP address), the device's current IP address is published to a DDNS server that resolves the static device name (used to access the device) with a changing IP address.

The DDNS server must be accessible from outside the network and must be configured as an address resolver.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
ddns [domainname|multiple-user-class|server|ttl]
ddns domainname <DDNS-DOMAIN-NAME>
ddns multiple-user-class
ddns server [<IP>|<HOST-ALIAS-NAME>] {<IP1>|<HOST-ALIAS-NAME1>}
ddns ttl <1-864000>
```

#### Parameters

```
ddns domainname <DDNS-DOMAIN-NAME>
```

|                    |                                                                                                                                                                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| domainname         | Sets the domain name used for DNS updates                                                                                                                                                                                                                                                           |
| <DDNS-DOMAIN-NAME> | The controller uses DNS to convert human readable host names into IP addresses. Host names are not case sensitive and can contain alphabetic or numeric letters or a hyphen. A FQDN (fully qualified domain name) consists of a host name plus a domain name. For example, computername.domain.com. |

```
ddns multiple-user-class
```

|                     |                                                               |
|---------------------|---------------------------------------------------------------|
| multiple-user-class | Enables the multiple user class options with this DDNS domain |
|---------------------|---------------------------------------------------------------|

```
ddns server [<IP>|<HOST-ALIAS-NAME>] {<IP1>|<HOST-ALIAS-NAME1>}
```

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| server                     | Configures the DDNS server used by this DHCP profile                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| [<IP> <HOST-ALIAS-NAME>]   | Configures the primary DDNS server. This is the default server. Use one of the following options to specify the primary DDNS server: <ul style="list-style-type: none"> <li>• &lt;IP&gt; – Specifies the primary DDNS server’s IP address</li> <li>• &lt;HOST-ALIAS-NAME&gt; – Specifies a host alias, mapped to the primary DDNS server’s IP address. The host alias should be existing and configured.</li> </ul> <p><b>Note:</b> A network host alias maps a name to a single network host. For example, ‘alias host \$HOST 1.1.1.100’. In this example the host alias is ‘\$HOST’ and it maps to a single host ‘1.1.1.100’. For more information, see <a href="#">alias</a> on page 237.</p> |
| {<IP1> <HOST-ALIAS-NAME1>} | Optional. Configures the secondary DDNS server. If the primary server is not reachable, this server is used. Use one of the following options to identify the secondary DDNS server: <ul style="list-style-type: none"> <li>• &lt;IP&gt; – Specifies the secondary DDNS server’s IP address</li> <li>• &lt;HOST-ALIAS-NAME&gt; – Specifies a host alias, mapped to the secondary DDNS server’s IP address. The host alias should be existing and configured.</li> </ul>                                                                                                                                                                                                                          |

```
ddns ttl <1-864000>
```

|                |                                                                                                                                                                        |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ttl <1-864000> | Configures the TTL (Time To Live) value for DDNS updates <ul style="list-style-type: none"> <li>• &lt;1-86400&gt; – Specify a value from 1- 864000 seconds.</li> </ul> |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Examples

```

## default-router (dhcpv4-pool-config)

Configures a default router or gateway IP address for the network pool

After a DHCP client has booted, the client begins sending packets to its default router. Set the IP address of one or a group of routers the controller uses to map host names into IP addresses available to DHCP supported clients. Up to 8 default router IP addresses are supported.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
default-router [<IP>|<HOST-ALIAS-NAME>] {<IP1>|<HOST-ALIAS-NAME1>}
```

#### Parameters

```
default-router [<IP>|<HOST-ALIAS-NAME>] {<IP1>|<HOST-ALIAS-NAME1>}
```

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [<IP> <HOST-ALIAS-NAME>]   | <p>Configures the primary default router, using one of the following options:</p> <ul style="list-style-type: none"> <li>• &lt;IP&gt; - Specifies the primary default router's IP address</li> <li>• &lt;HOST-ALIAS-NAME&gt; - Specifies a host alias, mapped to the primary default router's IP address. The host alias should be existing and configured.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                  |
| {<IP1> <HOST-ALIAS-NAME1>} | <p>Optional. Configures the secondary default router, using one of the following options:</p> <ul style="list-style-type: none"> <li>• &lt;IP1&gt; - Specifies the secondary default router's IP address</li> <li>• &lt;HOST-ALIAS-NAME1&gt; - Specifies a host alias, mapped to the secondary default router's IP address. If the primary default router is unavailable, the secondary router is used.</li> </ul> <p><b>Note:</b> A network host alias maps a name to a single network host. For example, 'alias host \$HOST 1.1.1.100'. In this example the host alias is '\$HOST' and it maps to a single host '1.1.1.100'. For more information, see <a href="#">alias</a> on page 237 .</p> <p><b>Note:</b> A maximum of 8 default routers can be configured..</p> |

#### Usage Guidelines

The IP address of the router should be on the same subnet as the client subnet.

#### Examples

```
rfs4000-229D58(config-dhcp-policy-test-pool-testPool)#default-router 192.168.13.8
192.168.13.9
rfs4000-229D58(config-dhcp-policy-test-pool-testPool)#show context
dhcp-pool testPool
 address 192.168.13.4 class dhcpclass1
 ddns server 192.168.13.9
 ddns domainname WID
 ddns multiple-user-class
 bootfile test.txt
 default-router 192.168.13.8 192.168.13.9
rfs4000-229D58(config-dhcp-policy-test-pool-testPool)#
```

### dns-server (dhcpv4-pool-config)

Configures a network's DNS server. The DNS server supports all clients connected to networks supported by the DHCP server.

For DHCP clients, the DNS server's IP address maps the hostname to an IP address. DHCP clients use the DNS server's IP address based on the order (sequence) configured.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
dns-server [<IP>|<HOST-ALIAS-NAME>] {<IP1>|<HOST-ALIAS-NAME1>}
```

#### Parameters

```
dns-server [<IP>|<HOST-ALIAS-NAME>] {<IP1>|<HOST-ALIAS-NAME1>}
```

|                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>[&lt;IP&gt; &lt;HOST-ALIAS-NAME&gt;]</p>   | <p>Configures the primary DNS server, using one of the following options:</p> <ul style="list-style-type: none"><li>• &lt;IP&gt; – Specifies the primary DNS server’s IP address</li><li>• &lt;HOST-ALIAS-NAME&gt; – Specifies a host alias, mapped to the primary DNS server’s IP address</li></ul> <p><b>Note:</b> A maximum of 8 DNS server’s can be configured.</p> <p>To enable redirection of DNS queries to OpenDNS it is necessary that the DNS server IP addresses provided here should point to the OpenDNS resolver (208.67.220.220 or 208.67.222.222). OpenDNS is a proxy DNS server that provides additional functionality, such as Web filtering, reporting, and performance enhancements in addition to DNS services. When configured on a WLAN, DNS queries from wireless clients are redirected to OpenDNS. The following example illustrates the configuration:</p> <pre>dhcp-server-policy dhcppolicy   dhcp-pool dhcppool     network 192.168.1.0/24     address range 192.168.1.160 192.168.1.200     default-router 192.168.1.105     dns-server 208.67.220.220</pre> <p>Note, the above example shows the OpenDNS server as being 208.67.220.220. The alternative IP address 208.67.222.222 can also be used.</p> <p>For more information on the entire configuration that needs to be done to integrate WiNG access point, controllers, and service platform with OpenDNS, see <a href="#">opendns (user and privi exec modes)</a> on page 86.</p> |
| <p>{&lt;IP1&gt; &lt;HOST-ALIAS-NAME1&gt;}</p> | <p>Optional. Configures the secondary DNS server, using one of the following options:</p> <ul style="list-style-type: none"><li>• &lt;IP1&gt; – Specifies the secondary DNS server’s IP address</li><li>• &lt;HOST-ALIAS-NAME1&gt; – Specifies a host alias, mapped to the secondary DNS server’s IP address. If the primary DNS server is unavailable, the secondary server is used.</li></ul> <p><b>Note:</b> A network host alias maps a name to a single network host. For example, ‘alias host \$HOST 1.1.1.100’. In this example the host alias is ‘\$HOST’ and it maps to a single host ‘1.1.1.100’. For more information, see <a href="#">alias</a> on page 237.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

### domain-name (dhcpv4-pool-config)

Sets the domain name for the DHCP pool. This is the domain name used by the controller with this pool.

Domain names are not case sensitive and can contain alphabetic or numeric letters or a hyphen. The FQDN consists of the host name and the domain name. For example, computername.domain.com.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

Syntax

```
domain-name <DOMAIN-NAME>
```

Parameters

```
domain-name <DOMAIN-NAME>
```

|               |                                     |
|---------------|-------------------------------------|
| <DOMAIN-NAME> | Defines the DHCP pool's domain name |
|---------------|-------------------------------------|

Examples

```

### excluded-address (dhcpv4-pool-config)

Identifies a single IP address or a range of IP addresses, included in the DHCP address pool, that cannot be assigned to clients by the DHCP server

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000

- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
excluded-address [<IP> | <HOST-ALIAS-NAME>] range]
excluded-address <IP>
excluded-address <HOST-ALIAS-NAME>
excluded-address range [<START-IP> | <START-HOST-ALIAS-NAME>] [<END-IP> | <END-HOST-ALIAS-NAME>]
```

### Parameters

```
excluded-address <IP>
```

|      |                                                      |
|------|------------------------------------------------------|
| <IP> | Adds a single IP address to the exclude address list |
|------|------------------------------------------------------|

```
excluded-address <HOST-ALIAS-NAME>
```

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <HOST-ALIAS-NAME> | <p>Adds a host alias. The host alias is mapped to a host's IP address. The host identified by the host alias is added to the excluded address list. The host alias should be existing and configured.</p> <p><b>Note:</b> A network host alias maps a name to a single network host. For example, 'alias host \$HOST 1.1.1.100'. In this example the host alias is '\$HOST' and it maps to a single host '1.1.1.100'. For more information, see <a href="#">alias</a> on page 237.</p> |

## lease (dhcpv4-pool-config)

A lease is the duration a DHCP issued IP address is valid. Once a lease expires, and if the lease is not renewed, the IP address is revoked and is available for reuse. Generally, before an IP lease expires, the client tries to get the same IP address issued for the next lease period. This feature is enabled by default, with a lease period of 24 hours (1 day).

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
lease [<0-365>|infinite]
lease infinite
lease <0-365> {<0-23>} {<0-59>} {<0-59>}
```

### Parameters

```
lease infinite
```

|          |                                                                   |
|----------|-------------------------------------------------------------------|
| infinite | The lease never expires (equal to a static IP address assignment) |
|----------|-------------------------------------------------------------------|

```
lease <0-365> {<0-23>} {<0-59>} {<0-59>}
```

|         |                                                                                                                        |
|---------|------------------------------------------------------------------------------------------------------------------------|
| <0-365> | Configures the lease duration in days<br><b>Note:</b> Days may be 0 only when hours and/or minutes are greater than 0. |
| <0-23>  | Optional. Sets the lease duration in hours                                                                             |
| <0-59>  | Optional. Sets the lease duration in minutes                                                                           |
| <0-59>  | Optional. Sets the lease duration in seconds                                                                           |

### Usage Guidelines

If lease parameter is not configured on the DHCP pool, the default is used. The default is 24 hours.

### Examples

```
rfs4000-229D58(config-dhcp-policy-test-pool-testPool)#lease 100 23 59 59
rfs4000-229D58(config-dhcp-policy-test-pool-testPool)#show context
dhcp-pool testPool
network 192.168.13.0/24
address 192.168.13.4 class dhcpclass1
lease 100 23 59 59
ddns server 192.168.13.9
ddns domainname WID
ddns multiple-user-class
excluded-address range 192.168.13.25 192.168.13.28
domain-name documentation
bootfile test.txt
default-router 192.168.13.8 192.168.13.9
dns-server 192.168.13.19
rfs4000-229D58(config-dhcp-policy-test-pool-testPool)#
```

## netbios-name-server (dhcpv4-pool-config)

Configures the NetBIOS (WINS) name server's IP address. This server is used to resolve NetBIOS host names.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
netbios-name-server [<IP>|<HOST-ALIAS-NAME>] {<IP1>|<HOST-ALIAS-NAME1>}
```

### Parameters

```
netbios-name-server [<IP>|<HOST-ALIAS-NAME>] {<IP1>|<HOST-ALIAS-NAME1>}
```

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [<IP> <HOST-ALIAS-NAME>]   | Configures the primary NetBIOS name server, using one of the following options: <ul style="list-style-type: none"><li>• &lt;IP&gt; – Specifies the primary NetBIOS name server's IP address</li><li>• &lt;HOST-ALIAS-NAME&gt; – Specifies a host alias, mapped to the primary NetBIOS name server's IP address</li></ul>                                                                                                                                                                                                                                                                                                                                                                                  |
| {<IP1> <HOST-ALIAS-NAME1>} | Optional. Configures the secondary NetBIOS name server, using one of the following options: <ul style="list-style-type: none"><li>• &lt;IP1&gt; – Specifies the secondary NetBIOS name server's IP address</li><li>• &lt;HOST-ALIAS-NAME1&gt; – Specifies a host alias, mapped to the secondary NetBIOS name server's IP address. If the primary NetBIOS name server is unavailable, the secondary server is used.</li></ul> <p><b>Note:</b> A network host alias maps a name to a single network host. For example, 'alias host \$HOST 1.1.1.100'. In this example the host alias is '\$HOST' and it maps to a single host '1.1.1.100'. For more information, see <a href="#">alias</a> on page 237.</p> |

### Examples

```

## netbios-node-type (dhcpv4-pool-config)

Defines the predefined NetBIOS node type. The NetBIOS node type resolves NetBIOS names to IP addresses.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

Syntax

```
netbios-node-type [b-node|h-node|m-node|p-node]
```

Parameters

```
netbios-node-type [b-node|h-node|m-node|p-node]
```

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## network (dhcpv4-pool-config)

Configures the DHCP server's network settings

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533

- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

`network` [`<IP/M>` | `<NETWORK-ALIAS-NAME>`]

#### Parameters

`network` [`<IP/M>` | `<NETWORK-ALIAS-NAME>`]

|                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;IP/M&gt;</code>               | Configures the network number and mask (for example, 192.168.13.0/24)                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>&lt;NETWORK-ALIAS-NAME&gt;</code> | <p>Configures a network alias to identify the network number and mask</p> <ul style="list-style-type: none"> <li>• <code>&lt;NETWORK-ALIAS-NAME&gt;</code> - Specify the network alias name. It should be existing and configured.</li> </ul> <p><b>Note:</b> A network alias defines a single network address. For example, 'alias network \$NET 1.1.0/24'. In this example, the network alias name is: \$NET, and the network it is mapped to is: 1.1.0/24. For more information, see <a href="#">alias</a> on page 237.</p> |

#### Examples

```
rfs4000-229D58(config-dhcp-policy-test-pool-testPool)#network 192.168.13.0/24
rfs4000-229D58(config-dhcp-policy-test-pool-testPool)#show context
dhcp-pool testPool
 network 192.168.13.0/24
 address 192.168.13.4 class dhcpclass1
 lease 100 23 59 59

### next-server (dhcpv4-pool-config)

Configures the next server in the boot process

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

`next-server` [`<IP>` | `<HOST-ALIAS-NAME>`]

#### Parameters

`next-server` [`<IP>` | `<HOST-ALIAS-NAME>`]

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <IP>              | Configures the next server's (the first server in the boot process) IP address                                                                                                                                                                                                                                                                                                                                                                                                               |
| <HOST-ALIAS-NAME> | <p>Configures a host alias, mapped to the next server's IP address</p> <ul style="list-style-type: none"> <li>• &lt;HOST-ALIAS-NAME&gt; – Specify the host alias name. It should be existing and configured.</li> </ul> <p><b>Note:</b> A host alias maps a name to a single network host. For example, 'alias host \$HOST 1.1.1.100'. In this example the host alias is '\$HOST' and it maps to a single host '1.1.1.100'. For more information, see <a href="#">alias</a> on page 237.</p> |

### Examples

```
rfs4000-229D58(config-dhcp-policy-test-pool-testPool)#next-server 192.168.13.26
rfs4000-229D58(config-dhcp-policy-test-pool-testPool)#show context
dhcp-pool testPool
 network 192.168.13.0/24
 address 192.168.13.4 class dhcpclass1
 lease 100 23 59 59
 ddns server 192.168.13.9
 ddns domainname WID
 ddns multiple-user-class
 excluded-address range 192.168.13.25 192.168.13.28
 domain-name documentation

### option (dhcpv4-pool-config)

Configures raw DHCP options. The DHCP option must be configured under the DHCP server policy. The options configured under the DHCP pool/DHCP server policy can also be used in static-bindings.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
option <OPTION-NAME> [<DHCP-OPTION-IP> | <DHCP-OPTION-ASCII>]
```

#### Parameters

```
option <OPTION-NAME> [<DHCP-OPTION-IP> | <DHCP-OPTION-ASCII>]
```

|                     |                                     |
|---------------------|-------------------------------------|
| <OPTION-NAME>       | Sets the name of the DHCP option    |
| <DHCP-OPTION-IP>    | Sets DHCP option as an IP address   |
| <DHCP-OPTION-ASCII> | Sets DHCP option as an ASCII string |

#### Note

An option name in ASCII format accepts a backslash (\) as an input, but is not displayed in the output. Use the **show > running > config** command to view the output. Use a double backslash to represent a single backslash.

#### Examples

```
rfs4000-229D58(config-dhcp-policy-test-pool-testPool)#option option1 157.235.208.80
rfs4000-229D58(config-dhcp-policy-test-pool-testPool)#show context
dhcp-pool testPool
address 192.168.13.4 class dhcpclass1
ddns server 192.168.13.9
ddns multiple-user-class
excluded-address range 192.168.13.25 192.168.13.28
netbios-node-type b-node
dns-server 192.168.13.19
netbios-name-server 192.168.13.25
option option1 157.235.208.80
rfs4000-229D58(config-dhcp-policy-test-pool-testPool)#
```

#### Related Commands

|                        |                                                         |

| <b>no</b> on page 1451 | Resets values or disables the DHCP pool option settings |
|------------------------|---------------------------------------------------------|

### respond-via-unicast (dhcpv4-pool-config)

Sends DHCP offer and acknowledgment as unicast messages

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
respond-via-unicast
```

#### Parameters

#### Note

None

#### Examples

```
rfs4000-229D58(config-dhcp-policy-test-pool-testPool)#respond-via-unicast
rfs4000-229D58(config-dhcp-policy-test-pool-testPool)#show context
dhcp-pool testPool
address 192.168.13.4 class dhcpclass1
ddns server 192.168.13.9
ddns multiple-user-class
excluded-address range 192.168.13.25 192.168.13.28
netbios-node-type b-node
dns-server 192.168.13.19
```

```

netbios-name-server 192.168.13.25
option option1 157.235.208.80
respond-via-unicast
rfs4000-229D58(config-dhcp-policy-test-pool-testPool)#

```

#### Related Commands

**no** on page 1451 Disables sending of a DHCP offer and DHCP Ack as unicast messages. When disabled, sends offer and acknowledgment as broadcast messages.

### static-route (dhcpv4-pool-config)

Configures a static route for a DHCP pool. Static routes define a gateway for traffic intended for other networks. This gateway is always used when an IP address does not match any route in the network.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
static-route <IP/M> <IP>
```

#### Parameters

```
static-route <IP/M> <IP>
```

|        |                                                               |
|--------|---------------------------------------------------------------|
| <IP/M> | Specifies the IP destination prefix (for example, 10.0.0.0/8) |
| <IP>   | Specifies the gateway IP address                              |

#### Examples

```

rfs4000-229D58(config-dhcp-policy-test-pool-testPool)#static-route 192.168.13.0/24
192.168.13.7
rfs4000-229D58(config-dhcp-policy-test-pool-testPool)#show context
dhcp-pool testPool
 address 192.168.13.4 class dhcpclass1
 ddns server 192.168.13.9
 ddns multiple-user-class
 excluded-address range 192.168.13.25 192.168.13.28
 netbios-node-type b-node
 dns-server 192.168.13.19
 netbios-name-server 192.168.13.25
 option option1 157.235.208.80
 respond-via-unicast
 static-route 192.168.13.0/24 192.168.13.7
rfs4000-229D58(config-dhcp-policy-test-pool-testPool)#

```

#### Related Commands

**no** on page 1451 Removes static route settings

### update (dhcpv4-pool-config)

Controls the use of the DDNS service

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
update dns {override}
```

#### Parameters

```
update dns {override}
```

|                           |                                                                                                                                                                 |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>dns {override}</pre> | Configures DDNS parameters <ul style="list-style-type: none"> <li>• <code>override</code> - Optional. Enables DDNS updates on an onboard DHCP server</li> </ul> |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|

#### Usage Guidelines

A DHCP client cannot perform updates for RR's A, TXT and PTR resource records. Use `update (dns) (override)` to enable the internal DHCP server to send DDNS updates for resource records. The DHCP server can override the client, even if the client is configured to perform the updates.

In the DHCP server's DHCP pool, FQDN is configured as the DDNS domain name. This is used internally in DHCP packets between the DHCP server and the DNS server.

#### Examples

```
rfs4000-229D58(config-dhcp-policy-test-pool-testPool)#update dns override
rfs4000-229D58(config-dhcp-policy-test-pool-testPool)#show context
dhcp-pool testPool
 address 192.168.13.4 class dhcpclass1
 update dns override
 ddns server 192.168.13.9
 ddns multiple-user-class
 excluded-address range 192.168.13.25 192.168.13.28
 netbios-node-type b-node
 dns-server 192.168.13.19
 netbios-name-server 192.168.13.25
 option option1 157.235.208.80
 respond-via-unicast
 static-route 192.168.13.0/24 192.168.13.7
rfs4000-229D58(config-dhcp-policy-test-pool-testPool)#
```

#### Related Commands

|               |                                                  |
|---------------|--------------------------------------------------|
| <pre>no</pre> | on page 1451 Removes dynamic DNS service control |
|---------------|--------------------------------------------------|

#### **no**

Removes or resets this DHCP user pool's settings

Supported in the following platforms:

- Access Points — AP 6522, AP 6532, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 81XX, AP 8232
- Wireless Controllers — RFS 4000, RFS 6000
- Service Platforms — NX 7500, NX 9500, NX 9510

## Syntax

```
no [address|bootfile|ddns|default-router|dns-server|domain-name|excluded-address|
 lease|netbios-name-server|netbios-node-type|network|next-server|option|
 respond-via-unicast|static-binding|static-route|update]
no [bootfile|default-router|dns-server|domain-name|lease|netbios-name-server|
 netbios-node-type|next-server|network|respond-via-unicast]
no address [<IP>|<HOST-ALIAS-NAME>|all]
no address range [<START-IP>|<START-HOST-ALIAS-NAME>] [<END-IP>|<END-HOST-ALIAS-NAME>]
no ddns [domainname|multiple-user-class|server|ttl]
no excluded-address [<IP>|<HOST-ALIAS-NAME>]
no excluded-address range [<START-IP>|<START-HOST-ALIAS-NAME>] [<END-IP>|<END-HOST-ALIAS-
NAME>]
no option <OPTION-NAME>
no static-binding client-identifier <CLIENT-IDENTIFIER>
no static-binding hardware-address <MAC>
no static-route <IP/MASK> <GATEWAY-IP>
no update dns {override}
```

## Parameters

```
no [bootfile|default-router|dns-server|domain-name|lease|netbios-name-server|
netbios-node-type|next-server|network|respond-via-unicast]
```

|                        |                                                             |
|------------------------|-------------------------------------------------------------|
| no bootfile            | Removes a BOOTP bootfile configuration                      |
| no default-router      | Removes the configured default router for the DHCP pool     |
| no dns-server          | Removes the configured DNS server for the DHCP pool         |
| no domain-name         | Removes the configured DNS domain name                      |
| no lease               | Resets the lease to its default (24 hours)                  |
| no netbios-name-server | Removes the configured NetBIOS name server                  |
| no netbios-node-type   | Removes the NetBIOS node type                               |
| no next-server         | Removes the next server utilized in the boot process        |
| no network             | Removes the DHCP server network information                 |
| no respond-via-unicast | Sets the DHCP offer and ACK as broadcast instead of unicast |

```
no address [<IP>|<HOST-ALIAS-NAME>|all]
```

|                   |                                                                                                       |
|-------------------|-------------------------------------------------------------------------------------------------------|
| no address        | Resets configured DHCP pool addresses                                                                 |
| <IP>              | Removes an IP address from the list of addresses                                                      |
| <HOST-ALIAS-NAME> | Removes the host alias (used to identify a single host) associated with this DHCP pool's address list |
| all               | Removes configured DHCP IP addresses                                                                  |

```
no address range [<START-IP>|<START-HOST-ALIAS-NAME>] [<END-IP>|<END-HOST-ALIAS-NAME>]
```

#### **static-binding (dhcpv4-pool-config)**

Configures static IP address information for a particular device. Static address binding is executed on the device's hostname, client identifier, or MAC address. Static bindings allow the configuration of client parameters, such as DHCP server, DNS server, default routers, fixed IP address, etc.

A static address binding is a collection of configuration parameters, including an IP address, associated with, or bound to, a DHCP client. Bindings are managed by DHCP servers. DHCP bindings automatically map a device MAC address to an IP address using a pool of DHCP supplied addresses. Static bindings assign IP addresses without creating numerous host pools with manual bindings. Static host bindings use a text file the DHCP server reads. It eliminates the need for a lengthy configuration file and reduces the space required to maintain address pools.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
static-binding [client-identifier <CLIENT>|hardware-address <MAC>]
```

### Parameters

```
static-binding [client-identifier <CLIENT>|hardware-address <MAC>]
```

| <a href="#">no (dhcpv4-pool-static-binding)</a> on page 1467                  | Negates or reverts to default this DHCP Pool's static binding settings |

[no \(dhcpv4-pool-static-binding\)](#) on page 1467  
bootfile (dhcpv4-pool-static-binding)

The Bootfile command provides a diskless node the path to the image file used while booting up. Only one file can be configured for each static IP binding.

For more information on the BOOTP protocol with reference to static binding, see [bootp \(dhcpv4-server-policy-config\)](#) on page 1430.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
bootfile <IMAGE-FILE-PATH>
```

#### Parameters

```
bootfile <IMAGE-FILE-PATH>
```

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <IMAGE-FILE-PATH>> | Sets the path to the boot image for BOOTP file used with this user pool. The file name can contain letters, numbers, dots and hyphens. Consecutive dots and hyphens are not permitted. Boot files (Boot Protocol) can be used to boot remote systems over the network. BOOTP messages are encapsulated inside UDP messages so requests and replies can be forwarded. Each DHCP network pool can use a different file as needed. |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

#### Examples

```
nx9500-6C8809(config-dhcp-policy-test-pool-pool1-binding-test)#bootfile test.txt

client-name (dhcpv4-pool-static-binding)

Configures the name of the client requesting DHCP Server support

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
client-name <NAME>
```

#### Parameters

```
client-name <NAME>
```

<NAME> Specify the name of the client using this static IP address host pool. Do not include the domain name.

#### Examples

```
nx9500-6C8809(config-dhcp-policy-test-pool-pool1-binding-test)#client-name test
nx9500-6C8809(config-dhcp-policy-test-pool-pool1-binding-test)#show context
static-binding client-identifier test
 client-name test
 bootfile test.txt
nx9500-6C8809(config-dhcp-policy-test-pool-pool1-binding-test)#
```

#### Related Commands

|                                                              |                                     |
|--------------------------------------------------------------|-------------------------------------|

|--------------------------------------------------------------|-------------------------------------|

#### default-router (dhcpv4-pool-static-binding)

Configures a default router or gateway IP address for the static binding configuration. After a DHCP client has booted, the client begins sending packets to its default router.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
default-router [<IP>|<HOST-ALIAS-NAME>] {<IP1>|<HOST-ALIAS-NAME1>}
```

#### Parameters

```
default-router [<IP>|<HOST-ALIAS-NAME>] {<IP1>|<HOST-ALIAS-NAME1>}
```

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [<IP> <HOST-ALIAS-NAME>]   | <p>Configures the primary default router, using one of the following options:</p> <ul style="list-style-type: none"> <li>• &lt;IP&gt; – Specifies the primary default router’s IP address</li> <li>• &lt;HOST-ALIAS-NAME&gt; – Specifies a host alias, mapped to the primary default router’s IP address</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| {<IP1> <HOST-ALIAS-NAME1>} | <p>Optional. Configures the secondary default router, using one of the following options:</p> <ul style="list-style-type: none"> <li>• &lt;IP1&gt; – Specifies the secondary default router’s IP address</li> <li>• &lt;HOST-ALIAS-NAME1&gt; – Specifies a host alias, mapped to the secondary default router’s IP address. If the primary default router is unavailable, the secondary router is used.</li> </ul> <p><b>Note:</b> A network host alias maps a name to a single network host. For example, ‘alias host \$HOST 1.1.1.100’. In this example the host alias is ‘\$HOST’ and it maps to a single host ‘1.1.1.100’. For more information, see <a href="#">alias</a> on page 237.</p> <p><b>Note:</b> A maximum of 8 default routers can be configured..</p> |

### Usage Guidelines

The IP address of the router should be on the same subnet as the client subnet.

### Examples

```

nx9500-6C8809(config-dhcp-policy-test-pool-pool1-binding-test)#default-router 172.16.10.8
172.16.10.9
nx9500-6C8809(config-dhcp-policy-test-pool-pool1-binding-test)#show context
static-binding client-identifier test
client-name RFID
bootfile test.txt
default-router 172.16.10.8 172.16.10.9
nx9500-6C8809(config-dhcp-policy-test-pool-pool1-binding-test)#

```

## dns-server (dhcpv4-pool-static-binding)

Configures a network’s DNS server. The DNS server supports all clients for which static binding has been configured.

For this client, the DNS server’s IP address maps the host name to an IP address. DHCP clients use the DNS server’s IP address based on the order (sequence) configured.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
dns-server [<IP>|<HOST-ALIAS-NAME>] {<IP1>|<HOST-ALIAS-NAME1>}
```

### Parameters

```
dns-server [<IP>|<HOST-ALIAS-NAME>] {<IP1>|<HOST-ALIAS-NAME1>}
```

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

### domain-name (dhcpv4-pool-static-binding)

Sets the domain name for static binding configuration

Domain names are not case sensitive and contain alphabetic or numeric letters (or a hyphen). An FQDN consists of a host name plus a domain name. For example, computername.domain.com.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
domain-name <DOMAIN-NAME>
```

### Parameters

```
domain-name <DOMAIN-NAME>
```

|               |                                     |
|---------------|-------------------------------------|
| <DOMAIN-NAME> | Defines the DHCP pool’s domain name |
|---------------|-------------------------------------|

### Examples

```

nx9500-6C8809(config-dhcp-policy-test-pool-pool1-binding-test)#domain-name documentation
nx9500-6C8809(config-dhcp-policy-test-pool-pool1-binding-test)#show context
 static-binding client-identifier test
 client-name RFID
 domain-name documentation
 bootfile test.txt

```

```

default-router 172.16.10.8 172.16.10.9
dns-server 172.16.10.7
nx9500-6C8809(config-dhcp-policy-test-pool-pool1-binding-test)#

```

#### Related Commands

Resets values or disables the DHCP pool static binding settings

#### ip-address (dhcpv4-pool-static-binding)

Sets an IP address of the client using this host pool for DHCP resources

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
ip-address [<IP>|<HOST-ALIAS-NAME>]
```

#### Parameters

```
ip-address [<IP>|<HOST-ALIAS-NAME>]
```

|                                |                                                                                                                                                                                                                                                                                                                                                                          |

#### netbios-node-type (dhcpv4-pool-static-binding)

Configures different predefined NetBIOS node types. The NetBIOS node defines the way a device resolves NetBIOS names to IP addresses.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
netbios-node-type [b-node|h-node|m-node|p-node]
```

#### Parameters

```
netbios-node-type [b-node|h-node|m-node|p-node]
```

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [b-node h-node m-node p-node] | <p>Defines the netbios node type</p> <ul style="list-style-type: none"> <li>• b-node – Sets the node type as broadcast. Uses broadcasts to query nodes on the network for the owner of a NetBIOS name.</li> <li>• h-node – Sets the node type as hybrid. Uses a combination of two or more nodes.</li> <li>• m-node – Sets the node type as mixed. A mixed node uses broadcasted queries to find a node, and failing that, queries a known p-node name server for the address.</li> <li>• p-node – Sets the node type as peer-to-peer. Uses directed calls to communicate with a known NetBIOS name server (such as a WINS server), for the IP address of a NetBIOS machine.</li> </ul> |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|-----------------------------------------------------------|-------------------------------------------------------------|

### next-server (dhcpv4-pool-static-binding)

Configures the next server utilized in the boot process

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
next-server [<IP> | <HOST-ALIAS-NAME>]
```

### Parameters

```
next-server [<IP> | <HOST-ALIAS-NAME>]
```

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <IP>              | Configures the next server's (the first server in the boot process) IP address                                                                                                                                                                                                                                                                                                                                                                                                               |
| <HOST-ALIAS-NAME> | <p>Configures a host alias, mapped to the next server's IP address</p> <ul style="list-style-type: none"> <li>• &lt;HOST-ALIAS-NAME&gt; – Specify the host alias name. It should be existing and configured.</li> </ul> <p><b>Note:</b> A host alias maps a name to a single network host. For example, 'alias host \$HOST 1.1.1.100'. In this example the host alias is '\$HOST' and it maps to a single host '1.1.1.100'. For more information, see <a href="#">alias</a> on page 237.</p> |

## Examples

```
nx9500-6C8809(config-dhcp-policy-test-pool-pool1-binding-test)#next-server 172.16.10.24
nx9500-6C8809(config-dhcp-policy-test-pool-pool1-binding-test)#show context
static-binding client-identifier test
ip-address 172.16.10.9
client-name RFID
domain-name documentation
netbios-node-type b-node
bootfile test.txt
default-router 172.16.10.8 172.16.10.9
dns-server 172.16.10.7
netbios-name-server 172.16.10.23
next-server 172.16.10.24
nx9500-6C8809(config-dhcp-policy-test-pool-pool1-binding-test)#
```

| <code>no (dhcpv4-pool-static-binding)</code> on page 1467 | Resets values or disables DHCP pool static binding settings |
|-----------------------------------------------------------|-------------------------------------------------------------|

## option (dhcpv4-pool-static-binding)

Configures raw DHCP options. The DHCP option must be configured under the DHCP server policy. The options configured under the DHCP pool/DHCP server policy can also be used in static-bindings.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
option <OPTION-NAME> [<DHCP-OPTION-IP> | <DHCP-OPTION-ASCII>]
```

## Parameters

```
option <OPTION-NAME> [<DHCP-OPTION-IP> | <DHCP-OPTION-ASCII>]
```

|                     |                                     |
|---------------------|-------------------------------------|
| <OPTION-NAME>       | Sets the name of the DHCP option    |
| <DHCP-OPTION-IP>    | Sets DHCP option as an IP address   |
| <DHCP-OPTION-ASCII> | Sets DHCP option as an ASCII string |

## Usage Guidelines

Defines non standard DHCP option codes (0-254)

### Note

An option name in ASCII format accepts a backslash (\) as an input, but is not displayed in the output (Use show runnig config to view the output). Use a double backslash to represent a single backslash.

## Examples

```
nx9500-6C8809(config-dhcp-policy-test-pool-pool1-binding-test)#option option1 172.16.10.10
nx9500-6C8809(config-dhcp-policy-test-pool-pool1-binding-test)#show context
static-binding client-identifier test
client-name RFID
domain-name documentation
netbios-node-type b-node
netbios-name-server 172.16.10.23
```

```
next-server 172.16.10.24
option option1 172.16.10.10
nx9500-6C8809(config-dhcp-policy-test-pool-pool1-binding-test)#
```

#### Related Commands

[no \(dhcpv4-pool-static-binding\)](#) on page 1467    Resets values or disables DHCP pool static binding settings

#### respond-via-unicast (dhcpv4-pool-static-binding)

Sends DHCP offer and acknowledgment as unicast messages

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
respond-via-unicast
```

#### Parameters

None

#### Examples

```
nx9500-6C8809(config-dhcp-policy-test-pool-pool1-binding-test)#respond-via-unicast
nx9500-6C8809(config-dhcp-policy-test-pool-pool1-binding-test)#show context
static-binding client-identifier test
client-name RFID
domain-name documentation
netbios-node-type b-node
netbios-name-server 172.16.10.23
next-server 172.16.10.24
option option1 172.16.10.10
respond-via-unicast
nx9500-6C8809(config-dhcp-policy-test-pool-pool1-binding-test)#
```

#### Related Commands

[no \(dhcpv4-pool-static-binding\)](#) on page 1467    Resets values or disables DHCP pool static binding settings

#### static-route (dhcpv4-pool-static-binding)

Adds static routes to the static binding configuration. Use this option to add static routes installed on clients.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
static-route <IP/Mask> <Gateway-IP>
```

#### Parameters

```
static-route <IP/Mask> <Gateway-IP>
```

|              |                                                               |
|--------------|---------------------------------------------------------------|
| <IP/Mask>    | Specifies the IP destination prefix (for example, 10.0.0.0/8) |
| <Gateway-IP> | Specifies the gateway IP address                              |

### Examples

```

nx9500-6C8809(config-dhcp-policy-test-pool-pool1-binding-1)#static-route 10.0.0.0/10
157.235.208.235
nx9500-6C8809(config-dhcp-policy-test-pool-pool1-binding-test)#show context
static-binding client-identifier test
client-name RFID
domain-name documentation
netbios-node-type b-node
netbios-name-server 172.16.10.23
next-server 172.16.10.24
option option1 172.16.10.10
respond-via-unicast
static-route 10.0.0.0/10 157.235.208.235
nx9500-6C8809(config-dhcp-policy-test-pool-pool1-binding-test)#

```

### Related Commands

|--------------------------------------------------------------|-------------------------------------------------------------|
| <a href="#">no (dhcpv4-pool-static-binding)</a> on page 1467 | Resets values or disables DHCP pool static binding settings |
|--------------------------------------------------------------|-------------------------------------------------------------|

## no (dhcpv4-pool-static-binding)

Negates or reverts static binding settings for the selected DHCP server policy

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```

no [bootfile|client-name|default-router|dns-server|domain-name|ip-address|
netbios-name-server|netbios-node-type|next-server|option|respond-via-unicast|
static-route]
no option <OPTION-NAME>
no option <OPTION-NAME>
no static-route <IP/MASK> <GATEWAY-IP>

```

### Parameters

no <PARAMETERS>

|                 |                                                                                |
|-----------------|--------------------------------------------------------------------------------|
| no <PARAMETERS> | Negates or reverts static binding settings for the selected DHCP server policy |
|-----------------|--------------------------------------------------------------------------------|

### Examples

The following example shows the DHCP pool settings before the 'no' commands are executed:

```

nx9500-6C8809(config-dhcp-policy-test-pool-pool1-binding-test)#show context
static-binding client-identifier test
ip-address 172.16.10.9
client-name RFID
domain-name documentation
netbios-node-type b-node
bootfile test.txt
default-router 172.16.10.8 172.16.10.9
dns-server 172.16.10.7
netbios-name-server 172.16.10.23

```

```

next-server 172.16.10.24
nx9500-6C8809(config-dhcp-policy-test-pool-pool1-binding-test)#
nx9500-6C8809(config-dhcp-policy-test-pool-pool1-binding-test)#no bootfile
nx9500-6C8809(config-dhcp-policy-test-pool-pool1-binding-test)#no ip-address
nx9500-6C8809(config-dhcp-policy-test-pool-pool1-binding-test)#no default-router
nx9500-6C8809(config-dhcp-policy-test-pool-pool1-binding-test)#no dns-server

```

The following example shows the DHCP pool settings after the 'no' commands are executed:

```

nx9500-6C8809(config-dhcp-policy-test-pool-pool1-binding-test)#show context
static-binding client-identifier test
client-name RFID
domain-name documentation
netbios-node-type b-node
netbios-name-server 172.16.10.23
next-server 172.16.10.24
nx9500-6C8809(config-dhcp-policy-test-pool-pool1-binding-test)#

```

### *ping (dhcpv4-server-policy-config)*

Configures the DHCP server's ping timeout interval. The controller uses the timeout to intermittently ping and discover whether a client requested IP address is available or in use.

#### **Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### **Syntax**

```
ping timeout <1-10>
```

#### **Parameters**

```
ping timeout <1-10>
```

|                |                                                                     |
|----------------|---------------------------------------------------------------------|
| timeout <1-10> | Sets the ping timeout from 1 - 10 seconds. The default is 1 second. |
|----------------|---------------------------------------------------------------------|

#### **Examples**

```

nx9500-6C8809(config-dhcp-policy-test)#ping timeout 2
nx9500-6C8809(config-dhcp-policy-test)#show context
dhcp-server-policy test
ping timeout 2
option option1 200 ascii
nx9500-6C8809(config-dhcp-policy-test)#

```

#### **Related Commands**

|                                                               |                                      |
|---------------------------------------------------------------|--------------------------------------|
| <a href="#">no (dhcpv4-server-policy-config)</a> on page 1471 | Resets the ping interval to 1 second |
|---------------------------------------------------------------|--------------------------------------|

### *option (dhcpv4-server-policy-config)*

Configures raw DHCP options. The DHCP option has to be configured in the DHCP server policy. The options configured in the DHCP pool/DHCP server policy can also be used in static bindings.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
option <OPTION-NAME> <0-250> [ascii|hexstring|ip]
```

### Parameters

```
option <OPTION-NAME> <0-250> [ascii|hexstring|ip]
```

|               |                                                    |
|---------------|----------------------------------------------------|
| <OPTION-NAME> | Configures the option name                         |
| <0-250>       | Configures the DHCP option code from 0 - 250       |
| ascii         | Configures the DHCP option as an ASCII string      |
| hexstring     | Configures the DHCP option as a hexadecimal string |
| ip            | Configures the DHCP option as an IP address        |

### Usage Guidelines

Defines non-standard DHCP option codes (0-254)

#### Note

An option name in ASCII format accepts a backslash (\) as an input, but is not displayed in the output. Use the **show > runnig > config** command to view the output. Use a double backslash to represent a single backslash.

### Examples

```
nx9500-6C8809(config-dhcp-policy-test)#option option1 200 ascii
nx9500-6C8809(config-dhcp-policy-test)#show context
dhcp-server-policy test
 option option1 200 ascii
nx9500-6C8809(config-dhcp-policy-test)#
```

### Related Commands

|---------------------------------------------------------------|-----------------------------|

### *dhcp-server (dhcpv4-server-policy-config)*

Configures the activation-criteria (run-criteria) that triggers dynamic activation of DHCP service running on a redundancy device

In a managed wireless network, when the primary, active DHCP server fails (is unreachable), network clients are unable to access DHCP services, such as new IP address leasing and renewal of existing IP address leases. In such a scenario, the activation-criteria, when configured, triggers dynamic activation of the secondary DHCP server, allowing network clients to continue accessing DHCP services. The WiNG implementation provides activation-criteria options specific to a RF Domain, cluster setup, and a VRRP (Virtual Router Redundancy Protocol) master/client setup.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
dhcp-server activation-criteria [cluster-master|rf-domain-manager|vrrp-master]
```

### Parameters

```
dhcp-server activation-criteria [cluster-master|rf-domain-manager|vrrp-master]
```

|                                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dhcp-server                                                        | Enables dynamic activation of the DHCP server, running on a redundancy device, based on the activation criteria specified                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| activation-criteria [cluster-master rf-domain-manager vrrp-master] | Configures the activation criteria. Specify one of the following options as the activation criteria: <ul style="list-style-type: none"><li>• cluster-master – Configures the cluster-master criteria in a cluster setup. Within a cluster, DHCP service is enabled on the cluster master. While it remains disabled on the other cluster members. In case of the cluster master failing, the cluster-master activation criteria, when configured, triggers dynamic activation of DHCP service on the new cluster master.</li><li>• rf-domain-manger – Configures the rf-domain-manager criteria on an RF Domain. Within a RF Domain, DHCP service is enabled on the RF Domain manager. While it remains disabled on the other devices within the RF Domain. In case of the RF Domain manager failing, the rf-domain-manager activation criteria, when configured, triggers dynamic activation of DHCP service on the new RF Domain manager.</li><li>• vrrp-master – Configures the vrrp-master criteria within a VRRP master/client setup. In such a setup, the DHCP service is enabled on the VRRP master. While it remains disabled on the other members. In case of the VRRP master failing, the vrrp-master activation criteria, when configured, triggers dynamic activation of DHCP service on the new VRRP master.</li></ul> |

### Examples

```
rfs4000-229D58(config-dhcp-policy-test)#dhcp-server activation-criteria rf-domain-manager
rfs4000-229D58(config-dhcp-policy-test)#show context
dhcp-server-policy test
dhcp-server activation-criteria rf-domain-manager
rfs4000-229D58(config-dhcp-policy-test)#
rfs4000-229D58(config-dhcp-policy-test)#no dhcp-server activation-criteria
rfs4000-229D58(config-dhcp-policy-test)#show context
dhcp-server-policy test
rfs4000-229D58(config-dhcp-policy-test)#
```

### Related Commands

|                                                               |                                                                                    |
|---------------------------------------------------------------|------------------------------------------------------------------------------------|
| <a href="#">no (dhcpv4-server-policy-config)</a> on page 1471 | Removes the DHCP service activation criteria configured on this DHCP server policy |
|---------------------------------------------------------------|------------------------------------------------------------------------------------|

## *no* (dhcpv4-server-policy-config)

Negates a command or sets its default. When used in the DHCP server configuration context, the 'no' command resets or reverts the DHCP server policy settings.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
no [bootp|dhcp-class|dhcp-pool|dhcp-server|option|ping]
no bootp ignore
no dhcp-class <DHCP-CLASS-NAME>
no dhcp-pool <DHCP-POOL-NAME>
no dhcp-server activation-criteria
no option <DHCP-OPTION>
no ping timeout
```

### Parameters

```
no <PARAMETERS>
```

```
no <PARAMETERS> Negates a command or sets its default. When used in the DHCP server configuration context, the 'no' command resets or reverts the DHCP server policy settings
```

### Examples

The following example shows the DHCP policy 'test' settings before the 'no' commands are executed:

```
nx9500-6C8809(config-dhcp-policy-test)#show context
dhcp-server-policy test
 bootp ignore
 dhcp-class dhcpclass1
 dhcp-pool pool1
 address 1.2.3.4 class dhcpclass1
 update dns override
 --More--
nx9500-6C8809(config-dhcp-policy-test)#
nx9500-6C8809(config-dhcp-policy-test)#no bootp ignore
nx9500-6C8809(config-dhcp-policy-test)#no dhcp-class dhcpclass1
nx9500-6C8809(config-dhcp-policy-test)#no dhcp-pool pool1
```

The following example shows the DHCP policy 'test' settings after the 'no' commands are executed:

```
nx9500-6C8809(config-dhcp-policy-test)#show context
dhcp-server-policy test
nx9500-6C8809(config-dhcp-policy-test)#
```

## dhcpv6-server-policy commands

DHCPv6 is a networking protocol for configuring IPv6 hosts with IP addresses, IP prefixes or other configuration attributes required on an IPv6 network.

DHCPv6 servers pass IPv6 network addresses to IPv6 clients. The DHCPv6 address assignment feature manages non duplicate addresses in the correct prefix based on the network where the host is connected. Assigned addresses can be from one or multiple pools. Additional options, such as the

default domain and DNS name-server address, can be passed back to the client. Address pools can be assigned for use on a specific interface or on multiple interfaces, or the server can automatically find the appropriate pool.

The following table summarizes the DHCPv6 server policy configuration mode commands:

**Table 45: DHCPv6-Server-Policy Config Mode Commands**

| Command                                                                         | Description                                                                                                   |
|---------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------|
| <code>dhcpv6-pool (dhcpv6-server-policy-config)</code> on page 1472             | Creates a DHCPv6 pool and enters its configuration mode                                                       |
| <code>restrict-vendor-options (dhcpv6-server-policy-config)</code> on page 1480 | Configures this DHCPv6 server policy's DHCP option settings, such as enterprise (vendor ID)                   |
| <code>server-preference (dhcpv6-server-policy-config)</code> on page 1480       | Restricts the use of vendor-specific DHCP options on this DHCPv6 server policy                                |
| <code>option (dhcpv6-server-policy-config)</code> on page 1478                  | Configures this DHCP server's preference value. This value is sent in DHCP server replies to the IPv6 client. |
| <code>no (dhcpv6-server-policy-config)</code> on page 1481t                     | Negates or reverts this DHCPv6 server policy's settings                                                       |

**Note**

For more information on common commands (clrscr, commit, help, revert, service, show, write, and exit), see **COMMON COMMANDS** on page 640.

**Note**

The input parameter <HOSTNAME>, wherever used in syntaxes across this chapter, cannot include an underscore (\_) character. In other words, the name of a device cannot contain an underscore.

*dhcpv6-pool (dhcpv6-server-policy-config)*

Configures a DHCPv6 server address pool and enters its configuration mode

A DHCPv6 IPv6 pool is a resource from which IPv6 formatted addresses can be issued on DHCPv6 client requests. IPv6 addresses are composed of eight groups of four hexadecimal digits separated by colons.

**Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

**Syntax**

`dhcpv6-pool <DHCPv6-POOL-NAME>`

**Parameters**

`dhcpv6-pool <DHCPv6-POOL-NAME>`

|                                       |                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;DHCPv6-POOL-NAME&gt;</code> | <p>Creates a DHCPv6 server address pool</p> <ul style="list-style-type: none"> <li><code>&lt;POOL-NAME&gt;</code> - Specify a name that appropriately identifies this DHCPv6 address pool. If the pool does not exist, it is created. The pool name cannot be modified as part of the edit process. However, an obsolete address pool can be deleted.</li> </ul> |
|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Examples

```

nx9500-6C8809(config-dhcpv6-server-policy-test)#dhcpv6-pool DHCPv6Pool1
nx9500-6C8809(config-dhcpv6-server-policy-test-pool-DHCPv6Pool1)#?
DHCPv6 pool Mode commands:
 dns-server DNS Servers
 domain-name Configure domain-name
 network Network on which DHCPv6 server will be deployed
 no Negate a command or set its defaults
 option Raw DHCPv6 options
 refresh-time Upper limit specifying the timer for which client should wait
 before refreshing information
 sip SIP server options

 clrscr Clears the display screen
 commit Commit all changes made in this session
 do Run commands from Exec mode
 end End current mode and change to EXEC mode
 exit End current mode and down to previous mode
 help Description of the interactive help system
 revert Revert changes
 service Service Commands
 show Show running system information
 write Write running configuration to memory or terminal

nx9500-6C8809(config-dhcpv6-server-policy-test-pool-DHCPv6Pool1)#
nx9500-6C8809(config-dhcpv6-server-policy-test)#show context
dhcpv6-server-policy test
 dhcpv6-pool DHCPv6Pool1
 network 2002::/64
 domain-name TechPubs
 sip domain-name TechPubsSIP
 dns-server 2002::1
nx9500-6C8809(config-dhcpv6-server-policy-test)#

```

|-------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------|
| <code>dns-server (dhcpv6-pool-config)</code> on page 1474   | Configures this DHCPv6 pool's DNS server                                                                       |
| <code>domain-name (dhcpv6-pool-config)</code> on page 1474  | Configures this DHCPv6 pool's domain name                                                                      |
| <code>network (dhcpv6-pool-config)</code> on page 1475      | Configures this DHCPv6 pool's network                                                                          |
| <code>option (dhcpv6-pool-config)</code> on page 1476       | Configures this DHCPv6 pool's raw DHCPv6 options. This is the vendor-specific option used in this DHCPv6 pool. |
| <code>refresh-time (dhcpv6-pool-config)</code> on page 1476 | Configures this DHCPv6 pool's refresh time in seconds                                                          |
| <code>sip (dhcpv6-pool-config)</code> on page 1477          | Configures this DHCPv6 pool's Session Initiation Protocol (SIP) server setting                                 |

`no (dhcpv6-pool-config)` on page 1478 Negates or reverts this DHCPv6 pool's settings

`no (dhcpv6-server-policy-config)` on page 1481 (dhcpv6-server-policy config) Removes this DHCPv6 pool

### dns-server (dhcpv6-pool-config)

Configures this DHCPv6 pool's DNS server. The DNS server supports all clients connected to networks supported by the DHCPv6 server.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
dns-server <IPv6> {<SECONDARY-IPv6>}
```

#### Parameters

```
dns-server <IPv6> {<SECONDARY-IPv6>}
```

|                  |                                                                                                                                                                                                                            |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <IPv6>           | Configures the primary DNS server's IPv6 address <ul style="list-style-type: none"><li>• &lt;IPv6&gt; - Specify the DNS server's IPv6 address (the server associated with this DHCP pool).</li></ul>                       |
| <SECONDARY-IPv6> | Configures the secondary DNS server's IPv6 address <ul style="list-style-type: none"><li>• &lt;SECONDARY-IPv6&gt; - Specify the secondary DNS server's IPv6 address (the server associated with this DHCP pool).</li></ul> |

#### Examples

```
nx9500-6C8809(config-dhcpv6-server-policy-test-pool-DHCPv6Pool1)#dns-server 2002::1
nx9500-6C8809(config-dhcpv6-server-policy-test-pool-DHCPv6Pool1)#show context
dhcpv6-pool DHCPv6Pool1
 dns-server 2002::1
nx9500-6C8809(config-dhcpv6-server-policy-test-pool-DHCPv6Pool1)#
```

#### Related Commands

`no (dhcpv6-pool-config)` on page 1478 Removes this DHCPv6 pool's configured DNS server settings

### domain-name (dhcpv6-pool-config)

Configures this DHCPv6 pool's domain name

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

domain-name <DOMAIN-NAME>

## Parameters

domain-name <DOMAIN-NAME>

|                           |                                                                        |
|---------------------------|------------------------------------------------------------------------|
| domain-name <DOMAIN-NAME> | Specify the DHCP pool's hostname or hostnames of the domain or domains |
|---------------------------|------------------------------------------------------------------------|

## Examples

```
nx9500-6C8809(config-dhcpv6-server-policy-test-pool-DHCPv6Pool1)#domain-name TechPubs
nx9500-6C8809(config-dhcpv6-server-policy-test-pool-DHCPv6Pool1)#show context
dhcpv6-pool DHCPv6Pool1
 domain-name TechPubs
 dns-server 2002::1
nx9500-6C8809(config-dhcpv6-server-policy-test-pool-DHCPv6Pool1)#
```

## Related Commands

| no (dhcpv6-pool-config) on page 1478 | Removes this DHCPv6 pool's domain name |
|--------------------------------------|----------------------------------------|

## network (dhcpv6-pool-config)

Configures this DHCPv6 pool's network. Use this command to configure the address of the network on which this DHCP server is deployed.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

network [<IPv6/M> | <NETWORK-ALIAS-NAME> ]

## Parameters

network [<IPv6/M> | <NETWORK-ALIAS-NAME> ]

|                      |                                                                                     |
|----------------------|-------------------------------------------------------------------------------------|
| <IPv6/M>             | Specify this DHCPv6 pool network's IPv6 address and mask (for example, 1:2::1:0/96) |
| <NETWORK-ALIAS-NAME> | Specify this DHCPv6 pool network's alias name                                       |

## Examples

```
nx9500-6C8809(config-dhcpv6-server-policy-test-pool-DHCPv6Pool1)#network 2002::0/64
nx9500-6C8809(config-dhcpv6-server-policy-test-pool-DHCPv6Pool1)#show context
dhcpv6-pool DHCPv6Pool1
 network 2002::/64
 domain-name TechPubs
 dns-server 2002::1
nx9500-6C8809(config-dhcpv6-server-policy-test-pool-DHCPv6Pool1)#
```

## Related Commands

|                                      |                                                                           |
|--------------------------------------|---------------------------------------------------------------------------|
| no (dhcpv6-pool-config) on page 1478 | Removes the network IPv6 address and mask configured for this DHCPv6 pool |
|--------------------------------------|---------------------------------------------------------------------------|

### option (dhcpv6-pool-config)

Configures this DHCPv6 pool's raw DHCPv6 options. This is the vendor-specific option used in this DHCPv6 pool.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

Syntax

```
option <OPTION-NAME> [<DHCPv6-OPTION-IP> | <DHCPv6-OPTION-ASCII>]
```

Parameters

```
option <OPTION-NAME> [<DHCPv6-OPTION-IP> | <DHCPv6-OPTION-ASCII>]
```

|                       |                                       |
|-----------------------|---------------------------------------|
| <OPTION-NAME>         | Sets the name of the DHCPv6 option    |
| <DHCPv6-OPTION-IP>    | Sets DHCPv6 option as an IPv6 address |
| <DHCPv6-OPTION-ASCII> | Sets DHCPv6 option as an ASCII string |

Usage Guidelines

An option name in ASCII format accepts backslash (\) as an input but is not displayed in the output. Use the **show > running > config** command to view the output. Use a double backslash to represent a single backslash.

Examples

```
nx9500-6C8809(config-dhcpv6-server-policy-test-pool-DHCPv6Pool1)#option DHCPv6Pool1Option
60
nx9500-6C8809(config-dhcpv6-server-policy-test-pool-DHCPv6Pool1)#show context
dhcpv6-pool DHCPv6Pool1
network 2002::/64
domain-name TechPubs
dns-server 2002::1
option DHCPv6Pool1Option 60
nx9500-6C8809(config-dhcpv6-server-policy-test-pool-DHCPv6Pool1)#
```

|------------------------------------------------------|-------------------------------------------------|

### refresh-time (dhcpv6-pool-config)

Configures this DHCPv6 pool's refresh time in seconds. This is the interval between two successive DHCP pool refreshes. The DHCP refresh process refreshes IPv6 client information.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
refresh-time <600-4294967295>
```

## Parameters

```
refresh-time <600-4294967295>
```

|                                                                                                     |
|-----------------------------------------------------------------------------------------------------|
| refresh-time <600-4294967295> Specify this DHCPv6 pool's refresh time from 600 -4294967295 seconds. |
|-----------------------------------------------------------------------------------------------------|

## Examples

```
nx9500-6C8809(config-dhcpv6-server-policy-test-pool-DHCPv6Pool1)#refresh-time 1000
nx9500-6C8809(config-dhcpv6-server-policy-test-pool-DHCPv6Pool1)#show context
dhcpv6-pool DHCPv6Pool1
 network 2002::/64
 refresh-time 1000
 domain-name TechPubs
 dns-server 2002::1
 option DHCPv6Pool1Option 60
nx9500-6C8809(config-dhcpv6-server-policy-test-pool-DHCPv6Pool1)#
```

## Related Commands

|                                                                                                                   |

| <a href="#">no (dhcpv6-pool-config)</a> on page 1478 Removes or reverts the configured DHCPv6 pool's refresh time |
|-------------------------------------------------------------------------------------------------------------------|

## sip (dhcpv6-pool-config)

Configures this DHCPv6 pool's SIP (Session Initiation Protocol) server setting

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
sip [address <IPv6>|domain-name <DOMAIN-NAME>]
```

## Parameters

```
sip [address <IPv6>|domain-name <DOMAIN-NAME>]
```

|                                                                                                                                       |
|---------------------------------------------------------------------------------------------------------------------------------------|
| sip [address <IPv6> domain-name <DOMAIN-NAME>] Configures the SIP server's setting, such as address and/or domain name <DOMAIN-NAME>] |
|---------------------------------------------------------------------------------------------------------------------------------------|

## Examples

```
nx9500-6C8809(config-dhcpv6-server-policy-test-pool-DHCPv6Pool1)#sip domain-name
TechPubsSIP
nx9500-6C8809(config-dhcpv6-server-policy-test-pool-DHCPv6Pool1)#show context
dhcpv6-pool DHCPv6Pool1
 network 2002::/64
 refresh-time 1000
 domain-name TechPubs
 sip domain-name TechPubsSIP
 dns-server 2002::1
 option DHCPv6Pool1Option 60
nx9500-6C8809(config-dhcpv6-server-policy-test-pool-DHCPv6Pool1)#
```

## Related Commands

|                                                   |                                               |
|---------------------------------------------------|-----------------------------------------------|
| <code>no (dhcpv6-pool-config)</code> on page 1478 | Removes this DHCPv6 pool's SIP server setting |
|---------------------------------------------------|-----------------------------------------------|

## **no (dhcpv6-pool-config)**

Negates a command or sets its default. When used in the DHCPv6 pool configuration context, the 'no' command resets or reverts the DHCPv6 pool's settings.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
no [dns-server | domain-name | network | option | refresh-time | sip]
```

### Parameters

```
no <PARAMETERS>
```

|                                    |                                                                                                                                                           |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>no &lt;PARAMETERS&gt;</code> | Negates a command or sets its default. When used in the DHCPv6 pool configuration context, the 'no' command resets or reverts the DHCPv6 pool's settings. |

```

## *option (dhcpv6-server-policy-config)*

Configures this DHCPv6 server policy's DHCP option settings, such enterprise (vendor) ID

DHCPv6 services are available for specific IP interfaces. A pool (or range) of IPv6 network addresses and DHCPv6 options can be created for each IPv6 interface defined. This range of addresses can be made available to DHCPv6 enabled devices on either a permanent or leased basis. DHCPv6 options are provided to each client with a DHCPv6 response and provide DHCPv6 clients information required to access network resources (default gateway, domain name, DNS server and WINS server configuration). An option exists to identify the vendor and functionality of a DHCPv6 client. The information is a

variable-length string of characters (or octets) with a meaning specified by the vendor of the DHCPv6 client.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
option <OPTION-NAME> <0-254> [ascii|hexstring|ipv6] <1-4294967295>
```

### Parameters

```
option <OPTION-NAME> <0-254> [ascii|hexstring|ipv6] <1-4294967295>
```

|                      |                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| option <OPTION-NAME> | Specify a unique name for this DHCP option. The name should describe option's function.                                                                                                                                                                                                                                                                                                  |
| <0-254>              | Specify a DHCP option code for this option. <ul style="list-style-type: none"> <li>• &lt;0-254&gt; - Specify a value from 0 -254.</li> </ul> <p>The system allows only one code, of the same value, for each DHCP option used in each DHCPv6 server policy.</p>                                                                                                                          |
| ascii                | Specifies the option type as ASCII (sends an ASCII compliant string to the client)                                                                                                                                                                                                                                                                                                       |
| hexstring            | Specifies the option type as a string of hexadecimal characters (sends a hexadecimal string to the client)                                                                                                                                                                                                                                                                               |
| ipv6                 | Specifies the option type as IPv6 address (sends an IPv6 compatible address to the client)                                                                                                                                                                                                                                                                                               |
| <1-4294967295>       | This parameter is common to all option types. <ul style="list-style-type: none"> <li>• &lt;1-4294967295&gt; - Specifies the enterprise (vendor) ID. Specify a value from 1 - 4294967295. The option code (1) is reserved for subnet-mask and cannot be used.</li> </ul> <p>Each vendor should have a unique vendor ID used by the DHCP server to issue vendor-specific DHCP options.</p> |

### Examples

```
nx9500-6C8809(config-dhcpv6-server-policy-test)#option DHCPServerOption1 10 ascii 50
nx9500-6C8809(config-dhcpv6-server-policy-test)#show context
dhcpv6-server-policy test
 option DHCPServerOption1 10 ascii 50
 dhcpv6-pool DHCPv6Pool1
 network 2002::/64
 domain-name TechPubs
 sip domain-name TechPubsSIP
 dns-server 2002::1
nx9500-6C8809(config-dhcpv6-server-policy-test)#
```

### *restrict-vendor-options (dhcpv6-server-policy-config)*

Restricts the use of vendor-specific DHCP options on this DHCPv6 server policy. When restricted, vendor-specific DHCP options, configured on this DHCPv6 server policy, are not included in the DHCPv6 server replies to IPv6 clients.

#### **Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### **Syntax**

```
restrict-vendor-options
```

#### **Parameters**

None

#### **Examples**

```
nx9500-6C8809(config-dhcpv6-server-policy-test)#restrict-vendor-options
nx9500-6C8809(config-dhcpv6-server-policy-test)#show context
dhcpv6-server-policy test
 option DHCPv6ServerOption1 10 ascii 50
 dhcpv6-pool DHCPv6Pool1
 network 2002::/64
 domain-name TechPubs
 sip domain-name TechPubsSIP
 dns-server 2002::1
 restrict-vendor-options
nx9500-6C8809(config-dhcpv6-server-policy-test)#
```

#### **Related Commands**

|                                                            |                                                                                                    |
|------------------------------------------------------------|----------------------------------------------------------------------------------------------------|
| <code>no (dhcpv6-server-policy-config)</code> on page 1481 | Removes restriction on sending of vendor-specific options in DHCPv6 server replies to IPv6 clients |
|------------------------------------------------------------|----------------------------------------------------------------------------------------------------|

### *server-preference (dhcpv6-server-policy-config)*

Configures this DHCPv6 server's preference value. When configured, the server preference value is included in the DHCPv6 server's replies to IPv6 clients.

#### **Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### **Syntax**

```
server-preference <0-255>
```

## Parameters

server-preference <0-255>one

|                           |                                                                                                 |
|---------------------------|-------------------------------------------------------------------------------------------------|
| server-preference <0-255> | Configures this DHCP server's preference value                                                  |
|                           | <ul style="list-style-type: none"><li>• &lt;0-255&gt; - Specify a value from 0 - 255.</li></ul> |

## Examples

```
nx9500-6C8809(config-dhcpv6-server-policy-test)#server-preference 1
nx9500-6C8809(config-dhcpv6-server-policy-test)#show context
dhcpv6-server-policy test
 option DHCPServerOption1 10 ascii 50
 dhcpv6-pool DHCPv6Pool1
 network 2002::/64
 domain-name TechPubs
 sip domain-name TechPubsSIP
 dns-server 2002::1
 server-preference 1
 restrict-vendor-options
nx9500-6C8809(config-dhcpv6-server-policy-test)#
```

## Related Commands

| <a href="#">no (dhcpv6-server-policy-config) on page 1481</a> | Removes this DHCPv6 server's preference value |
|---------------------------------------------------------------|-----------------------------------------------|

*no (dhcpv6-server-policy-config)*

Negates or reverts this DHCPv6 server policy's settings

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

no [dhcpv6-pool|option|restrict-vendor-options|server-preference]

## Parameters

no <PARAMETERS>

|                 |                                                       |
|-----------------|-------------------------------------------------------|
| no <PARAMETERS> | Negates or reverts this DHCPv6 server policy settings |
|-----------------|-------------------------------------------------------|

## Examples

```
nx9500-6C8809(config-dhcpv6-server-policy-test)#show context
dhcpv6-server-policy test
 option DHCPServerOption1 10 ascii 50
 dhcpv6-pool DHCPv6Pool1

 dns-server 2002::1
nx9500-6C8809(config-dhcpv6-server-policy-test)#
```

# FIREWALL POLICY

## FIREWALL-POLICY

---

This chapter summarizes the firewall policy commands in the CLI command structure.

A firewall protects a network from attacks and unauthorized access from outside the network. Simultaneously, it allows authorized users to access required resources. Firewalls work on multiple levels. Some work at layers 1, 2 and 3 to inspect each packet. The packet is either passed, dropped or rejected based on rules configured on the firewall.

Firewalls use application layer filtering to enforce compliance. These firewalls can understand applications and protocols and can detect if an unauthorized protocol is being used, or an authorized protocol is being abused in any malicious way.

The third set of firewalls, 'Stateful Firewalls', consider the placement of individual packets within each packet in the series of packets being transmitted. If there is a packet that does not fit into the sequence, it is automatically identified and dropped.

Use (config) instance to configure firewall policy commands. To navigate to the *config-fw-policy* instance, use the following commands:

```
<DEVICE>(config)#firewall-policy <POLICY-NAME>
nx9500-6C8809(config)#firewall-policy test
nx9500-6C8809(config-fw-policy-test)#?
Firewall policy Mode commands:
 acl-logging Log on flow creating traffic
 alg Enable ALG
 clamp Clamp value
 dhcp-offer-convert Enable conversion of broadcast dhcp offers to
 unicast
 dns-snoop DNS Snooping
 firewall Configure global firewall
 flow Firewall flow
 ip Internet Protocol (IP)
 ip-mac Action based on ip-mac table
 ipv6 Internet Protocol version 6 (IPv6)
 ipv6-mac Action based on ipv6-mac table
 logging Firewall enhanced logging
 no Negate a command or set its defaults
 proxy-arp Enable generation of ARP responses on behalf
 of another device
 proxy-nd Enable generation of ND responses (for IPv6)
 on behalf of another device
 stateful-packet-inspection-l2 Enable stateful packet inspection in layer2
 firewall
 storm-control Storm-control
 virtual-defragmentation Enable virtual defragmentation for IPv4 and
 IPv6 packets (recommended for proper
 functioning of firewall)

 clrscr Clears the display screen
 commit Commit all changes made in this session
 do Run commands from Exec mode
 end End current mode and change to EXEC mode
 exit End current mode and down to previous mode
```

```

help Description of the interactive help system
revert Revert changes
service Service Commands
show Show running system information
write Write running configuration to memory or
 terminal

```

```
nx9500-6C8809(config-fw-policy-test)#
```

## firewall-policy-commands

The following table summarizes the default firewall policy configuration commands:

*Table: Firewall-Policy Config Mode Commands*

| Command                                                    | Description                                                                   |
|------------------------------------------------------------|-------------------------------------------------------------------------------|
| <a href="#">acl-logging</a> on page 1485                   | Enables logging on flow creating traffic                                      |
| <a href="#">alg</a> on page 1485                           | Enables an algorithm                                                          |
| <a href="#">clamp</a> on page 1486                         | Sets a clamp value to limit TCP MSS to inner path-MTU for tunneled packets    |
| <a href="#">dhcp-offer-convert</a> on page 1487            | Enables the conversion of broadcast DHCP offers to unicast                    |
| <a href="#">dns-snoop</a> on page 1488                     | Sets the timeout value for DNS entries                                        |
| <a href="#">firewall</a> on page 1488                      | Configures the wireless firewall                                              |
| <a href="#">flow</a> on page 1489                          | Defines a session flow timeout                                                |
| <a href="#">ip</a> on page 1490                            | Configures IP components on this firewall policy                              |
| <a href="#">ip-mac</a> on page 1497                        | Defines an action based on IP-MAC table                                       |
| <a href="#">ipv6</a> on page 1499                          | Configures IPv6 components on this firewall policy                            |
| <a href="#">ipv6-mac</a> on page 1502                      | Defines an action based on IPv6-MAC table                                     |
| <a href="#">logging</a> on page 1504                       | Enables enhanced firewall logging                                             |
| <a href="#">proxy-arp</a> on page 1506                     | Enables the generation of ARP responses on behalf of another device           |
| <a href="#">proxy-nd</a> on page 1506                      | Enables the generation of ND responses (for IPv6) on behalf of another device |
| <a href="#">stateful-packet-inspection-12</a> on page 1507 | Enables stateful packets-inspection in layer 2 firewall                       |
| <a href="#">storm-control</a> on page 1507                 | Defines storm control and logging settings                                    |
| <a href="#">virtual-defragmentation</a> on page 1509       | Enables virtual defragmentation of IPv4 packets                               |
| <a href="#">no</a> on page 1510                            | Negates a command or reverts settings to their default                        |

### Note

For more information on common commands (clrsr, commit, help, revert, service, show, write, and exit), see [COMMON COMMANDS](#) on page 640.

#### Note

The input parameter <HOSTNAME>, wherever used in syntaxes across this chapter, cannot include an underscore ( `_` ) character. In other words, the name of a device cannot contain an underscore.

### *acl-logging*

Enables logging on flow creating traffic

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
acl-logging
```

#### Parameters

None

#### Examples

```
nx9500-6C8809(config-fw-policy-testFW)#acl-logging
nx9500-6C8809(config-fw-policy-testFW)#show context include-factory | include acl-logging
 acl-logging
nx9500-6C8809(config-fw-policy-testFW)#
```

#### Related Commands

|                                                                           |
|---------------------------------------------------------------------------|
| <a href="#">no</a> on page 1510 Disables logging on flow creating traffic |
|---------------------------------------------------------------------------|

### *alg*

Enables traffic filtering at the application layer using the ALG (Application Layer Gateway) feature

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
alg [dns|facetime|ftp|pptp|sccp|sip|tftp]
```

#### Parameters

```
alg [dns|facetime|ftp|pptp|sccp|sip|tftp]
```

|          |                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| alg      | Enables traffic filtering at the application layer. The ALG provides filters for the following common protocols: <b>DNS, Facetime, FTP, PPTP, SCCP, SIP,</b> and <b>TFTP</b> .                                                                                                                                                                                                                      |
| dns      | Allows DNS (Domain Name System) traffic through the firewall using its default ports. This option is enabled by default. When enabled, you can easily permit or deny traffic based on a packet's DNS name, instead of the IP address. Use this option when configuring ACLs allowing or denying traffic for Web sites that have a single domain name resolving to any one of multiple IP addresses. |
| facetime | Allows Apple's FaceTime video calling traffic through the firewall using its default ports. This option is disabled by default.                                                                                                                                                                                                                                                                     |
| ftp      | Allows FTP (File Transfer Protocol) traffic through the firewall using its default ports. This option is enabled by default.                                                                                                                                                                                                                                                                        |
| pptp     | Allows PPTP (Point-to-Point Tunneling Protocol) traffic through the firewall using its default ports. PPTP, a network protocol, enables secure transfer of data from a remote client to an enterprise server by encapsulating PPP packets into IP datagrams for transmission over the Internet or other public TCP/IP-based networks. This option is enabled by default.                            |
| sccp     | Allows SCCP (Signalling Connection Control Part) traffic through the firewall using its default ports. This option is disabled by default. SCCP is a network protocol that provides routing, flow control and error correction in telecommunication networks.                                                                                                                                       |
| sip      | Allows SIP (Session Initiation Protocol) traffic through the firewall using its default ports. This option is disabled by default.                                                                                                                                                                                                                                                                  |
| tftp     | Enables the TFTP (Trivial File Transfer Protocol) algorithm. When enabled, allows TFTP traffic through the firewall using its default ports. This option is enabled by default.                                                                                                                                                                                                                     |

### Examples

```

nx9500-6C8809(config-fw-policy-testFW)#show context
nx9500-6C8809(config-fw-policy-testFW)#show context
firewall-policy testFW
 no ip dos tcp-sequence-past-window
 alg facetime
nx9500-6C8809(config-fw-policy-testFW)#

```

### Related Commands

|                        |                                         |
|------------------------|-----------------------------------------|
| <b>no</b> on page 1510 | Removes or reverts ALG related settings |
|------------------------|-----------------------------------------|

### *clamp*

This option limits the TCP MSS (Maximum Segment Size) to the size of the MTU (Maximum Transmission Unit) discovered by path MTU discovery for the inner protocol. This ensures the packet traverses through the inner protocol without fragmentation. This option is enabled by default.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
clamp tcp-mss
```

## Parameters

```
clamp tcp-mss
```

|         |                                                                                     |
|---------|-------------------------------------------------------------------------------------|
| tcp-mss | Limits the TCP MSS size to the MTU value of the inner protocol for tunneled packets |
|---------|-------------------------------------------------------------------------------------|

## Examples

```
nx9500-6C8809(config-fw-policy-test)#clamp tcp-mss
nx9500-6C8809(config-fw-policy-testFW)#show context include-factory | include clamp
clamp tcp-mss
nx9500-6C8809(config-fw-policy-testFW)#
```

## *dhcp-offer-convert*

Enables the conversion of broadcast DHCP offers to unicast. Converting DHCP broadcast traffic to unicast traffic can help reduce network traffic loads. This option is disabled by default.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
dhcp-offer-convert
```

## Parameters

None

## Examples

```
nx9500-6C8809(config-fw-policy-testFW)#dhcp-offer-convert
nx9500-6C8809(config-fw-policy-testFW)#show context
firewall-policy testFW
no ip dos tcp-sequence-past-window
dhcp-offer-convert
alg facetime
nx9500-6C8809(config-fw-policy-testFW)#
```

## *dns-snoop*

Sets the timeout interval for DNS snoop table entries. DNS snoop entries provide information, such as client to IP address and client to default gateway(s) mappings. This information is used to detect if the client is sending routed packets to a wrong MAC address.

### **Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### **Syntax**

```
dns-snoop entry-timeout <30-86400>
```

### **Parameters**

```
dns-snoop entry-timeout <30-86400>
```

|                             |                                                                                                                                                                                                                            |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| entry-timeout<br><30-86400> | Sets the DNS snoop table entry timeout interval from 30 - 86400 seconds. An entry is retained in the DNS snoop table only for the specified time, and is deleted once this time is exceeded. The default is 1,800 seconds. |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### **Examples**

```
nx9500-6C8809(config-fw-policy-testFW)#dns-snoop entry-timeout 1200
nx9500-6C8809(config-fw-policy-testFW)#show context
firewall-policy testFW
 no ip dos tcp-sequence-past-window
 dhcp-offer-convert
 alg facetime
 dns-snoop entry-timeout 1200
nx9500-6C8809(config-fw-policy-testFW)#
```

### **Related Commands**

|------------------------------|----------------------------------------------------|

## *firewall*

Enables the firewall. The Firewall is enabled by default.

### **Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### **Syntax**

```
firewall enable
```

## Parameters

firewall enable

|                 |                           |
|-----------------|---------------------------|
| firewall enable | Enables wireless firewall |
|-----------------|---------------------------|

## Examples

```
nx9500-6C8809(config-fw-policy-testFW)#firewall enable
nx9500-6C8809(config-fw-policy-testFW)#show context include-factory | include firewall
firewall-policy testFW
 firewall enable
 ipv6 firewall enable
nx9500-6C8809(config-fw-policy-testFW)#
```

## flow

Defines the session flow timeout interval for different packet types

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
flow [dhcp|timeout]
flow dhcp stateful
flow timeout [icmp|other|tcp|udp]
flow timeout [icmp|other] <1-32400>
flow timeout udp <15-32400>
flow timeout tcp [close-wait|reset|setup|stateless-fin-or-reset| stateless-general]
<1-32400>
flow timeout tcp established <15-32400>
```

## Parameters

flow dhcp stateful

|          |                                                                                |
|----------|--------------------------------------------------------------------------------|
| dhcp     | Configures DHCP packet flow                                                    |
| stateful | Performs a stateful check on DHCP packets. This feature is enabled by default. |

flow timeout [icmp|other] <1-32400>

|           |                                                                                             |
|-----------|---------------------------------------------------------------------------------------------|
| timeout   | Configures a packet timeout                                                                 |
| icmp      | Configures the timeout for ICMP packets. The default is 30 seconds.                         |
| other     | Configures the timeout for packets other than ICMP, TCP, or UDP. The default is 30 seconds. |
| <1-32400> | Specify the timeout from 1 - 32400 seconds.                                                 |

flow timeout udp <15-32400>

|            |                                                                    |
|------------|--------------------------------------------------------------------|
| timeout    | Configures a packet timeout                                        |
| udp        | Configures the timeout for UDP packets. The default is 30 seconds. |
| <15-32400> | Specify the timeout from 15 - 32400 seconds.                       |

```
flow timeout tcp [close-wait|reset|setup|stateless-fin-or-reset|stateless-general]
<1-32400>
```

|                        |                                                                                                         |
|------------------------|---------------------------------------------------------------------------------------------------------|
| timeout                | Configures a packet timeout                                                                             |
| tcp                    | Configures the timeout for TCP packets                                                                  |
| close-wait             | Configures the closed TCP flow timeout. The default is 10 seconds.                                      |
| reset                  | Configures the reset TCP flow timeout. The default is 10 seconds.                                       |
| setup                  | Configures the opening TCP flow timeout. The default is 10 seconds.                                     |
| stateless-fin-or-reset | Configures stateless TCP flow timeout created with the FIN or RESET packets. The default is 10 seconds. |
| stateless-general      | Configures the stateless TCP flow timeout. The default is 90 seconds (1 m 30s).                         |
| <1-32400>              | Specify the timeout from 1 - 32400 seconds.                                                             |

```
flow timeout tcp established <15-32400>
```

|             |                                                                           |
|-------------|---------------------------------------------------------------------------|
| timeout     | Configures the packet timeout                                             |
| tcp         | Configures the timeout for TCP packets                                    |
| established | Configures the established TCP flow timeout. The default is 5400 seconds. |
| <15-32400>  | Specify the timeout from 15 - 32400 seconds.                              |

## Examples

```
nx9500-6C8809(config-fw-policy-testFW)#flow timeout udp 10000
nx9500-6C8809(config-fw-policy-testFW)#flow timeout icmp 16000
nx9500-6C8809(config-fw-policy-testFW)#flow timeout other 16000
nx9500-6C8809(config-fw-policy-testFW)#flow timeout tcp established 1500
nx9500-6C8809(config-fw-policy-testFW)#show context
firewall-policy testFW
no ip dos tcp-sequence-past-window
flow timeout icmp 16000
flow timeout udp 10000
flow timeout tcp established 1500
flow timeout other 16000
dhcp-offer-convert
alg facetime
dns-snoop entry-timeout 1200
nx9500-6C8809(config-fw-policy-testFW)#
```

log-level [<0-7>|alerts|critical|debug|emergencies|errors|informational|notifications|
warnings]
```

|                          |                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dos                      | Identifies IP events as DoS events                                                                                                                                                                                                                                                                                                              |
| ascend                   | Optional. Detects ASCEND DoS attacks<br>Ascend DoS attacks target known vulnerabilities in various versions of Ascend routers. Ascend routers listen on UDP port 9 for packets from Ascend's Java Configurator. Sending a formatted packet to this port can cause an Ascend router to crash.                                                    |
| broadcast-multicast-icmp | Optional. Detects broadcast or multicast ICMP Dos attacks<br>Broadcast or multicast ICMP DoS attacks take advantage of ICMP behavior in response to echo replies. These attacks spoof the source address of the target and send ICMP broadcast or multicast echo requests to the rest of the network, flooding the target machine with replies. |

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| chargen          | <p>Optional. Detects Chargen attacks</p> <p>The chargen (Character Generation Protocol) is an IP suite service primarily used for testing and debugging networks. It is also used as a source of generic payload for bandwidth and QoS measurements.</p> <p>The Chargen attack establishes a Telnet connection to port 19 and attempts to use the character generator service to create a string of characters which is then directed to the DNS service on port 53 to disrupt DNS services.</p>                                                                                                                                                                                                                            |
| fraggle          | <p>Optional. Detects Fraggle DoS attacks</p> <p>The Fraggle DoS attack uses a list of broadcast addresses to send spoofed UDP packets to each broadcast address' echo port (port 7). Each of those addresses that have port 7 open will respond to the request generating a lot of traffic on the network. For those that do not have port 7 open they will send an unreachable message back to the originator, further clogging the network with more traffic.</p>                                                                                                                                                                                                                                                         |
| ftp-bounce       | <p>Optional. Detects FTP bounce attacks</p> <p>A FTP bounce attack is a MIM attack that enables an attacker to open a port on a different machine using FTP. FTP requires that when a connection is requested by a client on the FTP port (21), another connection must open between the server and the client. To confirm, the PORT command has the client specify an arbitrary destination machine and port for the data connection. This is exploited by the attacker to gain access to a device that may not be the originating client.</p>                                                                                                                                                                             |
| invalid-protocol | <p>Optional. Enables a check for an invalid protocol number</p> <p>Attackers may use vulnerability in the endpoint implementation by sending invalid protocol fields, or may misuse the misinterpretation of endpoint software. This can lead to inadvertent leakage of sensitive network topology information, call hijacking, or a DoS attack.</p>                                                                                                                                                                                                                                                                                                                                                                        |
| ip-ttl-zero      | <p>Optional. Enables a check for the TCP/IP TTL field having a value of zero (0)</p> <p>The TCP IP TTL Zero DoS attack sends spoofed multicast packets onto the network which have a TTL (Time to Live) of 0. This causes packets to loop back to the spoofed originating machine, and can cause the network to overload.</p>                                                                                                                                                                                                                                                                                                                                                                                               |
| ipsproof         | <p>Optional. Enables a check for the IP spoofing DoS attack</p> <p>IP Spoof is a category of DoS attack that sends IP packets with forged source addresses. This can hide the identity of the attacker.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| land             | <p>Optional. Detects LAND DoS attacks</p> <p>A LAND (Local Area Network Denial) is a DoS attack where IP packets are spoofed and sent to a device where the source IP and destination IP of the packet are the target device's IP, and similarly, the source port and destination port are open ports on the same device. This causes the attacked device to reply to itself continuously.</p>                                                                                                                                                                                                                                                                                                                              |
| option-route     | <p>Optional. Enables an IP Option Record Route DoS check</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| router-adv       | <p>Optional. Detects router-advertisement attacks</p> <p>This attack uses ICMP to redirect the network router function to some other host. If that host can not provide router services, a DoS of network communications occurs as routing stops. This can also be modified to single out a specific system, so that only that system is subject to attack (because only that system sees the 'false' router). By providing router services from a compromised host, the attacker can also place themselves in a man-in-the-middle situation and take control of any open channel at will (as mentioned earlier, this is often used with TCP packet forgery and spoofing to intercept and change open TELNET sessions).</p> |

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| router-solicit   | <p>Optional. Detects router solicitation attacks</p> <p>The ICMP router solicitation scan is used to actively find routers on a network. A hacker could set up a protocol analyzer to detect routers as they broadcast routing information on the network. In some instances, however, routers may not send updates. For example, if the local network does not have other routers, the router may be configured to not send routing information packets onto the local network. ICMP offers a method for router discovery. Clients send ICMP router solicitation multicasts onto the network, and routers must respond (as defined in RFC 1122). (For more information about the process of ICMP router solicitation, see "Routing Sequences for ICMP:")</p> <p>By sending ICMP router solicitation packets (ICMP type 9) on the network and listening for ICMP router discovery replies (ICMP type 10), hackers can build a list of all of the routers that exist on a network segment. Hackers often use this scan to locate routers that do not reply to ICMP echo requests.</p> |
| smurf            | <p>Optional. In this attack, a large number of ICMP echo packets are sent with a spoofed source address. This causes the device with the spoofed source address to be flooded with a large number of replies.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| snork            | <p>Optional. This attack causes a remote Windows™ NT to consume 100% of the CPU's resources. This attack uses a UDP packet with a destination port of 135 and a source port of 7, 9, or 135. This attack can also be exploited as a bandwidth consuming attack.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| tcp-bad-sequence | <p>Optional. A DoS attack that uses a specially crafted TCP packet to cause the targeted device to drop all subsequent network traffic for a specific TPC connection.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| tcp-fin-scan     | <p>Optional. Detects TCP FIN scan attacks</p> <p>Hackers use the TCP FIN scan to identify listening TCP port numbers based on how the target device reacts to a transaction close request for a TCP port (even though no connection may exist before these close requests are made). This type of scan can get through basic firewalls and boundary routers that filter on incoming TCP packets with the <i>Finish</i> (FIN) and ACK flag combination. The TCP packets used in this scan include only the TCP FIN flag setting.</p> <p>If the target device's TCP port is closed, the target device sends a TCP RST packet in reply. If the target device's TCP port is open, the target device discards the FIN and sends no reply.</p>                                                                                                                                                                                                                                                                                                                                             |

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| tcp-intercept            | <p>Optional. Prevents TCP intercept attacks by using TCP SYN cookies</p> <p>A SYN-flooding attack occurs when a hacker floods a server with a barrage of requests for connection.</p> <p>Because these messages have unreachable return addresses, the connections cannot be established. The resulting volume of unresolved open connections eventually overwhelms the server and can cause it to deny service to valid requests, thereby preventing legitimate users from connecting to a Web site, accessing email, using FTP service, and so on.</p> <p>The TCP intercept feature helps prevent SYN-flooding attacks by intercepting and validating TCP connection requests. In intercept mode, the TCP intercept software intercepts TCP SYN (synchronization ) packets from clients to servers that match an extended access list. The software establishes a connection with the client on behalf of the destination server, and if successful, establishes the connection with the server on behalf of the client and knits the two half-connections together transparently. Thus, connection attempts from unreachable hosts will never reach the server. The software continues to intercept and forward packets throughout the duration of the connection. The number of SYNs per second and the number of concurrent connections proxied depends on the platform, memory, processor, and other factors. In the case of illegitimate requests, the software's aggressive timeouts on half-open connections and its thresholds on TCP connection requests protect destination servers while still allowing valid requests.</p> <p>When establishing a security policy using TCP intercept, you can choose to intercept all requests or only those coming from specific networks or destined for specific servers. You can also configure the connection rate and threshold of outstanding connections. Optionally operate TCP intercept in watch mode, as opposed to intercept mode. In watch mode, the software passively watches the connection requests flowing through the router. If a connection fails to get established in a configurable interval, the software intervenes and terminates the connection attempt.</p> |
| tcp-null-scan            | <p>Optional. Detects TCP NULL scan attacks</p> <p>Hackers use the TCP NULL scan to identify listening TCP ports. This scan also uses a series of strangely configured TCP packets, which contain a sequence number of 0 and no flags. Again, this type of scan can get through some firewalls and boundary routers that filter incoming TCP packets with standard flag settings.</p> <p>If the target device's TCP port is closed, the target device sends a TCP RST packet in reply. If the target device's TCP port is open, the target discards the TCP NULL scan, sending no reply.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| tcp-post-syn             | <p>Optional. Detects TCP post SYN DoS attacks</p> <p>A remote attacker may be attempting to avoid detection by sending a SYN frame with a different sequence number than the original SYN. This can cause an Intrusion Detection System (IDS) to become unsynchronized with the data in a connection. Subsequent frames sent during the connection are ignored by the IDS.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| tcp-sequence-past-window | <p>Optional. Enables a TCP SEQUENCE PAST WINDOW DoS attack check. Disable this check to work around a bug in Windows XP's TCP stack which sends data past the window when conducting a selective ACK.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

Enables the identification of truncated UDP headers and UDP header length fields</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|               |                                                                                                                                                                                                                                              |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| winnuke       | Optional. This DoS attack is specific to Windows™ 95 and Windows™ NT. The WINNUKE DoS attack sends a large amount of data to UDP port 137 to crash the NETBIOS service on windows and results in high CPU utilization on the target machine. |
| log-and-drop  | Logs the event and drops the packet                                                                                                                                                                                                          |
| log-only      | Logs the event only, the packet is not dropped                                                                                                                                                                                               |
| log-level     | Configures the log level                                                                                                                                                                                                                     |
| <0-7>         | Sets the numeric logging level                                                                                                                                                                                                               |
| emergencies   | Numerical severity 0. System is unusable                                                                                                                                                                                                     |
| alerts        | Numerical severity 1. Indicates a condition where immediate action is required                                                                                                                                                               |
| critical      | Numerical severity 2. Indicates a critical condition                                                                                                                                                                                         |
| errors        | Numerical severity 3. Indicates an error condition                                                                                                                                                                                           |
| warnings      | Numerical severity 4. Indicates a warning condition                                                                                                                                                                                          |
| notification  | Numerical severity 5. Indicates a normal but significant condition                                                                                                                                                                           |
| informational | Numerical severity 6. Indicates a informational condition                                                                                                                                                                                    |
| debugging     | Numerical severity 7. Debugging messages                                                                                                                                                                                                     |

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dos                      | Identifies IP events as DoS events                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| ascend                   | Optional. Enables an ASCEND DoS check. Ascend routers listen on UDP port 9 for packets from Ascend's Java Configurator. Sending a formatted packet to this port can cause an Ascend router to crash.                                                                                                                                                                                                                                                                                                   |
| broadcast-multicast-icmp | Optional. Detects broadcast or multicast ICMP packets as an attack                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| chargen                  | Optional. The chargen (Character Generation Protocol) is an IP suite service primarily used for testing and debugging networks. It is also used as a source of generic payload for bandwidth and QoS measurements.                                                                                                                                                                                                                                                                                     |
| fraggle                  | Optional. A Fraggle DoS attack checks for UDP packets to or from port 7 or 19                                                                                                                                                                                                                                                                                                                                                                                                                          |
| ftp-bounce               | Optional. A FTP bounce attack is a MIM attack that enables an attacker to open a port on a different machine using FTP. FTP requires that when a connection is requested by a client on the FTP port (21), another connection must open between the server and the client. To confirm, the PORT command has the client specify an arbitrary destination machine and port for the data connection. This is exploited by the attacker to gain access to a device that may not be the originating client. |
| invalid-protocol         | Optional. Enables a check for invalid protocol number                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| ip-ttl-zero              | Optional. Enables a check for the TCP/IP TTL field having a value of zero (0)                                                                                                                                                                                                                                                                                                                                                                                                                          |
| ipsproof                 | Optional. Enables a check for IP spoofing DoS attack                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|                          |                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| land                     | Optional. A LAND (Local Area Network Denial) is a DoS attack where IP packets are spoofed and sent to a device where the source IP and destination IP of the packet are the target device's IP, and similarly, the source port and destination port are open ports on the same device. This causes the attacked device to reply to itself continuously. |
| option-route             | Optional. Enables an IP Option Record Route DoS check                                                                                                                                                                                                                                                                                                   |
| router-advrt             | Optional. This is an attack, where a default route entry is added remotely to a device. This route entry is given preference, and thereby exposes an attack vector.                                                                                                                                                                                     |
| router-solicit           | Optional. Router solicitation messages are sent to locate routers as a form of network scanning. This information can then be used to attack a device.                                                                                                                                                                                                  |
| smurf                    | Optional. In this attack, a large number of ICMP echo packets are sent with a spoofed source address. This causes the device with the spoofed source address to be flooded with a large number of replies.                                                                                                                                              |
| snork                    | Optional. This attack causes a remote Windows™ NT to consume 100% of the CPU's resources. This attack uses a UDP packet with a destination port of 135 and a source port of 7, 9, or 135. This attack can also be exploited as a bandwidth consuming attack.                                                                                            |
| tcp-bad-sequence         | Optional. A DoS attack that uses a specially crafted TCP packet to cause the targeted device to drop all subsequent network traffic for a specific TPC connection                                                                                                                                                                                       |
| tcp-fin-scan             | Optional. A FIN scan finds services on ports. A closed port returns a RST. This allows the attacker to identify open ports.                                                                                                                                                                                                                             |
| tcp-intercept            | Optional. Prevents TCP intercept attacks by using TCP SYN cookies                                                                                                                                                                                                                                                                                       |
| tcp-null-scan            | Optional. A TCP null scan finds services on ports. A closed port returns a RST. This allows the attacker to identify open ports                                                                                                                                                                                                                         |
| tcp-post-syn             | Optional. Enables a TCP post SYN DoS attack                                                                                                                                                                                                                                                                                                             |
| tcp-sequence-past-window | Optional. Enables a TCP SEQUENCE PAST WINDOW DoS attack check. Disable this check to work around a bug in Windows XP's TCP stack which sends data past the window when conducting a selective ACK.                                                                                                                                                      |
| tcp-xmas-scan            | Optional. A TCP XMAS scan finds services on ports. A closed port returns a RST. This allows the attacker to identify open ports.                                                                                                                                                                                                                        |
| tcphdrfrag               | Optional. A DoS attack where the TCP header spans IP fragments                                                                                                                                                                                                                                                                                          |
| twinge                   | Optional. A twinge attack is a flood of false ICMP packets to try and slow down a system                                                                                                                                                                                                                                                                |
| udp-short-hdr            | Optional. Enables the identification of truncated UDP headers and UDP header length fields                                                                                                                                                                                                                                                              |
| winnuke                  | Optional. This DoS attack is specific to Windows™ 95 and Windows™ NT, causing devices to crash with a blue screen                                                                                                                                                                                                                                       |
| drop-only                | Optional. Drops a packet without logging                                                                                                                                                                                                                                                                                                                |

```
ip dos tcp-max-incomplete [high|low] <1-1000>
```

|                    |                                                                           |
|--------------------|---------------------------------------------------------------------------|
| dos                | Identifies IP events as DoS events                                        |
| tcp-max-incomplete | Sets the limits for the maximum number of incomplete TCP connections      |
| high               | Sets the upper limit for the maximum number of incomplete TCP connections |
| low                | Sets the lower limit for the maximum number of incomplete TCP connections |
| <1-1000>           | Sets the range limit from 1 - 1000 connections                            |

```
ip tcp adjust-mss <472-1460>
```

|            |                                                                                        |
|------------|----------------------------------------------------------------------------------------|
| tcp        | Identifies and configures TCP events and configuration items                           |
| adjust-mss | Adjusts the TCP MSS. Use this option to adjust the MSS for TCP segments on the router. |
| <472-1460> | Sets the TCP MSS value from 472 - 1460 bytes. The default is 472 bytes.                |

```
ip tcp [optimize-unnecessary-resends|recreate-flow-on-out-of-state-syn|
validate-icmp-unreachable|validate-rst-ack-number|validate-rst-seq-number]
```

|                                    |                                                                                                                       |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| tcp                                | Identifies and configures TCP events and configuration items                                                          |
| optimize-unnecessary-resends       | Enables the validation of unnecessary TCP packets                                                                     |
| recreate-flow-on-out-of-state-sync | Allows a TCP SYN packet to delete an old flow in TCP_FIN_FIN_STATE, and TCP_CLOSED_STATE states and create a new flow |
| validate-icmp-unreachable          | Enables the validation of the sequence number in ICMP unreachable error packets, which abort an established TCP flow  |
| validate-rst-ack-number            | Enables the validation of the acknowledgment number in RST packets, which abort a TCP flow                            |
| validate-rst-seq-number            | Enables the validation of the sequence number in RST packets, which abort an established TCP flow                     |

### Examples

```
nx9500-6C8809(config-fw-policy-testFW)#ip dos fraggle drop-only
nx9500-6C8809(config-fw-policy-testFW)#ip dos tcp-max-incomplete high 600
nx9500-6C8809(config-fw-policy-testFW)#ip dos tcp-max-incomplete low 60
nx9500-6C8809(config-fw-policy-testFW)#ip dos tcp-sequence-past-window drop-only
nx9500-6C8809(config-fw-policy-testFW)#show context
firewall-policy testFW
 ip dos fraggle drop-only
 ip dos tcp-sequence-past-window drop-only
 ip dos tcp-max-incomplete high 600
 ip dos tcp-max-incomplete low 60
 flow timeout icmp 16000
 flow timeout udp 10000
 flow timeout tcp established 1500
 flow timeout other 16000
 dhcp-offer-convert
 alg facetime
 dns-snoop entry-timeout 1200
nx9500-6C8809(config-fw-policy-testFW)#
```

### ip-mac

Defines an action based on the device IP MAC table, and also detects conflicts between IP addresses and MAC addresses

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000

- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
ip-mac [conflict|routing]
ip-mac conflict drop-only
ip-mac conflict [log-and-drop|log-only] log-level [<0-7>|alerts|critical|debug|
emergencies|errors|informational|notifications|warnings]
ip-mac routing conflict drop-only
ip-mac routing conflict [log-and-drop|log-only] log-level [<0-7>|alerts|critical|debug|
emergencies|errors|informational|notifications|warnings]
```

### Parameters

```
ip-mac conflict drop-only
```

|           |                                                                                                                    |
|-----------|--------------------------------------------------------------------------------------------------------------------|
| conflict  | Action performed when a conflict exists between the IP address and MAC address. This option is enabled by default. |
| drop-only | Drops a packet without logging                                                                                     |

```
ip-mac conflict [log-and-drop|log-only] log-level [<0-7>|alerts|critical|debug|
emergencies|errors|informational|notifications|warnings]
```

|               |                                                                                                                    |
|---------------|--------------------------------------------------------------------------------------------------------------------|
| conflict      | Action performed when a conflict exists between the IP address and MAC address. This option is enabled by default. |
| log-and-drop  | Logs the event and drops the packet. This is the default setting.                                                  |
| log-only      | Logs the event only, the packet is not dropped                                                                     |
| log-level     | Configures the log level                                                                                           |
| <0-7>         | Sets the numeric logging level                                                                                     |
| alerts        | Numerical severity 1. Indicates a condition where immediate action is required                                     |
| critical      | Numerical severity 2. Indicates a critical condition                                                               |
| debugging     | Numerical severity 7. Debugging messages                                                                           |
| emergencies   | Numerical severity 0. System is unusable                                                                           |
| errors        | Numerical severity 3. Indicates an error condition                                                                 |
| informational | Numerical severity 6. Indicates a informational condition                                                          |
| notification  | Numerical severity 5. Indicates a normal but significant condition                                                 |
| warnings      | Numerical severity 4. Indicates a warning condition. This is the default setting.                                  |

```
ip-mac routing conflict drop-only
```

|           |                                                                                                                                                                                                           |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| routing   | Enables IPMAC routing conflict detection. This is also known as a Hole-196 attack in the network. This feature helps to detect if the client is sending routed packets to the correct router-mac-address. |
| conflict  | Defines the action performed when a routing table conflict is detected. This option is enabled by default.                                                                                                |
| drop-only | Drops a packet without logging                                                                                                                                                                            |

```
ip-mac routing conflict [log-and-drop|log-only] log-level [<0-7>|alerts|critical|debug|
emergencies|errors|informational|notifications|warnings]
```

|               |                                                                                                  |
|---------------|--------------------------------------------------------------------------------------------------|
| routing       | Defines a routing table based action                                                             |
| conflict      | Action performed when a conflict exists in the routing table. This option is enabled by default. |
| log-and-drop  | Logs the event and drops the packet. This is the default setting.                                |
| log-only      | Logs the event only, the packet is not dropped                                                   |
| log-level     | Configures the log level to log this event under                                                 |
| <0-7>         | Sets the numeric logging level                                                                   |
| alerts        | Numerical severity 1. Indicates a condition where immediate action is required                   |
| critical      | Numerical severity 2. Indicates a critical condition                                             |
| debugging     | Numerical severity 7. Debugging messages                                                         |
| emergencies   | Numerical severity 0. System is unusable                                                         |
| errors        | Numerical severity 3. Indicates an error condition                                               |
| informational | Numerical severity 6. Indicates a informational condition                                        |
| notification  | Numerical severity 5. Indicates a normal but significant condition                               |
| warnings      | Numerical severity 4. Indicates a warning condition. This is the default setting.                |

### ipv6

Configures IPv6 components on this firewall policy

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000

- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```

ipv6 [dos|duplicate-options|firewall|option|rewrite-flow-label|routing-type|
strict-ext-hdr-check|unknown-options]
ipv6 dos {hop-limit-zero/multicast-icmpv6/tcp-intercept-mobility} [drop-only|
log-and-drop|log-only]
ipv6 [duplicate-options|routing-type [one|two]|strict-ext-hdr-check|unknown-options]
[drop-only|log-and-drop|log-only]
ipv6 option {endpoint-identification/network-service-access-point/router-alert/
strict-hao-opt-alert/strict-padding} [drop-only|log-and-drop|log-only]
ipv6 [firewall enable|rewrite-flow-label]

```

## Parameters

```

ipv6 dos {hop-limit-zero/multicast-icmpv6/tcp-intercept-mobility}
[drop-only|log-and-drop|log-only]

```

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dos                    | Identifies IPv6 events as DoS events                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| hop-limit-zero         | Optional. Enables checking of IPv6 hop limit field. If the IPv6 hop limit field is ZERO (0) it is considered as attack. This option is enabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| multicast-icmpv6       | Optional. Enables detection of multicast ICMPv6 traffic as attack. This option is applicable only to ICMPv6 Echo request or reply packets. This option is enabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| tcp-intercept-mobility | Optional. Enables detection of IPv6 TCP packets with mobility option "HAO(Home-Address-Option)" or "RH(Routing Header) type two". When enabled, this option also detects the "don't generate TCP syn cookies" for such packets. This option is enabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| drop-only              | This parameter is common to all of the above keywords. Drops all packets. Drops the specified packet type (hop-limit-zero, multicast-icmpv6, and tcp-intercept-mobility).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| log-and-drop           | Logs the event and drops the packet. Drops the specified packet type (hop-limit-zero, multicast-icmpv6, and tcp-intercept-mobility) and logs an event.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| log-only               | Logs the event only, the packet is not dropped. Does not drop the specified packet type (hop-limit-zero, multicast-icmpv6, and tcp-intercept-mobility). But, an event is logged.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| log-level              | If selecting the "log-and-drop" and "log-only" action type, specify the log level. The options are: <ul style="list-style-type: none"> <li>• &lt;0-7&gt; – Sets the numeric logging level</li> <li>• alerts – Numerical severity 1. Indicates a condition where immediate action is required</li> <li>• critical – Numerical severity 2. Indicates a critical condition</li> <li>• debugging – Numerical severity 7. Debugging messages</li> <li>• emergencies – Numerical severity 0. System is unusable</li> <li>• errors – Numerical severity 3. Indicates an error condition</li> <li>• informational – Numerical severity 6. Indicates a informational condition</li> <li>• notifications – Numerical severity 5. Indicates a normal but significant condition</li> <li>• warnings – Numerical severity 4. Indicates a warning condition. This is the default setting.</li> </ul> |

```

ipv6 [duplicate-options|routing-type [one|two]|strict-ext-hdr-check|unknown-options]
[drop-only|log-and-drop|log-only]

| duplicate-options      | Enables handling of duplicate options in hop-by-hop and destination option extension headers. This configuration excludes HAO handling. This option is enabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| routing-type [one two] | Enables checking of the following IPv6 routing types: <ul style="list-style-type: none"> <li>• one – Routing Type 1(Nimrod routing). This option is disabled by default.</li> <li>• two – Routing Type 2(Mobile IP). This option is disabled by default.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| strict-ext-hdr-check   | Enables strict checking for out of order and number of occurrences of extension header. This option is enabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| unknown-options        | Enables handling unknown options in hop-by-hop and destination option extension headers. This option is enabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| drop-only              | This parameter is common to all of the above keywords.<br>Drops all packets. Drops the packet if matching any of the above specified types.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| log-and-drop           | Logs the event and drops the packet. Drops the packet, if matching any of the above specified types, and logs an event.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| log-only               | Logs the event only, the packet is not dropped. Does not drop the packet, if matching any of the above specified types. But an event is logged.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| log-level              | If selecting the “log-and-drop” and “log-only” action type, specify the log level. The options are: <ul style="list-style-type: none"> <li>• &lt;0-7&gt; – Sets the numeric logging level</li> <li>• alerts – Numerical severity 1. Indicates a condition where immediate action is required</li> <li>• critical – Numerical severity 2. Indicates a critical condition</li> <li>• debugging – Numerical severity 7. Debugging messages</li> <li>• emergencies – Numerical severity 0. System is unusable</li> <li>• errors – Numerical severity 3. Indicates an error condition</li> <li>• informational – Numerical severity 6. Indicates a informational condition</li> <li>• notifications – Numerical severity 5. Indicates a normal but significant condition</li> <li>• warnings – Numerical severity 4. Indicates a warning condition. This is the default setting.</li> </ul> |

| log-only  | Logs the event only, the packet is not dropped. Does not drop the packet, if matching any of the above specified “option” types. But an event is logged.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| log-level | <p>If selecting the “log-and-drop” and “log-only” action type, specify the log level. The options are:</p> <ul style="list-style-type: none"> <li>• &lt;0-7&gt; – Sets the numeric logging level</li> <li>• alerts – Numerical severity 1. Indicates a condition where immediate action is required</li> <li>• critical – Numerical severity 2. Indicates a critical condition</li> <li>• debugging – Numerical severity 7. Debugging messages</li> <li>• emergencies – Numerical severity 0. System is unusable</li> <li>• errors – Numerical severity 3. Indicates an error condition</li> <li>• informational – Numerical severity 6. Indicates a informational condition</li> <li>• notifications – Numerical severity 5. Indicates a normal but significant condition</li> <li>• warnings – Numerical severity 4. Indicates a warning condition. This is the default setting.</li> </ul> |

```
ipv6 [firewall enable|rewrite-flow-label]
```

|                    |                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------|
| firewall enable    | Enables IPv6 firewall. This option is enabled by default.                               |
| rewrite-flow-label | Rewrites the IPv6 flow label field of every packet. This option is disabled by default. |

### Examples

```

### *ipv6-mac*

Defines an action based on conflicts detected in a device’s IPv6 and MAC addresses

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
ipv6-mac [conflict|routing]
ipv6-mac conflict [drop-only|log-and-drop|log-only]
ipv6-mac routing conflict [drop-only|log-and-drop|log-only]
```

### Parameters

```
ipv6-mac conflict [drop-only|log-and-drop|log-only]
```

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| conflict     | Enables detection of conflict between a device's IPv6 and MAC addresses. This option is enabled by default. This command also specifies the action to be performed when a such a conflict is detected. The options are: drop-only, log-and-drop, and log-only.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| drop-only    | Drops a packet (with conflicting IPv6 and MAC address) without logging                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| log-and-drop | Logs the event and drops the packet. This is the default setting.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| log-only     | Logs the event only, the packet is not dropped                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| log-level    | If selecting the "log-and-drop" and "log-only" action type, specify the log level. The options are: <ul style="list-style-type: none"><li>• &lt;0-7&gt; – Sets the numeric logging level</li><li>• alerts – Numerical severity 1. Indicates a condition where immediate action is required</li><li>• critical – Numerical severity 2. Indicates a critical condition</li><li>• debugging – Numerical severity 7. Debugging messages</li><li>• emergencies – Numerical severity 0. System is unusable</li><li>• errors – Numerical severity 3. Indicates a normal but significant condition</li><li>• warnings – Numerical severity 4. Indicates a warning condition. This is the default setting.</li></ul> |

```
ipv6-mac routing conflict [drop-only|log-and-drop|log-only]
```

|                  |                                                                                                                                                                                                                                                                    |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| routing conflict | Enables detection of conflict between the next-hop's IPv6 and MAC addresses. This option is enabled by default. This command also specifies the action to be performed when a such a conflict is detected. The options are: drop-only, log-and-drop, and log-only. |
| drop-only        | Drops a packet (with conflicting next-hop IPv6 and MAC addresses) without logging                                                                                                                                                                                  |
| log-and-drop     | Logs the event and drops the packet. This is the default setting.                                                                                                                                                                                                  |

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| log-only  | Logs the event only, the packet is not dropped                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| log-level | <p>If selecting the “log-and-drop” and “log-only” action type, specify the log level. The options are:</p> <ul style="list-style-type: none"> <li>• &lt;0-7&gt; – Sets the numeric logging level</li> <li>• alerts – Numerical severity 1. Indicates a condition where immediate action is required</li> <li>• critical – Numerical severity 2. Indicates a critical condition</li> <li>• debugging – Numerical severity 7. Debugging messages</li> <li>• emergencies – Numerical severity 0. System is unusable</li> <li>• errors – Numerical severity 3. Indicates an error condition</li> <li>• informational – Numerical severity 6. Indicates a informational condition</li> <li>• notifications – Numerical severity 5. Indicates a normal but significant condition</li> <li>• warnings – Numerical severity 4. Indicates a warning condition. This is the default setting.</li> </ul> |

### Examples

```

nx9500-6C8809(config-fw-policy-testFW)#ipv6-mac routing conflict drop-only
nx9500-6C8809(config-fw-policy-testFW)#show context
firewall-policy testFW
 ip dos fraggle drop-only
 ip dos tcp-sequence-past-window drop-only
 ip dos tcp-max-incomplete high 600
 ip dos tcp-max-incomplete low 60
 ip-mac conflict drop-only
 ip-mac routing conflict log-and-drop log-level notifications
 flow timeout icmp 16000
 flow timeout udp 10000
 flow timeout tcp established 1500
 flow timeout other 16000
 dhcp-offer-convert

### logging

Configures enhanced firewall logging

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
logging [icmp-all|icmp-packet-drop|malformed-packet-drop|verbose]
logging icmp-all
logging verbose
logging [icmp-packet-drop|malformed-packet-drop] [all|rate-limited]
```

## Parameters

```
logging icmp-all
```

|          |                                                                                                       |
|----------|-------------------------------------------------------------------------------------------------------|
| logging  | Configures enhanced firewall logging parameters                                                       |
| icmp-all | Enables logging of all ICMPv4/v6 packets allowed by the firewall. This option is disabled by default. |

```
logging verbose
```

|         |                                                                           |
|---------|---------------------------------------------------------------------------|
| logging | Configures enhanced firewall logging. This option is disabled by default. |
| verbose | Enables verbose logging                                                   |

```
logging [icmp-packet-drop|malformed-packet-drop] [all|rate-limited]
```

|                       |                                                                                                                 |
|-----------------------|-----------------------------------------------------------------------------------------------------------------|
| logging               | Configures enhanced firewall logging                                                                            |
| icmp-packet-drop      | Enables logging of ICMP (ICMPv4 and ICMPv6) packets that do not pass sanity checks. The default is none.        |
| malformed-packet-drop | Enables logging of raw IP (IPv4 and IPv6) packets that do not pass sanity checks. The default is none.          |
| all                   | Logs all messages                                                                                               |
| rate-limited          | Enables rate-limited logging. This option sets the rate limit for log messages to one message every 20 seconds. |

## Examples

```
nx9500-6C8809(config-fw-policy-testFW)#logging verbose
nx9500-6C8809(config-fw-policy-testFW)#logging icmp-packet-drop rate-limited
nx9500-6C8809(config-fw-policy-testFW)#logging malformed-packet-drop all
nx9500-6C8809(config-fw-policy-testFW)#show context
firewall-policy testFW
 ip dos fraggle drop-only
 ip dos tcp-sequence-past-window drop-only
 ip dos tcp-max-incomplete high 600
 ip dos tcp-max-incomplete low 60
 ip-mac conflict drop-only
 ip-mac routing conflict log-and-drop log-level notifications
 flow timeout icmp 16000
 flow timeout udp 10000
 flow timeout tcp established 1500
 flow timeout other 16000
 dhcp-offer-convert
 ipv6 routing-type two log-and-drop log-level warnings
 ipv6 dos hop-limit-zero drop-only
 alg facetime
 logging icmp-packet-drop rate-limited
 logging malformed-packet-drop all
 logging verbose
 dns-snoop entry-timeout 1200
```

```
ipv6-mac routing conflict drop-only
nx9500-6C8809(config-fw-policy-testFW)#
nx9500-6C8809(config-fw-policy-test2)#show context
firewall-policy test2
 no ip dos tcp-sequence-past-window
nx9500-6C8809(config-fw-policy-test2)#
nx9500-6C8809(config-fw-policy-test2)#logging icmp-all
nx9500-6C8809(config-fw-policy-test2)#show context
firewall-policy test2
 no ip dos tcp-sequence-past-window
 logging icmp-all
nx9500-6C8809(config-fw-policy-test2)
```

### Related Commands

`no` on page 1510

Disables enhanced firewall logging

### *proxy-arp*

Enables the generation of ARP responses on behalf of another device. Proxy ARP allows the Firewall to handle ARP routing requests for devices behind the firewall. This option is enabled by default.

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
proxy-arp
```

#### Parameters

None

#### Examples

```
nx9500-6C8809(config-fw-policy-test)#proxy-arp
nx9500-6C8809(config-fw-policy-testFW)#show context include-factory | include proxy-arp
 proxy-arp
nx9500-6C8809(config-fw-policy-testFW)#
```

### Related Commands

`no` on page 1510

Disables the generation of ARP responses on behalf of another device

### *proxy-nd*

Enables generation of ND responses (for IPv6) on behalf of another device

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000

- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

proxy-nd

### Parameters

None

### Examples

```
nx9500-6C8809(config-fw-policy-testFW)#proxy-nd
nx9500-6C8809(config-fw-policy-testFW)#show context include-factory | include proxy-nd
proxy-nd
nx9500-6C8809(config-fw-policy-testFW)#
```

## *stateful-packet-inspection-12*

Enables layer 2 firewall stateful packet inspection. When enabled, allows stateful packet inspection for RF Domain manager routed interfaces within the layer 2 firewall. This option is enabled by default.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

stateful-packet-inspection-12

### Parameters

None

### Examples

```
nx9500-6C8809(config-fw-policy-testFW)#stateful-packet-inspection-12
```

### Related Commands

|                 |                                                           |
|-----------------|-----------------------------------------------------------|
| no on page 1510 | Disables stateful packet inspection in a layer 2 firewall |
|-----------------|-----------------------------------------------------------|

## *storm-control*

Enables storm control on the firewall policy

Storms are packet bombardments that exceed the high threshold value configured for an interface. During a storm, packets are throttled until the rate falls below the configured rate, severely impacting performance for the RF Domain manager interface.

Storm control limits multicast, unicast and broadcast frames accepted and forwarded by a device. Messages are logged based on their severity level.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
storm-control [arp|broadcast|multicast|unicast]
storm-control [arp|broadcast|multicast|unicast] [level|log]
storm-control [arp|broadcast|multicast|unicast] level <1-1000000>
[fe <1-4>|ge <1-8>|port-channel <1-8>|up1|wlan <WLAN-NAME>]
storm-control [arp|broadcast|multicast|unicast] log [<0-7>|alerts|critical|
debugging|emergencies|errors|informational|none|notifications|warnings]
```

### Parameters

```
storm-control [arp|broadcast|multicast|unicast] level <1-1000000>
[fe <1-4>|ge <1-8>|port-channel <1-8>|up1|wlan <WLAN-NAME>]
```

|                    |                                                                                                                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| arp                | Configures storm control for ARP packets                                                                                                                                                                        |
| broadcast          | Configures storm control for broadcast packets                                                                                                                                                                  |
| multicast          | Configures storm control for multicast packets                                                                                                                                                                  |
| unicast            | Configures storm control for unicast packets                                                                                                                                                                    |
| level <1-1000000>  | Configures the allowed number of packets received per second before storm control begins <ul style="list-style-type: none"> <li>• &lt;1-1000000&gt; - Sets the number of packets received per second</li> </ul> |
| fe <1-4>           | Sets the FastEthernet port for storm control from 1 - 4                                                                                                                                                         |
| ge <1-8>           | Sets the GigabitEthernet port for storm control from 1 - 8                                                                                                                                                      |
| port-channel <1-8> | Sets the port channel for storm control from 1- 8                                                                                                                                                               |
| up1                | Sets the uplink interface                                                                                                                                                                                       |
| wlan <WLAN-NAME>   | Configures the WLAN <ul style="list-style-type: none"> <li>• &lt;WLAN-NAME&gt; - Sets the WLAN ID for the storm control configuration</li> </ul>                                                                |

```
storm-control [arp|bcast|multicast|unicast] log [<0-7>|alerts|critical|debugging|
emergencies|errors|informational|none|notifications|warnings]
```

|           |                                                                                |
|-----------|--------------------------------------------------------------------------------|
| arp       | Configures storm control for ARP packets                                       |
| broadcast | Configures storm control for broadcast packets                                 |
| multicast | Configures storm control for multicast packets                                 |
| unicast   | Configures storm control for unicast packets                                   |
| log       | Configures the storm control log level for storm control events                |
| <0-7>     | Sets the numeric logging level from 0 - 7                                      |
| alerts    | Numerical severity 1. Indicates a condition where immediate action is required |

|               |                                                                    |
|---------------|--------------------------------------------------------------------|
| critical      | Numerical severity 2. Indicates a critical condition               |
| debugging     | Numerical severity 7. Debugging messages                           |
| emergencies   | Numerical severity 0. System is unusable                           |
| errors        | Numerical severity 3. Indicates an error condition                 |
| informational | Numerical severity 6. Indicates a informational condition          |
| none          | Disables storm control logging                                     |
| notification  | Numerical severity 5. Indicates a normal but significant condition |
| warnings      | Numerical severity 4. Indicates a warning condition                |

### *virtual-defragmentation*

Enables the virtual de-fragmentation of IPv4 and IPv6 packets. This parameter is required for optimal firewall functionality and is enabled by default.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
virtual-defragmentation {maximum-defragmentation-per-host <1-16384>|
maximum-fragments-per-datagram <2-8129>|minimum-first-fragment-length <8-1500>|timeout
<1-60>}
```

## Parameters

```
virtual-defragmentation {maximum-defragmentation-per-host <1-16384>|
maximum-fragments-per-datagram <2-8129>|minimum-first-fragment-length <8-1500>|timeout
<1-60>}
```

|                                            |                                                                                                                                                                                                                                                                    |
|--------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| maximum-defragmentation-per-host <1-16384> | Optional. Configures the maximum number of active de-fragmentations allowed per host before it is dropped (applicable to IPv4 and IPV6 packets) <ul style="list-style-type: none"><li>• &lt;1-16384&gt; - Sets a value from 1 - 16384. The default is 8.</li></ul> |
| maximum-fragments-per-datagram <2-8129>    | Optional. Configures the maximum number of fragments allowed in a datagram before it is dropped (applicable to IPv4 and IPV6 packets) <ul style="list-style-type: none"><li>• &lt;2-8129&gt; - Sets a value from 2 - 8129. The default is 140.</li></ul>           |
| minimum-first-fragment-length <8-1500>     | Optional. Defines the minimum length required for the first fragment (applicable to IPv4 and IPV6 packets) <ul style="list-style-type: none"><li>• &lt;8-1500&gt; - Sets a value from 8 - 1500 bytes. The default is 8 bytes.</li></ul>                            |
| timeout <1-60>                             | Optional. Configures a virtual de-fragmentation timeout, in seconds, applicable to both IPv4 and IPV6 packets <ul style="list-style-type: none"><li>• &lt;1-60&gt; - Specify a value from 1 - 60 seconds. The default is 1 second.</li></ul>                       |

## Examples

```
nx9500-6C8809(config-fw-policy-testFW)#virtual-defragmentation maximum-fragments-per-
datagram 10
nx9500-6C8809(config-fw-policy-testFW)#virtual-defragmentation minimum-first-fragment-
length 100
nx9500-6C8809(config-fw-policy-testFW)#show context include-factory | include virtual-
defragmentation
virtual-defragmentation
virtual-defragmentation minimum-first-fragment-length 100
virtual-defragmentation maximum-fragments-per-datagram 10
virtual-defragmentation maximum-defragmentation-per-host 8
virtual-defragmentation timeout 1
nx9500-6C8809(config-fw-policy-testFW)#
```

```

## Parameters

```
no <PARAMETERS>
```

|                 |                                                                             |
|-----------------|-----------------------------------------------------------------------------|
| no <PARAMETERS> | Removes this firewall policy settings or reverts settings to default value. |
|-----------------|-----------------------------------------------------------------------------|

## Examples

The following example shows the firewall policy 'test' settings before the 'no' command are executed:

```
nx9500-6C8809(config-fw-policy-testFW)#show context
firewall-policy testFW
 ip dos fraggle drop-only
 ip dos tcp-sequence-past-window drop-only
 ip dos tcp-max-incomplete high 600
 ip dos tcp-max-incomplete low 60
 storm-control broadcast level 20000 ge 4
 storm-control arp log warnings
 ip-mac conflict drop-only
 ip-mac routing conflict log-and-drop log-level notifications
 flow timeout icmp 16000
 flow timeout udp 10000
 flow timeout tcp established 1500
 flow timeout other 16000
 dhcp-offer-convert
 ipv6 routing-type two log-and-drop log-level warnings
 ipv6 dos hop-limit-zero drop-only
 alg facetime
```

```

logging icmp-packet-drop rate-limited
logging malformed-packet-drop all
logging verbose
virtual-defragmentation minimum-first-fragment-length 100
virtual-defragmentation maximum-fragments-per-datagram 10

nx9500-6C8809(config-fw-policy-testFW)#

```

# MiNT Security Policy

## MINT-POLICY

---

This chapter summarizes MiNT policy commands in the CLI command structure.

All communication using the MiNT transport layer can be optionally secured. This includes confidentiality, integrity and authentication of all communications. In addition, a device can be configured to communicate over MiNT with other devices authorized by an administrator.

Use the (config) instance to configure mint-policy related configuration commands. To navigate to the config MiNT policy instance, use the following command:

```
<DEVICE>(config)#mint-policy global-default
nx9500-6C8809(config-mint-policy-global-default)#?
Mint Policy Mode commands:
 level Mint routing level
 lsp LSP
 mtu Configure the global Mint MTU
 no Negate a command or set its defaults
 router Mint router
 udp Configure mint UDP/IP encapsulation

 clrscr Clears the display screen
 commit Commit all changes made in this session
 do Run commands from Exec mode
 end End current mode and change to EXEC mode
 exit End current mode and down to previous mode
 help Description of the interactive help system
 revert Revert changes
 service Service Commands
 show Show running system information
 write Write running configuration to memory or terminal

nx9500-6C8809(config-mint-policy-global-default)#
```

### mint-policy-commands

The following table summarizes MiNT policy configuration commands:

**Table 46: MiNT-Policy Config Mode Commands**

| Command                             | Description                                                                      |
|-------------------------------------|----------------------------------------------------------------------------------|
| <a href="#">level</a> on page 1514  | Configures the MiNT routing level                                                |
| <a href="#">lsp</a> on page 1515    | Enables adding of checksum to LSP messages forwarded across MiNT links           |
| <a href="#">mtu</a> on page 1515    | Configures the global MiNT MTU                                                   |
| <a href="#">router</a> on page 1516 | Configures the priority for MiNT router packets (HELLO, LSP, PSNP, and EXT VLAN) |

**Table 46: MiNT-Policy Config Mode Commands (continued)**

| Command                       | Description                                         |
|-------------------------------|-----------------------------------------------------|
| <code>udp</code> on page 1517 | Configures the MiNT UDP/IP encapsulation parameters |
| <code>no</code> on page 1517  | Negates a command or sets its default               |

**Note**

For more information on common commands (clrscr, commit, help, revert, service, show, write, and exit), see [COMMON COMMANDS](#) on page 640.

**Note**

The input parameter <HOSTNAME>, wherever used in syntaxes across this chapter, cannot include an underscore (\_) character. In other words, the name of a device cannot contain an underscore.

*level*

Configures the global MiNT routing level

**Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

**Syntax**

```
level 2 area-id <1-16777215>
```

**Parameters**

```
level 2 area-id <1-16777215>
```

|                                         |                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>level 2</code>                    | Configures level 2 inter-site MiNT routing                                                                                                                                                                                                                                                                                                                                                               |
| <code>area-id &lt;1-16777215&gt;</code> | Configures the routing area identifier <ul style="list-style-type: none"> <li>• <code>&lt;1-16777215&gt;</code> – Specify a value from 1 - 16777215.</li> </ul> <p>The level 2 area ID is the global MiNT area identifier. This area identifier separates two overlapping MiNT networks. Configure the level 2 area ID only if there are two MiNT networks sharing the same packet broadcast domain.</p> |

**Examples**

```
nx9500-6C8809(config-mint-policy-global-default)#level 2 area-id 2000
nx9500-6C8809(config-mint-policy-global-default)#show context
mint-policy global-default
 level 2 area-id 2000
nx9500-6C8809(config-mint-policy-global-default)#
```

## *lsp*

Enables adding of checksum to LSP (label-switched path) messages forwarded across MiNT links. When enabled, this option helps to verify integrity of LSP messages. LSP messages exchanged over MiNT links are often corrupted. These LSP corruptions cause inaccuracies in the SPF (Shortest Path First) calculation process, leading to access point adoption related issues. Enabling LSP checksum helps troubleshooting adoption-related issues.

### **Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### **Syntax**

```
lsp checksum
```

### **Parameters**

```
lsp checksum
```

|              |                                                                                                                                                                                                                                                                                     |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| lsp checksum | Enables adding of checksum to LSP messages forwarded across MiNT links. When enabled, the integrity of LSP messages is verified by matching the LSP message checksum at the MiNT link end nodes. In case of a match the message is uncorrupted. This option is disabled by default. |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### **Examples**

```
nx9500-6C8809(config-mint-policy-global-default)#lsp checksum
nx9500-6C8809(config-mint-policy-global-default)#show context
mint-policy global-default
 lsp checksum
nx9500-6C8809(config-mint-policy-global-default)#
```

|-----------------|-------------------------------------------------------------------------|
| no on page 1517 | Disables adding of checksum to LSP messages forwarded across MiNT links |
|-----------------|-------------------------------------------------------------------------|

## *mtu*

Configures global MiNT MTU (Multiple Transmission Unit). Use this command to specify the maximum packet size, in bytes, for MiNT routing. Higher the MTU values, greater is the network efficiency. The user data per packet increases, while protocol overheads, such as headers or underlying per-packet delays remain the same.

### **Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
mtu <900-1500>
```

## Parameters

```
mtu <900-1500>
```

|                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| mtu <900-1500> | Specifies the maximum packet size from 900 - 1500 bytes<br>The maximum packet size specified is rounded down to a value using the following formula: 4 + a multiple of 8.<br>The MTU setting specifies the maximum packet size used for MiNT packets. Larger packets are fragmented to fit within the specified packet size limit. You may want to configure this parameter if the MiNT backhaul network requires or recommends smaller packet sizes. The default value is 1500 bytes. |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Examples

```
nx9500-6C8809(config-mint-policy-global-default)#mtu 1000
nx9500-6C8809(config-mint-policy-global-default)#show context
mint-policy global-default
 mtu 996
 level 2 area-id 2
nx9500-6C8809(config-mint-policy-global-default)#
```

## router

Configures the priority for MiNT router packets (HELLO, LSP, PSNP, and EXTVLAN)

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
router packet priority <0-7>
```

## Parameters

```
router packet priority <0-7>
```

|                              |                                                                                                                                                                                                           |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| router packet priority <0-7> | Allows you to configure the priority for MiNT router packets from 0 - 7. The default is 5.<br><br><b>Note:</b> Higher the value higher is the priority. Therefore, seven (7) represents highest priority. |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Examples

```
rfs4000-229D58(config-mint-policy-global-default)#router packet priority 4
rfs4000-229D58(config-mint-policy-global-default)#show context
mint-policy global-default
```

```
router packet priority 4
rfs4000-229D58(config-mint-policy-global-default)#
```

|------------------------------|--------------------------------------------------------|

### udp

Configures MiNT UDP/IP encapsulation parameters. Use this command to configure the default UDP port used for MiNT control packet encapsulation.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
udp port <2-65534>
```

### Parameters

```
udp port <2-65534>
```

|                                   |                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>port &lt;2-65534&gt;</code> | Configures default UDP port used for MiNT control packet encapsulation <ul style="list-style-type: none"><li>• <code>&lt;2-65534&gt;</code> – Enter a value from 2 - 65534. This value specifies an alternate UDP port used by MiNT control packets and must be an even number. The specified port number plus 1 is used to carry MiNT data packets. The default value is 24576.</li></ul> |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Examples

```
nx9500-6C8809(config-mint-policy-global-default)#udp port 1024
nx9500-6C8809(config-mint-policy-global-default)#show context
mint-policy global-default
 udp port 1024
 mtu 996
 level 2 area-id 2000
 sign-unknown-device
 security-level control-and-data
 rejoin-timeout 1000
nx9500-6C8809(config-mint-policy-global-default)#
```

### Related Commands

|                              |                                                  |
|------------------------------|--------------------------------------------------|
| <code>no</code> on page 1517 | Reverts MiNT UDP/IP encapsulation to its default |
|------------------------------|--------------------------------------------------|

### no

Negates a command or reverts values to their default. When used in the config MiNT policy mode, the no command resets or reverts the following global MiNT policy parameters: routing level, MTU, router packet priority, and UDP or IP encapsulation settings.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
no [level|lsp|mtu|router|udp]
no level 2 area-id
no lsp checksum
no mtu
no router packet priority
no udp port <LINE-SINK>
```

### Parameters

```
no <PARAMETERS>
```

no <PARAMETERS> The **no** command resets or reverts the following global MiNT policy parameters: routing level, MTU, router packet priority, and UDP or IP encapsulation settings.

### Examples

The following example shows the global Mint Policy parameters before the 'no' commands are executed:

```
nx9500-6C8809(config-mint-policy-global-default)#show context
mint-policy global-default
 udp port 1024
 mtu 996
 level 2 area-id 2000
 sign-unknown-device
 security-level control-and-data
 rejoin-timeout 1000
nx9500-6C8809(config-mint-policy-global-default)#
nx9500-6C8809(config-mint-policy-global-default)#no level 2 area-id
nx9500-6C8809(config-mint-policy-global-default)#no mtu
nx9500-6C8809(config-mint-policy-global-default)#no udp port
```

The following example shows the global Mint Policy parameters after the 'no' commands are executed:

```
nx9500-6C8809(config-mint-policy-global-default)#show context
mint-policy global-default
 sign-unknown-device
 security-level control-and-data
 rejoin-timeout 1000
nx9500-6C8809(config-mint-policy-global-default)#
```

# MANAGEMENT POLICY

## MANAGEMENT-POLICY

---

This chapter summarizes management policy commands in the CLI command structure.

A management policy contains configuration elements for managing a device, such as access control, SNMP, admin user credentials, and roles.

A controller (wireless controller, access point, or service platform) uses mechanisms to allow or deny device access to separate interfaces and protocols (HTTP, HTTPS, Telnet, SSH or SNMP). Management access can be enabled or disabled as required for unique policies. The management access functionality is not meant to function as an ACL (in routers or other firewalls), where administrators specify and customize specific IPs to access specific interfaces.

Controllers and service platforms can be managed using multiple interfaces (SNMP, CLI, and Web UI). By default, management access is unrestricted, allowing management access to any enabled IP interface from any host using any enabled management service.

To enhance security, administrators can apply various restrictions as needed to:

- Restrict SNMP, CLI and Web UI access to specific hosts or subnets.
- Disable un-used and insecure interfaces as required within managed access profiles. Disabling un-used management services can dramatically reduce an attack footprint and free resources on managed devices.
- Provide authentication for management users.
- Apply access restrictions and permissions to management users.

Management restrictions can be applied to meet specific policies or industry requirements requiring only certain devices or users be granted access to critical infrastructure devices. Management restrictions can also be applied to reduce the attack footprint of the device when guest services are deployed.

Access points utilize a single management access policy, so ensure all the intended administrative roles, permissions, authentication and SNMP settings are correctly set. If an access point is functioning as a virtual controller AP, these are the access settings used by adopted access points of the same model as the virtual controller AP.

It is recommended to disable un-used and insecure interfaces as required within managed access profiles. Disabling un-used management services can dramatically reduce an attack footprint and free resources on managed devices.

Use the (config) instance to configure a management policy. To navigate to the config management policy instance, use the following commands:

```
<DEVICE> (config)#management-policy <POLICY-NAME>
```

To commit a management-policy, at least one admin user account must always be present in the management-policy:

```
<DEVICE>(config-management-policy-<POLICY-NAME>)#user admin password 0 test role superuser
access all
<DEVICE>(config-management-policy-<POLICY-NAME>)#
nx9500-6C8809(config-management-policy-test)#?
Management Mode commands:
 aaa-login Set authentication for logins
 allowed-locations Add allowed locations
 banner Define a login banner
 ftp Enable FTP server
 http Hyper Text Terminal Protocol (HTTP)
 https Secure HTTP
 idle-session-timeout Configure idle timeout for a configuration session
 (GUI or CLI)
 ipv6 IPv6 Protocol
 no Negate a command or set its defaults
 passwd-retry Lockout user if too many consecutive login failures
 privilege-mode-password Set the password for entering CLI privilege mode
 rest-server Enable rest server for device on-boarding
 functionality
 restrict-access Restrict management access to the device
 snmp-server SNMP
 ssh Enable ssh
 t5 T5 configuration
 telnet Enable telnet
 user Add a user account

 clrscr Clears the display screen
 commit Commit all changes made in this session
 do Run commands from Exec mode
 end End current mode and change to EXEC mode
 exit End current mode and down to previous mode
 help Description of the interactive help system
 revert Revert changes
 service Service Commands
 show Show running system information
 write Write running configuration to memory or terminal

nx9500-6C8809(config-management-policy-test)#
```

## management-policy-commands

The following table summarizes management policy configuration mode commands:

**Table 47: Management-Policy Config Mode Commands**

| Command                                        | Description                                                                                                            |
|------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| <a href="#">aaa-login</a>                      | Configures login authentication settings                                                                               |
| <a href="#">allowed-locations</a> on page 1523 | Configures a user-role based access control to RF Domains and locations with respect to the NSight UI (user interface) |
| <a href="#">banner</a>                         | Configures the MOTD (message of the day) text                                                                          |
| <a href="#">ftp</a>                            | Enables FTP on this management policy                                                                                  |
| <a href="#">http</a>                           | Enables HTTP on this management policy                                                                                 |
| <a href="#">https</a>                          | Enables HTTPS on this management policy                                                                                |

**Table 47: Management-Policy  
Config Mode Commands  
(continued)**

| Command                                                   | Description                                                                                                                                       |
|-----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>idle-session-timeout</code>                         | Sets the interval after which an idle session is terminated                                                                                       |
| <code>ipv6 (management-policy)</code> on page 1529        | Restricts management access to specified hosts and/or subnets based on their IPv6 addresses and prefixes respectively                             |
| <code>no</code>                                           | Removes or resets this management policy's settings                                                                                               |
| <code>password-entry</code> on page 1530                  | Configures user-account lockout and unlock parameters                                                                                             |
| <code>privilege-mode-password</code>                      | Configures the CLI's privilege mode access password                                                                                               |
| <code>rest-server (management-policy)</code> on page 1534 | Enables the REST (Representational State Transfer) server to facilitate device on-boarding                                                        |
| <code>restrict-access</code>                              | Restricts management access to a set of hosts or subnets                                                                                          |
| <code>snmp-server</code>                                  | Sets the SNMP server settings on this management policy                                                                                           |
| <code>ssh</code>                                          | Enables SSH on this management policy                                                                                                             |
| <code>t5 (management-policy)</code> on page 1542          | Configures SNMP server settings for T5 devices on this management policy. This command is available only RFS 4000, NX 95XX and NX 96XX platforms. |
| <code>telnet</code>                                       | Enables Telnet on this management policy                                                                                                          |
| <code>user</code>                                         | Creates a new user account                                                                                                                        |
| <code>service</code>                                      | Invokes service commands to troubleshoot or debug (config-if) instance configurations                                                             |

**Note**

For more information on common commands (clrscr, commit, help, revert, service, show, write, and exit), see [COMMON COMMANDS](#) on page 640.

**Note**

The input parameter <HOSTNAME>, wherever used in syntaxes across this chapter, cannot include an underscore ( \_ ) character. In other words, the name of a device cannot contain an underscore.

*aaa-login*

Configures AAA (Authentication, Authorization and Accounting) modes used with this management policy

**Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
aaa-login [local|radius|tacacs]
aaa-login local
aaa-login radius [external|fallback|policy]
aaa-login radius [external|fallback|policy <AAA-POLICY-NAME>]
aaa-login tacacs [accounting|authentication|authorization|fallback|policy <AAA-TACACS-
POLICY-NAME>]
```

## Parameters

```
aaa-login local
```

|       |                                                                                                                                |
|-------|--------------------------------------------------------------------------------------------------------------------------------|
| local | Sets local as the preferred authentication mode. Local authentication uses the local username database to authenticate a user. |
|-------|--------------------------------------------------------------------------------------------------------------------------------|

```
aaa-login radius [external|fallback|policy <AAA-POLICY-NAME>]
```

|                          |                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| radius                   | Configures the RADIUS server parameters<br><br><b>Note:</b> If local authentication is disabled, use this command to specify if the RADIUS server used is external, fallback, or specified by a AAA policy.                                                                                                                                                                          |
| external                 | Configures external RADIUS server as the preferred authentication server                                                                                                                                                                                                                                                                                                             |
| fallback                 | Configures RADIUS server authentication as the primary authentication mode. When RADIUS server authentication fails, the system uses local authentication. This command configures local authentication as a backup mode.                                                                                                                                                            |
| policy <AAA-POLICY-NAME> | Associates a specified AAA policy with this management policy. The AAA policy determines if a client is granted access to the network. <ul style="list-style-type: none"><li>• &lt;AAA-POLICY-NAME&gt; - Specify the AAA policy name (should be existing and configured).</li></ul><br><b>Note:</b> For more information on configuring AAA policy, see <a href="#">AAA-POLICY</a> . |

```
aaa-login tacacs [accounting|authentication|authorization|fallback|policy <AAA-TACACS-
POLICY-NAME>]
```

|                                 |                                                                                                                                                                                                                                                                                                                                            |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tacacs                          | Configures TACACS (Terminal Access Control Access-Control System) server parameters                                                                                                                                                                                                                                                        |
| accounting                      | Configures TACACS accounting                                                                                                                                                                                                                                                                                                               |
| authentication                  | Configures TACACS authentication                                                                                                                                                                                                                                                                                                           |
| authorization                   | Configures TACACS authorization                                                                                                                                                                                                                                                                                                            |
| fallback                        | Configures TACACS as the primary authentication mode. When TACACS authentication fails, the system uses local authentication. This command configures local authentication as a backup mode.                                                                                                                                               |
| policy <AAA-TACACS-POLICY-NAME> | Associates a specified AAA TACACS policy with this management policy <ul style="list-style-type: none"><li>• &lt;AAA-TACACS-POLICY-NAME&gt; - Specify the TACACS policy name (should be existing and configured).</li></ul><br><b>Note:</b> For more information on configuring AAA TACACS policy, see <a href="#">AAA-TACACS-POLICY</a> . |

## Usage Guidelines

Use AAA login to determine whether management user authentication must be performed against a local user database or an external RADIUS server.

## Examples

```
rfs4000-6DB5D4(config-management-policy-test)#aaa-login radius policy test
rfs4000-6DB5D4(config-management-policy-test)#show context
management-policy test
 http server
 no ssh
 aaa-login radius policy test
rfs4000-6DB5D4(config-management-policy-test)#
```

## Related Commands

|-----------------|-------------------------------------------|
| <code>no</code> | Removes the TACACS server policy settings |
|-----------------|-------------------------------------------|

### *allowed-locations*

Configures a user-role based access control to RF Domains and locations with respect to the NSight UI (user interface). When configured, this access control is enforced only on the NSight UI. The WiNG and NSight applications may have the same users with different permissions defined in each application. Various user roles are supported in WiNG (superuser, system-admin, network-admin, security-admin, device-provisioning-admin, helpdesk and monitor). With NSight, users logging into the NSight UI should also have an access control restriction based on the role they are assigned. For example, a WiNG user with helpdesk privileges should have access to only the site (RF Domain) in which the helpdesk is situated, and the location tree should contain only one RF Domain. Similarly, when a user responsible for a set of sites logs in NSight, their location tree needs to contain the RF Domains for which they are responsible.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
allowed-locations <WORD> locations [NONE|ALL|<LIST-OF-LOCATIONS>]
```

### Parameters

```
allowed-locations <WORD> locations [NONE|ALL|<LIST-OF-LOCATIONS>]
```

|                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| allowed-locations <WORD>                 | Configures a location tag and associates a list locations with the tag <ul style="list-style-type: none"> <li>• &lt;WORD&gt; – Provide a location tag not exceeding 32 characters in length</li> </ul>                                                                                                                                                                                                                                                                               |
| locations [NONE ALL] <LIST-OF-LOCATIONS> | Associates locations with the above created location tag <ul style="list-style-type: none"> <li>• NONE – When specified, states that none of the locations are to be allowed access.</li> <li>• ALL – When specified, states that all the locations are to be allowed access.</li> <li>• &lt;LIST-OF-LOCATIONS&gt; – Specifies a list of locations or individual RF Domains. When specified, states that the specified list of locations or RF Domain are allowed access.</li> </ul> |

### Example

```

nx9500-6C8809(config-management-policy-test)#allowed-locations Ecospace locations TechPubs
ALL
nx9500-6C8809(config-management-policy-test)#allowed-locations TEST locations NONE
nx9500-6C8809(config-management-policy-test)#show context
management-policy test
 no telnet
 no http server
 https server
 ssh
 allowed-location TEST locations NONE
 allowed-location Ecospace locations TechPubs ALL
nx9500-6C8809(config-management-policy-test)#

```

|-----------------|-------------------------|

## ftp

Enables FTP (File Transfer Protocol) on this management policy. FTP is the standard protocol for transferring files over a TCP/IP network. FTP requires administrators enter a valid username and password authenticated locally. FTP access is disabled by default.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
ftp {password/rootdir/username}
ftp {password [1 <ENCRYPTED-PASSWORD>|<PASSWORD>]}
ftp {rootdir <DIR>}
ftp {username <USERNAME> password [1 <ENCRYPTED-PASSWORD>|<PASSWORD>] rootdir <DIR>}
```

## Parameters

```
ftp {password [1 <ENCRYPTED-PASSWORD>|<PASSWORD>]}
```

|                        |                                                                                                                                                                                                                                                                    |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ftp password           | Optional. Configures the FTP server password                                                                                                                                                                                                                       |
| 1 <ENCRYPTED-PASSWORD> | Configures an encrypted password. Use this option when copy pasting the password from another device. <ul style="list-style-type: none"><li>• &lt;ENCRYPTED-PASSWORD&gt; - Specify the password. The password should not exceed 63 characters in length.</li></ul> |
| <PASSWORD>             | Configures a clear text password                                                                                                                                                                                                                                   |

```
ftp {rootdir <DIR>}
```

|                   |                                                                                                                                                                                                         |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ftp rootdir <DIR> | Optional. Configures the root directory for FTP logins <ul style="list-style-type: none"><li>• &lt;DIR&gt; - Specify the root directory path. By default the root directory is set to flash:/</li></ul> |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
ftp {username <USERNAME> password [1 <ENCRYPTED-PASSWORD>|<PASSWORD>] rootdir <DIR>}
```

|                                              |                                                                                                                                                                                                                                                                                                                               |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ftp username <USERNAME>                      | Optional. Configures a new user account on the FTP server. The FTP user file lists users with FTP server access. <ul style="list-style-type: none"> <li>&lt;USERNAME&gt; - Specify the username. The username should not exceed 32 characters in length.</li> </ul>                                                           |
| password [1 <ENCRYPTED-PASSWORD> <PASSWORD>] | Configures an encrypted password <ul style="list-style-type: none"> <li>1 &lt;ENCRYPTED-PASSWORD&gt; - Specifies an encrypted password (use this option if copy pasting from another device). The password should not exceed 63 characters in length.</li> <li>&lt;PASSWORD&gt; - Configures a clear text password</li> </ul> |
| rootdir <DIR>                                | After specifying the password, configure the FTP root directory. <ul style="list-style-type: none"> <li>rootdir &lt;DIR&gt; - Configures the root directory for FTP logins. Specify the root directory path.</li> </ul>                                                                                                       |

### Usage Guidelines

The string size of an encrypted password (option 1, password is encrypted with a SHA1 algorithm) must be exactly 40 characters. Copy paste the encrypted password here.

### Examples

```
rfs4000-6DB5D4(config-management-policy-test)#ftp username superuser password test@123
rootdir dir
rfs4000-6DB5D4(config-management-policy-test)#show context
management-policy test
 http server
 ftp username superuser password 1
f617ca50c59fb47028f96db4baab5f3d8f03c03ab257960b0fd127c69f02cd7e rootdir dir
 no ssh
 aaa-login radius external
 aaa-login radius policy test
 banner motd "Have a Good Day"
rfs4000-6DB5D4(config-management-policy-test)#
```

### Related Commands

|-----------|---------------------------------------------------------------------------------------|
| <b>no</b> | Disables FTP and its settings, such as the server password, root directory, and users |
|-----------|---------------------------------------------------------------------------------------|

### http

Enables HTTPS (Hyper Text Transport Protocol) on this management policy

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
http server
```

### Parameters

```
http server
```

`http server` Enables HTTP on this management policy. HTTP provides limited authentication and no encryption.

### Examples

```
rfs4000-6DB5D4(config-management-policy-test)#http server
rfs4000-6DB5D4(config-management-policy-test)#show context
management-policy test
 http server
 ftp username superuser password 1
f617ca50c59fb47028f96db4baab5f3d8f03c03ab257960b0fd127c69f02cd7e rootdir dir
no ssh
aaa-login radius external
aaa-login radius policy test
banner motd "Have a Good Day"
rfs4000-6DB5D4(config-management-policy-test)#
```

### Related Commands

`no` Disables HTTP on this management policy

### *https*

Enables HTTPS (Hyper Text Transport Protocol Secure) on this management policy

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
[server|sslv3|use-secure-ciphers-only]
```

### Parameters

```
[server|sslv3|use-secure-ciphers-only]
```

|                                      |                                                                                                                                                                                                                                                      |
|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>https server</code>            | Configures secure HTTP related parameters on this management policy                                                                                                                                                                                  |
| <code>server</code>                  | Enables HTTPS on this management policy. HTTPS provides both authentication and data encryption as opposed to just authentication. This option is enabled by default.                                                                                |
| <code>sslv3</code>                   | Enables the use of SSLv3 protocol to connect to a Web page. When enabled, SSLv2 Web authentication is disabled, and enforces the use of Web browsers supporting SSLv3, which is a more secure protocol. This option is disabled by default.          |
| <code>use-secure-ciphers-only</code> | Enables the use of TLS v1.2 ciphers to secure client-server network communications. When enabled, for HTTPS connections the TLS v1.2 protocol is used, instead of the less secure TLS v1.0 or TLS v1.1 protocols. This option is enabled by default. |

### Examples

```
rfs4000-6DB5D4(config-management-policy-test)#https server
rfs4000-6DB5D4(config-management-policy-test)#show context
management-policy test
 http server
 https server
 ftp username superuser password 1
```

```
f617ca50c59fb47028f96db4baab5f3d8f03c03ab257960b0fd127c69f02cd7e rootdir dir
no ssh
aaa-login radius external
aaa-login radius policy test
banner motd "Have a Good Day"
rfs4000-6DB5D4(config-management-policy-test)#
```

The following example shows that the 'use-secure-ciphers-only' option is enabled by default:

```
rfs4000-6DB5D4(config-management-policy-default)#show context include-factory | include
https
https server
no https sslv3
https use-secure-ciphers-only
rfs4000-6DB5D4(config-management-policy-default)#
```

### Related Commands

|                 |                                          |
|-----------------|------------------------------------------|
| <code>no</code> | Disables HTTPS on this management policy |
|-----------------|------------------------------------------|

### *idle-session-timeout*

Configures a session's idle timeout. An idle session is automatically terminated after the specified interval is exceeded.

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
idle-session-timeout <1-4320>
```

### Parameters

```
idle-session-timeout <1-4320>
```

|                             |                                                                                                                                            |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;1-4320&gt;</code> | Sets the interval, in minutes, after which an idle session is timed out. Specify a value from 1 - 4320 minutes. The default is 30 minutes. |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|

### Examples

```
rfs4000-6DB5D4(config-management-policy-test)#idle-session-timeout 100
rfs4000-6DB5D4(config-management-policy-test)#show context
management-policy test
http server
https server
ftp username superuser password 1
7ccb4568cb83e54f1e402f785a78ee930a453afda152baaf7c2b79277f225872 rootdir dir
no ssh
aaa-login radius external
aaa-login radius policy test
idle-session-timeout 100
banner motd "Have a Good Day"
rfs4000-6DB5D4(config-management-policy-test)#
```

|-----------------|---------------------------------------------------|
| <code>no</code> | Removes the configured idle session timeout value |
|-----------------|---------------------------------------------------|

### *ipv6 (management-policy)*

Restricts management access to specified hosts and/or subnets based on their IPv6 addresses and prefixes respectively

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
ipv6 restrict-access [host|ipv6-access-list|subnet]
ipv6 restrict-access host <IPv6> {log|subnet}
ipv6 restrict-access host <IPv6> {log [all|denied-only]}
ipv6 restrict-access host <IPv6> {subnet <IPv6-PREFIX> {log [all|denied-only]}}
ipv6 restrict-access ipv6-access-list <IPv6-ACCESS-LIST-NAME>
ipv6 restrict-access subnet <IPv6-PREFIX> {host|log}
ipv6 restrict-access subnet <IPv6-PREFIX> {log [all|denied-only]}
ipv6 restrict-access subnet <IPv6-PREFIX> {host <IPv6> {log [all|denied-only]}}
```

#### Parameters

```
ipv6 restrict-access host <IPv6> {log [all|denied-only]}
```

|                       |                                                                                                                                                                                                                                                             |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| host <IPv6>           | Restricts management access to a specified host, based on the host's IPv6 address <ul style="list-style-type: none"><li>• &lt;IPv6&gt; - Specify the host's IPv6 address.</li></ul>                                                                         |
| log [all denied-only] | Optional. Configures a logging policy for access requests <ul style="list-style-type: none"><li>• all - Logs all access requests, both denied and permitted</li><li>• denied-only - Logs only denied access events (when a host is denied access)</li></ul> |

```
ipv6 restrict-access host <IPv6> {subnet <IPv6-PREFIX> {log [all|denied-only]}}
```

|                       |                                                                                                                                                                                                                                                                    |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| host <IPv6>           | Restricts management access to a specified host, based on the host's IPv6 address <ul style="list-style-type: none"><li>• &lt;IPv6&gt; - Specify the host's IPv6 address.</li></ul>                                                                                |
| subnet <IPv6-PREFIX>  | Optional. Restricts access to the host on a specified IPv6 subnet <ul style="list-style-type: none"><li>• &lt;IPv6-PREFIX&gt; - Specify the subnet's IPv6 prefix in the X:X::X:X/M format.</li></ul>                                                               |
| log [all denied-only] | Optional. Configures a logging policy for access requests <ul style="list-style-type: none"><li>• all - Logs all access requests, both denied and permitted</li><li>• denied-only - Logs only denied access events (when a host/subnet is denied access)</li></ul> |

```
ipv6 restrict-access ipv6-access-list <IPv6-ACCESS-LIST-NAME>
```

|                                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ipv6-access-list &lt;IPv6-ACCESS-LIST-NAME&gt;</code> | <p>Uses an IPv6 ACL (Access Control List) to filter access requests. IPv6 ACLs filter/mark packets based on the IPv6 address from which they arrive. IPv6 hosts configure themselves automatically when connected to an IPv6 network using the ND (neighbor discovery) protocol via ICMPv6 router discovery messages. These hosts require firewall packet protection unique to IPv6 traffic, as IPv6 addresses are composed of eight groups of four hexadecimal digits separated by colons. An existing IPv6 ACL can be created and used in the management policy context to permit or deny access to specific hosts and/or subnets.</p> <ul style="list-style-type: none"> <li>• <code>&lt;IPv6-ACCESS-LIST-NAME&gt;</code> - Specify the IPv6 ACL name.</li> </ul> |
|-------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
ipv6 restrict-access subnet <IPv6-PREFIX> {log [all|denied-only]}
```

### *password-entry*

Configures user-account lockout and unlock parameters. Use this option to configure the maximum number of consecutive, failed login attempts allowed before an account is locked out, and the duration of lockout.

## Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
passwd-entry role [device-provisioning-admin|helpdesk|monitor|network-admin|security-admin|superuser|system-admin|vendor-admin|web-user-admin] max-fail <1-100> lockout-time <0-600>
```

## Parameters

```
passwd-entry role [device-provisioning-admin|helpdesk|monitor|network-admin|security-admin|superuser|system-admin|vendor-admin|web-user-admin] max-fail <1-100> lockout-time <0-600>
```

|                                                                                                                                                                                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <pre>passwd-entry role [device-provisioning-admin helpdesk monitor network-admin security-admin superuser system-admin vendor-admin web-user-admin] max-fail &lt;1-100&gt; lockout-time &lt;0-600&gt;</pre> | <p>Configures user-role based account lockout criteria</p> <ul style="list-style-type: none"><li>• role - Select the user-role. The options are:<ul style="list-style-type: none"><li>• device-provisioning-admin</li><li>• helpdesk</li><li>• monitor</li><li>• network-admin</li><li>• security-admin</li><li>• system-admin</li><li>• vendor-admin</li><li>• web-user-admin</li></ul></li></ul> <p>max-fail &lt;1-100&gt; - Specify the maximum number of consecutive, failed attempts allowed before an account is locked. Specify a value from 1 - 100.</p> <p>lockout-time &lt;&lt;0-600&gt;&gt; - Specify the maximum time, in minutes, for which an account remains locked. The value '0' indicates that the account is permanently locked. Specify a value from 0 - 600 minutes.</p> <p>When configured, the lockout is individually applied to each account within the specified role/roles. For example, consider the 'monitor' role having two users: 'user1' and 'user2'. The max-fail and lockout-time is set at '5' attempts and '10' minutes respectively. In this scenario, user2 makes 5 consecutive, failed login attempts, and the user2 account is locked out for 10 minutes. However, during this lockout time the user1 account remains active.</p> <p><b>Note:</b> In the event-system-policy context, enable 'login-lockout' and 'login-unlocked' event notification to trigger e-mail or syslog notification to users on occurrence of the login-lockout and login-unlock events. For more information, see <a href="#">event</a> on page 378.</p> |

### *privilege-mode-password*

Configures the CLI's privilege mode access password. Use this option to strengthen security by enforcing a second level authentication to access the privilege configuration mode.

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
privilege-mode-password <PASSWORD/HASHED-STRING-ALIAS-NAME>
```

#### Parameters

```
privilege-mode-password <PASSWORD/HASHED-STRING-ALIAS-NAME>
```

|                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <PASSWORD/HASHED-STRING-ALIAS-NAME> | <p>&lt;PASSWORD/HASHED-STRING-ALIAS-NAME&gt; - Enter the password as a clear text, or provide a hashed-string alias. Enter the password as a clear text, or provide a hashed-string alias. If using a hashed-string alias, ensure that the alias is existing and configured.</p> <p><b>Note:</b> The clear text password is saved and displayed as a hashed string. Hashing is a means of establishing the integrity of transmitted messages. Before transmission, a hash of the message is generated, encrypted and sent along with the message. At the receiving end, the message and the hash are both decrypted, and another hash is generated from the received message. The two hashes are compared. If both are identical the message is considered to have been transmitted intact.</p> <p><b>Note:</b> For more information on configuring a hashed-string alias, see alias.</p> |

## Examples

The following example shows the privilege mode password being configured as a hashed string:

```
rfs4000-6DB5D4(config-management-policy-test)#privilege-mode-password 1
2e9f038ac2ed27f919ed5a4dceb3d30e32f356f2ceff6fbf26a153d0339c734f
rfs4000-6DB5D4(config-management-policy-test)#show context
management-policy test
 http server
 no ssh
 privilege-mode-password 1 2e9f038ac2ed27f919ed5a4dceb3d30e32f356f2ceff6fbf26a153d0339c734f
rfs4000-6DB5D4(config-management-policy-test)#
```

### Example: Configuring privilege mode password using a hashed-string alias.

Follow the steps below to configure a hashed-string alias and use it as a privilege mode password:

- 1 In the global-configuration context, create a hashed-string alias.

```
nx9500-6C8809(config)#alias hashed-string $PriMode Test12345
nx9500-6C8809(config)#show context | include alias
alias vlan $BLR-01 1
alias string $IN-Blr-EcoSpace-Floor-4 IBEF4
alias encrypted-string $READ 0 public
alias encrypted-string $WRITE 0 private
alias hashed-string $PriMode 1
faffdde27cb49ad634ea20df4f7c8ef2685894d10ffcblb2efba054112ecfc75
nx9500-6C8809(config)#
```

- 2 In the management-policy context, configure the hashed-string alias created in step 1 as the privilege mode password.

```
nx9500-6C8809(config-management-policy-default)#privilege-mode-password $PrivMode
nx9500-6C8809(config-management-policy-default)#show context
management-policy default
https server
rest-server
ssh
user admin password 1 ad4d8797f007444ccdda3788b9ee0e8b46f3facb4308e045239eb7771e127ed5
role superuser access all
snmp-server community 0 $WRITE rw
snmp-server community 0 $READ ro
snmp-server user snmptrap v3 encrypted des auth md5 2 yqr96yyVzmD4ZbU2I7Eh/
QAAAajWNKa4KXF95pruUCSnhOiT
snmp-server user snmpmanager v3 encrypted des auth md5 2 NOF8+2+AY2r4ZbU2I7Eh/

## *rest-server (management-policy)*

Enables the REST (Representational State Transfer) server. When enabled, the REST server allows vendor users access to the online device registration portal. All requests and responses to and from the on-boarding portal are handled by the REST server through restful API (Application Programming Interface) transactions. The REST server serves the Web pages used to associate a device's MAC address with a specific vendor group.

Each vendor has a 'vendor-admin' user who is assigned a unique, username/password credential for RADIUS server validation. Successfully validated vendor-admins can access the online device registration portal to on-board devices. For more information on vendor-admin user configuration, see [user \(management-policy\)](#) on page 1544.

The REST server is enabled by default.

### **Supported in the following platforms:**

- Service Platforms — NX 95XX, NX 96XX, VX 9000

### **Syntax**

```
rest-server
```

### **Parameters**

None

### **Example**

```
nx9500-6C8809(config-management-policy-testMNGTPolicy)#show context
management-policy testMNGTPolicy
 no telnet
 no http server
 https server
 rest-server
 ssh
nx9500-6C8809(config-management-policy-testMNGTPolicy)#
nx9500-6C8809(config-management-policy-testMNTPolicy)#no rest-server
nx9500-6C8809(config-management-policy-testMNGTPolicy)#show context
management-policy testMNGTPolicy
 no telnet
 no http server
 https server
 no rest-server
 ssh
nx9500-6C8809(config-management-policy-testMNGTPolicy)#
```

## *restrict-access*

Restricts management access to a set of hosts or subnets

Restricting remote access to a controller or service platform ensures only trusted hosts can communicate with enabled management services. This ensures only trusted hosts can perform

management tasks and provide protection from brute force attacks from hosts attempting to break into the controller or service platform managed network.

Administrators can permit management connections to be established on any IP interface on the controller or service platform (including IP interfaces used to provide captive portal guest access). Administrators can restrict management access by limiting access to a specific host (IP address), subnet, or ACL on the controller or service platform.

**Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

**Syntax**

```
restrict-access [host|ip-access-list|subnet]
restrict-access host <IP> {log|subnet}
restrict-access host <IP> {log [all|denied-only]}
restrict-access host <IP> {subnet <IP/M> {log [all|denied-only]}}
restrict-access ip-access-list <IP-ACCESS-LIST-NAME>
restrict-access subnet <IP/M> {host|log}
restrict-access subnet <IP/M> {log [all|denied-only]}
restrict-access subnet <IP/M> {host <IP> {log [all|denied-only]}}
```

**Parameters**

```
restrict-access host <IP> {log [all|denied-only]}
```

|                       |                                                                                                                                                                                                                                                                                                              |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| host <IP>             | Restricts management access to a specified host. Filters access requests based on a host's IP address <ul style="list-style-type: none"> <li>• &lt;IP&gt; - Specify the host's IPv4 address.</li> </ul>                                                                                                      |
| log [all denied-only] | Optional. Configures a logging policy for access requests. <ul style="list-style-type: none"> <li>• all - Logs all access requests, both denied and permitted</li> <li>• denied-only - Logs only denied access (when an access request is received from a host denied access, a record is logged)</li> </ul> |

```

## snmp-server

Enables the SNMP (Simple Network Management Protocol) engine settings. SNMP is an application layer protocol that facilitates the exchange of management information between the controller and a managed device. SNMP enabled devices listen on port 162 (by default) for SNMP packets from the controller's management server. SNMP uses read-only and read-write community strings as an authentication mechanism to monitor and configure supported devices. The read-only community string gathers statistics and configuration parameters from a supported wireless device. The read-write community string is used by a management server to set device parameters. SNMP is generally used to monitor a system's performance and other parameters.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
snmp-server [community|enable|display-vlan-info-per-radio|host|manager|max-pending-requests|request-timeout|suppress-security-configuration-level|throttle|user]
snmp-server community [0 <WORD>|2 <WORD>|<WORD>] [ro|rw] {ip-snmp-access-list <IP-SNMP-ACL-NAME>}
snmp-server enable traps
snmp-server host <IP> [v1|v2c|v3] {<1-65535>}
snmp-server manager [all|v1|v2|v3]
snmp-server [max-pending-requests {<64-1024>}|request-timeout {<2-720>}]
snmp-server [display-vlan-info-per-radio|throttle <1-100>|suppress-security-configuration-level [0|1]]
snmp-server user [snmpmanager|snmpoperator|snmptrap]
snmp-server user [snmpmanager|snmpoperator|snmptrap] v3 [auth|encrypted]
snmp-server user [snmpmanager|snmpoperator|snmptrap] v3 auth md5 [0 <PASSWORD>|2 <ENCRYPTED-PASSWORD>|<PASSWORD>]
snmp-server user [snmpmanager|snmpoperator|snmptrap] v3 encrypted [auth md5|des auth md5] [0 <PASSWORD>|2 <ENCRYPTED-PASSWORD>|<PASSWORD>]
```

### Parameters

```
snmp-server community [0 <WORD>|2 <WORD>|<WORD>] [ro|rw] {ip-snmp-access-list <IP-SNMP-ACL-NAME>}
```

|                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| community [0<br><WORD>] 2<br><WORD> <br><WORD>] | <p>Sets the community string and associated access privileges. Define a public or private community designation. By default, SNMPv2 community strings on most devices are set to public for the read-only community string, and private for the read-write community string.</p> <ul style="list-style-type: none"> <li>• 0 &lt;WORD&gt; – Sets a clear text SNMP community string</li> <li>• 2 &lt;WORD&gt; – Sets an encrypted SNMP community string</li> <li>• &lt;WORD&gt; – Sets the SNMP community string</li> </ul> |
| [ro rw]                                         | <p>After configuring the SNMP community string, set the access permission for each community string used by devices to retrieve or modify information. Available options include</p> <ul style="list-style-type: none"> <li>• ro – Assigns read-only access to the specified SNMP community (allows a remote device to retrieve information)</li> <li>• rw – Assigns read and write access to the specified SNMP community (allows a remote device to modify settings)</li> </ul>                                          |
| ip-snmp-access-<br>list <IP-SNMP-ACL-<br>NAME>  | <p>Optional. Associates an IP SNMP access list (should be existing and configured). The IP SNMP ACL sets the SNMP management station's IP address. SNMP trap information is received at this address.</p>                                                                                                                                                                                                                                                                                                                  |

#### snmp-server enable traps

| enable traps | <p>Enables trap generation (using the trap receiver configuration defined). This feature is disabled by default. Enabling this feature ensures the dispatch of SNMP notifications to all hosts.</p> <p>In a managed network, the controller uses SNMP trap receivers to notify faults. SNMP traps are unsolicited notifications triggered by thresholds (or actions) on devices and are therefore an important fault management tool.</p> <p>A SNMP trap receiver is the destination of SNMP messages (external to the controller). A trap is like a Syslog message, just over another protocol (SNMP). A trap is generated when a device consolidates event information and transmits the information to an external repository. The trap contains several standard items, such as the SNMP version, community, etc.</p> <p>SNMP trap notifications exist for most controller operations, but not all are necessary for day-to-day operation.</p> |

## ssh

Enables SSH (Secure Shell) for this management policy

SSH, like Telnet, provides a command line interface to a remote host. SSH transmissions are encrypted and authenticated, increasing the security of transmission. SSH access is enabled by default.

### Note

If the RADIUS server is not reachable, SSH management access to the controller or access point may be denied. RADIUS support is available locally on controllers and access points, with the exception of the AP 6522 model, which requires an external RADIUS resource.

## Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
ssh {login-grace-time <60-300>|port <1-65535>}
```

## Parameters

```
ssh {login-grace-time <60-300>|port <1-65535>}
```

### *t5 (management-policy)*

Configures SNMP server settings for T5 devices on this management policy

A T5 controller is an external device that can be adopted and managed by a WiNG controller. When enabled as a supported external device, a T5 controller can provide data to WiNG to assist in its management within a WiNG supported subnet.

This command enables SNMP to communicate with T5 devices within the network. SNMP facilitates the exchange of management information between the controller or service platform and the T5 device. For more information, see [snmp-server](#) on page 1537.

### Supported in the following platforms:

- Wireless Controllers — RFS 4000, RFS 6000
- Service Platforms — NX 95XX, NX 96XX

### Syntax

```

t5 snmp-server [community|contact|enable|host|location]
t5 snmp-server community <COMMUNITY-NAME> [ro|rw] <SNMP-STATION-IP>
t5 snmp-server contact <LINE>
t5 snmp-server enable [server|traps]
t5 snmp-server host <IP>
t5 snmp-server location <LINE>

```

### Parameters

```
t5 snmp-server [community|contact|enable|host|location]
```

|                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## telnet

Enables Telnet. Telnet provides a command line interface to a remote host over TCP. Telnet provides no encryption, but it does provide a measure of authentication. Telnet access is disabled by default.

By default Telnet, when enabled, uses TCP (Transmission Control Protocol) port 23. Use this command to change the TCP port.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
telnet {port <1-65535>}
```

### Parameters

```
telnet {port <1-65535>}
```

|                |                                                                                                                                                                                                               |

## user (management-policy)

Adds new user account. Use this option to add a new user, and define the role, access type, and allowed locations assigned to the user.

Management services like Telnet, SSHv2, HTTP, HTTPS and FTP require users (administrators) enter a valid username and password, which is authenticated locally or centrally on a RADIUS server. SNMPv3 also requires a valid username and password, which is authenticated by the SNMPv3 module. For CLI users, the controller or service platform also requires user role information to know what permissions to assign.

- If local authentication is used, associated role information is defined on the controller or service platform when the user account is created.
- If RADIUS is used, role information is supplied by RADIUS using vendor-specific return attributes. If no role information is supplied by RADIUS, the controller or service platform applies default read-only permissions.

Administrators can limit users to specific management interfaces. During authentication, the controller or service platform looks at the user's access assignment to determine if the user has permissions to access an interface:

- If local authentication is used, role information is defined on the controller or service platform when the user account is created.
- If RADIUS is used, role information is supplied by RADIUS using vendor-specific return attributes.

The controller or service platform authenticates users using the integrated local database. When user credentials are presented the controller or service platform validates the username and password against the local database and assigns permissions based on the associated roles assigned. The controller or service platform can also deny the authentication request if the user is attempting to access a management interface not specified in the account's access mode list.

#### **Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### **Syntax**

```
user <USERNAME> password [0 <PASSWORD>|1 <SHA1-PASSWORD>|<PASSWORD>] role [device-
provisioning-admin|helpdesk|monitor|network-admin|security-admin|superuser|
system-admin|vendor-admin|web-user-admin]
user <USERNAME> password [0 <PASSWORD>|1 <SHA1-PASSWORD>|<PASSWORD>] role [device-
provisioning-admin|helpdesk|monitor|network-admin|security-admin|superuser|
system-admin|web-user-admin] access [all|console|ssh|telnet|web] ({allowed-locations
<ALLOWED-LOCATIONS>})
user <USERNAME> password [0 <PASSWORD>|1 <SHA1-PASSWORD>|<PASSWORD>] role vendor-admin
group <VENDOR-GROUP-NAME>
```

#### **Parameters**

```
user <USERNAME> password [0 <PASSWORD>|1 <SHA1-PASSWORD>|<PASSWORD>] role [device-
provisioning-admin|helpdesk|monitor|network-admin|security-admin|
superuser|system-admin|web-user-admin] access [all|console|ssh|telnet|web] ({allowed-
locations <ALLOWED-LOCATIONS>})
```

| role vendor-admin                                      | <p>Configures this user's role as vendor-admin. Once created, the vendor-admin can access the online device-registration portal to add devices to the RADIUS vendor group to which he/she belongs. Vendor-admins have only Web access to the device registration portal.</p> <p>The WiNG software allows multiple vendors to securely on-board their devices through a single SSID. Each vendor has a 'vendor-admin' user who is assigned a unique, username/password credential for RADIUS server validation. Successfully validated vendor-admins can on-board their devices, which are, on completion of the on-boarding process, immediately placed on the vendor-allowed VLAN. On subsequent associations with this SSID, registered devices are dynamically placed into the vendor-allowed VLAN.</p> <p>If assigning the vendor-admin role, provide the vendor's group name for RADIUS authentication. The vendor's group takes precedence over the statically configured group for device registration.</p> <p><b>Note:</b> Use the <b>service &gt; show &gt; wireless &gt; credential-cache</b> command to view on-boarded device's VLAN assignment. Ensure that the REST server is enabled, to allow vendor users access to the online device registration portal.</p> <p><b>Note:</b> Note, by default the REST server is enabled. For more information, see <a href="#">rest-server</a>.</p> |
| group <VENDOR-GROUP-NAME>                              | <p>Associates this vendor-admin user with a vendor group, required for RADIUS authentication. The vendor group should be existing and configured in the RADIUS group policy. For more information on configuring RADIUS groups, see <a href="#">radius-group</a> on page 1551.</p> <ul style="list-style-type: none"> <li>• &lt;VENDOR-GROUP-NAME&gt; – Provide the vendor group name. In case of multiple allowed groups, provide a list of comma-separated group names.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| no <PARAMETERS> Removes or reverts this Management policy settings based on the parameters passed |
|---------------------------------------------------------------------------------------------------|

## Examples

The following example shows the management policy 'test' settings before the 'no' commands are executed:

```
rfs4000-6DB5D4(config-management-policy-test)#show context
management-policy test
 http server
 https server
 ftp username superuser password 1
 7ccb4568cb83e54f1e402f785a78ee930a453afda152baaf7c2b79277f225872 rootdir dir
 no ssh
 aaa-login radius external
 aaa-login radius policy test
 idle-session-timeout 100
 banner motd "Have a Good Day"
rfs4000-6DB5D4(config-management-policy-test)#
rfs4000-6DB5D4(config-management-policy-test)#no banner motd
rfs4000-6DB5D4(config-management-policy-test)#no idle-session-timeout
rfs4000-6DB5D4(config-management-policy-test)#no http server
```

The following example shows the management policy 'test' settings after the 'no' commands are executed:

```
rfs4000-6DB5D4(config-management-policy-test)#show context
management-policy test
 no http server
 https server
 ftp username superuser password 1
 626b4033263d6d2ae4e79c48cdfcccb60fd4c77a8da9e365060597a6d6570ec2 rootdir dir
 no ssh
 aaa-login radius external
 aaa-login radius policy test
 idle-session-timeout 0
rfs4000-6DB5D4(config-management-policy-test)#
```

# RADIUS POLICY

## RADIUS-POLICY

---

This chapter summarizes the RADIUS group, server, and user policy commands in the CLI command structure.

RADIUS (Remote Authentication Dial-In User Service) is a client/server protocol and software that enables remote access servers to authenticate users and authorize their access to the network. RADIUS is a distributed client/server system that secures networks against unauthorized access. RADIUS clients send authentication requests to the local RADIUS server containing user authentication and network service access information.

RADIUS enables centralized management of authentication data (usernames and passwords). When a client attempts to associate to a network, the authentication request is sent to the local RADIUS server. The authentication and encryption of communications takes place through the use of a shared secret password (not transmitted over the network).

The local RADIUS server stores the user database locally, and can optionally use a remote user database. It ensures higher accounting performance. It allows the configuration of multiple users, and assigns policies for group authorization.

Controllers and access points allow enforcement of user-based policies. User policies include dynamic VLAN assignment and access based on time of day. A certificate is required for EAP TTLS, PEAP and TLS RADIUS authentication (configured with the RADIUS service).

Dynamic VLAN assignment is achieved based on the RADIUS server response. A user who associates to WLAN1 (mapped to VLAN1) can be assigned a different VLAN after RADIUS server authentication. This dynamic VLAN assignment overrides the WLAN's VLAN ID to which the user associates.

The chapter is organized into the following sections:

- [radius-group](#) on page 1551
- [radius-server-policy](#) on page 1559
- [radius-user-pool-policy](#) on page 1576

### Note

The input parameter <HOSTNAME>, wherever used in syntaxes across this chapter, cannot include an underscore (\_) character. In other words, the name of a device cannot contain an underscore.

---

## radius-group

This section describes RADIUS user group configuration commands.

The local RADIUS server allows the configuration of user groups with common user policies. User group names and associated users are stored in the local database. The user ID in the received access request

is mapped to the associated wireless group for authentication. The configuration of groups allows enforcement of the following policies that control user access:

- Assign a VLAN to the user upon successful authentication
- Define start and end of time (HH:MM) when the user is allowed to authenticate
- Define the SSID list to which a user, belonging to this group, is allowed to associate
- Define the days of the week the user is allowed to login
- Rate limit traffic (for non-management users)

RADIUS users are categorized into three groups: normal user, management user, and guest user. A RADIUS group not configured as management or guest is a normal user group. User access and role settings depends on the RADIUS group the user belongs.

Use the (config) instance to configure RADIUS group commands. This command creates a group within the existing RADIUS group. To navigate to the RADIUS group instance, use the following commands:

```
<DEVICE>(config)#radius-group <GROUP-NAME>
nx9500-6C8809(config)#radius-group test
nx9500-6C8809(config-radius-group-test)#?
Radius user group configuration commands:
 guest Make this group a Guest group
 no Negate a command or set its defaults
 policy Radius group access policy configuration
 rate-limit Set rate limit for group

 clrscr Clears the display screen
 commit Commit all changes made in this session
 do Run commands from Exec mode
 end End current mode and change to EXEC mode
 exit End current mode and down to previous mode
 help Description of the interactive help system
 revert Revert changes
 service Service Commands
 show Show running system information
 write Write running configuration to memory or terminal

nx9500-6C8809(config-radius-group-test)#
```

#### Note

The RADIUS group name cannot exceed 32 characters, and cannot be modified as part of the group edit process.

The following table summarizes RADIUS group configuration commands.

*Table: RADIUS-Group Config Mode Commands*

| Command                             | Description                                      |
|-------------------------------------|--------------------------------------------------|
| <a href="#">guest</a> on page 1553  | Enables guest access for the newly created group |
| <a href="#">policy</a> on page 1554 | Configures RADIUS group access policy parameters |

| Command                              | Description                                                                       |
|--------------------------------------|-----------------------------------------------------------------------------------|
| <code>rate-limit</code> on page 1557 | Sets the default rate limit per user in Kbps, and applies it to all enabled WLANs |
| <code>no</code> on page 1558         | Negates a command or reverts settings to their default                            |

#### Note

For more information on common commands (clear, commit, help, revert, service, show, write, and exit), see [COMMON COMMANDS](#) on page 640.

#### Note

The input parameter <HOSTNAME>, wherever used in syntaxes across this chapter, cannot include an underscore (\_) character. In other words, the name of a device cannot contain an underscore.

### *guest*

Configures this group as a guest (non-management) group. A guest user group has temporary permissions to the controller's local RADIUS server. You can configure multiple guest user groups, each having a unique set of settings. Guest user groups cannot be made management groups with access and role permissions.

Guest users and policies are used for captive portal authorization to the network.

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
guest
```

#### Parameters

None

#### Examples

```
nx9500-6C8809(config-radius-group-test)#guest
nx9500-6C8809(config-radius-group-test)#show context
radius-group test
 guest
nx9500-6C8809(config-radius-group-test)#
```

#### Related Commands

|                              |                                    |
|------------------------------|------------------------------------|
| <code>no</code> on page 1558 | Makes this group a non-guest group |
|------------------------------|------------------------------------|

## policy

Sets a RADIUS group's authorization settings, such as access day/time, WLANs, etc.

### Note

A user-based VLAN is effective only if dynamic VLAN authorization is enabled for the WLAN.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
policy [access|day|inactivity-timeout|role|session-time|ssid|time|vlan]
policy vlan <1-4094>
policy access [all|console|ssh|telnet|web]
policy access [all|console|ssh|telnet|web] {(all/console/ssh/telnet/web)}
policy day [all|fr|mo|sa|su|th|tu|we|weekdays] {(fr/mo/sa/su/th/tu/we/weekdays)}
policy inactivity-timeout <60-86400>
policy role [device-provisioning-admin|helpdesk|monitor|network-admin|security-admin|
superuser|system-admin|web-user-admin]
policy session-time <5-144000>
policy ssid <SSID>
policy time start <HH:MM> end <HH:MM>
```

### Note

Access and role settings are applicable only to a management group. They cannot be configured for a RADIUS non-management group.

### Parameters

```
policy vlan <1-4094>
```

vlan <1-4094>

Sets the guest RADIUS group's VLAN ID from 1 - 4094. The VLAN ID is representative of the shared SSID each group member (user) employs to inter-operate within the network (once authenticated by the local RADIUS server). This option applicable to a guest user group, which has guest access and temporary permissions to the local RADIUS server. The terms of the guest access can be set uniquely for each group. Guest user groups cannot be made management groups with unique access and role permissions.

**Note:** Enable dynamic VLAN assignment for the WLAN for the VLAN assignment to take effect.

```
policy access [all|console|ssh|telnet|web] {(all/console/ssh/telnet/web)}
```

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| access | <p>Configures access type for a management group. Management groups can be assigned unique access and role permissions.</p> <ul style="list-style-type: none"> <li>• all – Allows all access. Allows access to the console, ssh, telnet, and/or Web</li> <li>• console – Allows console access only</li> <li>• ssh – Allows SSH access only</li> <li>• telnet – Allows Telnet access only</li> <li>• web – Allows Web access only</li> </ul> <p>These parameters are recursive, and you can provide access to more than one component.</p> |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
policy role [device-provisioning-admin|helpdesk|monitor|network-admin|security-admin|
superuser|system-admin|web-user-admin]

| role [device-provisioning-admin  helpdesk monitor network-admin  security-admin superuser system- admin web-user-admin] | <p>Configures the role assigned to a management RADIUS group. If a group is listed as a management group, it may also have a unique role assigned. Available roles include:</p> <ul style="list-style-type: none"> <li>• device-provisioning-admin – Device provisioning administrator. Has privileges to update (provision) device configuration files or firmware. Such updates run the risk of overwriting and losing a devices existing configuration unless the configuration is properly archived.</li> <li>• helpdesk – Helpdesk administrator. Performs troubleshooting tasks, such as clear statistics, reboot, create and copy tech support dumps. The helpdesk administrator can also create a guest user account and password for registration. These details can be e-mailed or sent as SMS to a mobile phone.</li> <li>• monitor – Monitor. Has read-only access to the network. Can view configuration and statistics except for secret information</li> <li>• network-admin – Network administrator. has wired and wireless access to the network. Manages layer 2, layer 3, Wireless, RADIUS server, DHCP server, and Smart RF</li> <li>• security-admin – Security administrator. Has full read/write access to the network. Modifies WLAN keys and passphrases</li> <li>• superuser – Superuser. Has full access, including halt and delete startup config</li> <li>• system-admin – System administrator. Upgrades image, boot partition, time, and manages admin access</li> <li>• web-user-admin – Web user administrator. This role is used to create guest users and credentials. The web-user-admin can access only the custom GUI screen and does not have access to the normal CLI and GUI.</li> </ul> |

|--------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**Usage Guidelines**

A management group access policy provides:

- access details
- user role
- policy's start and end time

The SSID, day, and VLAN settings are not applicable to a management user group.

## Examples

The following example shows a RADIUS guest group settings:

```
nx9500-6C8809(config-radius-group-test)#policy time start 13:30 end 17:30
nx9500-6C8809(config-radius-group-test)#policy day all
nx9500-6C8809(config-radius-group-test)#policy vlan 1
nx9500-6C8809(config-radius-group-test)#policy ssid test
nx9500-6C8809(config-radius-group-test)#show context
radius-group test
 guest
 policy vlan 1
 policy ssid test
 policy day mo
 policy day tu
 policy day we
 policy day th
 policy day fr
 policy day sa
 policy day su
 policy time start 13:30 end 17:30
nx9500-6C8809(config-radius-group-test)#
```

The following example shows a RADIUS management group settings:

```
nx9500-6C8809(config-radius-group-management)#policy access console ssh telnet
nx9500-6C8809(config-radius-group-management)#policy role network-admin
nx9500-6C8809(config-radius-group-management)#policy time start 9:30 end 20:30
nx9500-6C8809(config-radius-group-management)#show context
radius-group management
 policy time start 9:30 end 20:30
 policy access console ssh telnet web
 policy role network-admin
nx9500-6C8809(config-radius-group-management)#
```

### *rate-limit*

Sets the rate limit for the guest RADIUS server group

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
rate-limit [from-air|to-air] <100-1000000>
```

#### Note

The rate-limit setting is not applicable to a management group.

## Parameters

rate-limit [from-air|to-air] <100-1000000>

|                        |                                                                                                                                                                                                        |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| to-air <100-1000000>   | Sets the rate limit in the downlink direction, from the network to the wireless client <ul style="list-style-type: none"><li>&lt;100-1000000&gt; - Specify the rate from 100 - 1000000 kbps.</li></ul> |
| from-air <100-1000000> | Sets the rate limit in the uplink direction, from the wireless client to the network <ul style="list-style-type: none"><li>&lt;100-1000000&gt; - Specify the rate from 100 - 1000000 kbps.</li></ul>   |

## Examples

```
nx9500-6C8809(config-radius-group-test)#rate-limit to-air 200
nx9500-6C8809(config-radius-group-test)#show context
radius-group test
 guest
 policy vlan 1
 policy ssid test
 policy day mo
 policy day tu
 policy day we
 policy day th
 policy day fr
 policy day sa
 policy day su
 rate-limit to-air 200
 policy time start 13:30 end 17:30
nx9500-6C8809(config-radius-group-test)#
```

## Related Commands

|                 |                                              |
|-----------------|----------------------------------------------|
| no on page 1558 | Removes the RADIUS guest group's rate limits |
|-----------------|----------------------------------------------|

*no*

Negates a command or sets its default. Removes or modifies the RADIUS group policy settings. When used in the config RADIUS group mode, the *no* command removes or modifies the following settings: access type, access days, role type, VLAN ID, and SSID.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
no [guest|policy|rate-limit]
no guest
no policy [access|day|inactivity-timeout|role|session-time|ssid|time|vlan]
no policy access [all|console|ssh|telnet|web]
no policy day [all|fr|mo|sa|su|th|tu|we|weekdays]
no policy session-time
no policy ssid [<SSID>|all]
no policy [inactivity-timeout|role|time|vlan]
no rate-limit [from-air|to-air]
```

## Parameters

no <PARAMETERS>

no <PARAMETERS> Negates a command or sets its default. Removes or modifies the RADIUS group policy settings. When used in the config RADIUS group mode, the no command removes or modifies the following settings: access type, access days, role type, VLAN ID, and SSID.

## Examples

The following example shows the RADIUS guest group 'test' settings before the 'no' commands are executed:

```
nx9500-6C8809(config-radius-group-test)#show context
radius-group test
 guest
 policy vlan 1
 policy ssid test
 policy day mo
 policy day tu
 policy day we
 policy day th
 policy day fr
 policy day sa
 policy day su
 rate-limit to-air 200
 policy time start 13:30 end 17:30
nx9500-6C8809(config-radius-group-test)#
nx9500-6C8809(config-radius-group-test)#no guest
nx9500-6C8809(config-radius-group-test)#no rate-limit to-air
nx9500-6C8809(config-radius-group-test)#no policy day all
```

The following example shows the RADIUS guest group 'test' settings after the 'no' commands are executed:

```
nx9500-6C8809(config-radius-group-test)#show context
radius-group test
 policy vlan 1
 policy ssid test
 policy time start 13:30 end 17:30
nx9500-6C8809(config-radius-group-test)#
```

## radius-server-policy

Creates an onboard device RADIUS server policy.

A RADIUS server policy is a unique authentication and authorization configuration that receives user connection requests, authenticates users, and returns configuration information necessary for the RADIUS client to deliver service to the user. The client is the entity with authentication information requiring validation. The local RADIUS server has access to a database of authentication information used to validate the client's authentication request.

The local RADIUS server uses authentication schemes like PAP, CHAP, or EAP to verify and confirm information provided by a user. The user's proof of identification is verified, along with, optionally, other information. A local RADIUS server policy can also be configured to refer to an external LDAP (Lightweight Directory Access Protocol) (LDAP) resource to verify a user's credentials.

Use the (config) instance to configure RADIUS-Server-Policy related parameters. To navigate to the RADIUS-Server-Policy instance, use the following commands:

```
<DEVICE>(config)#radius-server-policy <POLICY-NAME>
nx9500-6C8809(config)#radius-server-policy test
nx9500-6C8809(config-radius-server-policy-test)#?
Radius Configuration commands:
 authentication Radius authentication
 bypass Bypass Certificate Revocation List(CRL) check
 chase-referral Enable chasing referrals from LDAP server
 crl-check Enable Certificate Revocation List(CRL) check
 ldap-agent LDAP Agent configuration parameters
 ldap-group-verification Enable LDAP Group Verification setting
 ldap-server LDAP server parameters
 local RADIUS local realm
 nas RADIUS client
 no Negate a command or set its defaults
 proxy RADIUS proxy server
 session-resumption Enable session resumption/fast reauthentication by
 using cached attributes
 termination Enable Eap termination for proxy requests
 use Set setting to use

 clrscr Clears the display screen
 commit Commit all changes made in this session
 do Run commands from Exec mode
 end End current mode and change to EXEC mode
 exit End current mode and down to previous mode
 help Description of the interactive help system
 revert Revert changes
 service Service Commands
 show Show running system information
 write Write running configuration to memory or terminal

nx9500-6C8809(config-radius-server-policy-test)#
```

The following table summarizes RADIUS server policy configuration commands.

*Table: RADIUS-Server-Policy Config Mode Commands*

| Commands                                             | Description                                                                                                                           |
|------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">authentication</a> on page 1561          | Configures RADIUS authentication settings                                                                                             |
| <a href="#">bypass</a> on page 1562                  | Enables bypassing of CRL check                                                                                                        |
| <a href="#">chase-referral</a> on page 1563          | Enables LDAP server referral chasing                                                                                                  |
| <a href="#">crl-check</a> on page 1564               | Enables a CRL (certificate revocation list ) check                                                                                    |
| <a href="#">ldap-agent</a> on page 1565              | Configures the LDAP agent settings                                                                                                    |
| <a href="#">ldap-group-verification</a> on page 1566 | Enables LDAP group verification                                                                                                       |
| <a href="#">ldap-server</a> on page 1567             | Configures the LDAP server settings                                                                                                   |
| <a href="#">local</a> on page 1569                   | Configures a local RADIUS realm                                                                                                       |
| <a href="#">nas</a> on page 1570                     | Configures the key sent to a RADIUS client                                                                                            |
| <a href="#">proxy</a> on page 1571                   | Configures the RADIUS proxy server's settings                                                                                         |
| <a href="#">session-resumption</a> on page 1572      | Enables session resumption                                                                                                            |
| <a href="#">termination</a> on page 1573             | Enables EAP termination on this current RADIUS server policy. When enabled, EAP authentication is terminated at the controller level. |

| Commands                      | Description                                           |
|-------------------------------|-------------------------------------------------------|
| <code>use</code> on page 1574 | Defines settings used with the RADIUS server policy   |
| <code>no</code> on page 1575  | Removes or resets the RADIUS server policy's settings |

## authentication

Specifies the RADIUS data source used for user authentication. Options include local for the local user database or LDAP for a remote LDAP resource.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
authentication [data-source|eap-auth-type]
authentication data-source [ldap|local]
authentication data-source [ldap {fallback}|local] {(ssid <SSID> precedence <1-5000>)}
authentication eap-auth-type [all|peap-gtc|peap-mschapv2|tls|ttls-md5|ttls-mschapv2|ttls-pap]
```

### Parameters

```
authentication data-source [ldap {fallback}|local] {(ssid <SSID> precedence <1-5000>)}
```

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| data-source   | The RADIUS sever can either use the local database or an external LDAP server to authenticate a user. It is necessary to specify the data source. The options are: <b>LDAP</b> and <b>local</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| ldap fallback | <p>Uses a remote LDAP server as the data source</p> <ul style="list-style-type: none"> <li>• fallback - Optional. Enables fallback to local authentication. This feature ensures that if the designated external LDAP resource were to fail or become unavailable, the client is authenticated against the local RADIUS resource. This option is disabled by default.</li> </ul> <p>When using LDAP as the authentication external source, PEAP-MSCHAPv2 authentication type can be used only if the LDAP server returns the password as plain-text. PEAP-MSCHAPv2 authentication is not supported if the LDAP server returns encrypted passwords. This restriction does not apply for Microsoft's Active Directory server.</p> |

|                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| local                                 | Uses the local user database to authenticate a user. This is the default setting.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| ssid <SSID><br>precedence<br><1-5000> | <p>The following keywords are recursive and common to both 'ldap' and 'local' parameters:</p> <ul style="list-style-type: none"> <li>• ssid – Optional. Associates the data source, selected in the previous step, with a SSID.</li> <li>• &lt;SSID&gt; – Specify the SSID for this authentication data source. The SSID is case sensitive and should not exceed 32 characters in length. Do not use any of the following characters (&lt; &gt;   " &amp; \ ? ,).</li> </ul> <p>precedence &lt;SSID&gt; – Sets the precedence for this authentication rule. The precedence value allows systematic evaluation and application of rules. Rules with the lowest precedence receive the highest priority.</p> <p>&lt;1-5000&gt; – Specify a precedence from 1 -5000.</p> <p><b>Note:</b> Specifying the SSID allows the RADIUS server to use the SSID attribute in access requests to determine the data source to use. This option is applicable to onboard RADIUS servers only.</p> |

```
authentication eap-auth-type [all|peap-gtc|peap-mschapv2|tls|ttls-md5|ttls-mschapv2|ttls-pap]
```

|               |                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| eap-auth-type | Uses EAP (Extensible Authentication Protocol), with this RADIUS server policy, for user authentication<br>The EAP authentication types supported by the local RADIUS server are: <b>all, peap-gtc, peap-mschapv2, tls, ttls-md5, ttls-mschapv2, ttls-pap.</b>                                                                                                                                      |
| all           | Enables both TTLS and PEAP authentication. This is the default setting.                                                                                                                                                                                                                                                                                                                            |
| peap-gtc      | Enables PEAP with default authentication using GTC                                                                                                                                                                                                                                                                                                                                                 |
| peap-mschapv2 | Enables PEAP with default authentication using MSCHAPv2<br>When using LDAP as the authentication external source, PEAP-MSCHAPv2 authentication type can be used only if the LDAP server returns the password as plain-text. PEAP-MSCHAPv2 authentication is not supported if the LDAP server returns encrypted passwords. This restriction does not apply for Microsoft's Active Directory server. |
| tls           | Enables TLS as the EAP type                                                                                                                                                                                                                                                                                                                                                                        |
| ttls-md5      | Enables TTLS with default authentication using md5                                                                                                                                                                                                                                                                                                                                                 |
| ttls-mschapv2 | Enables TTLS with default authentication using MSCHAPv2                                                                                                                                                                                                                                                                                                                                            |
| ttls-pap      | Enables TTLS with default authentication using PAP                                                                                                                                                                                                                                                                                                                                                 |

### Examples

```
nx9500-6C8809(config-radius-server-policy-test)#authentication eap-auth-type tls
nx9500-6C8809(config-radius-server-policy-test)#show context
radius-server-policy test
 authentication eap-auth-type tls
nx9500-6C8809(config-radius-server-policy-test)#
```

### bypass

Enables bypassing of a CRL check. When enabled, this feature bypasses checks for missing and expired CRLs. This option is enabled by default.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
bypass [crl-check|expired-crl]
```

### Parameters

```
bypass [crl-check|expired-crl]
```

|                                |                                                                                                                                                                                                                                                                                                                  |

### *chase-referral*

Enables chasing of referrals from an external LDAP server resource

An LDAP referral is a controller or service platform's way of indicating to a client it does not hold the section of the directory tree where a requested content object resides. The referral is the controller or service platform's direction to the client a different location is more likely to hold the object, which the client uses as the basis for a DNS search for a domain controller. Ideally, referrals always reference a domain controller that indeed holds the object. However, it is possible for the domain controller to generate another referral, although it usually does not take long to discover the object does not exist and inform the client.

This feature is disabled by default.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000

- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

chase-referral

### Parameters

None

### Examples

```
nx9500-6C8809(config-radius-server-policy-test)#chase-referral
```

### Related Commands

### *crl-check*

Enables a CRL check on this RADIUS server policy. A CRL is a list of revoked certificates issued and subsequently revoked by a CA (Certification Authority). Certificates can be revoked for a number of reasons including failure or compromise of a device using a certificate, a compromise of a certificate key pair or errors within an issued certificate. The mechanism used for certificate revocation depends on the CA.

This option is disabled by default.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

crl-check

### Parameters

None

### Examples

```
nx9500-6C8809(config-radius-server-policy-test)#crl-check
nx9500-6C8809(config-radius-server-policy-test)#show context
radius-server-policy test
 authentication eap-auth-type tls
 crl-check
nx9500-6C8809(config-radius-server-policy-test)#
```

### Related Commands

## ldap-agent

Configures the LDAP agent's settings in the RADIUS server policy context

When a user's credentials are stored on an external LDAP server, the local RADIUS server cannot successfully conduct PEAP-MSCHAPv2 authentication, since it is not aware of the user's credentials maintained on the external LDAP server resource. Therefore, up to two LDAP agents can be provided locally so remote LDAP authentication can be successfully accomplished on the remote LDAP resource (using credentials maintained locally).

This feature is available to all controller, service platforms and access point models.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
ldap-agent [join|join-retry-timeout|primary|secondary]
ldap-agent [join {on <DEVICE-NAME>}|join-retry-timeout <60-300>]
ldap-agent [primary|secondary] domain-name <LDAP-DOMAIN-NAME> domain-admin-user
<ADMIN-USER-NAME> domain-admin-password [0 <WORD>|2 <WORD>]
```

### Parameters

```
ldap-agent [join {on <DEVICE-NAME>}|join-retry-timeout <60-300>]
```

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ldap-agent                  | Configures the LDAP agent's settings                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| join {on <DEVICE-NAME>}     | Initiates the join process, which binds the RADIUS server with the LDAP server's (Windows) domain. When successful, the hostname (name of the AP, wireless controller, or service platform) is added to the LDAP server's Active Directory. <ul style="list-style-type: none"><li>• on &lt;DEVICE-NAME&gt; - Optional. Specifies the device name<ul style="list-style-type: none"><li>• &lt;DEVICE-NAME&gt; - Specify the name of the AP, wireless controller, or service platform.</li></ul></li></ul> <p><b>Note:</b> To confirm the join status of a controller, use the <b>show &gt; ldap-agent &gt; join-status</b> command.</p> |
| join-retry-timeout <60-300> | If the join process fails (i.e. the RADIUS server fails to join the LDAP server's domain), the process is retried after a specified interval. This command configures the interval (in seconds) between two successive join attempts. <ul style="list-style-type: none"><li>• &lt;60-300&gt; - Set the timeout value from 60 - 300 seconds. The default is 60 seconds.</li></ul> <p><b>Note:</b> A retry timer is initiated as soon as the join process starts, which tracks the time lapse in case of a failure.</p>                                                                                                                 |

```
ldap-agent [primary|secondary] domain-name <LDAP-DOMAIN-NAME> domain-admin-user
<ADMIN-USER-NAME> domain-admin-password [0 <WORD>|2 <WORD>]
```

|            |                                                                                                                                                                          |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ldap-agent | Configures the LDAP agent's settings                                                                                                                                     |
| primary    | Configures the primary LDAP server details, such as domain name, user name, and password. The RADIUS server uses these credentials to bind with the primary LDAP server. |

|                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| secondary                                        | Configures the secondary LDAP server details, such as domain name, user name, and password. The RADIUS server uses these credentials to bind with the secondary LDAP server.                                                                                                                                                                                                                                           |
| domain-name<br><LDAP-DOMAIN-NAME>                | This keyword is common to both the 'primary' and 'secondary' parameters. <ul style="list-style-type: none"> <li>domain-name - Configures the primary or secondary LDAP server's domain name <ul style="list-style-type: none"> <li>&lt;LDAP-DOMAIN-NAME&gt; - Specify the domain name.</li> </ul> </li> </ul>                                                                                                          |

### Examples

```
rfs4000-229D58(config-radius-server-policy-test)#ldap-agent primary domain-name
test domain-admin-user Administrator domain-admin-password 0 test@123
rfs4000-229D58(config-radius-server-policy-test)#show context
radius-server-policy test
 ldap-agent primary domain-name test domain-admin-user Administrator domain-admin-password
0 test@123
rfs4000-229D58(config-radius-server-policy-test)#
```

### *ldap-group-verification*

Enables LDAP group verification settings on this RADIUS server policy. This option is enabled by default.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
ldap-group-verification
```

### Parameters

None

### Examples

```
nx9500-6C8809(config-radius-server-policy-test)#ldap-group-verification
nx9500-6C8809(config-radius-server-policy-test)#show context include-factory | include
ldap-group-verification
```

```
ldap-group-verification
nx9500-6C8809(config-radius-server-policy-test)#
```

### ldap-server

Configures the LDAP server's settings. Configuring LDAP server allows users to login and authenticate from anywhere on the network.

Administrators have the option of using the local RADIUS server to authenticate users against an external LDAP server resource. Using an external LDAP user database allows the centralization of user information and reduces administrative user management overhead making RADIUS authorization more secure and efficient.

RADIUS is not just a database. It is a protocol for asking intelligent questions to a user database (like LDAP). LDAP however is just a database of user credentials used optionally with the local RADIUS server to free up resources and manage user credentials from a secure remote location. It is the local RADIUS resources that provide the tools to perform user authentication and authorize users based on complex checks and logic. A LDAP user database alone cannot perform such complex authorization checks.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
ldap-server [dead-period|primary|secondary]
ldap-server dead-period <0-600>
ldap-server [primary|secondary] host <IP> port <1-65535> login <LOGIN-NAME>
bind-dn <BIND-DN> base-dn <BASE-DN> passwd [0 <PASSWORD>|2 <ENCRYPTED-PASSWORD>|
<PASSWORD>]
passwd-attr <ATTR> group-attr <ATTR> group-filter <FILTER> group-membership <WORD>
{net-timeout <1-10>/start-tls net-timeout <1-10>/tls-mode net-timeout <1-10>}
```

### Parameters

```
ldap-server dead-period <0-600>
```

|                        |                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dead-period<br><0-600> | Sets an interval, in seconds, during which the local server does not contact its LDAP server resource once its been defined as unavailable. A dead period is only implemented when additional LDAP servers are configured and available. <ul style="list-style-type: none"><li>• &lt;0-600&gt; - Specify a value from 0 - 600 seconds. The default is 300 seconds.</li></ul> |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
ldap-server [primary|secondary] host <IP> port <1-65535> login <LOGIN-NAME>

| bind-dn <BIND-DN>                                                      | Configures a distinguished bind name. This is the DN (distinguished name) used to bind with the LDAP server. The DN is the name that uniquely identifies an entry in the LDAP directory. A DN is made up of attribute value pairs, separated by commas. <ul style="list-style-type: none"> <li>• &lt;BIND-DN&gt; – Specify a bind name (should not exceed 127 characters)</li> </ul>                                                                                                                                                                                                                                                                      |
| base-dn <BASE-DN>                                                      | Configures a distinguished base name. This is the DN that establishes the base object for the search. The base object is the point in the LDAP tree at which to start searching. LDAP DNs begin with a specific attribute (usually some sort of name), and continue with progressively broader attributes, often ending with a country attribute. The first component of the DN is referred to as the RDN (Relative Distinguished Name). It identifies an entry distinctly from any other entries that have the same parent <ul style="list-style-type: none"> <li>• &lt;BASE-DN&gt; – Specify a base name (should not exceed 127 characters).</li> </ul> |
| passwd [0<br><PASSWORD>  2<br><ENCRYPTED-<br>PASSWORD> <br><PASSWORD>] | Sets a valid password for the LDAP server. <ul style="list-style-type: none"> <li>• 0 &lt;PASSWORD&gt; – Sets an UNENCRYPTED password</li> <li>• 2 &lt;PASSWORD&gt; – Sets an ENCRYPTED password</li> <li>• &lt;PASSWORD&gt; – Sets the LDAP server bind password, specified UNENCRYPTED, with a maximum size of 31 characters</li> </ul>                                                                                                                                                                                                                                                                                                                 |
| passwd-attr <ATTR>                                                     | Specify the LDAP server password attribute (should not exceed 63 characters).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| group-attr <ATTR>                                                      | Specify a name to configure group attributes (should not exceed 31 characters). LDAP systems have the facility to poll dynamic groups. In an LDAP dynamic group an administrator can specify search criteria. All users matching the search criteria are considered a member of this dynamic group. Specify a group attribute used by the LDAP server. An attribute could be a group name, group ID, password or group membership name.                                                                                                                                                                                                                   |
| group-filter <FILTER>                                                  | Specify a name for the group filter attribute (should not exceed 255 characters). This filter is typically used for security role-to-group assignments and specifies the property to look up groups in the directory service.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| group-membership<br><WORD>                                             | Specify a name for the group membership attribute (should not exceed 63 characters). This attribute is sent to the LDAP server when authenticating users.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| net-time <1-10>                                                        | Optional. Select a value from 1 - 10 to configure the network timeout (number of seconds to wait for a response from the target primary or secondary LDAP server). The default is 10 seconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| start-tls net-timeout<br><1-10>                                        | Optional. Select a value from 1 - 10 to configure the network timeout for secure communication using start_tls support on the external LDAP server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| tls-mode net-timeout<br><1-10>                                         | Optional. Select a value from 1 - 10 to configure the network timeout for secure communication using tls_mode support on the external LDAP server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## *local*

Configures a local RADIUS realm on this RADIUS server policy

When the local RADIUS server receives a request for a user name with a realm, the server references a table of realms. If the realm is known, the server proxies the request to the RADIUS server.

## Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
local realm <RADIUS-REALM>
```

## Parameters

```
local realm <RADIUS-REALM>
```

|                      |                                                                                                                                                                                |

Removes the RADIUS local realm

*nas*

Configures the key sent to a RADIUS client.

A RADIUS client is a mechanism to communicate with a central server to authenticate users and authorize access to the controller, service platform or access point managed network.

The client and server share a secret (a password). That shared secret followed by the request authenticator is put through a MD5 hash algorithm to create a 16 octet value which is XORed with the password entered by the user. If the user password is greater than 16 octets, additional MD5 calculations are performed, using the previous ciphertext instead of the request authenticator. The server receives a RADIUS access request packet and verifies the server possesses a shared secret for the client. If the server does not possess a shared secret for the client, the request is dropped. If the client received a verified access accept packet, the username and password are considered correct, and the user is authenticated. If the client receives a verified access reject message, the username and password are considered to be incorrect, and the user is not authenticated.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

### *proxy*

Configures a proxy RADIUS server based on the realm/suffix. The realm identifies where the RADIUS server forwards AAA requests for processing.

A user's access request is sent to a proxy RADIUS server if it cannot be authenticated by the local RADIUS resources. The proxy server checks the information in the user access request and either accepts or rejects the request. If the proxy server accepts the request, it returns configuration information specifying the type of connection service required to authenticate the user.

The RADIUS proxy appears to act as a RADIUS server to NAS, whereas the proxy appears to act as a RADIUS client to the RADIUS server.

When the proxy server receives a request for a user name with a realm, the server references a table of realms. If the realm is known, the server proxies the request to the RADIUS server.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
proxy [realm|retry-count|retry-delay]
proxy realm <REALM-NAME> server <IP> port <1024-65535> secret [0 <PASSWORD>|2 <ENCRYPTED-
PASSWORD>|<PASSWORD>]
proxy retry-count <3-6>
proxy retry-delay <5-10>
```

### Parameters

```
proxy realm <REALM-NAME> server <IP> port <1024-65535> secret [0 <PASSWORD>|2 <ENCRYPTED-
PASSWORD>|<PASSWORD>]
```

proxy retry-count <3-6>

|                      |                                                                                                                                                                                                                                                                 |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| retry-count<br><3-6> | Sets the proxy server's retry count. This is the maximum number of attempts made by a controllers RADIUS server to connect to the proxy server. <ul style="list-style-type: none"> <li>• &lt;3-6&gt; - Sets a value from 3 - 6 (default is 3 counts)</li> </ul> |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

proxy retry-delay <5-10>

|                       |                                                                                                                                                                                                                                                                                 |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| retry-delay<br><5-10> | Sets the proxy server's retry delay count. This is the interval the controller's RADIUS server waits before making an additional connection attempt. <ul style="list-style-type: none"> <li>• &lt;5-10&gt; - Sets a value from 5 - 10 seconds (default is 5 seconds)</li> </ul> |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Usage Guidelines

A maximum of five RADIUS proxy servers can be configured. The proxy server attempts six retries before it times out. The retry count defines the number of times RADIUS requests are transmitted before giving up. The timeout value is the defines the interval between successive retransmission of a RADIUS request (in case of no reply).

### Examples

```
nx9500-6C8809(config-radius-server-policy-test)#proxy realm test1 server 172.16.10.7 port
1025 secret 0 test1123
nx9500-6C8809(config-radius-server-policy-test)#proxy retry-count 4
nx9500-6C8809(config-radius-server-policy-test)#proxy retry-delay 8
nx9500-6C8809(config-radius-server-policy-test)#show context
radius-server-policy test
 proxy retry-delay 8
 proxy retry-count 4
 proxy realm test1 server 172.16.10.7 port 1025 secret 0 test1123
 ldap-server primary host 172.16.10.19 port 162 login "test" bind-dn "bind-dn1" base-dn
"bas-dn1" passwd 0 test@123 passwd-attr test123 group-attr group1 group-filter
"groupfilter1" group-membership groupmembershipl net-timeout 2
nx9500-6C8809(config-radius-server-policy-test)#
```

| no on page 1575 | Removes or resets the RADIUS proxy server's settings |
|-----------------|------------------------------------------------------|

### *session-resumption*

Enables session resumption or fast re-authentication by using cached attributes. This feature controls the volume and duration cached data is maintained by the server policy, upon termination of a server policy session. The availability and quick retrieval of the cached data speeds up session resumption.

This feature is disabled by default.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
session-resumption {lifetime|max-entries}
session-resumption {lifetime <1-24> {max-entries <10-1024>}/max-entries <10-1024>}
```

### Parameters

```
session-resumption {lifetime <1-24> {max-entries <10-1024>}/max-entries <10-1024>}
```

|                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| lifetime <1-24><br>{max-entries<br><10-1024>} | Optional. Sets the lifetime of cached entries <ul style="list-style-type: none"><li>• &lt;1-24&gt; - Specify the lifetime period from 1 - 24 hours (default is 1 hour)</li><li>• max-entries - Optional. | <code>no</code> on page 1575 | Disables session resumption on this RADIUS server policy |
|------------------------------|----------------------------------------------------------|

### termination

Enables EAP termination on this RADIUS server policy. When enabled, EAP authentication is terminated at the controller level. This option is disabled by default.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000

- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

termination

### Parameters

None

### Examples

```
nx9500-6C8809(config-radius-server-policy-test)#termination
nx9500-6C8809(config-radius-server-policy-test)#show context
radius-server-policy test
 termination
 no bypass crl-check
nx9500-6C8809(config-radius-server-policy-test)#
```

### Related Commands

|-----------------|-------------------------------------------------------|
| no on page 1575 | Disables EAP termination on this RADIUS server policy |
|-----------------|-------------------------------------------------------|

use

Defines settings used with the RADIUS server policy

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
use [radius-group <RAD-GROUP-NAME1> {RAD-GROUP-NAME2}|radius-user-pool-policy <RAD-USER-POOL-NAME>]
```

### Parameters

```
use [radius-group <RAD-GROUP-NAME1> {RAD-GROUP-NAME2}|radius-user-pool-policy <RAD-USER-POOL-NAME>]
```

|                                                  |                                                                                                                                                                    |
|--------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| radius-group <RAD-GROUP-NAME1> {RAD-GROUP-NAME2} | Associates a specified RADIUS group (for LDAP users) with this RADIUS server policy. You can optionally associate two RADIUS groups with one RADIUS server policy. |
| radius-user-pool-policy <RAD-USER-POOL-NAME>     | Associates a specified RADIUS user pool with this RADIUS server policy. Specify a user pool name.                                                                  |

### Examples

```
nx9500-6C8809(config-radius-server-policy-test)#use radius-group test
nx9500-6C8809(config-radius-server-policy-test)#show context
radius-server-policy test
 proxy retry-delay 8
 proxy retry-count 4
 proxy realm test1 server 172.16.10.7 port 1025 secret 0 test1123
 ldap-server primary host 172.16.10.19 port 162 login "test" bind-dn "bind-dn1" base-dn
```

```
"bas-dn1" passwd 0 test@123 passwd-attr test123 group-attr group1 group-filter
"groupfilter1" group-membership groupmembershipl net-timeout 2
 use radius-group test
 session-resumption lifetime 10 max-entries 11
nx9500-6C8809(config-radius-server-policy-test)#
```

## Related Commands

`no` on page 1575 Disassociates a RADIUS group or a RADIUS user pool policy from this RADIUS server policy

*no*

Negates a command or reverts back to default settings. When used with in the config RADIUS server policy mode, the `no` command removes settings, such as `crl-check`, LDAP group verification, RADIUS client, etc.

## Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
no [authentication|bypass|chase-referral|crl-check|ldap-agent|ldap-group-verification|
ldap-server|local|nas|proxy|session-resumption|termination|use]
no bypass [crl-check|expired-crl]
no authentication [data-source|eap]
no authentication [data-source {ldap {fallback}|local|ssid}|eap configuration]
no [chase-referral|crl-check|ldap-group-verification|nas <IP/M>|session-resumption]
no ldap-agent [join-retry-timeout|primary|secondary]
no local realm [<REALM-NAME>|all]
no proxy [realm <REALM-NAME>|retry-count|retry-delay]
no ldap-server [dead-period|primary|secondary]
no termination
no use [radius-group [<RAD-GROUP-NAME>|all]|radius-user-pool-policy [<RAD-USER-POOL-NAME>|
all]]
```

## Parameters

`no` <PARAMETERS>

`no` <PARAMETERS> Negates a command or reverts back to default settings. When used with in the config RADIUS server policy mode, the `no` command removes settings, such as `crl-check`, LDAP group verification, RADIUS client, etc.

## Examples

The following example shows the RADIUS server policy 'test' settings before the 'no' commands are executed:

```
nx9500-6C8809(config-radius-server-policy-test)#show context
radius-server-policy test
 authentication eap-auth-type tls
 crl-check
 nas 172.16.10.10/24 secret 0 wirelesswell
 local realm realm1
 ldap-server primary host 172.16.10.19 port 162 login "test" bind-dn "bind-dn1" base-dn
"bas-dn1" passwd 0 test@123 passwd-attr test123 group-attr group1 group-filter
```

```

"groupfilter1" group-membership groupmembership1 net-timeout 2
 ldap-server dead-period 100
nx9500-6C8809(config-radius-server-policy-test)#
nx9500-6C8809(config-radius-server-policy-test)#no authentication eap configuration
nx9500-6C8809(config-radius-server-policy-test)#no curl-check
nx9500-6C8809(config-radius-server-policy-test)#no local realm realm1
nx9500-6C8809(config-radius-server-policy-test)#no nas 172.16.10.10/24
nx9500-6C8809(config-radius-server-policy-test)#no ldap-server dead-period

```

The following example shows the RADIUS server policy 'test' settings after the 'no' commands are executed:

```

nx9500-6C8809(config-radius-server-policy-test)#show context
radius-server-policy test
 ldap-server primary host 172.16.10.19 port 162 login "test" bind-dn "bind-dn1" base-dn
"bas-dn1" passwd 0 test@123 passwd-attr test123 group-attr group1 group-filter
"groupfilter1" group-membership groupmembership1 net-timeout 2
nx9500-6C8809(config-radius-server-policy-test)#

```

## radius-user-pool-policy

Configures a RADIUS user pool policy and enters its configuration mode

A user pool defines policies for individual user access to the internal RADIUS resources. User pool policies define unique permissions (either temporary or permanent) that control user access to the local RADIUS resources. A pool can contain a single user or multiple users.

Use the (config) instance to configure RADIUS user pool policy commands. To navigate to the radius-user-pool-policy instance, use the following commands:

```

<DEVICE>(config)#radius-user-pool-policy <POOL-NAME>
nx9500-6C8809(config)#radius-user-pool-policy testuser
nx9500-6C8809(config-radius-user-pool-testuser)#?
Radius User Pool Mode commands:
 duration Set a guest user's access duration
 no Negate a command or set its defaults
 user Radius user configuration

 clrscr Clears the display screen
 commit Commit all changes made in this session
 do Run commands from Exec mode
 end End current mode and change to EXEC mode
 exit End current mode and down to previous mode
 help Description of the interactive help system
 revert Revert changes
 service Service Commands
 show Show running system information
 write Write running configuration to memory or terminal

nx9500-6C8809(config-radius-user-pool-testuser)#

```

The following table summarizes RADIUS user pool policy configuration commands.

Table: RADIUS-User-Pool Config Mode Commands

| Commands                           | Description                                               |
|------------------------------------|-----------------------------------------------------------|
| <code>duration</code> on page 1577 | Modifies a guest user's duration of captive-portal access |
| <code>user</code> on page 1577     | Configures the RADIUS user parameters                     |
| <code>no</code> on page 1580       | Negates a command or sets its default                     |

### *duration*

Modifies the duration, in minutes, that a guest user can access the captive portal

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
duration <GUEST-USER-NAME> <0-525600>
```

#### Parameters

```
duration <GUEST-USER-NAME> <0-525600>
```

|                                                              |                                                                                                                                                                                                                                                                                                                                                                                                                 |

#### Examples

```
rfs4000-229D58(config-radius-user-pool-wdws)#show context
radius-user-pool-policy wdws
 user guestuser1 password 0 guestuser@1 group wdws guest expiry-time 12:30 expiry-date
12/15/2014 access-duration 500
rfs4000-229D58(config-radius-user-pool-wdws)#
rfs4000-229D58(config-radius-user-pool-wdws)#duration guestuser1 200
rfs4000-229D58(config-radius-user-pool-wdws)#show context
radius-user-pool-policy wdws
 user guestuser1 password 0 guestuser@1 group wdws guest expiry-time 12:30 expiry-date
12/15/2014 access-duration 200
rfs4000-229D58(config-radius-user-pool-wdws)#
```

### *user*

Configures RADIUS user parameters

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000

- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```

user <USERNAME> password [0 <UNENCRYPTED-PASSWORD>|2 <ENCRYPTED-PASSWORD>|<PASSWORD>]
{group <RAD-GROUP-NAME>} {guest}
user <USERNAME> password [0 <UNENCRYPTED-PASSWORD>|2 <ENCRYPTED-PASSWORD>|<PASSWORD>]
{group <RAD-GROUP-NAME>} {guest expiry-time <HH:MM> expiry-date <MM/DD/YYYY>
{access-duration <0-525600>|data-limit|email-id <EMAIL-ID>|start-time <HH:MM> start-date
<MM/DD/YYY>|
telephone <TELEPHONE-NUMBER>}}
user <USERNAME> password [0 <UNENCRYPTED-PASSWORD>|2 <ENCRYPTED-PASSWORD>|
<PASSWORD>] {group <RAD-GROUP-NAME>} {guest expiry-time <HH:MM> expiry-date <MM/DD/YYYY>
{access-duration <0-525600>|data-limit <1-102400> committed-downlink <100-1000000>
committed-uplink <100-1000000> reduced-downlink <100-1000000> reduced-uplink <100-1000000>|
email-id <EMAIL-ID>|start-time <HH:MM> start-date <MM/DD/YYY>|telephone <TELEPHONE-
NUMBER>}}

```

## Parameters

```

user <USERNAME> password [0 <UNENCRYPTED-PASSWORD>|2 <ENCRYPTED-PASSWORD>|
<PASSWORD>] {group <RAD-GROUP-NAME>} {guest expiry-time <HH:MM> expiry-date <MM/DD/YYYY>
{access-duration <0-525600>|data-limit <1-102400> committed-downlink <100-1000000>
committed-uplink <100-1000000> reduced-downlink <100-1000000> reduced-uplink <100-1000000>|
email-id <EMAIL-ID>|start-time <HH:MM> start-date <MM/DD/YYY>|telephone <TELEPHONE-
NUMBER>}}

```

## Examples

```
rfs4000-229D58(config-radius-user-pool-wdws)#user guestuser1 password 0 guestuser@1
group wdws guest expiry-time 12:30 expiry-date 12/15/2014 access-duration 500
rfs4000-229D58(config-radius-user-pool-wdws)#show context
radius-user-pool-policy wdws
 user guestuser1 password 0 guestuser@1 group wdws guest expiry-time 12:30 expiry-date
 12/15/2014 access-duration 500
rfs4000-229D58(config-radius-user-pool-wdws)#
```

## Related Commands

|                              |                                        |
|------------------------------|----------------------------------------|
| <code>no</code> on page 1580 | Deletes a user from a RADIUS user pool |
|------------------------------|----------------------------------------|

*no*

Negates a command or sets its default. When used in the RADIUS user pool policy mode, the `no` command deletes a user from a RADIUS user pool

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
no user <USERNAME>
```

## Parameters

```
no user <USERNAME>
```

|                                       |                                                                                                                                |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <code>no user &lt;USERNAME&gt;</code> | Deletes a RADIUS user <ul style="list-style-type: none"><li>• <code>&lt;USERNAME&gt;</code> - Specify the user name.</li></ul> |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|

## Examples

The following example shows the RADIUS user pool 'testuser' settings before the 'no' command is executed:

```
rfs4000-229D58(config-radius-user-pool-wdws)#show context
radius-user-pool-policy wdws
 user guestuser1 password 0 guestuser@1 group wdws guest expiry-time 12:30 expiry-date
 12/15/2014 access-duration 500
rfs4000-229D58(config-radius-user-pool-wdws)#
rfs4000-229D58(config-radius-user-pool-wdws)#no user guestuser1
```

The following example shows the RADIUS user pool 'testuser' settings after the 'no' command is executed:

```
rfs4000-229D58(config-radius-user-pool-wdws)#show context
radius-user-pool-policy wdws
rfs4000-229D58(config-radius-user-pool-wdws)#
```

# RADIO QoS POLICY

## RADIO-QOS-POLICY

---

This chapter summarizes the radio QoS policy in the CLI command structure.

Configuring and implementing a radio QoS policy is essential for WLANs with heavy traffic and less bandwidth. The policy enables you to provide preferential service to selected network traffic by controlling bandwidth allocation. The radio QoS policy can be applied to VLANs configured on an access point. In case no VLANs are configured, the radio QoS policy can be applied to an access point's Ethernet and radio ports.

Without a dedicated QoS policy, a network operates on a best-effort delivery basis, meaning all traffic has equal priority and an equal chance of being delivered in a timely manner. When congestion occurs, all traffic has an equal chance of being dropped!

When configuring a Radio QoS policy, select specific network traffic, prioritize it, and use congestion-management and congestion-avoidance techniques to provide deployment customizations best suited to each QoS policy's intended wireless client base.

A well designed QoS policy should:

- Classify and mark data traffic to accurately prioritize and segregate it (by access category) throughout the network.
- Minimize network delay and jitter for latency sensitive traffic.
- Ensure higher priority traffic has a better likelihood of delivery in the event of network congestion.
- Prevent ineffective utilization of access points degrading session quality by configuring admission control mechanisms within each radio QoS policy.

Within a managed wireless network, wireless clients supporting low and high priority traffic contend with one another for access and data resources. The IEEE 802.11e amendment has defined EDCA (Enhanced Distributed Channel Access) mechanisms stating high priority traffic can access the network sooner than lower priority traffic. The EDCA defines four traffic classes (or access categories); voice (highest), video (next highest), best effort, and background (lowest). The EDCA has defined a time interval for each traffic class, known as the TXOP (Transmit Opportunity). The TXOP prevents traffic of a higher priority from completely dominating the wireless medium, thus ensuring lower priority traffic is still supported.

IEEE 802.11e includes an advanced power saving technique called U-APSD (Unscheduled Automatic Power Save Delivery) that provides a mechanism for wireless clients to retrieve packets buffered by an access point. U-APSD reduces the amount of signaling frames sent from a client to retrieve buffered data from an access point. U-APSD also allows access points to deliver buffered data frames as bursts, without backing-off between data frames. These improvements are useful for voice clients, as they provide improved battery life and call quality.

The Wi-Fi alliance has created WMM (Wireless Multimedia) and WMM-PS (WMM Power Save) certification programs to ensure interoperability between 802.11e WLAN infrastructure implementations

and wireless clients. A wireless network supports both WMM and WMM-Power Save techniques. WMM and WMM-PS (U-APSD) are enabled by default in each WLAN profile.

Enabling WMM support on a WLAN just advertises the WLAN's WMM capability and radio configuration to wireless clients. The wireless clients must also support WMM and use the values correctly while accessing the WLAN to benefit.

WMM includes advanced parameters (CWMin, CWMax, AIFSN and TXOP) specifying back-off duration and inter-frame spacing when accessing the network. These parameters are relevant to both connected access point radios and their wireless clients. Parameters impacting access point transmissions to their clients are controlled using per radio WMM settings, while parameters used by wireless clients are controlled by a WLAN's WMM settings.

Wireless network controllers (access points, controllers, and service platforms) include a SIP (Session Initiation Protocol), SCCP (Skinny Call Control Protocol) and ALG (Application Layer Gateway) enabling devices to identify voice streams and dynamically set voice call bandwidth.

Wireless network controllers also support static QoS mechanisms per WLAN to provide prioritization of WLAN traffic when legacy (non WMM) clients are deployed. When enabled on a WLAN, traffic forwarded to a client is prioritized and forwarded based on the WLAN's WMM access control setting.

#### Note

Statically setting a WLAN WMM access category value only prioritizes traffic to the client.

Wireless network administrators can also assign weights to each WLAN in relation to user priority levels. The lower the weight, the lower the priority. Use a weighted technique to achieve different QoS levels across WLANs.

All devices rate-limit bandwidth for WLAN sessions. This form of per-user rate limiting enables administrators to define uplink and downlink bandwidth limits for users and clients. This sets the level of traffic a user or client can forward and receive over the WLAN. If the user or client exceeds the limit, excessive traffic is dropped.

Rate limits can be applied to WLANs using groups defined locally or externally from a RADIUS server using VSAs (Vendor Specific Attributes). Rate limits can be applied to users authenticating using 802.1X, captive portal authentication, and devices using MAC authentication.

Use the (config) instance to configure radios QoS policy related configuration commands. To navigate to the radio QoS policy instance, use the following commands:

```
<DEVICE>(config)#radio-qos-policy <POLICY-NAME>
nx9500-6C8809(config)#radio-qos-policy test
nx9500-6C8809(config-radio-qos-test)#?
Radio QoS Mode commands:
 accelerated-multicast Configure multicast streams for acceleration
 admission-control Configure admission-control on this radio for one or
 more access categories
 no Negate a command or set its defaults
 smart-aggregation Configure smart aggregation parameters
 wmm Configure 802.11e/Wireless MultiMedia parameters

 clrscr Clears the display screen
 commit Commit all changes made in this session
 do Run commands from Exec mode
 end End current mode and change to EXEC mode
```

```

exit End current mode and down to previous mode
help Description of the interactive help system
revert Revert changes
service Service Commands
show Show running system information
write Write running configuration to memory or terminal

```

```
nx9500-6C8809(config-radio-qos-test)#
```

## radio-qos-policy-commands

The following table summarizes radio QoS policy configuration commands:

**Table 48: Radio-QoS-Policy Config Mode Commands**

| Command                                            | Description                                                                   |
|----------------------------------------------------|-------------------------------------------------------------------------------|
| <a href="#">accelerated-multicast</a> on page 1583 | Configures multicast streams for acceleration                                 |
| <a href="#">admission-control</a> on page 1584     | Enables admission control across all radios for one or more access categories |
| <a href="#">smart-aggregation</a> on page 1588     | Configures smart aggregation parameters                                       |
| <a href="#">service</a> on page 1589               | Invokes service commands in the radio QoS configuration mode                  |
| <a href="#">wmm</a> on page 1590                   | Configures 802.11e/wireless multimedia parameters                             |
| <a href="#">no</a> on page 1592                    | Negates a command or resets configured settings to their default              |

### Note

For more information on common commands (clrscr, commit, help, revert, service, show, write, and exit), see [COMMON COMMANDS](#) on page 640.

### Note

The input parameter <HOSTNAME>, wherever used in syntaxes across this chapter, cannot include an underscore (\_) character. In other words, the name of a device cannot contain an underscore.

### *accelerated-multicast*

Configures multicast streams for acceleration. Multicasting allows group transmission of data streams.

#### **Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
accelerated-multicast [client-timeout|max-client-streams|max-streams|overflow-policy|
stream-threshold]
accelerated-multicast [client-timeout <5-6000>|max-client-streams <1-4>|max-streams
<0-256>|
overflow-policy [reject|revert]|stream-threshold <1-500>]
```

## Parameters

```
accelerated-multicast [client-timeout <5-6000>|max-client-streams <1-4>|max-streams
<0-256>|
overflow-policy [reject|revert]|stream-threshold <1-500>]
```

|                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| client-timeout<br><5-6000>>        | Configures a timeout period in seconds for wireless clients <ul style="list-style-type: none"><li>&lt;5-6000&gt; - Specify a value from 5 - 6000 seconds. The default is 60 seconds.</li></ul>                                                                                                                                                                                                                                                                                                                                                                  |
| max-client-streams<br><1-4>        | Configures the maximum number of accelerated multicast streams per client <ul style="list-style-type: none"><li>&lt;1-4&gt; - Specify a value from 1 - 4. The default is 2.</li></ul>                                                                                                                                                                                                                                                                                                                                                                           |
| max-streams<br><0-256>             | Configures the maximum number of accelerated multicast streams per radio <ul style="list-style-type: none"><li>&lt;0-256&gt; - Specify a value from 0 - 256. The default is 25.</li></ul>                                                                                                                                                                                                                                                                                                                                                                       |
| overflow-policy<br>[reject revert] | Specifies the policy in case too many clients register simultaneously. The radio QoS policy can be configured to follow one of the following courses of action: <ul style="list-style-type: none"><li>reject - Rejects new clients. The default overflow policy is reject.</li><li>revert - Reverts to regular multicast delivery</li></ul> When the number of wireless clients using accelerated multicast exceeds the configured value (max-streams), the radio can either reject new wireless clients or revert existing clients to a non-accelerated state. |
| stream-threshold<br><1-500>        | Configures the number of multicast packets per second threshold value. Once this threshold is crossed, the system triggers streams to accelerate. <ul style="list-style-type: none"><li>&lt;1-500&gt; - Specify a value from 1 - 500. The default is 25 packets per second.</li></ul>                                                                                                                                                                                                                                                                           |

## Examples

```
nx9500-6C8809(config-radio-qos-test)#accelerated-multicast client-timeout 500
nx9500-6C8809(config-radio-qos-test)#accelerated-multicast stream-threshold 15
nx9500-6C8809(config-radio-qos-test)#show context
radio-qos-policy test
 accelerated-multicast stream-threshold 15
 accelerated-multicast client-timeout 500
nx9500-6C8809(config-radio-qos-test)#
```

### *admission-control*

Enables admission control across all radios for one or more access categories. Enabling admission control for an access category ensures clients associated to an access point complete WMM admission control before using that access category.

## Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
admission-control [background|best-effort|firewall-detected-traffic|implicit-tspec|
video|voice]
admission-control [firewall-detected-traffic|implicit-tspec]
admission-control [background|best-effort|video|voice]
{max-airtime-percent|max-clients|max-roamed-clients|reserved-for-roam-percent}
admission-control [background|best-effort|video|voice] {max-airtime-percent <0-150>/
max-clients <0-256>/max-roamed-clients <0-256>/reserved-for-roam-percent <0-150>}
```

## Parameters

```
admission-control [firewall-detected-traffic|implicit-tspec]
```

|                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| admission-control firewall-detected-traffic | Enforces admission control for traffic whose access category is detected by the firewall ALG. For example, SIP voice calls. This feature is enabled by default. When enabled, the firewall simulates reception of frames for voice traffic when the voice traffic was originated via SIP or SCCP control traffic. If a client exceeds configured values, the call is stopped and/or received voice frames are forwarded at the next non admission controlled traffic class priority. This applies to clients that do not send TPSEC frames only.                                                                                                                                                                                                                                                               |
| admission-control implicit-tspec            | Enables implicit traffic specifiers for clients that do not support WMM TSPEC, but are accessing admission-controlled access categories. This feature is enabled by default. This feature requires wireless clients to send their traffic specifications to an access point before they can transmit or receive data. If enabled, this setting applies to this radio QoS policy. When enabled, the access point simulates the reception of frames for any traffic class by looking at the amount of traffic the client is receiving and sending. If the client sends more traffic than has been configured for an admission controlled traffic class, the traffic is forwarded at the priority of the next non admission controlled traffic class. This applies to clients that do not send TPSEC frames only. |

```
admission-control [background|best-effort|video|voice]
{max-airtime-percent|max-clients|max-roamed-clients|reserved-for-roam-percent}
```

|                               |                                                                     |
|-------------------------------|---------------------------------------------------------------------|
| admission-control background  | Configures background access category admission control parameters  |
| admission-control best-effort | Configures best effort access category admission control parameters |
| admission-control video       | Configures video access category admission control parameters       |
| admission-control voice       | Configures voice access category admission control parameters       |

|                                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>max-airtime-percent<br/>&lt;0-150&gt;</p> | <p>Optional. Specifies the maximum percentage of airtime, including over subscription, for the following access category:</p> <ul style="list-style-type: none"> <li>• background – Sets the maximum airtime (in the form of a percentage of the radio’s bandwidth) allotted to admission control for low (background) client traffic. Background traffic only needs a short radio airtime to process, so set an intermediate airtime value if this radio QoS policy is reserved to support background data.</li> <li>• best-effort – Sets the maximum airtime (in the form of a percentage of the radio’s bandwidth) allotted to admission control for normal (best-effort) client traffic. Normal best effort traffic needs a short radio airtime to process, so set an intermediate airtime value if this radio QoS policy is reserved for best effort data support.</li> <li>• video – Sets the maximum airtime (in the form of a percentage of the radio’s bandwidth) allotted to admission control for voice supported client traffic. Video traffic requires longer radio airtime to process, so set a longer airtime value if this radio QoS policy is intended to support video.</li> <li>• voice – Sets the maximum airtime (in the form of a percentage of the radio’s bandwidth) allotted to admission control for voice supported client traffic. Voice traffic requires longer radio airtime to process, so set a longer airtime value if this radio QoS policy is intended to support voice.</li> </ul> <p>The following keyword is common to all of the above traffic types:</p> <ul style="list-style-type: none"> <li>• &lt;0-150&gt; – Specify a value from 0 - 150. This is the maximum percentage of airtime, including over subscription, for the selected access category. The default is 75%.</li> </ul> |
| <p>max-clients &lt;0-256&gt;</p>             | <p>Optional. Specifies the maximum number of wireless clients admitted to the following access categories:</p> <ul style="list-style-type: none"> <li>• background – Sets the number of wireless clients supporting low (background) traffic allowed to exist (and consume bandwidth) within the radio’s QoS policy</li> <li>• best-effort – Sets the number of wireless clients supporting normal (best-effort) traffic allowed to exist (and consume bandwidth) within the radio’s QoS policy</li> <li>• video – Sets the number of video supported wireless clients allowed to exist (and consume bandwidth) within the radio’s QoS policy.</li> <li>• voice – Sets the number of voice supported wireless clients allowed to exist (and consume bandwidth) within the radio’s QoS policy.</li> </ul> <p>Since voice and video supported wireless clients use a greater portion of a controller’s resources than lower bandwidth traffic (like low and best effort categories), consider setting the max-client value proportionally to the number of other QoS policies supporting voice access category clients.</p> <p>The following keyword is common to all of the above traffic types:</p> <ul style="list-style-type: none"> <li>• &lt;0-256&gt; – Specify a value from 0 - 256. This is the maximum number of wireless clients admitted to the selected access category. The default is 100 clients.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                       |

|                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## smart-aggregation

Configures smart aggregation parameters on this Radio QoS policy. Smart aggregation enhances frame aggregation by dynamically selecting the time when the aggregated frame is transmitted. In a frame's typical aggregation, an aggregated frame is sent when:

- A pre-configured number of aggregated frames is reached
- An administrator-defined interval has elapsed since the first frame (of a set of frames to be aggregated) was received
- An administrator-defined interval has elapsed since the last frame (not necessarily the final frame) of a set of frames to be aggregated was received

With this enhancement, an aggregation delay is set uniquely for each traffic class. For example, voice traffic might not be aggregated, but sent immediately. Whereas, background data traffic is set a delay for aggregating frames, and these aggregated frames are sent.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
smart-aggregation {delay|max-mesh-hops|min-aggregation-limit}
smart-aggregation {delay [background|best-effort|streaming-video|video-conferencing|
voice] <0-1000>}
smart-aggregation {max-mesh-hops <1-10>}
smart-aggregation {min-aggregation-limit <0-64>}
```

### Parameters

```
smart-aggregation {delay [background|best-effort|streaming-video|video-conferencing|
voice] <0-1000>}
```

|                    |                                                                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| delay              | Optional. Configures the maximum delay parameter for each traffic type. This is the maximum delay, in milliseconds, in the transmission of the first frame received. |
| background         | Configures the maximum delay parameter, in milliseconds, for background traffic (250 msec)                                                                           |
| best-effort        | Configures the maximum delay parameter, in milliseconds, for best effort traffic (150 msec)                                                                          |
| streaming-video    | Configures the maximum delay parameter, in milliseconds, for streaming video traffic (150 msec)                                                                      |
| video-conferencing | Configures the maximum delay parameter, in milliseconds, for video conference traffic (40 msec)                                                                      |
| voice              | Configures the maximum delay parameter, in milliseconds, for voice traffic (0 msec)                                                                                  |
| <0-1000>           | This parameter is common to all of the above traffic types. <ul style="list-style-type: none"><li>• &lt;0-1000&gt; – Specify a value from 0 - 1000 msec.</li></ul>   |

```
smart-aggregation {max-mesh-hops <1-10>}
```

|                      |                                                                                                                                                                                                            |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| max-mesh-hops <1-10> | Optional. Sets the maximum number of expected hops to the destination within a mesh <ul style="list-style-type: none"> <li>• &lt;1-10&gt; – Specify a value from 1 - 10. The default is 3 hops.</li> </ul> |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

smart-aggregation {min-aggregation-limit <0-64>}

|                              |                                                                                                                                                                                                               |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| min-aggregation-limit <0-64> | Optional. Sets the minimum number of aggregates buffered before an aggregate is sent <ul style="list-style-type: none"> <li>• &lt;0-64&gt; – Specify a value from 0 - 64. The default is 8 frames.</li> </ul> |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**Examples**

```

nx9500-6C8809(config-radio-qos-test)#smart-aggregation delay voice 50
nx9500-6C8809(config-radio-qos-test)#smart-aggregation delay background 100
nx9500-6C8809(config-radio-qos-test)#show context
radio-qos-policy test
 smart-aggregation delay voice 50
 smart-aggregation delay background 100
nx9500-6C8809(config-radio-qos-test)#

```

*service*

Invokes service commands in the radio QoS configuration mode

**Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

**Syntax**

```

service [admission-control|show]
service admission-control across-reassoc
service show cli

```

**Parameters**

```
service admission-control across-reassoc
```

|                                  |                                                                                                                                                                                               |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| service                          | Invokes service commands                                                                                                                                                                      |
| admission-control across-reassoc | Retains previously negotiated TSPEC parameters across re-associations on the radio. For more information on admission-control parameters, see <a href="#">admission-control</a> on page 1584. |

```
service show cli
```

|                  |                                                                                                                                      |

## wmm

Configures 802.11e WMM (wireless multi media) parameters

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
wmm [background|best-effort|video|voice]
wmm [background|best-effort|video|voice] [aifsn <1-15>|cw-max <0-15>|cw-min <0-15>|
txop-limit <0-65535>]
```

### Parameters

```
wmm [background|best-effort|video|voice] [aifsn <1-15>|cw-max <0-15>|cw-min <0-15>|
txop-limit <0-65535>]
```

## Usage Guidelines

Before defining a radio QoS policy, refer to the following deployment guidelines to ensure the configuration is optimally effective:

- To support QoS, each multimedia application, wireless client, and WLAN is required to support WMM.
- WMM enabled clients can co-exist with non-WMM clients on the same WLAN. Non-WMM clients are always assigned a Best Effort access category.
- Default WMM values are recommended for all deployments. Changing these values can lead to unexpected traffic blockages, and the blockages might be difficult to diagnose.
- Overloading an access point radio with too much high priority traffic (especially voice) degrades overall service quality for all users.
- TSPEC admission control is only available with newer voice over WLAN phones. Many legacy voice devices do not support TPSEC or even support WMM traffic prioritization.

## Examples

```
nx9500-6C8809(config-radio-qos-test)#wmm best-effort aifsn 7
nx9500-6C8809(config-radio-qos-test)#wmm voice txop-limit 1
nx9500-6C8809(config-radio-qos-test)#show context
radio-qos-policy test
 wmm best-effort aifsn 7
 wmm voice txop-limit 1
 admission-control voice max-airtime-percent 9
 admission-control voice reserved-for-roam-percent 8
 accelerated-multicast stream-threshold 15
nx9500-6C8809(config-radio-qos-test)#
```

## Related Commands

|                             |                                                                         |
|-----------------------------|-------------------------------------------------------------------------|
| <code>no</code> on page 538 | Reverts or resets 802.11e/wireless multimedia settings to their default |
|-----------------------------|-------------------------------------------------------------------------|

*no*

Negates a command or resets configured settings to their default. When used in the radio QoS policy mode, the `no` command enables the resetting of accelerated multicast parameters, admission control parameters, and MultiMedia parameters.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
no [accelerated-multicast|admission-control|smart-aggregation|wmm|service]
no accelerated-multicast [client-timeout|max-client-streams|max-streams|
overflow-policy|stream-threshold]
no admission-control [firewall-detected-traffic|implicit-tspec|background|
best-effort|video|voice]
no admission-control [firewall-detected-traffic|implicit-tspec]
no admission-control [background|best-effort|video|voice] {max-airtime-percent /
max-clients/max-roamed-clients/reserved-for-roam-percent}
no smart-aggregation {delay|max-mesh-hops|min-aggregation-limit}
no smart-aggregation {delay [background|best-effort|streaming-video|
video-conferencing|voice]/max-mesh-hops|min-aggregation-limit}
no wmm [background|best-effort|video|voice] [aifsn|cw-max|cw-min|txop-limit]
no service admission-control across-reassoc
```

## Parameters

```
no <PARAMETERS>
```

no <PARAMETERS> Negates a command or resets configured settings to their default. When used in the radio QoS policy mode, the no command enables the resetting of accelerated multicast parameters, admission control parameters, and MultiMedia parameters.

## Examples

The following example shows the Radio-qos-policy 'test' settings before the 'no' commands are executed:

```
nx9500-6C8809(config-radio-qos-test)#show context
radio-qos-policy test
 admission-control voice max-airtime-percent 9
 admission-control voice reserved-for-roam-percent 8
 admission-control best-effort max-clients 200
 accelerated-multicast stream-threshold 15
 accelerated-multicast client-timeout 500
nx9500-6C8809(config-radio-qos-test)#
nx9500-6C8809(config-radio-qos-test)#no admission-control best-effort max-clients
nx9500-6C8809(config-radio-qos-test)#no accelerated-multicast client-timeout
```

The following example shows the Radio-qos-policy 'test' settings after the 'no' commands are executed:

```
nx9500-6C8809(config-radio-qos-test)#show context
radio-qos-policy test
 admission-control voice max-airtime-percent 9
 admission-control voice reserved-for-roam-percent 8
 accelerated-multicast stream-threshold 15
nx9500-6C8809(config-radio-qos-test)#
rfs4000-229D58(config-radio-qos-test)#show context
radio-qos-policy test
 service admission-control across-reassoc
rfs4000-229D58(config-radio-qos-test)#
rfs4000-229D58(config-radio-qos-test)#no service admission-control across-reassoc
rfs4000-229D58(config-radio-qos-test)#show context
radio-qos-policy test
rfs4000-229D58(config-radio-qos-test)#
```

# ROLE POLICY

## ROLE-POLICY

---

This chapter summarizes the role policy commands in the CLI command structure.

A well defined role policy simplifies user management, and is a significant aspect of WLAN management. It acts as a role based firewall (much like ACLs) consisting of user-defined roles. Each role has a set of match criteria (filters) used to filter wireless clients. The action taken when a client matches the defined filters, is determined by the IP or MAC ACL associated with the user-defined role. Based on the conditions specified in the IP and/or MAC ACL, clients are granted or denied access to the controller managed network. The role policy also defines the VLAN and data rates assigned to clients provided network access.

A role policy also enables LDAP service, allowing controllers and access points to retrieve user information from the LDAP server. This information is matched with the user-defined role filters to determine if a client matches the role or not, and should be allowed or denied access to the controller managed network.

Use the (config-role-policy) instance to configure role policy related configuration commands. To navigate to the config-role instance, use the following commands:

```
<DEVICE>(config)#role-policy <POLICY-NAME>
nx9500-6C8809(config)#role-policy test
nx9500-6C8809(config-role-policy-test)#?
Role Policy Mode commands:
 default-role Configuration for Wireless Clients not matching any role
 ldap-deadperiod Ldap dead period interval
 ldap-query Set the ldap query mode
 ldap-server Add a ldap server
 ldap-timeout Ldap query timeout interval
 no Negate a command or set its defaults
 user-role Create a role

 clrscr Clears the display screen
 commit Commit all changes made in this session
 do Run commands from Exec mode
 end End current mode and change to EXEC mode
 exit End current mode and down to previous mode
 help Description of the interactive help system
 revert Revert changes
 service Service Commands
 show Show running system information
 write Write running configuration to memory or terminal

nx9500-6C8809(config-role-policy-test)#
```

### role-policy-commands

The following table summarizes role policy configuration commands:

**Table 49: Role-Policy Config Mode Commands**

| Command                                   | Description                                                                                |
|-------------------------------------------|--------------------------------------------------------------------------------------------|
| <code>default-role</code> on page 1595    | When a client fails to find a matching role, the default action is assigned to that client |
| <code>ldap-deadperiod</code> on page 1596 | Configures the LDAP (Lightweight Directory Access Protocol) dead period interval           |
| <code>ldap-query</code> on page 1597      | Enables LDAP service and specifies the LDAP server query mode                              |
| <code>ldap-server</code> on page 1598     | Configures the LDAP server settings                                                        |
| <code>ldap-timeout</code> on page 1599    | Configures the LDAP query timeout                                                          |
| <code>user-role</code> on page 1600       | Creates a role and associates it to the newly created role policy                          |
| <code>no</code> on page 1627              | Negates a command or reverts settings to their default                                     |

**Note**

For more information on common commands (clrscr, commit, help, revert, service, show, write, and exit), see **COMMON COMMANDS** on page 640.

**Note**

The input parameter <HOSTNAME>, wherever used in syntaxes across this chapter, cannot include an underscore (\_) character. In other words, the name of a device cannot contain an underscore.

*default-role*

Assigns a default role to a wireless client that fails to match any of the user-defined roles

When a wireless client accesses a network, the client's details, retrieved from the LDAP server, are matched against all user-defined roles within the role policy. If the client fails to match any of these user-defined role filters, the client is assigned the default role. The action taken (permit or deny access) is determined by the IP and/or MAC ACL associated with the default role.

**Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

**Syntax**

```
default-role use [ip-access-list|ipv6-access-list|mac-access-list]
default-role use [ip-access-list|ipv6-access-list|mac-access-list] [in|out]
<IP/IPv6/MAC-ACCESS-LIST-NAME> precedence <1-100>
```

## Parameters

```
default-role use [ip-access-list|ipv6-access-list|mac-access-list] [in|out]
<IP/IPv6/MAC-ACCESS-LIST-NAME> precedence <1-100>
```

|                                                                                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

### *ldap-deadperiod*

Configures LDAP dead period interval

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

ldap-deadperiod <60-300>

## Parameters

ldap-deadperiod <60-300>

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ldap-deadperiod <60-300> | <p>Configures an LDAP dead period. When enabled, LDAP service allows the AP or controller to bind with the LDAP server and retrieve user details to match with user-defined role filters. The LDAP deadperiod is the interval between two consecutive attempts to bind with the LDAP server. To enable LDAP service, use the <a href="#">ldap-query</a> on page 1597 command.</p> <ul style="list-style-type: none"><li>• &lt;60-300&gt; – Specify the interval from 60 - 600 seconds. The default is 120 seconds.</li></ul> |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Examples

```
nx9500-6C8809(config-role-policy-test)#ldap-deadperiod 100
nx9500-6C8809(config-role-policy-test)#show context
role-policy test
 default-role use ip-access-list in test precedence 1
 ldap-deadperiod 100
nx9500-6C8809(config-role-policy-test)#
```

## ldap-query

Enables LDAP service and specifies the LDAP server query mode

Configuring the LDAP server query mode automatically enables LDAP service on this role policy. By default LDAP service is disabled.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

ldap-query [self|through-controller]

## Parameters

ldap-query [self|through-controller]

|                    |                                                                                                                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| self               | Configures LDAP query mode as <b>self</b> . The AP directly queries the LDAP server for user information. Select 'self' to use local LDAP server resources configured using the <a href="#">ldap-server</a> on page 1598 command. |
| through-controller | Configures LDAP query mode as <b>through-controller</b> . The AP queries the LDAP server, for user information, through the controller. Use this option when the AP is layer 2 adopted to the controller.                         |

## Examples

```
nx9500-6C8809(config-role-policy-test)#ldap-query self
nx9500-6C8809(config-role-policy-test)#show context
role-policy test
 default-role use ip-access-list in test precedence 1
 ldap-query self
 ldap-deadperiod 100
nx9500-6C8809(config-role-policy-test)#
```

|---------------------------------|-------------------------------------------|

### *ldap-server*

Associates a specified LDAP server with this role policy. Use this command to configure the credentials needed to bind with the LDAP server.

When enabled, LDAP service allows the AP or controller to bind with the LDAP server and retrieve user details. This information is matched with the user-defined roles within the role policy. If a match is made, the user is assigned the role and allowed or denied access to the controller managed network.

You can associate two LDAP servers with a role policy, allowing failover in case the primary server is unreachable.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
ldap-server <1-2> host [<IP>|<FQDN>] bind-dn <BIND-DN> base-dn <BASE-DN>
bind-password <PASSWORD> {port <1-65535>} {(server-type [active-directory/openldap])}
```

### Parameters

```
ldap-server <1-2> host [<IP>|<FQDN>] bind-dn <BIND-DN> base-dn <BASE-DN>
bind-password <PASSWORD> {port <1-65535>} {(server-type [active-directory/openldap])}
```

|                          |                                                                                                                                                       |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| ldap-server <1-2>        | Specify the LDAP server ID from 1 - 2.<br>The primary LDAP server (ID 1) is used to bind and query. The secondary LDAP server (ID 2) is for failover. |
| host [<IP> <FQDN>]       | Specify the LDAP server's IP address or FQDN (Fully Qualified Domain Name).                                                                           |
| bind-dn <BIND-DN>        | Specify the bind distinguished name (used for binding with the server).                                                                               |
| base-dn <BASE-DN>        | Specify the base distinguished name (used for searching). This should not exceed 127 characters.                                                      |
| bind-password <PASSWORD> | Specify the LDAP server password associated with the bind DN.                                                                                         |

|                                          |                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| port <1-65535>                           | Optional. Specify the LDAP server port from 1 - 65535. (default is 389).                                                                                                                                                                                                                                                                                                                        |
| server-type [active-directory  openldap] | The following keywords are common to the 'port' parameter: <ul style="list-style-type: none"> <li>server-type – Optional. Specifies the LDAP server type <ul style="list-style-type: none"> <li>active-directory – Enables support for active directory attribute search. This is the default setting.</li> <li>openldap – Enables support for openLDAP attribute search</li> </ul> </li> </ul> |

### Usage Guidelines

Use the `ldap-query` command to enable LDAP service on a role policy.

Use the `show > role > ldap-stats` command to view LDAP server status and state.

### Examples

```

nx9500-6C8809(config-role-policy-test)#ldap-server 1 host 192.168.13.7 bind-dn
"CN=Administrator,CN=Users,DC=TechPub,DC=com" base-dn "CN=Administrator,CN=Users,
DC=TechPub,DC=com" bind-password 0 superuser port 2
nx9500-6C8809(config-role-policy-test)#
nx9500-6C8809(config-role-policy-test)#show context
role-policy test
 default-role use ip-access-list in test precedence 1
 ldap-query self
 ldap-deadperiod 100
 ldap-server 1 host 192.168.13.7 bind-dn CN=Administrator,CN=Users,DC=TechPub,
DC=com base-dn CN=Administrator,CN=Users,DC=com bind-password 0 superuser port 2
nx9500-6C8809(config-role-policy-test)#

```

### *ldap-timeout*

Configures the LDAP timeout interval. This is the interval after which a LDAP query is timed out.

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
ldap-timeout <1-5>
```

### Parameters

```
ldap-timeout <1-5>
```

|                    |                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ldap-timeout <1-5> | Configures the LDAP query timeout interval from 1 - 5 seconds (default is 2 seconds)<br>When enabled, LDAP service allows the AP or controller to bind with the LDAP server and query it for user details. The LDAP query timeout is the interval between a request to and the response from the LDAP server. Once this interval is exceeded, the LDAP bind and query is timed out. |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Examples

```
nx9500-6C8809(config-role-policy-test)#ldap-timeout 1
nx9500-6C8809(config-role-policy-test)#show context
role-policy test default-role use ip-access-list in test precedence 1
 ldap-query self
 ldap-timeout 1
 ldap-deadperiod 100
 ldap-server 1 host 192.168.13.7 bind-dn CN=Adminstrator,CN=Users,DC=TechPub,
DC=com base-dn CN=Administrator,CN=Users,DC=com bind-password 0 superuser port 2
nx9500-6C8809(config-role-policy-test)#
```

### *user-role*

Creates a user-defined role and enters its configuration mode. Each role consists of a set of filters and action. The filters are match criteria used to filter wireless clients. And the action defines the action taken when a client matches the specified filters.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
user-role <ROLE-NAME> precedence <1-10000>
```

## Parameters

```
user-role <ROLE-NAME> precedence <1-10000>
```

|                       |                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| user-role <ROLE-NAME> | Configures the user role name <ul style="list-style-type: none"><li>• &lt;ROLE-NAME&gt; Specify a name for this user role.</li></ul>                                                                                                                                                                                                                                                                   |
| precedence <1-10000>  | Sets the precedence for this role <p><b>Note:</b> Lower the precedence, higher is the role priority. Precedence determines the order in which a role is applied. If a wireless client matches multiple roles, the role with the lower precedence is applied before those with higher precedence. While there is no default precedence for a role, two or more roles can share the same precedence.</p> |

## Examples

```
nx9500-6C8809(config-role-policy-test)#user-role testing precedence 10
nx9500-6C8809(config-role-policy-test)#show context
role-policy test
 user-role testing precedence 10
 default-role use ip-access-list in test precedence 1
nx9500-6C8809(config-role-policy-test)#
nx9500-6C8809(config-role-policy-test-user-role-testing)#?
Role Mode commands:
 ap-location AP Location configuration
 assign Assign parameters to the role
```

```

authentication-type Type of Authentication
captive-portal Captive-portal based Role Filter
city City configuration
client-identity Client identity
company Company configuration
country Country configuration
department Department configuration
emailid Emailid configuration
employee-type Employee-type configuration
employeeid Employeeid configuration
encryption-type Type of encryption
group Group configuration
memberOf MemberOf configuration
mu-mac MU MAC address configuration
no Negate a command or set its defaults
radius-user Radius-user configuration
ssid SSID configuration
state State configuration
title Title configuration
use Set setting to use
user-defined User-defined configuration

clrscr Clears the display screen

### user-role commands

The following table summarizes the user role configuration commands.

**Table 50: User-Role-Mode Commands**

| Commands                         | Description                                                                                                                      |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <code>ap-location</code>         | Configures an AP deployment location based filter                                                                                |
| <code>assign</code>              | Configures upstream/downstream rate limits and VLAN ID assigned to clients matching the filters defined in the user-defined role |
| <code>authentication-type</code> | Configures an authentication type based filter                                                                                   |
| <code>captive-portal</code>      | Configures a captive portal based filter                                                                                         |
| <code>city</code>                | Configures a city name based filter                                                                                              |
| <code>client-identity</code>     | Associates a client-identity (device fingerprinting) based filter                                                                |
| <code>company</code>             | Configures a company name based filter                                                                                           |
| <code>country</code>             | Configures a country name based filter                                                                                           |

**Table 50: User-Role-Mode Commands (continued)**

| Commands        | Description                                                                                                                      |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------|
| department      | Configures a department name based filter                                                                                        |
| emailid         | Configures a e-mail ID based filter                                                                                              |
| employee-type   | Configures a employee type ID based filter                                                                                       |
| employeeid      | Configures a employee ID based filter                                                                                            |
| encryption-type | Configures an encryption type filter                                                                                             |
| group           | Configures a RADIUS group based filter                                                                                           |
| memberOf        | Assigns an <i>Active Directory</i> (AD) group to this user-defined role                                                          |
| mu-mac          | Configures MAC address and mask based filter                                                                                     |
| no              | Removes or resets the filters configured on this user-defined role                                                               |
| ssid            | Configures a SSID based filter                                                                                                   |
| state           | Configures a user role state to match                                                                                            |
| title           | Configures a 'title' string to match                                                                                             |
| use             | Associates a IP and/or MAC ACL with this role. These ACLs specify the action taken when a client matches this user-defined role. |
| user-defined    | Defines a filter based on an attribute defined in the Active Directory or the OpenLDAP server                                    |

#### ap-location

Configures an AP's deployment location based filter for this user-defined role

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
ap-location [any|contains|exact|not-contains]
ap-location any
ap-location [contains|exact|not-contains] <WORD>
```

#### Parameters

```
ap-location any
```

|                 |                                                                                         |
|-----------------|-----------------------------------------------------------------------------------------|
| ap-location any | Specifies the AP location to match (in an RF Domain) or the AP's resident configuration |
| • any           | Defines an AP's location as any                                                         |

```
ap-location [contains|exact|not-contains] <WORD>
```

|                        |                                                                                                                                                                                                                                                                                    |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-location            | Specifies the AP location to match (in an RF Domain) or the AP's resident configuration. Select one of the following filter options: <b>contains</b> , <b>exact</b> , or <b>not-contains</b> .                                                                                     |
| contains<br><WORD>     | Applies role if the associating AP's location contains the location string specified in the role. <ul style="list-style-type: none"> <li>• &lt;WORD&gt; – Specify the location string to match.</li> </ul>                                                                         |
| exact <WORD>           | Applies role if the associating AP's location exactly matches the string specified in the role. <ul style="list-style-type: none"> <li>• &lt;WORD&gt; – Specify the exact location string to match.</li> </ul>                                                                     |
| not-contains<br><WORD> | Applies role if the associating AP's location does not contain the location string specified in the role. <ul style="list-style-type: none"> <li>• &lt;WORD&gt; – Specify the location string. The role is applied if the location does not match the specified string.</li> </ul> |

#### Examples

```

nx9500-6C8809nx9500-6C8809(config-role-policy-test-user-role-testing)#ap-location contains
office
nx9500-6C8809(config-role-policy-test-user-role-testing)#show context
 user-role testing precedence 10
 ap-location contains office
nx9500-6C8809(config-role-policy-test-user-role-testing)#

```

#### Related Commands

|           |                                                                        |
|-----------|------------------------------------------------------------------------|
| <b>no</b> | Removes an AP's deployment location string from this user-defined role |
|-----------|------------------------------------------------------------------------|

#### assign

Configures upstream/downstream rate limits and VLAN ID. Clients matching this user-defined role filters are associated with the specified VLAN, and assigned the specified data rates.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```

assign [rate-limit|VLAN]
assign rate-limit [from-client|to-client] <1-65536>
assign vlan <1-4094>

```

#### Parameters

```

assign rate-limit [from-client|to-client] <1-65536>

```

```
assign rate-limit [from-client|to-client] <1-65536>
```

Assigns an upstream and downstream traffic rate limit

- from-client - Assigns a rate limit, in Kbps, for the upstream (from client) traffic
- to-client - Assigns a rate limit, in Kbps, for the downstream (to client) traffic
- <1-65536> - Specify upstream and/or downstream rate limits from 1 - 65536 Kbps.

**Note:** Wireless clients matching this user-defined role are assigned the configured rate limits.

```
assign vlan <1-4094>
```

```
assign vlan <1-4094>
```

Assigns a VLAN (identified by VLAN's ID). Clients matching this user-defined role are associated with the specified VLAN. The VLAN ID represents the shared SSID each user employs to interoperate within the network (once authenticated by the local RADIUS server). This feature is disabled by default.

- <1-4094> - Specify the VLAN ID from 1 - 4094.

**Note:** A wireless client that fails to match any user-defined role is assigned to the default role (configured as a role policy setting) and is mapped to the default VLAN under the WLAN.

## User Guidelines

ACLs can only be used with tunnel or isolated-tunnel modes. They do not work with the local and automatic modes.

In case of bridge VLAN, the default bridging mode is 'auto'. Change the bridging mode to 'tunnel'. This extends the controller's existing VLAN onto the AP and ensures that wireless clients are served IP addresses.

The VLAN configured under the user-defined role need not exist under the WLAN. But, when using tunneled VLAN bridges, configure an additional bridge VLAN. If the VLAN bridging mode is 'local', no additional VLAN configuration is required.

## Examples

```
rfs4000-229D58(config-role-policy-test-user-role-test)#assign rate-limit to-client 200
rfs4000-229D58(config-role-policy-test-user-role-test)#commit
rfs4000-229D58(config-role-policy-test-user-role-test)#show context
 user-role test precedence 1
 assign vlan 1
 assign rate-limit to-client 200
rfs4000-229D58(config-role-policy-test-user-role-test)#
```

The following examples define a role used to forward the IP traffic from all engineers in Test\_Company, Santa Clara, USA onto VLAN 2.

- 1 Create a new role policy with name 'test-policy'..  
`<DEVICE>(config)#role-policy test-policy`
- 2 Specify the LDAP server used for this role policy.  
`<DEVICE>(config-role-policy-test-policy)#ldap-query self`  
`<DEVICE>(config-role-policy-test-policy)#ldap-server 1 host 192.160.1.1 bind-dn`  
`CN=Administrator,CN=Users,DC=testtest,DC=com base-dn CN=Administrator,CN=Users,`  
`DC=com bind-password 0 test port 389`  
`<DEVICE>(config-role-policy-test-policy)#ldap-timeout 2`
- 3 Create a user-defined role.  
`<DEVICE>(config-role-policy-test-policy)#user-role SCEngineer precedence 100`
- 4 Define the role by adding appropriate values and match operators.  
`<DEVICE>(config-role-policy-test-policy-user-role-SCEngineer)#city exact santa-clara`  
`<DEVICE>(config-role-policy-test-policy-user-role-SCEngineer)#company exact`  
`ExampleCompany`  
`<DEVICE>(config-role-policy-test-policy-user-role-SCEngineer)#country exact usa`  
`<DEVICE>(config-role-policy-test-policy-user-role-SCEngineer)#title contains engineer`  
`<DEVICE>(config-role-policy-test-policy-user-role-SCEngineer)#assign vlan-id 2`
- 5 Apply role policy to an access point.  
`ap7161-99BFA8(config-device-ap7161)# use role-policy test-policy`

#### Related Commands

**no** Removes the upstream and/or downstream rate limits applied to this user-defined role. Also removes the VLAN ID.

#### authentication-type

Configures the authentication-type filter for this user-defined role

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
authentication-type [any|eq|neq]
authentication-type any
authentication-type [eq|neq] [eap|kerberos|mac-auth|none]
{ (eap/kerberos/mac-auth/none) }
```

#### Parameters

```
authentication-type any
```

**any** The authentication type is any (eq or neq). This is the default setting.

```
authentication-type [eq|neq] [eap|kerberos|mac-auth|none]
{ (eap/kerberos/mac-auth/none) }
```

|                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>eq [eap kerberos  mac-auth none]</code>  | <p>The role is applied only when the authentication type matches (equals) one or more than one of the following types:</p> <ul style="list-style-type: none"> <li>• eap – Extensible authentication protocol</li> <li>• kerberos – Kerberos authentication</li> <li>• mac-auth – MAC authentication protocol</li> <li>• none – no authentication used</li> </ul> <p><b>Note:</b> These parameters are recursive, and you can configure more than one unique authentication type for this user-defined role.</p>          |
| <code>neq [eap kerberos  mac-auth none]</code> | <p>The role is applied only when the authentication type does not match (not equals) any of the following types:</p> <ul style="list-style-type: none"> <li>• eap – Extensible authentication protocol</li> <li>• kerberos – Kerberos authentication</li> <li>• mac-auth – MAC authentication protocol</li> <li>• none – no authentication used</li> </ul> <p><b>Note:</b> These parameters are recursive, and you can configure more than one unique 'not equal to' authentication type for this user-defined role.</p> |

#### Examples

```

nx9500-6C8809(config-role-policy-test-user-role-testing)#authentication-type eq kerberos
nx9500-6C8809(config-role-policy-test-user-role-testing)#show context
 user-role testing precedence 10
 authentication-type eq kerberos
 ap-location contains office
nx9500-6C8809(config-role-policy-test-user-role-testing)#

```

#### Related Commands

|-----------------|------------------------------------------------------------------------------|
| <code>no</code> | Removes the authentication type filter configured for this user-defined role |
|-----------------|------------------------------------------------------------------------------|

#### captive-portal

Configures a captive portal based filter for this user-defined role. A captive portal is a guest access policy that provides temporary and restrictive access to the wireless network. When applied to a WLAN, a captive portal policy ensures secure guest access.

This command defines user-defined role filters based on a wireless client's state of authentication.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
captive-portal authentication-state [any|post-login|pre-login]
```

#### Parameters

```
captive-portal authentication-state [any|post-login|pre-login]
```

|                      |                                                                                                                                                                                                                                           |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| authentication-state | Defines the authentication state of a client connecting to a captive portal                                                                                                                                                               |
| any                  | Specifies any authentication state (authenticated and pending authentication). This is the default setting.<br>This option makes no distinction on whether authentication is conducted before or after the wireless client has logged in. |
| post-login           | Specifies authentication is completed successfully<br>This option requires the wireless client to share authentication credentials after logging into the managed network.                                                                |
| pre-login            | Specifies authentication is pending<br>This option enables captive portal client authentication before the client is logged into the controller.                                                                                          |

### Examples

```

nx9500-6C8809(config-role-policy-test-user-role-testing)#captive-portal authentication-
state pre-login
nx9500-6C8809(config-role-policy-test-user-role-testing)#show context
user-role testing precedence 10
authentication-type eq kerberos
ap-location contains office
captive-portal authentication-state pre-login
nx9500-6C8809(config-role-policy-test-user-role-testing)#

```

### Related Commands

|-----------|-------------------------------------------------------|
| <b>no</b> | Removes the captive portal based role filter settings |
|-----------|-------------------------------------------------------|

### city

Configures a wireless client filter based on the city name

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```

city [any|contains|exact|not-contains]
city [any|exact <WORD>|contains <WORD>|not-contains <WORD>]

```

### Parameters

```

city [any|exact <WORD>|contains <WORD>|not-contains <WORD>]

```

|                 |                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| city            | Specifies a wireless client filter based on how the 'city' name, returned by the RADIUS server, matches the provided expression. Select one of the following options: <b>any</b> , <b>contains</b> , <b>exact</b> , or <b>not-contains</b> .                                                                                                                    |
| any             | No specific city associated with this user-defined role. This role can be applied to any wireless client from any city.                                                                                                                                                                                                                                         |
| contains <WORD> | The role is applied only when the city name, returned by the RADIUS server, contains the string specified in the role. <ul style="list-style-type: none"> <li>• &lt;WORD&gt; - Specify the string to match (this is case sensitive, and is compared against the city name returned by the RADIUS server). It should contain the provided expression.</li> </ul> |

|                        |                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| exact<br><WORD>        | The role is applied only when the city name, returned by the RADIUS server, exactly matches the string specified in the role. <ul style="list-style-type: none"> <li>&lt;WORD&gt; – Specify the exact string to match (this is case sensitive, and is compared against the city name returned by the RADIUS server). It should be an exact match.</li> </ul>                  |
| not-contains<br><WORD> | The role is applied only when the city name, returned by the RADIUS server, does not contain the string specified in the role. <ul style="list-style-type: none"> <li>&lt;WORD&gt; – Specify the string not to match (this is case sensitive, and is compared against the city name returned by the RADIUS server). It should not contain the provided expression.</li> </ul> |

### Examples

```
nx9500-6C8809(config-role-policy-test-user-role-testing)#city exact SanJose
nx9500-6C8809(config-role-policy-test-user-role-testing)#show context
 user-role testing precedence 10
 authentication-type eq kerberos
 ap-location contains office
 captive-portal authentication-state pre-login
 city exact SanJose
nx9500-6C8809(config-role-policy-test-user-role-testing)#
```

### Related Commands

|-----------|--------------------------------------------------------------|
| <b>no</b> | Removes the city name configured with this user-defined role |
|-----------|--------------------------------------------------------------|

### client-identity

Associates a client-identity (device fingerprinting) based filter. The role is assigned to a wireless client matching any of the defined client identities.

For more information on configuring client identity fingerprints, see [client-identity](#).

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
client-identity <CLIENT-IDENTITY-NAME> {<CLIENT-IDENTITY-NAME>}
```

### Parameters

```
client-identity <CLIENT-IDENTITY-NAME> {<CLIENT-IDENTITY-NAME>}
```

|                                        |                                                                                                                                                                                                                                                                                                          |
|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| client-identity <CLIENT-IDENTITY-NAME> | Specifies the client-identity fingerprint to match (should be existing and configured) <ul style="list-style-type: none"> <li>&lt;CLIENT-IDENTITY-NAME&gt; – Specify the client identity signature name.</li> </ul> <p><b>Note:</b> Multiple client identities can be configured with a role policy.</p> |
|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### User Guidelines

When associating a single or multiple client identities with a role policy, ensure that a client identity group, containing all the client identities used by the role policy, is attached to the device or profile using the role policy. In other words, group all the client identities (used in this role policy) in a client identity group, and associate this group to the profile or device using this role policy.

For more information on configuring client identities and client identity groups, see [client-identity](#) and [client-identity-group](#)

For more information on associating a client identity group and a role policy to a profile or a device, see [use](#) on page 1232.

#### Examples

```
rfs4000-229D58(config-role-policy-test-user-role-test)#client-identity TestClientIdentity
rfs4000-229D58(config-role-policy-test-user-role-test)#client-identity
ClientIdentityWindows
rfs4000-229D58(config-role-policy-test-user-role-test)#show context
 user-role test precedence 1
 client-identity TestClientIdentity
 client-identity ClientIdentityWindows
rfs4000-229D58(config-role-policy-test-user-role-test)#
```

|-----------|----------------------------------------------------------------|
| <b>no</b> | Removes the client identities associated with this role policy |
|-----------|----------------------------------------------------------------|

#### company

Configures a wireless client filter based on the company name

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
company [any|contains|exact|not-contains]
company [any|exact <WORD>|contains <WORD>|not-contains <WORD>]
```

#### Parameters

```
company [any|exact <WORD>|contains <WORD>|not-contains <WORD>]
```

|                     |                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| company             | Specifies a wireless client filter based on how the 'company' name, returned by the RADIUS server, matches the provided expression. Select one of the following options: <b>any</b> , <b>contains</b> , <b>exact</b> , or <b>not-contains</b> .                                                                                                                                     |
| any                 | No specific company associated with this user-defined role. This role is applied to any wireless client from any company (no strings to match). This is the default setting.                                                                                                                                                                                                        |
| contains <WORD>     | The role is applied only when the company name, returned by the RADIUS server, contains the string specified in the role. <ul style="list-style-type: none"><li>• &lt;WORD&gt; – Specify the string to match (this is case sensitive, and is compared against the company name returned by the RADIUS server). It should contain the provided expression.</li></ul>                 |
| exact <WORD>        | The role is applied only when the company name, returned by the RADIUS server, exactly matches the string specified in the role. <ul style="list-style-type: none"><li>• &lt;WORD&gt; – Specify the exact string to match (this is case sensitive, and is compared against the company name returned by the RADIUS server). It should be an exact match.</li></ul>                  |
| not-contains <WORD> | The role is applied only when the company name, returned by the RADIUS server, does not contain the string specified in the role. <ul style="list-style-type: none"><li>• &lt;WORD&gt; – Specify the string not to match (this is case sensitive, and is compared against the company name returned by the RADIUS server). It should not contain the provided expression.</li></ul> |

## Examples

```
nx9500-6C8809(config-role-policy-test-user-role-testing)#company exact ExampleCompany
nx9500-6C8809(config-role-policy-test-user-role-testing)#show context
 user-role testing precedence 10
 authentication-type eq kerberos
 ap-location contains office
 captive-portal authentication-state pre-login
 city exact SanJose
 company exact ExampleCompany
nx9500-6C8809(config-role-policy-test-user-role-testing)#
```

#### Related Commands

|                                                                          |
|--------------------------------------------------------------------------|
| <b>no</b> Removes the employee ID configured with this user-defined role |
|--------------------------------------------------------------------------|

#### encryption-type

Selects the encryption type for this user-defined role. Encryption ensures privacy between Access Points and wireless clients. There are various modes of encrypting communication on a WLAN, such as CCMP (Counter-model CBC-MAC Protocol), WEP (Wired Equivalent Privacy), keyguard, TKIP (Temporal Key Integrity Protocol), etc.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
encryption-type [any|eq|neq]
encryption-type any
encryption-type [eq|neq] [ccmp|keyguard|none|tkip|wep128|wep64]
(ccmp|keyguard|none|tkip|tkip-ccmp|wep128|wep64)
```

#### Parameters

```
encryption-type any
```

|                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------|
| any The encryption type can be any one of the listed options (ccmp keyguard tkip wep128 wep64). This is the default setting. |
|------------------------------------------------------------------------------------------------------------------------------|

```
encryption-type [eq|neq] [ccmp|keyguard|none|tkip|wep128|wep64]
(ccmp|keyguard|none|tkip|tkip-ccmp|wep128|wep64)
```

|                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

### group

Configures a wireless client filter based on the RADIUS group name

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
group [any|contains|exact|not-contains]
group [any|contains <WORD>|exact <WORD>|not-contains <WORD>]
```

## Parameters

```
group [any|contains <WORD>|exact <WORD>|not-contains <WORD>]
```

|                        |                                                                                                                                                                                                                                                                                                                                                        |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| group                  | Specifies a wireless client filter based on how the RADIUS group name matches the provided expression. Select one of the following options: <b>any</b> , <b>contains</b> , <b>exact</b> , or <b>not-contains</b> .                                                                                                                                     |
| any                    | This user-defined role can fit into any group (no strings to match). This is the default setting.                                                                                                                                                                                                                                                      |

|----|---------------------------------------------------------|
| no | Removes the group configured for this user-defined role |
|----|---------------------------------------------------------|

## memberOf

Applies an AD (Active Directory) group filter to this user-defined role. A wireless client can be a member of more than one group within the AD database. This command applies a AD group based firewall, which applies a role to a wireless client only if it belongs to the specified AD group.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

`memberOf <AD-GROUP-NAME>`

#### Parameters

`memberOf <AD-GROUP-NAME>`

|                                             |                                                                                                                                                                                                                     |
|---------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>memberOf &lt;AD-GROUP-NAME&gt;</code> | Applies this user-defined role to a client only if the client belongs to the specified AD group <ul style="list-style-type: none"> <li>• <code>&lt;AD-GROUP-NAME&gt;</code> - Specify the AD group name.</li> </ul> |
|---------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

#### Examples

```
rfs4000-229D58(config-role-policy-test-user-role-test)#memberOf ADTestgroup
rfs4000-229D58(config-role-policy-test-user-role-test)#show context
 user-role test precedence 1
 assign vlan 1
 assign rate-limit to-client 200
 memberOf ADTestgroup
rfs4000-229D58(config-role-policy-test-user-role-test)#
```

#### Related Commands

|                 |                                                         |
|-----------------|---------------------------------------------------------|
| <code>no</code> | Removes the AD group assigned to this user-defined role |
|-----------------|---------------------------------------------------------|

## mu-mac

Configures a MAC address and mask based filter for this role policy

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
mu-mac [<MAC> | any]
mu-mac any
mu-mac <MAC> {mask <MAC>}
```

#### Parameters

`mu-mac any`

|                  |                                                                                             |
|------------------|---------------------------------------------------------------------------------------------|
| <code>any</code> | Applies role to any wireless client (no MAC address to match). This is the default setting. |
|------------------|---------------------------------------------------------------------------------------------|

```
mu-mac <MAC> {mask <MAC>}
```

|                               |                                                                                                                                                                                                                                                                |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;MAC&gt;</code>      | Applies role to the wireless client having specified MAC address <ul style="list-style-type: none"> <li>• <code>&lt;MAC&gt;</code> - Sets the MAC address in the AA-BB-CC-DD-EE-FF format</li> </ul>                                                           |
| <code>mask &lt;MAC&gt;</code> | Optional. After specifying the client's MAC address, specify the mask in the <ul style="list-style-type: none"> <li>• AA-BB-CC-DD-EE-FF format. The role is applied to the wireless client exactly matching the specified MAC address and MAC mask.</li> </ul> |

## Examples

```
nx9500-6C8809(config-role-policy-test-user-role-testing)#mu-mac 11-22-33-44-55-66
nx9500-6C8809(config-role-policy-test-user-role-testing)#show context

## radius-user

Configures a wireless client filter based on the RADIUS user name

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
radius-user [any|contains|ends-with|exact|not-contains|starts-with]
```

## Parameters

```
radius-user [any|contains|ends-with|exact|not-contains|starts-with]
```

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| radius-user         | Specifies a wireless client filter based on how the 'radius-user' name, returned by the RADIUS server, matches the provided expression. Select one of the following options: any, contains, exact, or not-contains.                                                                                                                                                                                                                                                                                    |
| any                 | No specific RADIUS user name associated with this user-defined role. This role can be applied to any wireless client (no strings to match). This is the default setting.                                                                                                                                                                                                                                                                                                                               |
| contains<br><WORD>  | The role is applied only when the 'radius-user' name, returned by the RADIUS server, contains the string specified in the role. <ul style="list-style-type: none"><li>• &lt;WORD&gt; - Specify the string to match (this is case sensitive, and is compared against the 'radius-user' name returned by the RADIUS server). It should contain the provided expression.</li></ul> <b>Note:</b> You can use the realm or any sub-string of the user name.                                                 |
| ends-with<br><WORD> | Enables role assignment on the basis of the wireless client's "department" and/or "group" <ul style="list-style-type: none"><li>• &lt;WORD&gt; - Specify the string (could be department/group code). For example: 1005000002. In this the last three digits represent the department/group code. The remaining digits represent user's badge number.</li></ul> <b>Note:</b> The role is applied only when the 'radius-user' name, returned by the RADIUS server, ends with the string specified here. |

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

use

Configures an access list based firewall with this user role

A firewall is a mechanism enforcing access control, and is considered a first line of defense in protecting proprietary information within the network. The means by which this is accomplished varies, but in principle, firewalls are mechanisms both *blocking* and *permitting* data traffic based on inbound and outbound IP and MAC rules.

IP based firewall rules are specific to source and destination IP addresses and the unique rules and precedence orders assigned. Both IP and non-IP traffic on the same layer 2 interface can be filtered by applying both an IP ACL and a MAC.

A MAC firewall rule uses source and destination MAC addresses for matching operations, where the result is a typical allow, deny or mark designation to packet traffic.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
use [application-policy|bonjour-gw-discovery-policy|ip-access-list|ipv6-access-list|
mac-access-list|url-filter]
use [application-policy|bonjour-gw-discovery-policy]
use [ip-access-list|ipv6-access-list] [in|out] <IP/ipv6-ACCESS-LIST-NAME>
precedence <1-100>
use mac-access-list [in|out] <MAC-ACCESS-LIST-NAME> precedence <1-100>
use url-filter <URL-FILTER-NAME>
```

## Parameters

```
use [application-policy|bonjour-gw-discovery-policy|ip-access-list|ipv6-access-list|
mac-access-list|url-filter]
```

|------------------------------------------------------------------------------------------------------|

## user-defined

Enables you to define a filter based on an attribute defined in the Active Directory or the OpenLDAP server

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
user-defined <ATTR-STRING> [any|contains|exact|not-contains]
user-defined <ATTR-STRING> [any|contains <WORD>|exact <WORD>|not-contains <WORD>]
```

## Parameters

```
user-defined <ATTR-STRING> [any|contains <WORD>|exact <WORD>|not-contains <WORD>]
```

|                            |                                                                                                                                                                                                                                               |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| user-defined <ATTR-STRING> | Specify a filter based on an attribute defined in the AD or OpenLDAP server. <ul style="list-style-type: none"><li>• &lt;ATTR-NAME&gt; – Specify the attribute string.</li></ul> After specifying the attribute name, specify the match type. |
| any                        | No specific string to match. This role can be applied to any wireless client. This is the default setting.                                                                                                                                    |

|                        |                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| contains<br><WORD>     | The role is applied only when the user-defined attribute value, returned by the RADIUS server, contains the string specified in the role. <ul style="list-style-type: none"> <li>• &lt;WORD&gt; - Specify the string to match (this is case sensitive, and is compared against the value returned by the RADIUS server). It should contain the provided expression.</li> </ul>                 |
| exact<br><WORD>        | The role is applied only when the user-defined attribute value, returned by the RADIUS server, exactly matches the string specified in the role. <ul style="list-style-type: none"> <li>• &lt;WORD&gt; - Specify the exact string to match (this is case sensitive, and is compared against the value returned by the RADIUS server). It should be an exact match.</li> </ul>                  |
| not-contains<br><WORD> | The role is applied only when the user-defined attribute value, returned by the RADIUS server, does not contain the string specified in the role. <ul style="list-style-type: none"> <li>• &lt;WORD&gt; - Specify the string not to match (this is case sensitive, and is compared against the value returned by the RADIUS server). It should not contain the provided expression.</li> </ul> |

### Examples

```
rfs4000-229D58(config-role-policy-test-user-role-user1)#user-defined office-location exact EcoSpace
rfs4000-229D58(config-role-policy-test-user-role-user1)#show context
 user-role user1 precedence 1
 employee-type exact consultant
 user-defined office-location exact EcoSpace
rfs4000-229D58(config-role-policy-test-user-role-user1)#
```

### Related Commands

|           |                                                                |
|-----------|----------------------------------------------------------------|
| <b>no</b> | Removes the user-defined filter configured with this user role |
|-----------|----------------------------------------------------------------|

no

Negates a command or resets configured settings to their default. When used in the config role policy user-defined role mode, the no command removes or resets settings, such as AP location, authentication type, encryption type, captive portal, etc.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
no [ap-location|assign|authentication-type|captive-portal|city|client-identity|
company|country|department|emailid|employee-type|employeeid|encryption-type|
group|memberOf|mu-mac|radius-user|ssid|state|title|use|user-defined]
no [ap-location|assign|authentication-type|city|client-identity|company|country|
department|emailid|employee-type|employeeid|encryption-type|group|mu-mac|memberOf|ssid|
radius-user|state|title|user-defined]
no captive-portal authentication-state
no use [application-policy|bonjour-gw-discovery-policy|ip-access-list|
ipv6-access-list|mac-access-list|url-filter]
no use [ip-access-list|ipv6-access-list|mac-access-list] [in|out]
<IP/IPv6/MAC-ACCESS-LIST-NAME> precedence <1-100>
no use [application-policy|bonjour-gw-discovery-policy|url-filter]
```

### Parameters

no <PARAMETERS>

`no <PARAMETERS>` Negates a command or resets configured settings to their default. When used in the config role policy user-defined role mode, the `no` command removes or resets settings, such as AP location, authentication type, encryption type, captive portal, etc.

### Usage Guidelines

The `no` command negates any command associated with it. Wherever required, use the same parameters associated with the command getting negated.

### Examples

The following example shows the Role Policy 'test' User Role 'testing' configuration before the 'no' commands are executed:

```
nx9500-6C8809(config-role-policy-test-user-role-testing)#show context
user-role testing precedence 10
 authentication-type eq kerberos
 encryption-type eq wep128
 ap-location contains office
 mu-mac 11-22-33-44-55-66
 group contains testgroup
 captive-portal authentication-state pre-login
 city exact SanJose
 company exact ExampleCompany
 country exact America
 department exact TnV
 emailid exact testing@examplecompany.com
 employeeid contains TnVTest1
nx9500-6C8809(config-role-policy-test-user-role-testing)#
nx9500-6C8809(config-role-policy-test-user-role-testing)#no authentication-type
nx9500-6C8809(config-role-policy-test-user-role-testing)#no encryption-type
nx9500-6C8809(config-role-policy-test-user-role-testing)#no group
nx9500-6C8809(config-role-policy-test-user-role-testing)#no mu-mac
nx9500-6C8809(config-role-policy-test-user-role-testing)#no ap-location
nx9500-6C8809(config-role-policy-test-user-role-testing)#no employeeid
```

The following example shows the Role Policy 'test' User Role 'testing' configuration after the 'no' commands are executed:

```
nx9500-6C8809(config-role-policy-test-user-role-testing)#show context
user-role testing precedence 10
 captive-portal authentication-state pre-login
 city exact SanJose
 company exact ExampleCompany
 country exact America
 department exact TnV
 emailid exact testing@examplecompany.com
nx9500-6C8809(config-role-policy-test-user-role-testing)#
```

### `no`

Negates a command or resets settings to their default. When used in the config role policy mode, the `no` command removes or resets the role policy settings.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
no [default-role|ldap-deadperiod|ldap-query|ldap-server <1-2>|ldap-timeout|user-role]
no [ldap-deadperiod|ldap-query|ldap-server <1-2>|ldap-timeout]
no default-role use [ip-access-list|ipv6-access-list|mac-access-list]
no default-role use [ip-access-list|ipv6-access-list|mac-access-list] [in|out]
<IP/IPv6/MAC-ACCESS-LIST-NAME> precedence <1-100>
no user-role <ROLE-NAME>
```

## Parameters

```
no <PARAMETERS>
```

no <PARAMETERS> Negates a command or resets settings to their default. When used in the config role policy mode, the no command removes or resets the role policy settings.

## Examples

The following example shows the role policy 'test' setting before the 'no' commands are executed:

```
nx9500-6C8809(config-role-policy-test)#show context
role-policy test
 default-role use ip-access-list in test precedence 1
 ldap-query self
 ldap-timeout 1
 ldap-deadperiod 100
 ldap-server 1 host 192.168.13.7 bind-dn CN=Administrator,CN=Users,DC=TechPub,DC=com base-
dn
 CN=Administrator,CN=Users,DC=com bind-password 0 superuser port 2

nx9500-6C8809(config-role-policy-test)#
nx9500-6C8809(config-role-policy-test)#no ldap-deadperiod
nx9500-6C8809(config-role-policy-test)#no ldap-timeout
nx9500-6C8809(config-role-policy-test)#no ldap-server 1
```

The following example shows the role policy 'test' setting after the 'no' commands are executed:

```
nx9500-6C8809(config-role-policy-test)#show context
role-policy test
 default-role use ip-access-list in test precedence 1
 ldap-query self
nx9500-6C8809(config-role-policy-test)#
```

# SMART RF POLICY

## SMART-RF-POLICY

---

This chapter summarizes SMART RF (Self Monitoring at Run Time RF) management policy commands in the CLI command structure.

A Smart RF management policy defines operating and recovery parameters that can be assigned to groups of access points. A Smart RF policy is designed to scan the network to identify the best channel and transmit power for each access point radio.

A Smart RF policy reduces deployment costs by scanning the RF environment to determine the best channel and transmit power configuration for each managed radio. Smart RF policies when applied to specific RF Domains, apply site specific deployment configurations and self-healing values to groups of devices within pre-defined physical RF coverage areas.

Smart RF centralizes the decision process and makes intelligent RF configuration decisions using information obtained from the RF environment. Smart RF helps reduce ongoing management and maintenance costs through the periodic re-calibration of the network. Re-calibration can be initiated manually or can be automatically scheduled to ensure the RF configuration is optimized to factor for RF environment changes (such as new sources of interference, or neighboring access points).

Smart RF also provides self-healing functions by monitoring the network in real-time, and provides automatic mitigation from potentially problematic events such as radio interference, coverage holes and radio failures. Smart RF employs self-healing to enable a WLAN to better maintain wireless client performance and site coverage during dynamic RF environment changes, which typically require manual re-configuration to resolve.

Smart RF is supported on any RF Domain manager. In standalone environments, an individual wireless controller manages the calibration and monitoring phases. In clustered environments, a single wireless controller is elected a Smart RF master and the remaining cluster members operate as Smart RF clients. In cluster operation, the Smart RF master co-ordinates the calibration and configuration and during the monitoring phase receives information from the Smart RF clients.

Before defining a Smart RF policy, refer to the following deployment guidelines to ensure the configuration is optimally effective:

- The Smart RF calibration process impacts associated users and should not be run during business or production hours. The calibration process should be performed during scheduled maintenance intervals or non-business hours.
- For Smart RF to provide effective recovery, RF planning must be performed to ensure overlapping coverage exists at the deployment site. Smart RF can only provide recovery when access points are deployed appropriately. Smart RF is not a solution, it's a temporary measure. Administrators need to determine the root cause of RF deterioration and fix it. Smart RF history/events can assist.

Keep in mind that if a Smart RF managed radio is operating in WLAN mode on a channel requiring DFS, it will switch channels if radar is detected.

- If Smart RF is enabled, the radio picks a channel defined in the Smart RF policy.

- If Smart RF is disabled, but a Smart RF policy is mapped, the radio picks channels specified in the Smart RF policy
- If no SMART RF policy is mapped, the radio selects a random channel

If the radio is a dedicated sensor, it stops termination on that channel if a neighboring access point detects radar. The access point attempts to come back to its original channel (statically configured or selected by Smart RF) after the channel evacuation period has expired.

Change this behavior using the `dfs-rehome` on page 1104 command from the controller or service platform CLI. This keeps the radio on the newly selected channel and prevents the radio from coming back to the original channel, even after the channel evacuation period.

### Note

Perform RF planning to ensure overlapping coverage exists at a deployment site, for Smart RF to be a viable network performance tool. Smart RF can only provide recovery when access points are deployed appropriately. Smart RF is not a solution, it is a temporary measure. You need to determine the root cause of RF deterioration and fix it. Smart RF history/events can assist in trouble shooting.

Use the (config) instance to configure Smart RF Policy related configuration commands. To navigate to the Smart RF policy instance, use the following commands:

```
<DEVICE> (config)#smart-rf-policy <POLICY-NAME>
nx9500-6C8809(config)#smart-rf-policy testSmartRF
nx9500-6C8809(config-smart-rf-policy-testSmartRF)#?
Smart RF Mode commands:
 area Specify channel list/ power for an area
 assignable-power Specify the assignable power during power-assignment
 avoidance-time Time to avoid a channel once dfs/adaptivity
 avoidance is necessary
 channel-list Select channel list for smart-rf
 channel-width Select channel width for smart-rf
 coverage-hole-recovery Recover from coverage hole
 enable Enable this smart-rf policy
 group-by Configure grouping parameters
 interference-recovery Recover issues due to excessive noise and
 interference
 neighbor-recovery Recover issues due to faulty neighbor radios
 no Negate a command or set its defaults
 select-shutdown Select redundant 2.4GHz Radios to shutdown
 sensitivity Configure smart-rf sensitivity (Modifies various
 other smart-rf configuration items)
 smart-ocs-monitoring Smart off channel scanning

 clrscr Clears the display screen
 commit Commit all changes made in this session
 do Run commands from Exec mode
 end End current mode and change to EXEC mode
 exit End current mode and down to previous mode
 help Description of the interactive help system
 revert Revert changes
 service Service Commands
 show Show running system information
 write Write running configuration to memory or terminal

nx9500-6C8809(config-smart-rf-policy-testSmartRF)#
```

## smart-rf-policy commands

The following table summarizes Smart RF policy configuration commands.

**Table 51: Smart-RF-Policy Config Mode Commands**

| Command                                             | Description                                                                                                                                                                                                                |
|-----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">area</a> on page 1631                   | Configures the channel list and power for a specified area                                                                                                                                                                 |
| <a href="#">assignable-power</a> on page 1632       | Specifies the power range during power assignment                                                                                                                                                                          |
| <a href="#">avoidance-time</a> on page 1633         | Allows Smart RF-enabled radios to avoid DFS (Dynamic Frequency Selection) and/or adaptivity regulated channels on detection of interference or radar. This command configures the period for which the channel is avoided. |
| <a href="#">channel-list</a> on page 1635           | Assigns the channel list for the selected frequency                                                                                                                                                                        |
| <a href="#">channel-width</a> on page 1635          | Selects the channel width for Smart RF configuration                                                                                                                                                                       |
| <a href="#">coverage-hole-recovery</a> on page 1637 | Enables recovery from errors                                                                                                                                                                                               |
| <a href="#">enable</a> on page 1638                 | Enables the Smart RF policy                                                                                                                                                                                                |
| <a href="#">group-by</a> on page 1639               | Configures grouping parameters                                                                                                                                                                                             |
| <a href="#">interference-recovery</a> on page 1640  | Enables recovery from excessive noise and interference related issues                                                                                                                                                      |
| <a href="#">interference-recovery</a> on page 1640  | Enables recovery from faulty neighbor radios related issues                                                                                                                                                                |
| <a href="#">select-shutdown</a> on page 1643        | Enables selection and shutting down of 2.4 GHz radios, causing interference, in case the CCI (co-channel interference) value exceeds a specified threshold                                                                 |
| <a href="#">sensitivity</a> on page 1645            | Configures Smart RF sensitivity parameters                                                                                                                                                                                 |
| <a href="#">smart-ocs-monitoring</a> on page 1646   | Applies smart OCS (off-channel scanning) instead of dedicated detectors                                                                                                                                                    |
| <a href="#">no</a> on page 1650                     | Negates a command or reverts settings to their default                                                                                                                                                                     |

### Note

For more information on common commands (clrcsr, commit, help, revert, service, show, write, and exit), see [COMMON COMMANDS](#) on page 640.

### Note

The input parameter <HOSTNAME>, wherever used in syntaxes across this chapter, cannot include an underscore ( `_` ) character. In other words, the name of a device cannot contain an underscore.

### *area*

Configures the channel list and power for a specified area

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000

- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
area <AREA-NAME/STRING-ALIAS> channel-list [2.4GHz|5GHz] <CHANNEL-LIST>
```

### Parameters

```
area <AREA-NAME/STRING-ALIAS> channel-list [2.4GHz|5GHz] <CHANNEL-LIST>
```

|                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| area <AREA-NAME/STRING-ALIAS>             | <p>Specifies the area name</p> <ul style="list-style-type: none"> <li>• &lt;AREA-NAME/STRING-ALIAS&gt; - Specify the area name as clear text. Alternately, use a string-alias to specify the area name. If using a string-alias, ensure that the string-alias is existing and configured.</li> </ul> <p><b>Note:</b> For more information on aliases, see <a href="#">alias</a> on page 237.</p>                                                                                                                     |
| channel-list [2.4GHz 5GHz] <CHANNEL-LIST> | <p>Selects the channels for the specified area in the 2.4 GHz or 5.0 GHz band</p> <ul style="list-style-type: none"> <li>• 2.4GHz - Selects the channels for the specified area in the 2.4 GHz band</li> <li>• 5GHz - Selects the channels for the specified area in the 5.0 GHz band</li> </ul> <p>The following keyword is common to the 2.4 GHz and 5.0 GHz bands:</p> <ul style="list-style-type: none"> <li>• &lt;CHANNEL-LIST&gt; - Enter a comma-separated list of channels for the selected band.</li> </ul> |

### *assignable-power*

Configures the Smart RF power settings over both 2.4 GHz and 5.0 GHz radios

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
assignable-power [2.4GHz|5GHz] [max|min] <1-20>
```

## Parameters

`assignable-power [2.4GHz|5GHz] [max|min] <1-20>`

|                         |                                                                                                                                                                                                                                                                  |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### *avoidance-time*

Allows Smart-RF enabled radios to avoid channels with high levels of interference and channels where radar has been detected

This command configures the interval for which a channel is avoided on detection of interference or radar, and is applicable only if the channel selection mode is set to Smart and a Smart-RF policy is applied to the access point's RF Domain. For more information on configuring a radio's channel of operation, see [channel](#) on page 1098.

Certain 5.0 GHz channels are subject to FCC / ETSI DFS regulations that require channels transmitting critical radar signals to be free of interference from radio signals. Consequently, DFS-enabled 5.0 GHz radios scan and switch channels if radar is detected on their current channel of operation. If radar-free channels are not available, the radio stops transmitting until it identifies a radar-free channel.

Adaptivity is a new EU (European Union) stipulation that requires access points to monitor interference levels on their current channel of operation, and stop functioning on channels with interference levels exceeding ETSI-specified threshold values. When enabled, this feature ensures recovery by switching the radio to a new channel with less interference.

Once adaptivity or DFS is triggered, the radio's channel is switched based on the channel selection mode specified. If the channel is fixed, the radio attempts to come back to its specified channel of operation after the DFS/adaptivity channel evacuation period has expired.

#### Note

To optionally disable the radio from switching back to its original channel of operation, execute the **no > dfs-rehome** command in the radio interface configuration mode of the access point's profile or device. For more information, see [dfs-rehome](#) on page 1104.

#### Note

For radio's with channel selection mode set to **ACS**, **Random**, or **Fixed** adaptivity timeout can be configured in the access point's radio interface mode. For more information, see [adaptivity](#) on page 1076.

On the other hand, if the radio's channel selection mode is set to Smart or ACS, once adaptivity or DFS is triggered, the channel is avoided until the avoidance-time, specified here, expires. Once the evacuation period has expired, the channel is free for use by both Smart-RF and ACS.

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
avoidance-time [adaptivity|dfs] <30-3600>
```

#### Parameters

```
avoidance-time [adaptivity|dfs] <30-3600>
```

|                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

### *channel-list*

Assigns a list of channels, for the selected frequency, used in Smart RF scans

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
channel-list [2.4GHz|5GHz] <WORD>
```

#### Parameters

- `channel-list [2.4GHz|5GHz] <WORD>`

|               |                                                                                                                                                           |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2.4GHz <WORD> | Assigns a channel list for the 2.4 GHz band <ul style="list-style-type: none"> <li>• &lt;WORD&gt; - Specify a comma separated list of channels</li> </ul> |
| 5GHz <WORD>   | Assigns a channel list for the 5.0 GHz band <ul style="list-style-type: none"> <li>• &lt;WORD&gt; - Specify a comma separated list of channels</li> </ul> |

#### Examples

```

### *channel-width*

Selects the channel width for Smart RF configuration

## Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
channel-width [2.4GHz|5GHz]
channel-width 2.4GHz [20MHz|40MHz|auto]
channel-width 5GHz [20MHz|40MHz|80MHz|auto]
```

## Parameters

```
channel-width 2.4GHz [20MHz|40MHz|auto]
```

|                           |                                                                                                                                                                                                                                                                                                                                                |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2.4GHz [20MHz 40MHz auto] | Assigns the channel width for the 2.4 GHz band <ul style="list-style-type: none"><li>• 20MHz - Assigns the 20 MHz channel width. |---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
channel-width 5GHz [20MHz|40MHz|auto]
```

|                                       |                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| channel-width 5GHz [20MHz 40MHz auto] | Assigns the channel width for the 5.0 GHz band <ul style="list-style-type: none"><li>• 20MHz - Assigns the 20 MHz channel width.</li><li>• 40MHz - Assigns the 40 MHz channel width. This is the default setting.</li><li>• 80MHz - Assigns the 80 MHz channel width</li><li>• auto - Auto-selects the channel. Assigns the best possible channel in the 20 MHz or 40 MHz or 80 MHz channel width.</li></ul> |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Usage Guidelines

The 20/40 MHz operation allows the access point to receive packets from clients using 20 MHz, and transmit using 40 MHz. This mode is supported for 802.11n users on both the 2.4 GHz and 5.0 GHz radios. If an 802.11n user selects two channels (a primary and secondary channel), the system is configured for dynamic 20/40 operation. When 20/40 is selected, clients can take advantage of wider channels. 802.11n clients experience improved throughput using 40 MHz while legacy clients (either 802.11a or 802.11b/g depending on the radio selected) can still be serviced without interruption using 20 MHz. Select auto to enable automatic assignment of channels to working radios to avoid channel overlap and avoid interference from external RF sources.

## Examples

```
nx9500-6C8809(config-smart-rf-policy-test)#channel-width 2.4GHz auto
nx9500-6C8809(config-smart-rf-policy-test)#channel-width 5GHz auto
nx9500-6C8809(config-smart-rf-policy-test)#show context
smart-rf-policy test
assignable-power 2.4GHz max 20
assignable-power 2.4GHz min 8
channel-list 2.4GHz 1,12
channel-width 5GHz auto
channel-width 2.4GHz auto
area test channel-list 2.4GHz 1,2,3
```

```

## coverage-hole-recovery

Enables recovery from coverage hole errors detected by Smart RF. Use this command to configure the coverage hole recovery settings.

When coverage hole recovery is enabled, on detection of a coverage hole, Smart RF first determines the power increase needed based on the SNR (signal-to-noise ratio) for a client as seen by the access point radio. If a client's SNR is above the specified threshold, the transmit power is increased until the SNR falls below the threshold.

### Note

The coverage-hole-recovery parameters can be modified only if the sensitivity level is set to 'custom'. For more information, see [sensitivity](#) on page 1645.

## Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
coverage-hole-recovery {client-threshold/coverage-interval/interval/snr-threshold}
coverage-hole-recovery {client-threshold [2.4GHz|5GHz] <1-255>}
coverage-hole-recovery {coverage-interval/interval} [2.4GHz|5GHz] <1-120>
coverage-hole-recovery {snr-threshold [2.4Ghz|5Ghz] <1-75>}
```

## Parameters

```
coverage-hole-recovery {client-threshold [2.4GHz|5GHz] <1-255>}
```

|                  |                                                                                                                                                                            |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| client-threshold | Optional. Specifies the minimum number of clients associated to a radio in order to trigger coverage hole recovery.                                                        |
| 2.4GHz <1-255>   | Specifies the minimum number of clients on the 2.4 GHz band <ul style="list-style-type: none"><li>• &lt;1-255&gt; - Sets a value from 1 - 255. The default is 1.</li></ul> |
| 5GHz <1-255>     | Specifies the minimum number of clients on the 5.0 GHz band <ul style="list-style-type: none"><li>• &lt;1-255&gt; - Sets a value from 1 - 255. The default is 1.</li></ul> |

```
coverage-hole-recovery {coverage-interval/interval} [2.4GHz|5GHz] <1-120>
```

|                   |                                                                                                                        |
|-------------------|------------------------------------------------------------------------------------------------------------------------|
| coverage-interval | Optional. Specifies the interval between the discovery of a coverage hole and the initiation of coverage hole recovery |
| interval          | Optional. Specifies the interval at which coverage hole recovery is performed even before a coverage hole is detected  |

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                           |

### enable

Enables the Smart RF policy

Use this command to enable this Smart RF policy. Once enabled, the policy can be assigned to a RF Domain supporting a network.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

enable

### Parameters

None

### Examples

```
nx9500-6C8809(config-smart-rf-policy-test)#enable
nx9500-6C8809(config-smart-rf-policy-test)#show context include-factory | include
enable
enable
nx9500-6C8809(config-smart-rf-policy-test)#
```

### *group-by*

Enables grouping of APs on the basis of their location in a building (floor) or an area

Within a large RD Domain, grouping of APs (within an area or on the same floor in a building) facilitates statistics gathering and troubleshooting.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

group-by [area|floor]

### Parameters

### *interference-recovery*

Enables interference recovery from neighboring radios and other sources of WiFi and non-WiFi interference when excess noise and interference is detected within the Smart RF supported radio coverage area. Smart RF provides mitigation from interference sources by monitoring the noise levels and other RF parameters on an Access Point radio's current channel. When a noise threshold is exceeded, Smart RF can select an alternative channel with less interference. To avoid channel flapping, a hold timer is defined which disables interference avoidance for a specific period of time upon detection. Interference recovery is enabled by default.

#### Note

The `interference-recovery` parameters can be modified only if the sensitivity level is set to 'custom'. For more information, see [sensitivity](#) on page 1645.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
interference-recovery {channel-hold-time|channel-switch-delta|client-threshold|
interference|neighbor-offset|noise|noise-factor}
interference-recovery {channel-switch-delta [2.4GHz|5GHz] <5-35>}
interference-recovery {channel-hold-time <0-86400>|client-threshold <1-255>|
interference|neighbor-offset <3-10>|noise|noise-factor <1.0-3.0>}
```

### Parameters

```
interference-recovery {channel-switch-delta [2.4GHz|5GHz] <5-35>}
```

|                      |                                                                                                                                                                                                                                                                                                                                  |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| channel-switch-delta | Optional. Configures a threshold value for the difference between interference levels on the current channel and the prospective channel needed to trigger a channel change. If the difference in noise levels on the current channel and the prospective channel is below the configured threshold, the channel is not changed. |
| [2.4GHz]<br>5GHz]    | Selects the band <ul style="list-style-type: none"> <li>• 2.4GHz – Selects the 2.4 GHz band</li> <li>• 5GHz – Selects the 5.0 GHz band</li> </ul>                                                                                                                                                                                |
| <5-35>               | Specifies the threshold value for the difference between the current and prospective channel interference levels <ul style="list-style-type: none"> <li>• &lt;5-35&gt; – Sets a value from 5 dBm - 35 dBm. The default setting is 20 dBm for both 2.4 GHz and 5.0 GHz bands.</li> </ul>                                          |

```
interference-recovery {channel-hold-time <0-86400>|client-threshold <1-255>|
interference|neighbor-offset <3-10>|noise|noise-factor <1.0-3.0>}
```

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| channel-hold-time <0-86400> | Optional. Defines the minimum time between two channel change recoveries <ul style="list-style-type: none"> <li>• &lt;0-86400&gt; – Sets the time, in seconds, between channel change assignments based on interference or noise. The default is 1,800 seconds.</li> </ul>                                                                                                                                                                                                                          |
| client-threshold <1-255>    | Optional. Specifies client thresholds needed to avoid channel change. If the specified threshold number of clients are connected to a radio, the radio avoids changing channels even if the Smart RF master determines that a channel change is required. <ul style="list-style-type: none"> <li>• &lt;1-255&gt; – Sets the number of clients from 1 - 255. The default is 50.</li> </ul>                                                                                                           |
| interference                | Optional. Considers external interference values to perform interference recovery. This feature allows the Smart RF policy to scan for excess interference from supported radio devices. WLANs are susceptible to sources of interference, such as neighboring radios, cordless phones, microwave ovens and Bluetooth devices. When interference for WiFi sources is detected, Smart RF supported devices can change the channel and move to a cleaner channel. This feature is enabled by default. |
| neighbor-offset <3-10>      | Optional. Configures a noise factor value, which is taken into consideration when switching channels to avoid interference from neighboring access points. Smart RF enabled access points consider the difference in noise between candidate channels. <ul style="list-style-type: none"> <li>• &lt;3-10&gt; – Specify a noise factor value from 3 - 10.</li> </ul>                                                                                                                                 |
| noise                       | Optional. Considers noise values to perform interference recovery. This feature allows the Smart RF policy to scan for excess noise from WiFi devices. When detected, Smart RF supported devices can change their channel and move to a cleaner channel. This feature is enabled by default.                                                                                                                                                                                                        |
| noise-factor <1.0-3.0>      | Optional. Configures additional noise factor (the level of network interference detected) for non WiFi interference <ul style="list-style-type: none"> <li>• &lt;1.0-3.0&gt; – Specify the noise factor from 1.0 - 3.0. The default is 1.5.</li> </ul>                                                                                                                                                                                                                                              |

### *neighbor-recovery*

Enables recovery from errors due to faulty neighboring radios. Enabling neighbor recovery ensures automatic recovery from failed radios within the radio coverage area. Smart RF instructs neighboring access points to increase their transmit power to compensate for the failed radio. Neighbor recovery is enabled by default when the sensitivity setting is medium.

#### Note

The neighbor-recovery parameters can be modified only if the sensitivity level is set to 'custom'. For more information, see [sensitivity](#) on page 1645.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```

neighbor-recovery {dynamic-sampling/power-hold-time/power-threshold}
neighbor-recovery {dynamic-sampling} {retries <1-10>/threshold <1-30>}
neighbor-recovery {power-hold-time <0-3600>}
neighbor-recovery {power-threshold [2.4Ghz|5Ghz] <-85--55>}

```

### Parameters

```
neighbor-recovery {dynamic-sampling} {retries <1-10>/threshold <1-30>}
```

|                  |                                                                                                                                                                                                                                                               |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dynamic-sampling | Optional. Enables dynamic sampling on this Smart RF policy. Dynamic sampling allows you to define how Smart RF adjustments are triggered by locking the 'retry' and 'threshold' values. Dynamic sampling is disabled by default.                              |
| retries <1-10>   | Optional. Specifies the number of retries before allowing a power level adjustments to compensate for a potential coverage hole. <ul style="list-style-type: none"> <li>• &lt;1-10&gt; - Sets the number of retries from 1 - 10. The default is 3.</li> </ul> |
| threshold <1-30> | Optional. Specifies the minimum number of sample reports before which a power change requires dynamic sampling <ul style="list-style-type: none"> <li>• &lt;1-30&gt; - Sets the minimum number of reports from 1 - 30. The default is 5.</li> </ul>           |

```
neighbor-recovery {power-hold-time <0-3600>}
```

|                 |                                                                                                                 |
|-----------------|-----------------------------------------------------------------------------------------------------------------|
| power-hold-time | Optional. Specifies the minimum time, in seconds, between two power changes on a radio during neighbor-recovery |
| <0-3600>        | Sets the time from 0 - 3600 sec. The default is 0 seconds.                                                      |

neighbor-recovery {power-threshold [2.4GHz|5GHz] <-85--55>}

|                 |                                                                                                                                                                                                                                                                                                  |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| power-threshold | Optional. Specifies the power threshold based on which recovery is performed<br>The 2.4 GHz/5.0 GHz radio uses the value specified here as the maximum power increase threshold if the radio is required to increase its output power to compensate for a failed radio within its coverage area. |
| [2.4GHz 5GHz]   | Selects the band <ul style="list-style-type: none"> <li>• 2.4GHz - Selects the 2.4 GHz band</li> <li>• 5GHz - Selects the 5.0 GHz band</li> </ul>                                                                                                                                                |
| <-85--55>       | Specify the threshold value <ul style="list-style-type: none"> <li>• &lt;-85--55&gt; - Sets the power threshold from -85 dBm - -55 dBm. The default is -70 dBm for both the 2.4 GHz and 5.0 GHz bands.</li> </ul>                                                                                |

### select-shutdown

This feature enables auto-shutdown of select 2.4 GHz radios, in dual-band networks, to maintain CCI (co-channel interference) levels within specified limits. When enabled, Smart-RF monitors CCI levels to ensure that the deployment average CCI remains within specified minimum and maximum CCI limits. If the deployment average CCI is found to exceed the maximum threshold value, 2.4 GHz radios, causing neighbor interference, are shut down one-by-one until the deployment average CCI falls below the maximum threshold value. The reverse process occurs when the deployment average CCI falls below the minimum threshold value. In this scenario, previously disabled radios are one-by-one enabled until the deployed average CCI reaches acceptable levels.

Use this command to enable select-shutdown and configure the maximum and minimum CCI thresholds.

**Supported in the following platforms:**

- Access Points — , AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

**Syntax**

```
select-shutdown {cci-high-threshold/cci-low-threshold/frequency/frequency-limiter}
select-shutdown {cci-high-threshold <-85--55>}
select-shutdown {cci-low-threshold <-100--55>}
select-shutdown {frequency <0-3600>}
select-shutdown {frequency-limiter <1-1000>}
```

**Parameters**

```
select-shutdown {cci-high-threshold <-85--55>|cci-low-threshold <-100--55>|
frequency <0-3600>|frequency-limiter <1-1000>}
```

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

 select-shutdown cci-low-threshold -95
 coverage-hole-recovery snr-threshold 2.4GHz 35
nx9500-6C8809(config-smart-rf-policy-test)#
```

## Related Commands

`no` on page 1650

Disables select-shutdown of 2.4 GHz radios and reverts the select-shutdown parameters (maximum and minimum CCI thresholds, frequency, and frequency-limiter) to default values.

### *sensitivity*

Configures Smart RF sensitivity level. The sensitivity level determines Smart RF scanning and sampling aggressiveness. For example, a low sensitivity level indicates a less aggressive Smart-RF policy. This translates to fewer samples taken during off-channel scanning and short off-channel durations. When the sensitivity level is set to high, Smart-RF collects more samples, and remains off-channel longer.

The Smart RF sensitivity level options include **low**, **medium**, **high**, and **custom**. The custom option allows you to adjust the parameters and thresholds for interference recovery, coverage hole recovery, and neighbor recovery. However, the low, medium, and high settings still allow utilization of these features.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
sensitivity [custom|high|low|medium]
```

### Parameters

```
sensitivity [custom|high|low|medium]
```

|             |                                                                                                                    |
|-------------|--------------------------------------------------------------------------------------------------------------------|
| sensitivity | Configures Smart RF sensitivity levels. The options available are: custom, high, low, and medium.                  |
| custom      | Enables custom interference recovery, coverage hole recovery, and neighbor recovery as additional Smart RF options |
| high        | High sensitivity                                                                                                   |
| low         | Low sensitivity                                                                                                    |
| medium      | Medium sensitivity. This is the default setting.                                                                   |

### Usage Guidelines

To enable the *power* and *channel setting* parameters, set *sensitivity* to *custom* or *medium*.

To enable the *monitoring* and *scanning* parameters, set *sensitivity* to *custom*.

To enable the *neighbor recovery*, *interference* and *coverage hole recovery* parameters, set *sensitivity* to *custom*.

### Examples

|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extended-scan-frequency | Optional. Enables an extended scan, as opposed to a neighbor only scan, on this Smart RF policy. This is the frequency radios use to scan for non-peer radios.        |
| 2.4GHz <0-50>           | Enables extended scan on the 2.4 GHz band <ul style="list-style-type: none"> <li>• &lt;0-50&gt; - Sets the number of trails from 0 - 50. The default is 5.</li> </ul> |
| 5GHz <0-50>             | Enables extended scan on the 5.0 GHz band <ul style="list-style-type: none"> <li>• &lt;0-50&gt; - Sets the number of trails from 0 - 50. The default is 5.</li> </ul> |

`smart-ocs-monitoring {frequency [2.4GHz|5GHz] <1-120>}`

|                |                                                                                                                                                                    |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| frequency      | Optional. Specifies the scan frequency. This is the frequency, in seconds, in which smart-ocs-monitoring changes channels for an off-channel scan.                 |
| 2.4GHz <1-120> | Selects the 2.4 GHz band <ul style="list-style-type: none"> <li>• &lt;1-120&gt; - Sets a scan frequency from 1 sec - 120 sec. The default is 6 seconds.</li> </ul> |
| 5GHz <1-120>   | Selects the 5.0 GHz band <ul style="list-style-type: none"> <li>• &lt;1-120&gt; - Sets a scan frequency from 1 sec - 120 sec. The default is 6 seconds.</li> </ul> |

`smart-ocs-monitoring {off-channel-duration [2.4GHz|5GHz] <20-150>}`

|                      |                                                                                                                                                                                                                                                                                                                             |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| off-channel-duration | Optional. Specifies the duration to scan off channel<br>This is the duration for which an access point radio remains off-channel. During this period the radio monitors devices within the network and, if necessary, perform self healing and neighbor recovery to compensate for coverage area losses within a RF Domain. |
| 2.4GHz<br><20-150>   | Selects the 2.4 GHz band (in milliseconds) <ul style="list-style-type: none"> <li>• &lt;20-150&gt; - Sets the off channel duration from 20 - 150 milliseconds. The default is 50 milliseconds.</li> </ul>                                                                                                                   |
| 5GHz <20-150>        | Selects the 5.0 GHz band (in milliseconds) <ul style="list-style-type: none"> <li>• &lt;20-150&gt; - Sets the off channel duration from 20 - 150 milliseconds. The default is 50 milliseconds.</li> </ul>                                                                                                                   |

`smart-ocs-monitoring {power-save-aware [2.4GHz|5GHz] [disable|dynamic|strict]}`

|                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| power-save-aware                           | Optional. Enables power save awareness scanning mode on this Smart RF policy. The options are: disable, dynamic, and strict.<br>This setting allows Smart RF to detect power save clients and take them into consideration when performing off channel scans.<br>Strict disables smart monitoring as long as a power save capable client is associated to a radio.<br>Dynamic disables smart monitoring as long as there is data buffered for a power save client at the radio. |
| 2.4GHz<br>[disable <br>dynamic <br>strict] | Sets power save aware scanning mode on the 2.4 GHz band <ul style="list-style-type: none"> <li>• disable – Disables voice awareness scanning</li> <li>• dynamic – Dynamically avoids scanning based on traffic for power save (PSP) clients. This is the default setting.</li> <li>• strict – Strictly avoids scanning when PSP clients are present</li> </ul>                                                                                                                  |
| 5GHz [disable <br>dynamic <br>strict]      | Sets power save aware scanning mode on the 5.0 GHz band <ul style="list-style-type: none"> <li>• disable – Disables voice awareness .scanning</li> <li>• dynamic – Dynamically avoids scanning based on traffic for PSP clients. This is the default setting.</li> <li>• strict – Strictly avoids scanning when voice PSP are present</li> </ul>                                                                                                                                |

```
smart-ocs-monitoring {sample-count [2.4GHz|5GHz] <1-15>}
```

|               |                                                                                                                                                                       |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| sample-count  | Optional. Specifies the number of samples to collect before reporting an issue to the Smart RF master                                                                 |
| 2.4GHz <1-15> | Selects the 2.4 GHz band <ul style="list-style-type: none"> <li>• &lt;1-15&gt; – Specifies the number of samples to collect from 1 - 15. The default is 10</li> </ul> |
| 5GHz <1-15>   | Selects the 5.0 GHz band <ul style="list-style-type: none"> <li>• &lt;1-15&gt; – Specifies the number of samples to collect from 1 - 15. The default is 5.</li> </ul> |

```
smart-ocs-monitoring {tx-load-aware [2.4GHz|5GHz] <1-100>}
```

|                |                                                                                                                                                                                                                 |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tx-load-aware  | Optional. Specifies a transmit load percentage that serves as a threshold before scanning is avoided for an access point's 2.4 GHz or 5.0 GHz band. This option is disabled for both 2.4 GHz and 5.0 GHz bands. |
| 2.4GHz <1-100> | Selects the 2.4 GHz band <ul style="list-style-type: none"> <li>• &lt;1-100&gt; – Specify a transmit load percentage from 1 - 100%. When enabled, the default is 1%.</li> </ul>                                 |
| 5GHz <1-100>   | Selects the 5.0 GHz band <ul style="list-style-type: none"> <li>• &lt;1-100&gt; – Specify a transmit load percentage from 1 - 100%. When enabled, the default is 1%.</li> </ul>                                 |

### Related Commands

|                              |                                 |
|------------------------------|---------------------------------|
| <code>no</code> on page 1650 | Disables off-channel monitoring |
|------------------------------|---------------------------------|

*no*

Negates a command or sets its default. When used in the config Smart RF policy mode, the `no` command disables or resets Smart RF settings.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533

- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
no [area|assignable-power|avoidance-time|channel-list|channel-width|coverage-hole-recovery|

# WIPS POLICY

## WIPS-POLICY

---

This chapter summarizes the WIPS (Wireless Intrusion Protection Systems) policy commands in the CLI command structure.

WIPS is an additional measure of security designed to continuously monitor the network for threats and intrusions. Along with wireless VPNs, encryptions, and authentication policies WIPS enhances the security of a WLAN.

The WIPS policy enables detection of intrusions and threats that a managed network is likely to encounter. However, the WIPS policy does not include threat mitigation configurations. These intrusions and threats are available within the WIPS policy configuration mode as pre configured, fixed events. Each event consists of a set of frames or anomalies that may be harmful to the managed network. You can enable/disable various aspects of each individual event.

Events are broadly grouped into the following three categories:

- **Excessive/Thresholdable events:** These events detect DOS attacks, like excessive deauths, EAP floods, etc. Threshold limits for such events can be configured for MUs (mobile units) and radios. Once these threshold limits are exceeded, an event is triggered. Stations triggering an event are usually filtered. You can configure a filter ageout specifying the time for which the station, triggering the event, is filtered. However, the filter ageout only applies when the MU-threshold is exceeded. When radio threshold is reached, the system raises a warning about the same and updates event history with event details.
- **Station/MU anomalies:** These events are triggered when a MU performs suspicious activities that can compromise the security and stability of the managed network. You can configure a filter ageout, similar to the above class of events, to filter the station triggering such events.
- **AP/neighbor anomalies:** These events are triggered when an AP or neighbor sends suspicious frames. The system cannot filter APs or neighbors triggering such events. However, the system warns you about such attacks, allowing you to take further actions against such APs and neighbors.

In addition to event monitoring configuration, the WIPS policy allows you to configure a list of signatures. Unlike events, signatures are not fixed. You are free to define your own signatures based on a specific set of parameters. A signature is a rule, consisting of a set of fields to match and a corresponding set of actions in case of a match. By default, whenever a signature is matched an event log is triggered. This event log is similar to the one triggered upon an event. In addition to an event log, you can also configure other actions. Signatures have all the features supported by events. In fact most events are internally implemented as signatures.

Signature rules are of the following three types:

- **ssid, ssid length rule:** This signature matches a specified SSID or SSID length. It is mandatory to configure the frame type to match for this signature. When configured, only frame types allowed are beacons, probe requests, and probe responses. Example rule: `ssid : AirJack and frame type beacon` : Signature for AirJack attack.

- payload rule: This signature matches a particular payload at a particular frame offset. You can restrict these matches based on frame type. Example rule: Payload : 0x00601d Offset 3 : Netstumbler
- address-match rule: This signature matches one or more address fields. The address fields supported are BSSID, source-MAC, and destination-MAC. You can also specify frame types to match. The frame types supported are assoc, auth, beacon, data, death, disassoc, mgmt, probe-request, and probe-response.

A WIPS policy, once configured, has to be attached to a RF Domain to take effect. Multiple WIPS policies can be configured at the same time, but only one policy can be attached to a given RF Domain at any time.

#### Note

To attach a WIPS policy to a RF Domain, in the RF Domain configuration mode, execute the **use > wips-policy <WIPS-POLICY-NAME>** command. For more information, [use \(rf-domain-config-mode\)](#) on page 524.

#### Note

With this most recent release, AP 7522 and AP 7532 model access points can provide enhanced sensor support. AP 7522 and AP 7532 sensors can send data from off-channel-scans while in radio-share promiscuous/inline mode, in addition to the on-channel data captured in radio-share mode. ADSP uses the off-channel-scan data (in addition to the on-channel data) to monitor for rogue intrusions and trigger alarms. OTA Termination is triggered from ADSP to the appropriate radio-share AP to initiate termination.

#### Note

AP 7522 and AP 7532 models also support shared part-time scanning using WIPS in WiNG (using off-channel-scans) and no ADSP. WIPS on WiNG was enhanced to add rogue detection/classification (wired side detection based of MAC Address Offset) and OTA (over-the-air) termination for AP 7522 and AP 7532 deployments.

Use the (config) instance to configure WIPS policy commands. To navigate to the WIPS policy instance, use the following commands:

```
<DEVICE>(config)#wips-policy <POLICY-NAME>
nx9500-6C8809(config)#wips-policy test
nx9500-6C8809(config-wips-policy-test)#?
Wips Policy Mode commands:
 ap-detection Rogue AP detection
 enable Enable this wips policy
 event Configure an event
 history-throttle-duration Configure the duration for which event duplicates
 are not stored in history
 interference-event Specify events which will contribute to smart-rf
 wifi interference calculations
 no Negate a command or set its defaults
 signature Signature to configure
 use Set setting to use
 clrscr Clears the display screen
 commit Commit all changes made in this session
 do Run commands from Exec mode
 end End current mode and change to EXEC mode
 exit End current mode and down to previous mode
 help Description of the interactive help system
 revert Revert changes
```

```

service Service Commands
show Show running system information
write Write running configuration to memory or terminal

## wips-policy-commands

The following table summarizes WIPS policy configuration commands:

Table: WIPS-Policy Config Mode Commands

| Command                                                | Description                                                                  |
|--------------------------------------------------------|------------------------------------------------------------------------------|
| <a href="#">ap-detection</a> on page 1655              | Defines the WIPS AP detection configuration                                  |
| <a href="#">enable</a> on page 1657                    | Enables the WIPS policy                                                      |
| <a href="#">event</a> on page 1657                     | Configures events                                                            |
| <a href="#">history-throttle-duration</a> on page 1660 | Configures the duration event duplicates are omitted from the event history  |
| <a href="#">interference-event</a> on page 1661        | Specifies events contributing to the Smart RF WiFi interference calculations |
| <a href="#">signature</a> on page 1662                 | Configures a WIPS policy signature and enters its configuration mode         |
| <a href="#">use</a> on page 1673                       | Defines a WIPS policy settings                                               |
| <a href="#">no</a> on page 1672                        | Negates a command or sets its default                                        |

### Note

For more information on common commands (clrcr, commit, help, revert, service, show, write, and exit), see [COMMON COMMANDS](#) on page 640.

### Note

The input parameter <HOSTNAME>, wherever used in syntaxes across this chapter, cannot include an underscore (\_) character. In other words, the name of a device cannot contain an underscore.

### *ap-detection*

Enables the detection of unauthorized or unsanctioned APs. Unauthorized APs are untrusted access points connected to an access point managed network. These untrusted APs accept wireless client associations. It is important to detect such rogue APs and declare them unauthorized. Rogue AP detection is disabled by default.

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
ap-detection {ageout/air-termination/interferer-threshold/recurring-event-interval/wait-time}
ap-detection {ageout <30-86400>/interferer-threshold <-100--10>/recurring-event-interval <0-10000>/wait-time <10-600>}
ap-detection air-termination {allow-channel-switch/mode [auto/manual]}
```

## Parameters

```
ap-detection {ageout <30-86400>/interferer-threshold <-100--10>/recurring-event-interval <0-10000>/wait-time <10-600>}
```

|                                    |                                                                                                                                                                                                                                                                                   |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-detection                       | Enables detection of unauthorized or unsanctioned APs                                                                                                                                                                                                                             |
| ageout <30-86400>                  | Optional. Configures the unauthorized AP ageout interval. The WIPS policy uses this value to ageout unauthorized APs. <ul style="list-style-type: none"><li>&lt;30-86400&gt; - Sets an ageout interval from 30 - 86400 seconds. The default is 5 minutes (300 seconds).</li></ul> |
| recurring-event-interval <0-10000> | Configures recurring event interval help of unauthorized APs <ul style="list-style-type: none"><li>&lt;0-10000&gt; - Configures the recurring interval between 0 - 10000 seconds. The default is 300 seconds.</li></ul>                                                           |
| interferer-threshold <-100--10>    | Configures RSSI threshold value to determine if an unsanctioned ap is an interferer or not <ul style="list-style-type: none"><li>&lt;-100--10&gt; - Configures the rssi threshold between -100 - -10 dBm. The default is -75 dBm.</li></ul>                                       |
| wait-time <10-600>                 | Optional. Configures the wait time before a detected AP is declared as unauthorized and potentially removed <ul style="list-style-type: none"><li>&lt;10-600&gt; - Sets a wait time from 10 - 600 seconds. The default is 1 minute (60 seconds).</li></ul>                        |

```
ap-detection air-termination {allow-channel-switch/mode [auto/manual]}
```

|                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-detection                                               | Enables detection of unauthorized or unsanctioned APs                                                                                                                                                                                                                                                                                                                                                          |
| air-termination {allow-channel-switch} mode [auto/manual]} | Enables air termination of unauthorized APs. This option is disabled by default. <ul style="list-style-type: none"><li>allow-channel-switch - Optional. Allows channel switch of unauthorized APs based on the channel mode. This option is disabled by default.</li><li>mode [auto/manual] - Optional. Select the mode as <b>auto</b> or <b>manual</b> to configure. The default setting is manual.</li></ul> |

## Examples

```
nx9500-6C8809(config-wips-policy-test)#ap-detection wait-time 15
nx9500-6C8809(config-wips-policy-test)#ap-detection age-out 50
nx9500-6C8809(config-wips-policy-test)#show context
wips-policy test
 ap-detection-age-out 50
 ap-detection-wait-time 15
nx9500-6C8809(config-wips-policy-test)#
nx9500-6C8809(config-wips-policy-test2)#ap-detection recurring-event-interval 10
nx9500-6C8809(config-wips-policy-test2)#show context
wips-policy test2
 ap-detection recurring-event-interval 10
nx9500-6C8809(config-wips-policy-test2)#
```

## Related Commands

|                              |                                                                      |
|------------------------------|----------------------------------------------------------------------|
| <code>no</code> on page 1672 | Resets unauthorized or unsanctioned AP detection settings to default |
|------------------------------|----------------------------------------------------------------------|

### *enable*

Enables this WIPS policy

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

`enable`

#### Parameters

None

#### Examples

```
nx9500-6C8809(config-wips-policy-test)#enable
```

## Related Commands

|                              |                          |
|------------------------------|--------------------------|
| <code>no</code> on page 1672 | Disables the WIPS policy |
|------------------------------|--------------------------|

### *event*

Configures events, filters and threshold values for this WIPS policy. Events are grouped into three categories, AP anomaly, client anomaly, and excessive. WLANs are baselined for matching criteria. Any deviation from this baseline is considered an anomaly and logged as an event.

#### Note

By default all event monitoring is disabled.

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
event [ap-anomaly|client-anomaly|enable-all-events|excessive]
event ap-anomaly [ad-hoc-violation|airjack|ap-ssid-broadcast-in-beacon|asleep|
impersonation-attack|null-probe-response|transmitting-device-using-invalid-mac|
unencrypted-wired-leakage|wireless-bridge]
event client-anomaly [dos-broadcast-deauth|fuzzing-all-zero-macs|
fuzzing-invalid-frame-type|fuzzing-invalid-mgmt-frames|fuzzing-invalid-seq-num|
```

```

identical-src-and-dest-addr|invalid-8021x-frames|netstumbler-generic|
non-conforming-data|wellenreiter] {filter-ageout <0-86400>}
event enable-all-events
event excessive [80211-replay-check-failure|aggressive-scanning|auth-server-failures|
decryption-failures|dos-assoc-or-auth-flood|dos-eapol-start-storm|dos-unicast-deauth-or-
disassoc|
eap-flood|eap-nak-flood|frames-from-unassoc-station] {filter-ageout <0-86400>/
threshold-client <0-65535>/threshold-radio <0-65535>}

```

## Parameters

```

event ap-anomaly [ad-hoc-violation|airjack|ap-ssid-broadcast-in-beacon|asleep|
impersonation-attack|null-probe-response|transmitting-device-using-invalid-mac|
unencrypted-wired-leakage|wireless-bridge]

```

|                                       |                                                                                                                                                                                                                                                                       |
|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ap-anomaly                            | Enables AP anomaly event tracking<br>An AP anomaly event refers to suspicious frames sent by neighboring APs. An administrator enables or disables the filtering of each listed event and sets the thresholds for the generation of event notification and filtering. |
| ad-hoc-violation                      | Tracks ad-hoc network violations                                                                                                                                                                                                                                      |
| airjack                               | Tracks AirJack attacks                                                                                                                                                                                                                                                |
| ap-ssid-broadcast-in-beacon           | Tracks AP SSID broadcasts in beacon events                                                                                                                                                                                                                            |
| asleep                                | Tracks ASLEAP attacks. These attacks break LEAP (Lightweight Extensible Authentication Protocol) passwords                                                                                                                                                            |
| impersonation-attack                  | Tracks impersonation attacks. These are also referred to as spoofing attacks, where the attacker assumes the address of an authorized device.                                                                                                                         |
| null-probe-response                   | Tracks null probe response attacks                                                                                                                                                                                                                                    |
| transmitting-device-using-invalid-mac | Tracks the transmitting device using an invalid MAC address                                                                                                                                                                                                           |
| unencrypted-wired-leakage             | Tracks unencrypted wired leakage                                                                                                                                                                                                                                      |
| wireless-bridge                       | Tracks WDS (wireless bridge) frames                                                                                                                                                                                                                                   |

```

event client-anomaly [dos-broadcast-deauth|fuzzing-all-zero-macs|fuzzing-invalid-frame-
type|
fuzzing-invalid-mgmt-frames|fuzzing-invalid-seq-num|identical-src-and-dest-addr|
invalid-8021x-frames|
netstumbler-generic|non-conforming-data|wellenreiter] {filter-ageout <0-86400>}

```

|                             |                                                                                                                                                                                                                                                                                                                                        |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| client-anomaly              | Enables client anomaly event tracking<br>These are suspicious events performed by wireless clients that compromising the security of the network. An administrator can enable or disable the filtering of each listed event and set the thresholds required for the generation of the event notification and filtering action applied. |
| dos-broadcast-deauth        | Tracks DoS broadcast deauthentication events                                                                                                                                                                                                                                                                                           |

| filter-ageout <0-86400>     | <p>The following keywords are common to all of the above client anomaly events:</p> <ul style="list-style-type: none"> <li>filter-ageout &lt;0-86400&gt; – Optional. Configures the filter expiration time in seconds</li> <li>&lt;0-86400&gt; – Sets the filter ageout time from 0 - 86400 seconds. The default is 0 seconds.</li> </ul> <p><b>Note:</b> For each violation define a filter time in seconds, which determines how long the packets (received from an attacking device) are ignored once a violation has been triggered. Ignoring frames from an attacking device minimizes the effectiveness of the attack and the impact to the site until permanent mitigation can be performed.</p> <p>The filter ageout value is applicable across the entire RF Domain using this WIPS policy. If an MU is detected performing an attack and is filtered by one of the APs, the information is passed on to all APs and controllers within the RF Domain through the domain manager. Consequently the MU is filtered, for the specified period of time, across all devices.</p> |

### *history-throttle-duration*

Configures the duration event duplicates are omitted from the event history

The system maintains a history of all events that have occurred, on each device, within a RF Domain. Sometimes an event occurs for a prolonged period of time and tends to fill up the event history list. In such a scenario, duplicate information added to the event history list can be throttled for a specified period of time. Once this period is over, duplicate entries are once again allowed.

Event history statistics are periodically sent to the domain manager, which can be queried to ascertain the general health of the domain.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
history-throttle-duration <30-86400>
```

### Parameters

```
history-throttle-duration <30-86400>
```

|                           |                                                                                                                                        |

### *interference-event*

Specifies events contributing to the Smart RF WiFi interference calculations

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
interference-event [non-conforming-data|wireless-bridge]
```

### Parameters

```
interference-event [non-conforming-data|wireless-bridge]
```

|                     |                                                                               |
|---------------------|-------------------------------------------------------------------------------|
| non-conforming-data | Considers non conforming data packets when calculating Smart RF interference  |
| wireless-bridge     | Considers Wireless Bridge (WDS) frames when calculating Smart RF interference |

## Examples

```

### *signature*

Configures a WIPS policy signature. A WIPS signature is the set of parameters or patterns used by WIPS to identify and categorize particular sets of attack behaviors in order to classify them. Use this option to configure signatures in the WIPS policy. The WIPS policy compares packets in the network with pre configured signatures to identify threats.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
signature <SIGNATURE-NAME>
```

## Parameters

```
signature <SIGNATURE-NAME>
```

|                            |                                                                                                                                                                  |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| <a href="#">no</a> on page 1671                 | Negates a command or sets its default                                     |

[bssid](#)

Configures a BSSID MAC address with this WIPS signature for matching

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533

- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

`bssid <MAC>`

#### Parameters

`bssid <MAC>`

`bssid <MAC>` Configures a BSSID MAC address for matching purposes and potential device exclusion

- `<MAC>` - Specify the MAC address.

#### Examples

```
nx9500-6C8809(config-test-signature-test)#bssid 11-22-33-44-55-66
nx9500-6C8809(config-test-signature-test)#show context
signature test
bssid 11-22-33-44-55-66
nx9500-6C8809(config-test-signature-test)#
```

#### Related Commands

`no` on page 1671 Disables a WIPS signature BSS ID

### dst-mac

Configures the destination MAC address to be used as match criteria

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

`dst-mac <MAC>`

#### Parameters

`dst-mac <MAC>`

`dst-mac <MAC>` Configures the destination MAC address of the packet examined for matching purposes and potential device exclusion

- `<MAC>` - Specify the destination MAC address.

#### Examples

```
nx9500-6C8809(config-test-signature-test)#dst-mac 55-66-77-88-99-00
nx9500-6C8809(config-test-signature-test)#show context
signature test
 bssid 11-22-33-44-55-66
 dst-mac 55-66-77-88-99-00
nx9500-6C8809(config-test-signature-test)#
```

#### Related Commands

`no` on page 1671 Disables a WIPS signature destination MAC address

### filter-ageout

Configures the filter-ageout duration in seconds. This is the duration a client, triggering a WIPS event, is excluded from RF Domain manager radio association.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
filter-ageout <1-86400>
```

#### Parameters

```
filter-ageout <1-86400>
```

|                         |                                                              |
|-------------------------|--------------------------------------------------------------|
| filter-ageout <1-86400> | Configures the filter-ageout duration from 1 - 86400 seconds |
|-------------------------|--------------------------------------------------------------|

#### Examples

```
nx9500-6C8809(config-test-signature-test)#filter-ageout 8
nx9500-6C8809(config-test-signature-test)#show context
signature test
 bssid 11-22-33-44-55-66
 dst-mac 55-66-77-88-99-00
 filter-ageout 8
nx9500-6C8809(config-test-signature-test)#
```

#### Related Commands

|                                 |                                               |
|---------------------------------|-----------------------------------------------|
| <a href="#">no</a> on page 1671 | Removes the configured filter-ageout duration |
|---------------------------------|-----------------------------------------------|

## frame-type

Configures the frame type used for matching with this WIPS policy signature

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
frame-type [all|assoc|auth|beacon|data|deauth|disassoc|mgmt|probe-req|probe-req|reassoc]
```

#### Parameters

```
frame-type [all|assoc|auth|beacon|data|deauth|disassoc|mgmt|probe-req|probe-req|reassoc]
reassoc]
```

|            |                                             |
|------------|---------------------------------------------|
| frame-type | Configures the frame type used for matching |
| all        | Matches all frame types                     |
| assoc      | Matches only association frames             |
| auth       | Matches only authentication frames          |
| beacon     | Matches only beacon frames                  |
| data       | Matches only data frames                    |

|            |                                       |
|------------|---------------------------------------|
| deauth     | Matches only de-authentication frames |
| disassoc   | Matches only disassociation frames    |
| mgmt       | Matches only management frames        |
| probe-req  | Matches only probe request frames     |
| probe-resp | Matches only probe response frames    |
| reassoc    | Matches only re-association frames    |

### Usage Guidelines

The frame type configured determines the SSID match type. To set the SSID match type as SSID, the frame type must be set to **beacon**, **probe-req** or **probe-resp**. For more information see, [ssid-match](#) on page 1668.

### Examples

```

nx9500-6C8809(config-test-signature-test)#frame-type reassoc
nx9500-6C8809(config-test-signature-test)#show context
signature test
 bssid 11-22-33-44-55-66
 dst-mac 55-66-77-88-99-00
 frame-type reassoc
 filter-ageout 8
nx9500-6C8809(config-test-signature-test)#

```

### Related Commands

|                                 |                                    |
|---------------------------------|------------------------------------|
| <a href="#">no</a> on page 1672 | Resets a WIPS signature frame type |

## interference-event

Configures this WIPS policy signature as Smart RF interference source

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
interference-event
```

### Parameters

None

### Examples

```

nx9500-6C8809(config-test-signature-test)#interference-event
nx9500-6C8809(config-test-signature-test)#show context
signature test
 interference-event
 bssid 11-22-33-44-55-66
 dst-mac 55-66-77-88-99-00
 frame-type reassoc
 filter-ageout 8
nx9500-6C8809(config-test-signature-test)#

```

### Related Commands

no on page 1672

Disables this WIPS policy signature as Smart RF interference source

mode

Enables this WIPS policy signature

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

Syntax

```
mode enable
```

Parameters

```
mode enable
```

mode enable

Enables this WIPS signature

Examples

```
nx9500-6C8809(config-test-signature-test)#mode enable
nx9500-6C8809(config-test-signature-test)#
```

Related Commands

no on page 1672

Disables this WIPS signature

payload

Configures payload settings. The payload command sets a numerical index pattern and offset for this WIPS signature. Payload-based signatures detect patterns in the content of the file rather than attributes, such as a hash, allowing them to identify and block altered malware.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

Syntax

```
payload <1-3> pattern <WORD> offset <0-255>
```

Parameters

```
payload <1-3> pattern <WORD> offset <0-255>
```

|                |                                                                                                                                                              |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| payload <1-3>  | Configures payload settings <ul style="list-style-type: none"><li>• &lt;1-3&gt; – Set the payload index from 1 - 3.</li></ul>                                |
| pattern <WORD> | Specifies the pattern to match: hex or string <ul style="list-style-type: none"><li>• &lt;WORD&gt; – Set the pattern name.</li></ul>                         |

|---------------------------------|---------------------------------------------|

## ssid-match

Configures the SSID (and its character length) used as a match criteria

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533

- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
ssid-match [ssid|ssid-len]
ssid-match [ssid <SSID>|ssid-len <0-32>]
```

#### Parameters

```
ssid-match [ssid <SSID>|ssid-len <0-32>]
```

|                 |                                                                                                                                                                                                      |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ssid <SSID>     | Specifies the SSID match string <ul style="list-style-type: none"> <li>• &lt;SSID&gt; – Specify the SSID string.</li> </ul> <p><b>Note:</b> Specify the correct SSID to ensure proper filtering.</p> |
| ssid-len <0-32> | Specifies the length of the SSID <ul style="list-style-type: none"> <li>• &lt;0-32&gt; – Specify the SSID length from 0 - 32 characters.</li> </ul>                                                  |

#### Examples

```
nx9500-6C8809(config-test-signature-test)#ssid-match ssid PrinterLan
nx9500-6C8809(config-test-signature-test)#show context
signature test
 bssid 11-22-33-44-55-66
 src-mac 00-1E-E5-EA-1D-60
 dst-mac 55-66-77-88-99-00

#### threshold-client

Configures the client threshold limit. This is the threshold limit per client that, when exceeded, signals the event.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
threshold-client <1-65535>
```

#### Parameters

```
threshold-client <1-65535>
```

|                            |                                                                                                                                                                            |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| threshold-client <1-65535> | Configures the client threshold limit <ul style="list-style-type: none"> <li>• &lt;1-65535&gt; – Set the threshold limit for a 60 second window from 1 - 65535.</li> </ul> |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Examples

```
nx9500-6C8809(config-test-signature-test)#threshold-client 88
nx9500-6C8809(config-test-signature-test)#show context
signature test
 bssid 11-22-33-44-55-66
 src-mac 00-1E-E5-EA-1D-60
 dst-mac 55-66-77-88-99-00
 frame-type beacon
 ssid-match ssid PrinterLan
 filter-ageout 8
 threshold-client 88
 payload 1 pattern test offset 1
nx9500-6C8809(config-test-signature-test)#
```

## Related Commands

|                              |                                                                            |
|------------------------------|----------------------------------------------------------------------------|
| <code>no</code> on page 1671 | Removes the client threshold limit configured with a WIPS policy signature |
|------------------------------|----------------------------------------------------------------------------|

## threshold-radio

Configures the radio's threshold limit. When the radio exceeds the specified limit, an event is triggered.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
threshold-radio <1-65535>
```

## Parameters

```
threshold-radio <1-65535>
```

|                              |                                                                                                                                                                               |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| threshold-radio<br><1-65535> | Configures the radio's threshold limit <ul style="list-style-type: none"><li>• &lt;1-65535&gt; - Specify the threshold limit for a 60 second window from 1 - 65535.</li></ul> |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Examples

```
nx9500-6C8809(config-test-signature-test)#threshold-radio 88
nx9500-6C8809(config-test-signature-test)#show context
signature test
 bssid 11-22-33-44-55-66
 src-mac 00-1E-E5-EA-1D-60
 dst-mac 55-66-77-88-99-00
 frame-type beacon
 ssid-match ssid PrinterLan
 filter-ageout 8
 threshold-client 88
 threshold-radio 88
 payload 1 pattern test offset 1
nx9500-6C8809(config-test-signature-test)#
```

## Related Commands

|                              |                                                                             |
|------------------------------|-----------------------------------------------------------------------------|
| <code>no</code> on page 1671 | Removes the radio's threshold limit configured with a WIPS policy signature |
|------------------------------|-----------------------------------------------------------------------------|

no

Negates a command or resets settings to their default. When used in the config WIPS policy signature mode, the no command resets or removes WIPS signature settings.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
no [bssid|dst-mac|filter-ageout|frame-type|interference-event|mode|payload|
src-mac|ssid-match|threshold-client|threshold-radio]
no [bssid|dst-mac|filter-ageout|frame-type|interference-event|mode enable|
payload <1-3>|src-mac|ssid-match [ssid|ssid-len]|threshold-client|threshold-radio]
```

#### Parameters

```
no <PARAMETERS>
```

|                 |                                                       |
|-----------------|-------------------------------------------------------|
| no <PARAMETERS> | Negates a command or resets settings to their default |
|-----------------|-------------------------------------------------------|

#### Usage Guidelines

The **no** command negates any command associated with it. Wherever required, use the same parameters associated with the command getting negated.

#### Examples

The following is the WIPS signature 'test' settings before the execution of the 'no' command:

```
nx9500-6C8809(config-test-signature-test)#show context
signature test
 bssid 11-22-33-44-55-66
 src-mac 00-1E-E5-EA-1D-60
 dst-mac 55-66-77-88-99-00
 frame-type beacon
 ssid-match ssid PrinterLan
 filter-ageout 8
 threshold-client 88
 threshold-radio 88
 payload 1 pattern test offset 1
nx9500-6C8809(config-test-signature-test)#
nx9500-6C8809(config-test-signature-test)#no mode enable
nx9500-6C8809(config-test-signature-test)#no bssid
nx9500-6C8809(config-test-signature-test)#no dst-mac
nx9500-6C8809(config-test-signature-test)#no src-mac
nx9500-6C8809(config-test-signature-test)#no filter-ageout
nx9500-6C8809(config-test-signature-test)#no threshold-client
nx9500-6C8809(config-test-signature-test)#no threshold-radio
```

The following is the WIPS signature 'test' settings after the execution of the 'no' command:

```
nx9500-6C8809(config-test-signature-test)#
signature test
 no mode enable
 frame-type beacon
 payload 1 pattern test offset 1
nx9500-6C8809(config-test-signature-test)
```

no

Negates a command or resets configured settings to their default. When used in the config WIPS policy mode, the no command negates or resets filters and thresholds.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
no [ap-detection|enable|event|history-throttle-duration|interference-event|signature|use]
no [enable|history-throttle-duration]
no ap-detection {ageout <{LINE-SINK}>}/air-termination/interferer-threshold <-100--10>/recurring-event-interval <0-10000>wait-time <{LINE-SINK}>}
no event [ap-anomaly|client-anomaly|enable-all-events|excessive]
no event ap-anomaly [ad-hoc-violation|airjack|ap-ssid-broadcast-in-beacon|asleep|impersonation-attack|null-porbe-response|transmitting-device-using-invalid-mac|unencrypted-wired-leakage|wireless-bridge]
no event client-anomaly [dos-broadcast-deauth|fuzzing-all-zero-macs|fuzzing-invalid-frame-type|fuzzing-invalid-mgmt-frames|fuzzing-invalid-seq-num|identical-src-and-dest-addr|invalid-8021x-frames|netstumbler-generic|non-conforming-data|wellenreiter] {filter-ageout <0-86400>}
no event excessive [80211-replay-check-failure|aggressive-scanning|auth-server-failures|decryption-failures|dos-assoc-or-auth-flood|dos-eapol-start-storm|dos-unicast-deauth-or-disassoc|eap-flood|eap-nak-flood|frames-from-unassoc-station] {filter-ageout <0-86400>}/threshold-client <0-65535>/threshold-radio <0-65535>}
no interference-event [non-conforming-data|wireless-bridge]
no signature <WIPS-SIGNATURE>
no use device-categorization
```

### Parameters

```
no <PARAMETERS>
```

no <PARAMETERS> Negates a command or resets configured settings to their default. When used in the config WIPS policy mode, the no command negates or resets filters and thresholds.

### Usage Guidelines

The no command negates any command associated with it. Wherever required, use the same parameters associated with the command getting negated.

### Examples

The following example shows the WIPS Policy 'test' settings before the 'no' commands are executed:

```
nx9500-6C8809(config-wips-policy-test)#show context
wips-policy test
 history-throttle-duration 77
 event excessive 80211-replay-check-failure threshold-client 10 threshold-radio 99 filter-ageout 9
 event client-anomaly wellenreiter filter-ageout 99
 interference-event non-conforming-data
 ap-detection-ageout 50
```

```

ap-detection-wait-time 15
nx9500-6C8809(config-wips-policy-test)#
nx9500-6C8809(config-wips-policy-test)#no event client-anomaly wellenreiter filter-ageout
99
nx9500-6C8809(config-wips-policy-test)#no interference-event non-conforming-data
nx9500-6C8809(config-wips-policy-test)#no history-throttle-duration

```

The following example shows the WIPS Policy 'test' settings after the 'no' commands are executed:

```

nx9500-6C8809(config-wips-policy-test)#show context
wips-policy test
 event excessive 80211-replay-check-failure threshold-client 10 threshold-radio 99 filter-
ageout 9
 no event client-anomaly wellenreiter filter-ageout 99
 ap-detection-ageout 50
 ap-detection-wait-time 15
nx9500-6C8809(config-wips-policy-test)#

```

## use

Enables device categorization on this WIPS policy. This command uses an existing device categorization list. The list categorizes devices as authorized or unauthorized.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
use device-categorization <DEVICE-CATEGORIZATION>
```

### Parameters

```
use device-categorization <DEVICE-CATEGORIZATION>
```

|                                                  |                                                                                                                                                                                                               |

# WLAN QoS Policy

## WLAN-QOS-POLICY

---

This chapter summarizes the WLAN QoS policy in the CLI command structure.

A WLAN QoS policy increases network efficiency by prioritizing data traffic. Prioritization reduces congestion. This is essential because of the lack of bandwidth for all users and applications. QoS helps ensure each WLAN on the wireless controller receives a fair share of the overall bandwidth, either equally or as per the proportion configured. Packets directed towards clients are classified into categories such as Video, Voice and Data. Packets within each category are processed based on the weights defined for each WLAN

Each WLAN QoS policy has a set of parameters which it groups into categories, such as management, voice and data. Packets within each category are processed based on the weights defined for each WLAN.

Use the (config) instance to configure WLAN QoS policy commands. To navigate to the WLAN QoS policy instance, use the following commands:

```
<DEVICE> (config)#wlan-qos-policy <POLICY-NAME>
nx9500-6C8809(config)#wlan-qos-policy test
nx9500-6C8809(config-wlan-qos-test)#?
WLAN QoS Mode commands:
 accelerated-multicast Configure accelerated multicast streams address and
 forwarding QoS classification
 classification Select how traffic on this WLAN must be classified
 (relative prioritization on the radio)
 multicast-mask Egress multicast mask (frames that match bypass the
 PSPqueue. This permits intercom mode operation
 without delay even in the presence of PSP clients)
 no Negate a command or set its defaults
 qos Quality of service
 rate-limit Configure traffic rate-limiting parameters on a
 per-wlan/per-client basis
 svp-prioritization Enable spectralink voice protocol support on this wlan
 voice-prioritization Prioritize voice client over other client (for
 non-WMM clients)
 wmm Configure 802.11e/Wireless MultiMedia parameters

 clrscr Clears the display screen
 commit Commit all changes made in this session
 do Run commands from Exec mode
 end End current mode and change to EXEC mode
 exit End current mode and down to previous mode
 help Description of the interactive help system
 revert Revert changes
 service Service Commands
 show Show running system information
 write Write running configuration to memory or terminal
nx9500-6C8809(config-wlan-qos-test)#
```

## WLAN-QoS-Policy commands

WLAN QoS configurations differ significantly from QoS policies configured for radios. WLAN QoS configurations are designed to support the data requirements of wireless clients, including the data types they support and their network permissions. Radio QoS policies are specific to the transmit and receive characteristics of the connected radio's themselves, independent from the wireless clients these Access Point radios support.

The following table summarizes WLAN QoS policy configuration commands.

**Table 53: WLAN-QoS-Policy-Config Commands**

| Command                            | Description                                                                        |
|------------------------------------|------------------------------------------------------------------------------------|
| <code>accelerated-multicast</code> | Configures accelerated multicast stream addresses and forwards QoS classifications |
| <code>classification</code>        | Classifies WLAN traffic based on priority                                          |
| <code>multicast-mask</code>        | Configures the egress prioritization multicast mask                                |
| <code>no</code>                    | Negates a command or sets its default                                              |
| <code>qos</code>                   | Defines the QoS configuration                                                      |
| <code>rate-limit</code>            | Configures the WLAN traffic rate limit using a WLAN QoS policy                     |
| <code>svp-prioritization</code>    | Enables Spectralink voice protocol support on a WLAN                               |
| <code>voice-prioritization</code>  | Prioritizes voice client over other clients                                        |
| <code>wmm</code>                   | Configures 802.11e/wireless multimedia parameters                                  |

### Note

For more information on common commands (clrscr, commit, help, revert, service, show, write, and exit), see [COMMON COMMANDS](#) on page 640.

### Note

The input parameter <HOSTNAME>, wherever used in syntaxes across this chapter, cannot include an underscore ( \_ ) character. In other words, the name of a device cannot contain an underscore.

## accelerated-multicast

Configures the accelerated multicast stream address and forwarding QoS classification

*Supported in the following platforms:*

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
accelerated-multicast [<IP>|autodetect]
accelerated-multicast [<IP>|autodetect] {classification [background|best-effort|
trust|video|voice]}
```

## Parameters

```
accelerated-multicast [<IP>|autodetect] {classification [background|best-effort|
trust|video|voice]}
```

|                       |                                                                                                                                                                                                                                                                       |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| accelerated-multicast | Configures the accelerated multicast stream address and forwarding QoS classification                                                                                                                                                                                 |
| <IP>                  | Configures a multicast IP address in the A.B.C.D format. The system can configure up to 32 IP addresses for each WLAN QoS policy                                                                                                                                      |
| autodetect            | Allows the system to automatically detect multicast streams. This parameter allows the system to convert multicast streams to unicast, or to specify multicast streams converted to unicast.                                                                          |
| classification        | Optional. Configures the forwarding of the QoS classification (traffic class). When the stream is converted and queued for transmission, specify the type of classification applied to the stream. The options are: background, best-effort, trust, voice, and video. |
| background            | Forwards streams with background (low) priority. This parameter is common to both <IP> and autodetect.                                                                                                                                                                |
| best-effort           | Forwards streams with best effort (normal) priority. This parameter is common to both <IP> and autodetect.                                                                                                                                                            |
| trust                 | No change to the streams forwarding traffic class. This parameter is common to both <IP> and autodetect.                                                                                                                                                              |
| video                 | Forwards streams with video traffic priority. This parameter is common to both <IP> and autodetect.                                                                                                                                                                   |
| voice                 | Forwards streams with voice traffic priority. This parameter is common to both <IP> and autodetect.                                                                                                                                                                   |

## Examples

```
nx9500-6C8809(config-wlan-qos-test)#accelerated-multicast autodetect
classification voice
nx9500-6C8809(config-wlan-qos-test)#show context
wlan-qos-policy test
qos trust dscp
qos trust wmm
accelerated-multicast autodetect classification voice
nx9500-6C8809(config-wlan-qos-test)#
```

## classification

Specifies how traffic on this WLAN is classified. This classification is based on relative prioritization on the radio.

*Supported in the following platforms:*

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000

- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
classification [low|non-unicast|non-wmm|normal|video|voice|wmm]
classification [low|normal|video|voice|wmm]
classification non-unicast [voice|video|normal|low|default]
classification non-wmm [voice|video|normal|low]
```

### Parameters

```
classification [low|normal|video|voice|wmm]
```

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| low    | Optimized for background traffic. Implies all traffic on this WLAN is low priority on the radio                                                                                                                                                                                                                                                                                                                                      |
| normal | Optimized for best effort traffic. Implies all traffic on this WLAN is prioritized as best effort traffic on the radio                                                                                                                                                                                                                                                                                                               |
| video  | Optimized for video traffic. Implies all traffic on this WLAN is prioritized as video traffic on the radio                                                                                                                                                                                                                                                                                                                           |
| voice  | Optimized for voice traffic. Implies all traffic on this WLAN is prioritized as voice traffic on the radio                                                                                                                                                                                                                                                                                                                           |
| wmm    | Uses WMM based classification, using DSCP or 802.1p tags, to classify traffic into different queues. Implies WiFi Multimedia QoS extensions are enabled on this radio. This allows different traffic streams between the wireless client and the Access Point to be prioritized according to the type of traffic (voice, video etc). The WMM classification supports high throughput data rates required for 802.11n device support. |

```
classification non-unicast [voice|video|normal|low|default]
```

|             |                                                                                                                                                        |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| non-unicast | Optimized for non-unicast traffic. Implies all traffic on this WLAN is designed for broadcast or multiple destinations                                 |
| video       | Optimized for non-unicast video traffic. Implies all WLAN non-unicast traffic is classified and treated as video packets                               |
| voice       | Optimized for non-unicast voice traffic. Implies all WLAN non-unicast traffic is classified and treated as voice packets                               |
| normal      | Optimized for non-unicast best effort traffic. Implies all WLAN non-unicast traffic is classified and treated as normal priority packets (best effort) |
| low         | Optimized for non-unicast background traffic. Implies all WLAN non-unicast traffic is classified and treated as low priority packets (background)      |
| default     | Uses the default classification mode (same as unicast classification if WMM is disabled, normal if unicast classification is WMM)                      |

```
classification non-wmm [voice|video|normal|low]
```

|         |                                                                                                                                                       |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| non-wmm | Specifies how traffic from non-WMM clients is classified                                                                                              |
| voice   | Optimized for non-WMM voice traffic. Implies all WLAN non-WMM client traffic is classified and treated as voice packets                               |
| video   | Optimized for non-WMM video traffic. Implies all WLAN non-WMM client traffic is classified and treated as video packets                               |
| normal  | Optimized for non-WMM best effort traffic. Implies all WLAN non-WMM client traffic is classified and treated as normal priority packets (best effort) |
| low     | Optimized for non-WMM background traffic. Implies all WLAN non-WMM client traffic is classified and treated as low priority packets (background)      |

## Examples

```
nx9500-6C8809(config-wlan-qos-test)#classification wmm
nx9500-6C8809(config-wlan-qos-test)#classification non-wmm video
nx9500-6C8809(config-wlan-qos-test)#classification non-unicast normal
nx9500-6C8809(config-wlan-qos-test)#show context
wlan-qos-policy test
 classification non-wmm video
 classification non-unicast normal
 qos trust dscp
 qos trust wmm
 accelerated-multicast autodetect classification voice
nx9500-6C8809(config-wlan-qos-test)#
```

## multicast-mask

Configures an egress prioritization multicast mask for this WLAN QoS policy

Normally all multicast and broadcast packets are buffered until the periodic DTIM interval (indicated in the 802.11 beacon frame), when clients in power save mode wake to check for frames. However, for certain applications and traffic types, the administrator may want the frames transmitted immediately, without waiting for the DTIM interval. By configuring a primary or secondary prioritization multicast mask, the network administrator can indicate which packets are transmitted immediately.

*Supported in the following platforms:*

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
multicast-mask [primary|secondary] <MAC/MASK>
```

## Parameters

```
multicast-mask [primary|secondary] <MAC/MASK>
```

|                      |                                                                                                                                                                                                                                                                                                                                           |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| primary <MAC/MASK>   | Configures the primary egress prioritization multicast mask <ul style="list-style-type: none"><li>• &lt;MAC/MASK&gt; - Sets the MAC address and the mask in the AA-BB-CC-DD-EE-FF/XX-XX-XX-XX-XX-XX format</li></ul> <p><b>Note:</b> Setting masks is optional and only needed if there are traffic types requiring special handling.</p> |
| secondary <MAC/MASK> | Configures the primary egress prioritization multicast mask <ul style="list-style-type: none"><li>• &lt;MAC/MASK&gt; - Sets the MAC address and the mask in the AA-BB-CC-DD-EE-FF / XX-XX-XX-XX-XX-XX format</li></ul>                                                                                                                    |

## Examples

```
nx9500-6C8809(config-wlan-qos-test)#multicast-mask primary
11-22-33-44-55-66/22-33-44-55-66-77
nx9500-6C8809(config-wlan-qos-test)#show context
wlan-qos-policy test
 classification non-wmm video
 multicast-mask primary 11-22-33-44-55-66/22-33-44-55-66-77
```

```

classification non-unicast normal
qos trust dscp
qos trust wmm
accelerated-multicast autodetect classification voice
nx9500-6c8809(config-wlan-qos-test)#

```

## no

Removes this WLAN QoS Policy settings or reverts them to default values

*Supported in the following platforms:*

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```

no [accelerated-multicast|classification|multicast-mask|qos|rate-limit|
svp-prioritization|voice-prioritization|wmm]
no [accelerated-multicast [<IP>|autodetect]|classification {non-unicast|non-wmm}|
multicast-mask [primary|secondary]|qos trust [dscp|wmm]|svp-prioritization|
voice-prioritization]
no rate-limit [client|wlan] [from-air|to-air] {max-burst-size|rate|red-threshold}
no rate-limit [client|wlan] [from-air|to-air] {max-burst-size|rate|
red-threshold [background|best-effort|video|voice]}
no wmm [background|best-effort|power-save|qbss-load-element|video|voice]
no wmm [power-save|qbss-load-element]
no wmm [backgorund|best-effort|video|voice] [aifsn|cw-max|cw-min|txop-limit]

```

### Parameters

```

no [accelerated-multicast [<IP>|autodetect]|classification {non-unicast|non-wmm}|
multicast-mask [primary|secondary]|qos trust [dscp|wmm]|svp-prioritization|
voice-prioritization]

```

|                                            |                                                                                                                                                                                                                                                                                            |

| background  | Disables background access category parameters  |
| best-effort | Disables best effort access category parameters |
| video       | Disables video access category parameters       |
| voice       | Disables voice access category parameters       |

### Examples

The following example shows the WLAN QoS Policy 'test' settings before the 'no' commands are executed:

```
nx9500-6C8809(config-wlan-qos-test)#show context
wlan-qos-policy test
classification non-wmm video
multicast-mask primary 11-22-33-44-55-66/22-33-44-55-66-77
classification non-unicast normal
qos trust dscp
qos trust wmm
```

```

accelerated-multicast autodetect classification voice
nx9500-6C8809(config-wlan-qos-test)#
nx9500-6C8809(config-wlan-qos-test)#no classification non-wmm
nx9500-6C8809(config-wlan-qos-test)#no multicast-mask primary
nx9500-6C8809(config-wlan-qos-test)#no qos trust dscp

```

The following example shows the WLAN QoS Policy 'test' settings after the 'no' commands are executed:

```

nx9500-6C8809(config-wlan-qos-test)#show context
wlan-qos-policy test
 classification non-unicast normal
 no qos trust dscp
 qos trust wmm
 accelerated-multicast autodetect classification voice
nx9500-6C8809(config-wlan-qos-test)#

```

## qos

Enables QoS on this WLAN

*Supported in the following platforms:*

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
qos trust [dscp|wmm]
```

### Parameters

```
qos trust [dscp|wmm]
```

|                  |                                                                                                                                                                                                                                |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| trust [dscp wmm] | Trusts the QoS values of ingressing packets <ul style="list-style-type: none"> <li>• dscp - Trusts the IP DSCP values of ingressing packets</li> <li>• wmm - Trusts the 802.11 WMM QoS values of ingressing packets</li> </ul> |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Examples

```

nx9500-6C8809(config-wlan-qos-test)#qos trust wmm
nx9500-6C8809(config-wlan-qos-test)#qos trust dscp
nx9500-6C8809(config-wlan-qos-test)#show context
wlan-qos-policy test
 classification non-unicast normal
 qos trust dscp
 qos trust wmm
 accelerated-multicast autodetect classification voice
nx9500-6C8809(config-wlan-qos-test)#

```

## rate-limit

Configures the WLAN traffic rate limits using the WLAN QoS policy

Excessive traffic causes performance issues or brings down the network entirely. Excessive traffic can be caused by numerous sources including network loops, faulty devices or malicious software such as a

worm or virus that has infected one or more devices at the branch. Rate limiting limits the maximum rate sent to or received from the wireless network (and WLAN) per wireless client. It prevents any single user from overwhelming the wireless network. It can also provide differential service for service providers. The uplink and downlink rate limits are usually configured on a RADIUS server using vendor specific attributes. Rate limits are extracted from the RADIUS server's response. When such attributes are not present, settings defined on the controller (access point, wireless controller, or service platform) are applied. An administrator can set separate QoS rate limits for upstream (data transmitted from the managed network) and downstream (data transmitted to the managed network).

Before defining rate limit thresholds for WLAN upstream and downstream traffic, it is recommended that you define the normal number of ARP, broadcast, multicast and unknown unicast packets that typically transmit and receive from each supported WMM access category. If thresholds are defined too low, normal network traffic (required by end-user devices) are dropped resulting in intermittent outages and performance problems.

Connected wireless clients can also have QoS rate limit settings defined in both the upstream and downstream direction.

*Supported in the following platforms:*

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
rate-limit [client|wlan] [from-air|to-air]
{max-burst-size/rate/red-threshold}
rate-limit [client|wlan] [from-air|to-air] {max-burst-size <2-1024>/
rate <50-1000000>}
rate-limit [client|wlan] [from-air|to-air]
{red-threshold [background <0-100>/ best-effort <0-100>/video <0-100>/
voice <0-100>]}
```

### Parameters

```
rate-limit [client|wlan] [from-air|to-air] {max-burst-size <2-1024>/
rate <50-1000000>}
```

|            |                                                                         |
|------------|-------------------------------------------------------------------------|
| rate-limit | Configures traffic rate limit parameters                                |
| client     | Configures traffic rate limiting parameters on a per-client basis       |
| wlan       | Configures traffic rate limiting parameters on a per-WLAN basis         |
| from-air   | Configures traffic rate limiting from a wireless client to the network  |
| to-air     | Configures the traffic rate limit from the network to a wireless client |

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| max-burst-size<br><2-1024> | Optional. Sets the maximum burst size from 2 - 1024 kbytes. The chances of the upstream or downstream packet transmission getting congested for the WLAN's client destination are reduced for smaller burst sizes. The default is 320 kbytes.<br><b>Note:</b> Smaller the burst, lesser are the chances of upstream packet transmission resulting in congestion for the WLAN's client destinations. By trending the typical number of ARP, broadcast, multicast and unknown unicast packets over a period of time, the average rate for each access category can be obtained. Once a baseline is obtained, administrators should then add a 10% margin (minimally) to allow for traffic bursts at the site. |
| rate <50-1000000>          | Optional. Sets the traffic rate from 50 - 1000000 kbps. This limit is the threshold value for the maximum number of packets received or transmitted over the WLAN from all access categories. Any traffic that exceeds the specified rate is dropped and a log message is generated. The default is 5000 kbps.                                                                                                                                                                                                                                                                                                                                                                                              |

```
rate-limit [client|wlan] [from-air|to-air]
{red-threshold [background <0-100>| best-effort <0-100>|video <0-100>|
voice <0-100>]}
```

|                        |                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| rate-limit             | Configures traffic rate limit parameters                                                                                                                                                                                                                                                                                                                           |
| client                 | Configures traffic rate limiting parameters on a per-client basis                                                                                                                                                                                                                                                                                                  |
| wlan                   | Configures traffic rate limiting parameters on a per-WLAN basis                                                                                                                                                                                                                                                                                                    |
| from-air               | Configures traffic rate limiting from a wireless client to the network                                                                                                                                                                                                                                                                                             |
| to-air                 | Configures the traffic rate limit from the network to a wireless client                                                                                                                                                                                                                                                                                            |
| red-threshold          | Configures random early detection threshold values for a designated traffic class                                                                                                                                                                                                                                                                                  |
| background<br><0-100>  | The following is common to the 'from-air' and 'to-air' parameters:<br>Optional. Sets a percentage value for background traffic in the upstream or downstream direction. Background traffic exceeding the defined threshold is dropped and a log message is generated. The default threshold is 50% for traffic in both directions.                                 |
| best-effort<br><0-100> | The following is common to the 'from-air' and 'to-air' parameters:<br>Optional. Sets a percentage value for best effort traffic in the upstream or downstream direction. Best effort traffic exceeding the defined threshold is dropped and a log message is generated. The default threshold is 50% for traffic in both directions.                               |
| video <0-100>          | The following is common to the 'from-air' and 'to-air' parameters:<br>Optional. Sets a percentage value for video traffic in the upstream or downstream direction. Video traffic exceeding the defined threshold is dropped and a log message is generated. The default threshold is 25% fro traffic in both directions.                                           |
| voice <0-100>          | The following is common to the 'from-air' and 'to-air' parameters:<br>Optional. Sets a percentage value for voice traffic in the upstream or downstream direction. Voice traffic exceeding the defined threshold is dropped and a log message is generated. The default threshold is 0% for traffic in both directions. 0% means no early random drops will occur. |

### Usage Guidelines

The following information should be taken into account when configuring rate limits:

- Background traffic consumes the least bandwidth of any access category, so this value can be set to a lower value once a general downstream rate is known by the network administrator (using a time trend analysis).
- Best effort traffic consumes little bandwidth, so this value can be set to a lower value once a general upstream rate is known by the network administrator (using a time trend analysis).

- Video traffic consumes significant bandwidth, so this value can be set to a higher value once a general upstream rate is known by the network administrator (using a time trend analysis).
- Voice applications consume significant bandwidth, so this value can be set to a higher value once a general upstream rate is known by the network administrator (using a time trend analysis).

### Examples

```

nx9500-6C8809(config-wlan-qos-test)#rate-limit wlan from-air max-burst-size 6
nx9500-6C8809(config-wlan-qos-test)#rate-limit wlan from-air rate 55
nx9500-6C8809(config-wlan-qos-test)#rate-limit wlan from-air red-threshold best-effort 10
nx9500-6C8809(config-wlan-qos-test)#rate-limit client from-air red-threshold background 3
nx9500-6C8809(config-wlan-qos-test)#show context
wlan-qos-policy test
 classification non-wmm video
 multicast-mask primary 11-22-33-44-55-66/22-33-44-55-66-77
 classification non-unicast normal
 rate-limit wlan from-air rate 55
 rate-limit wlan from-air max-burst-size 6
 rate-limit wlan from-air red-threshold best-effort 10
 rate-limit client from-air red-threshold background 3
 qos trust dscp
 qos trust wmm
 accelerated-multicast autodetect classification voice
nx9500-6C8809(config-wlan-qos-test)#

```

## svp-prioritization

Enables WLAN SVP support on this WLAN QoS policy. SVP support enables the identification and prioritization of traffic from Spectralink/Ploycomm phones. This gives priority to voice, with voice management packets supported only on certain legacy VOIP phones. If the wireless client classification is WMM, non-WMM devices recognized as voice devices have all their traffic transmitted at voice priority. Devices are classified as voice, when they emit SIP, SCCP, or H323 traffic. Thus, selecting this option has no effect on devices supporting WMM..

This feature is enabled by default.

*Supported in the following platforms:*

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
svp-prioritization
```

### Parameters

None

### Examples

```

nx9500-6C8809(config-wlan-qos-test)#svp-prioritization
nx9500-6C8809(config-wlan-qos-test)#show context
wlan-qos-policy test
 classification non-wmm video
 svp-prioritization

```

```

qos trust dscp
qos trust wmm
accelerated-multicast autodetect classification voice
nx9500-6C8809(config-wlan-qos-test)#

```

## voice-prioritization

Prioritizes voice clients over other clients (for non-WMM clients). This gives priority to voice and voice management packets and is supported only on certain legacy VOIP phones. This feature is enabled by default.

*Supported in the following platforms:*

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
voice-prioritization
```

### Parameters

None

### Examples

```

nx9500-6C8809(config-wlan-qos-test)#voice-prioritization
nx9500-6C8809(config-wlan-qos-test)#show context

rate-limit wlan from-air max-burst-size 6
rate-limit wlan from-air red-threshold best-effort 10
rate-limit client from-air red-threshold background 3
qos trust dscp
qos trust wmm
accelerated-multicast autodetect classification voice
nx9500-6C8809(config-wlan-qos-test)#

```

## wmm

Configures 802.11e/Wireless Multimedia (WMM) parameters for this WLAN QoS policy

WMM makes it possible for both home networks and Enterprises to decide which data streams are most important and assign them a higher traffic priority.

---

WMM's prioritization capabilities are based on the four access categories (background, best-effort, video, and voice). Higher the *Access Category* (AC) higher is the transmission probability over the controller managed WLAN. ACs correspond to the 802.1d priorities, facilitating interoperability with QoS policy management mechanisms. WMM enabled controllers coexist with legacy devices (not WMM-enabled).

Packets not assigned to a specific access category are categorized as best effort by default. Applications assign each data packet to a given access category. Categorized packets are added to one of four independent transmit queues (one per access category). The client has an internal collision resolution mechanism to address collision among different queues, which selects the frames with the highest priority to transmit.

The same mechanism deals with external collision, to determine which client should be granted the *Opportunity to Transmit* (TXOP). The collision resolution algorithm responsible for traffic prioritization is probabilistic and depends on two timing parameters that vary for each access category. These parameters are:

- The minimum interframe space, or Arbitrary Inter-Frame Space Number (AIFSN)
- The contention window, sometimes referred to as the random back off wait

Both values are smaller for high-priority traffic. The value of the contention window varies through time. Initially the contention window is set to a value that depends on the AC. As frames with the highest AC tend to have the lowest back off values, they are more likely to get a TXOP.

After each collision the contention window is doubled until a maximum value (also dependent on the AC) is reached. After successful transmission, the contention window is reset to its initial, AC dependant value. The AC with the lowest back off value gets the TXOP.

*Supported in the following platforms:*

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### *Syntax*

```
wmm [background|best-effort|power-save|qbss-load-element|video|voice]
wmm [power-save|qbss-load-element]
wmm [background|best-effort|video|voice] [aifsn <2-15>|cw-max <0-15>|
cw-min <0-15>|txop-limit <0-65535>]
```

### *Parameters*

```
wmm [power-save|qbss-load-element]
```

|                   |                                                                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| wmm               | Configures 802.11e/wireless multimedia parameters                                                                                                                                            |
| power-save        | Enables support for the WMM-Powersave mechanism. This mechanism, also known as <i>Unscheduled Automatic Power Save Delivery</i> (U-APSD), is specifically designed for WMM voice devices.    |
| qbps-load-element | Enables support for the <i>QOS Basic Service Set</i> (QBSS) load information element in beacons and probe response packets advertised by access packets. This feature is enabled by default. |

```
wmm [background|best-effort|video|voice] [aifsn <2-15>|cw-max <0-15>|
cw-min <0-15>|txop-limit <0-65535>]
```

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| wmm           | Configures 802.11e/wireless multimedia parameters. This parameter enables the configuration of four access categories. Applications assign each data packet to one of these four access categories and queues them for transmission.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| background    | Configures background access category parameters                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| best-effort   | Configures best effort access category parameters. Packets not assigned to any particular access category are categorized by default as having best effort priority                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| video         | Configures video access category parameters                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| voice         | Configures voice access category parameters                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| aifsn <2-15>  | Configures <i>Arbitrary Inter-Frame Space Number</i> (AIFSN) from 2 - 15. AIFSN is the wait time between data frames. This parameter is common to background, best effort, video and voice.<br>The default for traffic voice categories is 2<br>The default for traffic video categories is 2<br>The default for traffic best effort (normal) categories is 3<br>The default for traffic background (low) categories is 7 <ul style="list-style-type: none"> <li>• &lt;2-15&gt; – Sets a value from 2 - 15</li> </ul>                                                                                                                                                                                                                               |
| cw-max <0-15> | Configures the maximum contention window. Wireless clients pick a number between 0 and the minimum contention window to wait before retransmission. Wireless clients then double their wait time on a collision, until it reaches the maximum contention window. This parameter is common to background, best effort, video and voice.<br>The default for traffic voice categories is 3<br>The default for traffic video categories is 4<br>The default for traffic best effort (normal) categories is 10<br>The default for traffic background (low) categories is 10 <ul style="list-style-type: none"> <li>• &lt;0-15&gt; – ECW: the contention window. The actual value used is <math>(2^{ECW} - 1)</math>. Set a value from 0 - 15.</li> </ul> |

|                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

# L2TPV3 Policy

## L2TPV3-POLICY

---

This chapter summarizes *Layer 2 Tunnel Protocol Version 3* (L2TPv3) policy commands in the CLI command structure.

The L2TPv3 policy defines control and encapsulation protocols for tunneling different types of layer 2 frames between two IP nodes. The L2TPv3 control protocol controls dynamic creation, maintenance, and tear down of L2TP sessions. The L2TPv3 encapsulation protocol is used to multiplex and demultiplex L2 data streams between two L2TP nodes across an IP network.

L2TPv3 is an IETF standard used for transporting different types of layer 2 frames in an IP network (and Access Point profile). L2TPv3 defines control and encapsulation protocols for tunneling layer 2 frames between two IP nodes. Use L2TPv3 to create tunnels for transporting layer 2 frames. L2TPv3 enables WING supported controllers and Access Points to create tunnels for transporting Ethernet frames to and from bridge VLANs and physical ports. L2TPv3 tunnels can be defined between WING devices and other vendor devices supporting the L2TPv3 protocol.

Multiple pseudowires can be created within an L2TPv3 tunnel. WING supported devices support an Ethernet VLAN pseudowire type exclusively. A pseudowire is an emulation of a layer 2 point-to-point connection over a packet-switching network (PSN). A pseudowire was developed out of the necessity to encapsulate and tunnel layer 2 protocols across a layer 3 network. Ethernet VLAN pseudowires transport Ethernet frames to and from a specified VLAN. One or more L2TPv3 tunnels can be defined between tunnel end points. Each tunnel can have one or more L2TPv3 sessions. Each tunnel session corresponds to one pseudowire. An L2TPv3 control connection (an L2TPv3 tunnel) needs to be established between the tunneling entities before creating a session.

### Note

A pseudowire is an emulation of a layer 2 point-to-point connection over a *packet-switching network* (PSN). A pseudowire was developed out of the necessity to encapsulate and tunnel layer 2 protocols across a layer 3 network.

Ethernet VLAN pseudowires transport Ethernet frames to and from a specified VLAN. One or more L2TPv3 tunnels can be defined between tunnel end points. Each tunnel can have one or more L2TPv3 sessions. Each tunnel session corresponds to one pseudowire. An L2TPv3 control connection (a L2TPv3 tunnel) needs to be established between the tunneling entities before creating a session.

For optimal pseudowire operation, both the L2TPv3 session originator and responder need to know the pseudowire type and identifier. These two parameters are communicated during L2TPv3 session establishment. An L2TPv3 session created within an L2TPv3 connection also specifies multiplexing parameters for identifying a pseudowire type and ID.

The working status of a pseudowire is reflected by the state of the L2TPv3 session. If a L2TPv3 session is down, the pseudowire associated with it must be shut down. The L2TPv3 control connection keep-

alive mechanism can serve as a monitoring mechanism for the pseudowires associated with a control connection.

#### Note

If connecting an Ethernet port to another Ethernet port, the pseudowire type must be *Ethernet port*, if connecting an Ethernet VLAN to another Ethernet VLAN, the pseudowire type must be *Ethernet VLAN*.

This chapter is organized into the following sections:

- [l2tpv3-policy-commands](#)
- [l2tpv3-tunnel-commands](#)
- [l2tpv3-manual-session-commands](#)

## l2tpv3-policy-commands

Use the (config) instance to configure L2TPV3 policy parameters. To navigate to the L2TPV3 policy instance, use the following commands:

```
<DEVICE>(config)#l2tpv3 policy <L2TPV3-POLICY-NAME>
nx9500-6C8809(config)#l2tpv3 policy L2TPV3Policy1
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#?
L2tpv3 Policy Mode commands:
 cookie-size Size of the cookie field present in each l2tpv3 data
 message
 failover-delay Time interval for re-establishing the tunnel after
 the failover (RF-Domain
 manager/VRRP-master/Cluster-master failover)
 force-l2-path-recovery Enables force learning of servers, gateways etc.,
 behind the l2tpv3 tunnel when the tunnel is
 established
 hello-interval Configure the time interval (in seconds) between
 l2tpv3 Hello keep-alive messages exchanged in l2tpv3
 control connection
 no Negate a command or set its defaults
 reconnect-attempts Maximum number of attempts to reestablish the
 tunnel.
 reconnect-interval Time interval between the successive attempts to
 reestablish the l2tpv3 tunnel
 retry-attempts Configure the maximum number of retransmissions for
 signaling message
 retry-interval Time interval (in seconds) before the initiating a
 retransmission of any l2tpv3 signaling message
 rx-window-size Number of signaling messages that can be received
 without sending the acknowledgment
 tx-window-size Number of signaling messages that can be sent
 without receiving the acknowledgment

 clrscr Clears the display screen
 commit Commit all changes made in this session
 end End current mode and change to EXEC mode
 exit End current mode and down to previous mode
 help Description of the interactive help system
 revert Revert changes
 service Service Commands
 show Show running system information
 write Write running configuration to memory or terminal
```

```
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#
```

The following table summarizes L2TPV3 policy configuration commands:

**Table 54: L2TPV3-Tunnel-Policy-Config Commands**

| Command                             | Description                                                                                                                |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <code>cookie-size</code>            | Configures the cookie field size for each L2TPV3 data packet                                                               |
| <code>failover-delay</code>         | Configures the L2TPV3 tunnel failover delay in seconds                                                                     |
| <code>force-12-path-recovery</code> | Enables the forced detection of servers and gateways behind the L2TPV3 tunnel                                              |
| <code>hello-interval</code>         | Configures the interval, in seconds, between L2TPV3 "Hello" keep-alive messages exchanged in the L2TPV3 control connection |
| <code>no</code>                     | Negates or reverts L2TPV3 tunnel commands                                                                                  |
| <code>reconnect-attempts</code>     | Configures the maximum number of retransmissions for signalling messages                                                   |
| <code>reconnect-interval</code>     | Configures the interval, in seconds, between successive attempts to re-establish a failed tunnel connection                |
| <code>retry-attempts</code>         | Configures the maximum number of retransmissions of signalling messages                                                    |
| <code>retry-interval</code>         | Configures the interval, in seconds, before initiating a retransmission of any L2TPV3 signaling message                    |
| <code>rx-window-size</code>         | Configures the number of signaling messages received without sending an acknowledgment                                     |
| <code>tx-window-size</code>         | Configures the number of signaling messages transmitted without receiving an acknowledgment                                |

**Note**

For more information on common commands (clrscr, commit, help, revert, service, show, write, and exit), see [COMMON COMMANDS](#) on page 640.

**Note**

The input parameter <HOSTNAME>, wherever used in syntaxes across this chapter, cannot include an underscore (\_) character. In other words, the name of a device cannot contain an underscore.

*cookie-size*

Configures the size of the cookie field present in each L2TPv3 data packet. L2TPv3 data packets contain a session cookie that identifies the session (pseudowire) corresponding to it. In a tunnel, the cookie is a 4-byte or 8-byte signature shared between the two tunnel endpoints. This signature is configured at both the source and destination routers. If the signature at both ends do not match, the data is dropped. All sessions within a tunnel have the same session cookie size.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
cookie-size [0|4|8]
```

### Parameters

```
cookie-size [0|4|8]
```

|                     |                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cookie-size [0 4 8] | Configures the cookie-field size for each data packet. Select one of the following options: <ul style="list-style-type: none"><li>• 0 - No cookie field present in each L2TPV3 data message (this is the default setting)</li><li>• 4 - 4 byte cookie field present in each L2TPV3 data message</li><li>• 8 - 8 byte cookie field present in each L2TPV3 data message</li></ul> |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Examples

```
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#cookie-size 8
<exswl>(config-l2tpv3-policy-L2TPV3Policy1)#show context
l2tpv3 policy L2TPV3Policy1
 cookie-size 8
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#
```

### Related Commands

|           |                                                                                                      |
|-----------|------------------------------------------------------------------------------------------------------|
| <b>no</b> | Resets the cookie-field size to its default (0 - no cookie field present in each L2TPV3 data packet) |
|-----------|------------------------------------------------------------------------------------------------------|

### *failover-delay*

Configures the L2TPV3 tunnel failover delay in seconds. This is the interval after which a failed over tunnel is re-established.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
fail-over <5-60>
```

### Parameters

```
fail-over <5-60>
```

|                  |                                                                                                                                                                                                                                                                   |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| fail-over <5-60> | Sets the delay interval to re-establish a failed L2TPV3 tunnel (RF-Domain manager/ VRRP-master/Cluster-master failover) <ul style="list-style-type: none"><li>• &lt;5-60&gt; - Specify a fail-over delay from 5 - 60 seconds. The default is 5 seconds.</li></ul> |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Examples

```
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#failover-delay 30
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#show context
l2tpv3 policy L2TPV3Policy1
hello-interval 200
failover-delay 30
retry-attempts 10
retry-interval 30
cookie-size 8
rx-window-size 9
tx-window-size 9
reconnect-interval 100
reconnect-attempts 8
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#
```

## Related Commands

|                                                                   |
|-------------------------------------------------------------------|
| <b>no</b> Resets the failover interval to its default (5 seconds) |
|-------------------------------------------------------------------|

### *force-l2-path-recovery*

Enables the forced detection of servers and gateways behind the L2TPV3 tunnel. This feature is disabled by default.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
force-l2-path-recovery
```

## Parameters

None

## Examples

```
<exsw1>(config-l2tpv3-policy-L2TPV3Policy1)#force-l2-path-recovery
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#show context
l2tpv3 policy L2TPV3Policy1
hello-interval 200
failover-delay 30
retry-attempts 10
retry-interval 30
cookie-size 8
rx-window-size 9
tx-window-size 9
reconnect-interval 100
reconnect-attempts 8
force-l2-path-recovery
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#
```

## Related Commands

|                                                                                          |
|------------------------------------------------------------------------------------------|
| <b>no</b> Disables the forced detection of servers and gateways behind the L2TPV3 tunnel |
|------------------------------------------------------------------------------------------|

## *hello-interval*

Configures the interval, in seconds, between L2TPV3 "Hello" keep-alive messages exchanged in a L2TPV3 control connection.

### **Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### **Syntax**

```
hello-interval <1-3600>
```

### **Parameters**

```
hello-interval <1-3600>
```

|                            |                                                                                                                                |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| hello-interval<br><1-3600> | Configures the interval for L2TPV3 "Hello" keep-alive messages. Specify a value from 1 - 3600 seconds (default is 60 seconds). |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------|

### **Examples**

```
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#hello-interval 200
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#show context
l2tpv3 policy L2TPV3Policy1
 hello-interval 200
 cookie-size 8
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#
```

### **Related Commands**

|           |                                                                             |
|-----------|-----------------------------------------------------------------------------|
| <b>no</b> | Resets the "Hello" keep-alive message interval to its default of 60 seconds |
|-----------|-----------------------------------------------------------------------------|

## *reconnect-attempts*

Configures the maximum number of attempts made to re-establish a tunnel connection

### **Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### **Syntax**

```
reconnect-attempts <0-8>
```

### **Parameters**

```
reconnect-attempts <0-8>
```

|                          |                                                                                                                                                    |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| reconnect-attempts <0-8> | Configures the maximum number of attempts made to re-establish a tunnel connection                                                                 |
|                          | <ul style="list-style-type: none"><li>• &lt;0-8&gt; - Specify a value from 0 - 8 (default is 0: configures infinite reconnect attempts).</li></ul> |

### Examples

```
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#reconnect-attempts 8
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#show context
l2tpv3 policy L2TPV3Policy1
hello-interval 200
cookie-size 8
reconnect-attempts 8
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#
```

### Related Commands

|    |                                                                                                        |
|----|--------------------------------------------------------------------------------------------------------|
| no | Resets the maximum number of reconnect attempts to default (0: configures infinite reconnect attempts) |
|----|--------------------------------------------------------------------------------------------------------|

### *reconnect-interval*

Configures the interval, in seconds, between successive attempts to re-establish a failed tunnel connection

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
reconnect-interval <1-3600>
```

### Parameters

```
reconnect-interval <1-3600>
```

|                             |                                                                                                                                    |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| reconnect-interval <1-3600> | Configures the interval between successive attempts to re-establish a failed tunnel connection                                     |
|                             | <ul style="list-style-type: none"><li>• &lt;1-3600&gt; - Specify a value from 1 - 3600 seconds (default is 120 seconds).</li></ul> |

### Examples

```
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#reconnect-interval 100
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#
l2tpv3 policy L2TPV3Policy1
hello-interval 200
cookie-size 8
reconnect-interval 100
reconnect-attempts 8
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#
```

### Related Commands

|    |                                                                                                                     |
|----|---------------------------------------------------------------------------------------------------------------------|
| no | Resets the interval between successive attempts to re-establish a failed tunnel connection to default (120 seconds) |
|----|---------------------------------------------------------------------------------------------------------------------|

## *retry-attempts*

Configures the maximum number of attempts made to retransmit signalling messages. Use this command to specify how many retransmission cycles occur before determining the target tunnel peer is not reachable.

### **Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### **Syntax**

```
retry-attempts <1-10>
```

### **Parameters**

```
retry-attempts <1-10>
```

`retry-attempts <1-10>` Configures the maximum number of attempts made to retransmit signalling messages

- `<1-10>` - Specify a value from 1 - 10 (default is 5 attempts).

### **Examples**

```
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#retry-attempts 10
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#show context
l2tpv3 policy L2TPV3Policy1
hello-interval 200
retry-attempts 10
cookie-size 8
reconnect-interval 100
reconnect-attempts 8
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#
```

### **Related Commands**

`no` Resets the maximum number of retransmissions for signalling messages to default (5 attempts)

## *retry-interval*

Configures the interval, in seconds, between two successive attempts at retransmitting a L2TPv3 signaling message

### **Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### **Syntax**

```
retry-interval <1-250>
```

## Parameters

retry-interval <1-250>

|                        |                                                                                                                                |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| retry-interval <1-250> | Configures the interval, in seconds, between two successive retransmission attempts                                            |
|                        | <ul style="list-style-type: none"><li>• &lt;1-250&gt; - Specify a value from 1 - 250 seconds (default is 5 seconds).</li></ul> |

## Examples

```
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#retry-interval 30
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#show context
l2tpv3 policy L2TPV3Policy1
hello-interval 200
retry-attempts 10
retry-interval 30
cookie-size 8
reconnect-interval 100
reconnect-attempts 8
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#
```

## Related Commands

|    |                                                  |
|----|--------------------------------------------------|
| no | Resets the retry interval to default (5 seconds) |
|----|--------------------------------------------------|

### *rx-window-size*

Configures the number of signaling packets received without sending an acknowledgment

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

rx-window-size <1-15>

## Parameters

rx-window-size <1-15>

|                       |                                                                                                                       |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------|
| rx-window-size <1-15> | Configures the number of packets received without sending an acknowledgment                                           |
|                       | <ul style="list-style-type: none"><li>• &lt;1-15&gt; - Specify a value from 1 - 15 (default is 10 packets).</li></ul> |

## Examples

```
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#rx-window-size 9
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#show context
l2tpv3 policy L2TPV3Policy1
hello-interval 200
retry-attempts 10
retry-interval 30
cookie-size 8
rx-window-size 9
reconnect-interval 100
reconnect-attempts 8
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#
```

## Related Commands

`no` Resets the number of packets received without sending an acknowledgement to default (10 packets)

### *tx-window-size*

Configures the number of signaling packets transmitted without receiving an acknowledgment

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
tx-window-size <1-15>
```

#### Parameters

```
tx-window-size <1-15>
```

`tx-window-size <1-15>` Configures the number of packets transmitted without receiving an acknowledgment

- `<1-15>` – Specify a value from 1 - 15 (default is 10 packets).

#### Examples

```
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#tx-window-size 9
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#show context
l2tpv3 policy L2TPV3Policy1
 hello-interval 200
 retry-attempts 10
 retry-interval 30
 cookie-size 8
 rx-window-size 9
 tx-window-size 9
 reconnect-interval 100
 reconnect-attempts 8
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#
```

## Related Commands

`no` Resets the number of packets transmitted without receiving an acknowledgment to default (10 packets)

### *no*

Negates or reverts L2TPV3 policy settings to default

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
no [cookie-size|failover-delay|force-l2-path-recovery|hello-interval|
reconnect-attempts|reconnect-interval|retry-attempts|retry-interval|rx-window-size|
tx-window-size]
```

## Parameters

```
no <PARAMETERS>
```

|                 |                                                      |
|-----------------|------------------------------------------------------|
| no <PARAMETERS> | Negates or reverts L2TPV3 policy settings to default |
|-----------------|------------------------------------------------------|

## Examples

The following example shows the l2tpv3 policy 'L2TPV3Policy1' settings before the 'no' commands are executed:

```
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#show context
l2tpv3 policy L2TPV3Policy1
 hello-interval 200
 retry-attempts 10
 retry-interval 30
 cookie-size 8
 reconnect-interval 100
 reconnect-attempts 50
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#no hello-interval
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#no reconnect-attempts
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#no reconnect-interval
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#no retry-attempts
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#no retry-interval
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#no cookie-size
```

The following example shows the l2tpv3 policy 'L2TPV3Policy1' settings after the 'no' commands are executed:

```
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#show context
l2tpv3 policy L2TPV3Policy1
nx9500-6C8809(config-l2tpv3-policy-L2TPV3Policy1)#
```

## l2tpv3-tunnel-commands

Use the (profile or device context) instance to configure a L2TPv3 tunnel. To navigate to the tunnel configuration mode, use the following command in the profile context:

```
<DEVICE>(config-profile-default-rfs4000)#l2tpv3 tunnel <TUNNEL-NAME>
nx9500-6C8809(config-profile-default-rfs4000)#l2tpv3 tunnel Tunnel1
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-tunnel-Tunnel1)#
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-tunnel-Tunnel1)#?
L2tpv3 Tunnel Mode commands:
 establishment-criteria Set tunnel establishment criteria
 fast-failover Configure fast failover for l2tpv3 tunnels
 hostname Tunnel specific local hostname
 local-ip-address Configure the IP address for tunnel. If not
 specified, tunnel source ip address would be chosen
 automatically based on the tunnel peer ip address
 mtu Configure the mtu size for the tunnel
 no Negate a command or set its defaults
 peer Configure the l2tpv3 tunnel peers. At least one peer
 must be specified
 preempt Preemption of secondary tunnel when primary comes
 back
 preemption Preemption of secondary tunnel
```

```

router-id Tunnel specific local router ID
session Create / modify the specified l2tpv3 session
use Set setting to use

clrscr Clears the display screen
commit Commit all changes made in this session
end End current mode and change to EXEC mode
exit End current mode and down to previous mode
help Description of the interactive help system
revert Revert changes
service Service Commands
show Show running system information
write Write running configuration to memory or terminal

```

```
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-tunnel-Tunnel1)#
```

The following table summarizes L2TPV3 tunnel configuration commands:

**Table 55: L2TPV3-Tunnel-Config Commands**

| Command                                 | Description                                                                                                                       |
|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <code>establishment-criteria</code>     | Configures L2TPV3 tunnel establishment criteria                                                                                   |
| <code>fast-failover</code> on page 1702 | Configures fast-failover support on the L2TPv3 tunnel                                                                             |
| <code>hostname</code>                   | Configures tunnel specific local hostname                                                                                         |
| <code>local-ip-address</code>           | Configures the tunnel's IP address                                                                                                |
| <code>mtu</code>                        | Configures the tunnel's <i>Maximum Transmission Unit</i> (MTU) size                                                               |
| <code>no</code>                         | Negates or reverts L2TPV3 tunnel commands                                                                                         |
| <code>peer</code>                       | Configures the tunnel's peers                                                                                                     |
| <code>preempt</code> on page 1708       | Enables preemption of secondary tunnel when primary tunnel comes back                                                             |
| <code>preemption</code> on page 1709    | Delays the preemption of secondary tunnel. Use this command to configure the time to wait before preempting the secondary tunnel. |
| <code>router-id</code>                  | Configures the tunnel's local router ID                                                                                           |
| <code>session</code>                    | Creates/modifies specified L2TPV3 session                                                                                         |
| <code>use</code>                        | Configures a tunnel to use a specified L2TPV3 tunnel policy                                                                       |

### *establishment-criteria*

Configures L2TPV3 tunnel establishment criteria

A L2TPV3 tunnel is established from the current device to the NOC Controller when the current device becomes the VRRP master, cluster master, or RF Domain Manager. Similarly, the L2TPV3 tunnel is closed when the current device switches to standby or backup mode.

#### **Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533

- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
establishment-criteria [always|cluster-master|rf-domain-manager|vrrp-master <1-255>]
```

### Parameters

```
establishment-criteria [always|cluster-master|rf-domain-manager|vrrp-master <1-255>]
```

|                     |                                                                                                                                                                                                                                                                                                                                                            |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| always              | Always establishes a L2TPv3 tunnel from the current device to the NOC controller. This is the default setting.<br>The 'always' option indicates the device need not be a cluster-master, rf-domain-manager, or vrrp-master to establish a tunnel.                                                                                                          |
| cluster-master      | Establishes a L2TPv3 tunnel from the current device to the NOC controller, only when the current device becomes the cluster master<br><br><b>Note:</b> The L2TPv3 tunnel is closed when the current device switches back the standby or backup mode.                                                                                                       |
| rf-domain-manager   | Establishes a L2TPv3 tunnel from the current device to the NOC controller, only when the current device becomes the RF Domain manager<br><br><b>Note:</b> The L2TPv3 tunnel is closed when the current device switches back the standby or backup mode.                                                                                                    |
| vrrp-master <1-255> | Establishes a L2TPv3 tunnel from the current device to the NOC controller, only when the current device becomes the VRRP master <ul style="list-style-type: none"> <li>• &lt;1-255&gt; – Specify the VRRP group number from 1 - 255.</li> </ul> <b>Note:</b> The L2TPv3 tunnel is closed when the current device switches back the standby or backup mode. |

### Examples

```
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-tunnel-Tunnell)#establishment-criteria
cluster-master
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-tunnel-Tunnell)#show context
l2tpv3 tunnel Tunnell
 establishment-criteria cluster-master
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-tunnel-Tunnell)#
```

|----|----------------------------|
| no | Resets to default (always) |
|----|----------------------------|

### *fast-failover*

Configures fast-failover support on the L2TPv3 tunnel. When configured, devices, using this profile, send tunnel requests to both peers, and in turn, establish tunnels with both peers. If not configured, tunnel establishment occurs on one peer, with failover and other functionality the same as legacy behavior. In case fast failover is configured when an active tunnel, with one peer, already exists, the tunnel establishment process is re-initiated with both peers. Of the two tunnels established, one is marked active while the other is standby. The sessions and routes from the active tunnel are only pushed to the dataplane, resulting in creation of data sessions. However, if the active tunnel fails,

sessions and routes from the standby tunnel are pushed to the dataplane thereby providing almost immediate fail over. Both tunnels individually perform connection health checkups through hello intervals. This option is disabled by default.

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
fast-failover {aggressive}
```

#### Parameters

```
fast-failover {aggressive}
```

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| fast-failover | Configures fast-failover support on the L2TPv3 tunnel                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| aggressive    | Optional. When enabled, tunnel initiation hello requests are set to zero. For failure detections, hello attempts are not retried, regardless of the number of retry attempts configured. This option is disabled by default.<br><br><b>Note:</b> The hello-interval and retry-attempts parameters are defined in the L2TPv3 Policy context. For more information on configuring an L2TPv3 policy, see <a href="#">l2tpv3-policy-commands</a> on page 1691. For more information on associating an L2TPv3 policy to an L2TPv3 tunnel, see <a href="#">use</a> on page 1712. |

#### Examples

```
nx9500-6C8809(config-profile testNX9500-l2tpv3-tunnel-TestTunnel2)#show context
include-factory | include fast-failover
 no fast-failover
nx9500-6C8809(config-profile testNX9500-l2tpv3-tunnel-TestTunnel2)#

|---------------------------------|----------------------------------------------------|
| <a href="#">no</a> on page 1713 | Removes fast-failover support on the L2TPv3 tunnel |
|---------------------------------|----------------------------------------------------|

#### hostname

Configures the tunnel's local hostname

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

hostname <WORD>

## Parameters

hostname <WORD>

|                 |                                                                                                                                            |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| hostname <WORD> | Configures the tunnel's local hostname <ul style="list-style-type: none"><li>&lt;WORD&gt; - Specify the tunnel's local hostname.</li></ul> |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------|

## Examples

```
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-tunnel-Tunnel1)#hostname TunnelHost1
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-tunnel-Tunnel1)#show context
 l2tpv3 tunnel Tunnel1
 hostname TunnelHost1
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-tunnel-Tunnel1)#
```

|----|-------------------------------------|
| no | Removes the tunnel's local hostname |
|----|-------------------------------------|

## *local-ip-address*

Configures the tunnel's source IP address. If no IP address is specified, the tunnel's source IP address is automatically configured based on the tunnel peer's IP address.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

local-ip-address <IP>

## Parameters

local-ip-address <IP>

|                       |                                                                                                                                                                                                                                                                                                             |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| local-ip-address <IP> | Configures the L2TPv3 tunnel's source IP address <ul style="list-style-type: none"><li>&lt;IP&gt; - Specify the tunnel's IP address. Ensure the IP address is available (or will become available - virtual IP) on an interface. Modifying a tunnel's local IP address re-establishes the tunnel.</li></ul> |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Examples

```
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-tunnel-Tunnel1)#local-ip-address
172.16.10.2
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-tunnel-Tunnel1)#show context
 l2tpv3 tunnel Tunnel1
 local-ip-address 172.16.10.2
 hostname TunnelHost1
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-tunnel-Tunnel1)#
```

|-----------------|--------------------------------------------------------------------|
| <code>no</code> | Resets the tunnel's local IP address and re-establishes the tunnel |
|-----------------|--------------------------------------------------------------------|

### *mtu*

Configures the MTU size for this tunnel. This value determines the packet size transmitted over this tunnel.

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
mtu <128-1460>
```

#### Parameters

```
mtu <128-1460>
```

|                                   |                                                                                                                                                                             |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>mtu &lt;128-1460&gt;</code> | Configures the MTU size for this tunnel <ul style="list-style-type: none"><li>• &lt;128-1460&gt; - Specify a value from 128 - 1460 bytes (default is 1460 bytes).</li></ul> |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

#### Examples

```
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-tunnel-Tunnel1)#mtu 1280
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-tunnel-Tunnel1)#show context
l2tpv3 tunnel Tunnel1
 local-ip-address 172.16.10.2
 mtu 1280
 hostname TunnelHost1
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-tunnel-Tunnel1)#
```

|-----------------|---------------------------------------------------------------------|
| <code>no</code> | Resets the MTU size for this manual session to default (1460 bytes) |
|-----------------|---------------------------------------------------------------------|

### *peer*

Configures the L2TPv3 tunnel's peers. At least one peer must be specified.

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
peer <1-2> {hostname/ip-address/ipsec-secure/router-id/udp}
peer <1-2> {hostname [<HOSTNAME>/any]} {ipsec-secure/router-id/udp}
peer <1-2> {ip-address <IP>} {hostname/ipsec-secure/router-id/udp}
peer <1-2> {ipsec-secure} {gw [<IP>/<WORD>]}
peer <1-2> {router-id [<IP>/<WORD>/any]} {ipsec-secure/udp}
peer <1-2> {udp} {ipsec-secure/port <1-65535>}
```

## Parameters

```
peer <1-2> {hostname [<HOSTNAME>/any]} {ipsec-secure/router-id/udp}
```

| no | Removes the peer configured for this tunnel |
|----|---------------------------------------------|

*preempt*

Enables preemption of secondary tunnel when primary tunnel comes back

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
preempt enable
```

### Parameters

```
preempt enable
```

|                |                                                                                                            |
|----------------|------------------------------------------------------------------------------------------------------------|
| preempt enable | Enables preemption of secondary tunnel when primary tunnel comes back. This option is disabled by default. |
|----------------|------------------------------------------------------------------------------------------------------------|

### Examples

```
nx9500-6C8809(config-profile test-l2tpv3-tunnel-tunnell)#preempt enable
nx9500-6C8809(config-profile test-l2tpv3-tunnel-tunnell)#show context
l2tpv3 tunnel tunnell
preempt enable
nx9500-6C8809(config-profile test-l2tpv3-tunnel-tunnell)#
```

### Related Commands

| no on page 1713 | Disables preemption of secondary tunnel when primary tunnel comes back |
|-----------------|------------------------------------------------------------------------|

### *preemption*

Delays the preemption of secondary tunnel. Use this command to configure the time to wait before preempting the secondary tunnel.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
preemption delay <60-600>
```

### Parameters

```
preemption delay <60-600>
```

|                           |                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| preemption delay <60-600> | When the primary L2TPv3 tunnel goes down, the system waits and watches for the tunnel to come back, for a specified time, before preempting the secondary tunnel. Use this command to configure that time period. <ul style="list-style-type: none"><li>• delay &lt;60-600&gt; - Specify a value from 60 - 600 seconds. The default is 60 seconds.</li></ul> |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Examples

```
nx9500-6C8809(config-profile test-l2tpv3-tunnel-tunnell)#preemption delay 100
nx9500-6C8809(config-profile test-l2tpv3-tunnel-tunnell)#show context
 l2tpv3 tunnel tunnell
 preempt enable
 preemption delay 100
nx9500-6C8809(config-profile test-l2tpv3-tunnel-tunnell)#
```

## Related Commands

## *session*

Configures a session's pseudowire ID, which describes the session's purpose. The session established message sends this pseudowire ID to the L2TPv3 peer.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
session <L2TPV3-SESSION-NAME> [pseudowire-id|rate-limit]
session <L2TPV3-SESSION-NAME> pseudowire-id <1-4294967295> traffic-source
vlan <VLAN-ID-RANGE> {native-vlan <1-4094>}
session <L2TPV3-SESSION-NAME> rate-limit [egress|ingress] rate <50-1000000>
max-burst-size <2-1024>
```

### Parameters

```
session <L2TPV3-SESSION-NAME> pseudowire-id <1-4294967295> traffic-source
vlan <VLAN-ID-RANGE> {native-vlan <1-4094>}
```

|                                     |                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| session <L2TPV3-SESSION-NAME>       | Configures this session's name <ul style="list-style-type: none"><li>• &lt;L2TPV3-SESSION-NAME&gt; - Specify the L2TPV3 session name (should not exceed 31 characters in length). A tunnel is usable only if it has one or more session(s) (having specific session names) configured. The L2TPv3 tunnel has no idle timeout, it closes when the last tunnel session is closed.</li></ul> |
| pseudowire-id <1-4294967295>        | Configures the pseudowire ID for this session from 1- 4204067295<br>A pseudowire is an emulation of a layer 2 point-to-point connection over a <i>packet-switching network</i> (PSN). A pseudowire is needed to encapsulate and tunnel layer 2 protocols across a layer 3 network.                                                                                                        |

| session <L2TPV3-SESSION-NAME> | Configures this session's name <ul style="list-style-type: none"><li>• &lt;L2TPV3-SESSION-NAME&gt; - Specify the L2TPV3 session name (should not exceed 31 characters in length). A tunnel is usable only if it has one or more session(s) (having specific session names) configured. The L2TPv3 tunnel has no idle timeout, it closes when the last tunnel session is closed.</li></ul>                                                                                                                                                                                                                   |
| rate-limit [egress ingress]   | Configures a rate for incoming and/or outgoing traffic on this L2TPv3 tunnel. When configured, this option limits the rate at which data is sent to or received from L2TPv3 tunnel members. <ul style="list-style-type: none"><li>• egress - Applies the specified rate to outbound traffic, from the L2TPv3 tunnel (going out from access points, wireless controllers, and service platforms) to the network</li><li>• ingress - Applies the specified rate to inbound traffic, from the network to the L2TPV3 tunnel (coming in to access points, wireless controllers, and service platforms)</li></ul> |

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| rate <50-1000000>       | Specify the data rate, in kilobits per second, for the incoming and/or outgoing traffic <ul style="list-style-type: none"> <li>&lt;50-1000000&gt; – Specify a value from 50 - 1000000 kbps. The default is 5000 Kbps.</li> </ul>                                                                                                                                                                                                                           |
| max-burst-size <2-1024> | Configures the maximum burst size, in kilobytes, for incoming/outgoing traffic rate limiting (depending on the direction selected) on a L2TPv3 tunnel. <ul style="list-style-type: none"> <li>&lt;2-1024&gt; – Specify the maximum burst size from 2 - 1024 kbytes. Smaller the burst size, lesser are the chances of the upstream packet transmission resulting in congestion of the L2TPv3 tunnel traffic. The default setting is 320 kbytes.</li> </ul> |

### Usage Guidelines

The working status of a pseudowire is reflected by the state of the L2TPv3 session. If the corresponding session is L2TPv3 down, the pseudowire associated with it must be shut down.

### Examples

```

nx9500-6C8809(config-profile default-rfs4000-l2tpv3-tunnel-Tunnel1)#session
tunnel1peer1session1 pseudowire-id 5000 traffic-source vlan 10-20 native-vlan 1
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-tunnel-Tunnel1)#show context
l2tpv3 tunnel Tunnel1
 peer 2 hostname tunnel1peer1 udp port 100
 session tunnel1peer1session1 pseudowire-id 5000 traffic-source vlan 10-20 native-vlan 1
 router-id 2000
 establishment-criteria cluster-master
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-tunnel-Tunnel1)#

```

### Related Commands

|    |                   |
|----|-------------------|
| no | Removes a session |
|----|-------------------|

*use*

Configures a tunnel to use a specified L2TPV3 tunnel policy and specified critical resources

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```

use [critical-resource|l2tpv3-policy]
use critical-resource <CRM-NAME1> {<CRM-NAME2>} {<CRM-NAME3>} {<CRM-NAME4>}
use l2tpv3-policy <L2TPV3-POLICY-NAME>

```

### Parameters

```

use critical-resource <CRM-NAME1> {<CRM-NAME2>} {<CRM-NAME3>} {<CRM-NAME4>}

```

use critical-resource <CRM-NAME1> {<CRM-NAME2>} {<CRM-NAME3>} {<CRM-NAME4>}

Specifies the critical resource(s) to use with this tunnel

- <CRM1-NAME> - Specify the first critical resource name (should be existing).
- <CRM-NAME2/3/4> - Optional. Specify the second/third/fourth critical resource names. Maximum of four critical resources can be monitored.

**Note:** In case of tunnel initiator, L2TPv3 tunnel is established only if the critical resources identified by the <CRM-NAME1>..... <CRM-NAME4> arguments are available at the time of tunnel establishment.

**Note:** In case of L2TPv3 tunnel termination, all incoming tunnel establishment requests are rejected if the critical resources specified by the <CRM-NAME1>..... <CRM-NAME4> arguments are not available.

use l2tpv3-policy <L2TPV3-POLICY-NAME>

use l2tpv3-policy <L2TPV3-POLICY-NAME>

Associates a specified L2TPV3 policy with this tunnel

- <L2TPV3-POLICY-NAME> - Specify the policy name.

## Examples

```
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-tunnel-Tunnel1)#use l2tpv3-policy L2TPV3Policy1
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-tunnel-Tunnel1)#show context
l2tpv3 tunnel Tunnel1
 peer 2 hostname tunnellopeer1 udp port 100
 use l2tpv3-policy L2TPV3Policy1
 session tunnellopeer1session1 pseudowire-id 5000 traffic-source vlan 10-20 native-vlan 1
 router-id 2000
 establishment-criteria cluster-master
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-tunnel-Tunnel1)#
```

## Related Commands

**no** Removes the L2TPV3 policy configured with a tunnel and reverts to the default tunnel policy

*no*

Negates or reverts a L2TPv3 tunnel settings to default

## Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
no [establishment-criteria|fast-failover|hostname|local-ip-address|mtu|peer <1-2>|preempt enable|preemption delay|router-id|session|use]
```

## Parameters

no <PARAMETERS>

no <PARAMETERS>

Negates or reverts a L2TPv3 tunnel settings to default

## Examples

The tunnel settings before the 'no' command is executed:

```
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-tunnel-Tunnel1)#show context
l2tpv3 tunnel Tunnel1
 local-ip-address 172.16.10.2
 mtu 1280
 hostname TunnelHost1
 establishment-criteria cluster-master
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-tunnel-Tunnel1)#
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-tunnel-Tunnel1)#no local-ip
-address
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-tunnel-Tunnel1)#no mtu
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-tunnel-Tunnel1)#no hostname
```

The tunnel settings after the 'no' command is executed:

```
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-tunnel-Tunnel1)#show context
l2tpv3 tunnel Tunnel1
 establishment-criteria cluster-master
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-tunnel-Tunnel1)#
```

## l2tpv3-manual-session-commands

After a successful tunnel connection and establishment, individual sessions can be created. Each session is a single data stream. After successful session establishment, data corresponding to that session (pseudowire) can be transferred. If a session is down, the pseudowire associated with it is shut down as well.

Use the (profile-context) instance to manually configure a L2TPv3 manual session. To navigate to the L2TPv3 manual session configuration mode, use the following command in the profile context:

```
<DEVICE>(config-profile-default-rfs4000)#l2tpv3 manual-session <SESSION-NAME>
nx9500-6C8809(config-profile-default-rfs4000)#l2tpv3 manual-session test
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-manual-session-test)#
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-manual-session-test)#?
L2tpv3 Manual Session Mode commands:
 local-cookie The local cookie for the session
 local-ip-address Configure the IP address for tunnel. If not specified,
 tunnel source ip address would be chosen automatically
 based on the tunnel peer ip address
 local-session-id Local session id for the session
 mtu Configure the mtu size for the tunnel
 no Negate a command or set its defaults
 peer Configure L2TPv3 manual session peer
 remote-cookie The remote cookie for the session
 remote-session-id Remote session id for the session
 traffic-source Traffic that is tunneled

 clrscr Clears the display screen
 commit Commit all changes made in this session
 end End current mode and change to EXEC mode
 exit End current mode and down to previous mode
 help Description of the interactive help system
 revert Revert changes
 service Service Commands
 show Show running system information
 write Write running configuration to memory or terminal

nx9500-6C8809(config-profile default-rfs4000-l2tpv3-manual-session-test)#
```

The following table summarizes L2TPV3 manual session configuration commands:

**Table 56: L2TPV3-Manual-Session-Config Commands**

| Command                        | Description                                                  |
|--------------------------------|--------------------------------------------------------------|
| <code>local-cookie</code>      | Configures the manual session's local cookie field size      |
| <code>local-ip-address</code>  | Configures the manual session's local source IP address      |
| <code>local-session-id</code>  | Configures the manual session's local session ID             |
| <code>mtu</code>               | Configures the MTU size for the manual session tunnel        |
| <code>no</code>                | Negates or reverts L2TPV3 manual session commands to default |
| <code>peer</code>              | Configures the manual session's peers                        |
| <code>remote-cookie</code>     | Configures the remote cookie for the manual session          |
| <code>remote-session-id</code> | Configures the manual session's remote session ID            |
| <code>traffic-source</code>    | Configures the traffic source tunneled by the manual session |

### *local-cookie*

Configures the local cookie field size for the manual session

#### **Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### **Syntax**

```
local-cookie size [4|8] <1-4294967295> {<1-4294967295>}
```

#### **Parameters**

```
local-cookie size [4|8] <1-4294967295> {<1-4294967295>}
```

|                                      |                                                                                                                                                                                                             |
|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>local-cookie size [4 8]</code> | Configures the local cookie field size for this manual session. The options are: <ul style="list-style-type: none"> <li>• 4 - 4 byte local cookie field</li> <li>• 8 - 8 byte local cookie field</li> </ul> |
| <code>&lt;1-4294967295&gt;</code>    | Configures the local cookie value first word. Applies to both the 4 byte and 8 byte local cookies                                                                                                           |
| <code>&lt;1-4294967295&gt;</code>    | Optional - Configures the local cookie value second word. Applicable to only 8 byte cookies. This parameter is ignored for 4 byte cookies.                                                                  |

#### **Examples**

```
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-manual-session-test)#local-cookie size
8 200 300
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-manual-session-test)#show context
l2tpv3 manual-session test
 local-cookie size 8 200 300
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-manual-session-test)#
```

## Related Commands

**no** Removes the local cookie size configured for a manual session

### *local-ip-address*

Configures the manual session's source IP address. If no IP address is specified, the tunnel's source IP address is automatically configured based on the tunnel peer IP address. This parameter is applicable when establishing the session and responding to incoming requests.

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
local-ip-address <IP>
```

#### Parameters

```
local-ip-address <IP>
```

|                       |                                                                                                                                                        |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| local-ip-address <IP> | Configures the manual session's source IP <ul style="list-style-type: none"><li>• &lt;IP&gt; – Specify the IP address in the A.B.C.D format.</li></ul> |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|

#### Examples

```
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-manual-session-test)#local-ip-address 1.2.3.4
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-manual-session-test)#show context
l2tpv3 manual-session test
local-cookie size 8 200 300
local-ip-address 1.2.3.4
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-manual-session-test)#
```

## Related Commands

**no** Resets the manual session's local source IP address. This re-establishes the session.

### *local-session-id*

Configures the manual session's local session ID

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
local-session-id <1-63>
```

## Parameters

local-session-id <1-63>

|                         |                                                                                                                                                                                                                       |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| local-session-id <1-63> | Configures this manual session's local session ID                                                                                                                                                                     |
|                         | <ul style="list-style-type: none"><li>&lt;1-63&gt; - Specify the ID from 1 - 63. This is the pseudowire ID for the session. This pseudowire ID is sent in a session establishment message to the L2TP peer.</li></ul> |

## Examples

```
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-manual-session-test)#local-session-id 1
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-manual-session-test)#show context
l2tpv3 manual-session test
 local-cookie size 8 200 300
 local-ip-address 1.2.3.4
 local-session-id 1
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-manual-session-test)#
```

## Related Commands

|    |                                               |
|----|-----------------------------------------------|
| no | Removes the manual session's local session ID |
|----|-----------------------------------------------|

## mtu

Configures the MTU size for the manual session tunnel. The MTU is the size (in bytes) of the largest protocol data unit the layer can pass between tunnel peers in this session. A larger MTU means processing fewer packets for the same amount of data.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

mtu <128-1460>

## Parameters

mtu <128-1460>

|                |                                                                                                                                   |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------|
| mtu <128-1460> | Configures the MTU size for this manual session tunnel                                                                            |
|                | <ul style="list-style-type: none"><li>&lt;128-1460&gt; - Specify a value from 128 - 1460 bytes (default is 1460 bytes).</li></ul> |

## Examples

```
nx9500-6C8809(config-profile default-rfs7000-l2tpv3-manual-session-test)#mtu 200
nx9500-6C8809(config-profile default-rfs7000-l2tpv3-manual-session-test)#show context
l2tpv3 manual-session test
 local-cookie size 8 200 300
 local-ip-address 1.2.3.4
 mtu 200
 local-session-id 1
nx9500-6C8809(config-profile default-rfs7000-l2tpv3-manual-session-test)#
```

## Related Commands

**no** Resets the MTU size for this manual session to default (1460 bytes)

### *peer*

Configures peer(s) allowed to establish the manual session tunnel. The peers are identified by their IP addresses.

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
peer ip-address <IP> {udp {port <1-65535>}}
```

#### Parameters

```
peer ip-address <IP> {udp {port <1-65535>}}
```

|                                         |                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>peer ip-address &lt;IP&gt;</code> | Configures the tunnel's peer IP address in the A.B.C.D format                                                                                                                                                                                                                                                                     |
| <code>udp {port &lt;1-65535&gt;}</code> | Optional. Configures the UDP encapsulation mode for this tunnel (default encapsulation is IP) <ul style="list-style-type: none"><li>• <code>port &lt;1-65535&gt;</code> - Optional. Configures the peer's UDP port running the L2TPv3 service.</li><li>• <code>&lt;1-65535&gt;</code> - Specify a value from 1 - 65535.</li></ul> |

#### Examples

```
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-manual-session-test)#peer ip-address 5.6.7.8 udp port 150
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-manual-session-test)#show context
l2tpv3 manual-session test
 local-cookie size 8 200 300
 local-ip-address 1.2.3.4
 peer ip-address 5.6.7.8 udp port 150
 mtu 200
 local-session-id 1
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-manual-session-test)#
```

## Related Commands

**no** Removes the manual session's peer configuration

### *remote-cookie*

Configures the manual session's remote cookie field size

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
remote-cookie size [4|8] <1-4294967295> {<1-4294967295>}
```

### Parameters

```
remote-cookie size [4|8] <1-4294967295> {<1-4294967295>}
```

|                          |                                                                                                                                                                                                             |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| remote-cookie size [4 8] | Configures the remote cookie field size for this manual session. The options are: <ul style="list-style-type: none"><li>• 4 – 4 byte remote cookie field</li><li>• 8 – 8 byte remote cookie field</li></ul> |
| <1-4294967295>           | Configures the remote cookie value first word. Applies to both the 4 byte and 8 byte local cookies                                                                                                          |
| <1-4294967295>           | Optional – Configures the remote cookie value second word. Applicable to only 8 byte cookies. This parameter is ignored for 4 byte cookies.                                                                 |

### Examples

```
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-manual-session-test)#remote-cookie
size 8 400 700
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-manual-session-test)#show context
l2tpv3 manual-session test
 local-ip-address 1.2.3.4
 peer ip-address 5.6.7.8 udp port 150
 mtu 200
 local-session-id 1
 remote-cookie size 8 400 700
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-manual-session-test)#
```

### Related Commands

|----|-------------------------------------------------------|
| no | Removes the manual session's remote cookie field size |
|----|-------------------------------------------------------|

### *remote-session-id*

Configures the manual session's remote ID. This ID is passed in the establishment of the tunnel session.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
remote-session-id <1-4294967295>
```

## Parameters

```
remote-session-id <1-4294967295>
```

|                                     |                                                                                                                                                        |

### *traffic-source*

Configures the traffic source tunneled by this session

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
traffic-source vlan <VLAN-ID-RANGE> {native-vlan <1-4094>}
```

## Parameters

```
traffic-source vlan <VLAN-ID-RANGE> {native-vlan <1-4094>}
```

|                                        |                                                                                                                                                                                                                                             |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| traffic-source vlan<br><VLAN-ID-RANGE> | Configures VLAN as the traffic source for this tunnel <ul style="list-style-type: none"><li>&lt;VLAN-ID-RANGE&gt; - Configures VLAN range list of traffic source. Specify the VLAN IDs as a range (for example, 10-20, 25, 30-35)</li></ul> |
| native-vlan <1-4094>                   | Optional - Configures the native VLAN ID for this session, which is not tagged <ul style="list-style-type: none"><li>&lt;1-4094&gt; - Specify the native VLAN ID from 1- 4094.</li></ul>                                                    |

## Examples

```
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-manual-session-test)#traffic-source vlan 50-60 native-vlan 2
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-manual-session-test)#show context
l2tpv3 manual-session test
 local-ip-address 1.2.3.4
 peer ip-address 5.6.7.8 udp port 150
```

```
traffic-source vlan 50-60 native-vlan 2
local-session-id 1
remote-session-id 200
remote-cookie size 8 400 700
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-manual-session-test)#
```

## Related Commands

|                                                                      |
|----------------------------------------------------------------------|
| <b>no</b> Removes the traffic source configured for a manual session |
|----------------------------------------------------------------------|

*no*

Negates or reverts L2TPV3 manual session settings to default

## Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
no [local-cookie|local-ip-address|local-session-id|mtu|peer|remote-cookie|
remote-session-id|traffic-source]
```

## Parameters

```
no <PARAMETERS>
```

|                                                                                           |
|-------------------------------------------------------------------------------------------|
| <b>no &lt;PARAMETERS&gt;</b> Negates or reverts L2TPv3 manual session settings to default |
|-------------------------------------------------------------------------------------------|

## Examples

The following example shows the manual session 'test' settings before the 'no' commands are executed:

```
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-manual-session-test)#show context
l2tpv3 manual-session test
 local-ip-address 1.2.3.4
 peer ip-address 5.6.7.8 udp port 150
 traffic-source vlan 50-60 native-vlan 2
 local-session-id 1
 remote-session-id 200
 remote-cookie size 8 400 700
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-manual-session-test)#
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-manual-session-test)#no local-ip-
address
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-manual-session-test)#no local-session-
id
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-manual-session-test)#no remote-session-
id
```

The following example shows the manual session 'test' settings after the 'no' commands are executed:

```
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-manual-session-test)#show context
l2tpv3 manual-session test
 peer ip-address 5.6.7.8 udp port 150
 traffic-source vlan 50-60 native-vlan 2
 remote-cookie size 8 400 700
nx9500-6C8809(config-profile default-rfs4000-l2tpv3-manual-session-test)#
```

## Router Mode

### ROUTER-MODE

---

This chapter summarizes OSPF (Open Shortest Path First) router mode commands in the CLI command structure. All router-mode commands are available on both device and profile modes.

OSPF is an IGMP (interior gateway protocol) used within large autonomous systems to distribute routing information. OSPF routes IP packets within a single routing domain (autonomous system), like an enterprise LAN. OSPF gathers link state information from neighbor routers and constructs a network topology. The topology determines the routing table presented to the Internet Layer, which makes routing decisions based solely on the destination IP address found in IP packets.

OSPF detects changes in the topology, like a link failure, and plots a new loop-free routing structure. It computes the shortest path for each route using a shortest path first algorithm. Link state data is maintained on each router and is periodically updated on all OSPF member routers. This enables routers to synchronize routing tables.

OSPF uses a route table managed by the link cost (external metrics) defined for each routing interface. The cost could be the distance of a router (round-trip time), link throughput or link availability.

Use the (config) instance to configure router commands. To navigate to the (config-router-mode) instance, use the following command:

```
<DEVICE>(config-profile-<PROFILE-NAME>)#router ospf
nx9500-6C8809(config-profile-default-rfs4000)#router ospf
nx9500-6C8809(config-profile default-rfs4000-router-ospf)#
nx9500-6C8809(config-profile default-rfs4000-router-ospf)#?
Router OSPF Mode commands:
 area OSPF area
 auto-cost OSPF auto-cost
 default-information Distribution of default information
 ip Internet Protocol (IP)
 network OSPF network
 no Negate a command or set its defaults
 ospf OSPF
 passive Make OSPF Interface as passive
 redistribute Route types redistributed by OSPF
 route-limit Limit for number of routes handled OSPF process
 router-id Router ID

```

## router-mode-commands

The following table summarizes OSPF router configuration mode commands:

**Table 57: OSPF-Router Config Mode Commands**

| Command                          | Description                                                       |
|----------------------------------|-------------------------------------------------------------------|
| <code>area</code>                | Specifies OSPF enabled interfaces                                 |
| <code>auto-cost</code>           | Specifies the reference bandwidth in terms of Mbits per second    |
| <code>default-information</code> | Controls the distribution of default information                  |
| <code>ip</code>                  | Configures <i>Internet Protocol</i> (IP) default gateway priority |
| <code>network</code>             | Defines OSPF network settings                                     |
| <code>ospf</code>                | Enables OSPF                                                      |
| <code>passive</code>             | Specifies the configured OSPF interface as passive interface      |
| <code>redistribute</code>        | Specifies the route types redistributed by OSPF                   |
| <code>route-limit</code>         | Specifies the limit for the number of routes managed by OSPF      |
| <code>router-id</code>           | Specifies the router ID for OSPF                                  |
| <code>no</code>                  | Negates a command or sets its defaults                            |

### Note

For information on common commands (clrscr, commit, help, revert, service, show, write, and exit), see [COMMON COMMANDS](#) on page 640.

### Note

The input parameter <HOSTNAME>, wherever used in syntaxes across this chapter, cannot include an underscore ( `_` ) character. In other words, the name of a device cannot contain an underscore.

## `area`

Configures OSPF network areas (OSPF enables interfaces)

An OSPF network can be subdivided into routing areas to simplify administration and optimize traffic utilization. Areas are logical groupings of hosts and networks, including routers having interfaces connected to an included network. Each area maintains a separate link state database whose information may be summarized towards the rest of the network by the connecting router. Areas are identified by 32-bit IDs, expressed either in decimal, or octet-based dot-decimal notation. Areas can be defined as: stub area, totally-stub, non-stub, nssa, totally nssa. Each of these area types have been discussed further in the [area-type](#) on page 1725 section of this chapter.

At least one default area, bearing number '0', should be configured for every OSPF network. In case of multiple areas, the default area 0 forms the backbone of the network. The default area 0 is used as a link to the other areas. Each area has its own link-state database.

A router running OSPF sends hello packets to discover neighbors and elect a designated router. The hello packet includes link state information and list of neighbors. OSPF is savvy with layer 2 topologies.

If on a point-to-point link, OSPF knows it is sufficient, and the link stays up. If on a broadcast link, the router waits for election before determining if the link is functional.

### Supported in the following platforms:

- Access Points — AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX

### Syntax

```
area [<0-4294967295>|<IP>]
```

### Parameters

```
area [<0-4294967295>|<IP>]
```

|                |                                                                                                                                                                      |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| area           | Defines an OSPF area                                                                                                                                                 |
| <0-4294967295> | Defines an OSPF area in the form of a 32 bit integer <ul style="list-style-type: none"><li>• &lt;0-4294967295&gt; - Specify the value from 0 - 4294967295.</li></ul> |
| <IP>           | Defines an OSPF area in the form of an IP address <ul style="list-style-type: none"><li>• &lt;IP&gt; - Specify the IP address.</li></ul>                             |

### Examples

```
nx9500-6C8809(config-profile default-rfs4000-router-ospf)#area 4
nx9500-6C8809(config-profile default-rfs4000-router-ospf-area-0.0.0.4)#?
Router OSPF Area Mode commands:
 area-type OSPF area type
 authentication Authentication scheme for OSPF area
 no Negate a command or set its defaults
 range Routes matching this range are considered for summarization
 (ABR only)

### Related Commands

The following table summarizes the OSPF area configuration mode commands:

**Table 58: OSPF-Area-Mode Commands**

| Command                                           | Description                                                  |
|---------------------------------------------------|--------------------------------------------------------------|
| <code>area-type</code>                            | Configures a particular OSPF area as STUB or NSSA            |
| <code>authentication</code>                       | Specifies the authentication scheme used for the OSPF area   |
| <code>range</code>                                | Specifies the routes matching address/mask for summarization |
| <code>no</code> (area-config-mode 'no' command)   | Negates a command or sets its defaults                       |
| <code>no</code> (router-config-mode 'no' command) | Removes area configuration settings                          |

### area-type

Configures a particular OSPF area as STUB, Totally STUB, NSSA or Totally NSSA

Areas can be defined as:

- `stub` area - Is an area that does not receive route advertisements external to the *autonomous system* (AS), and routing from within the area is based entirely on a default route.
- `totally-stub` - Is an area that does not allow summary routes and external routes. A default route is the only way to route traffic outside of the area. When there is only one route out of the area, fewer routing decisions are needed, lowering system resource utilization.
- `non-stub` - Is an area that imports autonomous system external routes and forwards to other areas. However, it still cannot receive external routes from other areas.
- `nssa` - A NSSA (Not-So-Stubby Area) is an extension of a stub that allows the injection of limited external routes into a stub area. If selecting NSSA, no external routes, except a default route, enter the area.
- `totally nssa` - Is a NSSA using 3 and 4 summary routes are not flooded into this type of area. It is also possible to declare an area both totally stubby and not-so-stubby, which means that the area will receive only the default route from area 0.0.0.0, but can also contain an ASBR (Autonomous System Boundary Router) that accepts external routing information and injects it into the local area, and from the local area into area 0.0.0.0.

Supported in the following platforms:

- Access Points — AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX

### Syntax

```

area-type [nssa|stub]
area-type nssa {default-cost|no-summary|translate-always|translate-candidate|
translate-never}
area-type nssa {default-cost <0-16777215> {no-summary}|no-summary
{default-cost <0-16777215>}}
area-type nssa {translate-always|translate-candidate|translate-never}
{(default-cost <0-16777215>|no-summary)}
area-type stub {default-cost <0-16777215> {no-summary}|no-summary
{default-cost <0-16777215>}}

```

## Parameters

`area-type nssa {default-cost|no-summary|translate-always|translate-candidate|translate-never}`

|                              |                                                                                                                                                                                                                  |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| area-type                    | Configures a particular OSPF area type as STUB, Totally STUB, NSSA or Totally NSSA                                                                                                                               |
| nssa                         | Configures the OSPF area as NSSA                                                                                                                                                                                 |
| stub                         | Configures the OSPF area as <i>Stubby Area</i> (STUB)                                                                                                                                                            |
| default-cost<br><0-16777215> | Specifies the default summary cost advertised, if the OSPF area is a STUB or NSSA <ul style="list-style-type: none"><li>&lt;0-16777215&gt; - Specify the default summary cost value from 0 - 16777215.</li></ul> |
| no-summary                   | Configures the OSPF area as totally STUB if the area-type is STUB or totally NSSA if the area-type is NSSA                                                                                                       |
| translate-always             | Always translates type-7 LSAs (Link State Advertisements) into type-5 LSAs                                                                                                                                       |
| translate-candidate          | Defines it as default behavior                                                                                                                                                                                   |
| translate-never              | Never translates type-7 LSAs into type-5 LSAs                                                                                                                                                                    |

## Examples

```
nx9500-6C8809(config-profile default-rfs4000-router-ospf-area-0.0.0.1)#area-type stub
default-cost 1
nx9500-6C8809(config-profile default-rfs4000-router-ospf-area-0.0.0.1)#show context
 area 0.0.0.1
 area-type stub default-cost 1
nx9500-6C8809(config-profile default-rfs4000-router-ospf-area-0.0.0.1)#
```

## Related Commands

|                                 |                                       |
|---------------------------------|---------------------------------------|
| <a href="#">no</a> on page 1728 | Removes configured area-type settings |
|---------------------------------|---------------------------------------|

## authentication

Specifies an authentication scheme used for an OSPF area used with the OSPF dynamic route

Supported in the following platforms:

- Access Points — AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX

## Syntax

```
authentication [message-digest|simple-password]
```

## Parameters

```
authentication [message-digest|simple-password]
```

|                 |                                                          |
|-----------------|----------------------------------------------------------|
| message-digest  | Configures a message-digest (MD-5) authentication scheme |
| simple-password | Configures a simple password authentication scheme       |

## Usage Guidelines

OSPF packet authentication enables routers to use predefined passwords and participate within a routing domain. The two authentication modes are:

- MD-5 – MD-5 authentication is a cryptographic authentication mode, where every router has a key (password) and key-id configured on it. This key and key-id together form the message digest that is appended to the OSPF packet.
- Simple Password – Simple password authentication allows a password (key) to be configured per area. Routers in the same area and participating in the routing domain have to be configured with the same key.

#### Examples

```
nx9500-6C8809(config-profile default-rfs4000-router-ospf-area-0.0.0.1)#authentication
simple-password
nx9500-6C8809(config-profile default-rfs4000-router-ospf-area-0.0.0.1)#show context
area 0.0.0.1
 authentication simple-password
 area-type stub default-cost 1
nx9500-6C8809(config-profile default-rfs4000-router-ospf-area-0.0.0.1)#
```

#### Related Commands

|                              |                                                             |
|------------------------------|-------------------------------------------------------------|
| <code>no</code> on page 1728 | Removes the authentication scheme associated with this area |
|------------------------------|-------------------------------------------------------------|

## range

Specifies a range of addresses for routes matching address/mask for OSPF summarization

Supported in the following platforms:

- Access Points – AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers – RFS 4000
- Service Platforms – NX 5500, NX 75XX

#### Syntax

```
range <IP/M>
```

#### Parameters

```
range <IP/M>
```

|        |                                                                              |
|--------|------------------------------------------------------------------------------|
| <IP/M> | Specifies the routes matching address/mask for summarization.                |
|        | <b>Note:</b> This command is applicable for a ABR (Area Border Router) only. |

#### Examples

```
nx9500-6C8809(config-profile default-rfs4000-router-ospf-area-0.0.0.1)#range 172.16.10.0/24
nx9500-6C8809(config-profile default-rfs4000-router-ospf-area-0.0.0.1)#show context
area 0.0.0.1
 authentication simple-password
 range 172.16.10.0/24
 area-type stub default-cost 1
nx9500-6C8809(config-profile default-rfs4000-router-ospf-area-0.0.0.1)#
```

#### Related Commands

|                              |                                         |
|------------------------------|-----------------------------------------|
| <code>no</code> on page 1728 | Removes the configured network IP range |
|------------------------------|-----------------------------------------|

## no

Removes this OSPF area settings

Supported in the following platforms:

- Access Points — AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX

Syntax

```
no [area-type|authentication|range]
```

Parameters

```
no <PARAMETERS>
```

|                 |                                 |
|-----------------|---------------------------------|
| no <PARAMETERS> | Removes this OSPF area settings |
|-----------------|---------------------------------|

Usage Guidelines

The **no** command negates any command associated with it. Wherever required, use the same parameters associated with the command getting negated.

Examples

The following example shows the OSPF router settings before the 'no' commands are executed:

```
nx9500-6C8809(config-profile default-rfs4000-router-ospf-area-0.0.0.1)#show context
 area 0.0.0.1
 authentication simple-password
 range 172.16.10.0/24
 area-type stub default-cost 1
nx9500-6C8809(config-profile default-rfs4000-router-ospf-area-0.0.0.1)#
nx9500-6C8809(config-profile default-rfs4000-router-ospf-area-0.0.0.1)#no authentication
nx9500-6C8809(config-profile default-rfs4000-router-ospf-area-0.0.0.1)#no range
172.16.10.0/24
```

The following example shows the OSPF router settings after the 'no' commands are executed:

```
nx9500-6C8809(config-profile default-rfs4000-router-ospf-area-0.0.0.1)#show context
 area 0.0.0.1
 area-type stub default-cost 1
nx9500-6C8809(config-profile default-rfs4000-router-ospf-area-0.0.0.1)#
```

### *auto-cost*

Configures the reference bandwidth in terms of megabits per second. Specifying the reference bandwidth allows you to control the default metrics for an interface, which is calculated by OSPF.

The formula used to calculate default metrics is: *ref-bw* divided by the *bandwidth*.

Use the **no > auto-cost > reference-bandwidth** command to configure default metrics calculation based on interface type.

#### **Supported in the following platforms:**

- Access Points — AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000

- Service Platforms — NX 5500, NX 75XX

### Syntax

```
auto-cost reference-bandwidth <1-4294967>
```

### Parameters

```
auto-cost reference-bandwidth <1-4294967>
```

|                                    |                                                                                                                                                                         |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| reference-bandwidth<br><1-4294967> | Defines the reference bandwidth in Mbps <ul style="list-style-type: none"> <li>• &lt;1-4294967&gt; - Specify the reference bandwidth value from 1 - 4294967.</li> </ul> |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Examples

```
nx9500-6C8809(config-profile default-rfs4000-router-ospf)#auto-cost reference-bandwidth 1
```

Ensure that auto-cost reference-bandwidth is configured uniformly on all routers

```
nx9500-6C8809(config-profile default-rfs4000-router-ospf)#
nx9500-6C8809(config-profile default-rfs4000-router-ospf)#show context router ospf
 area 0.0.0.4
 auto-cost reference-bandwidth 1
nx9500-6C8809(config-profile default-rfs4000-router-ospf)#
```

### Related Commands

|    |                                                |
|----|------------------------------------------------|
| no | Removes auto-cost reference bandwidth settings |
|----|------------------------------------------------|

## default-information

Controls the distribution of default route information. Use the **default-information > originate** command to advertise a default route in the routing table.

This option is disabled by default. When enabled, the default route becomes a distributed route.

### Supported in the following platforms:

- Access Points — AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX

### Syntax

```
default-information originate {always|metric|metric-type}
default-information originate {always|metric <0-16777214>|metric-type [1|2]}
{(metric <0-16777214>|metric-type [1|2])}
```

### Parameters

```
default-information originate {always|metric <0-16777214>|metric-type [1|2]}
{(metric <0-16777214>|metric-type [1|2])}
```

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| originate              | Originates default route information. Enabling this feature makes the default route a distributed route. This option is disabled by default.                                                                                                                                                                                                                                                                                               |
| always                 | Optional. Always distributes default route information (will continue to advertise default route information even if that information has been removed from the routing table for some reason). This option is disabled by default.                                                                                                                                                                                                        |
| metric<br><0-16777214> | This is a recursive parameter and can be optionally configured along with the metric-type option. <ul style="list-style-type: none"> <li>metric &lt;0-16777214&gt; – Optional. Specifies OSPF metric value for redistributed routes (this value is used to generate the default route)</li> <li>&lt;0-16777214&gt; – Specify a value from 0 - 16777214.</li> </ul>                                                                         |
| metric-type [1 2]      | This is a recursive parameter and can be optionally configured along with the metric option. <ul style="list-style-type: none"> <li>metric-type [1 2] – Optional. Sets OSPF exterior metric type for redistributed routes (this information is advertised with the OSPF routing domain) <ul style="list-style-type: none"> <li>1 – Sets OSPF external type 1 metrics</li> <li>2 – Sets OSPF external type 2 metrics</li> </ul> </li> </ul> |

### Examples

```

nx9500-6C8809(config-profile default-rfs4000-router-ospf)#default-information
originate metric-type 2 metric 1
nx9500-6C8809(config-profile default-rfs4000-router-ospf)#show context
router ospf
 area 0.0.0.4
 auto-cost reference-bandwidth 1
 default-information originate metric 1 metric-type 2
nx9500-6C8809(config-profile default-rfs4000-router-ospf)#

```

*ip*

Configures IP default gateway priority

### Supported in the following platforms:

- Access Points — AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX

### Syntax

```
ip default-gateway priority <1-8000>
```

### Parameters

```
ip default-gateway priority <1-8000>
```

|                   |                                                                                                                                                                                                                                                      |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| default-gateway   | Configures the default gateway                                                                                                                                                                                                                       |
| priority <1-8000> | Sets the priority for the default gateway acquired via OSPF <ul style="list-style-type: none"> <li>• &lt;1-8000&gt; – Specify an integer from 1 - 8000. The default is 7000.</li> </ul> <p><b>Note:</b> Lower the value, higher is the priority.</p> |

### Examples

```

nx9500-6C8809(config-profile default-rfs4000-router-ospf)#ip default-gateway priority 1
nx9500-6C8809(config-profile default-rfs4000-router-ospf)#show context
router ospf
 area 0.0.0.4
 auto-cost reference-bandwidth 1
 default-information originate metric 1 metric-type 2
 ip default-gateway priority 1
nx9500-6C8809(config-profile default-rfs4000-router-ospf)#

```

## network

Assigns networks to specified areas (defines the OSPF interfaces and their associated area IDs)

### Supported in the following platforms:

- Access Points — AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX

### Syntax

```
network <IP/M> area [<0-4294967295>|<IP>]
```

### Parameters

```
network <IP/M> area [<0-4294967295>|<IP>]
```

|                            |                                                                                                                                                                                                                                                                                                                |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <IP/M>                     | Specifies an OSPF network address/mask value. Defines networks (IP addresses and mask) participating in OSPF.                                                                                                                                                                                                  |
| area [<0-4294967295> <IP>] | Specifies an OSPF area, associated with the OSPF address range, in one of the following formats: <ul style="list-style-type: none"> <li>• &lt;0-4294967295&gt; – Specifies a 32 bit OSPF area ID from 0 - 4294967295</li> <li>• &lt;IP&gt; – Defines an OSPF area ID in the form of an IPv4 address</li> </ul> |

### Examples

```

nx9500-6C8809(config-profile default-rfs4000-router-ospf)#network 1.2.3.0/24 area 4.5.6.7
nx9500-6C8809(config-profile default-rfs4000-router-ospf)#show context
router ospf
 network 1.2.3.0/24 area 4.5.6.7
 area 0.0.0.4
 auto-cost reference-bandwidth 1
 default-information originate metric 1 metric-type 2

```

```
ip default-gateway priority 1
nx9500-6C8809(config-profile default-rfs4000-router-ospf)#
```

### *ospf*

Enables OSPF routing on a profile or device

#### Supported in the following platforms:

- Access Points — AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX

#### Syntax

```
ospf enable
```

#### Parameters

```
ospf enable
```

|                          |                                                                                         |
|--------------------------|-----------------------------------------------------------------------------------------|
| <code>ospf enable</code> | Enables OSPF routing on devices using this profile. This option is disabled by default. |
|--------------------------|-----------------------------------------------------------------------------------------|

#### Examples

```
cnx9500-6C8809(config-profile default-rfs4000-router-ospf)#ospf enable
nx9500-6C8809(config-profile default-rfs4000-router-ospf)#show context
router ospf
 ospf enable
 network 1.2.3.0/24 area 4.5.6.7
 area 0.0.0.4
 auto-cost reference-bandwidth 1
 default-information originate metric 1 metric-type 2
 ip default-gateway priority 1
nx9500-6C8809(config-profile default-rfs4000-router-ospf)#
```

### Related Commands

|-----------------|----------------------------------------------|
| <code>no</code> | Disables OSPF routing on a profile or device |
|-----------------|----------------------------------------------|

### *passive*

Configures specified OSPF interface as passive. This option is disabled by default.

A passive interface receives routing updates, but does not transmit them.

#### Supported in the following platforms:

- Access Points — AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000

- Service Platforms — NX 5500, NX 75XX

### Syntax

```
passive [<WORD>|all|vlan <1-4094>]
```

### Parameters

```
passive [<WORD>|all|vlan <1-4094>]
```

|               |                                                                                                                                                                                 |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <WORD>        | Enables the OSPF passive mode on the interface specified by the <WORD> parameter                                                                                                |
| all           | Enables the OSPF passive mode on all the L3 interfaces                                                                                                                          |
| vlan <1-4094> | Enables the OSPF passive mode on the specified VLAN interface <ul style="list-style-type: none"> <li>• &lt;1-4094&gt; – Specify the VLAN interface ID from 1 - 4094.</li> </ul> |

### Examples

```
cnx9500-6C8809(config-profile default-rfs4000-router-ospf)#passive vlan 1
nx9500-6C8809(config-profile default-rfs4000-router-ospf)#show context
router ospf
 ospf enable
 network 1.2.3.0/24 area 4.5.6.7
 area 0.0.0.4
 auto-cost reference-bandwidth 1
 default-information originate metric 1 metric-type 2
 passive vlan1
 ip default-gateway priority 1
nx9500-6C8809(config-profile default-rfs4000-router-ospf)#
```

### Related Commands

|-----------|---------------------------------------------------------|
| <b>no</b> | Disables the OSPF passive mode on a specified interface |
|-----------|---------------------------------------------------------|

### *redistribute*

Specifies the route types redistributed by OSPF

### Supported in the following platforms:

- Access Points — AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX

### Syntax

```
redistribute [bgp|connected|kernel|static] {metric <0-16777214>|metric-type [1|2]}
```

### Parameters

```
redistribute [bgp|connected|kernel|static] {metric <0-16777214>|metric-type [1|2]}
```

|           |                                                                              |
|-----------|------------------------------------------------------------------------------|
| bgp       | Redistributes all BGP routes by OSPF                                         |
| connected | Redistributes all connected interface routes by OSPF                         |
| kernel    | Redistributes all routes that are neither connected, nor static, nor dynamic |

|                     |                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| static              | Redistributes static routes by OSPF                                                                                                                                                                                                                                                                                                                                                  |
| metric <0-16777214> | The following keywords are common to the 'bgp', 'connected', 'kernel', and 'static' parameters: <ul style="list-style-type: none"> <li>metric &lt;0-16777214&gt; – Optional. Specifies the OSPF metric value for redistributed routes.</li> <li>&lt;0-16777214&gt; – Specify a value from 0 - 16777214.</li> </ul>                                                                   |
| metric-type[1 2]    | The following keywords are common to the 'connected', 'kernel', and 'static' parameters: <ul style="list-style-type: none"> <li>metric-type [1 2] – Optional. Sets the OSPF exterior metric type for redistributed routes <ul style="list-style-type: none"> <li>1 – Sets the OSPF external type 1 metrics</li> <li>2 – Sets the OSPF external type 2 metrics</li> </ul> </li> </ul> |

### Examples

```

nx9500-6C8809(config-profile default-rfs4000-router-ospf)#redistribute static metric-type 1
nx9500-6C8809(config-profile default-rfs4000-router-ospf)#show context

|----|--------------------------------------------------------|
| no | Removes the OSPF redistribution of various route types |
|----|--------------------------------------------------------|

### route-limit

Limits the number of routes managed by OSPF. The maximum limit supported by the platform is the default configuration defined under the router-ospf context.

#### Supported in the following platforms:

- Access Points — AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX

#### Syntax

```

route-limit [num-routes|reset-time|retry-count|retry-timeout]
route-limit [num-routes <DYNAMIC-ROUTE-LIMIT>|reset-time <1-86400>|retry-count <1-32>|
retry-timeout <1-3600>] {(num-routes|reset-time|retry-count|retry-timeout)}

```

#### Parameters

```

route-limit [num-routes <DYNAMIC-ROUTE-LIMIT>|reset-time <1-86400>|retry-count <1-32>|
retry-timeout <1-3600>] {(num-routes|reset-time|retry-count|retry-timeout)}

```

|                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| num-routes<br><DYNAMIC-ROUTE-LIMIT> | Specifies the maximum number of non self-generated LSAs this process can receive <ul style="list-style-type: none"> <li>• &lt;DYNAMIC-ROUTE-LIMIT&gt; - Specify the dynamic route limit.</li> </ul>                                                                                                                                                                                                                                          |
| reset-time<br><1-86400>             | Specifies the time, in seconds, after which the retry-count is reset to zero <ul style="list-style-type: none"> <li>• &lt;1-86400&gt; - Specify a value from 1 - 86400 seconds. The default is 360 seconds.</li> </ul>                                                                                                                                                                                                                       |
| retry-count <1-32>                  | Specifies the maximum number of times adjacencies can be suppressed. Each time OSPF gets into an ignore state, a counter increments. If the counter exceeds the timeout configured by the retry-count parameter, OSPF stays in the same ignore state. Manual intervention is required to get OSPF out of the ignore state. <ul style="list-style-type: none"> <li>• &lt;1-32&gt; - Specify a value from 1 - 32. The default is 5.</li> </ul> |
| retry-timeout<br><1-3600>           | Specifies the retry time in seconds. During this time, OSPF remains in ignore state and all adjacencies are suppressed. <ul style="list-style-type: none"> <li>• &lt;1-3600&gt; - Specify a value from 1 - 3600 seconds. The default is 60 seconds.</li> </ul>                                                                                                                                                                               |

### Examples

```

### Related Commands

|           |                                                           |
|-----------|-----------------------------------------------------------|
| <b>no</b> | Removes the limit on the number of routes managed by OSPF |
|-----------|-----------------------------------------------------------|

### *router-id*

Specifies the OSPF router ID

This ID must be established in every OSPF instance. If not explicitly configured, the highest logical IP address is duplicated as the router identifier. However, since the router identifier is not an IP address, it does not have to be a part of any routable subnet in the network.

### Supported in the following platforms:

- Access Points — AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX

### Syntax

```
router-id <IP>
```

## Parameters

router-id <IP>

|      |                                                                                                                                                                    |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <IP> | Identifies the OSPF router by its IP address <ul style="list-style-type: none"><li>• &lt;IP&gt; - Specify the router ID in the IP &lt;A.B.C.D&gt; format</li></ul> |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Examples

```
nx9500-6C8809(config-profile default-rfs4000-router-ospf)#router-id 172.16.10.8
```

Reload, or execute "clear ip ospf process" command, for this to take effect

```
nx9500-6C8809(config-profile default-rfs4000-router-ospf)#
```

## Related Commands

|    |                                       |
|----|---------------------------------------|
| no | Removes the configured OSPF router ID |
|----|---------------------------------------|

no

Removes this OSPF router settings or reverts them to default values

## Supported in the following platforms:

- Access Points — AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX

## Syntax

```
no [area|auto-cost|default-information|ip|network|ospf|passive|redistribute|route-limit|router-id]
```

## Parameters

no <PARAMETERS>

|                 |                                       |
|-----------------|---------------------------------------|
| no <PARAMETERS> | Negates a command or set its defaults |
|-----------------|---------------------------------------|

## Usage Guidelines

The no command negates any command associated with it. Wherever required, use the same parameters associated with the command getting negated.

## Examples

The following example shows the OSPF router interface settings before the 'no' commands are executed:

```
nx9500-6C8809(config-profile default-rfs4000-router-ospf)#show context
router ospf
 network 1.2.3.0/24 area 4.5.6.7
 area 0.0.0.4
 auto-cost reference-bandwidth 1
 default-information originate metric 1 metric-type 2
 redistribute static metric-type 1
 passive vlan1
```

---

```
route-limit num-routes 10 reset-time 10
ip default-gateway priority 1
nx9500-6C8809(config-profile default-rfs4000-router-ospf)#
nx9500-6C8809(config-profile default-rfs4000-router-ospf)#no area 4
nx9500-6C8809(config-profile default-rfs4000-router-ospf)#no auto-cost reference-bandwidth
nx9500-6C8809(config-profile default-rfs4000-router-ospf)#no network 1.2.3.0/24 area
4.5.6.7
```

The following example shows the OSPF router interface settings after the 'no' commands are executed:

```
nx9500-6C8809(config-profile default-rfs4000-router-ospf)#show context
router ospf
 default-information originate metric 1 metric-type 2
 redistribute static metric-type 1
 passive vlan1
 route-limit num-routes 10 reset-time 10
 ip default-gateway priority 1
nx9500-6C8809(config-profile default-rfs4000-router-ospf)#
```

# Routing Policy

## ROUTING-POLICY

---

This chapter summarizes routing-policy commands in the CLI command structure.

Routing policies enable network administrators to control data packet routing and forwarding. PBR (Policy-based routing) always overrides protocol-based routing. Network administrators can define routing policies based on parameters, such as access lists, packet size etc. For example, a routing policy can be configured to route packets along user-defined routes.

In addition to the above, PBR policies facilitate the provisioning of preferential service to specific traffic. PBR minimally provides the following:

- A means to use source address, protocol, application and traffic class as traffic routing criteria
- A means to load balance multiple WAN uplinks
- A means to selectively mark traffic for QoS (Quality of Service) optimization

Use the (config) instance to configure router-policy commands. To navigate to the (config-routing-policy mode) instance, use the following commands:

```
<DEVICE>(config)#routing-policy <ROUTING-POLICY-NAME>
nx9500-6C8809(config)#routing-policy testpolicy
nx9500-6C8809(config-routing-policy-testpolicy)#?
Routing Policy Mode commands:
 apply-to-local-packets Use Policy Based Routing for packets generated by
 the device
 logging Enable logging for this Route Map
 no Negate a command or set its defaults
 route-map Create a Route Map
 use Set setting to use

 clrscr Clears the display screen
 commit Commit all changes made in this session
 do Run commands from Exec mode
 end End current mode and change to EXEC mode
 exit End current mode and down to previous mode
 help Description of the interactive help system
 revert Revert changes
 service Service Commands
 show Show running system information
 write Write running configuration to memory or terminal

nx9500-6C8809(config-routing-policy-testpolicy)#
```

### routing-policy-commands

The following table summarizes routing policy configuration mode commands:

**Table 59: Routing-Policy-Config Commands**

| Command                             | Description                               |
|-------------------------------------|-------------------------------------------|
| <code>apply-to-local-packets</code> | Enables PBR for locally generated packets |
| <code>logging</code>                | Enables logging for a specified route map |
| <code>route-map</code>              | Creates a route map entry                 |
| <code>use</code>                    | Defines default settings to use           |
| <code>no</code>                     | Negates a command or sets its defaults    |

**Note**

For more information on common commands (clrscr, commit, help, revert, service, show, write, and exit), see [COMMON COMMANDS](#) on page 640.

**Note**

The input parameter <HOSTNAME>, wherever used in syntaxes across this chapter, cannot include an underscore (\_) character. In other words, the name of a device cannot contain an underscore.

*apply-to-local-packets*

Enables PBR for locally generated packets (packets generated by the device). When enabled, this option implements the match and action clauses defined within route maps. This option is enabled by default.

**Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

**Syntax**

```
apply-to-local-packets
```

**Parameters**

None

**Examples**

```
nx9500-6C8809(config-routing-policy-testpolicy)#apply-to-local-packets
nx9500-6C8809(config-routing-policy-testpolicy)#
```

**Related Commands**

|                 |                                            |
|-----------------|--------------------------------------------|
| <code>no</code> | Disables PBR for locally generated packets |
|-----------------|--------------------------------------------|

## logging

Enables logging for a specified route map. When enabled, this option logs events generated by the enforcement of route-maps. This option is disabled by default.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

logging

### Parameters

None

### Examples

```
nx9500-6C8809(config-routing-policy-testpolicy)#logging
nx9500-6C8809(config-routing-policy-testpolicy)#show context
routing-policy testpolicy
 logging
nx9500-6C8809(config-routing-policy-testpolicy)#
```

### Related Commands

|-----------------|----------------------------|
| no on page 1749 | Disables route map logging |
|-----------------|----------------------------|

## route-map

Creates a route map entry and enters the route map configuration mode

In PBR, route maps control the flow of traffic within the network. They override route tables and direct traffic along a specific path.

Route-maps contain a set of filters that select traffic (match clauses) and associated actions (mark clauses) for routing. Every route-map entry has a precedence value. Lower the precedence, higher is the route-map's priority. All incoming packets are matched against these route-maps entries. The route-map entry with highest precedence (lowest numerical value) is applied first. In case of a match, action is taken based on the mark clause specified in the route-map. In case of no match, the route-map entry with the next highest precedence is applied. If the incoming packet does not match any of the route-map entries, it is subjected to typical destination-based routing. Each route-map entry can optionally enable/disable logging.

The following criteria can optionally be used as traffic selection segregation criteria:

- *IP Access List* - A typical IP ACL can be used for routing traffic. The mark and log actions in ACL rules however are neglected. Route-map entries have separate logging. Only one ACL can be configured per route map entry.

---

ACL rules configured under route map entries merge to create a single ACL. Route map precedence values determine the prioritization of the rules in this merged ACL. An IP DSCP value is also added to the ACL rules.

- *IP DSCP* - Packet filtering can be performed by traffic class, as determined from the IP DSCP (Differentiated Services Code Point) field. One DSCP value can be configured per route map entry. If IP ACLs on a WLAN, ports or SVI mark packets, the new/marked DSCP value is used for matching.
- *Incoming WLAN* - Packets can be filtered on the basis of the incoming WLAN. Depending on whether the receiving device has an onboard radio or not, the following two scenarios are possible:
  - Device with an onboard radio: If a device having an onboard radio and capable of PBR receives a packet on a local WLAN, this WLAN is used for selection.
  - Device without an onboard radio: If a device, without an onboard radio, capable of PBR receives a packet from an extended VLAN, it passes the WLAN information in the MiNT packet to the PBR router. The PBR router uses this information as match criteria.
- *Client role* - The client role can be used as match criteria, similar to a WLAN. Each device has to agree on a unique identifier for role definition and pass the same MINT tunneled packets.
- *Incoming SVI* - A source IP address qualifier in an ACL typically satisfies filter requirements. But if the source host (where the packet originates) is multiple hops away, the incoming SVI can be used as match criteria. In this context the SVI refers to the device interface performing PBR, and not to the source device.

Mark (or action) clauses determine the routing function when a packet satisfies match criteria. If no mark clauses are defined, the default is to fallback to destination-based routing for packets satisfying the match criteria. If no mark clause is configured and fallback to destination-based routing is disabled, then the packet is dropped. The mark clause defines one of following actions:

- *Next hop* - The IP address of the next hop or the outgoing interface through which the packet should be routed. Up to two next hops can be specified. The outgoing interface should be a PPP, a tunnel interface or a SVI which has DHCP client configured. The first reachable hop should be used. But if all next hops are unreachable, typical destination-based route lookup is performed.
- *Default next hop* - If a packet subjected to PBR does not have an explicit route to the destination, the configured default next hop is used. This can be either the IP address of the next hop or the outgoing interface. Only one default next hop can be defined. The difference between the next hop and the default next-hop is: in case of the former, PBR occurs first, then destination-based routing. In case of the latter, the order is reversed. In both cases:
  - 1 If a defined next hop is reachable, it is used. If fallback is configured refer to (b).
  - 2 Perform normal destination-based route lookup. If a next hop is found, it is used, if not refer to (c).
  - 3 If default next hop is configured and reachable, it is used, if not, packet is dropped.
- *Fallback* - Enables fallback to destination-based routing if none of the configured next hops are reachable (or not configured). This is enabled by default.
- *Mark IP DSCP* - Configures IP DSCP bits for QoS using an ACL. The mark action of the route maps takes precedence over the mark action of an ACL.

#### **Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000

- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
route-map <1-100>
```

## Parameters

```
route-map <1-100>
```

|                   |                                                                                                                                                                                                                                                                                                         |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| route-map <1-100> | Creates a route map entry, sets a precedence value for the route map, and enters the route map configuration mode <ul style="list-style-type: none"> <li>• &lt;1-100&gt; - Specify a precedence value from 1 - 100.</li> </ul> <p><b>Note:</b> Lower the sequence number, higher is the precedence.</p> |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Examples

```
<DEVICE>(config-routing-policy-testpolicy)#route-map 1
nx9500-6C8809(config-routing-policy-testpolicy)#show context
routing-policy testpolicy
 logging

## Related Commands

The following table summarizes route-map configuration mode commands:

**Table 60: Route-Map-Config Commands**

| Command          | Description                                                     |
|------------------|-----------------------------------------------------------------|
| default-next-hop | Sets the default next hop for packets satisfying match criteria |
| fallback         | Configures a fallback to the next destination                   |
| mark             | Marks action clause for packets satisfying match criteria       |

**Table 60: Route-Map-Config Commands (continued)**

| Command                                                   | Description                                                      |
|-----------------------------------------------------------|------------------------------------------------------------------|
| <code>match</code>                                        | Sets match clauses for the route map                             |
| <code>next-hop</code>                                     | Sets the next hop for packets satisfying match criteria          |
| <code>no</code> (route-map config mode 'no' command)      | Removes the route-map settings or reverts them to default values |
| <code>no</code> (routing-policy config mode 'no' command) | Removes a route map from the routing policy                      |

**default-next-hop**

Sets the default next hop for packets satisfying match criteria.

If a packet, subjected to PBR, does not have an explicit route to the destination, the configured default next hop is used. This value is set as either the IP address of the next hop or the outgoing interface. Only one default next hop can be defined. The difference between the next hop and the default next-hop is: in case of the former, PBR occurs first, then destination-based routing. In case of the latter, the order is reverse. Use this command to set either the default next hop IP address or define either a WWAN1, PPPoE1, or VLAN interface.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

**Syntax**

```
default-next-hop [<IP> | <ROUTER-IF-NAME> | pppoe1 | serial <SLOT-ID> <PORT-ID>
<CHANNEL-GROUP-ID> | vlan <1-4094> | wwan1]
```

**Parameters**

```
default-next-hop [<IP> | <ROUTER-IF-NAME> | pppoe1 | serial <SLOT-ID> <PORT-ID>
<CHANNEL-GROUP-ID> | vlan <1-4094> | wwan1]
```

|                                                                              |                                                                                                                                                |
|------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>default-next--hop</code>                                               | Sets the next hop router to which packets are sent in case the next hop is not the adjacent router                                             |
| <code>&lt;IP&gt;</code>                                                      | Specifies next hop router's IP address                                                                                                         |
| <code>&lt;ROUTER-IF-NAME&gt;</code>                                          | Specifies the outgoing interface name (router interface name)                                                                                  |
| <code>pppoe1</code>                                                          | Specifies the PPPoE interface                                                                                                                  |
| <code>serial &lt;SLOT-ID&gt; &lt;PORT-ID&gt; &lt;CHANNEL-GROUP-ID&gt;</code> | Specifies the serial interface's slot, port, and channel group IDs                                                                             |
| <code>vlan &lt;1-4094&gt;</code>                                             | Specifies a VLAN interface ID <ul style="list-style-type: none"> <li>• <code>&lt;1-4094&gt;</code> - Specify a value from 1 - 4094.</li> </ul> |
| <code>wwan1</code>                                                           | Specifies the WAN interface                                                                                                                    |

## Examples

```
nx9500-6C8809(config-routing-policy-testpolicy-route-map-1)#default-next-hop wwan1
nx9500-6C8809(config-routing-policy-testpolicy-route-map-1)#show context
 route-map 1
 default-next-hop wwan1
nx9500-6C8809(config-routing-policy-testpolicy-route-map-1)#
```

## Related Commands

|    |                                          |
|----|------------------------------------------|
| no | Removes default next hop router settings |
|----|------------------------------------------|

## fallback

Enables fallback to destination-based routing. This option is enabled by default. To disable fallback, use the `no > fallback` command.

The action taken for packets satisfying the match criteria is determined by the mark (action) clauses. If no action is defined, the default is to fallback to destination-based routing.

### Note

If no mark clause is configured and fallback to destination-based routing is disabled, then the packet is dropped.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
fallback
```

## Parameters

None

## Examples

```
nx9500-6C8809(config-routing-policy-testpolicy-route-map-1)#fallback
nx9500-6C8809(config-routing-policy-testpolicy-route-map-1)#
```

|----|------------------------------------------------------------------------------------------------|
| no | Disables fallback to destination-based routing if no next hop is configured or are unreachable |
|----|------------------------------------------------------------------------------------------------|

## mark

Enables the marking of the DSCP field in the IP header

Use this command to set the IP DSCP bits for QoS using an ACL. The mark action of the route maps takes precedence over the mark action of an ACL.

The DSCP field in an IP header enables packet classification. Packet filtering can be done based on traffic class, determined from the IP DSCP field. One DSCP value can be configured per route map entry.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
mark ip dscp <0-63>
```

#### Parameters

```
mark ip dscp <0-63>
```

|                |                                                                                                                                            |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| ip dscp <0-63> | Marks the DSCP field in the IP header <ul style="list-style-type: none"> <li>• &lt;0-63&gt; - Specify a DSCP value from 0 - 63.</li> </ul> |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------|

#### Examples

```
nx9500-6C8809(config-routing-policy-testpolicy-route-map-1)#mark ip dscp 7
nx9500-6C8809(config-routing-policy-testpolicy-route-map-1)#show context
route-map 1
 default-next-hop wwan1
 mark ip dscp 7
nx9500-6C8809(config-routing-policy-testpolicy-route-map-1)#
```

## match

Sets the match clauses

Each route map entry has a set of match clauses used to segregate and filter packets. Packets can be segregated using any one of the following criteria:

- *IP Access List* - A typical IP ACL can be used for routing traffic. The mark and log actions in ACL rules however are neglected. Route-map entries have separate logging. Only one ACL can be configured per route map entry.

ACL rules configured under route map entries merge to create a single ACL. Route map precedence values determine the prioritization of the rules in this merged ACL. An IP DSCP value is also added to the ACL rules.

- *IP DSCP* - Packet filtering can be performed by traffic class, as determined from the IP Differentiated Services Code Point (DSCP) field. One DSCP value can be configured per route map entry. If IP ACLs on a WLAN, ports or SVI mark packets, the new/marked DSCP value is used for matching.
- *Incoming WLAN* - Packets can be filtered on the basis of the incoming WLAN. Depending on whether the receiving device has an onboard radio or not, the following two scenarios are possible:
  - Device with an onboard radio: If a device having an onboard radio and capable of PBR receives a packet on a local WLAN, this WLAN is used for selection.
  - Device without an onboard radio: If a device, without an onboard radio, capable of PBR receives a packet from an extended VLAN, it passes the WLAN information in the MiNT packet to the PBR router. The PBR router uses this information as match criteria.

- *Client role* - The client role can be used as match criteria, similar to a WLAN. Each device has to agree on a unique identifier for role definition and pass the same MINT tunneled packets.
- *Incoming SVI* - A source IP address qualifier in an ACL typically satisfies filter requirements. But if the source host (where the packet originates) is multiple hops away, the incoming SVI can be used as match criteria. In this context the SVI refers to the device interface performing PBR, and not to the source device.

The action taken for filtered packets is determined by the mark (action) clauses. If no action is defined, the default is to fallback to destination-based routing for packets satisfying the match criteria. For more information on configuring mark clauses, see [mark](#) on page 1744. And for more information on fallback action, see [fallback](#) on page 1744.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
match [incoming-interface|ip|ip-access-list|wireless-client-role|wlan]
match incoming-interface [<ROUTER-IF-NAME>|pppoe1|serial <SLOT-ID> <PORT-ID>
<CHANNEL-GROUP-ID>|vlan <1-4094>|wwan1]
match ip dscp <0-63>
match ip-access-list <IP-ACCESS-LIST-NAME>
match wireless-client-role <ROLE-POLICY-NAME> <ROLE-NAME>
match wlan <WLAN-NAME>
```

### Parameters

```
match incoming-interface [<ROUTER-IF-NAME>|pppoe1|serial <SLOT-ID> <PORT-ID>
<CHANNEL-GROUP-ID>|vlan <1-4094>|wwan1]
```

|                                                  |                                                                                                                                       |
|--------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| incoming-interface                               | Sets the incoming SVI match clause. Specify an interface name.                                                                        |
| <ROUTER-IF-NAME>                                 | Specifies the layer 3 interface name (route interface)                                                                                |
| pppoe1                                           | Specifies the PPP over Ethernet interface                                                                                             |
| serial <SLOT-ID> <PORT-ID><br><CHANNEL-GROUP-ID> | Specifies the serial interface's slot, port, and channel group IDs.                                                                   |
| vlan <1-4094>                                    | Specifies the VLAN interface ID <ul style="list-style-type: none"> <li>• &lt;1-4094&gt; - Specify a VLAN ID from 1 - 4094.</li> </ul> |
| wwan1                                            | Specifies the WAN interface name                                                                                                      |

```
match ip dscp <0-63>
```

|                |                                                                                                                                                                                                    |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ip dscp <0-63> | Sets the DSCP match clause <ul style="list-style-type: none"> <li>• &lt;0-63&gt; - Specify a value from 0 - 63. The defined DSCP value is used as a matching clause for this route map.</li> </ul> |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
match ip-access-list <IP-ACCESS-LIST-NAME>
```

|                                                         |                                                                                                                                                                                           |
|---------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ip-access-list &lt;IP-ACCESS-LIST-NAME&gt;</code> | Sets the match clause using a pre-configured IP access list <ul style="list-style-type: none"><li>• &lt;IP-ACCESS-LIST-NAME&gt; – Specify a pre-configured IP access list name.</li></ul> |
|---------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

`match wireless-client-role <ROLE-POLICY-NAME> <ROLE-NAME>`

|                                                                              |                                                                                                                                                                                                                                      |
|------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>wireless-client-role &lt;ROLE-POLICY-NAME&gt; &lt;ROLE-NAME&gt;</code> | Sets the wireless client role match clause <ul style="list-style-type: none"><li>• &lt;ROLE-POLICY-NAME&gt; – Specify a pre-configured role policy.</li><li>• &lt;ROLE-NAME&gt; – Specify a pre-configured role within it.</li></ul> |
|------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

`match wlan <WLAN-NAME>`

|                                     |                                                                                                                                |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <code>wlan &lt;WLAN-NAME&gt;</code> | Sets the incoming WLAN match clause <ul style="list-style-type: none"><li>• &lt;WLAN-NAME&gt; – Specify a WLAN name.</li></ul> |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|

### Examples

```
nx9500-6C8809(config-routing-policy-testpolicy-route-map-1)#match incoming-interface pppoe1
nx9500-6C8809(config-routing-policy-testpolicy-route-map-1)#show context
route-map 1
 match incoming-interface pppoe1
 default-next-hop wwan1
 mark ip dscp 7
nx9500-6C8809(config-routing-policy-testpolicy-route-map-1)#
```

|-----------------|---------------------------------------------------|
| <code>no</code> | Disables match clause settings for this route map |
|-----------------|---------------------------------------------------|

## next-hop

Sets the next hop for packets satisfying match criteria

This command allows you to configure the primary and secondary hop priority requests.

Define the primary and secondary hop settings. When defined, the primary hop resource is used with no additional considerations when ever it is available.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
next-hop [<IP>|<ROUTER-IF-NAME>|pppoe1|serial <SLOT-ID> <PORT-ID> <CHANNEL-GROUP-ID>|
vlan <1-4094>|wwlan1] {<IP>|<ROUTER-IF-NAME>|pppoe1|serial <SLOT-ID> <PORT-ID>
<CHANNEL-GROUP-ID>|vlan <1-4094>|wwlan1}
```

### Parameters

```
next-hop [<IP>|<ROUTER-IF-NAME>|pppoe1|serial <SLOT-ID> <PORT-ID> <CHANNEL-GROUP-ID>|
vlan <1-4094>|wwlan1] {<IP>|<ROUTER-IF-NAME>|pppoe1|serial <SLOT-ID> <PORT-ID>
<CHANNEL-GROUP-ID>|vlan <1-4094>|wwlan1}
```

|                                               |                                                                                                                                                                                                                                  |
|-----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| next-hop                                      | Sets the next hop (primary and secondary) for packets satisfying match criteria<br><br><b>Note:</b> It is not mandatory to define the secondary hop interface. The secondary hop is used in case the primary hop is unavailable. |
| <IP>                                          | Specifies the primary and secondary next hop router's IP address                                                                                                                                                                 |
| <WORD>                                        | Specifies the layer 3 Interface name (router interface)                                                                                                                                                                          |
| pppoe1                                        | Specifies the PPP over Ethernet interface                                                                                                                                                                                        |
| serial <SLOT-ID> <PORT-ID> <CHANNEL-GROUP-ID> | Specifies the serial interface's slot, port, and channel group IDs.                                                                                                                                                              |
| vlan <1-4094>                                 | Specifies the VLAN interface ID <ul style="list-style-type: none"> <li>• &lt;1-4094&gt; – Specify a VLAN ID from 1 - 4094. The VLAN interface should be a DHCP client.</li> </ul>                                                |
| wwan1                                         | Specifies the WAN interface                                                                                                                                                                                                      |

### Examples

```

nx9500-6C8809(config-routing-policy-testpolicy-route-map-1)#next-hop vlan 1
nx9500-6C8809(config-routing-policy-testpolicy-route-map-1)#show context
route-map 1
 match incoming-interface pppoe1
 next-hop vlan1
 default-next-hop wwan1
 mark ip dscp 7
nx9500-6C8809(config-routing-policy-testpolicy-route-map-1)#

```

### Related Commands

|    |                                       |
|----|---------------------------------------|
| no | Disables the next hop router settings |
|----|---------------------------------------|

## no

Removes this route-map settings or reverts them to default values

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
no [default-next-hop|fallback|mark|match|next-hop]
```

### Parameters

```
no <PARAMETERS>
```

|                 |                                                                                                   |
|-----------------|---------------------------------------------------------------------------------------------------|
| no <PARAMETERS> | Removes this route-map settings or reverts them to default values, based on the parameters passed |
|-----------------|---------------------------------------------------------------------------------------------------|

### Usage Guidelines

The **no** command negates any command associated with it. Wherever required, use the same parameters associated with the command getting negated.

## Examples

The following example shows the route-map '1' settings before the 'no' commands are executed:

```
nx9500-6C8809(config-routing-policy-testpolicy-route-map-1)#show context
route-map 1
 match incoming-interface pppoe1
 next-hop vlan1
 default-next-hop wwan1
 mark ip dscp 7
nx9500-6C8809(config-routing-policy-testpolicy-route-map-1)#
nx9500-6C8809(config-routing-policy-testpolicy-route-map-1)#no default-next-hop
nx9500-6C8809(config-routing-policy-testpolicy-route-map-1)#no next-hop
```

The following example shows the route-map '1' settings after the 'no' commands are executed:

```
nx9500-6C8809(config-routing-policy-testpolicy-route-map-1)#show context
route-map 1
 match incoming-interface pppoe1
 mark ip dscp 7
nx9500-6C8809(config-routing-policy-testpolicy-route-map-1)#
```

## use

Uses CRM (Critical Resource Monitoring) to monitor link status

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
use critical-resource-monitoring
```

### Parameters

```
use critical-resource-monitoring
```

|                                  |                                                                                                                                                                                                                                                                                              |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| use critical-resource-monitoring | Uses CRM to monitor the status of a link. Selecting this option determines the disposition of the route-map next hop via monitored critical resources. Link monitoring is the function used to determine a potential fail over to the secondary next hop. This option is enabled by default. |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Examples

```
nx9500-6C8809(config-routing-policy-testpolicy)#use critical-resource-monitoring
nx9500-6C8809(config-routing-policy-testpolicy)#
```

### Related Commands

|    |                                     |
|----|-------------------------------------|
| no | Disables CRM link status monitoring |
|----|-------------------------------------|

## no

Removes this Routing policy settings or reverts them to default values

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
no [apply-to-local-packets|logging|route-map|use]
```

### Parameters

```
no <PARAMETERS>
```

|                 |                                                                                                         |
|-----------------|---------------------------------------------------------------------------------------------------------|
| no <PARAMETERS> | Removes this routing policy settings or reverts them to default values, based on the parameters passed. |
|-----------------|---------------------------------------------------------------------------------------------------------|

### Usage Guidelines

The `no` command negates any command associated with it. Wherever required, use the same parameters associated with the command getting negated.

### Examples

The following example shows the routing policy 'testpolicy' settings before the 'no' commands are executed:

```
nx9500-6C8809(config-routing-policy-testpolicy)#show context
routing-policy testpolicy
 logging
 route-map 1
 match incoming-interface pppoe1
 default-next-hop wwan1 mark ip dscp 7
nx9500-6C8809(config-routing-policy-testpolicy)#
nx9500-6C8809(config-routing-policy-testpolicy)#no logging
nx9500-6C8809(config-routing-policy-testpolicy)#no route-map 1
nx9500-6C8809(config-routing-policy-testpolicy)#no apply-to-local-packets
```

The following example shows the routing policy 'testpolicy' settings after the 'no' commands are executed:

```
nx9500-6C8809(config-routing-policy-testpolicy)#show context
routing-policy testpolicy
 no apply-to-local-packets
nx9500-6C8809(config-routing-policy-testpolicy)#
```

# AAA TACACS POLICY COMMANDS

## AAA-TACACS-POLICY

---

This chapter summarizes the AAA (accounting, authentication, and authorization) TACACS (Terminal Access Control Access-Control System) policy commands in the CLI command structure.

TACACS is a network security application that provides additional network security by providing a centralized authentication, authorization, and accounting platform. TACACS implementation requires configuration of the TACACS authentication server and database.

Use the (config) instance to configure AAA-TACACS policy commands. To navigate to the config-aaa-tacacs-policy instance, use the following commands:

```
<DEVICE>(config)#aaa-tacacs-policy <POLICY-NAME>
nx9500-6C8809(config)#aaa-tacacs-policy test
nx9500-6C8809(config-aaa-tacacs-policy-test)#?
AAA TACACS Policy Mode commands:
 accounting Configure accounting parameters
 authentication Configure authentication parameters
 authorization Configure authorization parameters
 no Negate a command or set its defaults

 clrscr Clears the display screen
 commit Commit all changes made in this session
 do Run commands from Exec mode
 end End current mode and change to EXEC mode
 exit End current mode and down to previous mode
 help Description of the interactive help system
 revert Revert changes
 service Service Commands
 show Show running system information
 write Write running configuration to memory or terminal

nx9500-6C8809(config-aaa-tacacs-policy-test)#
```

### aaa-tacacs-policy-commands

The following table summarizes the AAA TACACS policy configuration mode commands:

**Table 61: AAA TACACS Policy Configuration Commands**

| Command        | Description                                 |
|----------------|---------------------------------------------|
| accounting     | Configures TACACS accounting parameters     |
| authentication | Configures TACACS authentication parameters |

**Table 61: AAA TACACS Policy Configuration Commands (continued)**

| Command                    | Description                                                            |
|----------------------------|------------------------------------------------------------------------|
| <code>authorization</code> | Configures TACACS authorization parameters                             |
| <code>no</code>            | Removes this TACACS policy settings or reverts them to default values. |

**Note**

For more information on common commands (clrscr, commit, help, revert, service, show, write, and exit), see [COMMON COMMANDS](#) on page 640.

**Note**

The input parameter <HOSTNAME>, wherever used in syntaxes across this chapter, cannot include an underscore (\_) character. In other words, the name of a device cannot contain an underscore.

*accounting*

Configures the server type and interval at which interim accounting updates are sent to the server. Up to 2 accounting servers can be configured.

This feature tracks user activities on the network, and provides information, such as resources used and the usage time. This information can be used for audit and billing purposes.

TACACS accounting tracks user activity and is useful for security audit purposes.

**Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

**Syntax**

```
accounting [access-method|auth-fail|commands|server|session]
accounting access-method [all|console|ssh|telnet] {(console|ssh|telnet)}
accounting [auth-fail|commands|session]
accounting server [<1-2>|preference]
accounting server preference [authenticated-server-host|authenticated-server-number|
authorized-server-host|authorized-server-number|none]
accounting server <1-2> [host|retry-timeout-factor <50-200>|timeout]
accounting server <1-2> host <IP/HOSTNAME> {secret [0 <SECRET>|2 <SECRET>|
<SECRET>]} {port <1-65535>}
accounting server <1-2> timeout <3-5> {attempts <1-3>}
```

**Parameters**

```
accounting access-method [all|console|ssh|telnet] {(console|ssh|telnet)}
```

|               |                                                                                           |
|---------------|-------------------------------------------------------------------------------------------|
| access-method | Configures TACACS accounting access mode. The options are: console, SSH, Telnet, and all. |
| all           | Configures TACACS accounting for all access modes                                         |
| console       | Configures TACACS accounting for console access only                                      |

|        |                                                     |
|--------|-----------------------------------------------------|
| ssh    | Configures TACACS accounting for SSH access only    |
| telnet | Configures TACACS accounting for Telnet access only |

accounting [auth-fail|commands|session]

|           |                                                                                            |
|-----------|--------------------------------------------------------------------------------------------|
| auth-fail | Enables accounting for authentication fail details. This option is disabled by default.    |
| commands  | Enables accounting of commands executed. This option is disabled by default.               |
| session   | Enables accounting for session start and stop details. This option is disabled by default. |

accounting server preference [authenticated-server-host|authenticated-server-number|authorized-server-host|authorized-server-number|none]

|                             |                                                                                                                                                                                                                      |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| server                      | Configures a TACACS accounting server                                                                                                                                                                                |
| preference                  | Configures the accounting server preference (specifies the method of selecting a server, from the pool, to send the request)                                                                                         |
| authenticated-server-host   | Sets the authentication server as the accounting server. This is the default setting. This parameter indicates the same server is used for authentication and accounting. The server is referred to by its hostname. |
| authenticated-server-number | Sets the authentication server as the accounting server. This parameter indicates the same server is used for authentication and accounting. The server is referred to by its index or number.                       |
| authorized-server-host      | Sets the authorization server as the accounting server. This parameter indicates the same server is used for authorization and accounting. The server is referred to by its hostname.                                |
| authorized-server-number    | Sets the authorized server as the accounting server. This parameter indicates the same server is used for authorization and accounting. The server is referred to by its index number.                               |
| none                        | Indicates the accounting server is independent of the authentication and authorization servers                                                                                                                       |

accounting server <1-2> retry-timeout-factor <50-200>

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| server <1-2>                  | Configures an accounting server. Up to 2 accounting servers can be configured                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| retry-timeout-factor <50-200> | <p>Sets the scaling factor for retry timeouts</p> <ul style="list-style-type: none"> <li>• &lt;50-200&gt; – Specify a value from 50 - 200. The default is 100.</li> </ul> <p>A value of 100 indicates the time gap between two consecutive retries remains the same irrespective of the number of retries.</p> <p>A value lesser than 100 indicates the time gap between two consecutive retries reduces with each successive retry.</p> <p>A value greater than 100 indicates the time gap between two consecutive retries increases with each successive retry.</p> |

accounting server <1-2> host <IP/HOSTNAME> {secret [0 <SECRET>|2 <SECRET>|<SECRET>]} {port <1-65535>}

|                    |                                                                               |
|--------------------|-------------------------------------------------------------------------------|
| server <1-2>       | Configures an accounting server. Up to 2 accounting servers can be configured |
| host <IP/HOSTNAME> | Configures the accounting server's IP address or hostname                     |

|                                           |                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| secret [0 <SECRET>  2 <SECRET>  <SECRET>] | Optional. Configures a common secret key used to authenticate with the accounting server <ul style="list-style-type: none"> <li>0 &lt;SECRET&gt; - Configures a clear text secret key</li> <li>2 &lt;SECRET&gt; - Configures an encrypted secret key</li> <li>&lt;SECRET&gt; - Specify the secret key. This shared secret should not exceed 127 characters.</li> </ul> |
| port <1-65535>                            | Optional. Configures the accounting server port (the port used to connect to the accounting server) <ul style="list-style-type: none"> <li>&lt;1-65535&gt; - Specify the TCP accounting port number from 1 - 65535. The default port is 49.</li> </ul>                                                                                                                 |

accounting server <1-2> timeout <3-5> {attempts <1-3>}

|                |                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| server <1-2>   | Configures an accounting server. Up to 2 accounting servers can be configured                                                                                                                                                                                                                                                                                                                     |
| timeout <3-5>  | Configures the timeout for each request sent to the TACACS accounting server. This is the time allowed to elapse before another request is sent to the TACACS accounting server. If a response is received from the server within this time, no retry is attempted. <ul style="list-style-type: none"> <li>&lt;3-5&gt; - Specify a value from 3 - 5 seconds. The default is 3 seconds.</li> </ul> |
| attempts <1-3> | Optional. Specifies the number of times a transmission request is attempted. This is the maximum number of times a request is sent to the TACACS accounting server before getting discarded. <ul style="list-style-type: none"> <li>&lt;1-3&gt; - Specify a value from 1 - 3. The default is 3.</li> </ul>                                                                                        |

### Examples

```

nx9500-6C8809(config-aaa-tacacs-policy-test)#accounting auth-fail
nx9500-6C8809(config-aaa-tacacs-policy-test)#accounting commands
nx9500-6C8809(config-aaa-tacacs-policy-test)#accounting server preference
authorized-server-number
nx9500-6C8809(config-aaa-tacacs-policy-test)#show context
aaa-tacacs-policy test
 accounting server preference authorized-server-number
 accounting auth-fail
 accounting commands
nx9500-6C8809(config-aaa-tacacs-policy-test)#

```

### Related Commands

|    |                                    |
|----|------------------------------------|
| no | Resets values or disables commands |
|----|------------------------------------|

### authentication

Configures user authentication parameters. Users are allowed or denied access to the network based on the authentication parameters set.

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
authentication [access-method|directed-request|server|service]
authentication access-method [all|console|ssh|telnet|web] {(console/ssh/telnet/
web)}
authentication directed-request
authentication server <1-2> [host|retry-timeout-factor|timeout]
authentication server <1-2> host <IP/HOSTNAME> {secret [0 <SECRET>|2 <SECRET>|
<SECRET>]} {port <1-65535>}
authentication server <1-2> retry-timeout-factor <50-200>
authentication server <1-2> timeout <3-60> {attempts <1-10>}
authentication service <SERVICE-NAME> {protocol <AUTHENTICATION-PROTO-NAME>}
```

## Parameters

```
authentication access-method [all|console|ssh|telnet|web] {(console/ssh/telnet/
web)}
```

|               |                                                                                                         |
|---------------|---------------------------------------------------------------------------------------------------------|
| access-method | Configures access modes for TACACS authentication. The options are: console, SSH, Telnet, Web, and all. |
| all           | Authenticates users using all access modes (console, SSH, and Telnet)                                   |
| console       | Authenticates users using console access only                                                           |
| ssh           | Authenticates users using SSH access only                                                               |
| telnet        | Authenticates users using Telnet access only                                                            |
| web           | Authenticates users using Web interface only                                                            |

```
authentication directed-request
```

|                  |                                                                                                                                                                                             |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| directed-request | Enables user to specify TACACS server to use with '@server'. This option is disabled by default.<br><br><b>Note:</b> The specified server should be present in the configured servers list. |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
authentication server <1-2> host <IP/HOSTNAME> {secret [0 <SECRET>|2 <SECRET>|
<SECRET>]} {port <1-65535>}
```

|                                          |                                                                                                                                                                                                                                                                                                                                     |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| server <1-2>                             | Configures a TACACS authentication server. Up to 2 TACACS servers can be configured <ul style="list-style-type: none"><li>&lt;1-2&gt; - Specify the TACACS server index from 1 - 2.</li></ul>                                                                                                                                       |
| host <IP/HOSTNAME>                       | Sets the TACACS server's IP address or hostname                                                                                                                                                                                                                                                                                     |
| secret [0 <SECRET> 2 <SECRET>  <SECRET>] | Configures the secret key used to authenticate with the TACACS server <ul style="list-style-type: none"><li>0 &lt;SECRET&gt; - Configures a clear text secret</li><li>2 &lt;SECRET&gt; - Configures an encrypted secret</li><li>&lt;SECRET&gt; - Specify the secret key. The shared key should not exceed 127 characters.</li></ul> |
| port <1-65535>                           | Optional. Specifies the port used to connect to the TACACS server <ul style="list-style-type: none"><li>&lt;1-65535&gt; - Specify a value for the TCP authentication port from 1 - 65535. The default port is 49.</li></ul>                                                                                                         |

```
authentication server <1-2> retry-timeout-factor <50-200>
```

|                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| server <1-2>                     | Configures a TACACS authentication server. Up to 2 TACACS servers can be configured <ul style="list-style-type: none"> <li>• &lt;1-2&gt; - Specify the TACACS server index from 1 - 2.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                   |
| retry-timeout-factor<br><50-200> | Configures timeout scaling between two consecutive TACACS authentication retries <ul style="list-style-type: none"> <li>• &lt;50-200&gt; - Specify the scaling factor from 50 - 200. The default is 100.</li> </ul> <p>A value of 100 indicates the interval between consecutive retries remains the same irrespective of the number of retries.</p> <p>A value lesser than 100 indicates the interval between consecutive retries reduces with each successive retry.</p> <p>A value greater than 100 indicates the interval between consecutive retries increases with each successive retry.</p> |

```
authentication server <1-2> timeout <3-60> {attempts <1-10>}
```

|                    |                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| server <1-2>       | Configures a TACACS authentication server. Up to 2 TACACS servers can be configured <ul style="list-style-type: none"> <li>• &lt;1-2&gt; - Specify the TACACS server index from 1- 2.</li> </ul>                                                                                                                                                                                                   |
| timeout<br><3-60>  | Configures the timeout, in seconds, for each request sent to the TACACS server. This is the time allowed to elapse before another request is sent to the TACACS server. If a response is received from the TACACS server within this time, no retry is attempted. <ul style="list-style-type: none"> <li>• &lt;3-60&gt; - Specify a value from 3- 60 seconds. The default is 3 seconds.</li> </ul> |
| attempts<br><1-10> | Optional. Indicates the number of retry attempts to make before giving up <ul style="list-style-type: none"> <li>• &lt;1-10&gt; - Specify a value from 1 -10. The default is 3.</li> </ul>                                                                                                                                                                                                         |

```
authentication service <SERVICE-NAME> {protocol <AUTHENTICATION-PROTO-NAME>}
```

|                                      |                                                                                                                                  |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| service <SERVICE-NAME>               | Configures the TACACS authentication service name                                                                                |
| protocol <AUTHENTICATION-PROTO-NAME> | Optional. Specify the authentication protocol used with this TACACS policy<br><b>Note:</b> A maximum of five entries is allowed. |

## Examples

```
nx9500-6C8809(config-aaa-tacacs-policy-test)#authentication directed-request
nx9500-6C8809(config-aaa-tacacs-policy-test)#show context
aaa-tacacs-policy test
 authentication directed-request
 accounting server preference authorized-server-number
 accounting auth-fail
 accounting commands
nx9500-6C8809(config-aaa-tacacs-policy-test)#
```

## Related Commands

|    |                                    |
|----|------------------------------------|
| no | Resets values or disables commands |
|----|------------------------------------|

## authorization

Configures AAA TACACS authorization parameters

This feature allows network administrators to limit user accessibility and configure varying levels of accessibility for different users.

## Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
authorization [access-method|allow-privileged-commands|server]
authorization access-method [all|console|telnet|ssh] {(console|ssh|telnet)}
authorization server [<1-2>|preference]
authorization server <1-2> [host|retry-timeout-factor|timeout]
authorizationserver <1-2> host <IP/HOSTNAME> {secret [0 <SECRET>|2 <SECRET>|
<SECRET>]} {port <1-65535>}
authorization server <1-2> retry-timeout-factor <50-200>
authorization server <1-2> timeout <3-5> {attempts <1-3>}
authorization server preference [authenticated-server-host|authenticated-server-number|
none]
```

## Parameters

```
authorization access-method [all|console|telnet|ssh] {(console|ssh|telnet)}
```

|                      |                                                                            |
|----------------------|----------------------------------------------------------------------------|
| access-method        | Configures the access method for command authorization                     |
| all                  | Authorizes commands from all access methods                                |
| console              | Authorizes commands from the console only                                  |
| telnet               | Authorizes commands from Telnet only                                       |
| ssh                  | Authorizes commands from SSH only                                          |
| {console ssh telnet} | Optional. Configures more than one access method for command authorization |

```
authorization allow-privileged-commands
```

|                           |                                                                                                         |
|---------------------------|---------------------------------------------------------------------------------------------------------|
| allow-privileged-commands | Allows privileged commands execution without command authorization. This option is disabled by default. |
|---------------------------|---------------------------------------------------------------------------------------------------------|

```
authorization server <1-2> host <IP/HOSTNAME> {secret [0 <SECRET>|2 <SECRET>|
<SECRET>]} {port <1-65535>}
```

|                                         |                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| server <1-2>                            | Configures a TACACS authorization server. Up to 2 TACACS servers can be configured <ul style="list-style-type: none"><li>• &lt;1-2&gt; - Specify the TACACS server index from 1 - 2.</li></ul>                                                                                                                                               |
| host <IP/HOSTNAME>                      | Sets the TACACS server's IP address or hostname                                                                                                                                                                                                                                                                                              |
| secret [0 <SECRET> 2 <SECRET> <SECRET>] | Optional. Configures the secret used to authorize with the TACACS server <ul style="list-style-type: none"><li>• 0 &lt;SECRET&gt; - Configures a clear text secret</li><li>• 2 &lt;SECRET&gt; - Configures an encrypted secret</li><li>• &lt;SECRET&gt; - Specify the secret key. The shared key should not exceed 127 characters.</li></ul> |
| port <1-65535>                          | Optional. Specifies the port used to connect to the TACACS server <ul style="list-style-type: none"><li>• &lt;1-65535&gt; - Specify a value for the TCP authorization port from 1 - 65535. The default port is 49.</li></ul>                                                                                                                 |

```
authorization server <1-2> retry-timeout-factor <50-200>
```

|                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| server <1-2>                     | Configures a TACACS authorization server. Up to 2 TACACS servers can be configured <ul style="list-style-type: none"> <li>• &lt;1-2&gt; – Specify the TACACS server index from 1 - 2.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                       |
| retry-timeout-factor<br><50-200> | Configures the scaling of timeouts between consecutive TACACS authorization retries <ul style="list-style-type: none"> <li>• &lt;50-200&gt; – Specify the scaling factor from 50 - 200. The default is 100.</li> </ul> <p>A value of 100 indicates the interval between consecutive retries remains the same irrespective of the number of retries.</p> <p>A value lesser than 100 indicates the interval between consecutive retries reduces with each successive retry.</p> <p>A value greater than 100 indicates the interval between consecutive retries increases with each successive retry.</p> |

```
authorization server <1-2> timeout <3-5> {attempts <1-3>}
```

|                |                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| server <1-2>   | Configures a TACACS authorization server. Up to 2 TACACS servers can be configured <ul style="list-style-type: none"> <li>• &lt;1-2&gt; – Specify the TACACS server's index from 1- 2.</li> </ul>                                                                                                                                                                                                 |
| timeout <3-5>  | Configures the timeout, in seconds, for each request sent to the TACACS server. This is the time allowed to elapse before another request is sent to the TACACS server. If a response is received from the TACACS server within this time, no retry is attempted. <ul style="list-style-type: none"> <li>• &lt;3-5&gt; – Specify a value from 3 - 5 seconds. The default is 3 seconds.</li> </ul> |
| attempts <1-3> | Optional. Indicates the number of retry attempts to make before giving up <ul style="list-style-type: none"> <li>• &lt;1-3&gt; – Specify a value from 1 - 3. The default is 3.</li> </ul>                                                                                                                                                                                                         |

```
authorization server preference [authenticated-server-host|authenticated-server-number|none]
```

|                             |                                                                                                                                                                                                        |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| preference                  | Configures the authorization server preference                                                                                                                                                         |
| authenticated-server-host   | Sets the authentication server as the authorization server<br>This parameter indicates the same server is used for authentication and authorization. The server is referred to by its hostname.        |
| authenticated-server-number | Sets the authentication server as the authorization server<br>This parameter indicates the same server is used for authentication and authorization. The server is referred to by its index or number. |
| none                        | Indicates the authorization server is independent of the authentication server                                                                                                                         |

## Examples

```
nx9500-6C8809(config-aaa-tacacs-policy-test)#authorization allow-privileged-commands
nx9500-6C8809(config-aaa-tacacs-policy-test)#show context
aaa-tacacs-policy test
 authentication directed-request
 accounting server preference authorized-server-number
 authorization allow-privileged-commands
 accounting auth-fail
 accounting commands
nx9500-6C8809(config-aaa-tacacs-policy-test)#
```

## Related Commands

|    |                                    |
|----|------------------------------------|
| no | Resets values or disables commands |
|----|------------------------------------|

no

Removes this AAA TACACS policy settings or reverts to default values

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
no [accounting|authentication|authorization]
```

#### Parameters

```
no <PARAMETERS>
```

no <PARAMETERS> Removes this AAA TACACS policy settings or reverts to default values, based on the parameters passed

#### Examples

The following example shows the AAA-TACACS policy 'test' settings before the 'no' commands are executed:

```
<exsw1>(config-aaa-tacacs-policy-test)#show context
aaa-tacacs-policy test
 authentication directed-request
 accounting server preference authorized-server-number
 authorization allow-privileged-commands
 accounting auth-fail
 accounting commands
<exsw1>(config-aaa-tacacs-policy-test)#
<exsw1>(config-aaa-tacacs-policy-test)#no authentication directed-request
<exsw1>(config-aaa-tacacs-policy-test)#no accounting auth-fail
<exsw1>(config-aaa-tacacs-policy-test)#no authorization allow-privileged-commands
```

The following example shows the AAA-TACACS policy 'test' settings after the 'no' commands are executed:

```
<exsw1>(config-aaa-tacacs-policy-test)#show context
aaa-tacacs-policy test
 accounting server preference authorized-server-number
 accounting commands
<exsw1>(config-aaa-tacacs-policy-test)#
```

# MESHPOINT

## MESHPOINT

---

This chapter summarizes the Meshpoint commands in the CLI command structure.

Meshpoints are detector radios that monitor their coverage areas for potential failed peers or coverage area holes requiring transmission adjustments for coverage compensation.

This chapter is organized as follows:

- [meshpoint config instance](#)
- [meshpoint-qos-policy-config-instance](#)
- [meshpoint-device-config-instance](#) on page 1787

### meshpoint-config-instance

MCX (MeshConnex) is a mesh networking technology that is comparable to the 802.11s mesh networking specification. MeshConnex meshing uses a hybrid proactive/on-demand path selection protocol, similar to AODV (Ad-hoc On Demand Distance Vector) routing protocols. This allows it to form efficient paths using multiple attachment points to a distribution WAN, or form purely ad-hoc peer-to-peer mesh networks in the absence of a WAN. Each device in the MeshConnex mesh proactively manages its own path to the distribution WAN, but can also form peer-to-peer paths on demand to improve forwarding efficiency.

MeshConnex is not compatible with MiNT Based meshing, though the two technologies can be enabled simultaneously in certain circumstances.

MeshConnex is designed for large-scale, high-mobility outdoor mesh deployments. MeshConnex continually gathers data from beacons and transmission attempts to estimate the efficiency and throughput of each MP-to-MP link. MeshConnex uses this data to dynamically form and continually maintain paths for forwarding network frames.

In MeshConnex systems, a MP (mesh point) is a virtual mesh networking instance on a device, similar to a WLAN AP. On each device, up to 4 MPs can be created and 2 can be created per radio. MPs can be configured to use one or both radios in the device. If the MP is configured to use both radios, the path selection protocols continuously selects the best radio to reach each destination. Each MP participates in a single Mesh Network, defined by the MeshID. The MeshID is typically a descriptive network name, similar to the SSID of a WLAN. All MPs configured to use the same MeshID attempt to form a mesh and interoperate. The MeshID allows overlapping mesh networks to discriminate and disregard MPs belonging to different networks.

Use the (config) instance to configure meshpoint related configuration commands. To navigate to the meshpoint instance, use the following command:

```
<DEVICE>(config)#meshpoint <MESHPOINT-NAME>
nx9500-6C8809(config)#meshpoint test
nx9500-6C8809(config-meshpoint-test)#?
Mesh Point Mode commands:
```

```

allowed-vlans Set the allowed VLANs
beacon-format The beacon format of this meshpoint
control-vlan VLAN for meshpoint control traffic
data-rates Specify the 802.11 rates to be supported on this meshpoint
description Configure a description of the usage of this meshpoint
force Force suboptimal paths
meshid Configure the Service Set Identifier for this meshpoint
neighbor Configure neighbor specific parameters
no Negate a command or set its defaults
root Set this meshpoint as root
security-mode The security mode of this meshpoint
shutdown Shutdown this meshpoint
use Set setting to use
wpa2 Modify ccmp wpa2 related parameters

clrscr Clears the display screen
commit Commit all changes made in this session
do Run commands from Exec mode
end End current mode and change to EXEC mode
exit End current mode and down to previous mode
help Description of the interactive help system
revert Revert changes
service Service Commands
show Show running system information
write Write running configuration to memory or terminal

```

nx9500-6C8809(config-meshpoint-test)#

The following table summarizes meshpoint configuration commands.

*Table: Meshpoint-Config commands*

| Command                                                       | Description                                                             |
|---------------------------------------------------------------|-------------------------------------------------------------------------|
| <a href="#">allowed-vlans (meshpoint-config)</a> on page 1762 | Configures VLANs allowed on the meshpoint                               |
| <a href="#">beacon-format (meshpoint-config)</a> on page 1763 | Configures the beacon format for the meshpoint AP                       |
| <a href="#">control-vlan (meshpoint-config)</a> on page 1764  | Configures the VLAN where meshpoint control traffic traverses           |
| <a href="#">data-rates (meshpoint-config)</a> on page 1765    | Configures the data rates supported per frequency band                  |
| <a href="#">description (meshpoint-config)</a> on page 1768   | Configures a human friendly description for this meshpoint              |
| <a href="#">force (meshpoint-config)</a> on page 1769         | Forces formation of sub-optimal paths through the meshpoint's root node |
| <a href="#">meshid (meshpoint-config)</a> on page 1769        | Configures a unique ID for this meshpoint                               |
| <a href="#">neighbor (meshpoint-config)</a> on page 1770      | Configures the neighbor inactivity time out for this meshpoint          |
| <a href="#">root (meshpoint-config)</a> on page 1771          | Configures a meshpoint as the root meshpoint                            |
| <a href="#">security-mode (meshpoint-config)</a> on page 1773 | Configures the security mode on the meshpoint.                          |
| <a href="#">service (meshpoint-config)</a> on page 1774       | Allows only 802.11n capable neighbors to create a mesh connection       |
| <a href="#">shutdown (meshpoint-config)</a> on page 1775      | Shuts down the meshpoint                                                |
| <a href="#">use (meshpoint-config)</a> on page 1775           | Associates a QoS policy with this meshpoint                             |

| Command                                           | Description                                |
|---------------------------------------------------|--------------------------------------------|
| <code>wpa2 (meshpoint-config)</code> on page 1776 | Configures WPA2 encryption settings        |
| <code>no (meshpoint-config)</code> on page 1780   | Removes or reverts this Meshpoint settings |

#### Note

For more information on common commands (clrscr, commit, help, revert, service, show, write, and exit), see [COMMON COMMANDS](#).

#### Note

The input parameter <HOSTNAME>, wherever used in syntaxes across this chapter, cannot include an underscore (\_) character. In other words, the name of a device cannot contain an underscore.

### *allowed-vlans (meshpoint-config)*

Defines VLANs allowed on the mesh network. A VLAN must be added to the allowed VLANs list for data to be allowed across the mesh network. Use this command to add and remove VLANs from the list of allowed VLANs.

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
allowed-vlans [<VLAN-ID> | add <VLAN-ID> | remove <VLAN-ID>]
```

#### Parameters

```
allowed-vlans [<VLAN-ID> | add <VLAN-ID> | remove <VLAN-ID>]
```

|                  |                                                                                                                                                                                                                                                                                                                    |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| allowed-vlans    | Defines VLANs allowed access on the mesh network                                                                                                                                                                                                                                                                   |
| <VLAN-ID>        | Specifies the VLAN ID or the range of IDs to be managed.<br>A single VLAN or multiple VLANs can be added to the list of allowed VLANs. When adding multiple VLANs, specify the range (for example, 10-20, 25, 30-35). Use this command to create a VLAN list on a new meshpoint.                                   |
| add <VLAN-ID>    | Adds a single VLAN or a range of VLANs to the list of allowed VLANs. To specify a range of VLANs, specify the first and last VLAN ID in the range separated by a hyphen (for example, 1-10). <ul style="list-style-type: none"> <li>• &lt;VLAN-ID&gt; - Specify the VLAN ID or the range of IDs to add.</li> </ul> |
| remove <VLAN-ID> | Removes a single VLAN or a range of VLANs from the list of allowed VLANs. <ul style="list-style-type: none"> <li>• &lt;VLAN-ID&gt; - Specify the VLAN ID or the range of IDs to remove.</li> </ul>                                                                                                                 |

## Examples

```
nx9500-6C8809(config-meshpoint-test)#allowed-vlans 1
nx9500-6C8809(config-meshpoint-test)#allowed-vlans add 10-23
nx9500-6C8809(config-meshpoint-test)#allowed-vlans remove 17
nx9500-6C8809(config-meshpoint-test)#show context
meshpoint test
 meshid test
 beacon-format mesh-point
 control-vlan 1
 allowed-vlans 1,10-16,18-23
 security-mode none
 no root
nx9500-6C8809(config-meshpoint-test)#
```

## Related Commands

|                                                 |                                                             |
|-------------------------------------------------|-------------------------------------------------------------|
| <code>no (meshpoint-config)</code> on page 1780 | Clears the list of VLANs allowed access to the mesh network |
|-------------------------------------------------|-------------------------------------------------------------|

### *beacon-format (meshpoint-config)*

Configures the beacon transmission format for this meshpoint. Beacons are transmitted periodically to advertise that a wireless network is available. It contains all the required information for a device to connect to the network.

The beacon format advertises how a mesh-capable access point acts. APs can act either as an access point or a meshpoint.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
beacon-format [access-point|mesh-point]
```

## Parameters

```
beacon-format [access-point|mesh-point]
```

|               |                                                                   |
|---------------|-------------------------------------------------------------------|
| beacon-format | Configures how a mesh capable access point acts in a mesh network |
| access-point  | Uses access point style beacons                                   |
| mesh-point    | Uses meshpoint style beacons (this is the default setting)        |

## Examples

```
nx9500-6C8809(config-meshpoint-test)#beacon-format access-point
nx9500-6C8809(config-meshpoint-test)#show context
meshpoint test
 meshid test
 beacon-format access-point
 control-vlan 1
 allowed-vlans 1,10-16,18-23
 security-mode none
```

```

no root
nx9500-6C8809(config-meshpoint-test)#
nx9500-6C8809(config-meshpoint-test)#no beacon-format
nx9500-6C8809(config-meshpoint-test)#show context
meshpoint test
meshid test
beacon-format mesh-point
control-vlan 1
allowed-vlans 1,10-16,18-23
security-mode none
no root
nx9500-6C8809(config-meshpoint-test)#

```

## Related Commands

`no (meshpoint-config)` on page 1780 Resets the beacon format for this meshpoint to its default (mesh-point)

### *control-vlan (meshpoint-config)*

Configures a VLAN as the dedicated control VLAN for this meshpoint

Mesh management traffic can be sent over a dedicated VLAN. This dedicated VLAN is known as the control VLAN, and should be configured in the backhaul port of all the access points configured as meshpoint roots. Once configured, the control VLAN carries the mesh point's control traffic.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
control-vlan [<1-4094>|<VLAN-ALIAS-NAME>]
```

### Parameters

```
control-vlan [<1-4094>|<VLAN-ALIAS-NAME>]
```

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| control-vlan                 | Configures a VLAN as a dedicated carrier of mesh management traffic                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| [<1-4094> <VLAN-ALIAS-NAME>] | <p>Configures the control VLAN</p> <ul style="list-style-type: none"> <li>• &lt;1-4094&gt; - Specify the control VLAN from 1 - 4094. The default is VLAN 1.</li> <li>• &lt;VLAN-ALIAS-NAME&gt; - Uses a vlan-alias to specify the control vlan. If using a vlan-alias, ensure that it is existing and configured.</li> </ul> <p>If VLAN 1 is configured as the control VLAN, ensure that the VLAN is configured in the wired port of all access points belonging to same meshpoint.</p> <p><b>Note:</b> Control VLAN need not necessarily be added in the allowed VLAN list.</p> |

### Examples

```

nx9500-6C8809(config-meshpoint-test)#control-vlan 25
nx9500-6C8809(config-meshpoint-test)#show context
meshpoint test
meshid test

```

```

beacon-format mesh-point
control-vlan 25
allowed-vlans 1,10-16,18-23
security-mode none
no root
nx9500-6C8809(config-meshpoint-test)#

```

### Related Commands

`no (meshpoint-config)` on page 1780 Resets the control VLAN for this meshpoint to its default value of VLAN 1

### *data-rates (meshpoint-config)*

Configures individual data rates for the 2.4 GHz and 5.0 GHz frequency bands. In Mesh network, a mesh point is a virtual mesh networking instance on a device, similar to a WLAN AP. On each device, up to 4 mesh points can be created and 2 can be created per radio. Each mesh point radio can have carefully administrated radio rates specific to the 2.4 or 5 GHz band. Use this command to configure these radio rates.

#### Note

Ensure that the basic data rates configured on a meshpoint's root and non-root access points is the same.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```

data-rates [2.4GHz|5GHz]
data-rates 2.4GHz [b-only|bg|bgn|default|g-only|gn]
data-rates 2.4GHz custom (1|11|12|18|2|24|36|48|5.5|54|6|9|basic-1|basic-11|
basic-12|basic-18|basic-2|basic-24|basic-36|basic-48|basic-5.5|basic-54|basic-6|basic-9|
mcs0-15|mcs0-7|mcs8-15|basic-mcs0-7)
data-rates 5GHz [a-only|an|default]
data-rates 5GHz custom (12|18|24|36|48|54|6|9|basic-1|basic-11|basic-12|basic-18|

### *description (meshpoint-config)*

Configures a brief description for this meshpoint

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

`no (meshpoint-config)` on page 1780 Removes the human friendly description provided for this meshpoint

### *force (meshpoint-config)*

Forces formation of sub-optimal paths through the meshpoint's root node. As per legacy behavior, non-root devices under the same root, communicated by forming direct paths through the network. This option allows non-root devices, within the meshpoint, to communicate by forming paths through the root node.

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
force [peer-paths-through-root|peer-paths-with-root]
```

#### Parameters

```
force [peer-paths-through-root|peer-paths-with-root]
```

|                         |                                                                                                                                                                                    |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| force                   | Forces formation of sub-optimal paths through the meshpoint root node.                                                                                                             |
| peer-paths-through-root | Forces non-root devices to communicate by forming sub-optimal paths through the root node. This option is disabled by default.                                                     |
| peer-paths-with-root    | Forces non-root devices to communicate by forming sub-optimal paths with the root node. Does not allow formation of ad-hoc peer-to-peer paths. This option is disabled by default. |

#### Examples

```
nx9500-6C8809(config-meshpoint-test)#force peer-paths-through-root
nx9500-6C8809(config-meshpoint-test)#show context
meshpoint test
 meshid test
 beacon-format mesh-point
 control-vlan 25
 security-mode none
 no root
 force peer-paths-through-root
nx9500-6C8809(config-meshpoint-test)#
```

## Related Commands

`no (meshpoint-config)` on page 1780 Disables formation of sub-optimal paths

### *meshid (meshpoint-config)*

Configures a unique SSID (Service Set Identifier) for this meshpoint. This ID is used to uniquely identify this meshpoint.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
meshid <MESH-SSID>
```

### Parameters

```
meshid <MESH-SSID>
```

|             |                                                                                   |
|-------------|-----------------------------------------------------------------------------------|
| meshid      | Configures a unique SSID for the meshpoint                                        |
| <MESH-SSID> | The unique SSID configured for this meshpoint                                     |
|             | <b>Note:</b> The mesh SSID is case sensitive and should not exceed 32 characters. |

### Examples

```
nx9500-6C8809(config-meshpoint-test)#meshid TestingMeshPoint
nx9500-6C8809(config-meshpoint-test)#show context
meshpoint test
description "This is an example of a meshpoint description"
meshid TestingMeshPoint
beacon-format mesh-point
control-vlan 1
allowed-vlans 1,10-16,18-23
data-rates 2.4GHz bgn
data-rates 5GHz an
security-mode none
no root
nx9500-6C8809(config-meshpoint-test)#
```

### Related Commands

|                                                    |                                                |

| <a href="#">no (meshpoint-config)</a> on page 1780 | Removes the SSID configured for this meshpoint |
|----------------------------------------------------|------------------------------------------------|

### *neighbor (meshpoint-config)*

This command configures the inactivity time out value for neighboring devices. If a frame is not received from the neighbor device for the configured time, then client resources are removed.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
neighbor inactivity-timeout <60-86400>
```

## Parameters

neighbor inactivity-timeout <60-86400>

|                                        |                                                                                                                                                                                                                                                                                                                           |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| neighbor inactivity-timeout <60-86400> | Configures the neighbor inactivity timeout in seconds. This represents the allowed interval between frames received from a neighbor before their client privileges are revoked. <ul style="list-style-type: none"><li>• &lt;60-86400&gt; – Specify a value from 60 - 86400 seconds. The default is 120 seconds.</li></ul> |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Examples

```
nx9500-6C8809(config-meshpoint-test)#neighbor inactivity-timeout 300
nx9500-6C8809(config-meshpoint-test)#show context
meshpoint test
 description "This is an example of a meshpoint description"
 meshid TestingMeshPoint
 beacon-format mesh-point
 control-vlan 25
 allowed-vlans 1,10-16,18-23
 neighbor inactivity-timeout 300
 data-rates 2.4GHz bgn
 data-rates 5GHz an
 security-mode none
 no root
nx9500-6C8809(config-meshpoint-test)#
```

|----------------------------------------------------|------------------------------------------------------------------------------|
| <a href="#">no (meshpoint-config)</a> on page 1780 | Removes the configured neighbor inactivity time out value for this meshpoint |
|----------------------------------------------------|------------------------------------------------------------------------------|

### *root (meshpoint-config)*

Configures this meshpoint as the root meshpoint. Root meshpoints are generally tied to an Ethernet backhaul for wired connectivity. By default this option is disabled.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

root

## Parameters

None

## Examples

There are two ways of configuring root access points within a meshpoint.

- 1 First method:
  - Configure two meshpoints, having the same meshid, one with the *root* option enabled and the other configured as *no root*

- Apply the root meshpoint to the root access point and the no-root meshpoint to the non-root access points.

The following examples show the configuration of a meshpoint for the root access point:

```

nx9500-6C8809(config)#meshpoint root
nx9500-6C8809(config-meshpoint-root)#
nx9500-6C8809(config-meshpoint-root)#meshid test
nx9500-6C8809(config-meshpoint-root)#root
nx9500-6C8809(config-meshpoint-root)#security-mode eap
nx9500-6C8809(config-meshpoint-root)#commit
nx9500-6C8809(config-meshpoint-root)#show context
meshpoint root
 meshid test
 beacon-format mesh-point
 control-vlan 1
 security-mode eap
 root
nx9500-6C8809(config-meshpoint-root)#

```

The following examples show the configuration of a meshpoint for non-root access points:

```

nx9500-6C8809(config)#meshpoint no-root
nx9500-6C8809(config-meshpoint-no-root)#
nx9500-6C8809(config-meshpoint-no-root)#meshid test
nx9500-6C8809(config-meshpoint-no-root)#security-mode eap
nx9500-6C8809(config-meshpoint-no-root)#show context
meshpoint no-root
 meshid test
 beacon-format mesh-point
 control-vlan 1
 security-mode eap
 no root
nx9500-6C8809(config-meshpoint-no-root)#

```

## 2 Second method:

- Configure a no-root meshpoint and apply to all access points in the meshpoint.
- Log into the **meshpoint-device > no-root** configuration mode of the root access point and enable root.

```

nx9500-6C8809(config-meshpoint-no-root)#show context
meshpoint no-root
 meshid test
 beacon-format mesh-point
 control-vlan 1
 security-mode eap
 no root
nx9500-6C8809(config-meshpoint-no-root)#
nx9500-6C8809(config)#ap8lxx B4-C7-99-71-17-28
nx9500-6C8809(config-device-B4-C7-99-71-17-28)#meshpoint-device no-root
nx9500-6C8809(config-device-B4-C7-99-71-17-28-meshpoint-no-root)#
nx9500-6C8809(config-device-B4-C7-99-71-17-28-meshpoint-no-root)#show context
meshpoint no-root
 meshid test
 beacon-format mesh-point
 control-vlan 1
 security-mode eap
 no rootnx9500-6C8809(config-device-B4-C7-99-71-17-28-meshpoint-no-root)#
nx9500-6C8809(config-device-B4-C7-99-71-17-28-meshpoint-no-root)#root
nx9500-6C8809(config-device-B4-C7-99-71-17-28-meshpoint-no-root)#show context
meshpoint no-root
 meshid test
 beacon-format mesh-point
 control-vlan 1
 security-mode eap

```

```
root
nx9500-6C8809(config-device-B4-C7-99-71-17-28-meshpoint-no-root)#
```

|-------------------------------------------------|------------------------------------------------------------------------|
| <code>no (meshpoint-config)</code> on page 1780 | Removes the configuration of this meshpoint device as a root meshpoint |
|-------------------------------------------------|------------------------------------------------------------------------|

### *security-mode (meshpoint-config)*

Configures the security mode for this meshpoint

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
security-mode [eap|none|psk]
```

#### Parameters

```
security-mode [eap|none|psk]
```

|                            |                                                                                                                                                                                                                        |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>security-mode</code> | Configures the security mode for this meshpoint                                                                                                                                                                        |
| <code>eap</code>           | Uses 802.1X/EAP as the security mode. When using this option, use the <code>wpa2</code> command to specify the EAP authentication type and related parameters.                                                         |
| <code>none</code>          | No security is configured for this meshpoint                                                                                                                                                                           |
| <code>psk</code>           | Uses PSK (Pre Shared Key) as the security mode. When using this option, use the <code>wpa2</code> command to enter a 64 character HEX or an 8-63 ASCII character passphrase used for authentication on the mesh point. |

#### Examples

The following example shows root meshpoint configuration with PSK authentication enabled:

```
nx9500-6C8809(config-meshpoint-test)#security-mode psk
nx9500-6C8809(config-meshpoint-test)#show context
meshpoint test
description "This is an example of a meshpoint description"
meshid TestingMeshPoint
beacon-format mesh-point
control-vlan 1
allowed-vlans 1,10-16,18-23
neighbor inactivity-timeout 300
data-rates 2.4GHz bgn
data-rates 5GHz an
security-mode psk
root
nx9500-6C8809(config-meshpoint-test)#
```

The following example shows root meshpoint configuration with EAP authentication enabled:

```
nx9500-6C8809(config-meshpoint-root)#show context
meshpoint root
meshid test
```

```

beacon-format mesh-point
control-vlan 101
allowed-vlans 101,103
use aaa-policy test
security-mode eap
root
nx9500-6C8809(config-meshpoint-test)#

```

### *service (meshpoint-config)*

Use this command to allow only those neighbors who are capable of 802.11n data rates to associate with this meshpoint.

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
service [allow-ht-only|show cli]
```

#### Parameters

```
service [allow-ht-only|show cli]
```

|                                    |                                                                                                                                |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <code>service allow-ht-only</code> | Allows only those neighbors who are capable of high throughput data rates (802.11n data rates) to associate with the meshpoint |

### *shutdown (meshpoint-config)*

Shuts down this meshpoint. Use this command to prevent an AP from participating in a mesh network.

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
shutdown
```

#### Parameters

None

#### Examples

```
nx9500-6C8809(config-meshpoint-test)#shutdown
```

## Related Commands

|-------------------------------------------------|------------------------------|

### *use (meshpoint-config)*

Uses a QoS (Quality of Service) policy defined specifically for meshpoints. To use this QoS policy, it must be defined.

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
use [aaa-policy <AAA-POLICY-NAME>|meshpoint-qos-policy <MESHPOINT-QOS-POLICY-NAME>]
```

#### Parameters

```
use [aaa-policy <AAA-POLICY-NAME>|meshpoint-qos-policy <MESHPOINT-QOS-POLICY-NAME>]
```

### *wpa2 (meshpoint-config)*

Use this command to configure the parameters of authentication mode specified using the 'security-mode' keyword. This command also allows you to set a unicast and broadcast key rotation interval.

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```

wpa2 [eap|psk|key-rotation]
wpa2 key-rotation [broadcast|unicast] <30-86400>
wpa2 psk [0 <SECRET>|2 <SECRET>|<SECRET>]
wpa2 eap [auth-type|identity|peap-mschapv2|tls]
wpa2 eap [auth-type [peap-mschapv2|tls]|identity <WORD>]
wpa2 eap peap-mschapv2 user <USER-NAME> password [0 <WORD>|2 <WORD>|<WORD>]
{trustpoint <TRUSTPOINT-NAME>}
wpa2 eap tls trustpoint <TRUSTPOINT-NAME>

```

## Parameters

`wpa2 key-rotation [broadcast|unicast] <30-86400>`

|                                |                                                                                                                                                                                                                                                                                                                       |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>wpa2 key-rotation</code> | Enables periodic rotation of encryption keys used for broadcast and unicast traffic                                                                                                                                                                                                                                   |
| <code>broadcast</code>         | Configures key rotation interval for broadcast and multicast traffic. This option is disabled by default.<br>When enabled, the key indices used for encrypting/decrypting broadcast traffic is alternatively rotated based on the defined interval. Key rotation enhances the broadcast traffic security on the WLAN. |
| <code>unicast</code>           | Configures key rotation interval for unicast traffic. This option is disabled by default.                                                                                                                                                                                                                             |
| <code>&lt;30-86400&gt;</code>  | Configures key rotation interval from 30 - 86400 seconds for unicast or broadcast transmission                                                                                                                                                                                                                        |

`wpa2 psk [0 <SECRET>|2 <SECRET>|<SECRET>]`

|                                                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## meshpoint-qos-policy-config-instance

Mesh QoS (Quality of Service) provides a data traffic prioritization scheme. QoS reduces congestion from excessive traffic. If there is enough bandwidth for all users and applications (unlikely because excessive bandwidth comes at a very high cost), then applying QoS has very little value. QoS provides policy enforcement for mission-critical applications and/or users that have critical bandwidth requirements when bandwidth is shared by different users and applications.

Mesh QoS helps ensure each mesh point on the mesh network receives a fair share of the overall bandwidth, either equally or as per the proportion configured. Packets directed towards clients are classified into categories such as video, voice and data packets within each category are processed based on the weights defined for each mesh point.

To create a meshpoint, see [meshpoint-config-instance](#) on page 1760.

A meshpoint QoS policy is created from the (config) instance. To create a meshpoint QoS policy use the following command:

```

<DEVICE>(config)#meshpoint-qos-policy <POLICY-NAME>
nx9500-6C8809(config)#meshpoint-qos-policy test
nx9500-6C8809(config-meshpoint-qos-test)#>

```

Mesh Point QoS Mode commands:

```
accelerated-multicast Configure accelerated multicast streams address and
 forwarding QoS classification
no Negate a command or set its defaults
rate-limit Configure traffic rate-limiting parameters on a
 per-meshpoint/per-neighbor basis

clrscr Clears the display screen
commit Commit all changes made in this session
do Run commands from Exec mode
end End current mode and change to EXEC mode
exit End current mode and down to previous mode
help Description of the interactive help system
revert Revert changes
service Service Commands

### *accelerated-multicast (meshpoint-qos-policy)*

Configures the accelerated multicast stream's address and forwarding QoS classification

#### Note

For accelerated multicast feature to work, IGMP querier must be enabled. When a user joins a multicast stream, an entry is created in the device's (AP or wireless controller) snoop table and the entry is set to expire after a set time period. Multicast packets are forwarded to the appropriate wireless LAN or mesh until this entry is available in the snoop table. Snoop querier keeps the snoop table current by updating entries that are set to expire. It also keeps an entry for each multicast stream till there are users registered for the stream.

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
accelerated-multicast [<MULTICAST-IP>|autodetect] {classification [background/best-effort|trust|video/voice]}
```

## Parameters

`accelerated-multicast [<MULTICAST-IP>|autodetect] {classification [background|best-effort|trust|video|voice]}`

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| accelerated-multicast | Configures the accelerated multicast stream address and forwarding QoS classification                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <MULTICAST-IP>        | Specify a list of multicast addresses and classifications. Packets are accelerated when the destination address matches.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| autodetect            | Lets the system to automatically detect multicast streams to be accelerated<br>This option allows the administrator to convert multicast packets to unicast in order to provide better overall airtime utilization and performance. The system can be configured to automatically detect multicast streams and convert them to unicast, or specify which multicast streams are to be converted to unicast. When the stream is converted and being queued up for transmission, there are a number of classification mechanisms applied to the stream and the administrator can select what type of classification they would want. Classification types are trust, voice, video, best effort, and background. |
| classification        | Optional. Defines the QoS classification to apply to a multicast stream. The following options are available: <ul style="list-style-type: none"><li>• background</li><li>• best effort</li><li>• trust</li><li>• video</li><li>• voice</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Examples

### *rate-limit (meshpoint-qos-policy)*

Configures the rate limiting of traffic on a per meshpoint or per neighbor basis

Excessive traffic can cause performance issues or bring down the network entirely. Excessive traffic, bombardments and interference are caused by numerous sources, such as network loops, faulty devices, or malicious software (such as a worm or virus) that has infected one or more branch-level devices. Rate limiting limits the maximum rate sent to or received from the wireless network (and meshpoint) per neighbor. It prevents any single user from overwhelming the wireless network. It also provides differential service for service providers. An administrator can set separate QoS rate limit configurations for data transmitted from the network and data transmitted from a mesh point's neighbor.

Before defining rate limit thresholds for meshpoint transmit and receive traffic, it is recommended that you define the normal number of ARP, broadcast, multicast, and unknown unicast packets that typically

transmit and receive from each supported WMM access category. If thresholds are defined too low, normal network traffic (required by end-user devices) is dropped, resulting in intermittent outages and performance problems.

A connected neighbor can also have QoS rate limit settings defined in both the transmit and receive direction.

**Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

**Syntax**

```
rate-limit [meshpoint|neighbor]
rate-limit [meshpoint|neighbor] [from-air|to-air] {max-burst-size <2-1024>/rate
<50-1000000>}
rate-limit [meshpoint|neighbor] [from-air|to-air]
{red-threshold [background <0-100>/best-effort <0-100>/video <0-100>/voice <0-100>]}
```

**Parameters**

```
rate-limit [meshpoint|neighbor] [from-air|to-air] {max-burst-size <2-1024>/rate
<50-1000000>}
```

|           |                                                                                                                                                                                                                                   |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| meshpoint | Configures rate limit parameters for all data received from any meshpoint in the mesh network. This option is disabled by default.                                                                                                |
| neighbor  | Configures rate limit parameters for neighboring meshpoint devices. Enables rate limiting for data transmitted from the client to its associated access point radio and connected controller. This option is disabled by default. |
| from-air  | Configures rate limits for traffic from the wireless neighbor to the network.                                                                                                                                                     |
| to-air    | Configures rate limits for traffic from the network to the wireless neighbor.                                                                                                                                                     |

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| max-burst-size<br><2-1024> | <p>Optional. Configures the maximum burst size in kilobytes.</p> <ul style="list-style-type: none"> <li>• &lt;2-1024&gt; – Set a value from 2 - 1024 kbytes.</li> </ul> <p>For a meshpoint: The smaller the burst, the less likely that the transmit packet transmission results in congestion for the meshpoint's client destinations. By trending the typical number of ARP, broadcast, multicast and unknown unicast packets over a period of time, the average rate for each access category can be obtained. Once a baseline is obtained, administrators should then add a 10% margin (minimally) to allow for traffic bursts at the site. The default burst size is 320 kbytes.</p> <p>For a neighbor: The smaller the burst, the less likely the transmit packet transmission will result in congestion for the wireless client. The default burst size is 64 kbytes.</p> |
| rate<br><50-1000000>       | <p>Optional. Defines a receive or transmit rate limit in kilobytes per second</p> <ul style="list-style-type: none"> <li>• &lt;50-1000000&gt; – Set a value from 50 - 1000000 kbps.</li> </ul> <p>For a meshpoint: This limit constitutes a threshold for the maximum the number of packets transmitted or received over the meshpoint (from all access categories). Traffic that exceeds the defined rate is dropped and a log message is generated. The default setting is 5000 kbps.</p> <p>For a neighbor: This limit constitutes a threshold for the maximum the number of packets transmitted or received (from all access categories). Traffic that exceeds the defined rate is dropped by the client and a log message is generated. The default rate is 1,000 kbps.</p>                                                                                                 |

```
rate-limit [meshpoint|neighbor] [from-air|to-air]
{red-threshold [background <0-100>|best-effort <0-100>|video <0-100>|voice <0-100>]}
```

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| to-air                 | Configures rate limits for traffic from the network to the wireless neighbor                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| red-threshold          | Optional. Configures RED (random early detection) threshold for traffic class                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| background<br><0-100>  | <p>The following keyword is applicable to the 'from-air' and 'to-air' traffics.</p> <ul style="list-style-type: none"> <li>• background &lt;0-100&gt; – Configures the threshold for low priority (background) traffic</li> <li>• &lt;0-100&gt; – Specify a value from 0 - 100.</li> </ul> <p>For a meshpoint: This is a percentage of the maximum burst size for low priority traffic. Background traffic exceeding the defined threshold is dropped and a log message is generated. Background traffic consumes the least bandwidth of any access category, so this value can be set to a lower value once a general transmit rate is known by the network administrator (using a time trend analysis). The default threshold is 50%.</p> <p>For a neighbor: This is a percentage of the maximum burst size for low priority traffic. Background traffic exceeding the defined threshold is dropped by the client and a log message is generated. The default threshold is 50%.</p> |
| best-effort<br><0-100> | <p>The following keyword is applicable to the 'from-air' and 'to-air' traffics.</p> <ul style="list-style-type: none"> <li>• best-effort &lt;0-100&gt; – Configures the threshold for best-effort traffic</li> <li>• &lt;0-100&gt; – Specify a value from 0 - 100.</li> </ul> <p>For a meshpoint: This is a percentage of the maximum burst size for normal priority traffic. Best effort traffic exceeding the defined threshold is dropped and a log message is generated. Best effort traffic consumes little bandwidth, so this value can be set to a lower value once a general transmit rate is known by the network administrator (using a time trend analysis). The default threshold is 50%.</p> <p>For a neighbor: This is a percentage of the maximum burst size for normal traffic. Best effort traffic exceeding the defined threshold is dropped by the client and a log message is generated. The default threshold is 50%.</p>                                        |

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <a href="#">no (meshpoint-qos-policy)</a> on page 1786 | Resets traffic rate limits for this meshpoint QoS policy |
|--------------------------------------------------------|----------------------------------------------------------|

*no (meshpoint-qos-policy)*

Negates the commands for meshpoint QoS policy or resets their values to their default

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
no [accelerated-multicast|rate-limit]
no accelerated-multicast [<MULTICAST-IP>|autodetect]
no rate-limit [meshpoint|neighbor] [from-air|to-air] {max-burst-size|rate}
no rate-limit [meshpoint|neighbor] [from-air|to-air] {red-threshold [background|
best-effort|video|voice]}
```

### Parameters

```
no <PARAMETERS>
```

```
no <PARAMETERS> Removes or reverts this meshpoint QoS policy settings to default based on the parameters
passed
```

### Examples

```
nx9500-6C8809(config-meshpoint-qos-test)#show context
meshpoint-qos-policy test

## meshpoint-device-config-instance

This `meshpoint-device` command configures an access point to use a defined meshpoint. To configure this feature use one of the following options:

- navigate to the device profile config context (used when configuring access point profile on a controller)
- navigate to the device's config context using the self command (used when configuring a logged on access point)

*Supported in the following platforms:*

- Access Points — AP 6522, AP 6532, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 81XX

### Syntax

```
meshpoint-device <MESHPOINT-NAME>
```

## Parameters

meshpoint-device <MESHPOINT-NAME>

|                  |                                                                                                 |
|------------------|-------------------------------------------------------------------------------------------------|
| meshpoint-device | Configures the AP as a meshpoint device and sets its parameters                                 |
| <MESHPOINT-NAME> | Specify the name of the meshpoint to configure the AP with (should be existing and configured). |

## Example

In the following examples, the meshpoint is applied to an access point profile.

```
nx9500-6C8809(config)#profile ap8432 testAP8432
nx9500-6C8809(config-profile-testAP8432)#meshpoint-device TestMeshpoint
nx9500-6C8809(config-profile-testAP8432-meshpoint-TestMeshpoint)#?
```

Mesh Point Device Mode commands:

```
acs Configure auto channel selection parameters
exclude Exclude neighboring Mesh Devices
hysteresis Configure path selection SNR hysteresis values
monitor Event Monitoring
no Negate a command or set its defaults
path-method Path selection method used to find a root node
preferred Configure preferred path parameters
root Set this meshpoint as root
root-select Root selection method parameters

clrscr Clears the display screen
commit Commit all changes made in this session
do Run commands from Exec mode
end End current mode and change to EXEC mode
exit End current mode and down to previous mode
help Description of the interactive help system
revert Revert changes
service Service Commands
show Show running system information
write Write running configuration to memory or terminal
```

```
nx9500-6C8809(config-profile-testAP8432-meshpoint-TestMeshpoint)#
ap8432-070235(config-device-74-67-F7-07-02-35)#meshpoint-device test
ap8432-070235(config-device-74-67-F7-07-02-35-meshpoint-test)#?
```

Mesh Point Device Mode commands:

```
acs Configure auto channel selection parameters
exclude Exclude neighboring Mesh Devices
hysteresis Configure path selection SNR hysteresis values
monitor Event Monitoring
no Negate a command or set its defaults
path-method Path selection method used to find a root node
preferred Configure preferred path parameters
root Set this meshpoint as root
root-select Root selection method parameters

```

The following table summarizes the meshpoint-device configuration mode commands.

**Table 63: Meshpoint-Device Config Commands**

| Command                                                            | Description                                                                             |
|--------------------------------------------------------------------|-----------------------------------------------------------------------------------------|
| <a href="#">acs (meshpoint-device-config)</a> on page 1789         | Enables ACS (Automatic Channel Selection) on this meshpoint device (access point)       |
| <a href="#">exclude (meshpoint-device-config)</a> on page 1794     | Excludes neighboring mesh devices                                                       |
| <a href="#">hysteresis (meshpoint-device-config)</a> on page 1795  | Configures path selection SNR hysteresis values on this meshpoint-device (Access Point) |
| <a href="#">monitor (meshpoint-device-config)</a> on page 1796     | Enables monitoring of critical resource and primary port links on a meshpoint device    |
| <a href="#">path-method (meshpoint-device-config)</a> on page 1796 | Configures the method used to select the path to the root node in a mesh network        |
| <a href="#">preferred (meshpoint-device-config)</a> on page 1797   | Configures the preferred path parameters for a meshpoint device                         |
| <a href="#">root (meshpoint-device-config)</a> on page 1799        | Configures a meshpoint device as the root meshpoint                                     |
| <a href="#">root-select (meshpoint-device-config)</a> on page 1798 | Configures this meshpoint device as the cost root                                       |
| <a href="#">no (meshpoint-device-config)</a> on page 1800          | Negates the commands for a meshpoint device or resets values to default                 |

#### *acs (meshpoint-device-config)*

Enables ACS (Automatic Channel Selection) on this meshpoint device (access point). When enabled, this feature automatically selects the best channel for a meshpoint-device radio based on the device configuration, channel conditions, and network layout.

In a wireless network deployment, it is advantageous for network devices to have the ability to operate in multiple channels and not be limited to only a single channel. Multiple channels increase the bandwidth and throughput of the wireless network. In such a scenario, each network device must have a mechanism to dynamically select a suitable channel of operation. ACS provides the required mechanism for a MCX enabled device.

Use this command to configure the ACS settings and override the default meshpoint configurations.

#### **Supported in the following platforms:**

- Access Points — AP 6522, AP 6532, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7632, AP 7662, AP 8432, AP 8533

## Syntax

```
acs [channel-hold-time|channel-switch-delta|channel-width|ocs-duration|ocs-frequency|

| <code>no (meshpoint-device-config)</code> on page 1800 | Reverts the configured ACS settings to default |
|--------------------------------------------------------|------------------------------------------------|

*exclude (meshpoint-device-config)*

Enables wired-peer (that are wired MiNT level-1 neighbors) exclusion

### Supported in the following platforms:

- Access Points — AP 6522, AP 6532, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7632, AP 7662, AP 8432, AP 8533

### Syntax

```
exclude wired-peer mint-level-1
```

### Parameters

```
exclude wired-peer mint-level-1
```

|                         |                                                                                                                                                 |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| exclude wired-peer      | Excludes neighboring mesh devices                                                                                                               |
| wired-peer mint-level-1 | Excludes neighboring wired mesh devices with MiNTlevel-1 link<br>When enabled, all neighboring wired mesh devices are excluded from mesh links. |

### Examples

```
rfs4000-229D58(config-profile-testAP71XX-meshpoint-test)#exclude wired-peer mint-level-1
rfs4000-229D58(config-profile-testAP71XX-meshpoint-test)#show context
meshpoint-device test

rfs4000-229D58(config-profile-testAP71XX-meshpoint-test)#
```

## Related Commands

`no (meshpoint-device-config)` on page 1800 Disables wired-peer exclusion on this meshpoint

### *hysteresis (meshpoint-device-config)*

Configures path selection SNR hysteresis values on this meshpoint-device (access point). These are settings that facilitate dynamic path selection. Configuring hysteresis prevents frequent re-ranking of the shortest path cost.

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6532, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7632, AP 7662, AP 8432, AP 8533

#### Syntax

```
hysteresis [min-threshold|period|root-sel-snr-delta|snr-delta]
hysteresis [min-threshold <-100-0>|period <0-600>|root-sel-snr-delta <1-100>|
snr-delta <1-100>]
```

#### Parameters

```
hysteresis [min-threshold <-100-0>|period <0-600>|root-sel-snr-delta <1-100>|
snr-delta <1-100>]
```

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| min-threshold<br><-100-0>     | Configures the minimum signal strength that a device should have to be considered a likely candidate in the mesh route (to the mesh root node) selection process. <ul style="list-style-type: none"><li>• &lt;-100-0&gt; - Specify a value from -100 - 0 dB. ## Related Commands

`no (meshpoint-device-config)` on page 1800 Removes the configured path selection SNR hysteresis values

### *monitor (meshpoint-device-config)*

Enables monitoring of critical resource and primary port links. It also configures the action taken in case a critical resource goes down or a primary port link is lost.

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6532, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7632, AP 7662, AP 8432, AP 8533

#### Syntax

```
monitor [critical-resource|primary-port-link-loss] action no-root
```

#### Parameters

```
monitor [critical-resource|primary-port-link-loss] action no-root
```

|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| critical-resource      | Enables critical resource down event monitoring                                                                                                                                                                                                                                                                                           |
| primary-port-link-loss | Enables primary port link loss event monitoring                                                                                                                                                                                                                                                                                           |
| action                 | The following are common to all of the above: <ul style="list-style-type: none"><li>• action - Sets the action taken if a critical resource goes down or if a primary port link is lost</li><li>• no-root - Changes the meshpoint to be non root (this is the action taken in case any of the above mentioned two events occur)</li></ul> |

#### Examples

```
nx9500-6C8809(config-profile-AP71XXTestProfile-meshpoint-test)#monitor critical-resource
action no-root
nx9500-6C8809(config-profile-AP71XXTestProfile-meshpoint-test)#show context
meshpoint-device test
name test
monitor critical-resource action no-root
nx9500-6C8809(config-profile-AP71XXTestProfile-meshpoint-test)#
```

## Related Commands

`no (meshpoint-device-config)` on page 1800 Disables monitoring of critical resource and primary port links.

### *path-method (meshpoint-device-config)*

Configures the path selection method used on a meshpoint device. This is the method used to select the route to the root node within a mesh network.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6532, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7632, AP 7662, AP 8432, AP 8533

### Syntax

```
path-method [bound-pair|mobile-snr-leaf|snr-leaf|uniform]
```

### Parameters

```
path-method [bound-pair|mobile-snr-leaf|snr-leaf|uniform]
```

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| path-method     | Sets the method used to select the path to the root node in a mesh network                                                                                                                                                                                                                                                                                                                                                                                                              |
| bound-path      | Enables a meshpoint to form an exclusive path with only one other meshpoint. Select this option to bind one mesh point connection at a time. Once established, other mesh point connection requests are denied.                                                                                                                                                                                                                                                                         |
| mobile-snr-leaf | Configures the path selection method as mobile-snr-leaf. When selected, the path to the root node is selected based on the SNR (Signal-to-Noise Ratio) to a neighboring device. This option allows meshpoint devices to select a neighbor with the strongest SNR. Meshpoint devices using the mobile-snr-leaf method are non-forwarding nodes in the meshpoint traffic.<br><br><b>Note:</b> Select this option for VMM (Vehicular Mounted Modem) access points or other mobile devices. |
| snr-leaf        | This option allows meshpoints to select a neighbor with the strongest SNR. It is similar to the mobile-snr-leaf option, but is not applicable to mobile devices, such as VMMs.                                                                                                                                                                                                                                                                                                          |
| uniform         | Indicates the path selection method is uniform. When selected, two paths will be considered equivalent if the average goodput is the same for both paths. This is the default setting.<br><br><b>Note:</b> Select this option for infrastructure devices.                                                                                                                                                                                                                               |

### Examples

```
nx9500-6C8809(config-profile-AP71XXTestProfile-meshpoint-test)#path-method mobile-snr-leaf
nx9500-6C8809(config-profile-AP71XXTestProfile-meshpoint-test)#show context
meshpoint-device TEST
 name TEST
 path-method mobile-snr-leaf
nx9500-6C8809(config-profile-AP71XXTestProfile-meshpoint-test)#
```

*preferred (meshpoint-device-config)*

Configures the preferred path parameters for this meshpoint device

### Supported in the following platforms:

- Access Points — AP 6522, AP 6532, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7632, AP 7662, AP 8432, AP 8533

### Syntax

```
preferred [neighbor <MAC>|root <MAC>|interface [2.4GHz|4.9GHz|5GHz]]
```

### Parameters

```
preferred [neighbor <MAC>|root <MAC>|interface [2.4GHz|4.9GHz|5GHz]]
```

|                                |                                                                      |
|--------------------------------|----------------------------------------------------------------------|
| preferred                      | Configures the preferred path parameters                             |
| neighbor <MAC>                 | Adds the MAC address of a neighbor meshpoint as a preferred neighbor |
| root <MAC>                     | Adds the MAC address of a root meshpoint as a preferred root         |
| interface [2.4GHz 4.9GHz 5GHz] | Sets the preferred interface                                         |

### Examples

```

nx9500-6C8809(config-profile-AP71XXTestProfile-meshpoint-test)#preferred neighbor
11-22-33-44-55-66
nx9500-6C8809(config-profile-AP71XXTestProfile-meshpoint-test)#preferred root
22-33-44-55-66-77
nx9500-6C8809(config-profile-AP71XXTestProfile-meshpoint-test)#preferred interface 5GHz
nx9500-6C8809(config-profile-AP71XXTestProfile-meshpoint-test)#show context
meshpoint-device test
 name test
 preferred root 22-33-44-55-66-77
 preferred neighbor 11-22-33-44-55-66
 preferred interface 5GHz
 monitor critical-resource action no-root
nx9500-6C8809(config-profile-AP71XXTestProfile-meshpoint-test)#

```

### *root-select (meshpoint-device-config)*

Configures this mesh-point device as the cost. root

### Supported in the following platforms:

- Access Points — AP 6522, AP 6532, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7632, AP 7662, AP 8432, AP 8533

### Syntax

```
root-select cost-root
```

### Parameters

```
root-select cost-root
```

|             |                                                                                                                                         |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| root-select | Configures this meshpoint device as the cost root. This is necessary for dynamic root selection                                         |
| cost-root   | process.<br>Select this option to set the meshpoint as the cost root for meshpoint root selection. This setting is disabled by default. |

### Examples

```

ap8432-070235(config-device-74-67-F7-07-02-35-meshpoint-test)#root-select cost-root
ap8432-070235(config-device-74-67-F7-07-02-35-meshpoint-test)#show context
meshpoint-device test
 root select-method auto-mint
 root-select cost-root
ap8432-070235(config-device-74-67-F7-07-02-35-meshpoint-test)#

```

## Related Commands

`no (meshpoint-device-config)` on page 1800 Removes this mesh-point device as the cost. root.

### *root (meshpoint-device-config)*

Configures this meshpoint device as the root meshpoint

You can optionally use the `select-method` option to enable dynamic mesh selection. When enabled, this option overrides `root` or `no-root` configuration and uses the selection method.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6532, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7632, AP 7662, AP 8432, AP 8533

### Syntax

```
root {select-method [auto-mint|auto-proximity]}
```

### Parameters

```
root {select-method [auto-mint|auto-proximity]}
```

|                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>root</code>                         | Configures this meshpoint device as the root meshpoint                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>select-method auto-mint]</code>     | <p>Optional. Enables dynamic mesh selection. When enabled, this option overrides <code>root</code> or <code>no-root</code> configuration and chooses the selection method.</p> <ul style="list-style-type: none"><li>• <code>auto-mint</code> - Enables dynamic root selection using Auto-MiNT (based on path cost)</li></ul> <p>The Auto-Mint or Cost Method dynamically determines the root/non-root configuration of a meshpoint by:</p> <ul style="list-style-type: none"><li>• Monitoring and ranking the signal strength and path cost of neighboring mesh points.</li><li>• Setting the configuration to:<ul style="list-style-type: none"><li>• <code>non-root</code>: If the link with the shortest path to the cost-root mesh device is a MCX meshpoint link</li><li>• <code>root</code>: If the link with the shortest path to the cost-root mesh device is a non MCX meshpoint link (wired link).</li></ul></li><li>• This requires that the meshpoint device, in the brain car, be configured as the 'cost root' and the 'cost root' meshpoint-device be the I2 gateway to the controller. Use the <code>root-select &gt; cost-root</code> command to configure a meshpoint-device as 'cost-root'.</li><li>• Using signal strength of neighboring meshpoint as the sole metric to determine the next mesh hop to the root.</li><li>• Loop detection with both meshpoints in a car select non-root and form a mesh link with the same root</li></ul> |
| <code>select-method auto-proximity</code> | Enables dynamic root selection using meshpoint proximity. When <code>auto-proximity</code> is selected, root selection is based on signal strength of candidate roots.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

### Examples

```
nx9500-6C8809(config-profile-testAP8432-meshpoint-test)#root select-method auto-mint
nx9500-6C8809(config-profile-testAP8432-meshpoint-test)#show context
meshpoint-device test
 name test
 root select-method auto-mint
 preferred root 22-33-44-55-66-77
```

```

 preferred neighbor 11-22-33-44-55-66
 preferred interface 5GHz
 monitor critical-resource action no-root
nx9500-6C8809(config-profile-testAP8432-meshpoint-test)#
ap8432-070235(config-device-74-67-F7-07-02-35-meshpoint-test)#root select-method auto-mint

|--------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>no (meshpoint-device-config)</code> on page 1800 | Removes the configuration of this meshpoint device as a root meshpoint. Also allows you to disable dynamic mesh selection (if enabled). |
|--------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|

*no (meshpoint-device-config)*

Negates the commands for a meshpoint device or resets values to default

### Supported in the following platforms:

- Access Points — AP 6522, AP 6532, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7632, AP 7662, AP 8432, AP 8533

### Syntax

```

no [acs|exclude|hysteresis|monitor|path-method|preferred|root|root-select]
no acs [channel-hold-time|channel-switch-delta|channel-width|ocs-duration|
ocs-frequency|path-min|path-threshold|preferred-interface-tolerance-period|
preferred-radio-interface|priority-meshpoint|sample-count|snr-delta|
signal-threshold|tolerance-period] [2.4GHZ|5GHz]
no exclude wired-peer mint-level-1
no hysteresis [min-threshold|period|root-sel-snr-delta|snr-delta]
no monitor [critical-resource|primary-port-link-loss]
no [path-method|root {select-method}]
no root-select cost-root
no preferred [interface|root|neighbor]

```

### Parameters

no <PARAMETERS>

|                 |                                                                                             |
|-----------------|---------------------------------------------------------------------------------------------|
| no <PARAMETERS> | Removes or reverts this meshpoint device settings to default based on the parameters passed |
|-----------------|---------------------------------------------------------------------------------------------|

### Examples

```

nx9500-6C8809(config-profile-testAP8432-meshpoint-test)#show context
 meshpoint-device test
 name test
 root
 preferred root 22-33-44-55-66-77
 preferred neighbor 11-22-33-44-55-66
 preferred interface 5GHz

```

# PASSPOINT POLICY

## PASSPOINT POLICY

---

A passpoint policy provides an interoperable platform for streamlining Wi-Fi access to access points deployed as public hotspots. Passpoint is supported across a wide range of wireless network deployment scenarios and client devices. Passpoint makes connecting to Wi-Fi networks easier by authenticating the user with an account based on an existing relationship, such as the user's mobile carrier or broadband ISP.

To migrate to the passpoint policy configuration mode, use the following command:

```
<DEVICE>(config)#passpoint-policy <POLICY-NAME>
rfs4000-229D58(config)#passpoint-policy test
rfs4000-229D58(config-passpoint-policy-test)#
rfs4000-229D58(config-passpoint-policy-test)#?
Passpoint Policy Mode commands:
 3gpp Configure a 3gpp plmn (public land mobile network) id
 access-network-type Set the access network type for the hotspot
 connection-capability Configure the connection capability for the hotspot
 domain-name Add a domain-name for the hotspot
 hessid Set a homogeneous ESSID value for the hotspot
 internet Advertise the hotspot having internet access
 ip-address-type Configure the advertised ip-address-type
 nai-realm Configure a NAI realm for the hotspot
 net-auth-type Add a network authentication type to the hotspot
 no Negate a command or set its defaults
 operator Add configuration related to the operator of the
 hotspot
 osu Online signup
 roam-consortium Add a roam consortium for the hotspot
 venue Set the venue parameters of the hotspot
 wan-metrics Set the wan-metrics of the hotspot

 clrscr Clears the display screen
 commit Commit all changes made in this session
 do Run commands from Exec mode
 end End current mode and change to EXEC mode
 exit End current mode and down to previous mode
 help Description of the interactive help system
 revert Revert changes
 service Service Commands
 show Show running system information
 write Write running configuration to memory or terminal

rfs4000-229D58(config-passpoint-policy-test)#
```

### passpoint-policy

The following table summarizes the Passpoint Policy configuration mode commands:

**Table 64: Passpoint-Policy Config Mode Commands**

| Command                                            | Description                                                                                        |
|----------------------------------------------------|----------------------------------------------------------------------------------------------------|
| <a href="#">3gpp</a> on page 1803                  | Configures a 3gpp (3rd Generation Partnership Project) PLMN (Public Land Mobile Network) ID        |
| <a href="#">access-network-type</a> on page 1804   | Configures the access network type element in this hotspot                                         |
| <a href="#">connection-capability</a> on page 1805 | Configures the connection capability element in this passpoint policy                              |
| <a href="#">domain-name</a> on page 1807           | Configures the RF Domains to which this hotspot is applicable                                      |
| <a href="#">hessid</a> on page 1807                | Configures the HESSID (Homogeneous Extended Service Set Identifier) for a specified hotspot zone   |
| <a href="#">internet</a> on page 1808              | Advertises the availability of Internet access in this hotspot                                     |
| <a href="#">ip-address-type</a> on page 1809       | Advertises the IP address type used in this hotspot.                                               |
| <a href="#">nai-realm</a> on page 1810             | Configures a NAI (Network Access Identifier) realm name and enters its configuration mode          |
| <a href="#">net-auth-type</a> on page 1813         | Configures the network authentication type used in this hotspot                                    |
| <a href="#">operator</a> on page 1814              | Configures the operator friendly name for this hotspot                                             |
| <a href="#">osu</a> on page 1815                   | Configures an OSU (online sign up) SSID/provider and enters its configuration mode                 |
| <a href="#">roam-consortium</a> on page 1822       | Configures the list of Roaming Consortium OIs (Organization Identifiers) supported on this hotspot |
| <a href="#">venue</a> on page 1823                 | Configures the venue group and type for this passpoint policy                                      |
| <a href="#">wan-metrics</a> on page 1828           | Configures the WAN performance metrics for this hotspot                                            |
| <a href="#">no</a> on page 1829                    | Removes or reverts passpoint policy configuration                                                  |

**Note**

The input parameter <HOSTNAME>, wherever used in syntaxes across this chapter, cannot include an underscore ( \_ ) character. In other words, the name of a device cannot contain an underscore.

**Note**

For more information on common commands (clrscr, commit, help, revert, service, show, write, and exit), see [COMMON COMMANDS](#).

*3gpp*

Configures a 3GPP (3rd Generation Partnership Project) PLMN (Public Land Mobile Network) information. The 3GPP PLMN information is a combination of the MCC (Mobile Country Code) and MNC (Mobile Network Code). This MCC and MNC combination uniquely identifies a cellular operator. For example, Telstar Corporation Ltd. in Australia is identified by MCC 505 and MNC 001.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
3gpp mcc <MOBILE-COUNTRY-CODE> mnc <MOBILE-NETWORK-CODE> {description <LINE>}
```

### Parameters

```
3gpp mcc <MOBILE-COUNTRY-CODE> mnc <MOBILE-NETWORK-CODE> {description <LINE>}
```

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3gpp                      | Configures the 3GPP PLMN information that is returned in response to an ANQP query                                                                                                                                                                                                                                                                                                                                                                                                         |
| mcc <MOBILE-COUNTRY-CODE> | Specifies the MCC. The MCC is a two or three digit decimal value. For example, the MCC for Australia is 505.                                                                                                                                                                                                                                                                                                                                                                               |
| mnc <MOBILE-NETWORK-CODE> | Specifies the MNC. The MNC is a two or three decimal value used in combination with the MCC to uniquely identify a mobile network operator. The MNC and MCC combination (also known as the MCC/MNC tuple) forms the first five or six digits of the IMSI's (International Mobile Subscriber Identity).<br><br><b>Note:</b> If the MCC and MNC values are not configured, the hotspot will not return the element in an ANQP capability request and ignores any ANQP query for the element. |
| description <LINE>        | Optional. Configures a description that uniquely identifies this PLMN. Provide a description not exceeding 64 characters in length.                                                                                                                                                                                                                                                                                                                                                        |

### Examples

```
rf4000-229D58(config-passpoint-policy-test)#3gpp mcc 505 mnc 14
rf4000-229D58(config-passpoint-policy-test)#3gpp mcc 310 mnc 970
rf4000-229D58(config-passpoint-policy-test)#show context
hotspot2-policy test
 3gpp mcc 310 mnc 970
 3gpp mcc 505 mnc 14
rf4000-229D58(config-passpoint-policy-test)#
```

### access-network-type

Configures the access network type for this hotspot. The beacons and probe responses communicate the type of hotspot (public, private, guest-use, emergency, etc.) to clients seeking access.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
access-network-type [chargeable-public|emergency-services|experimental|free-public|
personal-device|private|private-guest|wildcard]
```

## Parameters

```
access-network-type [chargeable-public|emergency-services|experimental|free-public|
personal-device|private|private-guest|wildcard]
```

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| access-network-type | Select the access network type for this hotspot. The options are: <ul style="list-style-type: none"><li>• chargeable-public – The network type is a chargeable public network.</li><li>• emergency-services – The network is used to provide emergency services only.</li><li>• experimental – The network is used for test or experimental purposes only.</li><li>• free-public – The network type is a free public.</li><li>• personal-device – The network is used for personal devices only.</li><li>• private – The network is a private network.</li><li>• private-guest – The network is a private network with guest access (default setting).</li><li>• wildcard – Includes all access network types.</li></ul> |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**Note:** If the network type is set to chargeable-public, probe responses advertise this hotspot as a chargeable-public hotspot.

## Examples

```
rfs4000-229D58(config-passpoint-policy-test)#access-network-type chargeable-public
rfs4000-229D58(config-passpoint-policy-test)#show context
hotspot2-policy test
 access-network-type chargeable-public
 3gpp mcc 310 mnc 970
 3gpp mcc 505 mnc 14
rfs4000-229D58(config-passpoint-policy-test)#
```

|----|--------------------------------------------------------------|
| no | Reverts to the default access network type setting (private) |
|----|--------------------------------------------------------------|

## *connection-capability*

Configures the connection capability element in this passpoint policy. When configured, it communicates which ports are open or closed on the Hotspot, in response to an ANQP query.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
connection-capability [ftp|http|icmp|ip-protocol|ipsec-vpn|pptp-vpn|sip|ssh|tls-vpn]
connection-capability [ftp|http|icmp|ipsec-vpn|pptp-vpn|sip|ssh|tls-vpn] [closed|open|
unknown]
connection-capability ip-protocol <0-255> port <0-65535> [closed|open|unknown]
```

## Parameters

connection-capability [ftp|http|icmp|ip-protocol|ipsec-vpn|pptp-vpn|sip|ssh|tls-vpn]

|                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| connection-capability                      | Configures the connection capability element in this passpoint policy                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| ftp                                        | Specifies the protocol type as FTP. Configures TCP port 20.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| http                                       | Specifies the protocol type as HTTP. Configures TCP port 80.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| icmp                                       | Specifies the protocol type as ICMP                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| ipsec-vpn                                  | Specifies the protocol type as IPSEC VPN. Configures ESP and UDP ports 500 and 4500.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| pptp-vpn                                   | Specifies the protocol type as PPTP VPN. Configures TCP port 1723.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| sip                                        | Specifies the protocol type as SIP. Configures TCP port 5060 and UDP port 5060.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| ssh                                        | Specifies the protocol type as SSH. Configures TCP port 20                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| tls-vpn                                    | Specifies the protocol type as TLS VPN. Configures TCP port 443.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| connection-capability                       | Configures the connection capability element in this passpoint policy                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| ip-protocol<br><0-255>                      | Identifies the IP protocol by the protocol's number. For example, for SMP (simple message protocol) specify 121.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| port <0-65535><br>[closed open <br>unknown] | <p>After specifying the IP protocol type, specify the port number.</p> <ul style="list-style-type: none"> <li>port &lt;0-65535&gt; – Select a port for the IP protocol identified.</li> </ul> <p>After specifying the port number, specify the port status.</p> <ul style="list-style-type: none"> <li>closed – Specifies that the port(s) is/are closed</li> <li>open – Specifies that the port(s) is/are open</li> <li>unknown – Specifies that the port(s) status is not known</li> </ul> <p><b>Note:</b> When the connection capability element is not configured, the hotspot does not return the element in an ANQP capability request and ignores any ANQP query for the element.</p> |

## Examples

```
rfs4000-229D58(config-passpoint-policy-test)#connection-capability 1 ip-protocol 2 port 10
closed
rfs4000-229D58(config-passpoint-policy-test)#show context
hotspot2-policy test
access-network-type chargeable-public
connection-capability ip-protocol 2 port 10 closed
3gpp mcc 310 mnc 970
3gpp mcc 505 mnc 14
rfs4000-229D58(config-passpoint-policy-test)#
```

## Related Commands

**no** Removes the configured connection capability element on the passpoint policy

### *domain-name*

Configures the RF Domain(s) that are returned in response to an ANQP query

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

domain-name <DOMAIN-NAME>

#### Parameters

domain-name <DOMAIN-NAME>

domain-name <DOMAIN-NAME> Specify the RF Domain name

**Note:** An hotspot can be applied across multiple RF Domains.

#### Examples

```
rfs4000-229D58(config-passpoint-policy-test)#domain-name TechPubs
rfs4000-229D58(config-passpoint-policy-test)#show context
hotspot2-policy test
 access-network-type chargeable-public
 connection-capability ip-protocol 2 port 10 closed
 domain-name TechPubs
 3gpp mcc 310 mnc 970
 3gpp mcc 505 mnc 14
rfs4000-229D58(config-passpoint-policy-test)#
```

## Related Commands

**no** Removes the RF Domain mapped to this passpoint policy

### *hessid*

Configures the HESSID (Homogeneous Extended Service Set Identifier) for the hotspot. The HESSID uniquely identifies a hotspot provider within a zone. This is essential in zones (such as an airport or shopping mall) having multiple hotspot service providers with overlapping coverage.

An HESSID is a 6 (six) byte identifier that uniquely identifies a set of APs belonging to the same network and exhibiting same network behaviour. It is the BSSID of one of the devices (AP) in the zone. When not configured, the radio's BSSID is used as the HESSID.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
hessid <MAC>
```

### Parameters

```
hessid <MAC>
```

|              |                                                                     |
|--------------|---------------------------------------------------------------------|
| hessid <MAC> | Specify a unique 6 (six) byte identifier for this passpoint policy. |
|--------------|---------------------------------------------------------------------|

### Examples

```
rfs4000-229D58(config-passpoint-policy-test)#hessid 00-23-68-88-0D-A7
rfs4000-229D58(config-passpoint-policy-test)#show context
hotspot2-policy test
 access-network-type chargeable-public
 connection-capability ip-protocol 2 port 10 closed
 domain-name TechPubs
 hessid 00-23-68-88-0D-A7
 3gpp mcc 310 mnc 970
 3gpp mcc 505 mnc 14
rfs4000-229D58(config-passpoint-policy-test)#
```

### Related Commands

|    |                                                                                                      |
|----|------------------------------------------------------------------------------------------------------|
| no | Removes the HESSID configured with this passpoint policy and reverts back to using the radio's BSSID |
|----|------------------------------------------------------------------------------------------------------|

### *internet*

Advertises the availability of Internet access on this hotspot. The Internet bit in the hotspot's beacon and probe responses indicates if Internet access is available or not. By default this feature is enabled.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
internet
```

### Parameters

None

### Examples

```
rfs4000-229D58(config-passpoint-policy-test)#internet
rfs4000-229D58(config-passpoint-policy-test)#
```

|-----------------|--------------------------------------------------|
| <code>no</code> | Removes Internet access on this passpoint policy |
|-----------------|--------------------------------------------------|

### *ip-address-type*

Advertises the IP address type used in this hotspot. This information is returned in response to ANQP queries.

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
ip-address-type [ipv4 | ipv6]
ip-address-type ipv4 [double-nat | not-available | port-restricted | port-restricted-double-nat |
port-restricted-single-nat | public | single-nat | unknown]
ip-address-type ipv6 [available | not-available | unknown]
```

#### Parameters

```
ip-address-type ipv4 [double-nat | not-available | port-restricted | port-restricted-double-nat |
port-restricted-single-nat | public | single-nat | unknown]
```

|                                         |                                                                                   |
|-----------------------------------------|-----------------------------------------------------------------------------------|
| <code>ip-address-type ipv4</code>       | Configures the IPv4 address type availability information                         |
| <code>double-nat</code>                 | Specifies double NATed private IPv4 address is available                          |
| <code>not-available</code>              | Specifies IPv4 address is not available                                           |
| <code>port-restricted</code>            | Specifies port-restricted IPV4 address is available                               |
| <code>port-restricted-double-nat</code> | Specifies port-restricted IPv4 address and double NATed IPv4 address is available |
| <code>port-restricted-single-nat</code> | Specifies port-restricted IPv4 address and single NATed IPv4 address is available |
| <code>public</code>                     | Specifies public IPv4 address is available                                        |
| <code>single-nat</code>                 | Specifies single NATed IPv4 address is available                                  |
| <code>unknown</code>                    | Specifies no information configured regarding the IPv4 address availability       |

```
ip-address-type ipv6 [available | not-available | unknown]
```

|                                   |                                                                             |
|-----------------------------------|-----------------------------------------------------------------------------|
| <code>ip-address-type ipv6</code> | Configures the IPv6 address type availability information                   |
| <code>available</code>            | Specifies IPv6 address is available                                         |
| <code>not-available</code>        | Specifies IPv6 address is not available                                     |
| <code>unknown</code>              | Specifies no information configured regarding the IPv6 address availability |

#### Examples

```
rfs4000-229D58(config-passpoint-policy-test)#ip-address-type ipv6 available
rfs4000-229D58(config-passpoint-policy-test)#show context
hotspot2-policy test
 access-network-type chargeable-public
```

```

connection-capability ip-protocol 2 port 10 closed
domain-name TechPubs
hessid 00-23-68-88-0D-A7
ip-address-type ipv6 available
3gpp mcc 310 mnc 970
3gpp mcc 505 mnc 14
rfs4000-229D58(config-passpoint-policy-test)#

```

## Related Commands

**no** Removes the IP address type configured for this passpoint policy

### *nai-realm*

Configures a NAI (Network Access Identifier) realm name and enters its configuration mode

The NAI is the user identity submitted by the hotspot requesting client during authentication. The standard syntax is user@realm. NAI is frequently used when roaming, to identify the user and assist in routing an authentication request to the user’s authentication server. The realm name is often the domain name of the service provider.

You can configure a list of NAI realm names of service providers operating within a specific hotspot zone. This NAI realm name list is presented in ANQP response to a NAI realm and NAI home realm query.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
nai-realm <NAI-REALM-NAME>
```

### Parameters

```
nai-realm <NAI-REALM-NAME>
```

### eap-method

Specifies the EAP authentication mechanisms supported by each of the service providers associated with this passpoint policy.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```

eap-method <1-10> [<1-255>|fast|gtc|identity|ikev2|ms-auth|mschapv2|otp|peap|psk|rsa-
public-key|
sim|tls|ttls] auth-param [credential|expanded-eap|expanded-inner-eap|inner-eap|non-eap-
inner|
tunn-eap-credential|vendor] [cert|hw-token|nfc-secure-elem|none|sim|soft-token|username-
password|usim|
vendor]

```

#### Parameters

```

eap-method <1-10> [<1-255>|fast|gtc|identity|ikev2|ms-auth|mschapv2|otp|peap|psk|rsa-
public-key|
sim|tls|ttls] auth-param [credential|expanded-eap|expanded-inner-eap|inner-eap|non-eap-
inner|
tunn-eap-credential|vendor] [cert|hw-token|nfc-secure-elem|none|sim|soft-token|username-
password|usim|
vendor]

```

|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| eap-method<br><1-10> | <p>Selects the EAP authentication method used and assigns it an index number</p> <ul style="list-style-type: none"> <li>• &lt;1-10&gt; - Specify an identifier for this EAP method from 1 - 10. The Index specified here is applied to this hotspot's EAP credential exchange and verification sessions. NAIs are often user identifiers in the EAP authentication protocol.</li> </ul> <p>A maximum of 10 (ten) authentication methods can be specified for every NAI realm. After creating the EAP authentication method, specify the associated authentication mechanisms (method types).</p> |
| <1-255>              | <p>Identifies the EAP authentication method type from the corresponding IANA (Internet Assigned Numbers Authority) number</p> <ul style="list-style-type: none"> <li>• &lt;1-255&gt; - Specify the IANA identity number for the authentication protocol from 1 - 255.</li> </ul>                                                                                                                                                                                                                                                                                                                 |
| fast                 | Specifies the EAP authentication method type as FAST (Flexible Authentication via Secure Tunneling)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| gtc                  | Specifies the EAP authentication method type as GTC (Generic Token Card)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| identity             | Specifies the EAP authentication method type as Identification                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| ikev2                | Specifies the EAP authentication method type as IKEv2 (Internet Key Exchange Protocol version 2)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| ms-auth              | Specifies the EAP authentication method type as MS-Auth (Microsoft Authentication)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| mschapv2             | Specifies the EAP authentication method type as MSCHAPv2 (Microsoft Challenge Handshake Authentication Protocol Version 2)                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| opt                  | Specifies the EAP authentication method type as OTP (One Time Password)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| peap                 | Specifies the EAP authentication method type as PEAP (Protected Extensible Authentication Protocol)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| psk                  | Specifies the EAP authentication method type as PSK (Pre-shared Key)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| rsa-public-key       | Specifies the EAP authentication method type as RSA public key protocol                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| sim                  | Specifies the EAP authentication method type as GSM SIM (Subscriber Identity Module)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| tls                  | Specifies the EAP authentication method type as TLS (Transport Layer Security)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| ttls                 | Specifies the EAP authentication method type as TTLS (Tunneled Transport Layer Security)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|                                                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| auth-param                                                                        | After specifying the EAP authentication method type, specify the authentication parameters. These parameters depend on the EAP authentication mechanism selected.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| [cert hw-token nfc-secure-elem none sim soft-token username-password usim vendor] | <p>The following parameters are common to all the above authentication parameters:</p> <ul style="list-style-type: none"> <li>• cert – Certificate</li> <li>• hw-token – Hardware token</li> <li>• nfc-secure-elem – NFC secure element</li> <li>• none – No credential</li> <li>• sim – Subscriber identity module</li> <li>• soft-token – Soft token</li> <li>• username-password – Username and password</li> <li>• usim – Universal subscriber identity module</li> <li>• vendor – Vendor specific credential</li> </ul> <p>If setting the authentication type to either <b>non-eap-inner</b>, <b>inner-eap-credential</b>, or <b>tunneleap-credential</b>, define an authentication value that must be shared with the EAP credential validation server resource.</p> <p>If setting the authentication type to either <b>expanded-eap</b> or <b>expanded-inner-eap</b>, set a required authentication vendor ID that must match the one utilized by the EAP server resource. The ID must be 6 characters in length.</p> <p>If required, enter a 2 - 510 character vendor-specific authentication data required for the selected authentication type. Enter the value in the a-FA -FO-9 format.</p> <p>Provide an authentication vendor type, used exclusively for the <b>expanded-eap</b> or <b>expanded-inner-eap</b> authentication types. The vendor type must be 8 characters in length.</p> |

```

### *net-auth-type*

Configures the network authentication type used in this hotspot. The details configured are returned in response to an ANQP query. Use this option to specify how W-iFi connection attempts are authenticated and validated using a dedicated redirection URL resource.

#### **Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000

- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
net-auth-type [accept-terms|dns-redirect|http-redirect|online-enroll] {url <URL>}
```

### Parameters

```
net-auth-type [accept-terms|dns-redirect|http-redirect|online-enroll] {url <URL>}
```

|               |                                                                                                                                                                                           |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| net-auth-type | Specifies the network authentication type used with this passpoint policy. The options are: <b>accept-terms</b> , <b>dns-redirect</b> , <b>http-redirect</b> , and <b>online-enroll</b> . |
| accept-terms  | Enables user acceptance of terms and conditions                                                                                                                                           |
| dns-redirect  | Enables DNS redirection of user                                                                                                                                                           |
| http-redirect | Enables HTTP redirection of user                                                                                                                                                          |
| online-enroll | Enables online user enrolment                                                                                                                                                             |
| url <URL>     | Optional. Specify the location for each of above network authentication types.                                                                                                            |

### Examples

```
nx9500-6C8809(config-passpoint-policy-test)#net-auth-type accept-terms url www.test.com
nx9500-6C8809(config-passpoint-policy-test)#show context
passpoint-policy test
 access-network-type chargeable-public
 connection-capability ip-protocol 2 port 10 closed
 nai-realm example
 eap-method 1 ttls auth-param vendor hex 00001E
 eap-method 2 rsa-public-key auth-param credential cert
 net-auth-type accept-terms url www.test.com
 3gpp mcc 505 mnc 14
nx9500-6C8809(config-passpoint-policy-test)#
```

### Related Commands

|----|-------------------------------------------------------------------------------|
| no | Removes the network authentication type configured with this passpoint policy |
|----|-------------------------------------------------------------------------------|

### operator

Configures a unique name of the administrator or operator responsible for the configuration and management of the hotspot. The name can be configured in English or in any language other than English. When the name is specified in English, the system allows an ASCII input. If using a language other than English, first specify the ISO-639 language code, and then specify the name as an hexadecimal code.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
operator name [<OPERATOR-NAME>|iso-lang <ISO-639-LANG-CODE> <OPERATOR-NAME>]
```

## Parameters

`operator name [<OPERATOR-NAME>|iso-lang <ISO-639-LANG-CODE> <OPERATOR-NAME>]`

|                                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## OSU

Adds an osu (online sign up) SSID (WLAN)/OSU provider and enters its configuration mode

WiNG managed clients can use OSU for registration and credential provisioning to obtain hotspot network access. Service providers have an OSU AAA server and CA (certificate authority). For a client and hotspot to trust one another, the OSU server holds a certificate signed by a CA whose root certificate is issued by a CA authorized by the Wi-Fi Alliance, and CA certificates are installed on the client device. A CA performs four functions:

- Issues certificates (creates and signs)
- Maintains certificate status information and issues CRLs (certificate revocation lists)
- Publishes current (non-expired) certificates and CRLs
- Maintains status archives for the expired or revoked certificates it has issued

Passpoint certificates are governed by the Hotspot 2.0 OSU Certificate Policy Specification. An OSU server certificate should be obtained from any of the CAs authorized by the Wi-Fi Alliance.

Once an OSU provider is selected, the client connects to the OSU WLAN (Open or OSEN). It then triggers an HTTPS connection to the OSU server, which was received with the OSU providers list. The client validates the server certificate to ensure it's a trusted OSU server. The client is then prompted to complete an online registration through their browser. When the client has a valid credential for the

hotspot 2.0 WLAN, it disassociates from the OSU WLAN and connects to the hotspot 2.0 WLAN using standard ANQP mechanisms.

**Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

**Syntax**

```
osu [provider <PASSPOINT-OSU-PROVIDER>|ssid <SSID>]
```

**Parameters**

```
osu [provider <PASSPOINT-OSU-PROVIDER>|ssid <SSID>]
```

|                                   |                                                                                                                                                                                                                                                                                                       |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| osu                               | Use this command to configure an OSU SSID/OSU provider.                                                                                                                                                                                                                                               |
| provider <PASSPOINT-OSU-PROVIDER> | Creates an OSU provider for this passpoint and enters its configuration mode <ul style="list-style-type: none"> <li>• &lt;PASSPOINT-OSU-PROVIDER&gt; - Specify an identification for this OSU passpoint provider serving as an online sign up identifier. Should not exceed 32 characters.</li> </ul> |
| ssid <SSID>                       | Configures an OSU WLAN's SSID. This is the open authentication SSID that a user can use to obtain credentials for the passpoint SSID. <ul style="list-style-type: none"> <li>• &lt;SSID&gt; - Specify the SSID.</li> </ul>                                                                            |

**Examples**

```
nx9500-6C8809(config-passpoint-policy-test)#osu provider test
nx9500-6C8809(config-passpoint-policy-test-osu-provider-test)#?
Passpoint OSU Provider Mode commands:

nx9500-6C8809(config-passpoint-policy-test-osu-provider-test)#
```

The following table summarizes NAI realm configuration mode commands:

**Table 66:**

| Command                                                    | Description                                                        |
|------------------------------------------------------------|--------------------------------------------------------------------|
| <a href="#">description (osu-config-mode)</a> on page 1817 | Configures the OSU provider's description                          |
| <a href="#">icon (osu-config-mode)</a> on page 1818        | Adds the OSU provider's icon                                       |
| <a href="#">method (osu-config-mode)</a> on page 1819      | Configures the open sign up methods available on this OSU provider |
| <a href="#">nai (osu-config-mode)</a> on page 1820         | Configures the OSU provider's NAI                                  |
| <a href="#">name (osu-config-mode)</a> on page 1820        | Configures the OSU provider's name                                 |
| <a href="#">server-url (osu-config-mode)</a> on page 1821  | Configures the OSU provider server's URL                           |
| <a href="#">no (osu-config-mode)</a> on page 1822          | Removes the settings configured for this OSU provider              |

**Related Commands**

|                                 |                                                                     |
|---------------------------------|---------------------------------------------------------------------|
| <a href="#">no</a> on page 1829 | Removes the OSU WLAN/provider configured with this passpoint policy |
|---------------------------------|---------------------------------------------------------------------|

**description (osu-config-mode)**

Configures the OSU SSID/provider's description. This value is returned in the ANQP OSU providers list.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
description [<DESCRIPTION>|iso-lang <ISO-LANG-CODE> <DESCRIPTION>]
```

## Parameters

```
description [<DESCRIPTION>|iso-lang <ISO-LANG-CODE> <DESCRIPTION>]
```

|                                           |                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <DESCRIPTION>                             | Configures the OSU provider's description in English. It should not exceed 253 characters in length. <ul style="list-style-type: none"> <li>• &lt;DESCRIPTION&gt; - Specify the description. By default the system configures the name in English.</li> </ul> <p><b>Note:</b> If configuring description in any language other than English, use the 'iso-lang' option to provide the language code.</p> |
| iso-lang <ISO-LANG-CODE><br><DESCRIPTION> | Identifies the language by its ISO 639 language code (for example, 'chi-chinese' or 'spa-spanish'). By default the language is set to English. If specifying the description in any language other than English, specify the ISO language code. <ul style="list-style-type: none"> <li>• &lt;DESCRIPTION&gt; - Specify the description in hexadecimal code.</li> </ul>                                   |

## Examples

```
nx9500-6C8809(config-passpoint-policy-test-osu-provider-test)#description "OSU created for testing purposes."
nx9500-6C8809(config-passpoint-policy-test-osu-provider-test)#show context
osu provider test
```

```
description "OSU created for testing purposes."
nx9500-6C8809(config-passpoint-policy-test-osu-provider-test)#
```

### method (osu-config-mode)

Configures the open sign up methods available on this OSU provider. This value is returned, in the specified order of precedence, in the ANQP OSU providers list.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
method [oma-dm|soap-xml-spp] priority <1-2>
```

#### Parameters

```
method [oma-dm|soap-xml-spp] priority <1-2>
```

|                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>method [oma-dm soap-xml-spp]</code><br><code>priority &lt;1-2&gt;</code> | <p>Configures the online sign up methods supported by this OSU provider</p> <ul style="list-style-type: none"><li>• <code>oma-dm</code> - <code>oma-dm</code> - Configures the OSU method used as OMA (Open Mobile Alliance) device management. The OMA is a standards body developing open standards for mobile clients. OMA is relevant to service providers working across countries (with different languages), operators and mobile terminals. Adherence to OMA is strictly voluntary.</li><li>• <code>soap-xml-spp</code> - Configures the OSU method used as Soap-xml subscription provisioning protocol. The SOAP (simple object access protocol) is a protocol for exchanging structured information in Web services. SOAP uses XML as its message format, and relies on other application layer protocols, like HTTP or SMTP for message negotiation and transmission.<ul style="list-style-type: none"><li>• <code>priority &lt;1-2&gt;</code> - Sets the priority of the specified method. Select a value from 1 - 2. The default is one (1).</li></ul></li></ul> |

## nai (osu-config-mode)

Configures the OSU provider's NAI. This value is returned in the ANQP OSU providers list.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

Syntax

```
nai <WORD>
```

Parameters

```
nai <WORD>
```

|            |                                                                                                                                                                                                                                                                                                                           |

## name (osu-config-mode)

Configures the OSU provider's name. This value is returned in the ANQP OSU providers list.

Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

Syntax

```
name [<NAME>|iso-lang <ISO-LANG-CODE> <NAME>]
```

Parameters

```
name [<NAME>|iso-lang <ISO-LANG-CODE> <NAME>]
```

|                                    |                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <NAME>                             | Configures the OSU provider's name. It should not exceed 253 characters in length. <ul style="list-style-type: none"> <li>&lt;NAME&gt; - Specify the name in ASCII format. By default the system configures the name in English.</li> </ul>                                                                                             |
| iso-lang <ISO-LANG-CODE><br><NAME> | Identifies the language by its ISO 639 language code (for example, 'chinese' or 'spanish'). By default the language is set to English. If specifying the name in any language other than English, specify the ISO language code. <ul style="list-style-type: none"> <li>&lt;NAME&gt; - Specify the name in hexadecimal code.</li> </ul> |

### Examples

```

### roam-consortium

Configures a list of RC (Roaming Consortium) OIs (Organization Identifiers) supported on this hotspot. The beacons and probe responses communicate this Roaming Consortium list to devices. This information enables a device to identify the networks available through this AP.

Each OI identifies a either a group of SSPs (Subscription Service Providers) or a single SSP.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
roam-consortium hex <WORD>
```

### Parameters

```
roam-consortium hex <WORD>
```

|                            |                                                                                                                                                                                                                                |

### venue

Configures the venue where this hotspot is located. The hotspot venue configuration informs prospective clients about the hotspot's nature of activity, such as educational, institutional, residential, etc.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
venue [group|name]
venue group [assembly|business|educational|industrial|institutional|mercantile|
outdoor|residential|storage|unspecified|utility-and-misc|vehicular] type
venue name [<VENUE-NAME>|iso-lang]
venue name <VENUE-NAME>
venue name iso-lang <ISO-LANG-CODE> <VENUE-NAME>
```

### Parameters

```
venue group [assembly|business|educational|industrial|institutional|mercantile|
outdoor|residential|storage|unspecified|utility-and-misc|vehicular] type
```

### wan-metrics

Configures the WAN performance metrics for this hotspot. This command configures the upstream and downstream speeds associated with this hotspot. The upstream and downstream speed values (in Kbps) are estimates of the bandwidth available on the WAN. This information is returned in response to client ANQP query, and is useful for clients having a minimum and/or large bandwidth requirement.

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
wan-metrics down-speed <0-4294967295> up-speed <0-4294967295>
```

#### Parameters

```
wan-metrics down-speed <0-4294967295> up-speed <0-4294967295>
```

# CRYPTO CMP POLICY

## CRYPTO-CMP-POLICY

---

This chapter summarizes the crypto CMP (certificate management protocol) policy commands in the CLI command structure.

CMP is an Internet protocol designed to enable devices (access point, wireless controller, or service platform) to obtain and manage digital certificates in a PKI (Public Key Infrastructure) network. A CA (Certificate Authority) issues the certificates using the defined CMP.

WiNG CMP implementation allows you to configure a crypto CMP policy that enables auto installation and auto management of device certificates. When configured and implemented on a device, the crypto CMP policy allows the device to automatically trigger a certification request to a configured, CMP supported CA server. Once the certificate is validated and confirmed from the CA server it is saved on the device and becomes part of the trustpoint. During the creation of the CMP policy the trustpoint is assigned a name and client information. You can use a manually created trustpoint for one service (like HTTPS) and use the CMP generated trustpoint for RADIUS EAP certificate based authentication.

Use the (config) instance to configure a crypto CMP policy. To navigate to the crypto CMP policy configuration instance, use the following commands:

```
<DEVICE>(config)#crypto-cmp-policy <CRYPTO-CMP-POLICY-NAME>
nx9500-6C8809(config)#crypto-cmp-policy CMPPolicy
nx9500-6C8809(config-cmp-policy-CMPPolicy)#?
CMP Policy Mode commands:
 ca-server CMP CA Server configuration commands
 cert-key-size Set key size for certificate request
 cert-renewal-timeout Trigger a cert renewal request on timeout
 cross-cert-validate Validate cross-cert using factory-cert
 hash-algorithm Set hash algorithm for certificate request
 no Negate a command or set its defaults
 subjectAltName Configure subjectAltName value
 trustpoint Trustpoint for CMP
 use Set setting to use

 clrscr Clears the display screen
 commit Commit all changes made in this session
 do Run commands from Exec mode
 end End current mode and change to EXEC mode
 exit End current mode and down to previous mode
 help Description of the interactive help system
 revert Revert changes
 service Service Commands
 show Show running system information
 write Write running configuration to memory or terminal
nx9500-6C8809(config-cmp-policy-CMPPolicy)#
```

This chapter is organized as follows:

- [crypto-cmp-policy-instance](#)
- [other-cmp-related-commands](#)

## crypto-cmp-policy-instance

The following table summarizes crypto CMP policy configuration commands:

**Table 67: Crypto-CMP-Policy Config Mode Commands**

| Description                                    | Command                                                                                                                                                                             |
|------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ca-server</code>                         | Configures the CA server details                                                                                                                                                    |
| <code>cert-key-size</code> on page 1833        | Configures the size of the key associated with a certificate request                                                                                                                |
| <code>cert-renewal-timeout</code> on page 1834 | Configures a certificate renewal timeout in days                                                                                                                                    |
| <code>cross-cert-validate</code> on page 1835  | Enables validation of the cross certificate with the factory certificate                                                                                                            |
| <code>hash-algorithm</code> on page 1836       | Configures the hashing algorithm to be used by the CA to sign the digital certificate. This information is sent in the request for certification (new or renewal) to the CA server. |
| <code>subjectAltName</code> on page 1836       | Configures an alternate subject name for this CMP policy                                                                                                                            |
| <code>trustpoint</code>                        | Configures a trustpoint and its associated information, such as the subject name, the sender's (device requesting certification) details, and the recipient's (CA) details          |
| <code>use</code>                               | Associates a device's autogen-uniqueid with this crypto CMP policy                                                                                                                  |
| <code>no</code>                                | Removes the crypto CMP policy settings                                                                                                                                              |

### Note

The input parameter <HOSTNAME>, wherever used in syntaxes across this chapter, cannot include an underscore ( \_ ) character. In other words, the name of a device cannot contain an underscore.

### Note

For more information on common commands (clrscr, commit, help, revert, service, show, write, and exit), see [COMMON COMMANDS](#).

### *ca-server*

Configures the primary and secondary CMP CA server details.

The CA is an external network authority (usually a trusted third-party server) that generates and issues digital certificates in response to requests received from network devices. Use this command to configure the primary and secondary CA server details, such as name of the device hosting the CA server, the port used to access the CA server, and the path where the certificate is stored. Once defined, devices using this CMP policy automatically send requests to the specified primary CA server, and retrieve the certificate from the specified location. If the primary CA server is not reachable, the requests are sent to the secondary CA server.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000

- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
ca-server [primary|secondary] host <IP> port <1-65535> path <PATH>
```

### Parameters

```
ca-server [primary|secondary] host <IP> port <1-65535> path <PATH>
```

|                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                     |

### cert-key-size

Configures the size of the key associated with a certificate request

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
cert-key-size [2048|3072|4096]
```

## Parameters

`cert-key-size [2048|3072|4096]`

|                                             |                                                                                                                                                                                                                                                                                     |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cert-key-size [2048 3072 4096]</code> | Configures the certificate request key size. The options are: <ul style="list-style-type: none"><li>• 2048 – Sets the key size to 2048 bits. This is the default setting.</li><li>• 3072 – Sets the key size to 3072 bits</li><li>• 4096 – Sets the key size to 4096 bits</li></ul> |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Examples

```
nx9500-6C8809(config-cmp-policy-test)#cert-key-size 3072
nx9500-6C8809(config-cmp-policy-test)#show context
crypto-cmp-policy test
 cert-key-size 3072
 ca-server primary host 192.168.8.74 port 8 path cmp
nx9500-6C8809(config-cmp-policy-test)#
```

## Related Commands

|                              |                                                                 |
|------------------------------|-----------------------------------------------------------------|
| <code>no</code> on page 1839 | Reverts the certificate request key size to default (2048 bits) |
|------------------------------|-----------------------------------------------------------------|

### *cert-renewal-timeout*

Configures a certificate renewal timeout in days. This is the number of days, before the expiration of the device's certificate, that a certificate renewal is triggered.

The expiration of device's certificate is checked once a day. When a certificate is about to expire a certificate renewal is initiated with the dedicated CMP CA server resource through an existing IPSec tunnel. If the tunnel is not established, the CMP renewal request is not sent. If a renewal succeeds the newly obtained certificate overwrites an existing certificate. If the renewal fails, an error is logged.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

`cert-renewal-timeout <1-60>`

## Parameters

`cert-renewal-timeout <1-60>`

|                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cert-renewal-timeout &lt;1-60&gt;</code> | Configures the certificate renewal timeout in days. This is the number of days, before the expiration of the device's certificate, that a certificate renewal is triggered. Once the configured time is completed, the device triggers a certificate renewal request. <ul style="list-style-type: none"><li>• &lt;1-60&gt; – Specify a value from 1 - 60 days. The default is fourteen (14) days. Therefore, by default a device triggers certificate renewal request 14 days before its certificate expires.</li></ul> |
|------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Examples

```
ap6522-D8273A(config-cmp-policy-CMP)#cert-renewal-timeout 60
ap6522-D8273A(config-cmp-policy-CMP)#show context
crypto-cmp-policy CMP
 cert-renewal-timeout 60
 ca-server primary host 192.168.8.74 port 8 path cmp
ap6522-D8273A(config-cmp-policy-CMP)#
```

## Related Commands

|                                 |                                                              |
|---------------------------------|--------------------------------------------------------------|
| <a href="#">no</a> on page 1839 | Reverts the certificate renewal timeout to default (14 days) |
|---------------------------------|--------------------------------------------------------------|

### *cross-cert-validate*

Enables validation of the cross certificate using the factory certificate. When enabled, the obtained cross-certificate is validated against the operator's certificate configured on the device. An error message is displayed in case the cross-certificate is not obtained or if the cross-certificate is found to be invalid. This option is disabled by default.

#### Note

To configure the operator certificate, in the device configuration mode execute the **trustpoint > cmp-auth-operator** command. For more information, see [trustpoint \(device-config-mode\)](#) on page 1282.

## Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
cross-cert-validate
```

## Parameters

None

## Examples

```
nx9500-6C8809(config-cmp-policy-test)#cross-cert-validate
nx9500-6C8809(config-cmp-policy-test)#show context
crypto-cmp-policy test
 cert-key-size 3072
 cross-cert-validate
 ca-server primary host 192.168.8.74 port 8 path cmp

## hash-algorithm

Configures the hashing algorithm to be used to sign the digital certificate. This information is sent to the CA in the request for certification (new or renewal). The CA uses the hash algorithm specified here to sign the digital certificate.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
hash-algorithm [sha1|sha256|sha384|sha512]
```

### Parameters

```
hash-algorithm [sha1|sha256|sha384|sha512]
```

|                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## subjectAltName

Configures the subjectAltName identity for this CMP policy

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
subjectAltName [address <IP>|dn <DISTINGUISHED-NAME>|email <EMAIL-ID>|fqdn <FQDN>|
string <USER-DEFINED-STRING>]
```

## Parameters

```
subjectAltName [address <IP>|dn <DISTINGUISHED-NAME>|email <EMAIL-ID>|fqdn <FQDN>|
string <USER-DEFINED-STRING>]
```

```
subjectAltName [address <IP>|dn
<DISTINGUISHED-NAME>|email
<EMAIL-ID>|fqdn <FQDN>|string
<USER-DEFINED-STRING>]
```

Configures an alternative name (disguise) for the subject using one of the following options:

- address <IP> – Uses IP address as identity
  - <IP> – Specify the IP address.
- dn <DISTINGUISHED-NAME> – Uses distinguished name as identity
  - <DISTINGUISHED-NAME> – Specify the DISTINGUISHED-NAME.
- email <EMAIL-ID> – Uses e-mail address as identity
  - <EMAIL-ID> – Specify the e-mail address.
- fqdn <FQDN> – Uses FQDN as identity
  - <FQDN> – Specify the FQDN.
- string <USER-DEFINED-STRING> – Uses a user specified name as identity
  - <USER-DEFINED-STRING> – Specify the string to use as identity.

**Note:** The alternative name value should not exceed 128 characters.

## Examples

### *trustpoint*

Configures a trustpoint and its associated information, such as the subject name, the sender's (device requesting certification) details, and the recipient's (CA) details. This information is needed to obtain the certificate from the CA server using CMP.

Each certificate is digitally signed by a CA and contains device-specific information, such as device name, IP address, serial number. It helps to uniquely identify a device.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000

- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
trustpoint <TRUSTPOINT-NAME> subject-name <WORD> secret [0 <WORD>|2 <WORD>]
reference-id <WORD> sender-name <WORD> [recipient-name <WORD>|ca-psk <CERT-PATH>]
```

## Parameters

```
trustpoint <TRUSTPOINT-NAME> subject-name <WORD> secret [0 <WORD>|2 <WORD>]
reference-id <WORD> sender-name <WORD> [recipient-name <WORD>|ca-psk <CERT-PATH>]
```

|                                 |                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| trustpoint<br><TRUSTPOINT-NAME> | Configures a trustpoint name (should not exceed 32 characters) <ul style="list-style-type: none"> <li>• &lt;TRUSTPOINT-NAME&gt; - Specify the trustpoint's name.</li> </ul>                                                                                                                                                                                               |
| subject-name <WORD>             | Configures a subject name for this trustpoint. The subject name should uniquely identify the certificate and should not exceed 512 characters in length.                                                                                                                                                                                                                  |
| secret [0 <WORD> 2 <WORD>]      | Configures the secret used to encrypt the trustpoint. The secret should not exceed 128 characters in length. <ul style="list-style-type: none"> <li>• 0 &lt;WORD&gt; - Configures a clear text password</li> <li>• 2 &lt;WORD&gt; - Configures an encrypted password <ul style="list-style-type: none"> <li>• &lt;WORD&gt; - Specify the password.</li> </ul> </li> </ul> |
| reference-id <WORD>             | Configures the reference ID. The CA server uses this information to identify the shared secret key used. <ul style="list-style-type: none"> <li>• &lt;WORD&gt; - Specify the reference ID.</li> </ul>                                                                                                                                                                     |
| sender-name <WORD>              | Configures the sender's name. The CA server uses this information to identify the shared secret key used. The sender's name should not exceed 512 characters in length. <ul style="list-style-type: none"> <li>• &lt;WORD&gt; - Specify the sender name.</li> </ul>                                                                                                       |
| recipient-name                  | Configures the recipient's name. The CA server uses this information to validate the request. The recipient's name should not exceed 256 characters in length.                                                                                                                                                                                                            |

|-----------|---------------------------------------------------------------|
| <b>no</b> | Removes the trustpoint associated with this crypto CMP policy |
|-----------|---------------------------------------------------------------|

*use*

Associates a device's autogen-uniqueid with this crypto CMP policy

A device's autogen-uniqueid is a combination of a user-defined string (prefix or suffix) and a substitution token. The WiNG software implementation provides two built-in substitution tokens: \$SN and \$MiNT-ID that represent the device's serial number and MiNT ID respectively. These substitution tokens are internally retrieved and combined with the user-defined string to auto generate a unique identity for a device.

To auto generate the device's unique ID, in the device configuration mode execute the following command:

```
autogen-uniqueid <WORD>
```

For more information on the autogen-uniqueid command, see [autogen-uniqueid](#) on page 883.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
use autogen-uniqueid
```

### Parameters

```
use autogen-uniqueid
```

`use autogen-uniqueid` Associates a device's autogen-uniqueid with this crypto CMP policy. The device's autogen-uniqueid should be existing and configured.

### Examples

```
ap6522-D8273A(config-cmp-policy-CMP)#use autogen-uniqueid
ap6522-D8273A(config-cmp-policy-CMP)#show context
crypto-cmp-policy CMP

## other-cmp-related-commands

The following table summarizes other commands associated with the implementation of the crypto CMP policy:

**Table 68: Other-CMP-Related Commands**

| Command           | Description                                                                                                                       |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <code>use</code>  | Associates a crypto CMP policy with a device                                                                                      |
| <code>show</code> | Displays current status of CMP requests in progress. This command also displays trustpoint details (CMP and non-CMP trustpoints). |

## use (other-cmp-related-commands)

Applies a crypto CMP policy to a device. Once CMP enabled, the device automatically requests for a certificate from the CA server and installs it. After applying the CMP policy, commit and write the change to memory. This is needed to apply this configuration across reboots.

To apply a CMP policy on a device, navigate to the device's config-device mode and execute the **use > crypto-cmp-policy <CRYPTO-CMP-POLICY-NAME>** command.

*Supported in the following platforms:*

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
use crypto-cmp-policy <CRYPTO-CMP-POLICY-NAME>
```

### Parameters

```
use crypto-cmp-policy <CRYPTO-CMP-POLICY-NAME>
```

|                                        |                                                                                                                                                                                                                                                                                                                    |
|----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

ap6522-D8273A(config-device-00-11-3F-D8-27-3A)#use crypto-cmp-policy CMP
ap6522-D8273A(config-device-00-11-3F-D8-27-3A)#commit
```

## show (other-cmp-related-commands)

Displays current status of CMP requests in progress. This command also displays trustpoint details (CMP and non-CMP trustpoints).

*Supported in the following platforms:*

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
show crypto [cmp|pki]
show crypto cmp request status {on <DEVICE-NAME>}
show crypto pki trustpoints {<TRUSTPOINT-NAME>|all} {on <DEVICE-NAME>}
```

### Parameters

```
show crypto cmp request status {on <DEVICE-NAME>}
```

|                                            |                                                                                                                                                                                                                                                                                        |
|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| show crypto cmp request {on <DEVICE-NAME>} | <p>Displays the current status of all on-going CMP requests</p> <ul style="list-style-type: none"> <li>on &lt;DEVICE-NAME&gt; - Optional. Optionally specify the name of the AP, wireless controller, or service platform to view CMP request status on a specified device.</li> </ul> |

2014 GMT
default-trustpoint default_rsa_key Fri Dec 30 00:00:40
2022 GMT

```

```
ap6522-D8273A#
ap6522-D8273A(config)#show crypto cmp request status
CMP Request Status: cmp-complete
```

```
ap6522-D8273A#
```

# ROAMING ASSIST POLICY

## ROAMING ASSIST POLICY

---

This chapter summarizes the Roaming Assist Policy commands in the CLI command structure.

By constantly monitoring a client's packets and the RSSI (received signal strength indicator) of a given client by a group of access points, decision can be made on the optimal access point to which the client needs to roam. Then forcefully direct the client to the optimal access point.

The threshold intervals are configurable and can be adjusted based on the client load.

Use the (config) instance to configure a roaming assist policy. To navigate to the roaming assist policy configuration instance, use the following commands:

```
<DEVICE> (config) roaming-assist-policy <ROAMING-ASSIST-POLICY-NAME>
nx9500-6C8809(config)roaming-assist-policy test
nx9500-6C8809(config-roaming-assist-policy-test)#?
Roaming Assist Mode commands:
 action Configure action - action is deauth / log /
 assisted-roam
 aggressiveness Configure the roaming aggressiveness for a wireless
 client
 detection-threshold Configure the detection threshold - when exceeded,
 client monitoring starts
 disassoc-time Configure the disassociation time - time after which a
 disassociation is sent
 handoff-count Configure the handoff count - number of times client
 can exceed handoff threshold
 handoff-threshold Configure the handoff threshold - when exceeds an
 action is taken.
 monitoring-interval Configure the monitoring interval - interval at which
 client monitoring occurs
 no Negate a command or set its defaults
 sampling-interval Configure the sampling interval - interval at which
 client rssi values are checked

 clrscr Clears the display screen
 commit Commit all changes made in this session
 end End current mode and change to EXEC mode
 exit End current mode and down to previous mode
 help Description of the interactive help system
 revert Revert changes
 service Service Commands
 show Show running system information
 write Write running configuration to memory or terminal

nx9500-6C8809(config-roaming-assist-policy-test)#
```

### roaming-assist-policy commands

The following table summarizes the roaming-assist-policy configuration mode commands:

Table: Roaming Assist Policy Config Mode Commands

| Command                                          | Description                                                                           |
|--------------------------------------------------|---------------------------------------------------------------------------------------|
| <a href="#">action</a> on page 1844              | Specifies the action to be invoked on the client                                      |
| <a href="#">aggressiveness</a> on page 1845      | Configures a roaming aggressiveness value for wireless clients                        |
| <a href="#">detection-threshold</a> on page 1846 | Configure detection-threshold interval value                                          |
| <a href="#">disassoc-time</a> on page 1847       | Configures the disassociation interval                                                |
| <a href="#">handoff-count</a> on page 1847       | Configures the handoff-count value                                                    |
| <a href="#">handoff-threshold</a> on page 1848   | Configures the handoff-threshold value                                                |
| <a href="#">monitoring-interval</a> on page 1849 | Configures the client monitoring interval                                             |
| <a href="#">sampling interval</a> on page 1850   | Configures the interval at which clients are sampled to determine their RSSI value    |
| <a href="#">no</a> on page 1850                  | Removes or reverts this roaming assist policy settings based on the parameters passed |

#### Note

For more information on common commands (clrscr, commit, help, revert, service, show, write, and exit), see [COMMON COMMANDS](#).

#### Note

The input parameter <HOSTNAME>, wherever used in syntaxes across this chapter, cannot include an underscore ( \_ ) character. In other words, the name of a device cannot contain an underscore.

### *action*

Specifies the action invoked on the client once it reaches a specified threshold value. The threshold values are configured based on the client load.

#### **Supported in the following platforms:**

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### **Syntax**

```
action [assisted-roam|deauth|log]
```

#### **Parameters**

```
action [assisted-roam|deauth|log]
```

|                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| action<br>[assisted-roam <br>deauth log] | <p>Configures the action invoked on the client once it reaches the specified threshold value. The options are:</p> <ul style="list-style-type: none"> <li>assisted-roam – Provides 802.11v assisted roaming facility to the client</li> <li>deauth – De-authenticates the client. This is the default setting.</li> <li>log – Generates a log</li> </ul> <p><b>Note:</b> In all three cases an event is generated. However, the message generated differs and is based on the action specified.</p> |
|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Examples

```

nx9500-6C8809(config-roaming-assist-policy-test)#action log
nx9500-6C8809(config-roaming-assist-policy-test)#show context
roaming-assist-policy test
 action log
nx9500-6C8809(config-roaming-assist-policy-test)#

```

### Related Commands

|                 |                                       |
|-----------------|---------------------------------------|
| no on page 1850 | Removes the configured action details |
|-----------------|---------------------------------------|

### *aggressiveness*

Configures a roaming aggressiveness value for wireless clients. Configuring this value increases the client's roaming capabilities in scenarios where the client's location is likely to change drastically and suddenly. For example, when a client hops on to a train that speeds up quickly. In such a scenario, the access point receives a maximum of 2 (two) messages, from the client, having relatively low RSSI value. This results in a decaying-average, which is above the specified handover-threshold value. Consequently, the client is unable to roam.

#### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
aggressiveness [highest|lowest|medium|medium-high|medium-low]
```

#### Parameters

```
aggressiveness [highest|lowest|medium|medium-high|medium-low]
```

aggressiveness [highest|lowest|medium|medium-high|medium-low]

Configures a roaming aggressiveness value for wireless clients. The options are:

- highest – De-authenticates client in case of any degradation in the client's link quality. When selected, the access point considers only the RSSI value of the last message received from the client.
- lowest – De-authenticates client only in case of significant degradation in the client's link quality. When selected, the access point uses a weighted average [80% of decaying average + 20% of last seen RSSI] as the final reported RSSI value. This is the default setting.
- medium – This is an intermediate setting between not roaming and performance.
- medium-high – Allows roaming even if performance goes down. When selected, the access point calculates the client's signal strength based on average received signal as well as last received signal level, weighted towards the last received value.
- medium-low – Allows roaming even if performance goes average. When selected, the access point calculates the client's signal strength based on average received signal as well as last received signal level, weighted towards the average value.

### Examples

```
nx9500-6C8809(config-roaming-assist-policy-test)#aggressiveness medium-high
nx9500-6C8809(config-roaming-assist-policy-test)#show context
roaming-assist-policy test
 aggressiveness medium-high
 action log
nx9500-6C8809(config-roaming-assist-policy-test)#
```

### Related Commands

`no` on page 1850

Reverts the aggressiveness value to default (lowest)

### *detection-threshold*

Specifies the detection-threshold determining when a client is monitored

#### Supported in the following platforms:

- Access Points – AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers – RFS 4000
- Service Platforms – NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

#### Syntax

```
detection-threshold <-100--40>
```

#### Parameters

```
detection-threshold <-100--40>
```

detection-threshold  
<-100--40>

Configures the detection threshold value determining when a client is monitored. The clients with bad RSSI values are monitored more frequently.

- <-100--40> – Specify the RSSI value from -100 dBm - -40 dBm. The default is -75 dBm.

## Examples

```
nx9500-6C8809(config-roaming-assist-policy-test)#detection-threshold -90
nx9500-6C8809(config-roaming-assist-policy-test)#show context
roaming-assist-policy test
 aggressiveness medium-high
 detection-threshold -90
 action log
nx9500-6C8809(config-roaming-assist-policy-test)#
```

## Related Commands

|                              |                                                    |
|------------------------------|----------------------------------------------------|
| <code>no</code> on page 1850 | Removes the configured detection threshold details |
|------------------------------|----------------------------------------------------|

## *disassoc-time*

Configures the disassociation time. This is the interval after which a disassociation message is sent.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

## Syntax

```
disassoc-time <1-10>
```

## Parameters

```
disassoc-time <1-10>
```

|                                         |                                                                                                                                                                               |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>disassoc-time &lt;1-10&gt;</code> | Configures the disassociation time in seconds <ul style="list-style-type: none"><li>• &lt;1-10&gt; - Specify a value from 1 - 10 seconds. The default is 5 seconds.</li></ul> |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Examples

```
nx9500-6C8809(config-roaming-assist-policy-test)#disassoc-time 7
nx9500-6C8809(config-roaming-assist-policy-test)#show context
roaming-assist-policy test
 aggressiveness medium-high
 detection-threshold -90
 action log
 disassoc-time 7
nx9500-6C8809(config-roaming-assist-policy-test)#
```

## Related Commands

|                              |                                            |
|------------------------------|--------------------------------------------|
| <code>no</code> on page 1850 | Removes the configured disassociation time |
|------------------------------|--------------------------------------------|

## *handoff-count*

Specifies the number of times a client can exceed the specified handoff-threshold value before an action is invoked

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
handoff-count <1-10>
```

### Parameters

```
handoff-count <1-10>
```

|                      |                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| handoff-count <1-10> | Specifies the number of times a client can exceed the specified handoff-threshold value before an action is invoked <ul style="list-style-type: none"><li>• &lt;1-10&gt; – Specify a value from 1 - 10. The default is 3.</li></ul> If the client's RSSI increases beyond the set handoff-threshold, it is removed from the queue for monitoring and action invocation. |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Examples

```
nx9500-6C8809(config-roaming-assist-policy-test)#handoff-count 5
nx9500-6C8809(config-roaming-assist-policy-test)#show context
roaming-assist-policy test
 aggressiveness medium-high
 handoff-count 5
 detection-threshold -90
 action log
 disassoc-time 7
nx9500-6C8809(config-roaming-assist-policy-test)#
```

### Related Commands

|                              |                                                 |
|------------------------------|-------------------------------------------------|
| <code>no</code> on page 1850 | Reverts the configured handoff-count to default |
|------------------------------|-------------------------------------------------|

### *handoff-threshold*

Configures the handoff-threshold, which specifies client status for handoff-action. Once exceeded an action is invoked.

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
handoff-threshold <-100--40>
```

### Parameters

```
handoff-threshold <-100--40>
```

### *monitoring-interval*

Configures the interval, in seconds, at which clients are monitored to determine if their RSSI value is below the specified handoff-threshold value

### Supported in the following platforms:

- Access Points — AP 6522, AP 6562, AP 7161, AP 7502, AP 7522, AP 7532, AP 7562, AP 7602, AP 7612, AP 7622, AP 7632, AP 7662, AP 8163, AP 8432, AP 8533
- Wireless Controllers — RFS 4000
- Service Platforms — NX 5500, NX 75XX, NX 95XX, NX 96XX, VX 9000

### Syntax

```
monitoring-interval <1-60>
```

### Parameters

```
monitoring-interval <1-60>
```

|                               |                                                                                                                                                                                                                                                                                      |

# BORDER GATEWAY PROTOCOL

## BORDER GATEWAY PROTOCOL

---

This chapter summarizes the BGP (Border Gateway Protocol) related configuration commands in the CLI command structure.

BGP is a routing protocol, which establishes routing between ISPs. ISPs use BGP to exchange routing information between ASs (Autonomous Systems) on the Internet. The routing information shared includes details, such as ASs traversed to a particular destination, reachable ASs, best paths available, network policies and rules applied on a route, etc. These details appear as BGP attributes carried in routing update packets. BGP uses this information to make routing decisions. Therefore, the primary role of a BGP system is to exchange routing information with other BGP peers.

BGP uses TCP as its transport protocol. This eliminates the need to implement explicit update fragmentation, retransmission, acknowledgement, and sequencing. BGP listens on TCP port 179. The error notification mechanism used in BGP assumes that TCP supports a graceful close (all outstanding data is delivered before the connection is closed). Routing information exchanged through BGP supports only destination-based forwarding (it assumes a router forwards packets based on the destination address carried in the IP header of the packet).

An AS is a set of routers under the same administration that use Interior Gateway Protocol (IGP) and common metrics to define how to route packets within the AS. There are two types of BGP systems: eBGP (external BGP) and iBGP (internal BGP). iBGP represents the exchange of routing information between BGP peers within an AS. Whereas, when two BGP peers, belonging to different ASs, are connected you have an eBGP setup.

BGP peers (also referred to as neighbors) are BGP enabled devices that are directly connected through an established TCP connection. When two BGP enabled peers establish a TCP connection the first time, they exchange their BGP routing tables. All subsequent route table modifications are exchanged as route updates. BGP tracks these route updates by maintaining route table version numbers. With every update the version number changes. At any given point in time, all BGP peers should have the same route table version. The peer-to-peer TCP connections are kept alive through keepalive packets exchanged at specified intervals. Errors and special events are communicated between peers as notification packets.

### Note

The input parameter <HOSTNAME>, wherever used in syntaxes across this chapter, cannot include an underscore (\_) character. In other words, the name of a device cannot contain an underscore.

---

## bgp ip-prefix-list

IP prefix lists are a convenient way to filter prefixes (contained in route update packets) transmitted to (or received from) other BGP supported routers. IP prefix lists are similar to access lists. They contain ordered entries (deny or permit prefix rules), identified by their sequence numbers. Each rule specifies

match criteria (network and subnet prefixes and prefix masks) to match. When a prefix (received or transmitted) matches the prefix specified in one of the rules, it is filtered and an action is applied depending on where the IP prefix list is used. For example, when used in the BGP neighbor context, the prefixes received from the neighbor are filtered and the filtered prefixes are either rejected or accepted depending on the rule type (deny or permit).

IP prefix lists are also used in the BGP route map context to filter prefixes. The action applied, on filtered prefixes is set within the route map. Another use case for IP prefix lists is to filter prefixes before redistribution of local OSPF routes to eBGP enabled ASs.

Like in access lists, these deny and permit prefix rules are processed sequentially, in ascending order of their sequence number. Once a match is made, the BGP enabled router stops processing all subsequent rules in the ip-prefix-list.

IP prefix lists are used as match criteria in the following contexts:

- BGP neighbor. For more information, see [use](#).
- BGP route-map context. For more information, see [match](#).

To navigate to the ip-prefix-list configuration instance, use the following command:

```
<DEVICE>(config)#bgp ip-prefix-list <IP-PREFIX-LIST-NAME>
<DEVICE>(config-bgp-ip-prefix-list-test)#?
BGP IP Prefix List Mode commands:
 deny IP Prefix deny rule to specify packets to reject
 no Negate a command or set its defaults
 permit IP Prefix permit rule to specify packets to forward

The following table summarizes the BGP IP prefix list configuration commands:

**Table 69: BGP IP-Prefix-List Config Mode Commands**

| Command                                              | Description                                                                    |
|------------------------------------------------------|--------------------------------------------------------------------------------|
| <a href="#">deny (ip-prefix-list)</a> on page 1853   | Creates and configures a deny, prefix-list rule                                |
| <a href="#">permit (ip-prefix-list)</a> on page 1854 | Creates and configures a permit, prefix-list rule                              |
| <a href="#">no (ip-prefix-list)</a> on page 1855     | Removes the specified deny or permit prefix-list rule from this IP prefix list |

### *deny (ip-prefix-list)*

Creates and configures a deny prefix-list rule. The deny rule specifies match criteria based on which prefixes received from (or transmitted to) a BGP neighbor are filtered. A deny action is applied on these filtered prefixes. For example, in the BGP router neighbor context a filter is applied using a IP prefix list.

The list contains a deny rule with a prefix to match as 192.168.13.0/24. All prefixes received from the neighbor matching this prefix are denied.

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

### Syntax

```
deny prefix-list <1-4292967294> [<PREFIX-TO-MATCH/MASK>|any]
deny prefix-list <1-4292967294> [<PREFIX-TO-MATCH/MASK> {ge <0-32>/le <0-32>}|any]
```

### Parameters

```
deny prefix-list <1-4292967294> [<PREFIX-TO-MATCH/MASK> {ge <0-32>/le <0-32>}|any]
```

|                                                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>deny prefix-list &lt;1-4294967295&gt; [&lt;PREFIX-TO-MATCH/MASK&gt; any]</pre> | <p>Creates and configures a deny prefix-list rule</p> <ul style="list-style-type: none"><li>• &lt;1-4294967295&gt; - Configures a sequence number for this deny rule. Specify a value from 1 - 4294967295. Within a prefix list, rules are applied in an ascending order of their sequence number. Rules with lower sequence number are applied first.</li><li>• &lt;PREFIX-TO-MATCH/MASK&gt; - Specify the prefix to match. For example 10.0.0.0/8 or 192.168.13.0/24. Routes matching the specified prefix are filtered.<ul style="list-style-type: none"><li>ge &lt;0-32&gt; - Optional. Specifies a greater than or equal to value for the IP prefix length (subnet mask)</li><li>le &lt;0-32&gt; - Optional. Specifies a less than or equal to value for the IP prefix length</li></ul></li></ul> <p>The 'ge' and 'le' options specify a IP prefix length range. Use these options to specify a more specific (granular) prefix match criteria.</p> <ul style="list-style-type: none"><li>any - Sets the prefix match criteria to any. When selected, all routes are filtered, and the action applied is deny. At the backend, this option sets the match criteria to 0.0.0.0/0 le 32.</li></ul> |
|-------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Examples

```
nx9500-6C8809(config-bgp-ip-prefix-list-test)#deny prefix-list 1 168.192.13.0/24
nx9500-6C8809(config-bgp-ip-prefix-list-test)#show context
bgp ip-prefix-list test
 deny prefix-list 1 168.192.13.0/24
nx9500-6C8809(config-bgp-ip-prefix-list-test)#
```

### Related Commands

|                                |              |                                                              |
|--------------------------------|--------------|--------------------------------------------------------------|
| <pre>no (ip-prefix-list)</pre> | on page 1855 | Removes a deny, ip-prefix-list rule from this IP prefix list |
|--------------------------------|--------------|--------------------------------------------------------------|

### *permit (ip-prefix-list)*

Creates and configures a permit prefix-list rule. The permit rule specifies match criteria based on which prefixes received from (or transmitted to) a BGP neighbor are filtered. A permit action is applied on these filtered prefixes. For example, in the BGP router neighbor context a filter is applied using a IP

prefix list. The list contains a permit rule with a prefix to match as 172.168.10.0/24. All prefixes received from the neighbor matching this prefix are permitted.

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

### Syntax

```
permit prefix-list <1-4294967295> [<PREFIX-TO-MATCH/MASK>|any]
```

### Parameters

```
permit prefix-list <1-4294967295> [<PREFIX-TO-MATCH/MASK>|any]
```

|                                                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

### Examples

```
nx9500-6C8809(config-bgp-ip-prefix-list-test)#permit prefix-list 2 172.122.10.0/24
nx9500-6C8809(config-bgp-ip-prefix-list-test)#show context
bgp ip-prefix-list test
 deny prefix-list 1 168.192.13.0/24
 permit prefix-list 2 172.122.10.0/24
nx9500-6C8809(config-bgp-ip-prefix-list-test)#
```

### Related Commands

|                                               |                                                                |
|-----------------------------------------------|----------------------------------------------------------------|
| <code>no (ip-prefix-list)</code> on page 1855 | Removes a permit, ip-prefix-list rule from this IP prefix list |
|-----------------------------------------------|----------------------------------------------------------------|

*no (ip-prefix-list)*

Removes the specified deny or permit prefix-list rule from this IP prefix list

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

## Syntax

```
no [deny|permit]
no [deny|permit] prefix-list <1-4294967295> {<PREFIX-TO-MATCH/MASK>|any}
```

## Parameters

```
no <PARAMETERS>
```

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| no <PARAMETERS> | Removes a deny or permit rule from this IP prefix list |
|-----------------|--------------------------------------------------------|

## Examples

The following example shows the IP prefix list 'test' settings before the 'no' command is executed:

```
nx9500-6C8809(config-bgp-ip-prefix-list-test)#show context
bgp ip-prefix-list test
 deny prefix-list 1 168.192.13.0/24
 permit prefix-list 2 172.122.10.0/24
nx9500-6C8809(config-bgp-ip-prefix-list-test)#
```

The following example shows the IP prefix list 'test' settings after the 'no' command is executed:

```
nx9500-6C8809(config-bgp-ip-prefix-list-test)#no deny prefix-list 1 168.192.13.0/24
nx9500-6C8809(config-bgp-ip-prefix-list-test)#show context
bgp ip-prefix-list test
 permit prefix-list 2 172.122.10.0/24
nx9500-6C8809(config-bgp-ip-prefix-list-test)#
```

## bgp ip-access-list

BGP peers and route maps can reference a single IP based ACL (access control list). Apply IP ACLs to both inbound and outbound route updates. When applied to a BGP enabled router, every route update is passed through the ACL. Each ACL contains deny and permit entries that are applied sequentially, in the order they appear within the list. When a route matches an entry, the decision to permit or deny the route is applied. Once a match is made the remaining entries in the ACL are not processed.

BGP IP ACLs are used as match criteria in the following contexts:

- BGP neighbor. For more information, see [use](#).
- BGP route-map context. For more information, see [match](#).

To navigate to the BGP IP ACL configuration instance, use the following command:

```
<DEVICE>(config)#bgp ip-access-list <IP-ACL-NAME>
<DEVICE>(config-bgp-ip-access-list-<IP-ACL-NAME>)#?
BGP IP Access List Mode commands:
 deny Specify packets to reject
 no Negate a command or set its defaults
 permit Specify packets to forward

The following table summarizes the BGP IP access list configuration commands:

**Table 70: BGP IP-Access-List Config Mode Commands**

| Command                                               | Description                                                  |
|-------------------------------------------------------|--------------------------------------------------------------|
| <code>deny (bgp-ip-access-list)</code> on page 1857   | Creates and configures a deny entry rule for this BGP IP ACL |
| <code>permit (bgp-ip-access-list)</code> on page 1857 | Creates and configures a permit entry for this BGP IP ACL    |
| <code>no (bgp-ip-access-list)</code> on page 1858     | Removes a deny or permit entry from this BGP IP ACL          |

### *deny (bgp-ip-access-list)*

Creates and configures a deny entry for this BGP IP ACL

#### **Supported in the following platforms:**

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

#### **Syntax**

```
deny access-list [<PREFIX-TO-MATCH/MASK> {exact-match}|any]
```

#### **Parameters**

```
deny access-list [<PREFIX-TO-MATCH/MASK> {exact-match}|any]
```

|                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>deny access-list [&lt;PREFIX-TO-MATCH/MASK&gt; {exact-match} any]</code> | <p>Creates and configures a deny entry for this BGP IP ACL</p> <ul style="list-style-type: none"><li>• <code>&lt;PREFIX-TO-MATCH/MASK&gt;</code> - Specify the prefix to match.<ul style="list-style-type: none"><li>• <code>exact-match</code> - Optional. Enables an exact match of the prefix provided in the previous step. When configured, the route is denied only in case of an exact match.</li></ul></li><li>• <code>any</code> - Specifies the prefix to match as 'any'.</li></ul> |
|--------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

#### **Examples**

```
nx9500-6C8809(config-bgp-ip-access-list-test)#deny access-list 192.168.13.0/24 exact-match
nx9500-6C8809(config-bgp-ip-access-list-test)#show context
bgp ip-access-list test
 deny access-list 192.168.13.0/24 exact-match
nx9500-6C8809(config-bgp-ip-access-list-test)#
```

#### **Related Commands**

|------------------------------------------------------|-----------------------------------------------------------|

*no (bgp-ip-access-list)*

Removes a deny or permit entry from this BGP IP ACL

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

### Syntax

```
no [deny|permit]
no [deny|permit] access-list [<PREFIX-TO-MATCH/MASK>|any]
```

### Parameters

```
no <PARAMETERS>
```

|                 |                                                     |
|-----------------|-----------------------------------------------------|
| no <PARAMETERS> | Removes a deny or permit entry from this BGP IP ACL |
|-----------------|-----------------------------------------------------|

## Examples

The following example shows the BGP IP ACL 'test' settings before the 'no' command is executed:

```
nx9500-6C8809(config-bgp-ip-access-list-test)#show context
bgp ip-access-list test
 permit access-list 172.168.10.0/24
 deny access-list 192.168.13.0/24 exact-match
nx9500-6C8809(config-bgp-ip-access-list-test)#
nx9500-6C8809(config-bgp-ip-access-list-test)#no permit access-list 172.168.10.0/24
```

The following example shows the BGP IP ACL 'test' settings after the 'no' command is executed:

```
nx9500-6C8809(config-bgp-ip-access-list-test)#show context
bgp ip-access-list test
 deny access-list 192.168.13.0/24 exact-match
nx9500-6C8809(config-bgp-ip-access-list-test)#
```

## bgp as-path-list

BGP enabled devices use routing updates to exchange network routing information with each other. This information includes route details, such as the network number, path specific attributes, and the list of ASNs (Autonomous System Numbers) that a route traverses to reach a destination. This list is contained in the AS path.

An AS path ACL (access control list) filters AS paths (routes) included in routing updates. Each AS path access list consists of deny and/or permit rules that define regular expressions (match criteria). When configured and applied on inbound and outbound routing updates, the BGP AS path attributes are matched against the regular expressions specified in the AS path ACL. In case of a match, the route is filtered and an action (deny or permit) is applied. Once a match is made subsequent rules in the AS path access list are not processed.

AS path access lists also help prevent looping within an AS. Routing loops are prevented by rejecting routing updates containing local ASNs. Since local ASNs indicate that the route has already traveled through that autonomous system, by rejecting them looping is avoided.

AS path access lists are used as match criteria in the following contexts:

- BGP neighbor. For more information, see [use](#).
- BGP route map context. For more information, see [match](#).

To navigate to the AS path configuration instance, use the following command:

```
<DEVICE>(config)#bgp as-path <AS-PATH-LIST-NAME>
<DEVICE>(config-bgp-as-path-list-<AS-PATH-LIST-NAME>)#?
BGP AS Path List Mode commands:
deny Specify packets to reject
no Negate a command or set its defaults
permit Specify packets to forward

clrscr Clears the display screen
commit Commit all changes made in this session

```
<DEVICE>(config-bgp-as-path-list-<AS-PATH-LIST-NAME>)#
```

The following table summarizes the BGP AS path list configuration commands:

**Table 71: BGP AS-Path-List Config Mode Commands**

| Command                                             | Description                                         |
|-----------------------------------------------------|-----------------------------------------------------|
| <code>deny (bgp-as-path-list)</code> on page 1860   | Creates and configures a deny as-path-list rule     |
| <code>permit (bgp-as-path-list)</code> on page 1861 | Creates and configures a permit as-path-list rule   |
| <code>no (bgp-as-path-list)</code> on page 1862     | Removes a deny or permit rule from this AS path ACL |

### *deny (bgp-as-path-list)*

Creates and configures a deny as-path-list rule. The deny rule specifies a regular expression to match. This regular expression, is matched against the BGP AS paths contained in routing updates. AS paths matching the provided string are filtered and a deny action is applied.

#### **Supported in the following platforms:**

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

#### **Syntax**

```
deny as-path <REG-EXP>
```

#### **Parameters**

```
deny as-path <REG-EXP>
```

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| deny as-path <REG-EXP> | Configures a match criteria (regular expression). <ul style="list-style-type: none"><li>• &lt;REG-EXP&gt; – Specify the regular expression to match (should not exceed 64 characters and should be unique to the AS path list rule)</li></ul> Regular expressions are treated as a 'ASCII string' and not as a sequence of numbers. Create a regular expression ideally suited to filter the required AS paths. |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

#### **Usage Guidelines**

The following table lists some of the characters used in forming regular expressions:

**Table 72:**

| Character to use | Description                                                                                                   |
|------------------|---------------------------------------------------------------------------------------------------------------|
| ^                | Indicates the start of a string                                                                               |
| \$               | Indicates the end of a string                                                                                 |
| _ (underscore)   | Indicates a comma, left brace, right brace, start and end of an input string, or a space. For example, “_ _”. |

## Examples

```
nx9500-6C8809(config-bgp-as-path-list-test)#deny as-path ^100$
nx9500-6C8809(config-bgp-as-path-list-test)#show context
bgp as-path-list test
 deny as-path ^100$
nx9500-6C8809(config-bgp-as-path-list-test)#
```

## Related Commands

|                                                 |                                          |
|-------------------------------------------------|------------------------------------------|
| <code>no (bgp-as-path-list)</code> on page 1862 | Removes the specified deny, as-path rule |
|-------------------------------------------------|------------------------------------------|

### *permit (bgp-as-path-list)*

Creates and configures a permit as-path-list rule. The permit rule specifies a regular expression to match. This regular expression is matched against the BGP AS paths contained in routing updates. AS paths matching the provided string are filtered and a permit action is applied.

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

### Syntax

```
permit as-path <REG-EXP>
```

### Parameters

```
permit as-path <REG-EXP>
```

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| permit as-path <REG-EXP> | Configures a match criteria (regular expression). <ul style="list-style-type: none"><li>• &lt;REG-EXP&gt; - Specify the regular expression to match (should not exceed 64 characters and should be unique to the AS path list rule)</li></ul> Regular expressions are treated as a 'ASCII string' and not as a sequence of numbers. Create a regular expression which is ideally suited to filter the required AS paths. |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Usage Guidelines

The following table lists some of the characters used in forming regular expressions:

**Table 73:**

| Character to use | Description                                                                                                   |
|------------------|---------------------------------------------------------------------------------------------------------------|
| ^                | Indicates the start of a string                                                                               |
| \$               | Indicates the end of a string                                                                                 |
| _ (underscore)   | Indicates a comma, left brace, right brace, start and end of an input string, or a space. For example, “_ _”. |

### Examples

```
nx9500-6C8809(config-bgp-as-path-list-test)#permit as-path _200_
nx9500-6C8809(config-bgp-as-path-list-test)#permit as-path _323_
nx9500-6C8809(config-bgp-as-path-list-test)#show context
bgp as-path-list test
```

```
deny as-path ^100$
permit as-path _323_
permit as-path _200_
nx9500-6C8809(config-bgp-as-path-list-test)#
```

### Related Commands

|                                                 |                                               |
|-------------------------------------------------|-----------------------------------------------|
| <code>no (bgp-as-path-list)</code> on page 1862 | Removes the specified permit as-path ACL rule |
|-------------------------------------------------|-----------------------------------------------|

*no (bgp-as-path-list)*

Removes a deny or permit rule from this AS path ACL

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

### Syntax

```
no as-path-list [deny|permit] <REG-EXP>
```

### Parameters

```
no <PARAMETERS>
```

|                                    |                                                     |
|------------------------------------|-----------------------------------------------------|
| <code>no &lt;PARAMETERS&gt;</code> | Removes a deny or permit rule from this AS path ACL |
|------------------------------------|-----------------------------------------------------|

### Examples

The following example shows the BGP As-Path-List 'test' configuration before the 'no' command is executed:

```
nx9500-6C8809(config-bgp-as-path-list-test)#show context
bgp as-path-list test
 deny as-path ^100$
 permit as-path _323_
 permit as-path _200_
nx9500-6C8809(config-bgp-as-path-list-test)#
nx9500-6C8809(config-bgp-as-path-list-test)#no permit as-path _323_
```

The following example shows the BGP As-Path-List 'test' configuration after the 'no' command is executed:

```
nx9500-6C8809(config-bgp-as-path-list-test)#show context
bgp as-path-list test
 deny as-path ^100$
 permit as-path _200_
nx9500-6C8809(config-bgp-as-path-list-test)#
```

## bgp community-list

Creates and configures a named community list

IP BGP routes have a set of attributes, mandatory and optional. The community and extended community attributes are optional. Optional attributes are specified by network administrators to mark (color) routes received in updates containing these attributes. These marked routes are filtered and special actions applied (accepted, preferred, distributed, or advertised). For example, the NO\_EXPORT

community, indicates that routes attached to it are local and not to be advertised to external ASs. Similarly, a set of routes using a common routing policy can be tagged to a community, and the policy applied to the community.

A BGP community is a group of routes sharing common attributes. Route updates contain community information in the form of path attributes. These attributes help identify community members.

A BGP community list is a list of deny or permit entries. It is either assigned a name (regular expressions, predefined community names) or a number. Assigning names to communities increases the number of configurable community lists. All rules applicable to numbered communities apply to named communities too. The only difference being in the number of attributes configurable for a named community list.

Since the community attribute is optional, it is shared only between devices that understand communities and are configured to handle communities. By default the community attribute is not sent to neighbors unless the `send-community` command option is enabled in the BGP neighbor context. For more information, see [send-community](#).

Some of the predefined, globally used communities are:

- no-export – Routes tagged to this community are not advertised to external BGP peers
- no-advertise – Routes tagged to this community are not advertised to any BGP peers
- local-as – Routes tagged to this community are not advertised outside the local AS
- internet – Routes tagged to this community are advertised to the Internet community. By default all BGP enabled devices belong to this community.

BGP community lists are used in the following context as match clauses:

- BGP route map context. For more information, see [match](#).

To navigate to the BGP community configuration instance, use the following command:

```
<DEVICE>(config)#bgp community-list <COMMUNITY-LIST-NAME>
<DEVICE>(config-bgp-community-list-<COMMUNITY-LIST-NAME>)#?
BGP Community List Mode commands:
deny Add a BGP Community List deny rule to Specify community to reject
no Negate a command or set its defaults
permit Add a BGP Community List permit rule to Specify community to accept

clrscr Clears the display screen
commit Commit all changes made in this session
do Run commands from Exec mode
end End current mode and change to EXEC mode
exit End current mode and down to previous mode
help Description of the interactive help system
revert Revert changes
service Service Commands
show Show running system information
write Write running configuration to memory or terminal

<DEVICE>(config-bgp-community-list-<COMMUNITY-LIST-NAME>)#
```

The following table summarizes the BGP community list configuration commands:

**Table 74: BGP Community-List Config Mode Commands**

| Command                                               | Description                                                                |
|-------------------------------------------------------|----------------------------------------------------------------------------|
| <code>deny (bgp-community-list)</code> on page 1864   | Creates and configures a deny community (expanded or standard) rule        |
| <code>permit (bgp-community-list)</code> on page 1865 | Creates and configures a permit community (expanded or standard) rule      |
| <code>no (bgp-community-list)</code> on page 1866     | Removes an existing deny or permit community rule from this community list |

### *deny (bgp-community-list)*

Creates and configures a deny community (expanded or standard) rule

#### **Supported in the following platforms:**

- Wireless Controllers – RFS 4000
- Service Platforms – NX 95XX, NX 96XX

#### **Syntax**

```
deny community [expanded|standard]
deny community expanded <LINE>
deny community standard [AA:NN|internet|local-AS|no-advertise|no-export]
```

#### **Parameters**

```
deny community expanded <LINE>
```

|                                                   |                                                                                                                                                                                                                                                                                                      |
|---------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>deny community expanded &lt;LINE&gt;</code> | <p>Configures a deny expanded community list entry and associates it with a regular expression to match. The regular expression represents the patterns to match in the community attributes.</p> <ul style="list-style-type: none"> <li>• &lt;LINE&gt; - Provide the regular expression.</li> </ul> |
|---------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
deny community standard [AA:NN|internet|local-AS|no-advertise|no-export]
```

|                                                                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>deny community standard [AA:NN internet local-AS no-advertise no-export]</code> | <p>Configures a deny standard community list entry and associates it with a predefined, globally used, known community or community number. The options are:</p> <ul style="list-style-type: none"> <li>• aa:nn - Configures the community number. The first part (aa) represents the AS number. The second part (nn) represents a 2-byte number.</li> <li>• internet - Advertises this route to the internet community</li> <li>• local-AS - Prevents transmission of this route outside the local AS</li> <li>• no-advertise - Prevents advertisement of this route to any peer (internal or external)</li> <li>• no-export - Prevents advertisement of this route to external BGP peers (keeping this route within an AS)</li> </ul> |
|---------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Examples

```
nx9500-6C8809(config-bgp-community-list-test)#deny community expanded 100
nx9500-6C8809(config-bgp-community-list-test)#show context
bgp community-list test
 deny community expanded 100
nx9500-6C8809(config-bgp-community-list-test)#
```

## Related Commands

|---------------------------------------------------|------------------------------------------------------------------------|
| <code>no (bgp-community-list)</code> on page 1866 | Removes the specified deny community rule from this BGP community list |
|---------------------------------------------------|------------------------------------------------------------------------|

## *permit (bgp-community-list)*

Creates and configures a permit community (expanded or standard) rule

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

### Syntax

```
permit community [expanded|standard]
permit community expanded <LINE>
permit community standard [AA:NN|internet|local-AS|no-advertise|no-export]
```

### Parameters

```
permit community expanded <LINE>
```

|                                                     |                                                                                                                                                                                                                                                                                               |
|-----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>permit community expanded &lt;LINE&gt;</code> | Configures a permit expanded community list entry and associates it with a regular expression to match. The regular expression represents the patterns to match in the community attributes. <ul style="list-style-type: none"><li>• &lt;LINE&gt; - Provide the regular expression.</li></ul> |
|-----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
permit community standard [AA:NN|internet|local-AS|no-advertise|no-export]
```

|                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>permit community standard [AA:NN internet local-AS no-advertise no-export]</code> | Configures a permit standard community list entry and associates it with a predefined, globally used, known community or community number. The options are: <ul style="list-style-type: none"><li>• aa:nn - Configures the community number. The first part (aa) represents the AS number. The second part (nn) represents a 2-byte number.</li><li>• internet - Advertises this route to the internet community</li><li>• local-AS - Allows transmission of this route outside the local AS</li><li>• no-advertise - Allows advertisement of this route to any peer (internal or external)</li><li>• no-export - Allows advertisement of this route to external BGP peers (keeping this route within an AS)</li></ul> |
|-----------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Examples

```
nx9500-6C8809(config-bgp-community-list-test)#permit community expanded 300
nx9500-6C8809(config-bgp-community-list-test)# show context
bgp community-list test
 permit community expanded 300
 deny community expanded 100
nx9500-6C8809(config-bgp-community-list-test)#
nx9500-6C8809(config-bgp-community-list-test1)#permit community standard no-export
nx9500-6C8809(config-bgp-community-list-test1)#show context
bgp community-list test1
 permit community standard no-export
nx9500-6C8809(config-bgp-community-list-test1)#
```

## Related Commands

|                                                   |                                                                      |
|---------------------------------------------------|----------------------------------------------------------------------|
| <code>no (bgp-community-list)</code> on page 1866 | Removes the specified permit community rule from this community list |
|---------------------------------------------------|----------------------------------------------------------------------|

### *no (bgp-community-list)*

Removes a deny or permit community rule from this community list

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

### Syntax

```
no [deny|permit] community expanded <LINE>
no [deny|permit] community standard [AA:NN|internet|local-AS|no-advertise|no-export]
```

### Parameters

no <PARAMETERS>

|                                    |                                                                                                                                                                                                     |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>no &lt;PARAMETERS&gt;</code> | Removes a deny or permit expanded community rule from this community list <ul style="list-style-type: none"><li>• &lt;LINE&gt; - Specify the regular expression associated with the rule.</li></ul> |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Examples

The following example shows the settings of the community list 'test' before the 'no' command is executed:

```
nx9500-6C8809(config-bgp-community-list-test)#show context
bgp community-list test
 permit community expanded 300
 deny community expanded 100
nx9500-6C8809(config-bgp-community-list-test)#
nx9500-6C8809(config-bgp-community-list-test)#no deny community expanded 100
```

The following example shows the settings of the community list 'test' after the 'no' command is executed:

```
nx9500-6C8809(config-bgp-community-list-test)#show context
bgp community-list test
 permit community expanded 300
nx9500-6C8809(config-bgp-community-list-test)#
```

## bop ext-community-list

Creates and configures a named extended community list

A BGP extended community is a group of routes sharing a common attribute, regardless of their network or physical boundary. By using a BGP extended community attribute, routing policies can implement inbound or outbound route filters based on the extended community tag, rather than a long list of individual permit or deny rules. A BGP extended community list is used to create groups of communities to use in a match clause of a route map. An extended community list is used to control which routes are accepted, preferred, distributed, or advertised.

The BGP extended community and standard community attributes are identical in function and structure, except that the former is an eight octet and the latter is a four octet attribute.

BGP extended community lists are used as match clauses in the following context:

- BGP route map context. For more information, see [match](#).

To navigate to the extended community configuration instance, use the following command:

```
<DEVICE>(config)#bgp extcommunity-list <EXTCOMMUNITY-LIST-NAME>
<DEVICE>(config-bgp-extcommunity-list-<EXTCOMMUNITY-LIST-NAME>)#?
BGP Extcommunity List Mode commands:
 deny Add a BGP Community List deny rule to specify extcommunity to
 reject
 no Negate a command or set its defaults
 permit Add a BGP Community List permit rule to specify extcommunity to
 accept

 clrscr Clears the display screen
 commit Commit all changes made in this session
 do Run commands from Exec mode
 end End current mode and change to EXEC mode
 exit End current mode and down to previous mode
 help Description of the interactive help system
 revert Revert changes
 service Service Commands

 write Write running configuration to memory or terminal

<DEVICE>(config-bgp-extcommunity-list-<EXTCOMMUNITY-LIST-NAME>)#
```

The following table summarizes the BGP extended community list configuration commands:

**Table 75: BGP-Ext-Community-List Config Mode Commands**

| Command                                                      | Description                                                                             |
|--------------------------------------------------------------|-----------------------------------------------------------------------------------------|
| <a href="#">deny (bgp-ext-community-list)</a> on page 1867   | Creates and configures a deny extended community (expanded or standard) rule            |
| <a href="#">permit (bgp-ext-community-list)</a> on page 1868 | Creates and configures a permit extended community (expanded or standard) rule          |
| <a href="#">no (bgp-ext-community-list)</a> on page 1869     | Removes an existing deny or permit extended community rule from this ext community list |

### *deny (bgp-ext-community-list)*

Creates and configures a deny extended community (expanded or standard) rule

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

### Syntax

```
deny extcommunity [expanded|standard]
deny extcommunity expanded <LINE>
deny extcommunity standard [rt|soo] <COMMUNITY-NUMBER>
```

### Parameters

```
deny extcommunity expanded <LINE>
```

|                                                    |                                                                                                                                                                                                                                                                                                                            |
|----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>deny extcommunity expanded &lt;LINE&gt;</pre> | <p>Configures a deny expanded named extended community list entry and associates it with a regular expression to match. The regular expression represents the patterns to match in the extended community attributes.</p> <ul style="list-style-type: none"><li>• &lt;LINE&gt; - Provide the regular expression.</li></ul> |
|----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
deny extcommunity standard [rt|soo] <COMMUNITY-NUMBER>
```

|                                                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>deny extcommunity standard [rt  soo] &lt;COMMUNITY-NUMBER&gt;</pre> | <p>Configures a deny standard named extended community list entry, and associates it with the target or origin community attributes.</p> <ul style="list-style-type: none"><li>• rt - Configures the RT (route target) extended community attribute</li><li>• soo - Configures the SOO (site-of-origin) extended community attribute</li></ul> <p>&lt;COMMUNITY-NUMBER&gt; - Specify the community number in one of the following formats: AA:NN or A.B.C.D:NN</p> |
|--------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Examples

```
nx9500-6C8809(config-bgp-extcommunity-list-test)#deny extcommunity standard rt 200:12
nx9500-6C8809(config-bgp-extcommunity-list-test)#show context
bgp extcommunity-list test
 deny extcommunity standard rt 200:12
nx9500-6C8809(config-bgp-extcommunity-list-test)#
```

### Related Commands

|                                                     |                                                                                       |
|-----------------------------------------------------|---------------------------------------------------------------------------------------|
| <pre>no (bgp-ext-community-list) on page 1869</pre> | <p>Removes the specified deny extended community rule from this extcommunity list</p> |
|-----------------------------------------------------|---------------------------------------------------------------------------------------|

### *permit (bgp-ext-community-list)*

Creates and configures a permit extended community (expanded or standard) rule

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

### Syntax

```
permit extcommunity [expanded|standard]
permit extcommunity expanded <LINE>
permit extcommunity standard [rt|soo] <COMMUNITY-NUMBER>
```

## Parameters

```
permit extcommunity expanded <LINE>
```

|                                     |                                                                                                                                                                                                                                                                                                                       |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| permit extcommunity expanded <LINE> | Configures a permit expanded named extended community list entry and associates it with a regular expression to match. The regular expression represents the patterns to match in the extended community attributes. <ul style="list-style-type: none"><li>• &lt;LINE&gt; - Provide the regular expression.</li></ul> |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
permit extcommunity standard [rt|soo] <COMMUNITY-NUMBER>
```

|                                                          |                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| permit extcommunity standard [rt soo] <COMMUNITY-NUMBER> | Configures a permit standard named extended community list entry, and associates it with the target or origin community attributes. <ul style="list-style-type: none"><li>• rt - Configures the RT extended community attribute</li><li>• soo - Configures the SOO extended community attribute</li></ul> <COMMUNITY-NUMBER> - Specify the community number in one of the following formats: AA:NN or A.B.C.D:NN |
|----------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Examples

```
nx9500-6C8809(config-bgp-extcommunity-list-test)#permit extcommunity standard rt 300:03
nx9500-6C8809(config-bgp-extcommunity-list-test)#show context
bgp extcommunity-list test
 permit extcommunity standard rt 300:03
 deny extcommunity standard rt 200:12
nx9500-6C8809(config-bgp-extcommunity-list-test)#
```

## Related Commands

|                                          |                                                                                  |
|------------------------------------------|----------------------------------------------------------------------------------|
| no (bgp-ext-community-list) on page 1869 | Removes the specified permit extended community rule from this extcommunity list |
|------------------------------------------|----------------------------------------------------------------------------------|

*no (bgp-ext-community-list)*

Removes an existing deny or permit extended community rule from this extcommunity list

## Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

## Syntax

```
no [deny|permit] extcommunity expanded <LINE>
no [deny|permit] extcommunity standard [rt|soo] <COMMUNITY-NUMBER>
```

## Parameters

```
no <PARAMETERS>
```

|                 |                                                                                    |
|-----------------|------------------------------------------------------------------------------------|
| no <PARAMETERS> | Removes a deny or permit expanded extended community rule from this community list |
|-----------------|------------------------------------------------------------------------------------|

## Examples

The following example shows the extended community 'test' settings before the 'no' command is executed:

```
nx9500-6C8809(config-bgp-extcommunity-list-test)#show context
bgp extcommunity-list test
 permit extcommunity standard rt 300:03
 deny extcommunity standard rt 200:12
nx9500-6C8809(config-bgp-extcommunity-list-test)#
nx9500-6C8809(config-bgp-extcommunity-list-test)#no permit extcommunity standard 300:03
```

The following example shows the extended community 'test' settings after the 'no' command is executed:

```
nx9500-6C8809(config-bgp-extcommunity-list-test)#show context
bgp extcommunity-list test
 deny extcommunity standard rt 200:12
nx9500-6C8809(config-bgp-extcommunity-list-test)#
```

## bgp route-map

BGP route maps are used to control and modify routing information. A BGP route map is a collection of deny and/or permit route rules that define and control redistribution of routes between routers and routing processes. Each rule consists of match criteria and set lines. If a route matches a criteria, the corresponding set line is applied, and the route is passed to the BGP table or to the neighbor, depending on whether the route map is set for incoming or outgoing route updates.

Use the (config) instance to configure BGP route map related parameters.

To navigate to this instance, use the following command:

```
<DEVICE>(config)#route-map <ROUTE-MAP-NAME>
<DEVICE>(config)#route-map test
<DEVICE>(config-dr-route-map-test)#?
Route Map Mode commands:
 deny Add a deny route map rule to deny set operations
 no Negate a command or set its defaults
 permit Add a permit route map rule to permit set operations

 clrscr Clears the display screen
 commit Commit all changes made in this session
 do Run commands from Exec mode
 end End current mode and change to EXEC mode
 exit End current mode and down to previous mode
 help Description of the interactive help system
 revert Revert changes
 service Service Commands
 show Show running system information
 write Write running configuration to memory or terminal

<DEVICE>(config-dr-route-map-test)#
```

In the route-map configuration mode, use the following commands to create and configure a deny or permit route map rule:

```
<DEVICE>(config-dr-route-map-test)#deny route-map <1-65535>
<DEVICE>(config-dr-route-map-test)#permit route-map <1-65535>
```

For example:

```
<DEVICE>(config-dr-route-map-test)#permit route-map 1
<DEVICE>(config-dr-route-map-test)#deny route-map 2
<DEVICE>(config-dr-route-map-test)#show context
route-map test
 permit route-map 1
 deny route-map 2
<DEVICE>(config-dr-route-map-test)#
<DEVICE>(config-dr-route-map-test-dr-route-map-rule-1)#?
Route Map Rule Mode commands:
 description Configure comment for this route map
 match Match values from routing table
 no Negate a command or set its defaults
 set Set values in destination routing protocol

 clrscr Clears the display screen
 commit Commit all changes made in this session
 do Run commands from Exec mode
 end End current mode and change to EXEC mode
 exit End current mode and down to previous mode
 help Description of the interactive help system
 revert Revert changes
 service Service Commands
 show Show running system information
 write Write running configuration to memory or terminal

<DEVICE>(config-dr-route-map-test-dr-route-map-rule-1)#
```

The following table summarizes BGP Route Map deny/permit route map rules configuration mode commands:

**Table 76: BGP-Route-Map Config Mode Commands**

| Command                                                  | Description                                                                                                                                  |
|----------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">description (bgp-route-map)</a> on page 1871 | Configures a description for this route-map rule (deny or permit) that uniquely distinguishes it from others with similar access permissions |
| <a href="#">match (bgp-route-map)</a> on page 1872       | Configures the match criteria associated with this deny or permit BGP route map                                                              |
| <a href="#">set (bgp-route-map)</a> on page 1875         | Configures the values attributed to a route matching the match criteria specified in the BGP deny or permit route-map rules                  |
| <a href="#">no (bgp-route-map)</a> on page 1878          | Removes or reverts the settings defined for a deny or permit route-map rule                                                                  |

*description (bgp-route-map)*

Configures a description for this route map rule (deny or permit) that uniquely distinguishes it from others with similar access permissions

**Supported in the following platforms:**

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

## Syntax

```
description <LINE>
```

## Parameters

```
description <LINE>
```

|                    |                                                                                          |
|--------------------|------------------------------------------------------------------------------------------|
| description <LINE> | Provide a description for the route map rule (should not exceed 64 characters in length) |
|--------------------|------------------------------------------------------------------------------------------|

## Examples

```
nx9500-6C8809(config-dr-route-map-test-dr-route-map-rule-1)#description "This is
a deny route map rule"
nx9500-6C8809(config-dr-route-map-test-dr-route-map-rule-1)#show context
deny route-map 1
 description "This is a deny route map rule"
nx9500-6C8809(config-dr-route-map-test-dr-route-map-rule-1)#
```

## Related Commands

|                                              |                                                       |
|----------------------------------------------|-------------------------------------------------------|
| <code>no (bgp-route-map)</code> on page 1878 | Removes this deny/permit route-map rule's description |
|----------------------------------------------|-------------------------------------------------------|

## *match (bgp-route-map)*

Configures the match criteria associated with this deny or permit BGP route map

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

## Syntax

```
match [as-path|community|extcommunity|ip-address|ip-next-hop|ip-route-source|metric|origin|
tag]
match [as-path <AS-PATH-LIST-NAME>|community <COMMUNITY-LIST-NAME> {exact-match}|
extcommunity <EXTCOMMUNITY-LIST-NAME>]
match [ip-address|ip-next-hop|ip-route-source] [BGP-IP-ACCESS-LIST <BGP-ACL-NAME>|prefix-
list <PREFIX-LIST-NAME>]
match metric <0-4294967295>
match origin [egp|igp|incomplete]
match tag <0-65535>
```

## Parameters

```
match [as-path <AS-PATH-LIST-NAME>|community <COMMUNITY-LIST-NAME> {exact-match}|
extcommunity <EXTCOMMUNITY-LIST-NAME>]
```

|                                               |                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| as-path <AS-PATH-LIST-NAME>                   | Configures a BGP AS path list to match<br>An AS path is a list of ASs a packet traverses to reach its destination. <ul style="list-style-type: none"> <li>&lt;AS-PATH-LIST-NAME&gt; - Specify the AS path list name (should be existing and configured)</li> </ul>                                                                                 |

| ip-address [BGP-IP-ACCESS-LIST <BGP-ACL-NAME>] prefix-list <PREFIX-LIST-NAME>]      | Configures a string of IP addresses, in the route, to match<br>The IP Address is a list of IP addresses in the route used to filter the route. Use one of the following options to provide a list of IP addresses: <ul style="list-style-type: none"> <li>BGP-IP-ACCESS-LIST &lt;BGP-ACL-NAME&gt; - Associates an existing BGP ACL with this BGP route map. Specify the BGP ACL name (should be existing and configured).</li> <li>prefix-list &lt;PREFIX-LIST-NAME&gt; - Associates an existing IP address prefix list with this BGP route map. The IP Address Prefix List is a list of prefixes in the route used to filter route. Specify the prefix list name (should be existing and configured).</li> </ul>                                                                                    |
| ip-next-hop [BGP-IP-ACCESS-LIST <BGP-ACL-NAME>] prefix-list <PREFIX-LIST-NAME>]     | Configures the next-hop's IP address to match<br>The IP Next Hop is a list of IP addresses used to filter routes based on the IP address of the next-hop in the route. Use one of the following options to provide next-hop's IP addresses: <ul style="list-style-type: none"> <li>BGP-IP-ACCESS-LIST &lt;BGP-ACL-NAME&gt; - Associates an existing BGP ACL with this BGP route map. Specify the BGP ACL name (should be existing and configured).</li> <li>prefix-list &lt;PREFIX-LIST-NAME&gt; - Associates an existing IP next-hop prefix list with this BGP route map. The IP Next Hop Prefix List is a list of prefixes for the route's next-hop determining how the route is filtered. Specify the prefix list name (should be existing and configured).</li> </ul>                            |
| ip-route-source [BGP-IP-ACCESS-LIST <BGP-ACL-NAME>] prefix-list <PREFIX-LIST-NAME>] | Configures the advertised route source IP address to match<br>The IP Route Source is a list of IP addresses used to filter routes based on the advertised IP address of the source. Use one of the following options to provide route-source IP addresses: <ul style="list-style-type: none"> <li>BGP-IP-ACCESS-LIST &lt;BGP-ACL-NAME&gt; - Associates an existing BGP ACL with this BGP route map. Specify the BGP ACL name (should be existing and configured).</li> <li>prefix-list &lt;PREFIX-LIST-NAME&gt; - Associates an existing IP route source prefix list with this BGP route map. The IP Route Source Prefix List is a list of prefixes used to filter routes based on the prefix list used for the source. Specify the prefix list name (should be existing and configured).</li> </ul> |

```
match metric <0-4294967295>
```

```
match metric <0-4294967295>
```

Defines the exterior metric, used for route map distribution, to match BGP uses a route table managed by the external metric defined. Setting a metric provides a dynamic way to load balance between routes of equal cost.

- <0-4294967295> – Specify the external metric value from 0 - 4294967295.

```
match origin [egp|igp|incomplete]
```

```
match origin [egp|igp|incomplete]
```

Configures the source of the BGP route to match. Options include:

- **egp** – Matches if the origin of the route is from the eBGP. eBGP exchanges routing table information between hosts outside an autonomous system.
- **igp** – Matches if the origin of the route is from the iBGP. iBGP exchanges routing table information between routers within an autonomous system.
- **incomplete** – Matches if the origin of the route is not identifiable

```
match tag <0-65535>
```

```
match tag <0-65535>
```

Configures the BGP route tag to match

The Tag is a way to preserve a route's AS path information for routers in iBGP. This option is disabled by default.

- <0-65535> – Specify the iBGP route's tag from 0 - 65535.

## Examples

The following examples show the configuration of match criteria for the deny route-map rule 1:

```
nx9500-6C8809(config-dr-route-map-test-dr-route-map-rule-1)#match as-path FilterList_01
nx9500-6C8809(config-dr-route-map-test-dr-route-map-rule-1)#match ip-route-source prefix-list PrefixList_01
nx9500-6C8809(config-dr-route-map-test-dr-route-map-rule-1)#show context
deny route-map 1
 description "This is a deny route map rule"
 match as-path FilterList_01
 match ip-route-source prefix-list PrefixList_01
nx9500-6C8809(config-dr-route-map-test-dr-route-map-rule-1)#
```

A permit route-map rule 2 is added to the BGP route-map "test".

```
nx9500-6C8809(config-dr-route-map-test)#permit route-map 2
```

A match criteria is added for the permit route-map rule 2.

```
nx9500-6C8809(config-dr-route-map-test-dr-route-map-rule-2)#match ip-next-hop DL_01
nx9500-6C8809(config-dr-route-map-test-dr-route-map-rule-2)#show context
permit route-map 2
 match ip-next-hop DL_01
nx9500-6C8809(config-dr-route-map-test-dr-route-map-rule-2)#
```

The following example displays the BGP route-map "test" settings:

```
nx9500-6C8809(config-dr-route-map-test)#show context
route-map test
 deny route-map 1
 description "This is a deny route map rule"
 match as-path FilterList_01
 match ip-route-source prefix-list PrefixList_01
 permit route-map 2
```

```
match ip-next-hop DL_01
nx9500-6C8809(config-dr-route-map-test)#
```

## Related Commands

`no (bgp-route-map)` on page 1878 Removes match criteria associated with a deny or permit route-map rule

## *set (bgp-route-map)*

Configures the values attributed to a route matching the match criteria specified in the BGP deny or permit route-map rules. These attributes are applied before the route is sent out.

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

### Syntax

```
set [aggregator-as|as-path|atomic-aggregate|comm-list|community|extcommunity|ip|
local-preference|metric|origin|originator-id|source-ip|tag|weight]
set aggregator-as <1-4294967295> <IP>
set as-path [exclude|prepend] <1-4294967295> {<1-4294967295>}
set atomic-aggregate
set comm-list delete <COMMUNITY-LIST-NAME>
set community [<COMMUNITY-NUMBER>|none]
set extcommunity [rt|soo] <EXTCOMMUNITY-NUMBER>
set ip next-hop [<IP>|peer-address]
set local-preference <0-4294967295>
set metric <0-4294967295>
set origin [egp|igp|incomplete]
set originatorid <IP>
set source-ip <IP>
set tag <0-65535>
set weight <0-4294967295>
```

### Parameters

```
set aggregator-as <1-4294967295> <IP>
```

set source-ip <IP>
```

|                                     |                                                                                                                                                                     |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>set source-ip &lt;IP&gt;</pre> | <p>Configures this route map's source IP address</p> <ul style="list-style-type: none"> <li>• &lt;IP&gt; - Specify the IP address in the A.B.C.D format.</li> </ul> |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
set tag <0-65535>
```

```
set tag <0-65535>
```

Configures this route map's tag value  
The Tag is a way to preserve a route's AS path information for routers in iBGP.

- <0-65535> - Specify a tag value from 0 - 65535.

```
set weight <0-4294967295>
```

```
set weight <0-4294967295>
```

Enables assignment of a weighted priority to the aggregate route

- <0-4292967295> - Specify a value from 0 - 4294967295.

## Examples

```
nx9500-6C8809(config-dr-route-map-test-dr-route-map-rule-1)#set aggregator-as 1
192.168.13.7
nx9500-6C8809(config-dr-route-map-test-dr-route-map-rule-1)#set as-path exclude 20
nx9500-6C8809(config-dr-route-map-test-dr-route-map-rule-1)#set community internet
nx9500-6C8809(config-dr-route-map-test-dr-route-map-rule-1)#set ip next-hop peer-address
nx9500-6C8809(config-dr-route-map-test-dr-route-map-rule-1)#set local-preference 30
nx9500-6C8809(config-dr-route-map-test-dr-route-map-rule-1)#set metric 300
nx9500-6C8809(config-dr-route-map-test-dr-route-map-rule-1)#show context
deny route-map 1
 description "This is a deny route map rule"
 match as-path FilterList_01
 match ip-route-source prefix-list PrefixList_01
 set aggregator-as 1 192.168.13.7
 set as-path exclude 20
 set ip next-hop peer-address
 set metric 300
 set local-preference 30
 set community internet
nx9500-6C8809(config-dr-route-map-test-dr-route-map-rule-1)#
```

## Related Commands

```
no (bgp-route-map) on page
1878
```

Removes the attributes configured for this route map

*no (bgp-route-map)*

Removes or reverts the settings defined for a deny or permit route-map rule

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

### Syntax

```
no [description|match <PARAMETERS>|set <PARAMETERS>]
```

### Parameters

```
no <PARAMETERS>
```

```
no <PARAMETERS>
```

Removes the description configured for a deny or permit route-map rule

## Examples

The following example shows the 'deny route-map rule-1' settings before the 'no' commands are executed:

```
nx9500-6C8809(config-dr-route-map-test-dr-route-map-rule-1)#show context
deny route-map 1
 description "This is a deny route map rule"
 match as-path FilterList_01
 match ip-route-source prefix-list PrefixList_01
 set aggregator-as 1 192.168.13.7
 set as-path exclude 20
 set ip next-hop peer-address
 set metric 300
 set local-preference 30
 set community internet
nx9500-6C8809(config-dr-route-map-test-dr-route-map-rule-1)#
nx9500-6C8809(config-dr-route-map-test-dr-route-map-rule-1)#no match as-path
nx9500-6C8809(config-dr-route-map-test-dr-route-map-rule-1)#no set aggregator-as
nx9500-6C8809(config-dr-route-map-test-dr-route-map-rule-1)#no set metric
```

The following example shows the 'deny route-map rule-1' settings after the 'no' commands are executed:

```
nx9500-6C8809(config-dr-route-map-test-dr-route-map-rule-1)#show context
deny route-map 1
 description "This is a deny route map rule"
 match ip-route-source prefix-list PrefixList_01
 set as-path exclude 20
 set ip next-hop peer-address
 set local-preference 30
 set community internet
nx9500-6C8809(config-dr-route-map-test-dr-route-map-rule-1)#
```

The following example shows the route-map 'test' settings:

```
nx9500-6C8809(config-dr-route-map-test)#show context
route-map test
 deny route-map 1
 description "This is a deny route map rule"
 match ip-route-source prefix-list PrefixList_01
 set as-path exclude 20
 set ip next-hop peer-address
 set local-preference 30
 set community internet
 permit route-map 2
 match ip-next-hop DL_01
nx9500-6C8809(config-dr-route-map-test)#
```

## bgp router-config

Use the (device-config) or (profile-config) instance to configure BGP router related parameters.

To navigate to the BGP router configuration instance, in the device-config mode, use the following commands:

```
<DEVICE>(config)#self
<DEVICE>(config-device-<MAC>)#router bgp
<DEVICE>config-device <MAC>-router-bgp)#
<DEVICE>config-device <MAC>-router-bgp)#?
Router BGP Mode commands:
 aggregate-address Configure aggregate address
 asn Configure local Autonomous System Number
 bgp Border Gateway Protocol
```

```
<DEVICE>config-device <MAC>-router-bgp)#
```

When configured as a profile, the router settings are applied to all devices using the profile.

To navigate to the BGP router configuration instance, in the profile-config mode, use the following commands:

```
<DEVICE>(config)#profile <DEVICE-TYPE> <PROFILE-NAME>
<DEVICE>(config-profile-<PROFILE-NAME>)#router bgp
<DEVICE>(config-profile <PROFILE-NAME>-router-bgp)#
<DEVICE>(config-profile <PROFILE-NAME>-router-bgp)#?
```

Router BGP Mode commands:

| no                  | Negate a command or set its defaults                   |
| route- redistribute | Redistribute information from another routing protocol |
| timers              | Adjust routing timers                                  |
|                     |                                                        |
| clrscr              | Clears the display screen                              |
| commit              | Commit all changes made in this session                |
| do                  | Run commands from Exec mode                            |
| end                 | End current mode and change to EXEC mode               |
| exit                | End current mode and down to previous mode             |
| help                | Description of the interactive help system             |
| revert              | Revert changes                                         |
| service             | Service Commands                                       |
| show                | Show running system information                        |
| write               | Write running configuration to memory or terminal      |

```
<DEVICE>(config-profile <PROFILE-NAME>-router-bgp)#
```

The following table summarizes BGP router configuration mode commands:

**Table 77: BGP-Router Config Mode Commands**

| Command                                                             | Description                                                                   |
|---------------------------------------------------------------------|-------------------------------------------------------------------------------|
| <a href="#">aggregate (bgp-router-config)</a> on page 1881          | Creates and configures an aggregate address entry in the BGP database         |
| <a href="#">asn (bgp-router-config)</a> on page 1882                | Configures this BGP router's ASN                                              |
| <a href="#">bgp (bgp-router-config)</a> on page 1882                | Configures BGP router parameters                                              |
| <a href="#">bgp-route-limit (bgp-router-config)</a> on page 1887    | Configures the BGP route limit parameters                                     |
| <a href="#">distance (bgp-router-config)</a> on page 1888           | Configures administrative distance parameters                                 |
| <a href="#">ip (bgp-router-config)</a> on page 1889                 | Configures the BGP default gateway's priority                                 |
| <a href="#">network (bgp-router-config)</a> on page 1890            | Configures the local network IP addresses and masks                           |
| <a href="#">route-redistribute (bgp-router-config)</a> on page 1891 | Enables redistribution of routes learnt from other routing protocols into BGP |
| <a href="#">timers (bgp-router-config)</a> on page 1892             | Enables adjustment of keepalive and holdtime intervals                        |
| <a href="#">no (bgp-router-config)</a> on page 1893                 | Removes the BGP router settings                                               |

### *aggregate (bgp-router-config)*

Creates and configures an aggregate address entry in the BGP database

#### **Supported in the following platforms:**

- Wireless Controllers – RFS 4000
- Service Platforms – NX 95XX, NX 96XX

#### **Syntax**

```
aggregate-address <IP/M> {as-set {summary-only}|summary-only}
```

#### **Parameters**

```
aggregate-address <IP/M> {as-set {summary-only}|summary-only}
```

|                          |                                                                                                                                                                                                        |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| aggregate-address <IP/M> | Specify the aggregate IP address and mask                                                                                                                                                              |
| as-set {summary-only}    | Optional. Summarizes the AS_PATH attributes of the individual routes aggregated <ul style="list-style-type: none"> <li>• summary-only – Optional. Filters more specific routes from updates</li> </ul> |

#### **Examples**

```

nx9500-6C8809(config-device B4-C7-99-6C-88-09-router-bgp)#aggregate-address
192.168.13.10/32 as-set summary-only
nx9500-6C8809(config-device B4-C7-99-6C-88-09-router-bgp)#show context
router bgp
 bgp enable
 asn 1
 aggregate-address 192.168.13.10/32 as-set summary-only

```

```

 bgp neighbor 192.168.13.199
 remote-as 1
 use route-map UnSupMap_01 in
 bgp neighbor 192.168.13.99
 remote-as 199
 timers connect 10
 timers 20 40
 maximum-prefix 9999 80 restart 50
 bgp neighbor 1.1.1.1
 remote-as 2
 timers connect 10
 timers 20 40
 maximum-prefix 1000000
 bgp-route-limit num-routes 10 reset-time 360
nx9500-6C8809(config-device B4-C7-99-6C-88-09-router-bgp)#

```

### Related Commands

|                                                  |                                     |
|--------------------------------------------------|-------------------------------------|
| <code>no (bgp-router-config)</code> on page 1893 | Removes the aggregate address entry |
|--------------------------------------------------|-------------------------------------|

### *asn (bgp-router-config)*

Configures the ASN. The ASN represents a group of routers under the same administration and using IGP and common metrics to define how to route packets. In short the ASN represents all routers within an AS.

#### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

#### Syntax

```
asn <1-4294967295>
```

#### Parameters

```
asn <1-4294967295>
```

|                                       |                                      |
|---------------------------------------|--------------------------------------|
| <code>asn &lt;1-4294967295&gt;</code> | Specify the ASN from 1 - 4294967295. |
|---------------------------------------|--------------------------------------|

#### Examples

```

nx9500-6C8809(config-profile NX9500Profile-router-bgp)#asn 1
nx9500-6C8809(config-profile NX9500Profile-router-bgp)#show context
 router bgp
 asn 1
nx9500-6C8809(config-profile NX9500Profile-router-bgp)#

```

#### Related Commands

|                                                  |                                 |
|--------------------------------------------------|---------------------------------|
| <code>no (bgp-router-config)</code> on page 1893 | Removes the configured the ASN. |
|--------------------------------------------------|---------------------------------|

### *bgp (bgp-router-config)*

Configures BGP router parameters

## Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

## Syntax

```
bgp [always-compare-med|bestpath|client-to-client|cluster-id|confederation|
dampening|default|deterministic-med|enable|enforce-first-as|fast-external-failover|
graceful-restart|log-neighbor-changes|neighbor|network|router-id|scan-time]
bgp [always-compare-med|deterministic-med|enable|enforce-first-as|
fast-external-failover|log-neighbor-changes]
bgp best-path [as-path [confed|ignore]|compare-router-id|med {confed {missing-as-worst}}|
missing-as-worst}]
bgp client-to-client reflection
bgp cluster <IP>
bgp confederation [identifier|peers] <1-4294967295>
bgp dampening {<1-45>} {<1-20000>} <1-20000> <1-255>
bgp default [ipv4-unicast|local-preference <0-4294967295>]
bgp graceful-restart {stalepath-time <1-3600>}
bgp neighbor <IP>
bgp network import-check
bgp router-id <IP>
bgp scan-time <5-60>
```

## Parameters

```
bgp [always-compare-med|deterministic-med|enable|enforce-first-as|
fast-external-failover|log-neighbor-changes]
```

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| always-compare-med | Enables comparison of MEDs (Multi-exit Discriminators) received from neighbors. This option is disabled by default.<br>MED is a value used by BGP peers to select the best route among multiple routes. When enabled, the MED value encoded in the route is always compared when selecting the best route to the host network. A route with a lower MED value is preferred over a route with a higher MED value. BGP does not discriminate between iBGP and eBGP when using MED for route selection. This option is mutually exclusive to the <i>deterministic-med</i> option. |
| deterministic-med  | Enables selection of the best MED path from amongst all paths advertised by neighboring ASs. This option is disabled by default.<br>MED is used by BGP peers to select the best route among multiple routes. When enabled, MED route values (from the same AS) are compared to select the best route. This best route is then compared with other routes in the BGP route table to select the best overall route. This option is mutually exclusive to the always-compare-med option.                                                                                          |
| enable             | Starts the BGP daemon on the device (wireless controller or service platform). BGP is disabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| enforce-first-as   | Enforces the first AS for all BGP routes. This option is disabled by default. When enforced, devices deny updates received from an external neighbor that does not have the neighbor's configured AS at the beginning of the received AS path parameter. This enhances security by not allowing traffic from an unauthorized AS.                                                                                                                                                                                                                                               |

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| fast-external-failover | <p>Enables immediate resetting of BGP session on the interface once the BGP connection goes down. This option is enabled by default.</p> <p>When enabled, a session is reset as soon as the direct link to an external peer goes down. Normally, when a BGP connection goes down, the device waits for the expiry of the duration specified in holdtime parameter before bringing down the interface.</p> <p>To configure the 'holdtime', use the <b>timers &gt; bgp &gt; &lt;keepalive-time&gt; &gt; &lt;holdtime&gt;</b> command in this (BGP router) configuration mode.</p> |
| log-neighbor-changes   | <p>Enables logging of a BGP neighbor's status change (active or not active) events. It also enables the logging of the reason for such change in status.</p>                                                                                                                                                                                                                                                                                                                                                                                                                    |

```
bgp best-path [as-path [confed|ignore]|compare-router-id|med {confed {missing-as-worst}}|missing-as-worst}]
```

|                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| best-path                                         | <p>Modifies the bestpath selection algorithm. The route selection algorithm uses the following criteria when selecting the preferred route: as-path, router-id, and med.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| as-path [confed ignore]                           | <p>Enables an AS path from being considered as a criteria for selecting the preferred route</p> <ul style="list-style-type: none"> <li>• confed – Enables comparison of path lengths (including confederation sets and sequences) when selecting a route (EXPERIMENTAL). This option is disabled by default.</li> <li>• ignores – Disables an AS path length from being considered as a criteria for selecting a preferred route. When, disabled the AS path length is ignored. This option is disabled by default.</li> </ul>                                                                                                                                                                                                                                                                                                                                  |
| compare-router-id                                 | <p>Enables the use of router ID as a selection criteria when selecting the preferred route. When enabled, the router ID is used to select the best path between two identical BGP routes. The route with the lower router ID is selected over a route with a higher router ID. This option is disabled by default.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| med {confed {missing-as-worst}} missing-as-worst} | <p>Enables comparison of AS path MED value when selecting the preferred route</p> <p>MED is a value used by BGP peers to select the best route among multiple routes. When enabled, the MED value encoded in the route is always compared to determine the best route to the host network. A route with a lower MED value is preferred over a route with a higher MED value.</p> <ul style="list-style-type: none"> <li>• confed – Optional. Enables comparison of MED value among confederation paths (EXPERIMENTAL). When enabled, you can optionally enable the treatment of AS paths without the MED value as the least preferable route. This option is disabled by default.</li> <li>• missing-as-worst – Optional. Enables the treatment of AS paths without the MED value as the least preferable route. This option is disabled by default.</li> </ul> |

```
bgp client-to-client reflection
```

|                             |                                                                                                                                                                                                                                                          |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| client-to-client reflection | <p>Enables client-to-client route reflection (EXPERIMENTAL)</p> <p>Route reflectors are used when all iBGP speakers are not fully meshed. If the clients are fully meshed, the route-reflectors are not required. This option is enabled by default.</p> |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
bgp cluster <IP>
```

cluster <IP>

Enables and sets a cluster ID, in case the BGP cluster has more than one route-reflector  
A cluster generally consists of a single route-reflector and its clients. The cluster is usually identified by the router ID of this single route-reflector. Sometimes, to increase redundancy, a cluster might have more than one route-reflector configured. In this case, all route-reflectors in the cluster are identified by the cluster ID (configured in the IP format).

`bgp confederation [identifier|peers] <1-4294967295>`

confederation [identifier|peers]  
<1-4294967295>

Configures AS confederation (group of ASs) parameters (identifier and peers)

- identifier – Enables and sets a BGP confederation identifier to allow an AS to be divided into several ASs. In other words an AS is divided into multiple ASs, and together they form a confederation. This confederation is visible to external routers as a single AS. The ASN is usually the confederation ID. Specify a value from 1 - 4294967295.

Forming AS confederation reduces iBGP mesh inside an AS.

- peers – Configures the maximum number of the ASs constituting this BGP confederation. Specify the AS number from 1 - 4294967295. Multiple ASs can be added to the list of confederation members.

`bgp dampening {<1-45>} {<1-20000>} <1-20000> <1-255>`

bgp dampening {<1-45>}  
{<1-20000>} <1-20000> <1-255>

Enables dampening and configures dampening parameters. This option is disabled by default.  
Dampening minimizes the instability caused by route flapping. A penalty is added for every flap in the flapping route. As soon as the total penalty reaches the specified Route Suppress Limit value, the advertisement of this route is suppressed. This penalty is delayed when the time specified in Half Lifetime occurs. Once the penalty becomes lower than the value specified in Start Route Reuse, the advertisement of the route is un-suppressed.

- <1-45> – Optional. Configures the half lifetime (in minutes). A penalty is imposed on a route that flaps. This is the time for the penalty to decrease to half its current value. Specify a value from 1 - 45 minutes. The default is 1 minute.
- <1-20000> – Optional. Configures the route reuse value. When the penalty for a suppressed route decays below the value specified here, the route is un-suppressed (reused). Specify a value from 1 - 20000.
- <1-20000> – Configures the route suppress value. When a route flaps, a penalty is added to the route. When the penalty reaches or exceeds the value specified as the 'maximum duration to suppress a stable route'. Specify a value from 1 - 20000.

The maximum duration to suppress a stable route, is the next set of value configured in this command from 1 - 255.

- <1-255> – Configures the maximum duration, in minutes, a suppressed route is suppressed. This is the maximum duration for which a route remains suppressed before it is reused. Specify a value from 1 - 255 minutes.

`bgp default [ipv4-unicast|local-preference <0-4294967295>]`

|                                 |                                                                                                                                                                                                           |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| default                         | Configures the following defaults for BGP neighbor-related parameters: IPv4 unicast and local preference                                                                                                  |
| ipv4-unicast                    | Enable IPv4 unicast traffic for neighbors. This option is enabled by default.                                                                                                                             |
| local-preference <0-4294967295> | Configures a local preference for the neighbor. Higher the value higher is the preference. <ul style="list-style-type: none"> <li>&lt;0-4294967295&gt; – Specify a value from 10 - 4294967295.</li> </ul> |

`bgp graceful-restart {stalepath-time <1-3600>}`

|                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| default graceful-restart {stalepath-time <1-3600>} | Enables graceful restart on this BGP router. This option is disabled by default <ul style="list-style-type: none"> <li>stalepath-time &lt;1-3600&gt; – Optional. Configures the maximum time, in seconds, to retain stale paths from restarting neighbor. This is the time the paths from a restarting neighbor are preserved. All stale paths, unless reinstated by the neighbor after re-establishment, are deleted at the expiry of the time specified here. <ul style="list-style-type: none"> <li>&lt;1-3600&gt; – Specify a value from 1 - 3600 seconds.</li> </ul> </li> </ul> |
|----------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

`bgp neighbor <IP>`

|               |                                                                                                                                                                                                                                                                                                                                                      |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| neighbor <IP> | Configures the BGP neighbor's IP address and enters its configuration mode. Use this command to configure a BGP neighbor's parameters. <ul style="list-style-type: none"> <li>&lt;IP&gt; – Specify the IP address in the A.B.C.D format.</li> </ul> <p>For BGP neighbor configuration parameters, see <code>bgp-neighbor-config</code> commands.</p> |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

`bgp network import-check`

|                      |                                                                                |
|----------------------|--------------------------------------------------------------------------------|
| network import-check | Enables checking of the existence of BGP network route in IGP before importing |
|----------------------|--------------------------------------------------------------------------------|

`bgp router-id <IP>`

|             |                                                                                                                                                                                                                                                                                                                               |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| router <IP> | Enables the device (BGP supported wireless controller or service platform) identified by the <IP> parameter as a router. The router's IP address is configured as its ID, and uniquely identifies it. When not specified, the IP address of the interface is configured as the router ID. This option is disabled by default. |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

`bgp scan-time <5-60>`

scan-time <5-60>

Configures the scanning interval, in seconds, for updating BGP routes. This is the interval between two consecutive scans the BGP device performs in order to validate routes in its routing table. To disable scanning, set the value to Zero (0).

- <5-60> - Specify a value from 5 - 60 seconds. The default is 60 seconds.

## Examples

```
nx9500-6C8809(config-profile testNX9000-router-bgp)#bgp router-id 192.168.13.13
nx9500-6C8809(config-profile testNX9000-router-bgp)#aggregate-address 116.117.118.0/24 as-
set summary-only
nx9500-6C8809(config-profile testNX9000-router-bgp)#bgp neighbor 192.168.13.99
nx9500-6C8809(config-profile testNX9000-router-bgp)#show context
router bgp
 aggregate-address 116.117.118.0/24 as-set summary-only
 bgp router-id 192.168.13.13
 bgp neighbor 192.168.13.99
 remote-as 199
 maximum-prefix 9999 80 restart 50
nx9500-6C8809(config-profile testNX9000-router-bgp)#
```

## Related Commands

**no (bgp-router-config)** on  
page 1893

Removes the BGP router parameters. The no > bgp > enable command disabled BGP.

## *bgp-route-limit (bgp-router-config)*

Configures the BGP route limit parameters

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

### Syntax

```
bgp-route-limit [num-routes <VALUE>|reset-time <1-86400>|retry-count <1-32>|
retry-timeout <1-3600>]
```

### Parameters

```
bgp-route-limit [num-routes <VALUE>|reset-time <1-86400>|retry-count <1-32>|
retry-timeout <1-3600>]
```

num-routes <VALUE>

Configures the number of routes that can be stored on this BGP router. Set this value based on the available memory on this BGP router (wireless controller or service platform).

- <VALUE> - Specify a value from 1 - 4,294,967,295. The default is 9216 routes.

reset-time <1-86400>

Configures the reset time in seconds. This is the time after which the retry count value is set to Zero (0).

- <1-86400> - Specify a value from 1 - 86,400 seconds. The default is 360 seconds.

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| retry-count <1-32>     | Configures the maximum number of times the BGP process is reset before being permanently shut down. Once shut down, the BGP process has to be started manually. The BGP process is reset if it is flooded with route entries that exceed the maximum number of routes configured for this device. <ul style="list-style-type: none"> <li>&lt;1-32&gt; – Specify a value from 1 - 32. The default is 5 routes.</li> </ul> |
| retry-timeout <1-3600> | Configures the duration, in seconds, the BGP process is temporarily shut down, before a reset of the process is attempted. <ul style="list-style-type: none"> <li>&lt;1-3600&gt; – Specify a value from 1 - 3600 seconds. The default is 60 seconds.</li> </ul>                                                                                                                                                          |

### Examples

```

nx9500-6C8809(config-profile NX9500Profile-router-bgp)#bgp-route-limit num-routes 10
nx9500-6C8809(config-profile NX9500Profile-router-bgp)#show context
router bgp
 bgp enable
 asn 1
 aggregate-address 116.117.118.0/24 as-set summary-only
 bgp neighbor 192.168.13.99
 remote-as 199
 maximum-prefix 9999 80 restart 50
 bgp-route-limit num-routes 10
nx9500-6C8809(config-profile NX9500Profile-router-bgp)#

### *distance (bgp-router-config)*

Configures administrative distance parameters. The distance parameter is a rating of the trustworthiness of a route. The higher the distance, lower is the trust rating. The distance can be set for each type of route indicating its trust rating.

#### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

#### Syntax

```
distance [<IP/M> <1-255> <BGP-ACL-NAME>|bgp <1-255> <1-255> <1-255>]
```

#### Parameters

```
distance [<IP/M> <1-255> <BGP-ACL-NAME>|bgp <1-255> <1-255> <1-255>]
```

|                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

### *ip (bgp-router-config)*

Configures the BGP default gateway's priority

#### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

#### Syntax

```
ip default-gateway priority <1-8000>
```

#### Parameters

```
ip default-gateway priority <1-8000>
```

|                                   |                                                                                                                                                                                                                                           |

### *network (bgp-router-config)*

Configures the local network IP addresses and masks. These network addresses are broadcasted to neighboring BGP peers. You can configure a single IP address or a range of IP addresses in the A.B.C.D/M notation.

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

### Syntax

```
network <IP/M> {backdoor/pathlimit/route-map}
network <IP/M> {backdoor pathlimit <1-255>}
network <IP/M> {pathlimit <1-255>}
network <IP/M> {route-map <ROUTE-MAP-NAME>}
```

### Parameters

```
network <IP/M> {backdoor pathlimit <1-255>/pathlimit <1-255>/route-map <ROUTE-MAP-NAME>}
```

|                            |                                                                                                                                                                                                                                                                                                    |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| network <IP/M>             | Configures the local network's address in the A.B.C.D/M format <ul style="list-style-type: none"><li>• &lt;IP/M&gt; - Specify the network address.</li></ul>                                                                                                                                       |
| backdoor pathlimit <1-255> | Optional. Configures a BGP backdoor route. After configuring the backdoor route, you can optionally configure the as-path hop count limit attribute for this backdoor route. <ul style="list-style-type: none"><li>• pathlimit &lt;1-255&gt; - Specify the hop count limit from 1 - 255.</li></ul> |
| pathlimit <1-255>          | Optional. Configures the maximum path limit for this AS <ul style="list-style-type: none"><li>• &lt;1-255&gt; - Specify the hop count limit from 1 - 255.</li></ul>                                                                                                                                |
| route-map <ROUTE-MAP-NAME> | Optional. Associates a BGP route map with this local network. When applied, the route-map values take precedence <ul style="list-style-type: none"><li>• &lt;ROUTE-MAP-NAME&gt; - Specify the route map name.</li></ul>                                                                            |

## Examples

```
nx9500-6C8809(config-profile testNX9000-router-bgp)#network 192.168.13.0/24 backdoor
pathlimit 200

### *route-redistribute (bgp-router-config)*

Enables redistribution of routes learnt from other routing protocols into BGP.

Large ISP networks using multiple routing protocols, need to enable redistribution of routes across routing protocols. Routing protocols differ in their basic characteristics, such as metrics, administrative distance, classful and classless capabilities, etc. When enabling redistribution, these differences have to be taken into consideration.

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

### Syntax

```
route-redistribute [connected|kernel|ospf|static] {metric <0-4294967295>/route-map <ROUTE-MAP-NAME>}
```

### Parameters

```
route-redistribute [connected|kernel|ospf|static] {metric <0-4294967295>/route-map <ROUTE-MAP-NAME>}
```

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| route-redistribute | Redistributes routes learnt from other protocols                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

### *no (bgp-router-config)*

Removes the BGP router settings

#### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

#### Syntax

```
no [aggregate-address|bgp|bgp-route-limit|distance|ip|network|route-redistribute|timers]
```

#### Parameters

```
no <PARAMETERS>
```

|                                    |                                                                |
|------------------------------------|----------------------------------------------------------------|
| <code>no &lt;PARAMETERS&gt;</code> | Removes the BGP router settings based on the parameters passed |
|------------------------------------|----------------------------------------------------------------|

### Examples

The following example shows the BGP router settings before the 'no' commands have been executed:

```

nx9500-6C8809(config-device B4-C7-99-6C-88-09-router-bgp)#show context
router bgp
 bgp enable

```

```

asn 1
aggregate-address 116.117.118.0/24 as-set summary-only
bgp neighbor 192.168.13.199
 remote-as 1
 use route-map UnSupMap_01 in
bgp neighbor 192.168.13.99

nx9500-6C8809(config-device B4-C7-99-6C-88-09-router-bgp)#no bgp-route-limit

```

The following example shows the BGP router settings after the 'no' commands have been executed:

```

nx9500-6C8809(config-device B4-C7-99-6C-88-09-router-bgp)#show context
router bgp
 bgp enable
 asn 1
 bgp neighbor 192.168.13.199
 remote-as 1
 use route-map UnSupMap_01 in
nx9500-6C8809(config-device B4-C7-99-6C-88-09-router-bgp)#

```

## bgp neighbor-config

BGP enabled devices connected through an established TCP connection are referred to as BGP peers or neighbors. To establish a TCP connection, BGP routers exchange open messages containing the following information: AS number, BGP version running, BGP router ID, and timer values (keepalive and holdtime). Once these values are accepted by both devices, the connection is established and the routers become neighbors. With the TCP connection established the BGP neighbors begin sharing routing information and updates. A failure in the establishment of the TCP connection indicates that the routers are not neighbors and cannot exchange routing information.

Use the (profile/device-config) instance to configure BGP neighbors.

To navigate to the BGP neighbor configuration instance, use the following commands:

```

<DEVICE>(config)#profile <PROFILE-NAME>
<DEVICE>(config-profile <PROFILE-NAME>)#router bgp
<DEVICE>(config-profile <PROFILE-NAME>-router-bgp)#?
<DEVICE>(config-profile <PROFILE-NAME>-router-bgp)#bgp neighbor ?
 A.B.C.D IP address of the bgp neighbor

<DEVICE>(config-profile <PROFILE-NAME>-router-bgp)#
<DEVICE>(config-profile <PROFILE-NAME>-router-bgp)#bgp neighbor <IP>
<DEVICE>(config-profile <PROFILE-NAME>-router-bgp-neighbor-<IP>)#?
Router BGP Neighbor Mode commands:
 activate Enable the Address Family for this Neighbor
 (EXPERIMENTAL)
 advertisement-interval Minimum interval between BGP routing updates
 allowas-in Accept as-path with my AS present in it
 (EXPERIMENTAL)
 attribute-unchanged BGP attribute is propagated unchanged to this
 neighbor (EXPERIMENTAL)
 capability Advertise capability to the peer
 default-originate Originate default route to this neighbor
 description Neighbor specific description
 disable-connected-check One-hop away EBGp peer using loopback address
 (EXPERIMENTAL)

```

```

dont-capability-negotiate Do not perform capability negotiation
 (EXPERIMENTAL)
ebgp-multihop Allow EBGp neighbors not on directly connected
 networks
enforce-multihop Enforce EBGp neighbors perform multihop
 (EXPERIMENTAL)
local-as Specify a local-as number (EXPERIMENTAL)
maximum-prefix Maximum number of prefix accept from this peer
next-hop-self Disable the next hop calculation for this
 neighbor
no Negate a command or set its defaults
override-capability Override capability negotiation result
passive Don't send open messages to this neighbor
password Set a password
peer-group Set peer-group for this neighbor (EXPERIMENTAL)
port Neighbor's BGP port (EXPERIMENTAL)
remote-as Specify a BGP neighbor
remove-private-as Remove private AS number from outbound updates
 (EXPERIMENTAL)
route-server-client Configure a neighbor as Route Server client
 (EXPERIMENTAL)
send-community Send Community attribute to this neighbor
shutdown Administratively shut down this neighbor
soft-reconfiguration Per neighbor soft reconfiguration
strict-capability-match Strict capability negotiation match
 (EXPERIMENTAL)
timers BGP per neighbor timers
unsuppress-map Route-map to selectively unsuppress suppressed
 routes
update-source Source of routing updates
use Set setting to use
weight Set default weight for routes from this neighbor

The following table summarizes BGP deny/permit route map rules configuration mode commands:

**Table 78: BGP-Neighbor Config Mode Commands**

| Command                                                                   | Description                                                                                          |
|---------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------|
| <a href="#">activate (bgp-neighbor-config)</a> on page 1897               | Enables an address family for this neighbor (EXPERIMENTAL)                                           |
| <a href="#">advertisement-interval (bgp-neighbor-config)</a> on page 1897 | Configures the minimum interval between two consecutive BGP router updates                           |
| <a href="#">allowas-in (bgp-neighbor-config)</a> on page 1898             | Enables re-advertisement of all prefixes containing duplicate ASNs (EXPERIMENTAL)                    |
| <a href="#">attribute-unchanged (bgp-neighbor-config)</a> on page 1899    | Enables the propagation of BGP attribute values unchanged to this neighbor BGP device (EXPERIMENTAL) |

**Table 78: BGP-Neighbor Config Mode Commands (continued)**

| Command                                                                      | Description                                                                                                                                                    |
|------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">capability (bgp-neighbor-config)</a> on page 1900                | Enables the advertisement of capability (dynamic and ORF) to BGP peers                                                                                         |
| <a href="#">default-originate (bgp-neighbor-config)</a> on page 1900         | Enables the sending of the default route to BGP neighbors. It also allows the configuration of the default route.                                              |
| <a href="#">description (bgp-neighbor-config)</a> on page 1901               | Configures a description for a BGP neighbor device                                                                                                             |
| <a href="#">disable-connected-check (bgp-neighbor-config)</a> on page 1902   | Enables one-hop away EBGP peer using loop back address (EXPERIMENTAL)                                                                                          |
| <a href="#">dont-capability-negotiate (bgp-neighbor-config)</a> on page 1902 | Disables capability negotiation with BGP neighbors (EXPERIMENTAL)                                                                                              |
| <a href="#">ebgp-multihop (bgp-neighbor-config)</a> on page 1903             | Enables eBGP Multihop on this BGP neighbor, and configures the maximum number of hops that can be between eBGP neighbors not directly connected to each other. |
| <a href="#">enforce-multihop (bgp-neighbor-config)</a> on page 1904          | Forces EBGP neighbors to perform multi-hop checks (EXPERIMENTAL)                                                                                               |
| <a href="#">local-as (bgp-neighbor-config)</a> on page 1904                  | Configures this neighbor's local AS number. Also enables the prepending of this AS number in route updates. (EXPERIMENTAL)                                     |
| <a href="#">maximum-prefix (bgp-neighbor-config)</a> on page 1905            | Configures the maximum number of prefixes that can be received from a BGP neighbor                                                                             |
| <a href="#">next-hop-self (bgp-neighbor-config)</a> on page 1906             | Enables next-hop calculation for this neighbor                                                                                                                 |
| <a href="#">override-capability (bgp-neighbor-config)</a> on page 1907       | Enables the overriding of capability negotiation results                                                                                                       |
| <a href="#">passive (bgp-neighbor-config)</a> on page 1908                   | Enables this BGP neighbor device (or devices using this profile) as passive                                                                                    |
| <a href="#">password (bgp-neighbor-config)</a> on page 1909                  | Sets a password for this BGP neighbor device (or devices using this profile)                                                                                   |
| <a href="#">peer-group (bgp-neighbor-config)</a> on page 1909                | Sets the peer group for this BGP neighbor device (or devices using this profile) (EXPERIMENTAL)                                                                |
| <a href="#">port (bgp-neighbor-config)</a> on page 1910                      | Configures a non-standard BGP port for this BGP neighbor (EXPERIMENTAL)                                                                                        |
| <a href="#">remote-as (bgp-neighbor-config)</a> on page 1911                 | Configures the ASN for this neighbor BGP device (or devices using this profile)                                                                                |
| <a href="#">remove-private-as (bgp-neighbor-config)</a> on page 1912         | Removes the private ASN from outbound updates (EXPERIMENTAL)                                                                                                   |
| <a href="#">route-server-client (bgp-neighbor-config)</a> on page 1913       | Enables this BGP neighbor device (or devices using this profile) to act as a route server client (EXPERIMENTAL)                                                |
| <a href="#">send-community (bgp-neighbor-config)</a> on page 1914            | Enables sending of the community attribute to the BGP neighbor                                                                                                 |
| <a href="#">shutdown (bgp-neighbor-config)</a> on page 1915                  | Shuts down this BGP neighbor device (or devices using this profile)                                                                                            |

**Table 78: BGP-Neighbor Config Mode Commands (continued)**

| Command                                                                    | Description                                                                                                                                                                                   |
|----------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">soft-reconfiguration (bgp-neighbor-config)</a> on page 1915    | Enables storing of updates for inbound soft reconfiguration                                                                                                                                   |
| <a href="#">strict-capability-match (bgp-neighbor-config)</a> on page 1916 | Enables a strict capability match before allowing a neighbor BGP peer to open a connection (EXPERIMENTAL)                                                                                     |
| <a href="#">timers (bgp-neighbor-config)</a> on page 1916                  | Configures this BGP neighbor's keepalive and holdtime durations                                                                                                                               |
| <a href="#">unsuppress-map (bgp-neighbor-config)</a> on page 1918          | Uses a route-map that selectively un suppresses routes that have been suppressed using the aggregate-address command                                                                          |
| <a href="#">update-source (bgp-neighbor-config)</a> on page 1918           | Allows BGP sessions to use any operational interface to establish the TCP connection with this neighbor                                                                                       |
| <a href="#">use (bgp-neighbor-config)</a> on page 1919                     | Configures filters for this neighbor. These filters are BGP IP ACL, IP prefix list, AS path list, and route map. Based on the filters used, updates received from this neighbor are filtered. |
| <a href="#">weight (bgp-neighbor-config)</a> on page 1920                  | Configures a weight for all routes learned from this BGP neighbor                                                                                                                             |
| <a href="#">no (bgp-neighbor-config)</a> on page 1921                      | Removes this BGP neighbor's settings, or reverts them back to default                                                                                                                         |

*activate (bgp-neighbor-config)*

Enables an address family for this neighbor. This option is enabled by default.

**Supported in the following platforms:**

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

**Syntax**

activate

**Parameters**

None

**Examples**

```
nx9500-6C8809(config-profile testNX9500-router-bgp-neighbor-192.168.13.99)#activate
```

**Related Commands**

|                                                       |                                                   |

*advertisement-interval (bgp-neighbor-config)*

Configures the minimum interval, in seconds, between two consecutive BGP router updates

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

### Syntax

```
advertisement-interval <0-600>
```

### Parameters

```
advertisement-interval <0-600>
```

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| advertisement-interval <0-600> | Configures the minimum interval, in seconds, between two consecutive BGP router updates. Sending too many router updates creates flapping of routes leading to possible disruptions. Specify a minimum interval so that the BGP routing updates are sent after the set interval. <ul style="list-style-type: none"><li>• &lt;0-600&gt; - Specify a value from 0 - 600 seconds. The default is 5 seconds.</li></ul> |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Examples

```
nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)# advertisement-interval 100
nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#show
context
 bgp neighbor 192.168.13.99
 advertisement-interval 100
nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#
```

### Related Commands

|----------------------------------------------------|------------------------------------------------------------------------------------------------|

### *allows-in (bgp-neighbor-config)*

Enables re-advertisement of all prefixes containing duplicate ASNs. Use this command to configure the maximum number of times an ASN is advertised. This option is disabled by default.

When enabled, PE (Provider Edge) routers can re-advertise all prefixes containing duplicate ASNs. This creates a pair of VRF (VPN Routing/Forwarding) instances on each PE router to receive and re-advertise prefixes. The PE router receives prefixes with ASNs from all PE routers and advertises to its neighbor PE routers on one VRF. The other VRF receives prefixes with ASNs from the CE (Customer Edge) routers and re-advertises them to all PE routers in the configuration.

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

### Syntax

```
allows-in <1-10>
```

### Parameters

```
allows-in <1-10>
```

allows-in <1-10>

Enables and configures the maximum number of times an ASN is advertised.

- <1-10> – Specify a value from 1 - 10.

### Examples

```
nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#allows-in 10
nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#show context
 bgp neighbor 192.168.13.99
 advertisement-interval 100
 allows-in 10
nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#
```

### Related Commands

[no \(bgp-neighbor-config\)](#) on page 1921

Disables re-advertisement of all prefixes containing duplicate ASNs.

### *attribute-unchanged (bgp-neighbor-config)*

Enables propagation of BGP attribute values unchanged to this neighbor BGP device. The BGP attributes are: as-path, med, and next-hop.

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

### Syntax

```
attribute-unchanged { (as-path|med|next-hop) }
```

### Parameters

```
attribute-unchanged { (as-path|med|next-hop) }
```

attribute-unchanged

Enables the propagation of the following BGP attribute values unchanged:

- as-path – Optional. Enables propagation of AS path BGP attribute unchanged to this neighbor BGP device. This option is disabled by default.
- med – Optional. Enables propagation of MED BGP attribute unchanged to this neighbor BGP device. This option is disabled by default.
- next-hop – Optional. Enables propagation of the next-hop BGP attribute value unchanged to this neighbor BGP device. This option is disabled by default.

### Examples

```
nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#attribute-
unchanged as-path
nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#show
context
 bgp neighbor 192.168.13.99
 advertisement-interval 100
 allows-in 10
 attribute-unchanged as-path
nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#
```

### *capability (bgp-neighbor-config)*

Enables the advertisement of capability (dynamic and ORF) to BGP peers

#### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

#### Syntax

```
capability [dynamic|orf]
capability dynamic
capability orf prefix-list [both|receive|send]
```

#### Parameters

```
capability dynamic
```

|                                 |                                                                                                                                                                                                                                             |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>capability dynamic</code> | Enables the advertisement of dynamic capability<br>Enable this option to show a neighbor device's capability to advertise or withdraw and address capability to other peers in a non-disruptive manner. This option is disabled by default. |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
capability orf prefix-list [both|receive|send]
```

|                                                             |                                                                                                              |
|-------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>capability orf prefix-list [both receive send]</code> | Enables the advertisement of Outbound Router Filtering (ORF) capability. This option is disabled by default. |
|-------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|

#### Examples

#### Related Commands

### *default-originate (bgp-neighbor-config)*

Enables the sending of the default route to BGP neighbors. It also allows the configuration of the default route. When enabled and configured, local BGP routers send the default route 0.0.0.0 (or a route map specified route) to its neighbor for use as the default route.

#### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

#### Syntax

```
default-originate {route-map <BGP-ROUTE-MAP-NAME>}
```

## Parameters

default-originate {route-map <BGP-ROUTE-MAP-NAME>}

|                                                       |                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| default-originate<br>{route-map <BGP-ROUTE-MAP-NAME>} | Enables default originate on this BGP neighbor. This option is disabled by default. <ul style="list-style-type: none"><li>route-map &lt;BGP-ROUTE-MAP&gt; – Optional. Use this keyword to specify a route map to use as the default originate route.</li></ul> <p><b>Note:</b> If no route-map is specified, the default route 0.0.0.0 is sent.</p> |
|-------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Examples

```
nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#default-originate
nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#show context
 bgp neighbor 192.168.13.99
 advertisement-interval 100
 allowas-in 10
 attribute-unchanged as-path
 capability orf prefix-list both

| no (bgp-neighbor-config) on page 1921 | Disables sending of the default route to BGP neighbors |
|---------------------------------------|--------------------------------------------------------|

*description (bgp-neighbor-config)*

Configures a description for this BGP neighbor device

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

## Syntax

description neighbor <LINE>

## Parameters

description neighbor <LINE>

|                             |                                                                                       |
|-----------------------------|---------------------------------------------------------------------------------------|
| description neighbor <LINE> | Specify a description for this BGP neighbor device (should not exceed 80 characters). |
|-----------------------------|---------------------------------------------------------------------------------------|

## Examples

```
nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#description
neighbor "This neighbor is an external AS neighbor"

|----------------------------------------------------|-----------------------------------------|

### *disable-connected-check (bgp-neighbor-config)*

Enables one-hop away eBGP peer using loop back address. This option is disabled by default.

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

### Syntax

```
disable-connected-check
```

### Parameters

None

### Examples

```
nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#disable-
connected-check
nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#show context
 bgp neighbor 192.168.13.99
 advertisement-interval 100
 allowas-in 10
 attribute-unchanged as-path
 capability orf prefix-list both
 default-originate

| <code>no (bgp-neighbor-config)</code> on page 1921 | Disables one-hop away eBGP peer using loop back address |
|----------------------------------------------------|---------------------------------------------------------|

### *dont-capability-negotiate (bgp-neighbor-config)*

Disables capability negotiation with BGP neighbors. This is to allow compatibility with older BGP versions that have no capability parameters used in the open messages between peers. Capability negotiation is enabled by default.

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

### Syntax

```
dont-capability-negotiate
```

## Parameters

None

## Examples

```
nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#dont-capability-
negotiate
nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#show context
 bgp neighbor 192.168.13.99
 advertisement-interval 100
 allowas-in 10
 attribute-unchanged as-path
 capability orf prefix-list both
 default-originate
 description neighbor "This neighbor is an external AS neighbor"
 disable-connected-check
 dont-capability-negotiate
nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#
```

## Related Commands

[no \(bgp-neighbor-config\)](#) on page 1921

Enables capability negotiation with BGP neighbors

### *ebgp-multihop (bgp-neighbor-config)*

Enables eBGP Multihop on this BGP neighbor. When enabled, allows neighbor connection to be established between two eBGP neighbors that are not directly connected to each other. Use this command to configure the maximum number of hops possible between two such eBGP neighbors. This option is disabled by default.

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

## Syntax

```
ebgp-multihop <1-255>
```

## Parameters

```
ebgp-multihop <1-255>
```

`ebgp-multihop <1-255>`

Configures the maximum number of hops that can be between eBGP neighbors not directly connected to each other.

- `<1-255>` - Specify a value from 1 - 255. The default is 255.

## Examples

```
nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#ebgp-multihop 20
nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#show context
 bgp neighbor 192.168.13.99
 advertisement-interval 100
 allowas-in 10
 attribute-unchanged as-path
 capability orf prefix-list both
 default-originate
 description neighbor "This neighbor is an external AS neighbor"
 disable-connected-check
```

```
dont-capability-negotiate
ebgp-multihop 20
nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#
```

### Related Commands

| <code>no (bgp-neighbor-config)</code> on page 1921 | Disables eBGP Multihop on this BGP neighbor |
|----------------------------------------------------|---------------------------------------------|

### *enforce-multihop (bgp-neighbor-config)*

Forces eBGP neighbors to perform multi-hop checks. A multihop route is a route to external peers on indirectly connected networks. When enforced, eBGP neighbors perform multi-hop check. This option is disabled by default.

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

### Syntax

```
enforce-multihop
```

### Parameters

None

### Examples

```
nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#enforce-multihop
nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#show context
 bgp neighbor 192.168.13.99
 advertisement-interval 100
 allowas-in 10
 attribute-unchanged as-path
 capability orf prefix-list both
 default-originate
 description neighbor "This neighbor is an external AS neighbor"
 disable-connected-check
 dont-capability-negotiate

### *local-as (bgp-neighbor-config)*

Configures this neighbor's local AS number

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

## Syntax

```
local-as <1-4294967295> {no-prepend}
```

## Parameters

```
local-as <1-4294967295> {no-prepend}
```

### *maximum-prefix (bgp-neighbor-config)*

Configures the maximum number of prefixes that can be received from a BGP neighbor. This option is disabled by default.

#### **Supported in the following platforms:**

- Wireless Controllers – RFS 4000
- Service Platforms – NX 95XX, NX 96XX

## Syntax

```
maximum-prefix <1-4294967295> {(<1-100>|restart <1-65535>|warning-only)}
```

## Parameters

```
maximum-prefix <1-4294967295> {(<1-100>|restart <1-65535>|warning-only)}
```

|                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|----------------------------------------------------|------------------------------------------------------------------|

### *next-hop-self (bgp-neighbor-config)*

Enables next-hop calculation for this neighbor. This option is disabled by default. When enabled, this device (or devices using this profile) are configured as the next hop for the BGP speaking neighbor or peer group. This allows the BGP device to change the next hop information that is sent to iBGP peers. The next hop address is set to the IP address of the interface used to communicate with the eBGP neighbor.

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

## Syntax

next-hop-self

## Parameters

None

## Examples

```
nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#next-hop-self
nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#show context

### *override-capability (bgp-neighbor-config)*

Enables the overriding of capability negotiation results. This option is disabled by default.

#### **Supported in the following platforms:**

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

## Syntax

override-capability

## Parameters

None

## Examples

```
nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#override-
capability

### *passive (bgp-neighbor-config)*

Enables this BGP neighbor device (or devices using this profile) as passive. When enabled, local devices do not attempt to open a connection to passive BGP neighbors. This option is disabled by default.

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

### Syntax

```
passive
```

### Parameters

None

### Examples

```

nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#passive

|----------------------------------------------------|------------------------------------------------------------------------------|
| <code>no (bgp-neighbor-config)</code> on page 1921 | Disables this BGP neighbor device (or devices using this profile) as passive |
|----------------------------------------------------|------------------------------------------------------------------------------|

### *password (bgp-neighbor-config)*

Sets a password for this BGP neighbor device (or devices using this profile). When configured, this password is used for MD5 (Message Digest 5) authentication between two BGP peers connected over TCP. To enable MD5 authentication between two BGP peers, configure both with the same password.

#### **Supported in the following platforms:**

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

#### **Syntax**

```
password neighbor <LINE>
```

#### **Parameters**

```
password neighbor <LINE>
```

|                          |                      |
|--------------------------|----------------------|

### *peer-group (bgp-neighbor-config)*

Sets the peer group for this BGP neighbor device (or devices using this profile). Peer groups are a set of BGP neighbors with the same update policies. This facilitates the updates of various policies, such as, distribute lists and filter lists.

#### **Supported in the following platforms:**

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

## Syntax

```
peer-group <PEER-GROUP-NAME>
```

## Parameters

```
peer-group <PEER-GROUP-NAME>
```

|                              |                                                                                                                                                                                                                                                            |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| peer-group <PEER-GROUP-NAME> | Specify the peer group name. Once specified, this neighbor device becomes a member of the peer group identified by the <PEER-GROUP-NAME> keyword. <ul style="list-style-type: none"><li>• &lt;PEER-GROUP-NAME&gt; - Specify the peer group name.</li></ul> |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Examples

### *port (bgp-neighbor-config)*

Configures a non-standard BGP port for this BGP neighbor. By default BGP uses port 179. Use this command to set a non standard port for this BGP neighbor.

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

## Syntax

```
port <0-65535>
```

## Parameters

```
port <0-65535>
```

```
port <0-65535>
```

Specify a value from 0 - 65535.

### Examples

```
nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#port 21
nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#show context

### Related Commands

```
no (bgp-neighbor-config) on
page 1921
```

Removes the non-standard port configured for this neighbor

### *remote-as (bgp-neighbor-config)*

Configures the ASN for this neighbor BGP device (or devices using this profile). ASN is a set of routers under the same administration that use IGP (Interior Gateway Protocol) and common metrics to define how to route packets within the AS.

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

### Syntax

```
remote-as <1-4294967295>
```

### Parameters

```
remote-as <1-4294967295>
```

```
remote-as <1-4294967295>
```

Specify the remote ASN from 1 - 4294967295.

### Examples

```
nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#remote-as 100
nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#show context

| <code>no (bgp-neighbor-config)</code> on page 1921 | Removes the ASN for this neighbor BGP device (or devices using this profile) |
|----------------------------------------------------|------------------------------------------------------------------------------|

### *remove-private-as (bgp-neighbor-config)*

Removes the private ASN from outbound updates. By default private ASNs are included in outbound updates.

Private AS numbers are not advertised to the Internet. This option is used with external BGP (eBGP) peers only. The router removes the AS numbers only if the update includes private AS numbers. If the update includes both private and public AS numbers, the system treats it as an error.

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

### Syntax

```
remove-private-as
```

### Parameters

None

### Examples

```

nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#remove-private-as

### *route-server-client (bgp-neighbor-config)*

Enables this BGP neighbor device (or devices using this profile) to act as a route server client. This option is disabled by default.

#### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

#### Syntax

```
route-server-client
```

#### Parameters

None

#### Examples

```

nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#route-server-
client

### *send-community (bgp-neighbor-config)*

Enables sending of the community attribute to the BGP neighbor. The community attribute groups destinations in a certain community and applies routing decisions based on the community. On receiving community attribute, the BGP router announces it to the neighbor.

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

### Syntax

```
send-community [both|extended|standard]
```

### Parameters

```
send-community [both|extended|standard]
```

|                                                      |                                                                                                                                                                                                                                       |

### *shutdown (bgp-neighbor-config)*

Shuts down this BGP neighbor device (or devices using this profile). When configured, this neighbor is administratively shut down. This option is disabled by default.

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

### Syntax

```
shutdown
```

### Parameters

None

### Examples

```
nx9500-6C8809(config-profile testNX500-router-bgp-neighbor-192.168.13.99)#shutdown

| <code>no (bgp-neighbor-config)</code> on page 1921 | Removes the administrative shut down of this neighbor |
|----------------------------------------------------|-------------------------------------------------------|

### *soft-reconfiguration (bgp-neighbor-config)*

Enables storing of updates for inbound soft reconfiguration. This option is disabled by default.

Soft-reconfiguration can be used in lieu of BGP route refresh capability. Enabling this option enables local storage of all received routes and their attributes. This requires additional memory on the BGP device.

When a soft reset (inbound) is performed on the neighbor device, the locally stored routes are reprocessed according to the inbound policy. The BGP neighbor connection is not affected.

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

---

## Syntax

```
soft-reconfiguration inbound
```

## Parameters

```
soft-reconfiguration inbound
```

|                              |                                                                      |
|------------------------------|----------------------------------------------------------------------|
| soft-reconfiguration inbound | Performs a soft reconfiguration (inbound) on the BGP neighbor device |
|------------------------------|----------------------------------------------------------------------|

## Examples

## *strict-capability-match (bgp-neighbor-config)*

Enforces a strict capability match before allowing a TCP connection with this neighbor. In case capabilities do not match, the BGP connection is not established. This option is disabled by default.

## Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

## Syntax

```
strict-capability-match
```

## Parameters

None

## Examples

```
nx9500-6C8809(config-profile testNX9000-router-bgp-neighbor-192.168.13.99)#strict-capability-match
```

## *timers (bgp-neighbor-config)*

Configures this BGP neighbor's keepalive and holdtime durations

### Note

The keepalive and holdtime settings configured at the neighbor level override those configured on the BGP router.

---

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

### Syntax

```
timers [<0-65535> <0-65535>|connect <0-65535>]
```

### Parameters

```
timers [<0-65535> <0-65535>|connect <0-65535>]
```

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|----------------------------------------------------|--------------------------------------------------|

### *unsuppress-map (bgp-neighbor-config)*

Un-suppresses map to selectively advertise routes that have been suppressed using the aggregate-address command. The aggregate-address command creates a route map with a IP/mask address that consolidates subnets under it. This reduces the number of route maps on the BGP device to one consolidated entry. Use unsuppress-map to selectively allow/deny a subnet or a set of subnets from this consolidated entry.

#### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

#### Syntax

```
unsuppress-map <ROUTE-MAP-NAME>
```

#### Parameters

```
unsuppress-map <ROUTE-MAP-NAME>
```

|                                                    |                                                                                                                                                           |
|----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>unsuppress-map &lt;ROUTE-MAP-NAME&gt;</code> | Un-suppresses the specified route map <ul style="list-style-type: none"><li>• <code>&lt;ROUTE-MAP-NAME&gt;</code> – Specify the route map name.</li></ul> |
|----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|

### *update-source (bgp-neighbor-config)*

Allows BGP sessions to use any operational interface to establish the TCP connection with this neighbor

#### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

#### Syntax

```
update-source <IPv4>
```

## Parameters

update-source <IPv4>

|                      |                                                  |
|----------------------|--------------------------------------------------|
| update-source <IPv4> | Specify the BGP enabled neighbor's IPv4 address. |
|----------------------|--------------------------------------------------|

## Examples

|----------------------------------------------------|---------------------------------------|
| <code>no (bgp-neighbor-config)</code> on page 1921 | Removes the source of routing updates |
|----------------------------------------------------|---------------------------------------|

*use (bgp-neighbor-config)*

Configures filters for this neighbor. These filters are BGP IP ACL, IP prefix list, AS path list, and route map. Based on the filters used, updates received from this neighbor are filtered.

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

## Syntax

```
use [distribute-list <BGP-IP-ACL-NAME>|filter-list <AS-PATH-LIST-NAME>|
prefix-list <IP-PREFIX-LIST-NAME>|route-map <BGP-ROUTE-MAP-NAME>]
```

## Parameters

```
use [distribute-list <BGP-IP-ACL-NAME>|filter-list <AS-PATH-LIST-NAME>|
prefix-list <IP-PREFIX-LIST-NAME>|route-map <BGP-ROUTE-MAP-NAME>]
```

|                                                                                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

### *weight (bgp-neighbor-config)*

Configures a weight for all routes learned from this BGP neighbor. Weight is used to decide the preferred route when the same route is learned from multiple neighbors. The highest weight is always chosen.

### Supported in the following platforms:

- Wireless Controllers — RFS 4000
- Service Platforms — NX 95XX, NX 96XX

## Syntax

```
weight <0-65535>
```

## Parameters

```
weight <0-65535>
```

|                                   |                                                                                                                                                                                     |

# CONTROLLER MANAGED WLAN USE CASE

## CREATING A FIRST CONTROLLER MANAGED WLAN

This section describes the process of creating managed WLAN on an RFS 4000 wireless controller, and associating it with the AP 7161 and AP 7602 access points.

Upon completion, you will have created a WLAN on a RFS 4000 model wireless controller using a DHCP server to allocate IP addresses to associated wireless clients.

### Assumptions

Verify the following conditions have been satisfied before attempting the WLAN configuration activities described in this section:

- It is assumed the RFS 4000 wireless controller has the latest firmware version available.
- It is assumed the AP 7161 and AP 7602 access points also have the latest firmware version available.
- It is assumed there are no previous configurations on the wireless controller or access point and default factory configurations are running on the devices.
- It is assumed you have administrative access to the wireless controller and access point CLI.
- It is assumed the individual administrating the network is a professional network installer.

### Designs

This section defines the network design being implemented.

**Figure 1: Network Design**

---

This is a simple deployment scenario, with the Access Points connected directly to the wireless controller. One wireless controller port is connected to an external network.

On the RFS 4000 wireless controller, the GE1 interface is connected to an external network. Interfaces GE3 and GE4 are used by the Access Points.

On the external network, the wireless controller is assigned an IP address of 192.168.10.188. The wireless controller acts as a DHCP server for the wireless clients connecting to it, and assigns IP addresses in the range of 172.16.11.11 to 172.16.11.200. The rest of IPs in the range are reserved for devices requiring static IP addresses.

## Using the Command Line Interface to Configure the WLAN

These instructions are for configuring your first WLAN using the wireless controller CLI.

Use a serial console cable when connecting to the wireless controller for the first time. Set the following configuration when using the serial connection:

- Bits per second: *19200*
- Data Bit: *8*
- Parity: *None*
- Stop Bit: *1*
- Flow Control: *None*

## Logging into the Controller for the First Time

When powering on the wireless controller for the first time, you are prompted to replace the existing administrative password. The credentials for logging into the wireless controller for the first time are:

- User Name: *admin*
- Password: *admin123*

Ensure the new password created is strong enough to provide adequate security for the wireless controller managed network.

After logging in to the controller, follow the steps below to configure a controller-managed WLAN:

- 1 [Create an RF Domain.](#)
- 2 [Create a controller profile, with WLAN, VLAN and GE interface configurations.](#)
- 3 [Create an access point profile.](#)
- 4 [Create a DHCP server policy.](#)
- 5 [Test your WLAN status.](#)

## Creating a RF Domain

A RF Domain is a collection of configurations specific to devices located at the same physical deployment, such as a building or a floor. Create a RF Domain and assign the country code where the devices are deployed. Configuring the country code is mandatory, or else the devices will not function as intended.

The instructions in this section must be performed from the Global Configuration mode of the wireless controller.

- 1 Navigate to the wireless controller's global configuration mode.

```
rfs4000>enable
rfs4000#
rfs4000#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
rfs4000(config)#
```

- 2 Create the RF Domain using the following commands:

```
rfs4000(config)#rf-domain <RF-DOMAIN-NAME>
rfs4000(config)#rf-domain RFDOMAIN_UseCase1
rfs4000(config-rf-domain-RFDOMAIN_UseCase1)#
```

This command creates a profile with the name RFDOMAIN\_UseCase1.

- 3 Set the RF Domain's country code (location of deployment).

```
rfs4000(config-rf-domain-RFDOMAIN_UseCase1)#country-code us
```

This sets the country code for this RF Domain. Save this change and exit the RF Domain configuration context.

```
rfs4000(config-rf-domain-RFDOMAIN_UseCase1)#commit write
rfs4000(config-rf-domain-RFDOMAIN_UseCase1)#exit
rfs4000(config)#
```

- 4 Apply the RF Domain to the wireless controller's self context.

```
rfs4000(config)#self
rfs4000(config-device-03-14-28-57-14-28)#
rfs4000(config-device-03-14-28-57-14-28)#use rf-domain RFDOMAIN_UseCase1
```

- 5 Commit the changes and write to memory. Exit this context.

```
rfs4000(config-device-03-14-28-57-14-28)#commit write memory
rfs4000(config-device-03-14-28-57-14-28)#exit
rfs4000(config)#
```

## Creating a Wireless Controller Profile

The first step in creating a WLAN is to configure a profile defining the parameters applied to a wireless controller.

- 1 **Creating A Profile.** To create a profile:

```
rfs4000(config)#profile rfs4000 RFS4000_UseCase1
rfs4000(config-profile-RFS4000_UseCase1)#
```

This creates a profile with the name *RFS400\_UseCase1* and moves the cursor into its context. Any configuration made under this profile is available when it is applied to a device.

- 2 **Configuring a VLAN on the Profile.** Create the VLAN to use with the WLAN configuration. In this example, we are configuring VLAN 2.

```
rfs4000(config-profile-RFS4000_UseCase1)#interface vlan 2
rfs4000(config-profile-RFS4000_UseCase1-if-vlan2)#ip address 172.16.11.1/24
```

The above command assigns the IP address 172.16.11.1 with the mask of 255.255.255.0 to VLAN2. Exit the VLAN2 context.

```
rfs4000(config-profile-RFS4000_UseCase1-if-vlan2)#exit
rfs4000(config-profile-RFS4000_UseCase1)#
```

- 3 **Mapping the configured VLAN to a physical interface.**

---

The next step is to assign this newly created VLAN to a physical interface. In this case, VLAN 2 is mapped to GE3 and GE4 to support two access points, an AP 7602 and AP 7161. The AP 7602 is connected to the gigabit interface GE3 and the AP 7161 to the GE4 interface.

- a Navigate to the physical interface's configuration context, as shown in the following example:

```
rfs4000(config-profile-RFS4000_UseCase1)#interface ge 3
rfs4000(config-profile-RFS4000_UseCase1-if-ge3)#
```

- b Map VLAN 2 to this interface. This assigns the IP address to the selected physical interface

```
rfs4000(config-profile-RFS4000_UseCase1-if-ge3)#switchport access vlan 2
rfs4000(config-profile-RFS4000_UseCase1-if-ge3)#exit
rfs4000(config-profile-RFS4000_UseCase1)#
```

- c Similarly, map the defined VLAN 2 to the GE4 interface.

```
rfs4000(config-profile-1_UseCase1)#interface ge 4
rfs4000(config-profile-RFS4000_UseCase1-if-ge4)#switchport access vlan 2
rfs4000(config-profile-RFS4000_UseCase1-if-ge4)#exit
rfs4000(config-profile-RFS4000_UseCase1)#
```

- 4 Save changes and Exit the profile configuration context.

```
rfs4000(config-profile-RFS4000_UseCase1)#exit
rfs4000(config)#commit write memory
```

- 5 **Applying the profile to the controller.** Before the wireless controller can be further configured, the profile must be applied to the wireless controller.

```
rfs4000(config)#self
rfs4000(config-device-03-14-28-57-14-28)#
rfs4000(config-device-03-14-28-57-14-28)#use profile RFS4000_UseCase1
rfs4000(config-device-03-14-28-57-14-28)#exit
rfs4000(config)#commit write
```

- 6 **Creating a WLAN.** Use the following commands to create a WLAN and configure it's mandatory parameters:

- a Create a WLAN.

```
rfs4000(config)#wlan 1
rfs4000(config-wlan-1)#
```

- b Configure the WLAN's SSID. This is the value that identifies and helps differentiate this WLAN.

```
rfs4000(config-wlan-1)#ssid WLAN_USECASE_01
```

- c Enable the SSID to be broadcasted so that wireless clients can find it and associate.

```
rfs4000(config-wlan-1)#broadcast-ssid
```

#### Note

The WLAN created for this usecase, is an *open* WLAN, with no authentication mode specified. Once the WLAN is mapped to an AP, clients will not require password for associating with the WLAN through the AP.

---

- d Associate VLAN 2 to the WLAN and exit.

```
rfs4000(config-wlan-1)#vlan 2
rfs4000(config-wlan-1)#exit
```

- 7 Commit the changes. Once these changes have been made, they have to be committed before proceeding.

```
rfs4000(config)#commit write memory
```

## Creating an AP Profile

An AP profile provides a method of applying common settings to Access Points of the same model. The profile significantly reduces the time required to configure Access Points within a large deployment.

For more information, see:

- [Creating an AP 7161 Profile](#) on page 1927
- [Creating a AP 7602Profile](#) on page 1928

### Creating an AP 7161 Profile

Follow the steps below to configure a AP 7161 profile:

- 1 In the wireless controller's global config mode, create a AP 7161 profile.
 

```
rfs4000(config)#profile ap7161 AP7161_UseCase1
rfs4000(config-profile-AP7161_UseCase1)#
```
- 2 Assign the profile to the VLAN defined in [Creating a Wireless Controller Profile](#). In this section, the VLAN was defined as VLAN 2. When applied to the AP 7161 access point, this profile will configure the AP to be a member of VLAN 2.
 

```
rfs4000(config-profile-AP7161_UseCase1)#interface vlan 2
rfs4000(config-profile-AP7161_UseCase1-if-vlan2)#
```
- 3 Configure this VLAN to use DHCP. Enabling DHCP on the VLAN ensures that devices associating using this access point are automatically assigned a unique IP address. Once completed, exit this context.
 

```
rfs4000(config-profile-AP7161_UseCase1-if-vlan2)#ip address dhcp
rfs4000(config-profile-AP7161_UseCase1-if-vlan2)#exit
```
- 4 Map the VLAN to a physical interface on the profile. In this example, VLAN 2 is mapped to the GE1 and GE2 interfaces of the AP profile. When applied to the AP 7161 access point, this profile will map VLAN 2 to the AP's GE1 and GE2 ports.
 

```
rfs4000(config-profile-AP7161_UseCase1)#interface ge 1
rfs4000(config-profile-AP7161_UseCase1-if-ge1)#switchport access vlan 2
rfs4000(config-profile-AP7161_UseCase1-if-ge1)#exit
```
- 5 Similarly configure the GE2 interface.
 

```
rfs4000(config-profile-AP7161_UseCase1)#interface ge 2
rfs4000(config-profile-AP7161_UseCase1-if-ge2)#switchport access vlan 2
rfs4000(config-profile-AP7161_UseCase1-if-ge2)#exit
```
- 6 Map the WLAN to a radio on the access point. An AP 7161 has 3 radios (on certain models), two of which can be configured for WLAN support. In this scenario, two radios 1 and 2 are mapped to [WLAN '1' created earlier](#).
 

```
rfs4000(config-profile-AP7161_UseCase1)#interface radio 1
rfs4000(config-profile-AP7161_UseCase1-if-radio1)#wlan 1
rfs4000(config-profile-AP7161_UseCase1-if-radio1)#exit
rfs4000(config-profile-AP7161_UseCase1)#interface radio 2
rfs4000(config-profile-AP7161_UseCase1-if-radio2)#wlan 1
rfs4000(config-profile-AP7161_UseCase1-if-radio2)#exit
rfs4000(config-profile-AP7161_UseCase1)#
```
- 7 Commit the changes made to the profile and exit this context.
 

```
rfs4000(config-profile-AP7161_UseCase1)#commit write
rfs4000(config-profile-AP7161_UseCase1)#exit
rfs4000(config)#
```
- 8 Apply this profile to the discovered AP 7161.
  - a Use the discovered AP 7161's MAC address to access the AP's configuration context, as shown here.
 

```
rfs4000(config)#ap7161 00-23-68-16-C6-C4
rfs4000(config-device-00-23-68-16-C6-C4)#
```
  - b Assign the profile to the AP 7161access point.
 

```
rfs4000(config-device-00-23-68-16-C6-C4)#use profile AP7161_UseCase1
rfs4000(config-device-00-23-68-16-C6-C4)#commit write
```
  - c Apply the RF Domain to the AP 7161access point.

Apply the [previously created RF Domain](#) to enable a country code to be assigned to the discovered access point. A discovered access point only works properly if its country code is the same as its associated wireless controller.

```
rfs4000(config-device-00-23-68-16-C6-C4)#use rf-domain RFDOMAIN_UseCase1
rfs4000(config-device-00-23-68-16-C6-C4)#commit write
rfs4000(config-device-00-23-68-16-C6-C4)#Exit
rfs4000(config)#
```

### Creating a AP 7602Profile

An AP 7602's firmware is updated directly by its associated wireless controller. The process is automatic, and no intervention is required.

Follow the steps below to configure an AP 7602 profile:

- 1 In the wireless controller's global config mode, create a AP 7602 profile.

```
rfs4000(config)#profile ap7602 AP7602_UseCase1
rfs4000(config-profile-AP7602_UseCase1)#
```
- 2 Assign the profile to the VLAN defined in [Creating a Wireless Controller Profile](#). In this section, the VLAN was defined as VLAN 2. When applied to the AP 7602 access point, this profile will configure the AP to be a member of VLAN 2.

```
rfs4000(config-profile-AP7602_UseCase1)#interface vlan 2
rfs4000(config-profile-AP7602_UseCase1-if-vlan2)#
```
- 3 Configure this VLAN to use DHCP. Enabling DHCP on the VLAN ensures that devices associating using this access point are automatically assigned a unique IP address. Once completed, exit this context.

```
rfs4000(config-profile-AP7602_UseCase1-if-vlan2)#ip address dhcp
rfs4000(config-profile-AP7602_UseCase1-if-vlan2)#exit
```
- 4 Map the VLAN to a physical interface on the profile. In this example, VLAN 2 is mapped the GE1 interface. When applied to the AP 7602 access point, this profile will map VLAN 2 to the AP's GE1 port.

```
rfs4000(config-profile-AP7602_UseCase1)#interface ge 1
rfs4000(config-profile-AP7602_UseCase1-if-ge1)#switchport access vlan 2
rfs4000(config-profile-AP7602_UseCase1-if-ge1)#exit
```
- 5 Map the WLAN to a radio on the access point. An AP 7602 has 2 radios, in this scenario, both radios are mapped to [WLAN '1' created earlier](#).

```
rfs4000(config-profile-AP7602_UseCase1)#interface radio 1
rfs4000(config-profile-AP7602_UseCase1-if-radio1)#wlan 1
rfs4000(config-profile-AP7602_UseCase1-if-radio1)#exit
rfs4000(config-profile-AP7602_UseCase1)#interface radio 2
rfs4000(config-profile-AP7602_UseCase1-if-radio2)#wlan 1
rfs4000(config-profile-AP7602_UseCase1-if-radio2)#exit
rfs4000(config-profile-AP7602_UseCase1)#
```
- 6 Commit the changes and exit.

```
rfs4000(config-profile-AP7602_UseCase1)#commit write memory
rfs4000(config-profile-AP7602_UseCase1)#exit
rfs4000(config)#
```
- 7 Apply this profile to the discovered AP 7602.
  - a Use the discovered AP 7602's MAC address to access the AP's configuration context, as shown here.

```
rfs4000(config)#ap7602 00-A0-F8-00-00-01
rfs4000(config-device-00-A0-F8-00-00-01)#
```
  - b Assign the profile to this AP 7602access point.

```
rfs4000(config-device-00-A0-F8-00-00-01)#use profile AP7602_UseCase1
rfs4000(config-device-00-A0-F8-00-00-01)#commit write
```

- c Apply the RF Domain profile to the AP.

Apply the previously [created RF Domain](#) to enable a country code to be assigned to the discovered access point. A discovered access point only works properly if its country code is the country code of its associated wireless controller.

```
rfs4000(config-device-00-A0-F8-00-00-01)#use rf-domain RFDOMAIN_UseCase1
rfs4000(config-device-00-A0-F8-00-00-01)#commit write
rfs4000(config-device-00-A0-F8-00-00-01)#exit
rfs4000(config)#
```

## Creating a DHCP Server Policy

The DHCP server policy defines the parameters required to run a DHCP server on the wireless controller and assign IP addresses automatically to devices that associate. Configuring DHCP enables the reuse of a limited set of IP addresses.

To create a DHCP server policy, in the wireless controller’s global configuration mode, execute the following command:

```
rfs4000-37FABE(config)#dhcp-server-policy <DHCP-SERVER-POLICY-NAME>
rfs4000(config)#dhcp-server-policy DHCP_POLICY_UseCase1
rfs4000(config-dhcp-policy-DHCP_POLICY_UseCase1)#
```

The following table displays how IP addresses are used.

*Table: IP Address Usage*

| IP Range                         | Usage                                                             |
|----------------------------------|-------------------------------------------------------------------|
| 172.16.11.1 till 172.16.11.10    | Reserved for devices that require a static IP address             |
| 172.16.11.11 till 172.16.11.200  | Range of IP addresses that can be assigned using the DHCP server. |
| 172.16.11.201 till 172.16.11.254 | Reserved for devices that require a static IP address             |

In the table, the IP address range of 172.16.11.11 to 172.16.11.200 is available using the DHCP server. To configure the DHCP server:

```
rfs4000(config-dhcp-policy-DHCP_POLICY_UseCase1)#dhcp-pool DHCP_POOL_USECASE1_01
rfs4000(config-dhcp-policy-DHCP_POLICY_UseCase1-pool-DHCP_POOL_USECASE1_01)#
```

- 1 Configure the address range as follows:

```
rfs4000(config-dhcp-policy-DHCP_POLICY_UseCase1-pool-DHCP_POOL_USECASE1_01)#address
range 172.16.11.11 172.16.11.200
rfs4000(config-dhcp-policy-DHCP_POLICY_UseCase1-pool-DHCP_POOL_USECASE1_01)#
```

- 2 Configure the IP pool used with a network segment. This starts the DHCP server on the specified interface.

```
rfs4000(config-dhcp-policy-DHCP_POLICY_UseCase1-pool-DHCP_POOL_USECASE1_01)#network
172.16.11.0/24
rfs4000(config-dhcp-policy-DHCP_POLICY_UseCase1-pool-DHCP_POOL_USECASE1_01)#exit
rfs4000(config-dhcp-policy-DHCP_POLICY_UseCase1)#exit
rfs4000(config)#commit write
```

- 3 Configure the RFS 4000 to use the DHCP Policy. For the DHCP to work, apply the policy to the wireless controller, as shown in the following example:

```
rfs4000-37FABE(config)#self
rfs4000-37FABE(config-device-03-14-28-57-14-28)#use dhcp-server-policy
DHCP_POLICY_UseCase1
rfs4000-37FABE(config-device-03-14-28-57-14-28)#commit write
```

---

```
rfs4000-37FABE(config-device-03-14-28-57-14-28)#exit
rfs4000-37FABE(config)#
```

## Completing and Testing the Configuration

Once your WLAN is up, test it using any mobile unit (example, mobile phone or laptop).

- Ensure that your mobile unit is Wi-Fi enabled.
- Search for the WLAN\_USECASE\_01 ssid. This is the SSID of the controller-managed WLAN created and mapped to the access points.
- Click **Connect**. You should get internet access.
