IGMP snooping is implemented primarily through ACLs, which are processed on the interfaces. These special purpose ACLs are called IGMP snooping hardware filters. The software allows you to choose between two types of IGMP snooping hardware filters: per-port filters (the default) and per-VLAN filters.

The two types of IGMP snooping hardware filters use switch hardware resources in different ways. The two primary hardware resources to consider when selecting the IGMP snooping hardware filters are the Layer 3 multicast forwarding table, and the interface *ACL (Access Control List)s*. The size of both of these hardware resources is determined by the switch model. In general, the per-port filters consume more resources from the multicast table and less resources from the ACL table. The per-VLAN filters consume less space from the multicast table, and more from the ACL table.

Using the per-port filters can fill up the multicast table and place an extra load on the CPU. To avoid this, configure the switch to use the per-VLAN filters.

**Note**

The impact of the per-VLAN filters on the ACL table increases with the number of VLANs configured on the switch. If you have a large number of configured VLANs, we suggest that you use the per-port filters.

## IGMP Snooping Filters

*IGMP* snooping filters allow you to configure a policy file on a port to allow or deny IGMP report and leave packets coming into the port. (For details on creating policy files, see [Policy Manager](#) on page 733.) The IGMP snooping filter feature is supported by IGMPv2 and IGMPv3.

**Note**

Do not confuse IGMP snooping filters with IGMP snooping hardware filters explained in previous section. IGMP snooping filters are software filters, and the action is applied at the software level by the ExtremeXOS multicast manager.

For the policies used as IGMP snooping filters, all the entries should be IP address type entries, and the IP address of each entry must be in the class-D multicast address space but should not be in the multicast control subnet range (224.0.0.x/24).

1. Use the following template to create a snooping filter policy file that denies IGMP report and leave packets for the 239.11.0.0/16 and 239.10.10.4/32 multicast groups:

```
#
Add your group addresses between "Start" and "end"
Do not touch the rest of the file!!!!
entry igmpFilter {
 if match any {
 #----- Start of group addresses -----
 nlri 239.11.0.0/16;
 nlri 239.10.10.4/32;
 #----- end of group addresses -----
 } then {
 deny;
 }
 entry catch_all {
 if {
 } then {
 permit;
 }
 }
}
```

2. After you create a policy file, use the following command to associate the policy file and filter to a set of ports:

```
configure igmp snooping vlan vlanname ports portlist filter [policy |
none]
```

3. To remove the filter, use the **none** option.
4. To display the IGMP snooping filters, use the following command:

```
show igmp snooping {vlan} name filter
```

## Static IGMP

To receive multicast traffic, a host must explicitly join a multicast group by sending an IGMP report; then, the traffic is forwarded to that host. In some situations, you might like multicast traffic to be forwarded to a port where a multicast-enabled host is not available (for example, when you test multicast configurations).

Static IGMP emulates a host or router attached to a switch port, so that multicast traffic is forwarded to that port, and the switch sends a proxy join for all the statically configured IGMP groups when an IGMP query is received. You can emulate a host to forward a particular multicast group to a port; and you may emulate a router to forward all multicast groups to a port. Static IGMP is only available with IGMPv2.

- To emulate a host on a port, use the following command:

```
configure igmp snooping {vlan} vlan_name {ports port_list}add static
group ip_address
```

- To emulate a multicast router on a port, use the following command:

```
configure igmp snooping {vlan} vlan_name {ports port_list}add static
router
```

- To remove these entries, use the corresponding commands:  

```
configure igmp snooping {vlan} vlan_name {ports port_list } delete
static group [ip_address | all]
configure igmp snooping vlan vlan_name {ports port_list } delete
static router
```
- To display the IGMP snooping static groups, use the following command:  

```
show igmp snooping {vlan} vlan_name static [group | router]
```

## IGMP Loopback

Prior to ExtremeXOS 15.3.2, you could configure static groups, but it was necessary to specify port(s). As of ExtremeXOS Release 15.3.2, the configuration of dynamic groups is supported. The *IGMP* Loopback feature, along with the existing static group feature, supports the configuration of static and/or dynamic groups with or without ports.

A *VLAN* in loopback mode may not have ports associated with it, but its operational status is up. However, it is not possible to have multicast receivers on a VLAN without having a port. Sometimes there is a need to pull the multicast traffic from upstream to the loopback VLAN for troubleshooting. The traffic need not always be forwarded to any ports/receivers. The IGMP Loopback feature allows you to configure groups on a VLAN without specifying a port, so the traffic is pulled from upstream but not forwarded to any port.

The loopback (Lpbk) port is the logical port on a VLAN in the application context. If you configure a group on a VLAN but do not specify the port, the switch forms an IGMPv2 join and assumes it to be received on the Lpbk port. A dynamic group ages out after the membership timeout if there are no other receivers. Membership joins refresh the dynamic group. The static group remains until it is removed from the configuration.

The following command is used to configure static or dynamic group entry :

```
configure igmp snooping {vlan} vlan_name {ports port_list} add [static |
dynamic] group ip_address
```

## Limiting the Number of Multicast Sessions on a Port

- The default configuration places no limit on the number of multicast sessions on each *VLAN* port. To place a limit on the number of learned *IGMP* groups, use the following command:

```
configure igmp snooping {vlan} vlan_name ports port_list set join-
limit {num}
```

- To remove a session limit, use the following command:

```
unconfigure igmp snooping {vlan} vlan_name ports port_list set join-
limit
```

## Enabling and Disabling IGMP Snooping Fast Leave

When the fast leave feature is enabled and the last host leaves a multicast group, the router immediately removes the port from the multicast group. The router does not query the port for other members of the multicast group before removing the group, and/or the port.

The default setting for *IGMP* snooping fast leave is disabled.

- To enable the fast leave feature, use the following command:  
`enable igmp snooping {vlan} name fast-leave`
- To disable the fast leave feature, use the following command:  
`disable igmp snooping {vlan} name fast-leave`

## IGMP-SSM Mapping

The *IGMP*-SSM Mapping feature allows IGMPv1 and IGMPv2 hosts to participate in SSM functionality, and eliminates the need for IGMPv3. You can configure SSM map entries that specify the sources used for a group/group range for which SSM functionality has to be applied. You also have the option to configure the domain name and DNS server to use to obtain the source list.

When a IGMPv1 or IGMPv2 report is received, the configured sources are provided to PIM so that it can send source specific joins. When the host leaves or when the membership times out, PIM is informed so that it can consider sending prunes.

In a multi-access network (where more than one router is receiving IGMP messages from the hosts), only the designated router sends joins towards the source, so it is desirable to have same configuration for SSM group range and SSM Mapping range on all routers in a *VLAN*.

### Limitations

- A single group address or range can be mapped to a maximum of 50 sources. If more than 50 sources are configured, the switch uses the 50 longest-matching prefixes.
- We recommend a maximum of 500 mappings per switch, but no limit is imposed by the software.

### Configuring IGMP-SSM Mapping

To support PIM-SSM for IGMPv1 and IGMPv2 clients, a PIM-SSM range must be configured, and that range should include all groups to which the clients want access. If IGMPv1 and IGMPv2 clients request group addresses outside the PIM-SSM range, those addresses are ignored by PIM-SSM and forwarded to PIM as (\*, G) requests.

- To enable *IGMP*-SSM mapping, first configure a PIM-SSM range, and then enable IGMP-SSM mapping using the following commands:

```
configure pim ssm range [default | policy policy-name]
enable igmp ssm-map {vr vr-name}
```

- To configure an IGMP-SSM mapping, use the following command:

```
configure igmp ssm-map add group_ip [prefix | mask] [source_ip |
src_domain_name] {vr vr-name}
```

- To remove a single IGMP-SSM mapping, use the following command:

```
configure igmp ssm-map delete group_ip [prefix} | mask] [source_ip |
all] vr vr-name }
```

- To remove all IGMP-SSM mappings on a *VR*, use the following command:

```
unconfigure igmp ssm-map {vr vr-name}
```

- To disable IGMP-SSM mapping on a virtual router, use the following command:

```
disable igmp ssm-map {vr vr-name}
```

### Displaying IGMP-SSM Mappings

To see whether or not *IGMP*-SSM mapping is enabled or disabled and to view the configured mappings for a multicast IP address, use the following command:

```
show igmp ssm-map {group_ip} {vr vr-name}
```

## IGMP Statistics

To view IGMP counters, use the following command:

```
show igmp counters
```

To clear IGMP counters, use the following command:

```
clear igmp counters
```

## Configuring EAPS Support for Multicast Traffic

The ExtremeXOS software provides several commands for configuring how *EAPS (Extreme Automatic Protection Switching)* supports multicast traffic after an EAPS topology change. For more information, see the descriptions for the following commands:

```
configure eaps multicast add-ring-ports [on | off]
```

```
configure eaps multicast send-query [on | off]
```

```
configure eaps multicast temporary-flooding [on | off]
```

These commands apply for both *IGMP* and MLD.

### Note

Using the `configure eaps multicast send-query` command applies to both IGMP and MLD. This also replaces the `configure eaps multicast send-igmp-query` command.

## Configuring IP Multicast Routing

### Enabling Multicast Forwarding

To enable IP multicast forwarding:

1. Configure the system for IP unicast routing.
2. Enable multicast forwarding on the interface.

```
enable ipmcforwarding {vlan name}
```

## Configuring PIM

To configure PIM multicast routing, enable multicast forwarding as described in [Enabling Multicast Forwarding](#) on page 1796 and do the following:

1. Configure PIM on all IP multicast routing interfaces using the following command:

```
configure pim {ipv4 | ipv6} add vlan [vlan-name | all] {dense | sparse} {passive}
```

2. To enable and configure the PIM-DM state refresh feature on one or all VLANs, use the following commands:

```
configure pim {ipv4 | ipv6} state-refresh {vlan} [vlan_name | all] [on | off]
```

```
configure pim { ipv4 | ipv6 } state-refresh timer origination-interval interval
```

```
configure pim {ipv4 | ipv6} state-refresh timer source-active-timer interval
```

```
configure pim {ipv4 | ipv6} state-refresh ttl ttlvalue
```

3. For PIM-SSM, specify the PIM-SSM range, enable IGMPv3, and enable PIM-SSM on the interfaces using the following commands:

```
configure pim {ipv4 | ipv6} ssm range [default | policy policy-name]
```

```
enable igmp {vlan vlan name } {IGMPv1 | IGMPv2 | IGMPv3}
```

```
enable pim {ipv4 | ipv6} ssm vlan [vlan_name | all]
```

4. Enable PIM on the router using the following command:

```
enable pim
```

## Configuring Multicast Static Routes

### Note

Multicast static routes are supported in the IPv4 address family, but not the IPv6 address family.

Static routes are used to reach networks not advertised by routers, and are manually entered into the routing table.

- You can use either of two commands to create multicast static routes. The recommended command is the following:

```
configure iproute add [ipNetmask | ip_addr mask] gateway {bfd} {metric} {multicast | multicast-only | unicast | unicast-only} {vr vrname}
```

For example:

```
configure iproute add 55.1.10.0/24 44.1.12.33 multicast
```

- The following command is still supported for backward compatibility with earlier ExtremeXOS software releases:

```
configure ipmroute add [source-net mask-len | source-net mask] {{protocol} protocol} rpf-address {metric} {vr vr-name}
```

In the following example, the `configure ipmroute add` command is used to specify protocol information for a route:

```
configure ipmroute add 58.1.10.0/24 ospf 44.1.12.33
```

#### Note

Iproute not supported for IPv6.

When a static route is configured with protocol information, the route is shown as UP only when the protocol route is available. Otherwise, the route is Down. In the example above, the multicast static route 58.1.10.0/24 is shown as UP only when the OSPF route is available to reach the network 58.1.10.0/24.

Static routes are stored in the switch configuration and can be viewed with the `show configuration` command. Static multicast routes that do not include protocol information are displayed using the `configure iproute` command format, even if they were created using the `configure ipmroute` command. Static routes that are created with a protocol field are displayed using the `configure ipmroute` command format.

## Disabling IP Multicast Compression

The IP multicast compression feature is enabled by default. You should only disable this feature if you suspect that switch processing resources are limited or if you think this feature is causing problems on the switch.

- To disable or enable IP multicast compression, use the following command:

```
configure forwarding ipmc compression {group-table | off}
```

## Configuring Anycast RP Using PIM (RFC 46010)

To configure or remove Anycast RPs, use the following command:

```
configure pim {ipv4 | ipv6} anycast-rp ip_address [policy | none]
```

## Multicast Over MLAG Configuration

For sample topology for MLAG (Multi-switch Link Aggregation Group), see [Layer 3 IP Multicast using PIM-SM](#) on page 274.

## PIM Configuration Examples

### *PIM-DM Configuration Example*

In [Figure 276](#), the system labeled IR 1 is configured for IP multicast routing, using PIM-DM.

**Figure 276: IP Multicast Routing Using PIM-DM Configuration Example**

**Note**

The above figure is used in the [the OSPF section](#) to describe the *OSPF* configuration on a switch.

The router labeled IR1 has the following configuration:

```
configure vlan HQ_10_0_1 ipaddress 10.0.1.2 255.255.255.0
configure vlan HQ_10_0_2 ipaddress 10.0.2.2 255.255.255.0
configure ospf add vlan all area 0.0.0.0
enable ipforwarding
enable ospf
enable ipmcf forwarding
configure pim add vlan all dense
enable pim
configure pim state-refresh vlan all on
```

*PIM-SM Configuration Example*

In [Figure 277](#), the system labeled ABR1 is configured for IP multicast routing using PIM-SM.

**Figure 277: IP Multicast Routing Using PIM-SM Configuration Example**

#### Note

The above figure is used in [the OSPF section](#) to describe the [OSPF](#) configuration on a switch.

The router labeled ABR1 has the following configuration:

```
configure vlan HQ_10_0_2 ipaddress 10.0.2.1 255.255.255.0
configure vlan HQ_10_0_3 ipaddress 10.0.3.1 255.255.255.0
configure vlan LA_161_48_2 ipaddress 161.48.2.2 255.255.255.0
configure vlan CHI_160_26_26 ipaddress 160.26.26.1 255.255.255.0
configure ospf add vlan all area 0.0.0.0
enable ipforwarding
enable ipmcf forwarding
configure pim add vlan all sparse
tftp TFTP_SERV -g -r rp_list.pol
configure pim crp HQ_10_0_3 rp_list 30
configure pim cbsr HQ_10_0_3 30
```

The policy file, `rp_list.pol`, contains the list of multicast group addresses serviced by this RP. This set of group addresses are advertised as candidate RPs. Each router then elects the common RP for a group address based on a common algorithm. This group to RP mapping should be consistent on all routers.

The following is a policy file that configures the CRP for the address ranges 239.0.0.0/24 and 232.144.27.0:

```
entry extremel {
 if match any {
 }
 then {
 nlri 239.0.0.0/24 ;
 nlri 232.144.27.0/24 ;
 }
}
```

```
}
}
```

### PIM-SSM Configuration Example

In the following example, the default PIM-SSM range of 232.0.0.0/8 is configured. For all interfaces, non-IGMPv3 messages and IGMPv3 exclude messages are ignored for addresses in this range. Hosts that use IGMPv3 on VLAN v13 can request and receive source specific multicast streams for addresses in the PIM-SSM range.

```
create vlan v12
create vlan v13
configure v12 add port 1
configure v13 add port 2
configure v12 ipaddress 12.1.1.1/24
configure v13 ipaddress 11.1.1.1/24
configure pim add vlan all sparse
enable ipforwarding
enable ipmcfwding
enable igmp IGMPv3
configure pim ssm range default
enable pim ssm vlan v13
enable pim
```

#### Note

(\*;G)s are created for groups outside the SSM range. SSM may not be enabled for the ingress VLAN (see [Table 169](#) on page 1777).

### PIM Snooping Configuration Example

[Figure 278](#) shows a network configuration that supports PIM snooping.

**Figure 278: PIM Snooping Configuration Example**

In [Figure 278](#) Layer 3 switches S2, S3, S4, and S5 are connected using the Layer 2 switch S1 through the VLAN comm\_vlan. Switches S3, S4, and S5 are multicast capable switches, and switch S2 is a non-multicast capable switch, which has no multicast routing protocol running.

Without PIM snooping, any ingress multicast data traffic on comm\_vlan is flooded to all the switches, including switch S2, which does not support multicast traffic. IGMP snooping does not reduce flooding because it floods the multicast traffic to all router ports.

The network design calls for most multicast traffic to egress switch S5. PIM snooping helps by intercepting the PIM joins received from the downstream routers and forwarding multicast traffic only to those ports that received PIM joins.

### Switch S1 (PIM Snooping Switch) Configuration Commands

The following is an example configuration for the PIM snooping switch S1:

```
create vlan comm_vlan
configure vlan comm_vlan add port 1,2,3,4
disable igmp snooping
disable igmp_snooping comm_vlan
enable pim snooping
enable pim_snooping comm_vlan
```

### Switch S3 Configuration Commands

The following is an example configuration for switch S3, which also serves as an RP:

```
create vlan comm_vlan
configure vlan comm_vlan add port 1
configure comm_vlan ipa 10.172.168.4/24
enable ipforwarding comm_vlan
enable ipmcforwarding comm._vlan
configure pim add vlan comm_vlan sparse
configure ospf add vlan comm._vlan area 0.0.0.0

create vlan sender_vlan
configure vlan sender_vlan add port 2
configure sender_vlan ipa 10.172.169.4/24
enable ipforwarding comm_vlan
enable ipmcforwarding comm._vlan
configure pim add vlan comm._vlan sparse
configure ospf add vlan comm_vlan area 0.0.0.0

enable pim
enable ospf

configure pim crp static 10.172.169.4 pim_policy // RP is configured using the policy
pim_policy for the group 224.0.0.0/4
```

### Switch S5 Configuration Commands

The following is an example configuration for switch S5, which serves as the last hop router for multicast traffic:

```
create vlan comm_vlan
configure vlan comm_vlan add port 1
configure comm_vlan ipa 10.172.168.2/24
enable ipforwarding comm_vlan
enable ipmcforwarding comm._vlan
configure pim add vlan comm_vlan sparse
configure ospf add vlan comm._vlan area 0.0.0.0

create vlan receiver_vlan
configure vlan sender_vlan add port 1
configure sender_vlan ipa 10.172.170.4/24
enable ipforwarding comm_vlan
enable ipmcforwarding comm._vlan
configure pim add vlan comm._vlan sparse
configure ospf add vlan comm_vlan area 0.0.0.0

enable pim
```

```
enable ospf

configure pim crp static 10.172.169.4 pim_policy // RP is configured using the policy
pim_policy for the group 224.0.0.0/4
```

### Switch S4 Configuration Commands

The following is an example configuration for switch S4, which is neither an LHR nor a RP:

```
create vlan comm_vlan
configure vlan comm_vlan add port 1
configure comm_vlan ipa 10.172.168.3/24
enable ipforwarding comm_vlan
enable ipmcforwarding comm._vlan
configure pim add vlan comm_vlan sparse
configure ospf add vlan comm._vlan area 0.0.0.0

enable pim
enable ospf

configure pim crp static 10.172.169.4 pim_policy // RP is configured using the policy
pim_policy for the group 224.0.0.0/4
```

### Switch S2 Configuration Commands

The following is an example configuration for switch S2, which is not enabled for PIM:

```
create vlan comm_vlan
configure vlan comm_vlan add port 1
configure comm_vlan ipa 10.172.168.6/24
enable ipforwarding comm_vlan
enable ipmcforwarding comm._vlan
configure ospf add vlan comm._vlan area 0.0.0.0

enable ospf
```

### PIM Snooping Example Configuration Displays

After the example configuration is complete, multicast receivers connect to the network through switch S5 and multicast sources connect through switch S3.

When switch S5 receives an IGMP request from the receiver\_vlan for group 225.1.1.1, it sends a PIM (\*, G) join towards switch S3, which is the RP. The PIM snooping feature on switch S1 snoops the (\*, G) join, and the resulting entry can be viewed by entering the following command at switch S1:

```
show pim snooping vlan comm_vlan
PIM Snooping ENABLED
Vlan comm_vlan(3971) Snooping ENABLED
Source Group RP UpPort DownPort Age HoldTime
* 225.1.1.1 10.172.169.4 1 2 15 210
Neighbor IP DR Port Age Hold Time
10.1272.168.4 YES 1 2 105
10.1272.168.2 NO 2 2 105
10.1272.168.3 NO 3 2 105
```

Once multicast traffic arrives from the sender\_vlan, the LHR (switch S2) sends the (S, G) join message, which is snooped by the PIM snooping switch, switch S1. The resulting entries can be viewed by entering the following command at switch S1:

```
show pim snooping vlan comm_vlan
PIM Snooping ENABLED
Vlan comm_vlan(3971) Snooping ENABLED
```

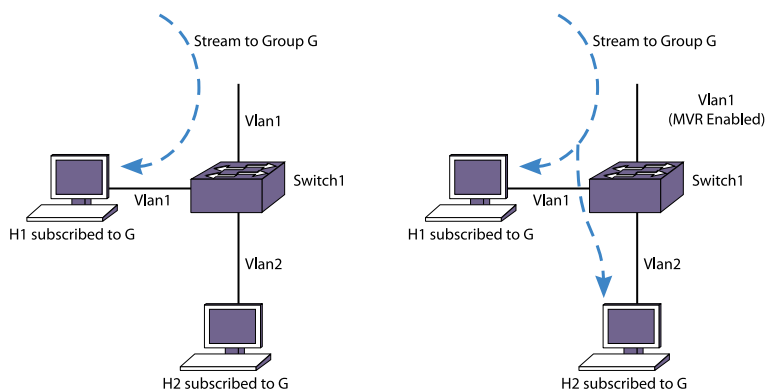

| Source        | Group     | RP           | UpPort | DownPort  | Age | HoldTime |
|---------------|-----------|--------------|--------|-----------|-----|----------|
| *             | 225.1.1.1 | 10.172.169.4 | 1      | 2         | 15  | 210      |
| 10.172.169.10 | 225.1.1.1 | 10.172.169.4 | 1      | 2         | 15  | 210      |
| Neighbor IP   | DR        | Port         | Age    | Hold Time |     |          |
| 10.1272.168.4 | YES       | 1            | 2      | 105       |     |          |
| 10.1272.168.2 | NO        | 2            | 2      | 105       |     |          |
| 10.1272.168.3 | NO        | 3            | 2      | 105       |     |          |

Multicast traffic is forwarded only to those ports that have received (\*, G) or (S, G) joins and designated router (DR) ports.

## Multicast VLAN Registration

Multicast VLAN Registration (MVR) is designed to support distributing multicast streams for IPTV to subscribers over a Layer 2 network. In a standard Layer 2 network, a multicast stream received on a VLAN is not forwarded to another VLAN. The streams are confined to the Layer 2 broadcast domain. In an IGMP snooping environment, streams are forwarded only to interested hosts on a VLAN. For inter-VLAN forwarding (routing) a multicast routing protocol, such as PIM/DVMRP must be deployed.

MVR breaks this basic rule, so that a stream received over Layer 2 VLANs is forwarded to another VLAN, eliminating the need for a Layer 3 routing protocol. It simplifies the multicast stream distribution and is a better solution for IPTV-like services. With MVR, a multicast stream is forwarded to all VLANs containing interested hosts.

**Figure 279: Standard VLAN Compared to an MVR VLAN**

In the above figure, the left side shows a standard VLAN carrying a multicast stream.

The host H1 receives the multicast stream because it resides on VLAN Vlan1, but host H2 does not receive the multicast traffic because no IP multicast routing protocol forwards the stream to VLAN Vlan2. On the right side of the figure, H2 does receive the multicast stream. Because Vlan1 was configured as an MVR VLAN, the multicast stream is forwarded to the other VLANs on the switch containing hosts that have requested the stream. To configure a VLAN as an MVR VLAN, use the following command: `configure mvr add vlan vlan-name`

Typically, IGMP snooping is enabled, so only hosts that have requested a stream can see the multicast traffic. For example, another host on VLAN2 cannot receive the traffic unless it has sent an IGMP request to be included in the group.

Notice that only VLAN1 is MVR enabled. Configure MVR only on the ingress VLAN. To enable MVR on the switch, use the following command: `enable mvr`

## Basic MVR Deployment

Because MVR is primarily targeted for IPTV and similar applications, a basic deployment for that application is shown [Figure 280](#). In the figure, an IPTV server is connected through a router to a network of switches. Switch 1 has three customer VLANs, Vlan2, Vlan3, and Vlan4. The multicast streams are delivered through the network core (Metro Ethernets), which often use a ring topology and some kind of redundant protection to provide high availability. For example, McastVlan forms a ring through switches Switch1 through Switch4. The link from Switch2 to Switch4 is shown as blocked, as it would be if some form of protection (such as *EAPS*) is used.

**Figure 280: Basic MVR Deployment**

Without MVR, there are two ways to distribute multicast streams in this topology:

- Extend subscriber VLANs (Vlan2, Vlan3, and Vlan4) to the network core, by tagging the ports connecting the switches.
- Configure all VLANs with an IP address and run PIM or DVMRP on each switch.

There are problems with both of these approaches. In the first approach, multiple copies of the same stream (IPTV channel) would be transmitted in the core, wasting bandwidth. In the second approach, all switches in the network core would have to be Layer 3 multicast aware, and would have to run a multicast protocol. Typical network cores are Layer 2 only.

MVR provides a simple solution to this problem. If McastVlan in Switch1 is configured with MVR, it leaks the traffic into the local subscriber VLANs that contain hosts that request the traffic. For simple cases, perform these configuration steps:

- Configure MVR on McastVlan.
- Configure an IP address and enable IGMP and IGMP snooping on the subscriber VLANs (by default IGMP and IGMP snooping are enabled on Extreme Networks switches).

- For all the multicast streams (IPTV channels), configure static IGMP snooping membership on the router on McastVlan.
- Enable MVR on the switches in the network.

**Note**

MVR works best with IGMPv1 and IGMPv2. We recommend that you do not use MVR with IGMPv3.

The strategy above conserves bandwidth in the core and does not require running PIM on the subscriber switches.

In this topology, a host (for example, a cable box or desktop PC) joins a channel through an IGMP join message. Switch1 snoops this message and adds the virtual port to the corresponding cache's egress list. This is possible because an MVR enabled VLAN can leak traffic to any other VLAN. When the user switches to another channel, the host sends an IGMP leave for the old channel and a join for the new channel. The corresponding virtual port is removed from the cache for the old channel and is added to the cache for the new channel.

As discussed in [Static and Dynamic MVR](#) on page 1806, McastVlan also proxies IGMP joins learned on other VLANs to the router. On an MVR network it is not mandatory to have a router to serve the multicast stream. All that is required is to have a designated IGMP querier on McastVlan. The IPTV server can also be directly connected to McastVlan.

### *Static and Dynamic MVR*

**Static MVR**

In a typical IPTV network, there are several high demand basic channels. At any instant there is at least one viewer for each of these channels (streams), and they should always be available at the core (ring). When a user requests one of these channels, it is quickly pulled locally from the multicast VLAN. You have the option to use the static router configuration in each of the switches in the core. But this will cause all the channels to be available in the core, which may not be desired. For example, on an Extreme Networks router, you can use the following commands:

```
configure igmp snooping {vlan} vlan_name ports port_list add static
router
```

You can use the static MVR configuration and choose the groups for which the multicast stream should be flooded. If a multicast stream for a group in the static MVR range is received on an MVR enabled VLAN, it is always flooded on the MVR VLAN. This allows the neighbor switch in the ring to receive all the static MVR streams.

**Dynamic MVR**

In contrast, since a video content provider would like to provide a variety of on-demand and other premium channels, there are often many lower demand (fewer viewers) premium channels that cannot all be made available simultaneously at the core network. These should be streamed from the router only if requested by a host.

IGMP is the standard method used by a host to request a stream. However, IGMP packets are constrained to a VLAN. Thus, subscribers' IGMP join requests on the VLAN cannot be forwarded onto other VLANs. You can use a dynamic MVR configuration, and choose the groups for which the IGMP

join requests should be proxied over the MVR VLAN. Thus, in [Figure 280](#) on page 1805, McastVlan sends join and leave messages on behalf of Vlan2, Vlan3, and Vlan4. The router receives the messages on McastVlan and streams corresponding channels onto the core network. This provides on-demand service, and an administrator does not need to configure static IGMP on the router for each of these channels.

### Configuring MVR Address Range

By default, all multicast groups belong to MVR address range. Use the following command to specify the MVR address range:

```
configure mvr vlan vlan-name mvr-address {policy-name | none}
```

- Only the groups listed in the policy with "allow" action belong to MVR address range.
- For non-MVR groups, snoop cache is created and join requests are not proxied over MVR VLAN.

### Configuring Static and Dynamic MVR

By default, all MVR streams are static.

- Use the following command to specify which groups are static:

```
configure mvr vlan vlan-name static group {policy-name | none}
```

- Only the groups listed in policy with "allow" action are static. Any other groups in MVR address range are dynamic.
- The groups in policy with "deny" action are dynamic. Any other groups in MVR address range are also dynamic, unless explicitly configured in the policy with "allow" action.
- A group should not be configured to be both static and dynamic.

### MVR Configuration Example

The following example configuration is a two DUT scenario, in L2 mode, with no routing protocol or PIM configured.

- DUT-1 is sender
- DUT-2 is receiver
- VLAN v1 spans over DUT-1 and DUT-2, DUT-2 also has v2 where IGMP joins are coming IN (225.1.1.1)
- DUT-2 has a VLAN v3, which also has a receiver connected sending IGMP join for same group as v2 (225.1.1.1)
- VLAN v1 in the DUT-2 has another port apart from the trunk port, no joins are being sent on this port.

Configure MVR on vlan v1 on DUT-2

```
show config "mcmgr"
#
Module mcmgr configuration.
#
enable mvr vr VR-Default
configure mvr add vlan v1
configure mvr vlan v1 mvr-address none
configure mvr vlan v1 static group none*
*X460-48t.158 #
```

The traffic will be flooded for the group only on MVR vlan (v1).

Since there are IGMP joins coming in on v2 and v3, v2, v3, and the second port in the MVR vlan v1 will receive traffic.

Configure the following policy file;

```
vi mvrPolicy.polentry policy1 {
if match any {
 nlri 225.1.1.1/24;
} then {
 permit;
}
}

```

When applying this policy file under static group on DUT-2

```
configure mvr vlan v1 static group mvrPolicy
#configure mvr vlan v1 mvr-address none
```

When the policy file contains "permit", the traffic flows to v2, v3, and the second port in MVR VLAN.

When the policy file is changed to "deny", the second port in the MVR VLAN v1 will stop receiving the traffic.

If you configure static policy (by default - permit), traffic for that group range will always be available in the MVR VLAN, that is, it will be forwarded to all the ports in MVR VLAN.

When applying this policy file under mvr-address (Dynamic) on DUT-2:

```
configure mvr vlan v1 static group none
configure mvr vlan v1 mvr-address mvrPolicy
```

When the policy file contains "permit", the traffic flows to v2,v3 and the second port in MVR vlan.

When the policy file is changed to "deny", the second port in MVR VLAN v1 continues receiving traffic, but VLAN v2 and v3 stop receiving traffic, in spite of IGMP groups being learned. This is because the join on v2 and v3 will not be leaked to MVR VLAN.

Essentially, the dynamic policy does not directly apply on traffic, but it affects the joins, based on which traffic is forwarded or blocked.

Dynamic means only if the join is sent then traffic is forwarded.

The join is leaked to MVR VLAN so traffic from MVR VLAN will be received by other VLANs (v2 and v3).

To confirm if a join was leaked to MVR VLAN use the `show igmp group` command. It should have the group learned on MVR VLAN (v1) with port as "MVR".

### *MVR Forwarding*

The goal for MVR is to limit the multicast traffic in the core Layer 2 network to only the designated multicast VLAN. If the backbone Layer 2 port is tagged with multiple VLANs, as shown in [Figure 281](#) on page 1809, a set of rules is needed to restrict the multicast streams to only one VLAN in the core.

**Figure 281: Multiple VLANs in the Core Network**

The core network has 2 more VLANs, vc1 and vc2, to provide other services. With MVR, multicast traffic should be confined to McastVlan, and should not be forwarded to vc1 and vc2. It should be noted that MVR is configured only on the ingress VLAN (McastVlan). MVR is not configured on any other VLANs.

In the same way as the *IGMP* snooping forwarding rules, the multicast stream is forwarded onto member ports and router ports on the VLAN. For a stream received on MVR enabled ports, this rule is extended to extend membership and router ports to all other VLANs. This rule works well on the topology in [Figure 281](#). However, in a tagged core topology, this rule forwards traffic onto VLANs, such as vc1 and vc2, on ports PC1 and PC2. This results in multiple copies of same stream on the core network, thus reintroducing the problem that MVR was intended to solve.

To avoid multiple copies of the same stream, MVR forwards traffic with some special restrictions. MVR traffic is not forwarded to another VLAN unless a host is detected on the port. On the ingress MVR VLAN, packets are not duplicated to ports belonging to MVR VLANs. This is to prevent duplicate multicast traffic streams on ingress ports. Streams belonging to static MVR groups are always forwarded on MVR VLANs so that any host can join such channels immediately. However, dynamic groups are streamed from the server only if some host is interested in them. A command is provided to receive traffic on a port which is excluded by MVR. However, regular IGMP rules still apply to these ports, so the ports must have a router connected or an IGMP host to receive the stream.

These rules are to prevent multicast packets from leaking into an undesired virtual port, such as p2 on VLAN pc2 in [Figure 281](#). These rules also allow that, in most topologies, MVR can be deployed with minimal configuration. However, unlike *EAPS* and *STP* (*Spanning Tree Protocol*), MVR is not intended to be a Layer 2 protocol to solve packet looping problems. Since multicast packets leak across VLANs, one can misconfigure and end up with a multicast storm. MVR does not attempt to solve such problems.

**Note**

If a port is blocked by Layer 2 protocols, that port is removed from the egress list of the cache. This is done dynamically per the port state.

For most situations, you do not need to manually configure ports to receive the MVR multicast streams. But if one of the forwarding rules denies forwarding to a port that requires the streams, you can manually receive the MVR multicast streams by using the following command:

```
configure mvr vlan vlan_name add receiver port port-list
```

## Inter-Multicast VLAN Forwarding

In [Basic MVR Deployment](#) on page 1805, only simple topologies are considered, in which subscribers on different VLANs access a multicast VLAN. There are topologies where streams need to be forwarded onto another multicast VLAN, as shown in [Figure 282](#). In this figure, a Multicast Service Provider (MSP) multicast VLAN is attached to ports 1:1-2 on both switches, SW1 and SW2. On the customer side, another multicast VLAN, delivers multicast streams to other switches around the ring.

**Figure 282: Inter-Multicast VLAN Forwarding**

In this topology, a multicast stream can be leaked into the customer multicast network through either switch SW1 or SW2. However, as described in [MVR Forwarding](#) on page 1808, packets are not forwarded to router ports (ports 1:4 and 1:5 can be router ports if SW2 is an [IGMP](#) querier). To get around this, MVR needs to be configured on CustVlan either on SW1 or SW2. Since the forwarding rules apply only to non-MVR VLANs, traffic from one MVR VLAN is leaked into the router ports of another VLAN, if MVR is enabled on that.

In the topology above, the MSP multicast VLAN is carried on two switches that also carry the customer multicast VLAN. When multiple switches carry both multicast VLANs, it is imperative that MVR is configured on only one switch. Only that switch should be used as the transit point for multicast streams from one multicast ring into another. Otherwise, duplicate packets are forwarded. Also on the non-MVR switches, the ring ports should be configured as static router ports, so that ring ports are excluded from forwarding packets onto the customer ring. There is no mechanism to elect a designated MVR forwarder, so it must be configured correctly.

## MVR Configurations

MVR enables Layer 2 network installations to deliver bandwidth intensive multicast streams. It is primarily aimed at delivering IPTV over Layer 2 networks, but it is valuable in many existing [EAPS](#) or [STP](#) installations. This section explores a few possible deployment scenarios and configuration details. Of course, real world networks can be lot different from these examples. This section is meant to present some ideas on how to deploy MVR over existing networks, as well as to design new networks that support MVR.

### *MVR with EAPS*

Since MVR is designed with a Layer 2 ring topology in mind, it is strongly recommended that it should be deployed with [EAPS](#). The MVR plus EAPS combination provides a superior solution for any triple play

network, where the service provider intends to provide data, voice, and video services. EAPS is a proven solution for providing sub-second SONET-like protection to Layer 2 rings. For more detail on EAPS refer to [EAPS](#) on page 1179.

Consider a typical EAPS topology in [Figure 283](#), where 3 VLANs on the core ring serve various clients on each switch. To provide video service, one of the VLANs on the EAPS ring is designated as a multicast VLAN. MVR is enabled only on this VLAN (mcastvlan). V1 is the control VLAN, and V2 is another protected VLAN. A router serving the multicast feed would typically run PIM on mcastvlan, to support the static and dynamic *IGMP* membership on the VLAN.

**Figure 283: MVR on an EAPS Ring**

The following is a typical configuration for the router and switches.

**Router1:**

```
create vlan mcastvlan
configure mcastvlan add port 1:1
create vlan server
configure server add port 1:2
configure mcastvlan ipaddress 10.1.1.1/24
configure server ipaddress 11.1.1.1/24
configure igmp snooping mcastvlan port 1:1 add static group 239.1.1.1
enable ipforwarding
enable ipmcforwarding
configure igmp snooping leave-timeout 2000
configure pim add vlan all
enable pim
```

**Switch1:**

```
create vlan mcastvlan
create vlan v1
create vlan v2
create vlan vlan2
configure vlan vlan2 add port 1:3
configure vlan vlan2 ipaddress 10.20.1.1/24
configure mcastvlan tag 20
configure mcastvlan add port 1:1,1:2 tag
```

```

configure mvr add vlan mcastvlan
configure vlan v1 tag 30
configure v1 add port 1:1,1:2 tag
configure vlan v2 tag 40
configure v2 add port 1:1,1:2 tag

create eaps e1
configure eaps e1 mode transit
configure eaps e1 add control vlan v1
configure eaps e1 add protect vlan mcastvlan
configure eaps e1 add protect vlan v2
configure eaps port primary port 1:1
configure eaps port secondary port 1:2
enable eaps
enable mvr

```

**Switch3:**

```

create vlan McastVlan
create vlan v1
create vlan v2
configure mcastvlan tag 20
configure mcastvlan add port 1:2,1:3 tag
configure mcastvlan add port 1:1
configure mvr add vlan mcastvlan
configure vlan v1 tag 30
configure v1 add port 1:2,1:3 tag
configure vlan v2 tag 40
configure v2 add port 1:2,1:3 tag

create eaps e1
configure eaps e1 mode master
configure eaps e1 add control vlan v1
configure eaps e1 add protect vlan mcastvlan
configure eaps e1 add protect vlan v2
configure eaps port primary port 1:3
configure eaps port secondary port 1:2
enable eaps
enable mvr

```

**Note**

In this example, Switch3 is the EAPS master, but any of the other switches in the ring could have been configured as the master.

*MVR with STP*

In a Layer 2 ring topology, MVR works with STP as it works with EAPS. However, in other Layer 2 topologies, additional configuration steps may be needed to make sure that multicast feeds reach all network segments. Extra configuration is required because all ports in the VLAN are part of an STP domain, so that solely by examining the configuration it is not clear whether a port is part of bigger ring or is just serving a few hosts. In EAPS this problem is solved by distinguishing between configured primary or secondary ports from other VLAN ports. Consider a simplified Layer 2 STP network as shown in [Figure 284](#).

**Figure 284: MVR with STP**

In this topology, subscribers are in a Layer 2 cloud on VLAN V1.

STP is configured for all ports of V1. Since V1 spans on the ring as well, multicast cannot be forwarded on V1 blindly. Forwarding rules (described in [MVR Forwarding](#) on page 1808), dictate that multicast traffic is not forwarded on STP enabled ports. This is to make sure that multiple copies of multicast packets are not forwarded on the ring. However, since other STP enabled ports on V1 (1:3,1:4) are not part of the ring multicast stream, they need to be configured so that they get the packets. To configure the ports to receive packets, use the following command (mentioned in [MVR Forwarding](#) on page 1808):

```
configure mvr vlan vlan-name add receiver port port-list
```

**Note**

If the Layer 2 cloud is connected back to ring ports, traffic may end up leaking into VLAN V1 in the ring. There is no way to avoid that. So, such topologies must be avoided.

The following is a typical configuration for Switch 1:

```
create vlan v1
configure v1 tag 200
configure v1 add port 1:1, 1:2 tag
configure v1 add port 1:3, 1:4
create vlan mvlan
configure mvlan add port 1:1, 1:2
configure mvr add vlan mvlan
create stpd stp1
configure stp1 add vlan v1 port all
enable stpd stp1 port all
configure mvr vlan v1 add receiver port 1:3,1:4
enable mvr
```

### *MVR in a VMAN Environment*

In the case of a VMAN, a packet is tagged with a VMAN tag in addition to a possible VLAN tag. This is to provide VLAN aggregation for all customer traffic in the VMAN ring. Each customer is given its own VLAN, and traffic from all customers can be tunneled on a single VMAN tag into the metro ring to an outside Broadband Remote Access Server (BRAS). In a VMAN network, multicast traffic can be

distributed over a separate VLAN in the metro core. These packets are not subjected to VMAN tunneling. Thus, IPTV service can be provided on this multicast VLAN on a VMAN network.

MVR deployment in a VMAN environment is not any different from that in an *E-APS* environment, since a separate multicast VLAN on the metro ring is used for multicasting. However, it provides interesting capabilities to MSPs for their video offerings. Different service bundles can be offered on separate VLANs. Packets are not forwarded to any metro link segments where a stream is not required.

Figure 285 illustrates an example design for MVR in a VMAN environment. Any multicast packet entering on MVlan is forwarded on MVlan to the next switch. These multicast packets are not tunneled.

With MVR, switches on the VMAN do not have to run any routing protocol. If MVR is enabled on the multicast VLAN, MVlan, traffic is pulled from the IPTV server. Such multicast packets egressing from the CE port are always untagged. The downstream DSLAM distributes untagged multicast packets to the respective subscriber VLANs.

**Figure 285: MVR in a VMAN Environment**

The following is a typical configuration for Switch 1 in the above figure:

```
create vman vman2
configure vman vman2 tag 300
configure vman vman2 add port 2:2-2:3 untagged
configure vman vman2 add port 1:1,1:2 tagged
enable port 2:*
enable port 1:*
create vlan mvlan
configure vlan mvlan tag 200
configure vlan mvlan add port 1:1,1:2 tag
configure mvr add vlan mvlan
enable mvr
```

## Displaying Multicast Information

---

### Displaying the Multicast Routing Table

- To display part or all of the entries in the multicast routing table, use the following command:  

```
show iproute {ipv4} {{vlan} name | [ipaddress netmask | ipNetmask] | origin [direct | static | mbgp | imbgp | embgp]} multicast {vr vr_name}
```

### Displaying the Multicast Cache

- The multicast cache stores information about multicast groups. To display part or all of the entries in the multicast cache, use the following command:  

```
show mcast cache {{vlan} vlan_name} {{[group grpaddressMask | grpaddressMask] {source sourceIP | sourceIP} {type [snooping | pim | mvr]}| {summary}}
```

### Looking Up a Multicast Route

- To look up the multicast route to a specific destination, use the following command with the **multicast** option:  

```
rtlookup [ipv4_address | ipv6_address] { unicast | multicast | rpf } {vr vr_name}
```

### Looking Up the RPF for a Multicast Source

- To look up the RPF for a multicast source, use the following command with the **rpf** option:  

```
rtlookup [ipv4_address | ipv6_address] { unicast | multicast | rpf } {vr vr_name}
```

### Displaying the PIM Snooping Configuration

- To display the PIM snooping configuration for a VLAN, use the following command:  

```
show pim snooping {vlan} vlan_name
```

### Displaying Anycast Rendezvous Point (RP) Using PIM (RFC 4610)

To display rendezvous point (RP) for Anycast RP using PIM (RFC 4610) information, use the following command:

```
show pim {ipv4 | ipv6} anycast-rp {ip_address}
```

## Troubleshooting PIM

---

### Multicast Trace Tool

The multicast trace tool is the multicast equivalent of unicast trace route mechanism and is an effective tool for debugging multicast reachability problems. This tool is based on an IETF draft and uses IGMP.

Because it is harder to trace a multicast path from the source to the destination, a multicast trace is run from the destination to the source. The multicast trace can be used to do the following:

- Locate where a multicast traffic flow stops
- Identify sub-optimal multicast paths

A multicast trace is used for tracing both potential and actual multicast forwarding tree paths. When the multicast tree is established and traffic is flowing, this tool traces the actual traffic flow. If there is no traffic while executing the command, this tool displays the potential path for the group and source being traced.

You can direct a multicast trace to any network destination, which can be a multicast source or destination, or a node located between a source and destination. After you initiate the trace, a multicast trace query packet is sent to the last-hop multicast router for the specified destination. The query packet contains the source address, group address, destination/receiver address, response address, maximum number of hops, and TTL to be used for the multicast trace response.

The previous hop router selection is based on the multicast routing protocol and the state for the S,G entry in the processing router.

For example:

- If there is no S,G state in the router, the parent closest to the RP is chosen as the previous hop.
- If the S,G state exists in the router, the parent closest to the source is chosen as the previous hop.

The last hop router converts the multicast trace query into a unicast traceroute request by appending response data (for the last hop router) into the received query packet, and the last hop router forwards the request packet to the router that it believes is the proper previous hop for the given source and group.

Each multicast router adds its response data to the end of the request packet, and then forwards the modified unicast request to the previous hop.

The first hop router (the router that determines that packets from the source originate on one of its directly connected networks) changes the packet type to response packet and sends the completed response to the query generator. If a router along the multicast route is unable to determine the forwarding state for a multicast group, that router sends a response back to the originator with NO ROUTE forwarding code.

To initiate a multicast trace, use the following command:

```
mtrace source src_address {destination dest_address} {group grp_address}
{from from_address} {gateway gw_address} {timeout seconds} {maximum-hops
number} {router-alert [include | exclude]} {vr vrname}
```

## Multicast Router Information Tool

The multicast router information tool is an ExtremeXOS command that allows you to request information from a specific multicast router. For more information, see the command description for the following command:

```
mrinfo {router_address} {from from_address} {timeout seconds} {multiple-
response-timeout multi_resp_timeout} {vr vrname}
```

# IPv6 Multicast

---

[Multicast Listener Discovery \(MLD\) Overview](#) on page 1817  
[Managing MLD](#) on page 1818

This chapter introduces IPv6 multicast, which allows a single IPv6 host to send a packet to a group of IPv6 hosts, and the features and configuration of the Multicast Listener Discovery (MLD) protocol. For more information on IPv6 multicasting, refer to the following publications:

- RFC 2710—Multicast Listener Discovery (MLD) for IPv6
- RFC 3810—Multicast Listener Discovery Version 2 (MLDv2) for IPv6

## Multicast Listener Discovery (MLD) Overview

---

Multicast Listener Discovery (MLD) is a protocol used by an IPv6 host to register its IP multicast group membership with a router. To receive multicast traffic, a host must explicitly join a multicast group by sending an MLD report; then, the traffic is forwarded to that host. Periodically, the router queries the multicast group to see if the group is still in use. If the group is still active, a single IP host responds to the query, and group registration is maintained.

MLD is the IPv6 equivalent to *IGMP (Internet Group Management Protocol)*, and MLDv1 is equivalent to IGMPv2. The ExtremeXOS software supports both MLDv1 and MLDv2 protocol.

### Note

This release does not support MVR, PVLAN, *VLAN (Virtual LAN)* Aggregation, and Multicast Troubleshooting tools for MLD/IPv6.

## ExtremeXOS Resiliency Enhancement for IPv6 Static Routes

The ExtremeXOS Resiliency Enhancement feature provides a resilient way to use *ECMP (Equal Cost Multi Paths)* to load balance IPv6 traffic among multiple servers or other specialized devices. ExtremeXOS automatically manages the set of active devices using ECMP static routes configured with ping protection to monitor the health of these routes. Such servers or specialized devices do not require special software to support Bidirectional Forwarding Detection (BFD), or IP routing protocols such as *OSPF (Open Shortest Path First)*, or proprietary protocols to provide keepalive messages. ExtremeXOS uses industry-standard and required protocols ICMPv6/Neighbor Discovery for IPv6 to accomplish the following automatically:

- Initially verify devices and activate their static routes, without waiting for inbound user traffic, and without requiring configuration of device MAC addresses.
- Detect silent device outages and inactivate corresponding static routes.
- Reactivate static routes after device recovery, or hardware replacement with a new MAC address.

ExtremeXOS currently supports similar protection and resiliency using Bidirectional Forwarding Detection (BFD) on IPv4 and IPv6 static routes. However, BFD can only be used when the local and remote device both support BFD.

## Managing MLD

---

### Enabling and Disabling MLD on a VLAN

MLD is disabled by default on all VLANs. You can enable MLD using the `enable mld {vlan vlan_name} {MLDv1 | MLDv2}` command.

This allows IPv6 hosts to register with IPv6 multicast groups and receive IPv6 multicast traffic.

- To disable MLD on a VLAN after it has been enabled, use the `disable mld {vlan name}` command.
- To enable MLD on a VLAN after it has been disabled, use the `enable mld {vlan vlan_name} {MLDv1 | MLDv2}` command.

### MLD Snooping

Similar to IGMP snooping, MLD snooping is a Layer 2 function of the switch; it does not require multicast routing to be enabled. In MLD snooping, the Layer 2 switch keeps track of MLD reports and only forwards multicast traffic to the part of the local network that requires it. MLD snooping optimizes the use of network bandwidth and prevents multicast traffic from being flooded to parts of the local network that do not need it.

MLD snooping is disabled by default on all VLANs in the switch.

When MLD snooping is disabled on a VLAN, all MLD and IPv6 multicast traffic floods within the VLAN.

MLD snooping expects at least one device on every VLAN to periodically generate MLD query messages.

- Enable or disable MLD snooping:

```
enable mld snooping
```

```
disable mld snooping
```

Multicast packets with a scope id less than 2 are not forwarded by the MLD snooping enabled switch. Kill entry is installed in the hardware for this traffic.

Multicast packets with a scope id of 2 and group address in the range of FF02::/111 (Addresses allocated by IANA as per RFC 3307) are always flooded to all ports of the VLAN by hardware and a copy of the packet is provided to slow path. There are no cache entries in software or hardware for these addresses.

- Multicast packets with a scope id of 2 and group address as solicited multicast address (FF02::1:FFXX:XXXX/104) are flooded to all ports of VLAN for 135 seconds (Default MLD query interval + Maximum response time), if there are no members for this group.

Otherwise, the traffic is forwarded based on the snooping database. Multicast cache entries for these addresses are maintained only in the software and traffic is always slow path forwarded.

Multicast addresses with a scope id of 2 and that do not qualify in the above categories will be forwarded based on the snooping database.

Cache entries for these multicast addresses will be installed in hardware. Unregistered packets are dropped.

- In general, all multicast data traffic on a PIMv6 enabled VLAN is controlled by the PIMv6 protocol. However, multicast traffic with either the group address or source address as the link local address will not be controlled by PIMv6. Instead, it will be L2 forwarded based on the snooping database.

For multicast packets with a scope id greater than 2 on PIMv6 enabled VLANs, cache entries are controlled by the PIMv6 protocol.

PIMv6 provides a list of egress VLANs for which packets need to be forwarded. The snooping database is used to construct the set of ports for ingress VLANs as well as for each egress VLAN.

On PIMv6 disabled VLANs, traffic is forwarded based on the snooping database on the ingress VLAN.

In both cases, cache entry is installed in the hardware, and traffic is fast path forwarded.

- The MLD snooping proxy feature is enabled automatically when MLD snooping is enabled. This feature optimizes the forwarding of MLDv1 reports. The following conditions apply for each group:
  - Only the first received MLD join is forwarded upstream.
  - Only the MLD leave for last host is forwarded upstream.

When a switch receives an MLD leave message on a port, it sends a group-specific query on that port if proxy is enabled (even if it is a non-querier). The switch removes the port from the group after the leave timeout (a configurable value from 0 - 175000ms with a default of 1000ms). If all the ports are removed from the group, the group is deleted and the MLD leave is forwarded upstream. If MLD snooping proxy is disabled, then all the MLD reports are forwarded upstream.

**Note**

MLD snooping proxy does not apply to MLDv2 reports.

- MLD snooping is implemented primarily through ACLs, which are processed on the interfaces. These special purpose ACLs are called MLD snooping hardware filters. The software allows you to choose between two types of MLD snooping hardware filters: per-port filters (the default) and per-VLAN filters.

The two types of MLD snooping hardware filters use switch hardware resources in different ways.

- The two primary hardware resources to consider when selecting the MLD snooping hardware filters are the Layer 3 multicast forwarding table, and the interface ACLs. The size of both of these hardware resources is determined by the switch model. In general, the per-port filters consume more

resources from the multicast table and less resource from the ACL table. The per-VLAN filters consume less space from the multicast table and more from the ACL table.

- Using the per-port filters can fill up the multicast table and place an extra load on the CPU. To avoid this, configure the switch to use the per-VLAN filters.

#### Note

The impact of the per-VLAN filters on the ACL table increases with the number of VLANs configured on the switch. If you have a large number of configured VLANs, we suggest that you use the per-port filters.

### MLD Snooping Filters

MLD snooping filters allow you to configure a policy file on a port to allow or deny MLD report and leave packets coming into the port.

(For details on creating policy files, see [Policy Manager](#) on page 733.) The MLD snooping filter feature is supported by MLDv1 and MLDv2.

#### Note

Do not confuse MLD snooping filters with MLD snooping hardware filters explained in previous section. MLD snooping filters are software filters, and the action is applied at software level by the ExtremeXOS multicast manager.

For the policies used as MLD snooping filters, all the entries should be IPv6 address type entries, and the IPv6 address of each entry must not be in the range of FF02::/96.

Use the following template to create a snooping filter policy file that denies MLD report and leave packets for the FF03::1/128 and FF05::1/112 multicast groups:

```
#
Add your group addresses between "Start" and "end"
Do not touch the rest of the file!!!!
entry mldFilter {
 if match any {
 #----- Start of group addresses -----
 nlri FF03::1/128;
 nlri FF05::1/112;
 #----- end of group addresses -----
 } then {
 deny;
 }
}
entry catch_all {
 if {
 } then {
 permit;
 }
}
```

After you create a policy file, use the following command to associate the policy file and filter to a set of ports:

```
configure mld snooping vlan vlan_name ports port_list filter [policy]
```

To remove the filter, use the **none** option.

To display the MLD snooping filters, use the following command:

```
show mld snooping {vlan} name filter
```

### Limiting the Number of Multicast Sessions on a Port

The default configuration places no limit on the number of multicast sessions on each *VLAN* port. To place a limit on the number of learned MLD reports, or remove the limit, use the command:

```
configure mld snooping {vlan} vlan_name ports port_list join-limit
[num_joins | no-limit]
```

## Configuring MLD Snooping

- To configure the timers that control MLD operation, use the command:
 

```
configure mld query_interval query_response_interval
last_member_query_interval {robustness}
```
- Similar to *IGMP* snooping, MLD snooping is a Layer 2 function of the switch. It does not require multicast routing to be enabled. MLD snooping keeps track of MLD reports, and only forwards multicast traffic to that part of the local network that requires it. MLD snooping is disabled by default on all *VLANs*. If MLD snooping is disabled on a VLAN, all MLD and IPv6 multicast traffic floods within the VLAN. To enable MLD snooping, use the command:
 

```
enable mld snooping {vlan name}
```

## Clearing MLD Group Registration

To clear a single group or all groups in a *VLAN* learned through MLD, use the command:

```
clear mld group {v6grpipaddress} {{vlan} name}
```

## Configuring Static MLD

In some situations, you might want multicast traffic to be forwarded to a port where a multicast-enabled host is not available (for example, when you test multicast configurations). Static MLD emulates a host or router attached to a switch port, so that multicast traffic is forwarded to that port, and the switch sends a proxy join for all the statically configured MLD groups when an MLD query is received. You can emulate a host to forward a particular multicast group to a port; and you may emulate a router to forward all multicast groups to a port.

- To emulate a host on a port, use the command:
 

```
configure mld snooping {vlan} vlan_name{ ports port_list } add static
group v6grpipaddress
```
- To emulate a multicast router on a port, use the command:
 

```
configure mld snooping {vlan}vlan_name ports port_list add static
router
```
- To remove these entries, use the corresponding commands:
 

```
configure mld snooping {vlan} vlan_name {ports port_list } delete
static group [all | v6grpipaddress]
configure mld snooping {vlan} vlan_name ports port_list delete static
router
```

## MLD Loopback

Prior to ExtremeXOS 15.3.2, you could configure static groups, but it was necessary to specify port(s). As of 15.3.2, the configuration of dynamic groups is now supported. The MLD Loopback feature along with the existing static group feature supports the configuration of static and/or dynamic groups with or without ports.

A VLAN in loopback mode may not have ports associated with it, but its operational status is up. However, it is not possible to have multicast receivers on a VLAN without having a port. Sometimes, there is a need to pull the multicast traffic from upstream to the loopback VLAN for troubleshooting. The traffic need not always be forwarded to any ports/receivers. The MLD Loopback feature allows you to configure groups on a VLAN without specifying a port, so the traffic is pulled from upstream but not forwarded to any port.

The loopback (Lpbk) port is the logical port on a VLAN in the application context. When you configure a group on a VLAN but do not specify the port, the switch forms an MLDv1 join and assumes it to be received on the Lpbk port. A dynamic group ages out after the membership timeout if there are no other receivers. Membership joins refresh the dynamic group. The static group remains until it is removed from the configuration.

The following command is used to configure static or dynamic group entry:

```
configure mld snooping {vlan} vlan_name {ports portlist} add [static |
dynamic] group ip_address
```

## Displaying MLD Information

- To display MLD configuration and operation information, use the command:  

```
show mld group {{vlan} {name} | {v6grpipaddress}} {MLDv2}
```
- To display the MLD static group information, use the command:  

```
show igmp snooping {vlan} name static [group | router]
```

## MLD SSM Mapping

The MLD-SSM Mapping feature allows MLDv1 hosts to participate in SSM functionality, and eliminates the need for MLDv2. You can configure SSM map entries that specify the sources used for a group/group range for which SSM functionality is applied. You also have the option to configure domain name and DNS server to use to obtain the source list.

When a MLDV1 report is received, the configured sources are provided to PIM so that it can send source specific joins. When the host leaves, or when the membership times out, PIM is informed so that it can consider sending prunes.

### Note

The sources mapped to only the LPM group are used.

### Feature Implementation Information

- This feature is implemented as an extension to existing IGMP SSM support.
- The CLI commands for this feature are applicable in VR context.

- PIM is completely unaware of existence of this feature, so there is no change in PIM processing.
- On last hop the (S, G) cache created through MLDv1 join is similar to the (S, G) cache created as a result of RPT to SPT switchover in PIM-SM. There is no indication that the cache is created as result of MLDv1 join, or MLDv2 report.

### Limitations

- Only 50 sources (static or dynamic) are allowed for each group address, or group range.

#### Note

The DNS server may send only 14 IPv6 source addresses in its response thereby limiting the number of dynamic sources supported.

- Only one DNS name is allowed for each group address/group range.

### SSM Address Range

The address prefix FF3x::/32 is reserved by IANA for SSM use. All SSM addresses must have P=1, T=1 and plen=0. RFC 3306 mandates that the network prefix is zero, which results in the SSM address range to be in FF3x::/96 range. Since future documents may allow a non-zero network prefix, this feature allows the addresses in range FF3x::/32 in SSM map configuration. The default SSM range is FF3x::/96.

SSM address range is configured from the PIM context using the following command:

```
configure pim ipv6 ssm range default | policy policy_name
```

When this command is issued, PIM notifies MCMGR with the details of the SSM address range. MCMGR applies this range for the MLD SSM feature.

### Handling MLD Reports

[Table 171](#) captures the enhanced functionality.

**Table 171: MLD Mapping**

| MLDv1 Join                            | MLD SSM Map Disabled         | MLD SSM Map Enabled          |
|---------------------------------------|------------------------------|------------------------------|
| Group in SSM range but no map entries | Dropped                      | Dropped                      |
| Group in SSM range with map entries   | Dropped                      | SSM map sources included     |
| Group not in SSM range                | SSM map sources not included | SSM map sources not included |

MLDv1 reduction messages in the SSM range are accepted and processed normally. Multicast manager will send out a group-specific query and refresh the receivers on receiving joins.

When an MLDv2 report is received, following group records types are ignored if they refer to SSM group range:

- MODE\_IS\_EXCLUDE
- CHANGE\_TO\_EXCLUDE\_MODE

Other group records in the same report are processed.

If the DNS response is not received and the DNS age timer expires, the mapping entry is removed (if there are no static addresses). The SSM data traffic forwarding is stopped immediately when the group is removed.

### DNS Server

This feature does not check or track DNS servers configured in the switch. You must correctly configure and administer the DNS server.

The following command is used to configure the DNS server:

```
configure dns-client add name-server ip_address {vr vr_name}
```

The server(s) are displayed using the following command:

```
show dns-client
Number of domain suffixes: 0
Number of domain servers: 1
Name Server 0: 10.120.89.75 VR-Default
```

MCMGR uses nettools library to perform DNS lookups. `gethostbyname_c` is used by specifying the callback function to be invoked when DNS response is received.

### Configuring MLD SSM Mapping

Use the following commands to configure MLD SSM Mapping in ExtremeXOS:

- Enable or disable MLD SSM Mapping on a VR: `[enable | disable] mld ssm-map { {vr} vrname }`
- Add an MLD SSM Mapping entry on a VR: `configure mld ssm-map add v6groupnetmask [v6sourceip | src_domain_name] { {vr} vrname }`
- Delete an MLD SSM Mapping entry on a VR: `configure mld ssm-map delete v6groupnetmask [v6sourceip | src_domain_name] { {vr} vrname }`
- Delete all MLD SSM Mapping entries on a VR: `unconfigure mld ssm-map { {vr} vrname }`
- Display the status of MLD-SSM mapping feature on a VR, and display the MLD-SSM mapping entries: `show mld ssm-map { v6groupnetmask } { {vr} vrname }`
- Send out a DNS request for a particular group. On receiving the DNS response, the "DNS Age" in the SSM mapping entry is refreshed: `refresh mld ssm-map v6groupnetmask { {vr} vrname }`
- Configure the DNS server: `configure dns-client add name-server ip_address {vr vr_name}}`
- Display the DNS Servers: `show dns-client`

# MSDP

---

- [MSDP Overview on page 1826](#)
- [PIM Border Configuration on page 1827](#)
- [MSDP Peers on page 1827](#)
- [MSDP Mesh-Groups on page 1830](#)
- [Anycast RP on page 1830](#)
- [SA Cache on page 1832](#)
- [SNMP MIBs on page 1834](#)

This chapter introduces MSDP (Multicast Source Discovery Protocol), an interdomain multicast protocol used to connect multiple multicast routing domains that run PIM-SM (Protocol Independent Multicast-Sparse Mode). This chapter discusses the features and configuration for PIM border, MSDP peers, mesh groups, anycast RP, SA cache, redundancy, and [SNMP \(Simple Network Management Protocol\) MIBs](#).

#### Note

For more information about MSDP, refer to RFC 3618.

## MSDP Overview

---

*MSDP (Multicast Source Discovery Protocol)* is an interdomain multicast protocol used to connect multiple multicast routing domains that run Protocol Independent Multicast-Sparse Mode (PIM-SM).

MSDP speakers are configured on each PIM-SM domain. These speakers establish a peering relationship with other MSDP speakers through secured TCP connections. When the source sends traffic, the MSDP speaker learns about the source through its Rendezvous Point (RP). In turn, the RP advertises the source to its peers through Source Active (SA) messages. The peers receive these advertisements and inform their RPs about the presence of the active source in the other PIM-SM domain, which triggers the normal PIM operation in the corresponding domains.

For example, as businesses expand and networks grow in size, it might become necessary to connect PIM domains to allow multicast applications to reach other offices across the network. MSDP simplifies this process by providing a mechanism to connect those multicast routing domains without reconfiguring existing domains. Each PIM domain remains separate and has its own RP. The RP in each domain establishes an MSDP peering relationship over a TCP connection either with RPs in other domains or with border routers leading to other domains. When an RP learns about a new multicast source in its own domain (using the normal PIM registration process), it then sends a SA message to all of its MSDP peers, letting them know about the new stream. In this way, the network can receive multicast traffic from all over the network without having to reconfigure each existing PIM domain.

## Supported Platforms

*MSDP* is supported on all platforms running a minimum software version of ExtremeXOS 12.0 with the Core or Premier license.

Our implementation of MSDP is compliant with RFC 3618 and RFC 3446, and compatible with other devices that are compliant with these standards.

## Limitations

The limitations of *MSDP* are as follows:

- There is no support for MSDP operating with SA cache disabled (transit node). MSDP will always cache/store received SA messages.
- There is no support for logical RP.
- There is no support for MSDP on user-created virtual routers (VRs).
- *RIP (Routing Information Protocol)* routes are not used for peer-RPF checking. So, our implementation of MSDP does not exactly conform to rule (iii) in section 10.1.3 of RFC 3618. However, our implementation of MSDP uses *BGP (Border Gateway Protocol)/OSPF (Open Shortest Path First)* for peer-RPF checking as per rule (iii) in section 10.1.3.
- Read-write/read-create access is not supported on MSDP MIB objects.

## PIM Border Configuration

To create a PIM-SM domain for *MSDP*, you must restrict the reach of Bootstrap Router (BSR) advertisements by defining a *VLAN (Virtual LAN)* border. BSR advertisements are not sent out of a PIM interface configured as a VLAN border, thereby defining a PIM domain for MSDP.

To configure a PIM VLAN border, use the command:

```
configure pim vlan_name border
```

## MSDP Peers

*MSDP* peers exchange messages to advertise active multicast sources. The peer with the higher IP address passively listens to a well-known port number and waits for the side with the lower IP address to establish a Transmission Control Protocol (TCP) connection on port 639. When a PIM-SM RP that is running MSDP becomes aware of a new local source, it sends an SA message over the TCP connection to its MSDP peer. When the SA message is received, a peer-RPF check is performed to make sure the peer is toward the originating RP. If so, the RPF peer floods the message further. If not, the SA message is dropped and the message is rejected.

- Configure an MSDP peer using the command:  

```
create msdp peer remoteaddr {remote-as remote-AS} {vr vrname}
```
- Delete an MSDP peer using the command:  

```
delete msdp peer [all | remoteaddr] {vr vr_name}
```
- Display configuration and run-time parameters about an MSDP peer using the command:  

```
show msdp [peer {detail} | {peer} remoteaddr] {vr vr_name}
```

## MSDP Default Peers

You can configure a default peer to accept all SA messages. Configuring a default peer simplifies the peer-RPF checking of SA messages. If no policy is specified, the current peer is the default RPF peer for all SA messages.

When configuring a default peer, you can also specify an optional policy filter. If the peer-RPF check fails, and a policy filter is configured, the default peer rule is applied to see if the SA message should be accepted or rejected.

You can configure multiple default peers with different policies. However, all default peers must either be configured with a default policy or not. A mix of default peers, with a policy and without a policy, is not allowed.

- Configure an *MSDP* default peer, and optional policy filter using the command:

```
configure msdp peer [remoteaddr | all] default-peer {default-peer-policy filter-name} {vr vrname}
```

- Remove the default peer using the command:

```
configure msdp peer [remoteaddr | all] no-default-peer {vr vrname}
```

- Verify that a default peer is configured using the command:

```
show msdp [peer {detail} | {peer} remoteaddr] {vr vr_name}
```

## Peer Authentication

*MSDP* supports TCP RSA Data Security, Inc. *MD5 (Message-Digest algorithm 5)* Message-Digest Algorithm authentication (RFC 2385) to secure control messages between MSDP peers. You must configure a secret password for an MSDP peer session to enable TCP RSA Data Security, Inc. MD5 Message-Digest Algorithm authentication. When a password is configured, MSDP receives only authenticated MSDP messages from its peers. All MSDP messages that fail TCP RSA Data Security, Inc. MD5 Message-Digest Algorithm authentication are dropped.

- Configure TCP RSA Data Security, Inc. MD5 Message-Digest Algorithm authentication on an MSDP peer using the command:

```
configure msdp peer [remoteaddr | all] password [none | {encrypted} tcpPassword] {vr vrname}
```

- Remove the password using the command:

```
configure msdp peer {all | remoteaddr} password none
```

The password displays in encrypted format and cannot be seen as simple text. Additionally, the password is saved in encrypted format.

- Display the password in encrypted format using the command:

```
show msdp [peer {detail} | {peer} remoteaddr] {vr vr_name}
```

## Policy Filters

You can configure a policy filter to control the flow of SA messages going to or coming from an *MSDP* peer. For example, policy filters can help mitigate state explosion during denial of service (DoS) or other attacks by limiting what is propagated to other domains using MSDP.

You can use the following policy attributes in an SA filter policy. All other attributes are ignored:

- Match:
  - multicast-group
  - multicast-source
  - pim-rp
- Set:
  - permit
  - deny

The following shows some examples of policy files taking into account multicast-source with permit/deny action:

```
entry policy2 {
 if match any{
 nlri 10.10.10.0/24;
 }
 then {
 deny;
 }
}

entry policy1 {
 if match any{
 nlri 10.10.10.0/24;
 nlri 20.20.20.0/24 ;
 }
 then {
 permit;
 }
}
<= permit these sources
```

- To configure an incoming or outgoing policy filter for SA messages:
 

```
configure msdp peer [remoteaddr | all] sa-filter [in | out] [filter-name | none] {vr vr_name}
```
- To remove a policy filter for SA messages, use the **none** keyword:
 

```
configure msdp [{peer} remoteaddr | peer all] sa-filter [in | out] none
```
- To verify that a policy filter is configured on an MSDP peer:
 

```
show msdp [peer {detail} | {peer} remoteaddr] {vr vr_name}
```

## SA Request Processing

You can configure the router to accept or reject SA request messages from a specified *MSDP* peer or all peers. If an SA request filter is specified, only SA request messages from those groups permitted are accepted. All others are ignored.

- Configure the router to accept SA request messages from a specified MSDP peer or all peers using the command:
 

```
enable msdp [{peer} remoteaddr | peer all] process-sa-request {sa-request-filter filter-name } {vr vr_name}
```

- Configure the router to reject SA request messages from a specified MSDP peer or all peers using the command:

```
disable msdp [{peer} remoteaddr | peer all] process-sa-request {vr
vrname}
```

- Display configuration and run-time parameters about MSDP peers using the command:

```
show msdp [peer {detail} | {peer} remoteaddr] {vr vr_name}
```

## MSDP Mesh-Groups

*MSDP* can operate in a mesh-group topology. A mesh-group limits the flooding of SA messages to neighboring peers. In a mesh-group, every MSDP peer must be connected to every other peer in the group. In this fully-meshed topology, when an SA message is received from a member of the mesh-group, the SA message is always accepted, but not flooded to other members of the same group. Because MSDP peers are connected to every other peer in the mesh-group, an MSDP peer is not required to forward SA messages to other members of the same mesh-group. However, SA messages are flooded to members of other mesh-groups. An MSDP mesh-group is an easy way to implement inter-domain multicast, as it relaxes the requirement to validate looping of MSDP control traffic (that is, peer-RPF checking is not required). Consequently, SA messages do not loop in the network.

### Note

We recommend that you configure anycast RP peers in a mesh topology.

- Configure an MSDP mesh-group using the command:

```
create msdp mesh-group mesh-group-name {vr vrname}
```

- Remove an MSDP mesh-group using the command:

```
delete msdp mesh-group mesh-group-name {vr vrname}
```

- Display information about an MSDP mesh-group using the command:

```
show msdp [mesh-group {detail} | {mesh-group} mesh-group-name] {vr
vrname}
```

- Configure a peer to be a member of an MSDP mesh-group using the command:

```
configure msdp peer [remoteaddr | all] mesh-group [mesh-group-name |
none] {vr vrname}
```

- Remove a peer from an MSDP mesh-group using the command:

```
configure msdp [{peer} remoteaddr | peer all] mesh-group none {vr
vrname}
```

## Anycast RP

Anycast RP is an application of *MSDP* that allows multiple RPs to operate simultaneously in a PIM-SM domain. Without anycast RP, multiple routers can be configured as candidate RPs, but at any point in time, only one router can serve as RP. Because anycast RP allows multiple RPs to be simultaneously

active, anycast RP provides both load sharing and redundancy, as each RP serves the receivers that are closest to it in the network and can take over for additional receivers if another RP fails.

#### Note

Starting with ExtremeXOS 31.1, you can use Anycast RP without MSDP using the Anycast RP Using PIM (*RFC 4610*) feature (see [Anycast Rendezvous Point \(RP\) Using PIM \(RFC 4610\)](#) on page 1789).

In an anycast RP topology, all RPs in a PIM-SM domain are configured with the same IP address on a loopback *VLAN*. The loopback VLAN IP address should have a 32-bit mask, so that it specifies a host address. All the routers within the PIM-SM domain select the nearest RP for each source and receiver. If the senders and receivers within the PIM-SM domain are distributed evenly, the number of senders that register with each RP is approximately equal.

Another requirement of the anycast RP topology is that MSDP must run on all RPs in the PIM-SM domain, so all RPs are also MSDP peers. We recommend that you configure an MSDP mesh connection between all MSDP peers in the domain.

Whenever any multicast source becomes active, this information is sent in an MSDP SA message to the other MSDP peers in the domain, announcing the presence of the source. If any RP within the domain fails, the IP routing protocol mechanism ensures that next available RP is chosen. If a sender registers with one RP and a receiver joins another RP, the information shared through MSDP enables PIM-SM to establish an SPT between the receiver and the source.

#### Note

We recommend that you configure anycast RP peers in a mesh topology.

The exchange of information in an anycast RP process works as follows:

- When the first-hop router sends a PIM Register message to the nearest RP, the PIM router checks to see if the nearest RP is the RP for the group.
- If the nearest RP is the RP for the group, an MSDP SA message is created and forwarded to the other MSDP peers.
- The MSDP SA message includes the configured originator ID, which is a mandatory configuration component.
- Each remote peer checks the RPF of the originator ID address and informs the PIM process on that remote router about active multicast sources.
- Remote receivers get data packets through the remote shared tree, and can then switch over to the SPT by sending join messages directly towards the source.

To configure anycast RP, do the following at each anycast RP router:

1. Create and configure a loopback VLAN using the commands:

```
create vlan vlan_name {tag tag } {description vlan-description } {vr
name }

enable loopback-mode vlan vlan_name
```

- Assign the anycast RP address to the loopback VLAN with a 32 bit subnet mask using the command:

```
configure {vlan} vlan_name ipaddress [ipaddress {ipNetmask} | ipv6-link-local | {eui64} ipv6_address_mask]
```

#### Note

The anycast RP address must be unique to the loopback VLAN and be the same on all anycast RP peers. It must not match the router IP address, the PIM BSR address, or any other IP addresses used by the router or any other network devices.

- Enable IP forwarding and IP multicast forwarding on the loopback VLAN using the commands:

```
enable ipforwarding {ipv4 | broadcast} {vlan vlan_name}
```

```
enable ipmcforwarding {vlan name}
```

- Add the loopback VLAN into the unicast routing domain using the appropriate command for your unicast routing protocol:

```
configure ospf add vlan vlan-name area area-identifier link-type [auto | broadcast | point-to-point] {passive}
```

```
configure rip add vlan [vlan_name | all]
```

```
configure isis add [vlan all | {vlan} vlan_name] area area_name {ipv4 | ipv6}
```

- Add the loopback VLAN into the PIM-SM domain and configure it as an RP using the commands:

```
configure pim {ipv4 | ipv6} add vlan [vlan-name | all] {dense | sparse} {passive}
```

```
configure pim {ipv4 | ipv6} crp static ip_address [none | policy] {priority [0-254]}
```

- Enable MSDP and establish a peering relationship with similar anycast RP neighbors using the commands:

```
create msdp peer remoteaddr {remote-as remote-AS} {vr vrname}
```

```
configure msdp peer [remoteaddr | all] password [none | {encrypted} tcpPassword] {vr vrname}
```

```
configure msdp peer remoteaddr description {peer-description} {vr vrname}
```

```
enable msdp [{peer} remoteaddr | peer all] {vr vr_name}
```

```
enable msdp {vr vrname}
```

- Configure a unique originator ID for each anycast RP peer using the command:

```
configure msdp originator-id ip-address {vr vrname}
```

## SA Cache

As an MSDP router learns of new sources either through a PIM-SM Source-Register (SR) message or SA message from its RPF peer, it creates an entry in SA cache (or refreshes the entry if it is already there) and forwards this information to its peers. These entries are refreshed by periodic SA messages

received from the MSDP peers. If these entries are not refreshed within six minutes, they will time out. When a PIM-SM RP detects that the source is no longer available it informs MSDP, which in turn removes the SA information from the local database.

Caching makes it easy for local receivers to know immediately about inter-domain multicast sources and to initiate building a source tree towards the source. However, maintaining a cache is heavy both in CPU processing and memory requirements.

#### Note

Our implementation of MSDP does not support operating with local cache disabled.

- Remove an SA cache server.

```
unconfigure msdp sa-cache-server {vr vrname}
```

As MSDP uses the flood-and-join model to propagate information about sources, there is a restriction that no more than two advertisements per cache entry will be forwarded per advertisement interval. This is helpful in reducing an SA message storm and unnecessarily forwarding them to peers.

By default, the router does not send SA request messages to its MSDP peers when a new member joins a group and wants to receive multicast traffic. The new member simply waits to receive SA messages, which eventually arrive.

- Configure the MSDP router to send SA request messages immediately to the MSDP peer when a new member becomes active in a group.

```
configure msdp sa-cache-server remoteaddr {vr vr_name}
```

- Purge all SA cache entries.

```
clear msdp sa-cache {{peer} remoteaddr | peer all} {group-address grp-addr} {vr vrname}
```

- Display the SA cache database.

```
show msdp [sa-cache | rejected-sa-cache] {group-address grp-addr}
{source-address src-addr} {as-number as-num} {originator-rp
originator-rp-addr} {local} {peer remoteaddr} {vr vrname}
```

## Maximum SA Cache Entry Limit

You can configure a limit on the maximum number of SA cache entries that can be stored in the cache database. Once the number of SA cache entries exceeds the pre-configured limit, any newly received cache entries are discarded. You can configure the limit on a per-peer basis. By default, no SA message limit is set. The router can receive an unlimited number of SA entries from an [MSDP](#) peer.

- Configure a limit on the number of SA entries that can be stored in cache.

```
configure msdp peer [remoteaddr | all] sa-limit max-sa {vr vr_name}
```

To allow an unlimited number of SA entries, use 0 (zero) as the value for *max-sa*.

- Display the SA cache limit.

```
show msdp [peer {detail} | {peer} remoteaddr] {vr vr_name}
```

## SNMP MIBs

---

SNMP MIB access is not supported for MSDP.

[Upgrading the BootROM](#) on page 1859

[Upgrading the Firmware \(ExtremeSwitching X440-G2, X465, X620, and 5520 Series Switches Only\)](#) on page 1860

[Displaying the BootROM and Firmware Versions](#) on page 1861

This chapter provides instructions for upgrading ExtremeXOS software and firmware, including how to download and install a new image, perform a hitless upgrade, upload and download the configuration using TFTP, and synchronize nodes.

To upgrade your ExtremeXOS images and modules, start with [ExtremeXOS Upgrade Process](#) on page 1835.

To install modules on top of an existing ExtremeXOS image that will not be upgraded, see [Installing a Modular Software Package](#) on page 1847.

## ExtremeXOS Upgrade Process

---

Upgrading your ExtremeXOS image and modules uses the following process:

1. Backup all configuration files (see [Creating a Backup Configuration File](#) on page 1837).
2. Download ExtremeXOS and module package images from the Extreme Networks support portal (see [Downloading a New Image](#) on page 1841).

### Note

Beginning with ExtremeXOS 16.1, there are two methods available for the upgrade process:

- `download url filename` - provides a means of downloading multiple files at the same time over TFTP, HTTP, or anonymous FTP.
- `download image filename` - downloads a single .xos or .xmod file from a TFTP server.

3. Place the image files on a server that your switch can locate (see [Installing a Core Image](#) on page 1843).

4. Discover your inactive partition (see [Finding the Inactive Partition](#) on page 1842).
5. Use the `download image` command to install each image on the inactive partition (see [Installing a Core Image](#) on page 1843).
6. Reboot the switch (see [Reboot Options](#) on page 1844).

## Upgrade Example

We recommend upgrading ExtremeXOS images and any modular packages at the same time. The following example shows the ExtremeXOS image `summitX-15.7.1.4.xos` being installed before rebooting the switch.

```
show switch

SysName: DUT1
SysLocation:
SysContact: support@extremenetworks.com, +1 888 257 3000
System MAC: 00:04:96:97:D1:7B
System Type: X460G2-48t-10G4

SysHealth check: Enabled (Normal)
Recovery Mode: All
System Watchdog: Enabled

Current Time: Wed Feb 8 17:48:45 2017
Timezone: [Auto DST Disabled] GMT Offset: 0 minutes, name is UTC.
Boot Time: Mon Feb 6 19:36:52 2017
Boot Count: 108
Next Reboot: None scheduled
System UpTime: 1 day 22 hours 11 minutes 53 seconds

Current State: OPERATIONAL
Image Selected: primary
Image Booted: primary
Primary ver: 22.2.0.43
Secondary ver: 22.2.0.41

Config Selected: primary.cfg
Config Booted: primary.cfg
Config Automatic: NONE

primary.cfg Created by ExtremeXOS version 22.2.0.41
 499811 bytes saved on Mon Feb 6 19:36:12 2017

download image 10.68.9.7 summitX-15.7.1.4.xos primary
Debug information files are present in internal-memory.
These files will be removed if you continue with download.
Do you want to continue with download and remove existing files from internal-memory?
(y/N) Yes
Do you want to install image after downloading? (y - yes, n - no, <cr> - cancel) Yes

Downloading to Switch.....
Installing to primary partition!

Installing to
Switch.....
Image installed successfully
This image will be used only after rebooting the switch!

reboot
Are you sure you want to reboot the switch? (y/N) Yes
```

## Creating a Backup Configuration File

Before upgrading ExtremeXOS on a switch, it is highly recommended that you create a backup copy of the configuration. Creating a copy of the "Config Booted" configuration file, with the version number of the ExtremeXOS image included in the name of the backup copy, is the simplest method.

To do this:

1. Save the configuration to the database so the switch can reapply the configuration after the switch reboot using the `save` command.
2. Enter `y` at the prompt to save your changes.
3. Execute the `show switch` command to view the "Config Booted" file. The following output is displayed:

```
show switch
SysName: XXXXX
SysLocation:
SysContact: support@extremenetworks.com, +1 888 257 3000
System MAC: 00:04:96:51:FE:E2
System Type: XXXXXX

SysHealth check: Enabled (Normal)
Recovery Mode: All
System Watchdog: Enabled

Current Time: Thu Sep 4 00:57:18 2014
Timezone: [Auto DST Disabled] GMT Offset: 0 minutes, name is UTC.
Boot Time: Wed Sep 3 20:07:11 2014
Boot Count: 402
Next Reboot: None scheduled
System UpTime: 4 hours 50 minutes 7 seconds

Current State: OPERATIONAL
Image Selected: primary
Image Booted: primary
Primary ver: 15.7.1.4
Secondary ver: 15.7.1.5

Config Selected: ssh-privatekey.cfg
Config Booted: ssh-privatekey.cfg
 ssh-privatekey.cfg Created by ExtremeXOS version
15.7.1.5
 219131 bytes saved on Mon Jul 14 23:03:08 2014
```

4. Using the ExtremeXOS version shown in the "Config Booted:" line, enter the "copy" command as shown:

```
cp config selected config-booted-exos_ver
```

For example: `cp ssh-privatekey.cfg ssh-privatekey-15_7_1_5`

### Note

For more information about version strings, see [Understanding the Image Version String](#) on page 1845.

For more information about ExtremeXOS configuration files, see [Configuration Changes](#) on page 1849.

In addition, Extreme Management Center and Ridgeline products have documented methods for backing up and restoring configuration for Extreme devices.

For Extreme Management Center procedures, visit <https://extranet.extremenetworks.com/> (a valid customer account is required access this site) or access the online help available from the **Help** menu in the Extreme Management Center application.

For Ridgeline procedures, see the Configuration Manager section of the *Ridgeline Reference Guide*.

## Download URL Method

ExtremeXOS 21.1 provides an enhancement to the download CLI command so that it now accepts a URL as the name of the file to download.

### Note

This feature is not available unless you are currently running ExtremeXOS 21.1 or later.

URL protocols can be TFTP, HTTP, or anonymous FTP. The format of a URL is:

- <http://10.10.10.1/filename.xos>
- <tftp://10.10.10.1/filename.xos>
- <ftp://10.10.10.1/filename.xmod>

In addition to accepting a URL that ends in .xos or .xmod, the URL filename can now end in .lst.

A .lst file contains filenames at the same location as the .lst file URL and will be downloaded, and then installed one after the other. The .lst file method can define bundles of downloads for:

- Large image file sizes
- Files ending in '.cfg', '.xsf', '.pol', '.xlic', '.py', '.ssh'
- Any additional .lst files so that you can create lists of lists
- Any bundling that makes it easier to download with a single command

The .lst file allows you to download .xos, .xmods, and other files at the same time. Once downloaded as a list, simply reboot and the files become active. This feature allows for better organization of downloads across switches.

All of the filenames in any .lst must be available at the same URL path provided in the download command.

Any .xos and .xmod files are installed to the inactive partition.

For any other file types, the /usr/local/cfg directory is used.

See the following for an example of .lst files

#### *Example*

An HTTP server on 10.68.9.7 for directory 16.1/xxxx/xxxx/release:

This example shows how the .lst file can contain filenames ending in .lst to get a list of lists (of lists etc...)

**cat big.lst** – big.lst contains other list file names

```
xos.lst
```

```
xmod.lst
```

```
script.lst
```

**cat xos.lst** – xos.lst contains an ExtremeXOS image

```
summitX-16.1.0.18.xos
```

**cat xmod.lst** – xmod.lst contains a number of .xmod filenames

summitX-16.1.0.18-debug.xmod

summitX-16.1.0.18-LegacyCLI.xmod

summitX-16.1.0.18-reachnxt-1.8.1.8.xmod

summitX-16.1.0.18-techSupport.xmod

**cat script.lst** – script.lst contains a number of python scripts the user wants to download to a switch

jsonrpc.py

jsontest.py

otst.py

ping.py

readvr.py

A single download command downloads all of the above files. Example uses big.lst:

```
X460G2-24t-10G4.1 # download url http://10.68.9.7/big.lst
http://10.68.9.7/xos.lst
Downloading http://10.68.9.7/summitX-16.1.0.18.xos

Downloading to
Switch.....
.....

http://10.68.9.7/readvr.py
(pacman debug) X460G2-24t-10G4.2 #
```

## Downloading a New Image

The ExtremeXOS core image (.xos) file contains the executable code that runs on the switch and is preinstalled at the factory. An ExtremeXOS module image (.xmod) supplements the core image. Note that the version number of the core image and the module must match. As new versions of this image are released, you should upgrade both the software and modular packages running on your system.

To find and install image files:

1. Point your browser to <http://esupport.extremenetworks.com> and log in with your eSupport account.

If you do not have an eSupport account, you can request one with the **Request Web Login** link.

### Note

You can also download release notes from the eSupport site. The [ExtremeXOS Release Notes](#) will always have the most current download and install instructions.

2. Find the ExtremeXOS image and all modules you wish to upgrade. Later you will install all files on the image at the same time.
3. Save the files to a TFTP server on the network. You can also store them on a USB 2.0 device.
4. When you have all images downloaded and saved, proceed to [Finding the Inactive Partition](#) on page 1842.

### Image Integrity Checking

This feature adds digital signature verification in ExtremeXOS image and XMOD modules. Image integrity is checked against the digital signature before actual installation.

#### Digital Signature

Prior to ExtremeXOS 16.1, the ExtremeXOS image or XMOD modules downloaded to the switch were only protected by CRC check. This is sufficient for checking corrupted image. However, it cannot prevent malicious attacks. For example, an attacker can de-package the image, replace certain fields, recompute CRC and then repackage the image.

Digital signature is commonly used to demonstrate of the authenticity of a digital message, in this case, the image downloaded to the switch. Only images with digital signature validated on the switch can be installed. Otherwise, the installation should be aborted.

This feature uses the Public Key Infrastructure (PKI) approach. Specifically, with the RSA algorithm, two keys, the private key and the public key are generated using openssl utility. The ExtremeXOS image or XMOD module is digitally signed with the private key. The public key is installed on the switch in the format of a X.509 certificate, which is verified before being used.

When building the image, the signature is computed for the ExtremeXOS image or XMOD module, then included in the final image provided to the customer. On the switch, during downloading process, the signature is verified against the image using the public key previously installed.

In order to deliver the public key to the customer securely, it is also digitally signed and it is distributed in the format of a X.509 certificate. In order to do so, another set of keys are generated to sign this certificate. A self-signed root certificate is also installed on the switch to verify the certificate containing the image signing public key.

All these keys and certificates are generated offline and the private keys should be stored safely.

Transition from an image without signature to one with needs two steps, the first step is to download the ExtremeXOS image and install the public key certificates. At this time, the signature cannot be verified because there is no key to validate the image. But after the first installation, all subsequent downloaded images can be validated using the installed key.

The certificates are only included in the ExtremeXOS image; XMOD modules do not need to include certificates.

Downgrading from an ExtremeXOS version supporting digital signature to one that does not is allowed. No special handling is needed. A warning message is printed on the console to remind the user that the image is not digitally signed. The user does have the choice to either proceed with downgrading or not.

### Hash Verification

Currently, each ExtremeXOS image or XMOD is posted along side with an *MD5 (Message-Digest algorithm 5)* hash checksum, which can be verified using any offline tools. As of ExtremeXOS 16.1, an enhancement now provides a stronger SHA256 hash checksum is generated for you to verify offline.

## Finding the Inactive Partition

A switch can store up to two core images: an active and inactive. When downloading a new image, you must select on which partition to install the new image. You must install the software image to the inactive partition, and must specify that partition while downloading the image to the switch.

To find the inactive partition:

1. From the CLI, enter the command `show switch` (or `show slot detail` on SummitStack).

```
show switch
SysName: XXXXXXXX
SysLocation:
SysContact: support@extremenetworks.com, +1 888 257 3000
System MAC: 00:04:96:51:FE:E2
System Type: XXXXXXXX
```

```

SysHealth check: Enabled (Normal)
Recovery Mode: All
System Watchdog: Enabled

Current Time: Thu Sep 4 00:57:18 2014
Timezone: [Auto DST Disabled] GMT Offset: 0 minutes, name is UTC.
Boot Time: Wed Sep 3 20:07:11 2014
Boot Count: 402
Next Reboot: None scheduled
System UpTime: 4 hours 50 minutes 7 seconds

Current State: OPERATIONAL
Image Selected: primary
Image Booted: primary
Primary ver: 15.7.1.4
Secondary ver: 15.7.1.5

Config Selected: ssh-privatekey.cfg
Config Booted: ssh-privatekey.cfg
 ssh-privatekey.cfg Created by ExtremeXOS version
 15.7.1.5

 219131 bytes saved on Mon Jul 14 23:03:08 2014

```

2. Locate the `Image Booted:` line. If it indicates `primary`, you will know to install the images on the secondary partition. If it indicates `secondary`, you will know to install the images on the primary partition.

For help with versions and image filenames, refer to the following:

- [Understanding the Image Version String](#) on page 1845
- [Image Types and Image Filename Prefixes](#) on page 1846
- [Software Signatures](#) on page 1847

When you know the inactive partition, proceed to [Installing a Core Image](#) on page 1843.

## Installing a Core Image

Once `.xos` and `.xmod` files are stored on a network server (see [Downloading a New Image](#) on page 1841), download the image to the switch using the following procedure:

1. Use a login session on the master node of the SummitStack to verify which virtual router (VR) connects to your server. Use one of the following ping commands to confirm which virtual router reaches your server:

```

ping vr vr-Mgmt host
ping vr vr-Default host

```

At least one of these commands must successfully reach your server for you to download the image. After verifying the virtual router that reaches your server, specify that virtual router when you download the image.

2. Download the new image to the switch using the command:

```
download [url url {vr vrname} | image [active | inactive] [[hostname |
ipaddress] filename {{vr} vrname} {block-size block_size}] {partition}
{install {reboot}}
```

#### Note

If you configure the switch to write core dump (debug) files to the internal memory card and attempt to download a new software image, you might have insufficient space to complete the image download. If this occurs, you will need to move or delete the core dump files from the internal memory. You will be asked during the download process if you want to remove these files. For more information, see [Understanding Core Dump Messages](#) on page 1847.

3. Before the download begins, the switch asks if you want to install the image immediately after the download is finished. Enter `y` to install the image after download.

If you enter `n` to install the image at a later time, the image is still downloaded and saved to the switch, but you must use the `install image` command when ready to install the image.

4. Install .xmod images to the inactive partition using the same command shown above.
5. After installing the .xos and all .xmod images, reboot the switch (see [Reboot Options](#) on page 1844).

For information about installing a new BootROM image on an ExtremeSwitching series switch, see [Upgrading the BootROM](#) on page 1859.

### Installing a Core Image with NMS

Depending on your platform, you can use Extreme Management Center or Ridgeline to download the core image.

You can either load the new image to the NMS server on your network or configure it to automatically poll and download newly released images to the server. Follow the instructions described in the NMS documentation to appropriately configure the server for your network environment.

For more information about installing the NMS client and server, configuring it, and the platforms the NMS supports, refer to the NMS documentation that comes with the product or the documentation available from the Extreme Networks website at [www.extremenetworks.com/documentation/](http://www.extremenetworks.com/documentation/).

## Copying an Image from the Active to Inactive Partition

To copy the image on the active partition to the inactive partition, use the following command:

```
install image inactive {slot slot}
```

#### Note

The ExtremeSwitching X435 series switches do not support copying an image from the active to the inactive partition.

## Reboot Options

### Reboot the Switch

- To reboot the switch immediately, use the following command

```
reboot
```

#### Note

The reboot occurs immediately and any previously schedule reboots are cancelled.

On SummitStack, the `reboot` command reboots the *active* topology and can be run from the master node only.

- To schedule a time to reboot the switch, use the command:

```
reboot {[time mon day year hour min sec] | cancel} {slot slot-number}
{all}
```

The options use the following format:

- **date** — in mm dd yyy format
- **time** — 24-hour clock in hh mm ss format

#### Note

When you configure a timed reboot of the switch, you can use the `show switch` command to see the scheduled time.

- To reboot the entire stack topology, use the command:

```
reboot stack-topology {as-standby}
```

#### Note

This command can be run on any node and can be used to eliminate the dual master condition manually.

- To cancel a previously scheduled reboot, use the **cancel** option of the `reboot` command.

### Reboot a Node in a SummitStack

To reboot a single node in the SummitStack, use the command:

```
reboot {[time mon day year hour min sec] | cancel} {slot slot-number}
{all}
```

The `reboot slot` command works only on the active master node for other slots, and on an active non-master node for its own slot.

The `reboot stack-topology {as-standby}` command can also be used to reboot a single node by specifying the MAC address of the node.

The `reboot node-address` command reboots the specified node from any node.

## Understanding the Image Version String

The image version string contains build information for each version of ExtremeXOS.

You can use the `show version` and `show switch` commands to display the ExtremeXOS version running on your switch. The output will be structured as one of the following:

- ExtremeXOS Version <major>.<minor>.<sustaining>.<build>

In the case of a patch release, the version structure is ExtremeXOS Version <major>.<minor>.<sustaining>.<build>-patchX-Y where X is the patch type and Y is the build number for the patch.

- <major>.<minor>.<sustaining>.<build>patchX-Y

Table 172 describes the image version fields.

**Table 172: Image Version Fields**

| Field      | Description                                         |
|------------|-----------------------------------------------------|
| major      | Specifies the ExtremeXOS major version number.      |
| minor      | Specifies the ExtremeXOS minor version number.      |
| sustaining | Specifies the ExtremeXOS sustaining version number. |
| build      | Specifies the ExtremeXOS build number.              |
| patch      | Identifies a specific patch release.                |

The `show version` command also displays information about the firmware (BootROM) images running on the switch. For more information, see [Displaying the BootROM and Firmware Versions](#) on page 1861.

## Image Types and Image Filename Prefixes

The software image file can be an .xos file, which contains an ExtremeXOS core image, or an .xmod file, which contains an ExtremeXOS modular software package.

### *Filename Prefixes*

You can identify the appropriate image or module for your platform based on the filename prefix of the image.

**Table 173: ExtremeXOS Image Types (Prefixes)**

| Switches                                                   | Image File Type (Prefix)                                                                                                   |
|------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| ExtremeSwitching X465, X690, X695, X590, and X870          | onie-<br>Example: onie-22.2.1.2.xos<br><br><b>Note:</b> These image files use the Open Network Install Environment (ONIE). |
| ExtremeSwitching X440-G2, X450-G2, X460-G2, X670-G2, X620, | summitX-<br>Example: summitX-22.2.1.2.xos                                                                                  |

**Table 173: ExtremeXOS Image Types (Prefixes) (continued)**

| Switches              | Image File Type (Prefix)                                     |
|-----------------------|--------------------------------------------------------------|
| ExtremeSwitching X435 | summitlite_arm-<br>Example:<br>summitlite_arm-30.5.0.102.xos |
| ExtremeSwitching 5520 | summit_arm<br>Example: summit_arm-31.1.0.3.xos               |

For additional installation requirements see the sections, [Installing a Core Image](#) on page 1843 and [Installing a Modular Software Package](#) on page 1847.

## Software Signatures

Each ExtremeXOS image contains a unique signature.

The BootROM checks for signature compatibility and denies an incompatible software upgrade. In addition, the software checks both the installed BootROM and software and also denies an incompatible upgrade.

## Understanding Core Dump Messages

If you configure the switch to write core dump (debug) files to internal memory (`/usr/local/tmp`) and attempt to download a new software image, you might have insufficient space to complete the image download.

If this occurs, move or delete the core dump files from the internal memory. For example, if the switch supports a USB 2.0 storage device and space is available, transfer the files to the storage device. On switches without removable storage devices, transfer the files from internal memory to a TFTP server. This frees up space on the internal memory card while keeping the core dump files.

The switch displays a message similar to the following and prompts you to take action:

```
Core dumps are present in internal-memory and must be removed before this download can
continue.
(Please refer to documentation for the "configure debug core-dumps" command for
additional information)
Do you want to continue with download and remove existing core dumps? (y/n)
```

Type `y` to remove the core dump files and download the new software image. Type `n` to cancel this action and transfer the files before downloading the image.

For information about configuring and sending core dump information, see the `configure debug core-dumps [ off | directory_path ]` and `save debug tracefiles directory_path` commands.

## Installing a Modular Software Package

In addition to the functionality available in the ExtremeXOS core image, you can add functionality to your switch by installing modular software packages or feature packs. A complete listing of these

feature packs can be found with their availability requirements in the [ExtremeXOS 31.2 Feature License Requirements](#) document.

Modular software packages are contained in files named with the file extension `.xmod`, while the core images use the file extension `.xos`.

Modular software packages are built at the same time as core images and are designed to work in concert with the core image, so the `<major>.<minor>.<patch>` field of a modular software package must match the `<major>.<minor>.<patch>` field of the core image that it will be running with. For example, the modular software package for tech support named:

```
summitX-21.1.1.4-techSupport.xmod
```

Can run only with the core image named:

```
summitX-21.1.1.4.xos
```

You can install a modular software package on the active or inactive partition. You would install on the active partition if you want to add the package functionality to the currently running core image without having to reboot the switch. You would install on the inactive partition if you want the functionality available after a switch reboot.

To install the package on the inactive partition, you use the same process that you use to install a new core image. Follow the process described in [Installing a Core Image](#) on page 1843.

Activate the installed modular software package either by rebooting the switch or by issuing the following command: `run update`

You can uninstall packages by issuing the following command:

```
uninstall image fname partition {msm slotid} {reboot}
```

#### Note

Do not terminate a process that was installed since the last reboot unless you have saved your configuration. If you have installed a software module and you terminate the newly installed process without saving your configuration, your module may not be loaded when you attempt to restart the process with the `start process` command.

## Upgrading a Modular Software Package

When Extreme Networks introduces a new core software image, a new feature pack or modular software package is also available. If you have a software module installed and upgrade to a new core image, you need to upgrade to the corresponding feature pack at the same time (see [ExtremeXOS Upgrade Process](#) on page 1835).

If you wish to upgrade your existing module software package *without* upgrading your ExtremeXOS image, two methods are available. Regardless of which method you choose, you must terminate and restart the processes associated with the software module.

#### 1. Method One

- a. Terminate the processes associated with the software module using one of the following commands:

```
terminate process name [forceful | graceful] (modular switches)
```

```
terminate process name [forceful | graceful] {slot slot} (SummitStack)
```

- b. Download the software module from your TFTP server, compact flash card, or USB 2.0 storage device using the following command:

```
download [url url {vr vrname} | image [active | inactive] [[hostname | ipaddress] filename {vr vrname} {block-size block_size}] {partition} {install {reboot}}
```

- c. Activate the installed modular package, if installed on the active partition, using the following command: `run update`

- d. Restart the processes associated with the software module using one of the following commands:

```
start process name {msm slot} (modular switches)
```

```
start process name {slot slot} (SummitStack)
```

#### 2. Method Two

- a. Download the software module from your TFTP server, compact flash card, or USB 2.0 storage device using the following command:

```
download [url url {vr vrname} | image [active | inactive] [[hostname | ipaddress] filename {vr vrname} {block-size block_size}] {partition} {install {reboot}}
```

- b. Activate the installed modular package, if installed on the active partition, using the following command: `run update`

- c. Terminate and restart the processes associated with the software module using one of the following commands:

```
restart process [class cname | name {msm slot}] (modular switches)
```

```
restart process [class cname | name {slot slot}] (SummitStack)
```

## Configuration Changes

---

### Image Configuration Overview

The configuration is the customized set of parameters that you have selected to run on the switch. As you make configuration changes, the new settings are stored in run-time memory. Settings that are stored in run-time memory are not retained by the switch when the switch is rebooted. To retain the settings and have them loaded when you reboot the switch, you must save the configuration to nonvolatile storage.

The switch can store multiple user-defined configuration files, each with its own filename. By default, the switch has two prenamed configurations: a primary and a secondary configuration. When you save configuration changes, you can select to which configuration you want the changes saved or you can

save the changes to a new configuration file. If you do not specify a filename, the changes are saved to the configuration file currently in use. Or if you have never saved any configurations, you are asked to save your changes to the primary configuration.

**Note**

Configuration files have a .cfg file extension. When you enter the name of the file in the CLI, the system automatically adds the .cfg file extension.

If you have made a mistake or you must revert to the configuration as it was before you started making changes, you can tell the switch to use the backup configuration on the next reboot.

Each filename must be unique and can be up to 32 characters long. Filenames are also case sensitive. For information about filename restrictions, see the specific command in the [ExtremeXOS 31.2 Command Reference Guide](#).

- First, save the configuration using the command:

```
save configuration {primary | secondary | existing-config | new-config}
```

Where the options are:

- **primary** — Specifies the primary saved configuration
  - **secondary** — Specifies the secondary saved configuration
  - **existing-config** — Specifies an existing user-defined configuration (displays a list of available user-defined configuration files)
  - **new-config**— Specifies a new user-defined configuration
- You are prompted to save the changes. Enter *y* to save the changes or enter *n* to cancel the process.
  - Next, use the configuration command:

```
use configuration file-name
```

Where the options are:

- **primary** — Specifies the primary saved configuration
- **secondary** — Specifies the secondary saved configuration
- **file\_name** — Specifies an existing user-defined configuration (displays a list of available user-defined configuration files)

The configuration takes effect on the next reboot.

**Note**

When a switch boots up after executing this command, examine the log to determine if a subsequent save and a reboot of the switch or slot is necessary for the configuration to be correctly applied.

**Note**

If the switch is rebooted while in the middle of saving a configuration, the switch boots to factory default settings if the previously saved configuration file is overwritten. The configuration that is not in the process of being saved is unaffected.

## Automatic Saving of Configuration Files

The currently running switch configuration can be configured to be saved at automatic intervals. This feature is turned off by default, but can be enabled and configured to save at specified time intervals and to a designated file.

To configure automatic configuration saving, use the command `save configuration automatic {every minutes {primary | secondary | existing-config | new-config} | never}` .

### Note

Automatic save of the running configuration on system reboot, irrespective of the interval between saves is handled for only immediate reboot, not for scheduled reboots or rebooting through other techniques such as [\*SNMP \(Simple Network Management Protocol\)\*](#).

## View a Configuration

- To view the current configuration, enter the command: on the switch.

```
show configuration {module-name} {detail}
```

You can also view just that portion of the configuration that applies to a particular module (for example, [\*SNMP\*](#)) by using the `module-name` parameter.

Beginning with ExtremeXOS 12.1, when you specify show configuration only, the switch displays configuration information for each of the switch modules excluding the default data.

You can send output from the `show configuration {module-name} {detail}` command to the [Extreme Networks Technical Support](#) for problem-solving purposes. The output maintains the command line interface (CLI) format of the current configuration on the switch.

## Comparing Configurations

You can view the differences between switch configuration files or a configuration file with the running configuration using the command:

```
show configuration difference { from-config-file {to-config-file} }
{module-name} {detail} {context lines}
```

When using the `save configuration automatic {every minutes {primary | secondary | existing-config | new-config} | never}` command this can be especially helpful for comparing what changed between the running (or "startup") configuration and the most recently autosaved configuration.

## Restore Factory Defaults

The following two procedures restore the switch to factory defaults and reboot the switch. Use the first procedure when you can log in to the switch and issue a CLI command and the second when you cannot.

- When you can log in to the switch, use the following command:

```
unconfigure switch
```

This command resets most of the configuration, with the exception of user-configured user accounts and passwords, the date, and the time. On SummitStack, the command also preserves stacking-specific parameters so the stack can be formed after reboot.

- Unset the currently selected configuration image, reset all switch parameters, and reboot the switch.

```
unconfigure switch all
```

- If you cannot log in because the switch is in a continuous booting loop, use the following procedure:
  - a. Reboot the switch while pressing the space bar. This puts the switch in Bootstrap mode.
  - b. From the Bootstrap prompt, type `boot` and then press **[Enter]** and press the spacebar. This puts the switch in BootROM mode.
  - c. From the BootROM prompt, type `config none`.

The following appears:

```
Configuration selected: none
```

- d. From the BootROM prompt, enter `reboot`. The switch reboots and restores the factory defaults.

## Uploading ASCII-Formatted Configuration Files

You can upload your current configuration in ASCII format to a TFTP server.

The uploaded ASCII file retains the CLI format and allows you do the following:

- View and modify the configuration using a text editor, and later download a copy of the file to the same switch or to one or more different switches.
- Send a copy of the configuration file to [Extreme Networks Technical Support](#) for problem-solving purposes.

### Summary of Tasks

The following summary describes only the CLI involved to transfer the configuration and load it on the switch; it is assumed that you know how to modify the configuration file with a text editor. As previously described, to use these commands, use the .xsf file extension, as these steps are not applicable to configurations that use the .cfg file extension.

To work with an ASCII-formatted configuration file, complete the following tasks:

1. Upload the configuration to a network TFTP server using the following command:

```
upload configuration [hostname | ipaddress] filename {vr vr-name}
{block-size block_size}
```

After the configuration file is on the TFTP server, use a text editor to enter the desired changes, and rename the file if necessary so it has the .xsf extension.

2. Download the configuration from the TFTP server to the switch using one of the `tftp` and `tftp get` commands.
3. Verify the configuration file is on the switch using the `ls` command
4. Load and restore the new configuration file on the switch using the following command:

```
load script filename {arg1} {arg2} ... {arg9}
```

5. Save the configuration to the configuration database so the switch can reapply the configuration after switch reboot using the following command:

```
save configuration {primary | secondary | existing-config | new-config}
```

When you save the configuration file, the switch automatically adds the .cfg file extension to the filename. This saves the ASCII configuration as an XML-based configuration file.

#### Note

Configuration files are forward compatible only and not backward compatible. That is, configuration files created in a newer release, such as ExtremeXOS 15.5, might contain commands that do not work properly in an older release, such as ExtremeXOS 15.3.

### Upload the ASCII Configuration File To a TFTP Server

To upload the current switch configuration as an ASCII-based file to the TFTP server, use the `upload configuration` command and save the configuration with the .xsf file extension.

For example, to transfer the current switch configuration as an ASCII-based file named `meg_upload_config1.xsf` to the TFTP server with an IP address of 10.10.10.10, do the following:

```
upload configuration 10.10.10.10 meg_upload_config1.xsf
```

If you successfully upload the configuration to the TFTP server, the switch displays a message similar to the following:

```
Uploading meg_upload_config1.xsf to 10.10.10.10 ... done!
```

### Download the ASCII Configuration File to the Switch

To download the configuration from the TFTP server to the switch, use the `tftp` or `tftp get` command.

For example, to retrieve the configuration file named `meg-upload_config1.xsf` from a TFTP server with an IP address of 10.10.10.10, you can use one of the following commands:

```
tftp 10.10.10.10 -g -r meg_upload_config1.xsf
tftp get 10.10.10.10 meg_upload_config1.xsf
```

If you successfully download the configuration to the switch, the switch displays a message similar to the following:

```
Downloading meg_upload_config1.xsf to switch... done!
```

### Verify that the ASCII Configuration File is on the Switch

To confirm that the ASCII configuration file is on the switch, use the `ls` command. The file with an .xsf extension is the ASCII configuration.

The following sample output contains an ASCII configuration file:

```
-rw-r--r-- 1 root 0 98362 Nov 2 13:53 Nov022005.cfg
-rw-r--r-- 1 root 0 117136 Dec 12 12:56 ridgeline.cfg
-rw-r--r-- 1 root 0 68 Oct 26 11:17 mcastgroup.pol
-rw-r--r-- 1 root 0 21203 Dec 13 15:40 meg_upload_config1.xsf
-rw-r--r-- 1 root 0 119521 Dec 6 14:35 primary.cfg
-rw-r--r-- 1 root 0 96931 Nov 11 11:01 primary_11_11_05.cfg
-rw-r--r-- 1 root 0 92692 Jul 19 16:42 secondary.cfg
```

### Load the ASCII Configuration File

After downloading the configuration file, you must load the new configuration on the switch.

To load and restore the ASCII configuration file, use the command:

```
load script filename {arg1} {arg2} ... {arg9}
```

After issuing this command, the ASCII configuration quickly scrolls across the screen.

The following is an example of the type of information displayed when loading the ASCII configuration file:

```
script.meg_upload_config1.xsf.389 # enable snmp access
script.meg_upload_config1.xsf.390 # enable snmp traps
script.meg_upload_config1.xsf.391 # configure mstp region purple
script.meg_upload_config1.xsf.392 # configure mstp revision 3
script.meg_upload_config1.xsf.393 # configure mstp format 0
script.meg_upload_config1.xsf.394 # create stpd s0
```

Instead of entering each command individually, the script runs and loads the CLI on the switch.

### Save the Configuration

After you load the configuration, save it to the configuration database for use by the switch. This allows the switch to reapply the configuration after a switch reboot.

- To save the configuration, use the command;

```
save configuration {primary | secondary | existing-config | new-
config}
```

When you save the configuration file, the switch automatically adds the .cfg file extension to the filename. This saves the ASCII configuration as an XML-based configuration file.

You can use any name for the configuration.

For example, after loading the file `meg_upload_config1.xsf`, you need to save it to the switch.

To save the configuration as `configuration1.cfg`, enter the command:

```
save configuration configuration1
```

### Using Autoconfigure and Autoexecute Files

Two features allow you automatically execute scripts that can manage the switch configuration.

#### **Autoconfigure:**

Configuration commands placed in the `default.xsf` file are executed by the switch as it comes up and is unable to find its usual configuration file or if the switch is unconfigured or if the configuration file cannot be determined due to a corrupt NVRAM.

This returns the switch to some basic configuration. When `default.xsf` is executed, the `show switch` command shows `default.xsf` as the booted configuration file.

The `default.xsf` file can have any CLI commands as long as they are all executed within 500 seconds.

The script is aborted when the commands are not executed within that time. When the file is loaded, the results can be seen by executing the `show script output default` command.

**Autoexecute:**

Configuration commands placed in the autoexec.xsf file are executed after a switch loads its configuration.

The file is not executed when a default.xsf file has been executed. Use the file to execute commands after a switch is up and running and also to revert changes made to the configuration by UPM scripts that run persistent commands. The commands must be executed within 500 seconds or the script execution is aborted.

When an autoexec.xsf file is executed, the results can be seen by executing the `show script output autoexec` command.

## Using TFTP to Upload the Configuration

You can upload the current configuration to a TFTP server on your network. Using TFTP, the uploaded configuration file retains your system configuration and is saved in XML format. This allows you to send a copy of the configuration file to [Extreme Networks Technical Support](#) for problem-solving purposes.

- To view your current switch configuration, use the `show configuration {module-name} {detail}` command available on your switch. Do not use a text editor to view or modify your XML-based switch configuration files.

To view your current switch configuration in ASCII-format, see [Uploading ASCII-Formatted Configuration Files](#) on page 1852 for more information about uploading and downloading ASCII-formatted configuration files.

For more information about TFTP, see [Using the Trivial File Transfer Protocol](#) on page 83.

- To upload the configuration from the switch to a TFTP server, you can use either the `tftp` or the `tftp put` command:

```
tftp [ip-address | host-name] { -v vr_name } { -b block_size } [-g
| -p] [-l local-file { -r remote-file } | -r remote-file { -l local-
file }]
```

Where the options are:

- **host-name** — Specifies the host name of the TFTP server
- **ip-address** — Specifies the IP address of the TFTP server
- **-p** — Puts the specified file from the local host and copies it to the TFTP server
- **-l local-file** — Specifies the name of the configuration file that you want to save to the TFTP server
- **-r remote-file** — Specifies the name of the configuration file on the TFTP server

```
tftp put [ip-address | host-name] {vr vr_name} {block-size
block_size}local-file { remote-file}
```

Where the options are:

- **put** —P uts the specified file from the local host and copies it to the TFTP server
- **host-name** — Specifies the host name of the TFTP server
- **ip-address** — Specifies the IP address of the TFTP server

- *local-file* — Specifies the name of the configuration file that you want to save to the TFTP server
- *remote-file* — Specifies the name of the configuration file on the TFTP server

If you upload a configuration file and see the following message:

```
Error: No such file or directory
```

Check to make sure that you entered the filename correctly, including the .cfg extension, and that you entered the correct host name or IP address for the TFTP server.

If your upload is successful, the switch displays a message similar to the following:

```
Uploading megtest1.cfg to TFTPHost ... done!
```

You can also upload the current configuration in ASCII format from the switch to a TFTP server on your network. For more information, see [Uploading ASCII-Formatted Configuration Files](#) on page 1852.

## Using TFTP to Download the Configuration

You can download previously saved XML formatted XOS configuration files from a TFTP host to the switch to modify the switch configuration. Do not use a text editor to view or modify your switch configuration files; modify your switch configurations directly in the CLI.

To view your current switch configuration in ASCII-format, see [Uploading ASCII-Formatted Configuration Files](#) on page 1852 for more information about uploading and downloading ASCII-formatted configuration files.

For more information about TFTP, see [Using the Trivial File Transfer Protocol](#) on page 83.

### Note

By default, if you transfer a file with a name that already exists on the system, the switch prompts you to overwrite the existing file. For more information, see the `tftp get` command in the [ExtremeXOS 31.2 Command Reference Guide](#).

- To download the configuration from a TFTP host to the switch, you can use either the `tftp` or the `tftp get` command:

```
tftp [ip-address | host-name] { -v vr_name } { -b block_size } [-g
| -p] [-l local-file { -r remote-file } | -r remote-file { -l local-
file }]
```

Where the options are:

- **host-name** — Specifies the host name of the TFTP server
- **ip-address** — Specifies the IP address of the TFTP server
- **-p** — Puts the specified file from the local host and copies it to the TFTP server
- **-l** *local-file* — Specifies the name of the configuration file that you want to save to the TFTP server
- **-r** *remote-file* — Specifies the name of the configuration file on the TFTP server

```
tftp get [ip-address | host-name] { vr vr_name } { block-size
block_size } remote-file local-file} {force-overwrite}
```

Where the options are:

- **get** — Gets the specified file from the TFTP server and copies it to the local host
- *host-name* — Is the host name of the TFTP server
- *ip-address* — Is the IP address of the TFTP server
- *remote\_file* — Specifies the name of the configuration file that you want to retrieve from the TFTP server
- *local-file* — Specifies the name of the configuration file on the switch
- **force-overwrite** — Specifies the switch to automatically overwrite an existing file

If you download a configuration file and see the following message:

```
Error: Transfer timed out
```

Make sure that you entered the filename correctly, including the .cfg extension, and that you entered the correct host name or IP address for the TFTP server.

If your download is successful, the switch displays a message similar to the following:

```
Downloading megtest2.cfg to switch... done!
```

Configurations are downloaded and saved into the switch nonvolatile memory. The configuration is applied after you reboot the switch.

If the configuration currently running in the switch does not match the configuration that the switch used when it originally booted, an asterisk (\*) appears before the command line prompt when using the CLI.

You can also download the current configuration in ASCII format from a TFTP server on your network to the switch. For more information, see [Uploading ASCII-Formatted Configuration Files](#) on page 1852.

## Synchronizing Nodes

---

Before synchronizing nodes on a SummitStack, confirm that all nodes are active nodes and running ExtremeXOS 12.0 or later, so as to support the `synchronize` command.

On a SummitStack with redundancy, you can take the primary node configurations and images and replicate them on the backup node using the `save configuration` command.

### Caution

During a synchronization on a SummitStack, the active stack briefly alternates between a ring and daisy-chain topology. When the primary node finishes replicating its configurations and images to the backup node, the full the stack ring is restored.

In addition to replicating the configuration settings and images, this command also replicates which configuration or image the node should use on subsequent reboots. This command does not replicate the run-time configuration. You must use the `save configuration {primary | secondary | existing-config | new-config}` command to store the run-time configuration first.

On a SummitStack, you can synchronize an active node in the stack with the master node using the following command:

```
synchronize {slot slotid}
```

**Note**

You cannot synchronize a master switch running a version earlier than ExtremeXOS 22.2 to a target node running ExtremeXOS 22.2 or later. The command fails and the following error message appears: `Error: the target slot's partitions are not compatible with the Master's for synchronize.`

## Automatic Synchronization of Configuration Files

On a SummitStack where redundancy is in use, ExtremeXOS automatically synchronizes all of the configuration files from the primary node to the backup node if the switch detects that the backup node's configuration file contents are different from the primary node.

You cannot configure this behavior.

The switch deletes the old configuration files on the backup node only upon a successful file synchronization. If an error occurs, the switch does not delete the old configuration files on the backup node. For example, if you install a backup node that contains different configuration files from the primary node, the old configuration files are deleted after a successful bootup of the backup node.

To see a complete listing of the configuration files on your system, use the `ls` command.

For more detailed information, see [Replicating Data Between Nodes](#) on page 86.

## Accessing the Bootloader

The Bootloader of the switch initializes certain important switch variables during the boot process. In the event the switch does not boot properly, you can access some boot option functions through the Bootloader.

Aside from directing which installed ExtremeXOS image to install during bootup, interaction with the Bootloader is required only under special circumstances and should be done only under the direction of Extreme Networks Customer Support. The necessity of using these functions implies a nonstandard problem that requires the assistance of [Extreme Networks Customer Support](#).

To access the Bootloader to select an installed ExtremeXOS image to load:

1. Attach a serial cable to the console port of the switch.
2. Attach the other end of the serial cable to a properly configured terminal or terminal emulator, power cycle the switch, and then press spacebar on the terminal during the bootup process:
  - For all switches, except the ExtremeSwitching X465, X690, X695, X590, and X870 series switches, the `BootRom>` prompt appears.

To see a list of available commands or additional information about a specific command, type `h` or `help`.

- For the ExtremeSwitching X435, X465, X690, X695, X590, and X870 series switches, the **GNU GRUB** menu appears.

In the GNU GRUB menu a list of installed images that you can load appears.

3. To load a particular installed image:
  - For all switches, except the ExtremeSwitching X435, X465, X690, X695, X590, and X870 series switches, type `boot [1 | 2]`, where **1** loads the image installed on the primary partition, and **2** loads the secondary partition image.
  - For the ExtremeSwitching X435, X465, X690, X695, X590, and X870 series switches, use the arrow keys to select the desired image, and then press **[Enter]**.

## Upgrading the BootROM

The ExtremeSwitching series switches have a two-stage bootROM. The first stage, called bootstrap, does basic initialization of the switch processor and loads one of two second-stage bootloaders (called primary and secondary).

If the switch does not boot properly, both the bootstrap and the bootloader allow you to access the boot options using the CLI.

If necessary, the bootloader can be updated after the switch has booted, using TFTP. You can upgrade the bootROM from a TFTP server on the network after the switch has booted and only when asked to do so by an Extreme Networks technical representative. For information about loading an image to a TFTP server and verifying which *VR* connects to your TFTP server, see [Installing a Core Image](#) on page 1843.

### Note

bootROM update is not supported on ExtremeSwitching X435 series switches.

- To upgrade the bootROM, use the following command: `download bootrom [[ipaddress | hostname] filename {{vr} vrname} {block-size block_size}] {slot slotid}`  
 On a SummitStack, the bootROM can be centrally upgraded.  
 Use the command above on the primary (Master) stack node to download a bootROM to all stacking nodes.
- To download to a single stacking node, you need to specify the slot parameter:  
`download bootrom [[ipaddress | hostname] filename {{vr} vrname} {block-size block_size}] {slot slotid}`

### Note

User-created VRs are supported only on the platforms listed for this feature in the [ExtremeXOS 31.2 Feature License Requirements](#) document.

- For ExtremeSwitching 5520 series switches only, you can upgrade the bootROM with the version packaged in the ExtremeXOS `.xos` image file using the `from-exos` option: This command uses the bootROM image from the booted ExtremeXOS image. After reboot, the new bootROM image is used.  
`install bootrom {from-exos} [fname | local-file] {reboot} {slot slotid}`

When you download and install new version of ExtremeXOS image, the system automatically compares the currently installed bootROM image against the bootROM image contained in the new

ExtremeXOS image. If the installed version is older version, the system automatically upgrades bootROM to the version contained in new ExtremeXOS image.

To view which version bootROM is on each partition, use the `show version {detail | process name | images {partition partition}}` command.

If the bootROM image is invalid, this command shows 0.0.0.0. If the primary bootROM is invalid, the bootROM upgrade will be canceled. To fix this, re-install the bootROM on the primary partition.

## Upgrading the Firmware (ExtremeSwitching X440-G2, X465, X620, and 5520 Series Switches Only)

Firmware images are bundled with ExtremeXOS software images. The bundled firmware images include system FPGA and PLD images. When you download and install a new version of ExtremeXOS, ExtremeXOS automatically compares the existing firmware image against the firmware images bundled with the ExtremeXOS image, and prompts to install the firmware if there is a new version. If the firmware install is skipped during an ExtremeXOS install, firmware can be installed later by following the procedure below using the `install firmware` command.

After a firmware image upgrade, messages are sent to the log.

To view the current firmware version, use the `show version detail` command:

```
show version detail
Switch : 800906-00-02 1907F-10042 Rev 02 IMG: 30.2.0.34
 FPGA: 1.1.34 CPLD: 1.1.13

Image : ExtremeXOS version 30.2.0.34 by release-manager
 on Wed Mar 27 20:36:16 EDT 2019
Diagnostics : 1.1.6
Certified Version : EXOS Linux 4.14.107, FIPS fips-ecp-2.0.16

Build Tools Version : exos-x32-sdk-2.5.1.1.3
```

1. To install the firmware bundled with the ExtremeXOS image, use the `install firmware {force} {slot slot-number}` command.

If the bundled firmware image is newer than the existing firmware image, the switch prompts you to confirm the upgrade.

2. At the prompt:

- Type `y` to upgrade the firmware.
- Type `n` to cancel the firmware upgrade for the specified hardware, and continue scanning for other hardware that needs to be upgraded.

3. Press **Enter** to cancel the upgrade.

During the firmware upgrade, the switch also prompts you to save your configuration changes to the current, active configuration.

4. To save your configuration changes to the current, active configuration, type `y` or to discard your changes, type `n`.

The new firmware overwrites the older version.

You must reboot the switch to load the newly installed firmware. However, you do not need to do this immediately after a firmware upgrade. Use the `reboot` command to reboot the switch and activate the

new firmware. During the firmware upgrade, do not turn off or disrupt the power to the switch. During the firmware upgrade, do not cycle down or disrupt the power to the switch. If a power interruption occurs, the installed firmware may be corrupted. In this case, the switch uses a backup version, and you can run the upgrade again to install the latest version.

## Displaying the BootROM and Firmware Versions

To display the bootROM (firmware) version on the switch and on all of the modules and PSU controllers, use the `show version` command.

The following is sample output for a standalone ExtremeSwitching X440-G2 series switch:

```
X440G2-48p-10G4.1 # show version detail
Switch : 800618-00-02 1530G-00048 Rev 2.0 BootROM: 1.0.1.7 IMG: 22.2.1.2
 FPGA: 1.1.44.0 PLD1: 1.0.10.0
PSU-1 : Internal Power Supply
PSU-2 :

Image : ExtremeXOS version 22.2.1.2 by release-manager
 on Wed Feb 15 17:52:45 EST 2017
BootROM : 1.0.1.7
Diagnostics : 5.10
Certified Version : EXOS Linux 3.18.24, FIPS fips-ecp-2.0.12

Switch PCB Info: EVTFC48.2A1G
Subsystem PCB Info: EVTFC48.2A1G
```

The following is sample output for a stack of ExtremeSwitching X440-G2 and X620 switches series switches:

```
Slot-1 Stack.3 # show version detail
Slot-1 : 800617-00-00 1443G-00572 Rev 0.0 BootROM: 1.0.1.9 IMG: 22.2.1.2
 FPGA: 1.1.42.0 PLD1: 1.0.10.0
Slot-2 : 800630-00-00 1510G-00210 Rev 0.0 BootROM: 1.0.1.9 IMG: 22.2.1.2

## Troubleshooting Checklists

---

This section provides simple troubleshooting checklists for Layer 1, Layer 2, and Layer 3. The commands and recommendations described are applicable to both IPv4 and IPv6 environments unless otherwise specified. If more detailed information about a topic is available, you are referred to the applicable section in this appendix.

### Layer 1

When troubleshooting Layer 1 issues, verify:

- The installation of cables and connectors.
- The behavior of LED status lights. For additional information about LEDs, see [LEDs](#).
- That the port is enabled, the link status is active, and speed and duplex parameters match the port settings at the other end of the cable.
  - a. To display the configuration of one or more ports, use the [show ports configuration](#) command.

- That the packets are being received and transmitted.
  - a. To display the number of packets being received and transmitted, use the `show ports {port_list | stack-ports stacking-port-list} statistics {no-refresh}` command.
- That there are no packet errors.
  - a. To display packet error statistics, use the following commands:

```
show ports {port_list | stack-ports stacking-port-list} rxerrors {no-refresh}—Displays receive error statistics
```

```
show ports {port_list | stack-ports stacking-port-list} txerrors {no-refresh}—Displays transmit error statistics
```

```
show ports {mgmt | port_list |tag tag} collisions {no-refresh}—Displays collision statistics
```

## Layer 2

When troubleshooting Layer 2 issues, verify:

- That the MAC addresses are learned, in the correct VLAN (Virtual LAN), and are not blackhole entries.
  - a. To display FDB (forwarding database) entries, use the `show fdb` command.
- Your VLAN configuration, including the VLAN tag, ports in the VLAN, and whether or not the ports are tagged.
  - a. To display detailed information for each VLAN configured on the switch, use the `show vlan detail` command.

For additional VLAN troubleshooting tips, see [VLANs](#).
- Your STP (Spanning Tree Protocol) configuration, including the STP domain (STPD (Spanning Tree Domain)) number, VLAN assignment, and port state.
  - a. To display STP information, use the following commands:

```
show stpd detail—Displays the STP settings on the switch
```

```
show stpd ports—Displays the STP state of a port
```

```
show vlan stpd—Displays the STP configuration of the ports assigned to a specific VLAN
```

For additional STP troubleshooting tips, see [STP](#).

## Layer 3

When troubleshooting Layer 3 issues, verify:

- The IP address assigned to each VLAN router interface.
  - a. To display summary information for all of the VLANs configured on the device, use the `show vlan` command.
- That IP forwarding is enabled, the routing protocol is globally enabled, and the routing protocol is enabled for a VLAN.
  - a. To display the configuration information for a specific VLAN, use one of the following commands:  
`show ipconfig {ipv4} {vlan vlan_name}`—IPv4 environment  
`show ipconfig ipv6 {vlan vlan_name | tunnel tunnelname}`—IPv6 environment
- Which destination networks are in the routing table and the source of the routing entry.
  - a. To display the contents of the routing table or the route origin priority, use one of the following commands:  
`show iproute`—IPv4 environment  
`show iproute ipv6`—IPv6 environment
  - b. To display the contents of the routing table only for routes of a specified origin, use one of the following commands:  
`show iproute origin`—IPv4 environment  
`show iproute ipv6 origin`—IPv6 environment
- That the IP Address Resolution Protocol (ARP) table has the correct entries.
  -  **Note**  
The ARP table is applicable only in IPv4 environments.
  - a. To display the contents of the IP ARP table, use the `show iparp` command.
- That the Neighbor Discovery (ND) cache has the correct entries.
  -  **Note**  
The ND cache is applicable only in IPv6 environments.
  - a. To display the contents of the ND cache, use the `show neighbor-discovery cache ipv6` command.
- IP routing protocol statistics for the CPU of the switch.
  - a. Only statistics of the packets handled by the CPU appear. To display IP statistics for the CPU of the switch per VLAN, use one of the following commands:  
`show ipstats`—IPv4 environment  
`show ipstats ipv6`—IPv6 environment

- Your *OSPF (Open Shortest Path First)* configuration, including the OSPF area ID, router state, link cost, OSPF timers, interface IP address, and neighbor list.

**Note**

OSPF is applicable only in IPv4 environments.

- a. To display OSPF information, use the following commands:

`show ospf`—Displays global OSPF information for the switch

`show ospf area`—Displays information related to OSPF areas

`show ospf area`—Displays detailed information related to OSPF areas

`show ospf interfaces detail`—Displays detailed information about OSPF interfaces

- Your *OSPFv3 (Open Shortest Path First version 3)* configuration, including the OSPFv3 area ID, router state, link cost, OSPFv3 timers, interface IP address, and neighbor list.

OSPFv3 is applicable only in IPv6 environments.

- a. To display OSPFv3 information, use the following commands:

`show ospfv3`—Displays global OSPFv3 information for the switch

`show ospfv3 area`—Displays information related to OSPFv3 areas

`show ospfv3 interfaces`—Displays detailed information about OSPFv3 interfaces

- Your *RIP (Routing Information Protocol)* configuration, including RIP poison reverse, split horizon, triggered updates, transmit version, and receive version.

**Note**

RIP is applicable only in IPv4 environments.

- a. To display detailed information about how you have RIP configured on the switch, use the `show rip` command.

- RIP activity and statistics for all VLANs on the switch.

**Note**

RIP is applicable only in IPv4 environments.

- a. To display RIP-specific statistics for all VLANs, use the `show rip interface detail` command.

- Your *RIPng (Routing Information Protocol Next Generation)* configuration, including RIPng poison reverse, split horizon, triggered updates, transmit version, and receive version.

**Note**

RIPng is applicable only in IPv6 environments.

- a. To display detailed information about how you have RIPng configured on the switch, use the `show ripng` command.

- RIPng activity and statistics for all VLANs on the switch.

**Note**

RIPng is applicable only in IPv6 environments.

- a. To display RIPng-specific statistics for all VLANs, use the `show ripng interface` command.
- End-to-end connectivity.
  - a. To test for connectivity to a specific host, use the `ping` command.
- The routed path between the switch and a destination end station.
  - a. To verify and trace the routed path, use the `traceroute` command.

## LEDs

---

### Power LED does not light:

Check that the power cable is firmly connected to the device and to the supply outlet.

### On powering-up, the MGMT LED lights yellow:

The device has failed its Power On Self Test (POST) and you should contact your supplier for advice.

### A link is connected, but the Status LED does not light:

Check that:

- All connections are secure.
- Cables are free from damage.
- The devices at both ends of the link are powered-up.
- Both ends of the Gigabit link are set to the same autonegotiation state.

The Gigabit link must be enabled or disabled on both sides. If the two sides are different, typically the side with autonegotiation disabled will have the link LED lit, and the side with autonegotiation enabled will not be lit. The default configuration for a Gigabit port is autonegotiation enabled. Verify by entering the following command:

```
show ports configuration
```

### Predictive Failure LED on the AC power supply blinks amber:

Check the current status of the power supply. If the speed of both fans is above 2000 RPM, the AC power supply unit (PSU) is operating normally and no failure is imminent. To check and view the health of the installed PSU, use the following command:

```
show power {ps_num} {detail}
```

## Switch does not power up:

All products manufactured by Extreme Networks use digital power supplies with surge protection. In the event of a power surge, the protection circuits shut down the power supply.

To reset the power, unplug the switch for 1 minute, plug it back in, and attempt to power-up the switch. If this does not work, try using a different power source (different power strip/outlet) and power cord.

## Using the Command Line Interface

---

This section describes helpful information for using and understanding the command line interface (CLI).

### General Tips and Recommendations

#### *The initial welcome prompt does not appear:*

Check that:

- Your terminal or terminal emulator is correctly configured
- Your terminal or terminal emulator has the correct settings:
  - 115200 baud for ExtremeSwitching X465, X690, X695, X590, , X870, and 5520 switches; or 9600 baud for all other switches
  - 8 data bits
  - 1 stop bit
  - no parity
  - XON/OFF flow control enabled

For console port access, you might need to press [Return] several times before the welcome prompt appears.

#### *The SNMP Network Manager cannot access the device:*

Check that:

- The SNMP (Simple Network Management Protocol) access is enabled for the system.
- The device IP address, subnet mask, and default router are correctly configured, and that the device has been reset.
- The device IP address is correctly recorded by the SNMP Network Manager (refer to the user documentation for the Network Manager).
- The community strings configured for the system and Network Manager are the same.
- The SNMPv3 USM, Auth, and VACM configured for the system and Network Manager are the same.

#### *The Telnet workstation cannot access the device:*

Check that:

- The device IP address, subnet mask, and default router are correctly configured, and that the device has been reset.
- You entered the IP address of the switch correctly when invoking the Telnet facility.
- Telnet access is enabled for the switch.

If you attempt to log in and the maximum number of Telnet sessions are being used, you should receive an error message indicating so.

***Traps are not received by the SNMP Network Manager:***

Check that the SNMP Network Manager’s IP address and community string are correctly configured, and that the IP address of the Trap Receiver is configured properly on the system.

***The SNMP Network Manager or Telnet workstation can no longer access the device:***

Check that:

- Telnet access or SNMP access is enabled for the system.
- The port through which you are trying to access the device has not been disabled. If it is enabled, check the connections and network cabling at the port.
- The port through which you are trying to access the device is in a correctly configured VLAN.
- The community strings configured for the device and the Network Manager are the same.

Try accessing the device through a different port. If you can now access the device, a problem with the original port is indicated. Re-examine the connections and cabling.

A network problem might be preventing you from accessing the device over the network. Try accessing the device through the console port.

***Permanent entries remain in the FDB:***

If you have made a permanent entry in the FDB that requires you to specify the VLAN to which the entry belongs and then deleted the VLAN, the FDB entry remains. Although this does not harm the system, if you want to removed the entry, you must manually delete it from the FDB.

***Default and static routes:***

If you have defined static or default routes, those routes remain in the configuration independent of whether the VLAN and VLAN IP address that used them remains. You should manually delete the routes if no VLAN IP address is capable of using them.

***You forget your password and cannot log in:***

If you are not an administrator, another user having administrator access level can log in, delete your user name, and create a new user name for you, with a new password.

Alternatively, another user having administrator access level can log in and initialize the device. This will return all configuration information (including passwords) to the initial values.

In the case where no one knows a password for an administrator level user, contact your supplier.

## The ExtremeSwitching switch displays only the “(pending-AAA) login” prompt

It is possible that the switch has not yet been fully initialized in the SummitStack. Wait for the Authentication Service (AAA) on the master node is now available for login. message to appear and then log in normally.

It is also possible that the stack has no master-capable node. In this case, AAA authentication will not be possible. This can occur when a stack has been deliberately dismantled and stacking was not unconfigured beforehand.

In either case, you may log in to the node using the failsafe account. If you have forgotten this account, and the stack has no master-capable node or has been dismantled, see [Rescuing a Stack that has No Master-Capable Node](#) on page 201.

### The "(Pending-AAA) login:" prompt on other switches.

This login prompt is discussed in [Logging in to the Switch](#) on page 33.

## Node Prompt—SummitStack Only

*You do not know which Node you are connected to:*

If you use a console connection to access and configure the switch, you should connect to the console port of the master node.

The word "Slot" followed by a hyphen and a single decimal digit slot number will be inserted into the prompt in stacking mode. A sample of this prompt is:

```
* Slot-6 Stack.21 #
```

The sample indicates a changed configuration (\*), the stackable is in stacking mode and is currently using the slot number 6 in the active topology ("Slot-6"), the system name is the default of "Stack", the command about to be executed is the 21st command, and the user is logged in as the administrator on the Master node (#).

There will be no specific prompt that indicates the node role. Run show switch command to discover the identities of the Master and Backup nodes. A successful login on a Standby node will show the ">" character instead of the "#" character at the end of the prompt.

## Command Prompt

*You do not know if the switch configuration has been saved:*

If an asterisk (\*) precedes the command prompt, a new change to the switch configuration has not been saved. To save the configuration, use the [save configuration](#) command. After you save the configuration, the asterisk (\*) no longer precedes the command prompt.

*You do not know if you are logged in as an administrator or a user:*

Observe the console prompt. If you are logged in as an administrator, the prompt ends with the hash symbol (#). If you are logged in as a user, the prompt ends with a greater than sign (>).

The following is sample output from an administrator-level account:

```
BD-10808.1 #
```

The following is sample output from a user-level account:

```
BD-10808.1 >
```

## Port Configuration

### *No link light on 10/100 Base port:*

If patching from a switch to another switch, ensure that you are using a category 5 (CAT5) crossover cable. This is a CAT5 cable that has pins 1 and 2 on one end connected to pins 3 and 6 on the other end.

### *Excessive RX CRC errors:*

When a device that has autonegotiation disabled is connected to an Extreme Networks switch with autonegotiation enabled, the Extreme Networks switch links at the correct speed, but in half-duplex mode. The Extreme Networks switch 10/100 physical interface uses a method called parallel detection to bring up the link. Because the other network device is not participating in autonegotiation (and does not advertise its capabilities), parallel detection on the Extreme Networks switch is able only to sense 10 Mbps versus 100 Mbps speed and not the duplex mode. Therefore, the switch establishes the link in half-duplex mode using the correct speed.

The only way to establish a full-duplex link is either to force it at both sides, or run autonegotiation on both sides (using full-duplex as an advertised capability, which is the default setting on the Extreme Networks switch).

#### Note

A mismatch of duplex mode between the Extreme switch and another network device causes poor network performance. Viewing statistics using the `show ports rxerrors` command on the Extreme Networks switch may display a constant increment of CRC errors. This is characteristic of a duplex mismatch between devices. This is NOT a problem with the Extreme Networks switch.

Always verify that the Extreme Networks switch and the network device match in configuration for speed and duplex.

### *No link light on Gigabit fiber port:*

Check that:

- The transmit fiber goes to the receive fiber side of the other device and vice-versa. All Gigabit fiber cables are of the crossover type.
- The Gigabit ports are set to Auto Off (using the command `configure ports port_list {medium [copper | fiber]} auto off speed speed duplex [half | full]`) if you are connecting the Extreme Networks switch to devices that do not support autonegotiation.

By default, the Extreme Networks switch has autonegotiation set to On for Gigabit ports and set to Off for 10 Gigabit ports.

- You are using multimode fiber (MMF) when using a 1000BASE-SX small form-factor pluggable (SFP), and single-mode fiber (SMF) when using a 1000BASE-LX SFP. 1000BASE-SX technology does not work with SMF. The 1000BASE-LX technology works with MMF but requires the use of a mode conditioning patchcord (MCP).

## Software License Error Messages

### *You do not have the required software license:*

If you attempt to execute a command and you do not have the required license, the switch returns the following message:

```
Error: This command cannot be executed at the current license level.
```

### *You have reached the limits defined by the current software license level:*

If you attempt to execute a command and you have reached the limits defined by the current license level the switch returns the following message:

```
Error: You have reached the maximum limit for this feature at this license level.
```

For more information about licensing requirements, see the [ExtremeXOS 31.2 Feature License Requirements](#) document.

## VLANs

### *You cannot add a port to a VLAN:*

If you attempt to add a port to a VLAN and get an error message similar to:

```
localhost:7 # configure vlan marketing add ports 1:1,1:2
Error: Protocol conflict when adding untagged port 1:1. Either add this port as tagged or
assign another protocol to this VLAN.
```

You already have a VLAN using untagged traffic on a port. Only one VLAN using untagged traffic can be configured on a single physical port.

You verify the VLAN configuration using the following command:

```
show vlan {virtual-router vr-name}
```

The solution for this error using this example is to remove ports 1 and 2 from the VLAN currently using untagged traffic on those ports.

If this were the “default” VLAN, the command would be:

```
localhost:23 # configure vlan default delete ports 1:1,1:2
```

You can now re-enter the previous command without error:

```
localhost:26 # configure vlan marketing add ports 1:1,1:2
```

### *VLAN names:*

There are restrictions on VLAN names. They cannot contain whitespaces and cannot start with a numeric value.

***VLANs, IP addresses, and default routes:***

The system can have an IP address for each configured VLAN. You must configure an IP address associated with a VLAN if you intend to manage (Telnet, [SNMP](#), ping) through that VLAN or route IP traffic.

You can also configure multiple default routes for the system. The system first tries the default route with the lowest cost metric.

**STP**

*You have connected an endstation directly to the switch and the endstation fails to boot correctly:*

The switch has the [STP](#) enabled, and the endstation is booting before the STP initialization process is complete. Specify that STP has been disabled for that [VLAN](#), or turn off STP for the switch ports of the endstation and devices to which it is attempting to connect; then, reboot the endstation.

***Spanning Tree Domain names:***

There are restrictions on [STPD](#) names. They cannot contain whitespaces and cannot start with a numeric value.

*You cannot add ports within a VLAN to the specified STPD:*

Check to ensure that you are adding ports that already exist in the carrier VLAN.

If you see an error similar to the following:

```
Error: Cannot add VLAN default port 3:5 to STP domain
```

You might be attempting to add:

- Another 802.1D mode STP port to a physical port that already contains an 802.1D mode STP port (only one 802.1D encapsulation STP port can be configured on a particular STP port).
- A carrier VLAN port to a different STP domain than the carrier VLAN belongs.
- A VLAN and/or port for which the carrier VLAN does not yet belong.

**Note**

This restriction is only enforced in an active STPD and when you enable STP to make sure you have a legal STP configuration.

*Only one carrier VLAN can exist in an STPD:*

Only one carrier VLAN can exist in a given STPD although some of the ports on the carrier VLAN can be outside the control of any STPD at the same time.

The StpdID must be identical to the VLANid of the carrier VLAN in that STPD.

*The switch keeps aging out endstation entries in the switch FDB:*

If the switch continues to age out endstation entries in the switch [FDB](#):

- Reduce the number of topology changes by disabling STP on those systems that do not use redundant paths.

- Specify that the endstation entries are static or permanent.

## ESRP

### *ESRP names:*

There are restrictions on Extreme Standby Router Protocol (ESRP) names. They cannot contain whitespaces and cannot start with a numeric value.

### *You cannot enable an ESRP domain:*

Before you enable a specific ESRP domain, it must have a domain ID. A domain ID is either a user-configured number or the 802.1Q tag (VLANid) of the tagged master VLAN. The domain ID must be identical on all switches participating in ESRP for that particular domain. If you do not have a domain ID, you cannot enable ESRP on that domain.

Note the following on the interaction of tagging, ESRP, and ESRP domain IDs:

- If you have an untagged Master VLAN, you must specify an ESRP domain ID.
- If you have a tagged master VLAN, ESRP uses the 802.1Q tag (VLANid) of the master VLAN for the ESRP domain ID. If you do not use the VLANid as the domain ID, you must specify a different domain ID.

### *You cannot delete the master VLAN from the ESRP domain:*

If you attempt to remove the master VLAN before disabling the ESRP domain, you see an error message similar to the following:

```
ERROR: Failed to delete master vlan for domain "esrp1" ; ESRP is enabled!
```

If this happens:

- Disable the ESRP domain using the `disable esrp` command.
- Remove the master VLAN from the ESRP domain using the `configure esrp delete master` command.

## VRRP

### *You cannot define VRRP virtual router parameters:*

Before configuring any virtual router (VR) parameters for VRRP, you must first create the VRRP instance on the switch.

If you define VRRP parameters before creating the VRRP, you may see an error similar to the following:

```
Error: VRRP VR for vlan vrrp1, vrid 1 does not exist.
Please create the VRRP VR before assigning parameters.
Configuration failed on backup MSM, command execution aborted!
```

If this happens:

- Create a VRRP instance using the `create vrrp vlan vrid` command.
- Configure the VRRP instance's parameters.

## Using ELRP to Perform Loop Tests

The Extreme Loop Recovery Protocol (ELRP) is used to detect network loops in a Layer 2 network. A switch running ELRP transmits multicast packets with a special MAC destination address out of some or all of the ports belonging to a VLAN. All of the other switches in the network treat this packet as a regular, multicast packet and flood it to all of the ports belonging to the VLAN. When the packets transmitted by a switch are received back by that switch, this indicates a loop in the Layer 2 network.

### Note

The ELRP source MAC address is changed from "00:e0:2b:00:00:01" to "0e:Switch-MAC".

After a loop is detected through ELRP, different actions can be taken such as blocking certain ports to prevent loop or logging a message to system log. The action taken is largely dependent on the protocol using ELRP to detect loops in the network.

You can use ELRP on a "standalone" basis or with other protocols such as ESRP (Extreme Standby Router Protocol), as described in [Using ELRP with ESRP](#). Protocols such as EAPS (Extreme Automatic Protection Switching) require that a network have a ring topology to operate. In this case you can use ELRP to ensure that the network has a ring topology.

The "standalone" ELRP commands determine whether or not a network has an Layer 2 loop.

## About Standalone ELRP

Standalone ELRP gives you the ability to send ELRP packets, either periodically or on an ad hoc "one-shot" basis on a specified subset of VLAN ports. If any of these transmitted packets is received back then standalone ELRP can perform a configured action such as sending a log message to the system log file, sending a trap to the SNMP manager, and disabling the port where the looped packet arrived.

ELRP uses QP8 to send/receive control packets over the network to detect loops, so it is advisable to not use QP8 in for user traffic in the network.

Standalone ELRP allows you to:

- Configure ELRP packet transmission on specified VLANs.
- Specify some or all the ports of the VLAN for packet transmission. Each VLAN must be configured individually for ELRP.

### Note

Reception of packets is not limited to any specific ports of the VLAN and cannot be configured.

- Save and restore standalone ELRP configuration across reboots.
- Request non-periodic or periodic transmission of ELRP packets on specified ports of a VLAN.

### Note

Starting with ExtremeXOS 22.2, ELRP works on both static and dynamic VLANs.

### Non-periodic ELRP Requests

You can specify the number of times ELRP packets must be transmitted and the interval between consecutive transmissions. A message is printed to the console and logged into the system log file indicating detection of network loop when ELRP packets are received back or no packets are received within the specified duration.

### Periodic ELRP Requests

You can configure the interval between consecutive transmissions. If ELRP packets are received back, a message is printed to the system log file and/or a trap is sent to the SNMP manager indicating detection of a network loop.

You have the option to configure the switch to automatically disable the port where the looped packet arrived as well as the length of time (in seconds) that the port should remain disabled. When this hold time expires, the port is automatically enabled.

Should a loop occur on multiple ports, only the first port in the VLAN on which the PDU is received is disabled. The second port is ignored for 1 or 2 seconds and then if another PDU is received, that port is disabled until the loop is gone. This prevents shutting down all ports in the VLAN.

### ELRP Egress Port Disable

When a loop is detected via ELRP, an option to disable the port where the packet egressed was added to suppress the loop in ExtremeXOS 16.1. All existing functionalities supported on disabling the port where the packet ingressed are supported on this enhancement as well. A log message or SNMP trap will be generated based on the configuration. The user must specify a holdtime or keep the port disabled until a user enables it.

ELRP egress blocking enhancement adds the following value:

- More efficient bandwidth utilization.
- Better loop protection in MLAG (Multi-switch Link Aggregation Group) environment. If an edge device is dual-homed to an MLAG pair and this edge device loses its LAG (Link Aggregation Group) configuration, ELRP will be able to prevent the loop by disabling egress port.

**Figure 286: ELRP Egress Port Disable (1)**

**Figure 287: ELRP Egress Port Disable (2)**

### *Exclude Port List*

When you have configured the switch to automatically disable the port where the looped packet arrived, there may be certain ports that you do not want disabled. You can then create a list of ports that are excluded from this automatic disabling and that remain enabled. This list can also contain [EAPS](#) ring ports. When this option is selected, the actual EAPS ring ports do not have to be explicitly listed. You can also specify that [VXLAN \(Virtual Extensible LAN\)](#) remote end points are to be excluded from getting disabled when a loop is detected.

You can configure any port on the switch into the exclude port list. The list can also be edited to add or delete any port on the switch. Then when ELRP detects a loop and the disable feature is enabled, it checks to see if the port from which the PDU arrived is on the user defined exclude port list or is part of a trunk port that is defined on the list. When the port is on the list, ELRP logs the event and does not disable the port. When the port is not on the list, ELRP disables the port.

### **Limitations**

The following are limitations to this feature:

- A specified port is added to the list regardless of its corresponding [VLAN](#).
- Only ports on the local switch can be added.
- A loop detected on an excluded port may persist indefinitely until user action is taken.
- [MLAG](#) ISC links should not be blocked, therefore they should be added to the excluded port list.

### *ELRP with Dynamic VLANs*

Starting with ExtremeXOS 22.2, ELRP supports dynamically created VLANs created by:

- [NetLogin](#)
- [Extreme Network Virtualization \(XNV\)](#)
- Multiple Registration Protocol (MVRP)

ELRP on NetLogin-enabled ports is supported.

### **Limitations**

ELRP is not supported on dynamic VLANs when created by ONEPolicy or ONEPolicy with NetLogin.

### *ELRP with Virtual Extensible LAN (VXLAN)*

Starting with ExtremeXOS 22.4, ELRP is supported on Virtual Extensible LAN (VXLAN).

VXLAN is an encapsulation mechanism. A VXLAN header is added to an L2 (ELRP PDU) frame and encapsulated in a UDP/IP packet. Transit nodes see only an ordinary IP packet. For more information about VXLAN, see [VXLAN](#) on page 966.

ELRP detects loops across VXLAN tunnels. If a loop is detected across the tunnel and the **disable-port** option is configured (see [Configuring Periodic Requests](#) on page 1879), ELRP takes down the VXLAN remote endpoint.

If the VXLAN remote endpoint has been disabled using the **permanent** option, you can use the following command to re-enable the remote endpoint:

```
enable virtual-network remote-endpoint vxlan [ipaddress ipaddress {vr vr_name} | all]
```

To manually disable a remote endpoint, use the following command:

```
disable virtual-network remote-endpoint vxlan [ipaddress ipaddress {vr vr_name} | all]
```

To see if a remote endpoint is enabled or disabled, use the following command:

```
show virtual-network {vn_name} remote-endpoint vxlan {vni vni}
{ipaddress ipaddress {vr vr_name}}
```

### *Hardware-Assisted ELRP*

Hardware-assisted ELRP allows ELRP to detect loops faster and to support more ELRP clients.

#### **Supported Platforms**

ExtremeSwitching X450-G2, X460-G2, X670-G2, X440-G2, X465, X590, X620, X690, X695, X870, 5520 series switches.

#### **Limitations**

For hardware-assisted ELRP:

- Only front panel ports can be configured as the loopback port.
- Only disabling ingress port is supported after a loop is detected.
- MLAG ports are not supported.
- Software ELRP and hardware-assisted ELRP cannot operate simultaneously.
- Only standalone clients are supported.
- Not supported on dynamic VLANs.
- Maximum loop detection interval is determined by each platform's hardware capability. For most platforms, an ELRP packet is 70 bytes.
- Non-periodic requests are not supported.
- Extended Edge Switching is not supported.

## Configuring Standalone ELRP

The ELRP client (standalone ELRP) must be enabled globally in order for it to work on any VLAN.

- Globally enable the ELRP client for static VLANs:

```
enable elrp-client {software | hardware-assist}
```

The ELRP client can be disabled globally so that none of the ELRP VLAN configurations take effect.

- Globally disable the ELRP client for static VLANs:

```
disable elrp-client
```

- Globally enable or disable ELRP for dynamic VLANs:

```
configure elrp-client dynamic-vlans {mvrp | netlogin | vm-tracking | all} [on | off]
```

- Globally enable or disable inter-VLAN loop detection:

```
configure elrp-client inter-vlan-loop-detection [on | off]
```

- Configure or unconfigure a front panel port as the designated loopback port for hardware-assisted ELRP:

```
configure elrp-client hardware-assist loopback-port [port | none]
```

### Note

Do not configure a trunk port as the loopback port. In a stack, make sure the loopback port is not on the master slot.

### Configuring Non-periodic Requests

- To start one-time, non-periodic ELRP packet transmission on specified ports of a VLAN using a particular count and interval, use one of the following commands:

```
configure elrp-client one-shot {vlan [vlan_name | all] ports [ports | all | none] {remote-endpoints vxlan all} {interval interval {seconds | milliseconds}} {retry count} {log | print | print-and-log}}
```

```
run elrp {vlan}vlan_name {ports [ports | all | none]} {remote-endpoints vxlan all} {interval interval {seconds | milliseconds}} {retry count}
```

These commands start one-time, non-periodic ELRP packet transmission on the specified ports of the VLAN using the specified count and interval. If any of these transmitted packets is returned, indicating loopback detection, the ELRP client performs the configured actions of logging a message in the system log file and/or printing a log message to the console. There is no need to trap to the SNMP manager for non-periodic requests.

### Configuring Periodic Requests

- To start periodic ELRP packet transmission on specified ports of a VLAN using a particular interval, use the following command:

```
configure elrp-client periodic {vlan} vlan_name ports [ports | all | none] {remote-endpoints vxlan all} {interval interval {seconds | milliseconds}} {log | log-and-trap | trap} {disable-port {egress | ingress} {duration {seconds} | permanent}}
```

This command starts periodic ELRP packet transmission on the specified ports of the VLAN using a specified interval. If any of these transmitted packets is returned, indicating loopback detection, the

ELRP client performs the configured action of logging a message in the system log file and/or sending a trap to the *SNMP* manager.

When the option of disabling a port is configured, you choose the duration in seconds as a hold time, or you disable the port permanently. When ELRP disables the port, the operation is not persistent. When the switch is rebooted, the port is enabled when the switch comes up.

#### Note

ELRP detects loops on a per VLAN basis. When you select the **disable-port** option keep in mind that the entire port is disabled. In the case of *VXLAN*, the remote tunnel endpoint's (RTEP) state is taken down for all VXLAN virtual networks. This may affect connectivity for other VLANs configured on that port that did not have any data loop problems. ELRP also does not distinguish between uplink ports and host ports. When the **disable port** option is selected and ELRP detects a loop, any and all ports where the loop was detected will be disabled, including uplink ports.

- To disable a pending one-shot or periodic ELRP request for a specified VLAN or all dynamic VLANs, use the following command:

```
unconfigure elrp-client {vlan_name | dynamic-vlans}
```

#### Configuring Exclude Port List

- To configure an ELRP exclude port list, use the following command:

```
configure elrp-client disable-ports [exclude | include] [ports | eaps-ring-ports | remote-endpoints vxlan | inter-vlan-loop]
```

- To unconfigure an ELRP exclude port list, use the following command:

```
unconfigure elrp-client disable-ports
```

## Displaying Standalone ELRP Information

- To display summary ELRP status information, use the following command:

```
show elrp
```

- To display information about ELRP disabled ports, use the following command:

```
show elrp disabled-ports
```

- To display information ELRP configuration on dynamic VLANs, use the following command:

```
show elrp dynamic-vlans {vm-tracking | netlogin | mvrp | all}
```

## Example: ELRP on Protocol-Based VLANs

For ELRP to detect loops on a protocol-based VLAN (other than the protocol any), you need to add the ethertype 0x00bb to the protocol.

- Create VLANs:

```
create vlan v1
create vlan v2
```

- Configure protocol filters:

```
configure vlan v1 protocol IP
configure vlan v2 protocol decnet
```

3. Add ports to the VLANs:

```
configure vlan v1 add ports 1
configure vlan v2 add ports 2
```

4. Enable ELRP on the created VLANs:

```
enable elrp-client
configure elrp-client periodic v1 ports all interval 5 seconds log
configure elrp-client periodic v2 ports all interval 5 seconds log
```

5. Add the ethertype to the protocol:

```
configure protocol IP add snap 0x00bb
configure protocol decnet add snap 0x00bb
```

VLANs v1 and v2 can now detect the loop on their respective broadcast domains.

## Using Simple Loop Prevention Protocol (SLPP) Guard

Simple Loop Prevention Protocol (SLPP) is an application that detects loops in an [MLAG](#) or Split Multi-link Trunking (SMLT) network on VOSS/BOSS switches.

SLPP Guard is a complementary feature for ExtremeXOS switches that helps prevent loops in networks by administratively disabling an edge port if a switch receives an SLPP PDU from an SMLT network. SLPP Guard detects and discards SLPP control PDUs on a per port basis. SLPP Guard identifies SLPP PDUs using the Ethernet type field of the packet, which is configurable. When an SLPP PDU is received on a port that has SLPP Guard activated on it, it is immediately disabled. After a configurable timeout value expires (associated with each port), the port is automatically re-enabled.

### Note

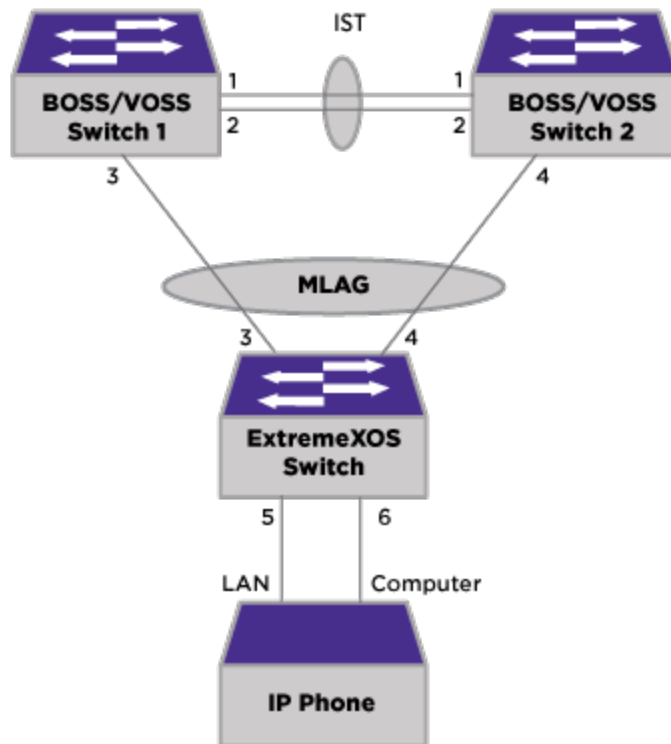

When SLPP Guard disables a port, the disabled status is not persistent. If the switch reboots, the port is enabled when the switch comes back up.

### Note

If you use the CLI to enable or disable a port that has been disabled by SLPP Guard, the port is enabled or disabled as applicable and the recovery timer is stopped for that port.

The most common use case is with an IP phone with two ports: one for a switch and one for a computer (see [Figure 288](#)). If you plug both IP phone ports onto the edge switch, a loop is created. To avoid a loop in the SMLT network, on the ExtremeXOS edge switch, enable SLPP Guard on the ports that are connected to the IP phone.

**Figure 288: SLPP Use Case**

## Supported Platforms

ExtremeSwitching X435, X450-G2, X460-G2, X670-G2, X440-G2, X465, X590, X620, X690, X695, X870, 5520 series switches.

## Limitations

- SNMP for SLPP Guard is not supported.
- The SLPP Guard active state per port is limited by the number of available ACL filters.

## Configuring Simple Loop Prevention Protocol (SLPP) Guard

For Simple Loop Prevention Protocol (SLPP) Guard to operate, SLPP must have already been configured in the core of the network.

The following information explains how to configure SLPP Guard on ExtremeXOS switches.

1. Enable SLPP on the desired ports using the following command:

```
enable slpp guard ports [port_list | all]
```

**Note**

To view the SLPP status of ports, use the `show slpp guard {ports port_list} {disabled-ports}` command.

2. (Optional) Set the recovery timeout period using the following command:

```
configure slpp guard [ports [port_list | all] recovery-timeout
[seconds | none]
```

After the configured timeout value set by this command expires (associated with each port), the port is automatically re-enabled.

3. (Optional) Configure the Ethertype for SLPP Guard using the following command:

```
configure slpp guard ethertype hex
```

This command configures the Ethertype that the SLPP Guard feature uses to identify SLPP PDUs.

If you need to disable SLPP Guard on a port, use the following command:

```
disable slpp guard ports [port_list | all]
```

To view SLPP Guard status for selected ports or all SLPP Guard-disabled ports, use the following command:

```
show slpp guard {ports port_list} {disabled-ports}
```

## Debug Mode

---

The EMS provides a standard way to filter and store messages generated by the switch. With EMS, you must enable debug mode to display debug information. You must have administrator privileges to use these commands. If you do not have administrator privileges, the switch rejects the commands.

- Enable or disable debug mode for EMS:

```
enable log debug-mode
```

After debug mode has been enabled, you can configure EMS to capture specific debug information from the switch. Details of EMS can be found in [Status Monitoring and Statistics](#).

## Saving Debug Information

---

You can save switch data and statistics to a network TFTP server, an internal memory card that comes pre-installed in the switch or a removable USB 2.0 storage device (ExtremeSwitching X450-G2, X460-G2, X670-G2, X465, X590, X690, X695, X870, and 5520 series switches).

With assistance from [Extreme Networks Technical Support](#) personnel, you can configure the switch to capture troubleshooting information, such as a core dump file, to these locations.

The switch only generates core dump files in the following situations:

- If an ExtremeXOS process fails.
- When forced under the guidance of Extreme Networks Technical Support.

The core dump file contains a snapshot of the process when the error occurred.

#### Note

Use the commands described in this section only under the guidance of Extreme Networks Technical Support personnel to troubleshoot the switch.

Before you can enable and save process core dump information to removable storage devices, you must install a compact flash card or USB 2.0 storage device. .

## Enabling the Send Debug Information Switch

This allows information to be sent to the internal memory card or a removable storage device.

- Enable the switch to save process core dump information.

```
configure debug core-dumps [off | directory_path]
```

A removable storage device is a USB 2.0 storage device on a ExtremeSwitching series switch.

Core dump files have a .gz file extension. The filename format is: core.<process-name.pid>.gz where process-name indicates the name of the process that failed and pid is the numerical identifier of that process.

If you configure the switch to write core dump files to the internal memory card and attempt to download a new software image, you might have insufficient space to complete the image download.

If this occurs, you must decide whether to continue the software download or move or delete the core dump files from the internal memory. For example, if your switch supports a removable storage device with space available, transfer the files to the storage device. On switches that do not have a removable storage device, transfer the files from the internal memory card to a TFTP server. This frees up space on the internal memory card while keeping the core dump files.

## Copy Debug Information to Removable Storage Devices

- Save and copy debug information to the specified USB 2.0 storage device.

```
save debug tracefiles directory_path
```

After the switch writes a core dump file or other debug information to the storage device, and before you can view the contents on the device, you must ensure it is safe to remove the device from the switch. Use the `eject usb-device` command to prepare the device for removal. After you run the `eject usb-device` command, you can manually remove the storage device from the switch and read the data on the device.

To access and read the data on a removable storage device, use a PC with the appropriate hardware, such as a compact flash reader/writer and follow the manufacturer's instructions to access the compact flash card and read the data.

## Copying Debug Information to a TFTP Server

**SummitStack only**—To get debug information from a node in the SummitStack that is not a master node, you must configure an alternate IP address on the node and have its management port connected. You may then use the `tftp` command to upload specific files. The upload debug command functions only on the master node.

1. Save and copy debug information to the specified TFTP server.

```
upload debug [ipaddress | hostname] {{vr} vrname} {block-size
block_size}
```

Progress messages are displayed that indicate the file being copied and when the copying is finished.

Depending on your platform, the switch displays a message similar to the following:

```
The following files on have been uploaded:
Tarball Name: TechPubsLab_C_09271428.tgz
./primary.cfg
```

You can also use this command in conjunction with the `show tech` command.

Prior to uploading debug information files, the switch prompts you with the following message to run the `show tech-support` command with the `logto` file option:

```
Do you want to run show tech logto file first? (y/n)
```

2. Enter `y` to run the `show tech-support` command before uploading debug information.

If you enter `y`, the `show_tech.log.tgz` file is included during the upload. Enter `n` to upload debug information without running the `show tech` command.

After you upload the debug information, you should see a compressed TAR file on the TFTP server, which contains the debug information.

The TAR file naming convention is

```
<SysName>_<{slot#}|A|B|I|C>_<Current Time>.tgz
- Current Time = mmddhhmm (month(01-12), date(01-31), hour(0-24), minute(00-59)).
```

## Managing Debug Files

For the purposes of this section, it is assumed that you have configured the switch to send core dump information under the guidance of [Extreme Networks Technical Support](#).

Managing the debug files might include any of the following tasks: renaming or copying a core dump file, displaying a comprehensive list of files including core dump files, transferring core dump files, and deleting a core dump file. You can manage the debug files using the same commands that you use to manage other switch files.

### Note

Filenames are case-sensitive. For information on filename restrictions, refer to the specific command in the [ExtremeXOS 31.2 Command Reference Guide](#).

---

## Evaluation Precedence for ACLs

---

The ACLs on a port are evaluated in the following order:

- Persistent dynamic ACLs
- Host-integrity permit ACLs
- MAC source address deny ACLs
- Source IP lockdown source IP permit ACLs
- Source IP lockdown deny all ACLs
- ARP validation CPU ACLs
- ACLs created using the CLI
- DoS Protect-installed ACLs
- MAC-in-MAC installed ACLs
- ACLs applied with a policy file (see [ACLs](#) on page 738 for precedence among these ACLs)

---

## TOP Command

---

The `top` command is a UNIX-based command that displays real-time CPU utilization information by process.

The output contains a list of the most CPU-intensive tasks and can be sorted by CPU usage, memory usage, and run time. For more detailed information about the `top` command, refer to your UNIX documentation.

---

## TFTP Server Requirements

---

We recommend using a TFTP server that supports blocksize negotiation (as described in RFC 2348, TFTP Blocksize Option), to enable faster file downloads and larger file downloads.

---

## System Odometer

---

Each field replaceable component contains a system odometer counter in EEPROM.

The `show odometers` command displays an approximate days of service duration for an individual component since the component was manufactured.

---

## Monitored Components

The odometer monitors the following components:

- Switch
- XGN-2xn card

---

## Recorded Statistics

### *Description*

The following odometer statistics are collected by the switch:

- Service Days—The amount of days that the component has been running
- First Recorded Start Date—The date that the component was powered-up and began running

Depending on the software version running on your switch, additional or different odometer information may appear.

The following is sample output from an ExtremeSwitching series switch:

```
show odometers
Service First Recorded
Field Replaceable Units Days Start Date

Switch : SummitX4 7 Dec-08-2004
XGM-2xn-1 :
```

## Temperature Operating Range

On ExtremeSwitching series switches, if a switch runs outside the expected range, the switch logs an error message, generates a trap, and one of the following actions occurs:

- On a SummitStack slots, the **reset/none** option from `configure sys-recovery-level [all | none]` command determines the action that occurs.
- On ExtremeSwitching X430-8p switches, the device is shut down regardless of the recovery level, and after reboot you are prompted whether or not to boot the switch.
- For all switches, other than the ExtremeSwitching X430-8p, only a warning is logged and the switch continues to run with the system state as "overheat." If the temperature increases further into overheat condition, after the operating temperature exceed a further higher temperature, the hardware resets the switch.

## Understanding the Error Reading Diagnostics Message

For more detailed information about error messages and their meanings, see the [ExtremeXOS 31.2 EMS Messages Catalog](#).

If you have never run diagnostics on the switch or stack ports and use the `show diagnostics` command, the switch displays a message similar to the following:

```
Result: FAIL
Test date run is invalid. Please run Diagnostics.
Error reading diagnostics information.
```

This message is normal and expected if you have never run diagnostics on the switch. After running diagnostics, you see information about the executed test using the `show diagnostics` command.

## Proactive Tech Support

---

Proactive tech support functionality allows you to collect system information when support is required. System information is pushed into a cloud-hosted collector where the Extreme TAC can use it to identify problems to provide solutions. Proactive Tech Support provides the following functionality:

- Proactive tech support is implemented as a loadable application, called techSupport.xmod. The XMOD is bundled with ExtremeXOS image packages, but can also be upgraded independently at any time without restarting the switch.
- Proactive tech support allows the switch to proactively collect switch status and send the status report to up to four cloud-hosted collectors.
- Proactive tech support allows both automatic and manual status report.
- Proactive tech support allows each collector to have different report data set, report frequency, or report mode. A default collector is configured automatically to minimize the configuration required to enable the feature.

### Limitations

- Proactive tech support uses SSL to secure the switch information transmission on the Internet. If the feature is not enabled, the switch information is transmitted as clear text.
- XMOD applications can be dynamically upgraded without restarting the switch. But the upgraded XMOD version needs to match the installed ExtremeXOS version.

### Locating a Collector

The switch attempts to locate a data collector using the DNS hostname, or the IP address of a collector. You specify the DNS hostname or IP address of a collector when you add a collector. When a DNS hostname is configured for a collector, the switch attempts to resolve the IP address for the configured DNS hostname before it attempts to connect to the collector. If the process of resolving IP address for a collector fails, the connection process stops and logs an error message.

When you start the feature a default collector is automatically configured with an IP address set to 12.38.14.200; this is a public IP address of a Splunk server hosted in Extreme's internal network. When you enable the feature, the switch automatically attempts to locate the default collector and send switch status information to the collector. You can configure up to four collectors on the switch. If you want to collect switch status information in your own collector (beside the default collector), you can use the `configure tech-support add collector` command to configure an additional collector. The switch will send independent status reports to each collector based on each collector's configuration.

By default, the primary IP address on the Mgmt VLAN interface is used for the discovery process of a collector. If an IP address is not found on the Mgmt VLAN, an error message is displayed. Optionally, you can specify a source IP address to connect to a collector. The connection between the switch and a collector is established and maintained with TCP.

### Data Collection

These sections discuss various ways that data is collected and presented.

### *Encrypted or Open Text*

Status reports are sent either in encrypted or clear text. By default, this is determined by the installation of the SSL module. If the SSL module is installed, the status report is sent using an SSL over TCP session in encrypted text. Otherwise, the status report is sent over a regular TCP session in clear text. You can disable the SSL transport even if the SSL module is installed by using the `configure tech-support collector [hostname | ip_address] tcp-port port {vr vr_name} {from source_ip_address} {ssl [on | off]}` command.

### *Push vs. Pull*

For security reasons, status reports are never pushed from a collector out to a switch. The switch always pushes status reports to a collector. The first release of the tech-support application supports local configuration only. The switch pushes status reports to a collector based solely on the local configuration.

### *Report Format*

The status report format is the output of the `show tech-support` command. You can limit the amount of information in the report using the **data-set** configuration parameter. Two data-sets are available in the first release. With SSH, we recommend that you configure the data-set as detail to include all output of the `show tech-support` command in the switch status report. Without SSH, we recommend that you configure the data-set as summary to include certain output of the `show tech area` command in the switch status report for just a few critical areas, such as general, config, log, VLAN, and EPM.

### *Frequency*

You can also configure when the switch sends a status report. The switch can send a report based on a critical severity event occurrence, daily, at boot-up, or manually when directed by the network administrator. Because of the amount of information that can be transmitted, automatic status reports are sent no more frequently than one report per hour. When a series of critical severity events occurs, only the first one triggers the switch to send status reports. All other critical severity events that occur within one hour after the first critical severity event are ignored.

### *Authentication and Verification*

To keep the required configuration minimal, the ExtremeXOS tech-support application does not perform authentications. The switch does not verify that the collector is a valid, authorized server before starting the transmission, but the data that has to be transmitted is encrypted.

You can discard or purge the status report from the database for the following reasons:

- The status report is not in a valid format.
- The status report does not contain the minimum required information.
- The serial number of the hardware in the status report is invalid or does not match any serial number in Extreme Network's manufacturing database.
- The status report is received from the same device more than once per hour.

## Configuring Proactive Tech Support

The examination and reporting of switch status is implemented as a loadable application, called `techSupport.xmod`. You can dynamically upgrade the XMOD applications without restarting the switch by issuing `download image ip_address app.xmod`, `run update`, and then `restart process techSupport` commands.

### *Safe Default Startup*

By default proactive tech support services are disabled. You can opt-out of this service either by answering “Yes”, “Y”, or pressing the ENTER key to answer the question that is posed when accessing the switch for the first time. You can also use the `disable tech-support collector` command. Here is the system output prompt for the tech support feature:

```
The switch will proactively attempt to send basic configuration and
operational switch information for the purpose of assisting Extreme
Networks resolve customer reported issues. Uploaded data is encrypted if
the ssh.xmod is installed. Otherwise, a reduced switch data set is sent
in clear text that contains no customer specific information.
```

```
Would you like to disable the automatic switch reporting service? [Y/n]:
```

# Supported Standards, Protocols, and MIBs

**Extreme Networks Proprietary MIBs on page 1891**  
**MIB Support Details on page 2057**

This appendix provides information about the MIB support provided by the ExtremeXOS *SNMP (Simple Network Management Protocol)* agent residing on Extreme Networks devices running ExtremeXOS and Extreme Networks proprietary MIBs.

**Note**

All information for supported standards and protocols can be found in the following location: <http://www.extremenetworks.com/resources>. This appendix contains only the MIB support details.

## Extreme Networks Proprietary MIBs

The Extreme Networks MIBs are located at <http://www.extremenetworks.com/support/policies/mibs/>.

### EXTREME ACL MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group          | Supported Variables        | Comments                                                                                           |
|----------------------|----------------------------|----------------------------------------------------------------------------------------------------|
| extremeAcIStatsTable | extremeAcIStatsVlanIfIndex | The IfIndex of the <i>VLAN (Virtual LAN)</i> in which this policy/rule is applied                  |
|                      | extremeAcIStatsPortIfIndex | The IfIndex of the the port in which this policy/rule is applied                                   |
|                      | extremeAcIDirection        | The ingress/egress direction to which this policy/rule is applied (0 for ingress and 1 for Egress) |
|                      | extremeAcIStatsCounterName | Name of the counter for which the stats is requested                                               |
|                      | extremeAcIStatsPktCount    | The total number of packets that matches this rule                                                 |
|                      | extremeAcIStatsByteCount   | The total number of bytes that matches this rule                                                   |

## CTRON Alias MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group  | Supported Variables | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ctAliasTable |                     | <p>The ctAliasTable contains information about the aliases known by the agent. This table is indexed using a unique and arbitrary ID and a TimeFilter to allow a management station to learn all alias entries that have been modified since time X. This table is NOT designed to do a single GET. This Table is designed for MIB Walks only. This table contains objects that map upper-layer network services and entities to the physical location of the associated port, and the MAC address of the associated end-system (node). All entries in this table are deleted when sysUpTime is reset to zero. This table allows for a time filtered view. It is useful for determining what has been modified in the Alias Table since a specified time. If a management station reads the ctAliasTable of an entity at time X, subsequent updates can be realized by performing get-next requests of this table to determine which entries have been modified since time X. Then the management station can use GET requests to retrieve only the records of interest from the Alias table. There is a delay between retrieving the Alias Reference values from this table, and a GET request to retrieve a modified row from the Alias table. The management station should be prepared for two possibilities: 1) the GET request may fail if the Alias table entry has been deleted during the delay, and 2) the entry may have been modified during the delay, so the modification time of the retrieved entry may differ from the modification time of the Delta entry. If the entry in the Alias Control table identified by ctAliasID is marked inactive by management request, and subsequently deleted to free resources, all corresponding entries in this table are also deleted. If the agent needs to free resources, it can delete entries from this table. It SHOULD first remove those which have been marked inactive in the ctAliasControlTable, then it SHOULD remove those entries with the oldest modification times.</p> |

| Table/Group | Supported Variables | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|             |                     | Access = not-accessible                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|             | CtAliasEntry        | Each entry contains information pertaining to the alias of a node.<br>Access = not-accessible                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|             | ctAliasTimeFilter   | The value of sysUpTime when this entry was last modified.<br>Access = not-accessible                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|             | ctAliasReference    | An integer ID assigned by the agent. The value of this object is equal to an existing ctAliasID.<br>Access = not-accessible                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|             | ctAliasInterface    | The ifIndex of the interface on which this entry was discovered. The ifIndex is an 'external value' that identifies a physical component associated with the Alias entry. This object can be used to identify the physical location of the interface in the ifTable [RFC2863]. The possibility of ifIndex value re-assignment must be accommodated by a management application whenever the value of sysUpTime is reset to zero. Since ifIndex values in different 'naming scopes' are not related to one another, the interface to physical component associations are relative to the same logical entity within the agent. For more discussion of naming scopes, see the ENTITY-MIB [RFC2037].<br>Access = read-only |
|             | ctAliasMacAddress   | The MAC address associated with this alias. The TEXTUAL-CONVENTION MacAddress is defined in SNMPv2-TC as an 802 MAC address represented in 'canonical' order as defined by IEEE 802.1a, i.e., as if it were transmitted least significant bit first."<br>Access = read-only                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|             | ctAliasVlanID       | The <u>VLAN</u> ID contained in the header of the message associated with this alias. On agents which support this MIB but do not support VLANs, the value for this object MUST be (1).<br>Access = read-only                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|             | ctAliasProtocol     | The address type of this alias address.<br>Access = read-only                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|             | ctAliasAddress      | The address associated with this entry. The exact format of this object will depend upon the protocol type in ctAliasProtocol. The value returned for this object MUST be in a non-textual format.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

|---------------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                     |                     | Access = read-only                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                     | ctAliasIsActive     | The status of this entry. A true(1) value indicates the alias is active. A false(2) value indicates an entry which has been marked inactive by network management, using the ctAliasEntryStatus object in the ctAliasControlTable. Entries which have been marked inactive may remain in the table to allow consistent mappings between network management stations until an agent needs to free resources. Access = read-only                |
|                     | ctAliasAddressText  | The address associated with this entry in a human readable textual format. Access = read-only                                                                                                                                                                                                                                                                                                                                                 |
| ctAliasControlTable |                     | This table allows for control of Alias entries. Currently control is limited to marking entries as marked for deletion. If the entry in the Alias Control table identified by ctAliasID is marked inactive by management request, and subsequently deleted to free resources, all corresponding entries in the ctAlias table are also deleted. All entries in this table are deleted when sysUpTime is reset to zero. Access = not-accessible |
|                     | CtAliasControlEntry | Each entry contains a unique identifier of an Alias entry and a control object to mark the entry as 'marked for deletion'. Access = not-accessible                                                                                                                                                                                                                                                                                            |

| Table/Group | Supported Variables | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | ctAliasID           | A unique and arbitrary integer ID assigned by the agent to identify this entry. Each identifier must not be reused until the agent is re-initialized, i.e. sysUpTime is reset to zero.<br>Access = not-accessible                                                                                                                                                                                                                                                                                                                                                                                      |
|             | ctAliasMarkInactive | This object provides the control to mark this entry to inactive. When an entry is created by the agent, this is set to false(2). A network management application can set this value to true(1), indicating that the entry is no longer needed. Once this object has been set to true(1), it cannot be set to false(2). If the alias is detected again by the agent, the agent may create a new entry for the Alias. When an agent needs to free up resources, it may choose to delete those entries marked inactive.<br>Access = read/write                                                           |
|             | ctAliasEntryStatus  | This object provides the control to remove or inactivate entries that are no longer needed. active(1) - indicates that this entry is active. inactive(2) - indicates that this entry is no longer of any interest and can be removed, as needed, by the entity. If the alias is marked inactive and is seen again by the agent, the alias ID's status will be changed to active. remove(3) - indicates that the agent SHOULD immediately remove the entry from the table. If the alias is seen again by the agent after having been removed, it will be added as a new aliasID.<br>Access = read/write |

|                           | ctAliasConfigurationInterfaceTotalEntries | The total number of alias entries currently in use by this ctAliasInterface.<br>Access = read-only                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                           | ctAliasConfigurationInterfaceMaxEntries   | This object represents the maximum number of alias entries in the ctAliasTable which were created by this ctAliasInterface. When the object ctAliasConfigurationInterfaceTotalEntries equals this object, the next alias appearing on this ctAliasInterface causes the oldest entry created by this ctAliasInterface to be deleted. The sum of this object across all ctAliasInterface shall not exceed ctAliasConfigurationSystemTotalEntries. If the value of this object is increased, then oldest entry removal ceases until the maximum is reached again. If management reduces the value of this object, then, starting with the oldest, alias entries are removed until the new number of entries is reached.<br>Access = read/write |
|                           | ctAliasConfigurationInterfaceEnableState  | The enable state of the alias agent on this ctAliasInterface.<br>Access = read/write                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|                           | ctAliasConfigurationNumQueueWraps         | This object represents the number of times the queue for this ctAliasConfigurationEntry has wrapped. Since circular queues are used for storing the entries, when all allocated entries are used, the oldest entries are reused, thus creating a wrap condition. A value of zero indicates the queue has not wrapped, except in the case that the counter itself has wrapped.<br>Access = read-only                                                                                                                                                                                                                                                                                                                                         |

| Table/Group | Supported Variables                     | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------|-----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | ctAliasConfigurationProtocolEnableState | A bit field of the protocol types where a set indicates the detection of that protocol is enabled. A bit position with a cleared bit indicates detection of that protocol is not enabled.<br>Access = read-only                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|             | ctAliasMacAddressInterface              | The ifIndex of the interface on which this entry was discovered. The ifIndex is an 'external value' that identifies a physical component associated with the Alias entry. This object can be used to identify the physical location of the interface in the ifTable [RFC2863]. The possibility of ifIndex value re-assignment must be accommodated by a management application whenever the value of sysUpTime is reset to zero. Since ifIndex values in different 'naming scopes' are not related to one another, the interface to physical component associations are relative to the same logical entity within the agent. For more discussion of naming scopes, see the ENTITY-MIB [RFC2037]<br>Access = read-only |
|             | ctAliasMacAddressVlanID                 | The VLAN ID contained in the header of the message associated with this alias. On agents which support this MIB but do not support VLANs, the value for this object MUST be (1).<br>Access = read-only                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|             | ctAliasMacAddressIsActive               | The status of this entry. A true(1) value indicates the alias is active. A false(2) value indicates an entry which has been marked inactive by network management, using the ctAliasEntryStatus object in the ctAliasControlTable. Entries which have been marked inactive may remain in the table to allow consistent mappings between network management stations until an agent needs to free resources.<br>Access = read-only                                                                                                                                                                                                                                                                                      |
|             | ctAliasMacAddressAddressText            | The address associated with this entry in a human readable textual format.<br>Access = read-only                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|             | ctAliasProtocolAddressInterface   | The ifIndex of the interface on which this entry was discovered. The ifIndex is an 'external value' that identifies a physical component associated with the Alias entry. This object can be used to identify the physical location of the interface in the ifTable [RFC2863]. The possibility of ifIndex value re-assignment must be accommodated by a management application whenever the value of sysUpTime is reset to zero. Since ifIndex values in different 'naming scopes' are not related to one another, the interface to physical component associations are relative to the same logical entity within the agent. For more discussion of naming scopes, see the ENTITY-MIB [RFC2037]<br>Access = read-only |
|             | ctAliasProtocolAddressVlanID      | The VLAN ID contained in the header of the message associated with this alias. On agents which support this MIB but do not support VLANs, the value for this object MUST be (1).<br>Access = read-only                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|             | ctAliasProtocolAddressIsActive    | The status of this entry. A true(1) value indicates the alias is active. A false(2) value indicates an entry which has been marked inactive by network management, using the ctAliasEntryStatus object in the ctAliasControlTable. Entries which have been marked inactive may remain in the table to allow consistent mappings between network management stations until an agent needs to free resources.<br>Access = read-only                                                                                                                                                                                                                                                                                      |

|                           | ctAliasInterfaceVlanID      | The VLAN ID contained in the header of the message associated with this alias. On agents which support this MIB but do not support VLANs, the value for this object MUST be (1).<br>Access = read-only                                                                                                                                                                                                                                |
|                           | ctAliasInterfacelsActive    | The status of this entry. A true(1) value indicates the alias is active. A false(2) value indicates an entry which has been marked inactive by network management, using the ctAliasEntryStatus object in the ctAliasControlTable. Entries which have been marked inactive may remain in the table to allow consistent mappings between network management stations until an agent needs to free resources.<br>Access = read-only     |
|                           | ctAliasInterfaceAddressText | The address associated with this entry in a human readable textual format.<br>Access = read-only                                                                                                                                                                                                                                                                                                                                      |
|                           | ctAliasInterfaceTime        | The value of sysUpTime when this entry was last modified.<br>Access = read-only                                                                                                                                                                                                                                                                                                                                                       |
| ctAliasMacAddressTable    |                             | The ctAliasMacAddressTable contains information about the aliases known by the agent indexed by MAC address and protocol. This table contains information that is identical to the ctAliasTable, but it is instanced by MAC address and protocol to allow management entities to search for a MAC address and protocol, or part of a MAC address and protocol, using a single <i>SNMP</i> GetNext request.<br>Access = not-accessible |
|                           | ctAliasMacAddressEntry      | Each entry contains information pertaining to the alias of a node in a table indexed by MAC address, protocol type, protocol address, and alias ID.<br>Access = not-accessible                                                                                                                                                                                                                                                        |
| ctAliasBasicGroup         |                             | A collection of objects for the discovery and mapping of end systems and aliases.                                                                                                                                                                                                                                                                                                                                                     |
| ctAliasStatsGroup         |                             | A collection of objects pertaining to discovery and mapping of end systems and aliases.                                                                                                                                                                                                                                                                                                                                               |
| ctAliasControlGroup       |                             | This group has been deprecated. See ctAliasControlGroupl.                                                                                                                                                                                                                                                                                                                                                                             |
| ctAliasConfigurationGroup |                             | A collection of objects for configuring port buffer queues.                                                                                                                                                                                                                                                                                                                                                                           |

| Table/Group                 | Supported Variables | Comments                                                                                           |
|-----------------------------|---------------------|----------------------------------------------------------------------------------------------------|
| ctAliasMacAddressGroup      |                     | A collection of objects for the discovery and mapping of end systems and aliases.                  |
| ctAliasProtocolAddressGroup |                     | A collection of objects for the discovery and mapping of end systems and aliases.                  |
| ctAliasControlGroup         |                     | A collection of objects which make the Aliases accessible using the TimeFilter TEXTUAL CONVENTION. |
| ctAliasGroup                |                     | An object used for removing alias entries.                                                         |
| ctAliasConfigurationGroup   |                     | An object to indicate queue usage.                                                                 |
| ctAliasConfigurationGroup 2 |                     | A collection of objects for configuring port buffer queues.                                        |
| ctAliasInterfaceGroup       |                     | A collection of objects for the discovery and mapping of end systems and aliases.                  |

## EXTREME-CFGMGMT-MIB

This MIB provides the ability to query configuration activity and to perform switch management operations. The following features are part of this MIB:

- Expose the time and date of the last configuration save operation.
- Issue a notification to NMS upon completion of a database save operation.
- Provide the ability for ExtremeXOS to report on-demand the presence of unsaved configuration changes on the system.
- Issue a notification whenever any system configuration is altered, added, or deleted.

The following tables, groups, and variables are supported in this MIB.

| Table/Group             | Supported Variables           | Comments                                                                                                                                                                                                                                            |
|-------------------------|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeLastSaveCfgTable | extremeLastSavedEntry         | This group of objects contain details of the last saved configuration operation for the running configure. If the value of extremeLastChangeConfigTime is greater than extremeLastSaveConfigTime, the configuration has been changed but not saved. |
|                         | extremeLastSaveConfigSlotId   | Specifies the MSM/MM module number of a switch or the slot number currently being used by the active stack node.                                                                                                                                    |
|                         | extremeLastSaveConfigTime     | This object return the date and time of the last configuration save operation. This data reflects the last command or the last setting of the extremeSaveConfiguration object.                                                                      |
|                         | extremeLastSaveConfigFileName | This object returns the configuration file name of the last save operation.                                                                                                                                                                         |
|                         | extremeLastSaveConfigSource   | This object indicates the source of the last configuration save operation for the configuration file associated with this entry, extremeLastSaveConfigFileName .                                                                                    |

| Table/Group               | Supported Variables             | Comments                                                                                                                                                                                                                                            |
|---------------------------|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeLastChangeCfgTable | extremeLastChangeEntry          | This group of objects contain details of the last change configuration operation for the running configure. If the value of extremeLastChangeConfigTime is greater than extremeLastSaveConfigTime, the configuration has been changed but not saved |
|                           | extremeLastChangeConfigSlotId   | Specifies the slot number currently being used by the active stack node.                                                                                                                                                                            |
|                           | extremeLastChangeConfigTime     | This object returns the date and time of the last configuration change operation. This data reflects the last command or the last setting of the extremeSaveConfiguration object.                                                                   |
|                           | extremeLastChangeConfigFileName | This object returns the configuration file name of the last change operation.                                                                                                                                                                       |
|                           | extremeLastChangeConfigSource   | This object indicates the source of the last configuration change operation for extremeLastChangeConfigFileName.                                                                                                                                    |
| cfgMgmtTraps              | cfgMgmtConfigSaveTrap           | This notification indicates that the running configuration of the managed system has updated the NVRAM storage of the current configuration.                                                                                                        |
|                           | cfgMgmtConfigChangeTrap         | This notification contain details of the last change configuration operation for the running configure.                                                                                                                                             |
| cfgMgmtControl            | cfgMgmtConfigSaveTrapEnable     | This variable indicates whether the system produces the cfgMgmtConfigSaveTrap notification. A false value prevents notifications from being generated by this system.                                                                               |
|                           | cfgMgmtConfigChangeTrapEnable   | This variable indicates whether the system produces the cfgMgmtConfigChangeTrap notification. A false value prevents notifications from being generated by this system.                                                                             |

## ENTERASYS-APPLICATION-SIGNATURE-MIB

| Table/Group             | Supported Variables    | Comments                                                                                                                     |
|-------------------------|------------------------|------------------------------------------------------------------------------------------------------------------------------|
| Application Group Table | etsysAppSignGroupTable | A table that contains the standard Application Groups for the Extreme Network deep packet inspection engine. Not-accessible. |
|                         | etsysAppSignGroupEntry | An entry that ties a given application Group Name to a particular application group ID. Not-accessible.                      |
|                         | etsysAppSignGroupId    | A pre-defined unique group index that points to the group to which the application belongs. Not-accessible.                  |
|                         | etsysAppSignGroupName  | A pre-defined application group name. Read-only.                                                                             |

| Table/Group                    | Supported Variables              | Comments                                                                                                                                                                                                                                                                                                           |
|--------------------------------|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Application Display Name Table | etsysAppSignDisplayNameTable     | A table that describes attributes of a user-defined application display name.<br>Not-accessible.                                                                                                                                                                                                                   |
|                                | etsysAppSignDisplayNameEntry     | Describes a particular entry within the etsysAppSignDisplayNameTable.<br>"<br>Not-accessible.                                                                                                                                                                                                                      |
|                                | etsysAppSignDisplayId            | A unique ID assigned to a specific extended signature. The user can only assign an index in a range from 5,000 to 5,999. The rest of the indices are reserved for internal use.<br>Not-accessible.                                                                                                                 |
|                                | etsysAppSignDisplayName          | A user-friendly name assigned to this extended signature. The display name and display ID <i>must</i> be unique within the scope of a single managed entity. This object <i>must not</i> be modifiable while this entry's RowStatus is active (1) or if etsysAppSignDisplayId is a reserved index.<br>Read-create. |
|                                | etsysAppSignDisplayNameRowStatus | This object allows for the dynamic creation and deletion of entries within the etsysAppSignDisplayNameTable as well as the activation and deactivation of these entries.<br>Read-create.                                                                                                                           |

| Table/Group                      | Supported Variables          | Comments                                                                                                                                                                                                                                                                                                                        |
|----------------------------------|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Application Pattern String Table | etsysAppSignPatternTable     | A table that describes attributes of a user-defined pattern string. Not-accessible.                                                                                                                                                                                                                                             |
|                                  | etsysAppSignPatternEntry     | An entry describing the matching pattern of a WebAppRule and its assigned index. For use by the Extreme Networks deep packet inspection engine. Not-accessible.                                                                                                                                                                 |
|                                  | etsysAppSignPatternIndex     | A unique identifier for a pattern string. The user can only assign an index in a range from 1,000,000 to 2,000,000. The rest of the indices are reserved for internal use. Not-accessible.                                                                                                                                      |
|                                  | etsysAppSignPattern          | A case-sensitive string for matching against the 'host' field of an HTTP request packet, or the 'server name' in the 'client Hello' packet of a TLS session. This is used to identify the application. Read-create.                                                                                                             |
|                                  | etsysAppSignPatternRowStatus | This object allows the dynamic creation and deletion of entries within the etsysAppSignPatternTable, as well as the activation and deactivation of these entries. etsysAppSignPatternRowStatus <i>must not</i> be set to active (1) and createAndGo(4) if the etsysAppSignPattern object contains an empty string. Read-create. |

## ENTERASYS-CONVERGENCE-END-POINT-MIB

| Table/Group                          | Supported Variables                        | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------------------------|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysConvEndPointGlobalConfig Enable |                                            | When set to enabled(1) this object activates the current Convergence End Point configuration. When set to disabled(2) this MIB SHALL be configurable, but MUST NOT be applied, all entries will be removed from the etsysConvEndPointConnMacTable and the etsysConvEndPointConnPortTable, and any policies that have been changed as a result of End Point detection will revert to their default states. Maintaining the value of this object across agent reboots is REQUIRED. Read-write.        |
| etsysConvEndPointGlobalConfig Table  |                                            | This table represents all Convergence End Point types supported by this entity, and provides a default policy profile for each Convergence End Point type. Not-accessible.                                                                                                                                                                                                                                                                                                                          |
|                                      | etsysConvEndPointGlobalConfig Entry        | Defines the default policy to be applied when this type of Convergence End Point is detected or discovered. Not-accessible.                                                                                                                                                                                                                                                                                                                                                                         |
|                                      | etsysConvEndPointGlobalDefault PolicyIndex | The policy that should be applied for this type of Convergence End Point. This value is an etsysPolicyProfileIndex as defined in the ENTERASYS-POLICY-PROFILE-MIB. If no such policy index exists, then no policy will be applied when this type of Convergence End Point is detected or discovered. The value zero is not a valid etsysPolicyProfileIndex, so zero indicates that no policy should be applied. Maintaining the value of this object across system reboots is REQUIRED. Read-write. |

| Table/Group                                | Supported Variables | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------------------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysConvEndPointProtocolConfigTable       |                     | This table provides control of Convergence End Point detection and discovery on a per interface and per Convergence End Point type basis. Maintaining the values of this table across system reboots is REQUIRED. Not-accessible.                                                                                                                                                                                                                                                                                                 |
| etsysConvEndPointProtocolConfigEntry       |                     | The current Convergence End Point detection and discovery status for an interface. Not-accessible.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| etsysConvEndPointProtocolEndPointType      |                     | The Convergence End Point type. Not-accessible.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| etsysConvEndPointProtocolEnable            |                     | When set to enabled(1), Convergence End Point detection and discovery will be enabled on this interface for the Convergence End Point type specified. When set to disabled(2), the Convergence End Points that have been discovered or detected on this interface of the type specified will be removed from the etsysConvEndPointConnMacTable and the etsysConvEndPointConnPortTable. After all of the End Points have been removed from an interface the policy on that interface will revert to its default state. Read-write. |
| etsysConvEndPointGlobalConfigAccountEnable |                     | When enabled(1), <i>RADIUS (Remote Authentication Dial In User Service)</i> accounting start, interim and stop frames are sent to the configured RADIUS server(s). When disabled(2), accounting packets are not sent to the RADIUS server. Read-write.                                                                                                                                                                                                                                                                            |

| Table/Group                   | Supported Variables                     | Comments                                                                                                                                                                                                                                                 |
|-------------------------------|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysConvEndPointConnMacTable |                                         | This table provides information on each of the Convergence End Points that has been discovered or detected by this entity. Maintaining the value of this object across system reboots is NOT REQUIRED. Not-accessible.                                   |
|                               | etsysConvEndPointConnMacEntry           | Information about an individual Convergence End Point. Not-accessible.                                                                                                                                                                                   |
|                               | etsysConvEndPointConnMacMacAddress      | The MAC address of this Convergence End Point. Not-accessible.                                                                                                                                                                                           |
|                               | etsysConvEndPointConnMacPortNumber      | The interface on which this Convergence End Point was detected or discovered. Read-only.                                                                                                                                                                 |
|                               | etsysConvEndPointConnMacEndPointType    | The type of Convergence End Point described by this row. Read-only.                                                                                                                                                                                      |
|                               | etsysConvEndPointConnMacPolicyIndex     | The policy applied for this Convergence End Point. This value is an etsysPolicyProfileIndex as defined in the ENTERASYS-POLICY-PROFILE-MIB. If the desired policy does not currently exist, or never did exist, then a zero MUST be returned. Read-only. |
|                               | etsysConvEndPointConnMacDiscoveryTime   | The time and date that this Convergence End Point was detected or discovered. Read-only.                                                                                                                                                                 |

|             | etsysConvEndPointDetectionTable      | <p>A table that describes the IP address and IP port based Convergence End Point detection parameters. Packets on interfaces that are configured to detect End Points, via the etsysConvEndPointProtocolConfigTable, that are defined in this table are inspected to determine if a Convergence End Point exists on that interface. Rules applying to Convergence End Point types that are configured for detection are evaluated according to the following:</p> <ol style="list-style-type: none"> <li>1. If etsysConvEndPointDetectionProtocol does not have any bits set, this indicates that the port based detection should not be performed, proceed to step 2. Otherwise the value in etsysConvEndPointDetectionProtocol is evaluated against the protocol field in the IP header, if it is of a, or the, type specified then the destination port must be between the values of etsysConvEndPointDetectionPortLow and etsysConvEndPointDetectionPortHigh, inclusive.</li> <li>2. If the etsysConvEndPointDetectionAddr is null, this indicates that no detection address check should be performed, consider the End Point detected. Otherwise the value the of etsysConvEndPointDetectionAddr will be masked with the value of etsysConvEndPointDetectionAddrMask, via a bitwise AND</li> </ol> |

Only ports that are capable of participating in Cisco CDP protocol are represented in this table.<br>Not-accessible.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                            | etsysCEPCdpPortConfigEntry         | An entry containing per port Convergence End Point data. Only interfaces that are able to detect Convergence End Points are represented in this table.<br>Not-accessible.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                            | etsysCEPCiscoCDPVoicePortVlan      | This object controls the behavior of the remote configuration of Cisco VOIP phones via Cisco CDP. Setting this object to a value of -1 will cause the device to not attempt to remotely configure a Cisco phone using CDP. Setting this object to a value of 0 will cause the device to configure the phone to send 802.1p priority tagged frames. A value of 4095 will cause the device to configure the phone to send untagged frames. A value in the range 1..4094 will cause the device to configure the phone to send 802.1Q tagged frames using that value as the <u>VLAN</u> ID encoded in the tag. This object SHOULD be maintained across device reboots.<br>Read-write. |
|                            | etsysConvEndPointGlobalConfigGroup | Objects which provide global control of the Convergence End Point features.<br>Status = deprecated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## EXTREME ENTERASYS ENTITY SENSOR MIB

The Extreme Enterasys Entity Sensor MIB's extremeEntityTempSfpSensorExtEntry contains objects for representing per transceiver sensor information that extends the information provided in the Entity Sensor MIB Extensions' entPhySensorTable of the SFP/QSFP. The following table list the objects supported.

| Table/Group                     | Description                                                                                              | Comments   |
|---------------------------------|----------------------------------------------------------------------------------------------------------|------------|
| etsysEntitySfpSensorState       | Integer indicates temperature state of sensor                                                            | Read-only  |
| etsysEntitySfpSensorHighAlarm   | Integer representing the sensor's high alarm threshold                                                   | Read-only  |
| etsysEntitySfpSensorHighWarning | Integer representing the sensor's high warning threshold                                                 | Read-only  |
| etsysEntitySfpSensorLowAlarm    | Integer representing the sensor's low alarm threshold                                                    | Read-only  |
| etsysEntitySfpSensorLowWarning  | Integer representing the sensor's low warning threshold                                                  | Read-only  |
| etsysEntitySfpSensorTrapEnable  | Indicates if notification will be sent when sensor state changes as defined by etsysEntitySfpSensorState | Read-Write |

## ENTERASYS-MAC-AUTHENTICATION-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group                       | Supported Variables                               | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------------------|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysMACAuthenticationSystemGroup | etsysMACAuthenticationSystemEnable                | When enabled(1), all objects in this MIB are fully active. When disabled(2), this object overrides all other object settings in this MIB without affecting their values.                                                                                                                                                                                                                                                                                                                    |
|                                   | etsysMACAuthenticationMACUserPassword             | This is the string to be used as a password credential when authenticating a MAC address when etsysMACAuthenticationMode is set to sharedSecret(1).                                                                                                                                                                                                                                                                                                                                         |
|                                   | etsysMACAuthenticationPortUserNameSignificantBits | This object represents the number of significant bits in the MAC addresses to be used starting with the left-most bit of the vendor portion of the MAC address. The significant portion of the MAC address is sent as a user-name credential when the primary attempt to authenticate the full MAC address fails. Any other failure to authenticate the full address, (i.e. authentication server timeout) causes the the next attempt to start once again with a full MAC authentication." |
|                                   | etsysMACAuthenticationMode                        | This object is used to determine the type of password credential to use when authenticating a MAC address.<br>password(1) - Attempt to authenticate a user with the password credential provided by etsysMACAuthenticationMACUserPassword.<br>radiusUsername(2) - Attempt to authenticate a user with a password credential that is the same as their radius username credential.                                                                                                           |
|                                   | etsysMACAuthenticationSystemAccountEnable         | When enabled(1), RADIUS accounting start, interim and stop frames are sent to the configured RADIUS server(s). When disabled(2), accounting packets are not sent to the RADIUS server.                                                                                                                                                                                                                                                                                                      |
|                                   | etsysMACAuthenticationSystemUserNameCase          | "When LOWER(1), the user-name credential is the MAC address formatted as xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx or xxxxxxxxxxxx. When set to UPPER(2), the user-name credential is the MAC address formatted as XX:XX:XX:XX:XX:XX or XX-XX-XX-XX-XX-XX or XXXXXXXXXXXXX." DEFVAL { upper } ::= { etsysMACAuthenticationSystem 7 }                                                                                                                                                           |
|                                   |                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Table/Group                           | Supported Variables                      | Comments                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------|------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysMACAuthenticationPortConfigGroup | etsysMACAuthenticationPortConfigTable    | A table containing configuration objects for each MAC authentication port. The configuration for each port in this table must be non-volatile.                                                                                                                                                                                                                                  |
|                                       | etsysMACAuthenticationPortConfigEntry    | Each conceptual row provides control over all of the initial values used by each authenticated MAC on this port. Subsequent changes to rows in this table, except where noted, have no effect on existing MACs authenticated on this port.                                                                                                                                      |
|                                       | etsysMACAuthenticationPort               | This is the InterfaceIndex associated with this row.                                                                                                                                                                                                                                                                                                                            |
|                                       | etsysMACAuthenticationPortInitialize     | When set to true(1), the MAC authentication logic on this port is initialized, forcibly ending all MAC authentication sessions currently in existence on this port. A set with the value false(2) has no affect and a read always returns false.                                                                                                                                |
|                                       | etsysMACAuthenticationPortReauthenticate | When set to true(1), the MAC authentication entity on this port is required to immediately verify all currently authenticated MACs on this port. This requires that each MAC address be authenticated with the authentication server through the local authentication client or some other authentication mechanism. Each supplicant remains authenticated pending the outcome. |
|                                       | etsysMACAuthenticationPortEnable         | When set to enabled(1), a platform dependent triggering mechanism initiates an authentication exchange using a MAC address for authentication credentials. When disabled(2), authentication attempts are disabled and all currently authenticated MAC sessions or those in the process of authentication on this port are terminated.                                           |
|                                       | etsysMACAuthenticationPortQuietPeriod    | The value, in seconds, following a failed authentication before another may be attempted on this port. This object allows network management to provide hysteresis for failed authentication requests from the same port.                                                                                                                                                       |
|                                       | etsysMACAuthenticationPortReauthPeriod   | The value, in seconds, between attempts to re-authenticate any current MAC authenticated on this port.                                                                                                                                                                                                                                                                          |
|                                       | etsysMACAuthenticationPortReauthEnabled  | If enabled(1), then every etsysMACAuthenticationReauthPeriod the switch attempts to validate all currently authenticated MACs on this                                                                                                                                                                                                                                           |

| Table/Group | Supported Variables                            | Comments                                                                                                                                                                                                                                                                                                                                                                         |
|-------------|------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |                                                | port. When set to disabled(2) all current re-authentications in progress are allowed to complete and the requisite actions are taken. When set to disabled(2), no further re-authentications are attempted.                                                                                                                                                                      |
|             | etsysMACAuthenticationAuthenticationsAllowed   | The maximum number of concurrent authentications supported on this port on this module. The default value of this object is platform and resource dependent.                                                                                                                                                                                                                     |
|             | etsysMACAuthenticationAuthenticationsAllocated | The maximum number of MAC authentications permitted on this port on this module. This value must be non-zero and be less than or equal to the value of etsysMACAuthenticationAuthenticationsAllowed. Setting this object to a value less than the current number of authenticated MACs on this port prevents further authentications, but has no affect on the current sessions. |
|             | etsysMACAuthenticationLastFailedAuthCause      | The string will be formatted with 'XX-XX-XX-XX-XX-XX: TIME&DATE: Textual failure reason'; where XX-XX-XX-XX-XX-XX is the MAC address and TIME&DATE is the time (hh/mm/ss) and date (mm/dd/yyyy) of the failure. It is also only best effort; as there could be multiple failures per port and the agent may query this at any random time.                                       |

| Table/Group                          | Supported Variables                     | Comments                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------------------------|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysMACAuthenticationMACConfigGroup | etsysMACAuthenticationMACConfigTable    | A table containing configuration objects for each MAC authenticated on a port. Each row in this table is created dynamically when a MAC authenticates on a port.                                                                                                                                                                                                                                   |
|                                      | etsysMACAuthenticationMACConfigEntry    | Each conceptual row inherits its initial information from the row in the etsysMACAuthenticationPortConfigTable corresponding to the correct port. Each row represents an authenticated MAC.                                                                                                                                                                                                        |
|                                      | etsysMACAuthenticationMACAddress        | This is the MAC address that was authenticated on this port.                                                                                                                                                                                                                                                                                                                                       |
|                                      | etsysMACAuthenticationSupplierPort      | This is the InterfaceIndex associated with this rows authenticated MAC.                                                                                                                                                                                                                                                                                                                            |
|                                      | etsysMACAuthenticationMACInitialize     | When set to true(1), this MAC session terminates causing the corresponding row in this table and in the etsysMACAuthenticationSessionTable to be removed. Setting this object to false(2) has no effect on the system. Reads of this object always return false(2).                                                                                                                                |
|                                      | etsysMACAuthenticationMACReauthenticate | When set to true(1), this MAC authentication session on this port is required to immediately verify its credentials. This requires that each MAC address be authenticated with the authentication server through the local authentication client or some other authentication mechanism. Setting this object to false(2) has no effect on the system. Reads of this object always return false(2). |
|                                      | etsysMACAuthenticationMACReauthPeriod   | The value, in seconds, between attempts to re-authenticate the MAC associated with this row.                                                                                                                                                                                                                                                                                                       |
|                                      | etsysMACAuthenticationMACReauthEnabled  | If enabled(1), then every etsysMACAuthenticationReauthPeriod the switch attempts to validate all currently authenticated MACs on this port. If disabled(2), reauthentication is not attempted.                                                                                                                                                                                                     |

| Table/Group                        | Supported Variables                | Comments                                                                                                                                                                                                                                                                                                                                           |
|------------------------------------|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysMACAuthenticationSessionGroup | etsysMACAuthenticationSessionTable | A table containing configuration objects for each MAC authentication on a port. The successful completion of an authentication causes the creation of a new row in this table. When a MAC becomes unauthenticated because of a link-down, a management change, or system re-initialization, then the corresponding row is removed from this table. |
|                                    | etsysMACAuthenticationSessionEntry | Each conceptual row inherits its initial information from the row in the etsysMACAuthenticationPortConfigTable corresponding to the correct port. Each row represents an authenticated MAC.                                                                                                                                                        |
|                                    | etsysMACAuthenticationSessionPort  | This is the InterfaceIndex associated with the authenticated MACs session.                                                                                                                                                                                                                                                                         |
|                                    | etsysMACAuthenticationDuration     | The value, in seconds, which have elapsed since the start of this session.                                                                                                                                                                                                                                                                         |

## ENTERASYS-MIRROR-CONFIG-MIB

The following tables, groups, and variables are supported in this MIB.

**Table 174: ENTERASYS-MIRROR-CONFIG-MIB**

| Table/Group                                        | Supported Variables | Comments                                                                                              |
|----------------------------------------------------|---------------------|-------------------------------------------------------------------------------------------------------|
| etsysMirrorSystemMaxLocalMirrors                   |                     | This value represents the maximum number of local mirrors that the device supports. Read-only         |
| etsysMirrorSystemMaxRemoteMirrors                  |                     | This value represents the maximum number of remote mirrors that the device supports. Read-only        |
| etsysMirrorSystemMaxLocalMirrorDestinationPorts    |                     | This value represents the maximum number of destination ports supported for a local mirror. Read-only |
| etsysMirrorSystemMaxMirrorDestinationControlGroups |                     | This value represents the maximum number of rows in the etsysMirrorDestinationControlTable. Read-only |

**Table 174: ENTERASYS-MIRROR-CONFIG-MIB (continued)**

| Table/Group                          | Supported Variables | Comments                                                                                                                                                                 |
|--------------------------------------|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysMirrorSystemMaxMirrorFirst<br>N |                     | This value represents the maximum configurable number of initial packets of a flow that can be mirrored. If this value is 0, this feature is not supported.<br>Read-only |

**Table 174: ENTERASYS-MIRROR-CONFIG-MIB (continued)**

| Table/Group  | Supported Variables                      | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Mirror Table | etsysMirrorDestinationNextAvailableIndex | <p>This object indicates the numerically lowest available index within this entity, which may be used for the value of etsysMirrorDestinationControlIndex in the creation of a new entry in the etsysMirrorDestinationControlTable.</p> <p>An index is considered available if the index value falls within the range of 1 to (newLeaf with max dest groups) and is not being used to index an existing entry in the etsysMirrorDestinationControlTable contained within this entity. A value of zero indicates that all of the entries in the etsysMirrorDestinationControlTable are currently in use. This value SHOULD only be considered a guideline for management creation of etsysMirrorDestinationControlTable entries, there is no requirement on management to create entries based upon this index value.</p> <p>Read-only</p> |
|              | etsysMirrorDestinationControlTable       | <p>Controls the setup of mirror destination ports on the managed device.</p> <p>Not-accessible</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|              | etsysMirrorDestinationControlEntry       | <p>A conceptual row in the etsysMirrorDestinationControlTable.</p> <p>Not-accessible</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|              | etsysMirrorDestinationControlIndex       | <p>A unique arbitrary index for this etsysMirrorDestinationControlEntry. This object MUST have a value between 1 and etsysMirrorSystemMaxMirrorDestinationControlGroups.</p> <p>Not-accessible</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|              | etsysMirrorDestinationControlOwner       | <p>Administratively assigned name of the owner of this entry. It usually defines the entity that created this entry and is therefore using the resources assigned to it, though there is no</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## ENTERASYS-MULTI-AUTH-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group                          | Supported Variables                   | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------------|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Multiple Authentication System Group | etsysMultiAuthSystemSupportedTypes    | This object specifies that authentication types that the device supports. A bit will be set for each corresponding type that is supported.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                                      | etsysMultiAuthSystemMaxNumUsers       | The maximum number of users the can be actively authenticated or have authentications in progress at one time in the system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                                      | etsysMultiAuthSystemCurrentNumUsers   | The current number of users the are actively authenticated, have authentications in progress, or the device is keeping authentication termination information for in the system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|                                      | etsysMultiAuthSystemMode              | The value strictIEEE8021x(1) will cause the device to authenticate in strict adherence to IEEE Std. 802.1X-2001. In this mode no other authentication mechanisms will be active. While in this mode, changes may be made to other objects in the MIB, but they will have no effect on the operation of the device until such time as the system mode is changed to etsysMultiAuth(2). A set of this object to a value of etsysMultiAuth(2) will cause the device to authenticate using multiple authenticators simultaneously.                                                                                                                                                                  |
|                                      | etsysMultiAuthSystemDefaultPrecedence | The precedence that authentication results will be applied to network traffic by default. This object will have a size equal to the number of enumerations specified by the EtsysMultiAuthTypes textual convention.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|                                      | etsysMultiAuthSystemAdminPrecedence   | This object allows one to modify the default precedence by which authentication results will be applied to network traffic. Sets to this object are not required to specify all of the types that the device supports. If less types are specified than are supported, then all types that were not specified will be given an operational precedence based on that type's default precedence relative to the last type specified. For example, if the default precedence is '030102'H and the object is set to '02'H then operational precedence would be '020301'H. A set to this object of a zero length octet string will clear the administrative precedence. In this case the operational |

|             |                                    | precedence would be equal to the default precedence.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|             | etsysMultiAuthSystemOperPrecedence | This object returns the operational precedence of authentication types as they will be applied to network traffic. The value returned by this object is the calculated result of the etsysMultiAuthSystemDefaultPrecedence and etsysMultiAuthSystemAdminPrecedence objects. This object will have a size equal to the number of enumerations specified by the EtsysMultiAuthTypes textual convention.                                                                                                                                                         |
|             | etsysMultiAuthTypeProperties Table | A table of properties per authentication type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|             | etsysMultiAuthTypeProperties Entry | An entry containing per authentication type properties.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|             | etsysMultiAuthType                 | The authentication type the entry properties pertain to.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|             | etsysMultiAuthSessionTimeout       | The maximum number of seconds an authenticated session may last before termination of the session. A value of zero indicates that no session timeout will be applied. This value MAY be superseded by a session timeout value provided by the authenticating server. For example, if a session is authenticated by a RADIUS server, that server may encode a Session-Timeout Attribute in its authentication response. The operational timeout value of a given authenticated session is specified by the etsysMultiAuthSessionSessionTimeout object.         |
|             | etsysMultiAuthIdleTimeout          | The maximum number of consecutive seconds an authenticated session may be idle before termination of the session. A value of zero indicates that no idle timeout will be applied. This value MAY be superseded by a idle timeout value provided by the authenticating server. For example, if a session is authenticated by a RADIUS server, that server may encode a Idle-Timeout Attribute in its authentication response. The operational idle timeout value of a given authenticated session is specified by the etsysMultiAuthSessionIdleTimeout object. |
|             | etsysMultiAuthCurrentNumUsers      | The current number of users the are actively authenticated or have                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Table/Group | Supported Variables                               | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Multiple Authentication Port Group | etsysMultiAuthPortTable            | A table of per port information and configuration for user authentication.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                                    | -etsysMultiAuthPortEntry           | An entry containing per port authentication data. Only interfaces that are able to authenticate users are represented in this table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|                                    | etsysMultiAuthPortMode             | <p>This object specifies the authorization mode to use for packets received on this interface.</p> <p>A value of forceUnauthorized(1) indicates that the interface is always unauthenticated.</p> <p>A value of forceAuthorized(2) indicates that users on this port will always be considered to be authenticated.</p> <p>A value of authOptional(3) indicates that authentication is optional on this interface. Packets received from unauthenticated users on the interface will be processed using the static configuration of the interface. Users may promote the policy applied to their traffic by actively authenticating on this interface.</p> <p>A value of authRequired(4) indicates that all packets received on the interface will be dropped until authentication succeeds. Some authentication types, such as PWA, will not be fully functional in this mode of operation.</p> |
|                                    | etsysMultiAuthPortMaxNumUsers      | The maximum number of users that can be actively authenticated or have authentications in progress at one time on this interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|                                    | etsysMultiAuthPortNumUsers Allowed | The user configured number of users that can be actively authenticated or have authentications in progress at one time on this interface. This object has a default value equal to the value of etsysMultiAuthPortMaxNumUsers for this interface. If the value set to this object is less than its current value, it will have the same effect as setting the etsysMultiAuthPortClearUsers object to a value of true(1).                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                                    | etsysMultiAuthPortCurrentNumUsers  | The current number of users that are actively authenticated or have authentications in progress at one time on this interface. By definition this value can not exceed the value specified by                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Table/Group | Supported Variables                   | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |                                       | etsysMultiAuthPortMaxNumUsers for the same interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|             | etsysMultiAuthPortClearUsers          | Setting this object to a value of true(1) will cause all users that are currently authenticated or that have authentications in progress on this interface to become unauthenticated. This will cause any such entries with matching ifIndex values in the etsysMultiAuthSessionStationTable tables to change their authorization status to authTerminated(5)<br>Setting this object to a value of false(2) has no effect. This object will always return a value of false(2).                                                                                                                                         |
|             | etsysMultiAuthPortTrapEnable          | This object allows for the enabling or disabling of each trap on a per interface basis. Setting a given bit to a value of 1 allows traps of that type to be sent for events on that interface. Setting a given bit to a value of 0 disallows traps of that type to be sent for events on that interface. The individual bits correlate to specific traps as follows:<br>BIT NOTIFICATION<br>-----<br>----- authSuccessTrap(0)<br>etsysMultiAuthSuccess authFailedTrap(1)<br>etsysMultiAuthFailed<br>authTerminatedTrap(2)<br>etsysMultiAuthTerminated<br>maxNumUsersReachedTrap(3)<br>etsysMultiAuthMaxNumUsersReached |
|             | etsysMultiAuthPortTypeTable           | A table of per port, per authentication type information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|             | etsysMultiAuthPortTypeEntry           | An entry containing per port, per authentication type data. Only interfaces that are able to authenticate users are represented in this table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|             | etsysMultiAuthPortTypeCurrentNumUsers | The current number of users that are actively authenticated or have authentications in progress for this authentication type on the specified port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Table/Group                                                                    | Supported Variables                    | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Multiple Authentication Station Group<br>Multiple Authentication Session Group | etsysMultiAuthStationTable             | A table of station configuration on specific interfaces.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                                                                                | etsysMultiAuthStationEntry             | An entry containing authentication information on a per station, per port basis. Only interfaces that are able to authenticate users are represented in this table.                                                                                                                                                                                                                                                                                                                                        |
|                                                                                | etsysMultiAuthStationAddrType          | The type of station represented by etsysMultiAuthStationAddr.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|                                                                                | etsysMultiAuthStationAddr              | The station address for the authenticated user.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                                                                                | etsysMultiAuthStationClearUsers        | Setting this object to a value of true(1) will cause any users with the specified station address that are currently authenticated or that have authentications in progress to become unauthenticated. This will cause any entries with matching etsysMultiAuthStationAddr values in the etsysMultiAuthSessionStationTable tables to change their authorization status to authTerminated(5). Setting this object to a value of false(2) has no effect. This object will always return a value of false(2). |
|                                                                                | etsysMultiAuthSessionStationTable      | A table of session information and configuration for user authentication. Entries in this table represent users in various stages of authentication. Entries that do not have a etsysMultiAuthSessionStationAuthStatus value of authSuccess(1) or authInProgress(3) MAY be removed by the agent as required in order to free resources for new user authentications.                                                                                                                                       |
|                                                                                | etsysMultiAuthSessionStationEntry      | An entry containing authentication information on a per station, per port, per authentication agent type basis. Only interfaces that are able to authenticate users are represented in this table.                                                                                                                                                                                                                                                                                                         |
|                                                                                | etsysMultiAuthSessionAgentType         | The type of authentication agent for this session.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                                                                                | etsysMultiAuthSessionStationAuthStatus | The status of authentication for this session.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|                                                                                | etsysMultiAuthSessionAuthAttemptTime   | The value of sysUpTime when this session last attempted authorization. For entries that have a value of authInProgress(3) for                                                                                                                                                                                                                                                                                                                                                                              |

|             | The network address of the authentication server for this session. If the etsysMultiAuthSessionAuthServerType leaf for this entry has a value of local(2) then this object MUST return a zero length string. | The Policy Profile Index returned from the authentication server for this session. The value of zero indicates that no policy will be applied for this session. If the etsysMultiAuthSessionStationAuthStatus object returns a value of authSuccess(1), then a value of zero is the result of the policy not being configured on the authorization server. For all other values of etsysMultiAuthSessionStationAuthStatus a value of zero for this object is the result of authorization not succeeding or not having completed. All values other than zero are valid Policy Profile Indexes that specify the policy profile the user will receive on this interface. If a given user has been authenticated by multiple authentication types on the same interface the policy that is applied to the user's packets is determined by the precedence of the agents as specified by etsysMultiAuthSystemOperPrecedence. These indexes are suitable for indexing in the ENTERASYS-POLICY-PROFILE-MIB. |
|             | etsysMultiAuthSessionIsApplied                                                                                                                                                                               | This object indicates whether this entry and the policy index contained within it are actively being applied to traffic                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|----------------------------------------|--------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Multiple Authentication Module Group   | etsysMultiAuthModuleTable                        | A table of per module information for user authentication.                                                                                                                                                                                                                                  |
|                                        | etsysMultiAuthModuleEntry                        | An entry containing per module authentication data. Only physical indexes with a entPhysicalClass of module(9) are represented in this table. Furthermore, each entity represented in this table must have authentication resources that are separate from every other entity in the table. |
|                                        | etsysMultiAuthModuleMaxNumUsers                  | The maximum number of users that can be actively authenticated or have authentications in progress at one time on the specified module.                                                                                                                                                     |
|                                        | etsysMultiAuthModuleCurrentNumUsers              | The current number of users that are actively authenticated or have authentications in progress at one time on the specified module. By definition this value can not exceed the value specified by etsysMultiAuthModuleMaxNumUsers for the same module.                                    |
|                                        | etsysMultiAuthModuleMaxNumUsersReachedTrapEnable | This object allows for the enabling or disabling the transmission of the etsysMultiAuthModuleMaxNumUsersReached NOTIFICATION.                                                                                                                                                               |
| Multiple Authentication Counters Group | etsysMultiAuthCounterTable                       | A table of per station and port user counter data.                                                                                                                                                                                                                                          |
|                                        | etsysMultiAuthCounterEntry                       | An entry containing user counter data.                                                                                                                                                                                                                                                      |
|                                        | etsysMultiAuthCounterInboundBytes                | The number of bytes of user data received on this interface.                                                                                                                                                                                                                                |
|                                        | etsysMultiAuthCounterInboundPackets              | The number of packets of user data received on this interface.                                                                                                                                                                                                                              |
|                                        | etsysMultiAuthCounterOutboundBytes               | The number of bytes of user data transmitted on this interface.                                                                                                                                                                                                                             |
|                                        | etsysMultiAuthCounterOutboundPackets             | The number of packets of user data transmitted on this interface.                                                                                                                                                                                                                           |
|                                        | etsysMultiAuthCounterEnable                      | This object allows for the enabling or disabling of per-user counters.                                                                                                                                                                                                                      |

| Table/Group                                | Supported Variables                        | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------------------|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Multiple Authentication Notification Group | etsysMultiAuthSuccess NOTIFICATION-TYPE    | An etsysMultiAuthSuccess trap signifies that the SNMP entity, acting in an agent role, has successfully authenticated a station on one of its interfaces. The included objects of etsysMultiAuthStationAddrType and etsysMultiAuthStationAddr uniquely identify the station that has been authenticated. The interface that the station was authenticated on is specified by the ifIndex object, and the type of authentication used to authenticate the station is specified by the etsysMultiAuthSessionAgentType object. This trap will only be generated on interfaces that are in the authOptional(3) or authRequired(4) state.                                    |
|                                            | etsysMultiAuthFailed NOTIFICATION-TYPE     | An etsysMultiAuthFailed trap signifies that the SNMP entity, acting in an agent role, has identified a station that attempted and subsequently failed to authenticate on one of its interfaces. The included objects of etsysMultiAuthStationAddrType and etsysMultiAuthStationAddr uniquely identify the station that attempted to authenticate. The interface that the station attempted to authenticate on is specified by the ifIndex object, and the type of authentication attempted is specified by the etsysMultiAuthSessionAgentType object. This trap will only be generated on interfaces that are in the authOptional(3) or authRequired(4) state.          |
|                                            | etsysMultiAuthTerminated NOTIFICATION-TYPE | An etsysMultiAuthTerminated trap signifies that the SNMP entity, acting in an agent role, has terminated the authentication of a station on one of its interfaces. The included objects of etsysMultiAuthStationAddrType and etsysMultiAuthStationAddr uniquely identify the station for which authentication was terminated. The interface that the station was previously authenticated on is specified by the ifIndex object, and the type of authentication that the station was terminated for is specified by the etsysMultiAuthSessionAgentType object. This trap will only be generated on interfaces that are in the authOptional(3) or authRequired(4) state. |

| Table/Group | Supported Variables                                      | Comments                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------|----------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | etsysMultiAuthMaxNumUsersReached NOTIFICATION-TYPE       | An etsysMultiAuthMaxNumUsersReached trap signifies that the SNMP entity, acting in an agent role, has an interface where subsequent to a successful authentication, the number of current sessions on the interface equals the maximum number of sessions allowed for that interface. The interface that the maximum number of sessions has been reached is specified by the ifIndex object.   |
|             | etsysMultiAuthModuleMaxNumUsersReached NOTIFICATION-TYPE | An etsysMultiAuthModuleMaxNumUsersReached trap signifies that the SNMP entity, acting in an agent role, has a module where subsequent to a successful authentication, the number of current sessions on the module equals the maximum number of sessions allowed for that module. The module that the maximum number of sessions has been reached is specified by the entPhysicalIndex object. |
|             | etsysMultiAuthSystemMaxNumUsersReached NOTIFICATION-TYPE | An etsysMultiAuthSystemMaxNumUsersReached trap signifies that the SNMP entity, acting in an agent role, where subsequent to a successful authentication, has the number of current sessions on the system equals the maximum number of sessions allowed for that system, .                                                                                                                     |

## ENTERASYS-MULTI-USER-8021X-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group                | Supported Variables                                            | Comments                                                                                                                                                                                                                                                   |
|----------------------------|----------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 802.1X System Group        | etsysMultiixSystemAccountEnable                                | When enabled(1), RADIUS accounting start, interim and stop frames are sent to the configured RADIUS server(s). When disabled(2), accounting packets are not sent to the RADIUS server.                                                                     |
| 802.1X Access Entity Table | etsysMultiixAccessEntityTable                                  | The system and configuration information for all the Access Entities.                                                                                                                                                                                      |

|             |                                                    | result of an EAPOL-Logoff message being received from the Supplicant.                                                                                                                                                                                                                                              |
|             | etsysMulti1xAeAuthReauthsWhileAuthenticated        | Counts the number of times that the state machine transitions from AUTHENTICATED to CONNECTING, as a result of a reauthentication request (reAuthenticate = TRUE).                                                                                                                                                 |
|             | etsysMulti1xAeAuthEapStartsWhileAuthenticated      | Counts the number of times that the state machine transitions from AUTHENTICATED to CONNECTING, as a result of an EAPOL-Start message being received from the Supplicant.                                                                                                                                          |
|             | etsysMulti1xAeAuthEapLogoffWhileAuthenticated      | Counts the number of times that the state machine transitions from AUTHENTICATED to DISCONNECTED, as a result of an EAPOL-Logoff message being received from the Supplicant.                                                                                                                                       |
|             | etsysMulti1xAeBackendResponses                     | Counts the number of times that the state machine sends an initial Access-Request packet to the Authentication server (i.e., executes sendRespToServer on entry to the RESPONSE state). Indicates that the Authenticator attempted communication with the Authentication Server.                                   |
|             | etsysMulti1xAeBackendAccessChallenges              | Counts the number of times that the state machine receives an initial Access-Challenge packet from the Authentication server (i.e., aReq becomes TRUE, causing exit from the RESPONSE state). Indicates that the Authentication Server has communication with the Authenticator.                                   |
|             | etsysMulti1xAeBackendOtherRequestsToSupplicant     | Counts the number of times that the state machine sends an EAP-Request packet (other than an Identity, Notification, Failure or Success message) to the Supplicant (i.e., executes txReq on entry to the REQUEST state). Indicates that the Authenticator chose an EAP-method.                                     |
|             | etsysMulti1xAeBackendNonNakResponsesFromSupplicant | Counts the number of times that the state machine receives a response from the Supplicant to an initial EAP-Request, and the response is something other than EAP-NAK (i.e., rxResp becomes TRUE, causing the state machine to transition from REQUEST to RESPONSE, and the response is not an EAP-NAK). Indicates |

| Table/Group                     | Supported Variables                | Comments                                                                                                                                                                                                                                                                                  |
|---------------------------------|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                 |                                    | that the Supplicant can respond to the Authenticator's chosen EAP-method.                                                                                                                                                                                                                 |
|                                 | etsysMulti1xAeBackendAuthSuccesses | Counts the number of times that the state machine receives an EAP-Success message from the Authentication Server (i.e., aSuccess becomes TRUE, causing a transition from RESPONSE to SUCCESS). Indicates that the Supplicant has successfully authenticated to the Authentication Server. |
|                                 | etsysMulti1xAeBackendAuthFails     | Counts the number of times that the state machine receives an EAP-Failure message from the Authentication Server (i.e., aFail becomes TRUE, causing a transition from RESPONSE to FAIL). Indicates that the Supplicant has not authenticated to the Authentication Server.                |
| 802.1X Session Statistics Table | etsysMulti1xSessionStatsTable      | The session statistics for all the Access Entities.                                                                                                                                                                                                                                       |
|                                 | etsysMulti1xSessionStatsEntry      | The session statistics for an individual Access Entity. This shows the current values being collected for each session that is still in progress, or the final values for the last valid session on each Access Entity where there is no session currently active.                        |
|                                 | etsysMulti1xSessionOctetsRx        | The number of octets of user data received on this port for this session.                                                                                                                                                                                                                 |
|                                 | etsysMulti1xSessionOctetsTx        | The number of octets of user data transmitted on this port for this session.                                                                                                                                                                                                              |
|                                 | etsysMulti1xSessionFramesRx        | The number of user data frames received on this port for this session.                                                                                                                                                                                                                    |
|                                 | etsysMulti1xSessionFramesTx        | The number of user data frames transmitted on this port for this session.                                                                                                                                                                                                                 |
|                                 | etsysMulti1xSessionId              | A unique identifier for the session, in the form of a printable ASCII string of at least three characters.                                                                                                                                                                                |
|                                 | etsysMulti1xSessionAuthenticMethod | The authentication method used to establish the session.                                                                                                                                                                                                                                  |
|                                 | etsysMulti1xSessionTime            | The duration of the session in seconds.                                                                                                                                                                                                                                                   |
|                                 | etsysMulti1xSessionTerminateCause  | The reason for the session termination.                                                                                                                                                                                                                                                   |
|                                 | etsysMulti1xSessionUserName        | The User-Name representing the identity of the Supplicant PAE.                                                                                                                                                                                                                            |
|                                 | etsysMulti1xSessionActive          | Indicates if this session is currently active.                                                                                                                                                                                                                                            |

|-----------------------------------|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 802.1X Supplicant Address Table   | etsysMulti1xSupplicantAddressTable  | The Access Entities relative to the supplicant MAC address, port, and access entity index.                                                                                                                                                                                                                                                                                    |
|                                   | etsysMulti1xSupplicantAddressEntry  | Some basic information about an individual Access Entity.                                                                                                                                                                                                                                                                                                                     |
|                                   | etsysMulti1xSupplicantActive        | Indicates if the associated Access Entity is currently active.                                                                                                                                                                                                                                                                                                                |
|                                   | etsysMulti1xSupplicantUserName      | The User-Name representing the identity of the Supplicant PAE.                                                                                                                                                                                                                                                                                                                |
| 802.1X User Name Table            | etsysMulti1xUserNameTable           | The Access Entities relative to the supplicant user name, or the initial part of the supplicant user name, port, and access entity index.                                                                                                                                                                                                                                     |
|                                   | etsysMulti1xUserNameEntry           | Some basic information about an individual Access Entity.                                                                                                                                                                                                                                                                                                                     |
|                                   | etsysMulti1xUserNameIndex           | The fixed length equivalent of the etsysMulti1xUserName object. When the length of the corresponding etsysMulti1xUserName object is less than 8 octets this object is padded with null octets. When the length of the corresponding etsysMulti1xUserName object is greater than 8 octets this object has the value of the etsysMulti1xUserName object truncated to 20 octets. |
|                                   | etsysMulti1xUserName                | The User-Name representing the identity of the Supplicant PAE.                                                                                                                                                                                                                                                                                                                |
|                                   | etsysMulti1xUserActive              | Indicates if the associated Access Entity is currently active.                                                                                                                                                                                                                                                                                                                |
|                                   | etsysMulti1xUserAddress             | The User-Name representing the identity of the Supplicant PAE.                                                                                                                                                                                                                                                                                                                |
| 802.1X Active Access Entity Table | etsysMulti1xActiveAccessEntityTable | The active Access Entities.                                                                                                                                                                                                                                                                                                                                                   |
|                                   | etsysMulti1xActiveAccessEntityEntry | An individual active Access Entity.                                                                                                                                                                                                                                                                                                                                           |
|                                   | etsysMulti1xActiveSupplicantAddress | The MAC address that this active Access Entity is currently bound to.                                                                                                                                                                                                                                                                                                         |

## ENTERASYS-POLICY-PROFILE-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group              | Supported Variables                       | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------------|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysPolicyProfile group | etsysPolicyProfileMaxEntries              | The maximum number of entries allowed in the etsysPolicyProfileTable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                          | etsysPolicyProfileNumEntries              | The current number of entries in the etsysPolicyProfileTable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                          | etsysPolicyProfileLastChange              | The sysUpTime at which the etsysPolicyProfileTable was last modified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                          | etsysPolicyProfileTableNextAvailableIndex | This object indicates the numerically lowest available index within this entity, which may be used for the value of etsysPolicyProfileIndex in the creation of a new entry in the etsysPolicyProfileTable.<br>An index is considered available if the index value falls within the range of 1 to 65535 and is not being used to index an existing entry in the etsysPolicyProfileTable contained within this entity.<br>This value should only be considered a guideline for management creation of etsysPolicyProfileEntries, there is no requirement on management to create entries based upon this index value. |
|                          | etsysPolicyProfileTable                   | A table containing policy profiles. A policy is a group of classification rules which may be applied on a per user basis, to ports or to stations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                          | etsysPolicyProfileEntry                   | Conceptually defines a particular entry within the etsysPolicyProfileTable. Entries within this table MUST be considered non-volatile and MUST be maintained across entity resets.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                          | etsysPolicyProfileIndex                   | A unique arbitrary identifier for this Policy. Since a policy will be applied to a user regardless of his or her location in the network fabric policy names SHOULD be unique within the entire network fabric. Policy IDs and policy names MUST be unique within the scope of a single managed entity.                                                                                                                                                                                                                                                                                                             |
|                          | etsysPolicyProfileName                    | Administratively assigned textual description of this Policy. This object MUST NOT be modifiable while this entry's RowStatus is active(1).                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                          | etsysPolicyProfileRowStatus               | This object allows for the dynamic creation and deletion of entries within the etsysPolicyProfileTable as well as the activation and deactivation of these entries.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Table/Group | Supported Variables | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|-------------|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |                                    | A value of (0) indicates no HTTP Redirect group is specified for this profile.                                                                                                                                                                                                                                                                                                                                                                                       |
|             | etsysPolicyProfilePortAuthOverride | If a port has an active policy and that policy's etsysPolicyProfilePortAuthOverride is set to enabled(1), all frames arriving on the port will have that policy applied. In addition, any pre-existing entries with matching port values in the etsysMultiAuthSessionStationTable tables will change their authorization status to authTerminated(5). No further authentication will occur on this port. If disabled(2), the actions described above will not occur. |

|                                 | etsysPolicyClassificationLastChange | The sysUpTime at which the etsysPolicyClassificationTable was last modified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|                                 | etsysPolicyClassificationTable      | A table containing reference OIDs to entries within the classification tables. These classification tables include but may not be limited to:<br>ctPriClassifyTable<br>ctVlanClassifyTable<br>ctRatePolicingConfigTable<br>This table is used to map a list of classification rules to an instance of the etsysPolicyProfileTable.                                                                                                                                                                                                                       |
|                                 | etsysPolicyClassificationEntry      | Describes a particular entry within the etsysPolicyClassificationTable. Entries within this table MUST be considered non-volatile and MUST be maintained across entity resets.                                                                                                                                                                                                                                                                                                                                                                           |
|                                 | etsysPolicyClassificationIndex      | Administratively assigned unique value, greater than zero. Each etsysPolicyClassificationIndex instance MUST be unique within the scope of its associated etsysPolicyProfileIndex.                                                                                                                                                                                                                                                                                                                                                                       |
|                                 | etsysPolicyClassificationOID        | This object follows the RowPointer textual convention and is an OID reference to a classification rule. This object MUST NOT be modifiable while this entry's etsysPolicyClassificationStatus object has a value of active(1).                                                                                                                                                                                                                                                                                                                           |
|                                 | etsysPolicyClassificationRowStatus  | The status of this row.<br>When set to active(1) this entry's classification rule, as referenced by etsysPolicyClassificationOID, becomes one of its associated policy's set of rules.<br>When this entry's associated policy, as defined by etsysPolicyProfileIndex, is active and assigned to a port through the etsysPortPolicyProfileTable or to a station through the etsysStationPolicyProfileTable, this classification rule will be applied to the port or station. The exact behavior of this application depends upon the classification rule. |

| Table/Group                  | Supported Variables                  | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------------------|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                              |                                      | When this object is set to notInService(2) or notReady(3) this entry is not considered one of its associated policy's set of rules and this classification rule will not be applied. An entry MAY NOT be set to active(1) unless this row's etsysPolicyClassificationOID is set to a valid classification rule.                                                                                                                                                                                                                                           |
|                              | etsysPolicyClassificationIngressList | The ports on which an active policy profile has defined this classification rule applies.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| etsysPortPolicyProfile group | etsysPortPolicyProfileLastChange     | sysUpTime at which the etsysPortPolicyProfileTable was last modified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                              | etsysPortPolicyProfileEntry          | Describes a particular entry within the etsysPortPolicyProfileTable. Entries within this table MUST be considered non-volatile and MUST be maintained across entity resets.                                                                                                                                                                                                                                                                                                                                                                               |
|                              | etsysPortPolicyProfileIndexType      | This object defines the specific type of port this entry represents.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                              | etsysPortPolicyProfileIndex          | An index value which represents a unique port of the type defined by this entry's etsysPortPolicyProfileIndexType.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|                              | etsysPortPolicyProfileAdminID        | This object represents the desired Policy Profile for this dot1dBasePort or this ifIndex.<br>Setting this object to any value besides zero (0) should, if possible, immediately place this entry's dot1dBasePort or ifIndex into the given Policy Profile.<br>This object and etsysPortPolicyProfileOperID may not be the same if this object is set to a Policy (i.e. an instance of the etsysPolicyProfileTable) which is not in an active state or if the etsysPortPolicyProfileOperID has been set by an underlying security protocol such as RADIUS. |

| Table/Group | Supported Variables                    | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|--------------------------------|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                |                                   | by an underlying security protocol such as RADIUS.                                                                                                                                                                                                                                                                                                                                                                          |
|                                | etsysStationPolicyProfilePortType | A textual convention that defines the specific type of port designator the corresponding entry represents.                                                                                                                                                                                                                                                                                                                  |
|                                | etsysStationPolicyProfilePortID   | A value which represents the physical port, of the type defined by this entry's etsysStationPolicyProfilePortType, on which the associated station entity is connected. This object is for convenience in cross referencing stations to ports.                                                                                                                                                                              |
| etsysInvalidPolicyPolicy group | etsysInvalidPolicyAction          | Specifies the action that the edge device should take if asked to apply an invalid or unknown policy.<br>applyDefaultPolicy(1) - Ignore the result and search for the next policy assignment rule.<br>dropPackets(2) - Block traffic.<br>forwardPackets(3) - Forward traffic, as if no policy had been assigned (via 802.1D/Q rules).<br>Although dropPackets(2) is the most secure option, it may not always be desirable. |
|                                | etsysInvalidPolicyCount           | Increments to indicate the number of times the device has detected an invalid/unknown policy.                                                                                                                                                                                                                                                                                                                               |
| etsysDevicePolicyProfile group | etsysDevicePolicyProfileDefault   | If this value is non-zero, the value indicates the etsysPolicyProfileEntry (and its associated etsysPolicyClassificationTable entries) which should be used by the device if the device is incapable of using the profile (or specific parts of the profile) explicitly applied to an inbound frame. A value of zero indicates that no default profile is currently active.                                                 |

| Table/Group                 | Supported Variables                 | Comments                                                                                                                                                                                                                                                                                                                            |
|-----------------------------|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysPolicyCapability group | etsysPolicyCapabilities             | A list of capabilities related to policies. A set bit, with the value 1, indicates support for the described functionality. A clear bit, with the value 0, indicates the described functionality is not supported.                                                                                                                  |
|                             | etsysPolicyDynaPIDRuleCapabilities  | A list of rule types which are supported by this device for the purpose of dynamically assigning a profile to the network traffic described by the bit. A set bit, with the value 1, indicates support for the described functionality. A clear bit, with the value 0, indicates the described functionality is not supported.      |
|                             | etsysPolicyAdminPIDRuleCapabilities | A list of rule types which are supported by this device for the purpose of administratively assigning a profile to the network traffic described by the bit. A set bit, with the value 1, indicates support for the described functionality. A clear bit, with the value 0, indicates the described functionality is not supported. |
|                             | etsysPolicyVlanRuleCapabilities     | A list of rule types which are supported by this device for the purpose of assigning a VlanId to the network traffic described by the bit. A set bit, with the value 1, indicates support for the described functionality. A clear bit, with the value 0, indicates the described functionality is not supported.                   |
|                             | etsysPolicyCosRuleCapabilities      | A list of rule types which are supported by this device for the purpose of assigning a CoS to the network traffic described by the bit. A set bit, with the value 1, indicates support for the described functionality. A clear bit, with the value 0, indicates the described functionality is not supported.                      |
|                             | etsysPolicyDropRuleCapabilities     | A list of rule types which are supported by this device for the purpose of discarding the network traffic described by the bit. A set bit, with the value 1, indicates support for the described functionality. A clear bit, with the value                                                                                         |

| Table/Group | Supported Variables                    | Comments                                                                                                                                                                                                                                                                                                                                                             |
|-------------|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |                                        | 0, indicates the described functionality is not supported.                                                                                                                                                                                                                                                                                                           |
|             | etsysPolicyForwardRuleCapabilities     | A list of rule types which are supported by this device for the purpose of forwarding the network traffic described by the bit. A set bit, with the value 1, indicates support for the described functionality. A clear bit, with the value 0, indicates the described functionality is not supported.                                                               |
|             | etsysPolicySyslogRuleCapabilities      | A list of rule types which are supported by this device for the purpose of issuing syslog messages when the rule is used to identify the network traffic described by the bit. A set bit, with the value 1, indicates support for the described functionality. A clear bit, with the value 0, indicates the described functionality is not supported.                |
|             | etsysPolicyTrapRuleCapabilities        | A list of rule types which are supported by this device for the purpose of issuing an SNMP notify (trap) messages when the rule is used to identify the network traffic described by the bit. A set bit, with the value 1, indicates support for the described functionality. A clear bit, with the value 0, indicates the described functionality is not supported. |
|             | etsysPolicyDisablePortRuleCapabilities | A list of rule types which are supported by this device for the purpose of disabling the ingress port identified when the rule matches the network traffic described by the bit. A set bit, with the value 1, indicates support for the described functionality. A clear bit, with the value 0, indicates the described functionality is not supported.              |
|             | etsysPolicySupportedPortList           | The list ports which support policy profile assignment (i.e. the ports which <u>_do_</u> policy). This object may be useful to management entities which desire to scope action to only those ports which support policy. A port which appears in this list, must support, at minimum, the assignment                                                                |

| Table/Group | Supported Variables                  | Comments                                                                                                                                                                                                                                                                                                                                                                             |
|-------------|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |                                      | of a policy profile to all traffic ingressing the port.                                                                                                                                                                                                                                                                                                                              |
|             | etsysPolicyEnabledTable              | This table allows for the configuration of policy profile assignment methods, per port, including the ability to disable policy profile assignment, per port. In addition, a ports capabilities, with respect to policy profile assignment are reported.                                                                                                                             |
|             | etsysPolicyEnabledTableEntry         | Describes a particular entry within the etsysPolicyEnabledTable.                                                                                                                                                                                                                                                                                                                     |
|             | etsysPolicyEnabledSupportedRuleTypes | The list of rule types which the devices supports for the purpose of assigning policy profiles to network traffic ingressing this dot1dBasePort.                                                                                                                                                                                                                                     |
|             | etsysPolicyEnabledEnabledRuleTypes   | The list of rule types from which the device will assign policy profiles to network traffic ingressing this dot1dBasePort. Rules which have a type not enumerated here must not be used to assign policy profiles, but must still be used to interrogate the rule-set bound to the determined policy profile. A set of all cleared bits will effectively disable policy in the port. |
|             | etsysPolicyEnabledEgressEnabled      | Controls the enabling and disabling the application of policy as packets egress the switching process on the dot1dBasePort specified in the indexing.                                                                                                                                                                                                                                |
|             | etsysPolicyRuleAttributeTable        | This table details each supported rule type attribute for rule data length in bytes, rule data length in bits, and the maximum number of rules that may use that type.                                                                                                                                                                                                               |
|             | etsysPolicyRuleAttributeTableEntry   | Describes a particular entry within the etsysPolicyRuleAttributeTable.                                                                                                                                                                                                                                                                                                               |
|             | etsysPolicyRuleAttributeByteLength   | This rule type's maximum length, in bytes of the etsysPolicyRuleData. Devices supporting this object MUST allow sets for this rule data of any valid length up to and including the length value represented by this object. Management entities must also expect to read back the maximum data length for each type regardless of the length the data was set with.                 |
|             | etsysPolicyRuleAttributeBitLength    | This rule type's maximum bit length for traffic data. This value also                                                                                                                                                                                                                                                                                                                |

| Table/Group | Supported Variables                     | Comments                                                                                                                                                                                                                                                                                                                                                                            |
|-------------|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |                                         | represents the maximum mask that may be used for rule data. The mask MUST NOT exceed the rule data size. Masks that exceed the data size shall be considered invalid and result in an SNMP set failure.                                                                                                                                                                             |
|             | etsysPolicyRuleAttributeMaxCreatable    | If this value is non-zero, the value indicates the maximum number of rules of this type the agent can support.                                                                                                                                                                                                                                                                      |
|             | etsysPolicyRuleTciOverwriteCapabilities | A list of rule types which are supported by this device for the purpose of overwriting the TCI in received packets described by the bit. A set bit, with the value 1, indicates support for the described functionality. A clear bit, with the value 0, indicates the described functionality is not supported.                                                                     |
|             | etsysPolicyRuleMirrorCapabilities       | A list of rule types which are supported by this device for the purpose of mirroring the network traffic described by the bit. A set bit, with the value 1, indicates support for the described functionality. A clear bit, with the value 0, indicates the described functionality is not supported.                                                                               |
|             | etsysPolicyRuleQuarantineCapabilities   | A list of rule types which are supported by this device for the purpose of quarantining the user to a specified profile id when the rule is used to identify the network traffic described by the bit. A set bit, with the value of 1, indicates support for the described functionality. A clear bit, with the value of 0, indicates the described functionality is not supported. |

| Table/Group               | Supported Variables               | Comments                                                                                                                                                                                                                                                                                                                                 |

| etsysPolicyMapPolicyIndex | This has been obsoleted.          |                                                                                                                                                                                                                                                                                                                                          |
| etsysPolicyRules group    | etsysPolicyRulesMaxEntries        | The maximum number of entries allowed in the etsysPolicyRulesTable.                                                                                                                                                                                                                                                                      |
|                           | etsysPolicyRulesNumEntries        | The current number of entries in the etsysPolicyRulesTable.                                                                                                                                                                                                                                                                              |
|                           | etsysPolicyRulesLastChange        | The sysUpTime at which the etsysPolicyRulesTable was last modified.                                                                                                                                                                                                                                                                      |
|                           | etsysPolicyRulesAccountingEnable  | Controls the collection of rule usage statistics. If disabled, no usage statistics are gathered and no auditing messages will be sent. When enabled, rule will gather usage statistics, and auditing messages will be sent, if enabled for a given rule.                                                                                 |
|                           | etsysPolicyRulesPortDisabled List | A portlist containing bits representing the dot1dBridgePorts which have been disabled via the mechanism described in the etsysPolicyRuleDisablePort leaf. A set bit indicates a disabled port. Ports may be enabled by performing a set with the corresponding bit cleared. Bits which are set will be ignored during the set operation. |

| Table/Group          | Supported Variables         | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysPolicyRuleTable | etsysPolicyRuleTable        | A table containing rules bound to individual policies. A Rule is comprised of three components, a unique description of the network traffic, an associated list of actions, and an associated list of accounting and auditing controls and information. The unique description of the network traffic, defined by a PolicyClassificationRuleType together with a length, matching data and a relevant bits field, port type, and port number (port number zero is reserved to mean any port), and scoped by a etsysPolicyProfileIndex, is used as the table index. |
|                      | etsysPolicyRuleEntry        | Describes a particular entry within the etsysPolicyRuleTable. Entries within this table MUST be considered non-volatile and MUST be maintained across entity resets.                                                                                                                                                                                                                                                                                                                                                                                               |
|                      | etsysPolicyRuleProfileIndex | The etsysPolicyProfileIndex for which the rule is defined. A value of zero(0) has special meaning in that it scopes rules which are used to determine the Policy Profile to which the frame belongs. See the etsysPolicyRuleResult1 and etsysPolicyRuleResult2 descriptions for specifics of how the results of a rule hit differ when the etsysPolicyRuleProfileIndex is zero.                                                                                                                                                                                    |
|                      | etsysPolicyRuleType         | The type of network traffic reference by the etsysPolicyRuleData.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                      | etsysPolicyRuleData         | The data pattern to match against, as defined by the etsysPolicyRuleType, encoded in network-byte order.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                      | etsysPolicyRulePrefixBits   | The relevant number of bits defined by the etsysPolicyRuleData, to be used when matching against a frame, relevant bits are specified in longest-prefix-first style (left to right). A value of zero carries the special meaning of all bits are relevant.                                                                                                                                                                                                                                                                                                         |
|                      | etsysPolicyRulePortType     | The port number on which the rule will be applied. Zero(0) is a special case, indicating that the rule should be applied to all ports.                                                                                                                                                                                                                                                                                                                                                                                                                             |
|                      | etsysPolicyRulePort         | The port number on which the rule will be applied. Zero(0) is a special case,                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

|--------------------------|-------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysPolicyRulePortTable | etsysPolicyRulePortTable                        | The purpose of this table is to provide an agent the ability to easily determine which rules have been used on a given bridge port. A row will only be present when the rule which the instancing describes has been used. The agent may remove a row (and clear the used status) by setting the etsysPolicyRulePortHit leaf to False. PolicyClassificationRuleType together with a length, matching data and a relevant bits field, port type, and port number (port number zero is reserved to mean any port), scoped by a etsysPolicyRuleProfileIndex, and preceded by a dot1dBasePort is used as the table index. |
|                          | etsysPolicyRulePortEntry                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                          | etsysPolicyRulePortHit                          | Every row will report a value of True, indicating that the Rule described by the instancing was used on the given port. An agent may be set this leaf to False to clear remove the row and clear the Rule Use bit for the specified Rule, on the given bridgePort.                                                                                                                                                                                                                                                                                                                                                    |
|                          | etsysPolicyRuleDynamicProfileAssignmentOverride | If true, administratively assigned profile assignment rules override dynamically assigned profiles assignments for a given rule. If false, the dynamically assigned value (typically created by a successful authentication attempt) overrides the administratively configured value. The agent may optionally implement this leaf as read-only.                                                                                                                                                                                                                                                                      |
|                          | etsysPolicyRuleDefaultDynamicSyslogStatus       | If enabled(1), rules dynamically created will set etsysPolicyRuleAuditSyslogEnable to enabled. If disabled(2) a dynamically created rule will have etsysPolicyRuleAuditSyslogEnable set to disabled. The agent may optionally implement this leaf as read-only.                                                                                                                                                                                                                                                                                                                                                       |
|                          | etsysPolicyRuleDefaultDynamicTrapStatus         | If enabled(1), rules dynamically created will set etsysPolicyRuleAuditTrapEnable to enabled. If disabled(2) a dynamically created rule will have etsysPolicyRuleAuditTrapEnable set to                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Table/Group | Supported Variables                    | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------|----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |                                        | disabled. The agent may optionally implement this leaf as read-only.                                                                                                                                                                                                                                                                                                                                                                                                                       |
|             | etsysPolicyRuleStatsAutoClearOnLink    | If set to enabled(1), when operstatus up is detected on any port the agent will clear the rule usage information associated with that port. This ability is further scoped to the list of ports defined by etsysPolicyRuleStatsAutoClearPorts. This leaf is optional and will have no effect on an agent which has rule use accounting disabled or does not support rule use accounting. By default, the rule use accounting information will not be modified by operstatus transitions.   |
|             | etsysPolicyRuleStatsAutoClearInterval  | The interval at which the device will automatically clear rule usage statistics, in minutes. This ability is disabled (usage statistics will not be automatically cleared) if set to zero(0). This ability is further scoped to the list of ports defined by etsysPolicyRuleStatsAutoClearPorts. This leaf is optional and will have no effect on an agent which has rule use accounting disabled or does not support rule use accounting.                                                 |
|             | etsysPolicyRuleStatsAutoClearPorts     | The list ports on which rule usage statistics will be cleared by one of the AutoClear actions (etsysPolicyRuleStatsAutoClearInterval, etsysPolicyRuleStatsAutoClearOnProfile, or etsysPolicyRuleStatsAutoClearOnLink). By default, no ports will be set in this list. This leaf is optional, unless the agent claims support for one of the other 'autoclear' objects, and will have no effect on an agent which has rule use accounting disabled or does not support rule use accounting. |
|             | etsysPolicyRuleStatsAutoClearOnProfile | If set to enabled(1), when a rule assigning a PolicyProfile (whose etsysPolicyRuleProfileIndex is zero(0)) is activated, all the rule usage bits associated with the rules bound to the PolicyProfile specified by the etsysPolicyRuleOperPid and the port specified by the etsysPolicyRulePort are cleared (if there is no port specified or no valid                                                                                                                                     |

| Table/Group | Supported Variables                       | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |                                           | etsysPolicyRuleProfileIndex specified, then no action follows). This ability is further scoped to the list of ports defined by etsysPolicyRuleStatsAutoClearPorts. This leaf is optional and will have no effect on an agent which has rule use accounting disabled or does not support rule use accounting. By default, the rule use accounting information will not be modified by the creation or activation of PolicyProfile assignment rules." DEFVAL { disabled } |
|             | etsysPolicyRuleStatsDropped Notifications | A count of the number of times the agent has dropped notification (syslog or trap) of a etsysPolicyRuleUsageList bit transition. A management entity might use this leaf as an indication to read the etsysPolicyRuleUsageList objects for important rules. This count should be kept to the best of the device's ability, and explicitly does not cover notifications discarded by the network.                                                                        |
|             | etsysPolicyRuleSylogMachineReadableFormat | If enabled, the device should format rule usage messages so that they might be processed by a machine (scripting backend, etc). If disabled, the messages should be formatted for human consumption.                                                                                                                                                                                                                                                                    |
|             | etsysPolicyRuleSylogExtendedFormat        | If enabled, the device should provide additional information in rule-hit syslog messages. This information MAY include what actions may have been initiated by the rule (if any) or data mined from the packet which matched the rule.                                                                                                                                                                                                                                  |
|             | etsysPolicyRuleSylogEveryTime             | If enabled, the device will syslog on every rule hit (or profile hit) which specifies SYSLOG as the action, instead of only when the associated bit in the etsysPolicyProfileUsageList or the etsysPolicyRuleUsageList is clear. It should be noted that this may cause MANY messages to be generated.                                                                                                                                                                  |

| Table/Group                     | Supported Variables                   | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------------|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysPolicyNonVolatileRuleTable | etsysPolicyNonVolatileRulesLastChange | The sysUpTime at which the etsysPolicyNonVolatileRuleTable was last modified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                                 | etsysPolicyNonVolatileRuleTable       | A table containing rules bound to individual policies. The rules here contained are representations of the non-volatile rules contained in the etsysPolicyRuleTable defined in this MIB.<br>A Rule comprises three components, a unique description of the network traffic, an associated list of actions, and an associated list of accounting and auditing controls and information. The unique description of the network traffic, defined by a PolicyClassificationRuleType together with a length, matching data and a relevant bits field, port type, and port number (port number zero is reserved to mean any port), and scoped by a etsysPolicyProfileIndex, is used as the table index. |
|                                 | etsysPolicyNonVolatileRuleEntry       | Describes a particular entry within the etsysPolicyNonVolatileRuleTable. Entries within this table are representations of the non-volatile entries found in the etsysPolicyRuleTable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|                                 | etsysPolicyNonVolatileRuleRowStatus   | The status of this row.<br>When active(1) this entry's classification rule, is one of its associated policy's set of rules. When this entry's associated policy, as defined by etsysPolicyRuleProfileIndex, is active and assigned to a port through the etsysPortPolicyProfileTable or to a station through the etsysStationPolicyProfileTable, this classification rule will be applied to the port or station. The exact behavior of this application depends upon the classification rule.<br>When this object is notInService(2) or notReady(3) this entry is not considered one of its associated policy's set of rules and this classification rule will not be applied.                   |
|                                 | etsysPolicyNonVolatileRuleStorageType | The storage type of this row. For all entries in the table this is set to nonVolatile(1), and as such, this entry's                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Table/Group | Supported Variables                         | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|-------------|--------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |                                                  | etsysPolicyNonVolatileRuleUsageList transitions from 0 to 1.                                                                                                                                                                                                                                                                                                                                                                           |
|             | etsysPolicyNonVolatileRuleAuditTrapEnable        | If enabled, an SNMP NOTIFICATION is sent when a bit in the etsysPolicyNonVolatileRuleUsageList transitions from 0 to 1.                                                                                                                                                                                                                                                                                                                |
|             | etsysPolicyNonVolatileRuleDisablePort            | If enabled, a port is disabled (ifOperStatus of the corresponding ifIndex will be down) when a bit in the etsysPolicyNonVolatileRuleUsageList transitions from 0 to 1.                                                                                                                                                                                                                                                                 |
|             | etsysPolicyNonVolatileRuleOperPid                | If the etsysPolicyRuleProfileIndex is 0 then this field contains the currently applied profile ID for frames matching this rule. This may be either the administratively applied value or the dynamically applied value. If the etsysPolicyRuleProfileIndex is not 0, then this object will return -1. Note that one special value exists: -1 Indicates that no profile ID is being applied by this rule.                              |
|             | etsysPolicyNonVolatileRuleOverwriteTCI           | If set, the information contained within the TCI field of inbound, tagged packets will not be used by the device after the ingress classification stage of packet relay. The net effect will be that the TCI information may be used to classify the packet, but will be overwritten (and ignored) by subsequent stages of packet relay.                                                                                               |
|             | etsysPolicyNonVolatileRuleMirrorIndex            | A reference to a packet mirror destination (defined elsewhere). A value of (-1) indicates no mirror is specified, but a mirror is not explicitly prohibited. A value of (0) indicates that mirroring is explicitly prohibited, unless a higher precedence rule has specified a mirror.                                                                                                                                                 |
|             | etsysPolicyNonVolatileRuleQuarantineProfileIndex | If the etsysPolicyRuleProfileIndex is not 0 this field defines the profile ID which will be used as the quarantine provisioning agents mux response for the mac address and port whose frames matched this rule. A value of (-1) indicates no quarantine profile is specified, but quarantine is not explicitly prohibited. A value of (0) indicates that quarantine is explicitly prohibited. If the etsysPolicyRuleProfileIndex is 0 |

|-----------------------------|---------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysPolicyRFC3580Map group | etsysPolicyRFC3580MapResolveReponseConflict | Indicates which field to use in the application of the RADIUS response in the event that both the proprietary filter-id indicating a policy profile and the standard (RFC3580) vlan-tunnel-attribute are present. If policyProfile(1) is selected, then the filter-id will be used, if vlanTunnelAttribute(2) is selected, then the vlan-tunnel-attribute will be used (and the policy-map will be applied, if present). A value of vlanTunnelAttributeWithPolicyProfile(3) indicates that both attributes should be applied, in the following manner: the policyProfile should be enforced, with the exception of the etsysPolicyProfilePortVid (if present), the returned vlan-tunnel-attribute will be used in its place. In this case, the policy-map will be ignored (as the policyProfile was explicitly assigned). VLAN classification rules will still be applied, as defined by the assigned policyProfile. Modifications of this value will not effect the current status of any users currently authenticated. The new state will be applied to new, successful authentications. The current status of current authentication may be modified through the individual agents or through the ENTERASYS-MULTI-AUTH-MIB, if supported. |

Entries within this table MUST be considered non-volatile and MUST be maintained across entity resets.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|             | etsysPolicyRFC3580MapVlanId      | The VlanIndex which will map to the policy profile specified by the etsysPolicyRFC3580MapPolicyIndex of this row. This will be used to map the VLAN returned by value from the Tunnel- Private-Group-ID RADIUS attribute.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|             | etsysPolicyRFC3580MapPolicyIndex | <p>The index of a Policy Profile as defined in the etsysPolicyProfileTable. A value of 0 indicates that the row is functionally non- operational (no mapping exists). Devices which support the ENTERASYS-VLAN-AUTHORIZATION-MIB, and for which the value of etsysVlanAuthorizationEnable is Enabled and the value of etsysVlanAuthorizationStatus is Enabled on the port referenced by the authorization request, should then use the VlanIndex provisioned (e.g. from the Tunnel-Private-Group-ID RADIUS attribute) as defined by RFC3580, otherwise, the device should treat the result as if no matching Policy Profile had been found (e.g. as a simple success). In the case where a Policy Profile is already being applied to the referenced station, but no mapping exists, the device MUST treat the Tunnel-Private-Group-ID as an override to the etsysPolicyProfilePortVid defined by that profile (any matched classification rules which explicit provision a VLAN MUST still override both the etsysPolicyProfilePortVid and the Tunnel-Private-Group-ID.) A non-zero value of this object indicates that the VlanIndex provisioned (e.g. from the Tunnel-Private-Group-ID RADIUS attribute) should be mapped to a Policy Profile as defined in the etsysPolicyProfileTable, and that policy applied as if the Policy name had been provisioned instead (e.g. in the Filter-ID RADIUS attribute). If the mapping references a non-existent row of the etsysPolicyProfileTable, or</p> |

|                         | etsysPolicyHttpRedirectServerStatus | <p>optionally include a query and/or fragment portions as well.</p> <p>A value of enabled(1) causes the entry to be made ready for use in redirecting HTTP traffic. A set of enabled(1) will only succeed if the other entries with STATUS of read-write in table have been set to appropriate non-default values.</p>                                                                                                                                                                                                                                                                     |
| etsysPolicySystem group | etsysPolicyEnabledState             | <p>Controls the enabling and disabling the entire Policy application. A value of enabled(1) indicates that all objects in this MIB module are actively being applied on the device. A value of disabled(2) indicates that none of the objects in this MIB are actively being applied.</p> <p>The agent may optionally implement this leaf as read-only. All other objects in this MIB module MUST remain available and configurable regardless of the current value of this object. This object MUST be considered non-volatile and its value MUST be maintained across entity resets.</p> |

## ENTERASYS-RADIUS-ACCT-CLIENT-EXT-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group | Supported Variables                    | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MIB Objects | etsysRadiusAcctClientEnable            | This object indicates whether or not RADIUS Accounting is enabled or disabled. This parameter value is maintained across system reboots.                                                                                                                                                                                                                                                                                                                                                                                                                        |
|             | etsysRadiusAcctClientUpdateInterval    | This indicates how many seconds elapse between accounting interim updates. This parameter value is maintained across system reboots. A value of zero means no Interim Updates. If the value is less than etsysRadiusAcctClientIntervalMinimum, the etsysRadiusAcctClientIntervalMinimum value will be used for the update interval time. If RADIUS Accounting is not enabled, this object is ignored. Note that Accounting Interim Updates are not issued by the RADIUS Accounting Client, unless so requested by the RADIUS Server in an Access Accept packet. |
|             | etsysRadiusAcctClientIntervalMinimum   | This indicates the minimum value in seconds between accounting interim updates supported by the managed entity. This parameter value is maintained across system reboots. If RADIUS Accounting is not enabled, this object is ignored.                                                                                                                                                                                                                                                                                                                          |
|             | etsysRadiusAcctClientServerTable       | The (conceptual) table listing the RADIUS Accounting servers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|             | etsysRadiusAcctClientServerEntry       | An entry (conceptual row) representing a RADIUS Accounting server with which the client shares a secret. If RADIUS Accounting is not enabled, this table is ignored. All created conceptual rows are non-volatile and as such must be maintained upon restart of the agent.                                                                                                                                                                                                                                                                                     |
|             | etsysRadiusAcctClientServerIndex       | A number uniquely identifying each conceptual row in the etsysRadiusAcctClientServerTable. In the event of an agent restart, the same value of etsysRadiusAcctClientServerIndex must be used to identify each conceptual row in etsysRadiusAcctClientServerTable as was used prior to the restart.                                                                                                                                                                                                                                                              |
|             | etsysRadiusAcctClientServerAddressType | The type of Internet address by which the RADIUS Accounting server is reachable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|             | etsysRadiusAcctClientServerAddress     | The Internet address for the RADIUS Accounting server. Note that implementations must limit themselves to                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Table/Group | Supported Variables                      | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |                                          | a single entry in this table per reachable server. The etsysRadiusAcctClientServerAddress may not be empty due to the SIZE restriction. Also the size of a DNS name is limited to 64 characters. This parameter value is maintained across system reboots.                                                                                                                                                                                         |
|             | etsysRadiusAcctClientServerPortNumber    | The UDP port number (1-65535) the client is using to send requests to this server. The officially assigned port number for RADIUS Accounting is 1813. This parameter value is maintained across system reboots.                                                                                                                                                                                                                                    |
|             | etsysRadiusAcctClientServerSecret        | This object is the secret shared between the RADIUS Accounting server and RADIUS client. This parameter value is maintained across system reboots. While the 'official' MAX-ACCESS for this object is read-create, all security-conscious implementations will 'lie' on a read, and return a null-string, or something else that is fairly innocuous. The ability to read back passwords and secret encryption keys is generally a Bad Thing (tm). |
|             | etsysRadiusAcctClientServerSecretEntered | This indicates the existence of a shared secret.                                                                                                                                                                                                                                                                                                                                                                                                   |
|             | etsysRadiusAcctClientServerRetryTimeout  | The number of seconds to wait for a RADIUS Accounting Server to respond to a request. This parameter value is maintained across system reboots. A value of -1 indicates that the appropriate realm value should be used - etsysRadiusAcctClientMgmtRetryTimeout or etsysRadiusAcctClientNetworkRetryTimeout.                                                                                                                                       |
|             | etsysRadiusAcctClientServerRetries       | The number of times to resend an accounting packet if a RADIUS Accounting Server does not respond to a request. This parameter value is maintained across system reboots.                                                                                                                                                                                                                                                                          |
|             | etsysRadiusAcctClientServerClearTime     | On a read, this value indicates the number of seconds since the counters, as defined in the IETF standard RADIUS Accounting Client MIB (RFC2618), were cleared. On a write, the client counters will be cleared and the clear time will be set to zero.                                                                                                                                                                                            |
|             | etsysRadiusAcctClientServerStatus        | Lets users create and delete RADIUS Accounting server entries on systems that support this capability.                                                                                                                                                                                                                                                                                                                                             |

|-------------|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |                                            | <p>Rules</p> <ol style="list-style-type: none"> <li>When creating a RADIUS Accounting Client, it is up to the management station to determine a suitable etsysRadiusAcctClientServerIndex. To facilitate interoperability, agents should not put any restrictions on the etsysRadiusAcctClientServerIndex beyond the obvious ones that it be valid and unused.</li> <li>Before a new row can become 'active', values must be supplied for the columnar objects etsysRadiusAcctClientClientServerAddress, and etsysRadiusAcctClientServerSecret.</li> <li>The value of etsysRadiusAcctClientServerStatus must be set to 'notInService' in order to modify a writable object in the same conceptual row.</li> <li>etsysRadiusAcctClientServer entries whose status is 'notReady' or 'notInService' will not be used for Accounting.</li> </ol>                         |
|             | etsysRadiusAcctClientServerUpdateInterval  | <p>This indicates how many seconds elapse between accounting interim updates from the client to this RADIUS server. This parameter value is maintained across system reboots. A value of zero means no Interim Updates. If the value is less than etsysRadiusAcctClientServerIntervalMinimum, the etsysRadiusAcctClientServerIntervalMinimum value will be used for the update interval time. If RADIUS Accounting is not enabled, this object is ignored. Note that Accounting Interim Updates are not issued by the RADIUS Accounting Client, unless so requested by the RADIUS Server in an Access Accept packet. A value of -1 indicates that this object is not configured and this device will use the value configured in etsysRadiusAcctClientUpdateInterval for the minimum value in seconds between accounting interim updates for this RADIUS server.</p> |
|             | etsysRadiusAcctClientServerIntervalMinimum | <p>This indicates the minimum value in seconds between accounting interim updates supported by the managed entity for this RADIUS server. This parameter value is maintained across</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|             | etsysRadiusAcctClientServerClientVirtualRouterName | <p>The name of the local system virtual router that traffic sent to this RADIUS server should be associated with. Writing this object with a zero length string clears the virtual router name for this server.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Table/Group                           | Supported Variables                      | Comments                                                                                                                                                                                                                                                        |
|---------------------------------------|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Additional RADIUS Acct Client Scalars | etsysRadiusAcctClientMgmtEnable          | This object indicates whether or not RADIUS Accounting is enabled or disabled for management sessions. This parameter value is maintained across system reboots. The unset value (0) indicates that the value in etsysRadiusAcctClientEnable should be used.    |
|                                       | etsysRadiusAcctClientNetworkEnable       | This object indicates whether or not RADIUS Accounting is enabled or disabled for network sessions. This parameter value is maintained across system reboots. The unset value (0) indicates that the value in etsysRadiusAcctClientEnable should be used.       |
|                                       | etsysRadiusAcctClientMgmtRetryTimeout    | The number of seconds to wait for a RADIUS Accounting Server in the management realm to respond to a request. This parameter value is maintained across system reboots. This value may be overridden by the per server etsysRadiusAcctClientServerRetryTimeout. |
|                                       | etsysRadiusAcctClientNetworkRetryTimeout | The number of seconds to wait for a RADIUS Accounting Server in the network realm to respond to a request. This parameter value is maintained across system reboots. This value may be overridden by the per server etsysRadiusAcctClientServerRetryTimeout.    |

## ENTERASYS-RADIUS-AUTH-CLIENT-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group                                      | Supported Variables               | Comments                                                                                                                                                                                                                                                                          |
|--------------------------------------------------|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Branches of the Enterasys RADIUS Auth Client MIB | etsysRadiusAuthClientMIBObjects   |                                                                                                                                                                                                                                                                                   |
| RADIUS Auth Client Scalars                       | etsysRadiusAuthClientRetryTimeout | The number of seconds to wait for a RADIUS Server to respond to a request. Maintaining the value of this object across agent reboots is REQUIRED.                                                                                                                                 |
|                                                  | etsysRadiusAuthClientRetries      | The number of times to resend an authentication packet if a RADIUS Server does not respond to a request. Maintaining the value of this object across agent reboots is REQUIRED.                                                                                                   |
|                                                  | etsysRadiusAuthClientEnable       | Controls and indicates the operational state of the RADIUS client functionality. Maintaining the value of this object across agent reboots is REQUIRED.                                                                                                                           |
|                                                  | etsysRadiusAuthClientAuthType     | This indicates which method is being used for authentication.<br>mac(1) - indicates MAC address authentication<br>eapol(2) - indicates EAPOL authentication<br>This list of enumeration constants is subject to change. This parameter value is maintained across system reboots. |

| Table/Group                     | Supported Variables                      | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RADIUS Auth Client Server Table | etsysRadiusAuthServerTable               | A list of RADIUS servers that this client may attempt to use.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                                 | etsysRadiusAuthServerEntry               | A RADIUS server that this client may attempt to use.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|                                 | etsysRadiusAuthServerIndex               | A number uniquely identifying each conceptual row in the etsysRadiusAuthServerTable. etsysRadiusAuthServerIndices with range between 2147483642 and 2147483647 indicate the highest priority servers stored for backwards compatibility. After consideration of these special indice values this value indicates the relative priority of the servers. Relative priority of the servers is used when using the standard authentication retransmission algorithm. Maintaining the value of etsysRadiusAuthServerIndex for all active(1) entries across agent reboots is REQUIRED. |
|                                 | etsysRadiusAuthClientServerAddressType   | This object specifies how etsysRadiusAuthClientServerAddress is encoded. Support for all possible enumerations defined by InetAddressType is NOT REQUIRED.                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                                 | etsysRadiusAuthClientServerAddress       | The encoded unicast IP address or hostname of a RADIUS server. RADIUS requests will be sent to this address. If this address is a DNS hostname, then that hostname SHOULD be resolved into an IP address each time an authentication session is initialized.                                                                                                                                                                                                                                                                                                                     |
|                                 | etsysRadiusAuthClientServerPortNumber    | The UDP port number (0-65535) the client will use to send RADIUS requests to this server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|                                 | etsysRadiusAuthClientServerSecret        | This object is the secret shared between the RADIUS authentication server and the RADIUS client. On a read operation this object MUST return a zero length string. Writing this object with a zero length string clears the secret.                                                                                                                                                                                                                                                                                                                                              |
|                                 | etsysRadiusAuthClientServerSecretEntered | true(1) - Indicates that etsysRadiusAuthClientServerSecret was last set with some value other than the empty string.<br>false(2) - Indicates that etsysRadiusAuthClientServerSecret has                                                                                                                                                                                                                                                                                                                                                                                          |

|-------------|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |                                              | network via 802.1X, Port Web Authentication, MAC Authentication, etc. nms(4) - the server will only be available for authenticating users that are attempting to gain access to the network via network virtualization or virtual machine tracking using a network management system. This realm type is only allowed for backwards compatibility and is not included when any is specified. Non-default values for this object should be used when there is a desire to have one set of servers used for authenticating management access requests and a different set used for authenticating network access requests. When this object has the value of any(1) then the associated server will be in each of the mgmtAccess and networkAccess sets. The precedence order defined by the relative value of the etsysRadiusAuthServerIndex will be maintained within each set of servers." |
|             | etsysRadiusAuthClientServerTimeout           | The number of seconds to wait for a RADIUS Server to respond to a request. A value of -1 indicates that the server timeout specified by etsysRadiusAuthClientRetryTimeout should be used for this server. Maintaining the value of this object across agent reboots is REQUIRED.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|             | etsysRadiusAuthClientServerRetries           | The number of times to resend an authentication packet if a RADIUS Server does not respond to a request. A value of -1 indicates that the server retries specified by etsysRadiusAuthClientRetries should be used for this server. Maintaining the value of this object across agent reboots is REQUIRED.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|             | etsysRadiusAuthClientServerStickyMaxSessions | The maximum number of sessions associated with this server when using the sticky round robin authentication retransmission algorithm. This value is not used when other retransmission algorithms are being utilized. Sessions that are successfully authenticated with this server are considered associated. Maintaining the value of this object across agent reboots is REQUIRED.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|             | etsysRadiusAuthClientServerStickyCurSessions | The current number of sessions associated with this server when using                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| MIB Objects | etsysRadiusDynAuthorServerMIBObjects        | This object indicates whether or not RADIUS Dynamic Authorization is enabled or disabled. This parameter value MUST be maintained across system reboots.                                                                                                                                                                                                                             |
|             | etsysRadiusDynAuthorServerClientTable       | The (conceptual) table listing the RADIUS Accounting servers.                                                                                                                                                                                                                                                                                                                        |
|             | etsysRadiusDynAuthorServerClientEntry       | An entry (conceptual row) representing a RADIUS dynamic authorization server with which the server shares a secret. If RADIUS dynamic authorization is not enabled, this table is ignored. All created conceptual rows are non-volatile and as such MUST be maintained upon restart of the agent.                                                                                    |
|             | etsysRadiusDynAuthorServerClientIndex       | A number uniquely identifying each conceptual row in the etsysRadiusDynAuthorServerClientTable. In the event of an agent restart, the same value of etsysRadiusDynAuthorServerClientIndex MUST be used to identify each conceptual row in etsysRadiusDynAuthorServerClientTable as was used prior to the restart.                                                                    |
|             | etsysRadiusDynAuthorServerClientAddressType | The type of Internet address by which the RADIUS Dynamic Authorization Client is reachable.                                                                                                                                                                                                                                                                                          |
|             | etsysRadiusDynAuthorServerClientAddress     | The Internet address for the RADIUS Dynamic Authorization Client. Note that implementations MUST limit themselves to a single entry in this table per reachable server. The etsysRadiusDynAuthorServerClientAddress may not be empty due to the SIZE restriction. Also the size of a DNS name is limited to 64 characters. This parameter value is maintained across system reboots. |
|             | etsysRadiusDynAuthorServerClientSecret      | This object is the secret shared between the RADIUS Dynamic Authorization client and RADIUS server. This parameter value is maintained across system reboots. While the 'official' MAX-ACCESS for this                                                                                                                                                                               |

| Table/Group | Supported Variables                           | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|             | etsysRadiusDynAuthorClientServerClientVirtualRouterName | The name of the local system virtual router that traffic sent to this RADIUS Dynamic Authorization server should be associated with.<br>Writing this object with a zero length string clears the virtual router name for this server. |

## ENTERASYS SYSLOG MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group                   | Supported Variables                      | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------------|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysSyslogServer table group | etsysSyslogServerMaxEntries              | The maximum number of entries allowed in the etsysSyslogServerTable.<br>Read-only.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                               | etsysSyslogServerNumEntries              | The number of entries currently in the etsysSyslogServerTable.<br>Read-only.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|                               | etsysSyslogServerTableNextAvailableIndex | This object indicates the numerically lowest available index within this entity, which may be used for the value of etsysSyslogServerIndex in the creation of a new entry in the etsysSyslogServerTable.<br>An index is considered available if the index value falls within the range of 1 to 16 and is not being used to index an existing entry in the etsysSyslogServerTable contained within this entity.<br>A value of zero indicates that all of the entries in the etsysSyslogServerTable are currently in use.<br>This value should only be considered a guideline for management creation of etsysSyslogServerEntries, there is no requirement on management to create entries based upon this index value.<br>Read-only. |

| Table/Group             | Supported Variables          | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysSyslogServer Table | etsysSyslogServerTable       | A table containing Syslog server information.<br>Not-accessible                                                                                                                                                                                                                                                                                                                                                                                      |
|                         | etsysSyslogServerEntry       | Defines the information to generate syslog messages to an aggregating agent or server. Entries within this table with an access level of read- create MUST be considered non-volatile and MUST be maintained across entity resets.<br>Not-accessible                                                                                                                                                                                                 |
|                         | etsysSyslogServerIndex       | A unique arbitrary identifier for this syslog server.<br>Not-accessible                                                                                                                                                                                                                                                                                                                                                                              |
|                         | etsysSyslogServerDescription | Administratively assigned textual description of this syslog server.<br>Not supported                                                                                                                                                                                                                                                                                                                                                                |
|                         | etsysSyslogServerAddressType | The type of Internet address by which the Syslog server is specified in etsysSyslogServerAddress. Only IPv4 and IPv6 are supported for etsysSyslogServerAddressType<br>Read-create                                                                                                                                                                                                                                                                   |
|                         | etsysSyslogServerAddress     | The Internet address for the Syslog message server. The use of DNS domain names is discouraged, and agent support for them is optional. Deciding when, and how often, to resolve them is an issue. Not resolving them often enough means you might lose synchronization with the associated entry in the DNS server, and resolving them too often might leave you without access to the Syslog server during critical network events.<br>Read-create |
|                         | etsysSyslogServerUdpPort     | The UDP port number the client is using to send requests to this server.<br>If an entity only supports sending messages using a single UDP port to all servers then this may optionally be implemented read-only, in which case the current value of etsysSyslogServerDefaultUdpPort will be used.                                                                                                                                                   |

| Table/Group | Supported Variables                | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |                                    | Read-create                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|             | etsysSyslogServerFacility          | <p>The syslog facility (local0-local7) that will be encoded in messages sent to this server.</p> <p>If an entity only supports encoding a single facility in all messages to all servers then this may optionally be implemented read-only, in which case the current value of etsysSyslogServerDefaultFacility will be used.</p> <p>Read-create</p>                                                                                                                                                                                 |
|             | etsysSyslogServerSeverity          | <p>The maximum severity level of the messages that should be forwarded to the syslog server. The higher the level, the lower the severity.</p> <p>If an entity only supports filtering based on a single severity level for all servers then this may optionally be implemented read-only, in which case the current value of etsysSyslogServerDefaultSeverity will be used.</p> <p>Read-create</p>                                                                                                                                  |
|             | etsysSyslogServerRowStatus         | <p>This object allows for the dynamic creation and deletion of entries within the etsysSyslogServerTable as well as the activation and deactivation of these entries.</p> <p>When this object's value is set to notInService(2) this server will not be sent any messages, nor will any of its counters be incremented.</p> <p>The agent should not delete a row, except in the case of the loss of persistent storage. Refer to the RowStatus convention for further details on the behavior of this object.</p> <p>Read-create</p> |
|             | etsysSyslogServerVirtualRouterName | <p>The name of the local system virtual router that traffic sent to this syslog server should be associated with.</p> <p>Writing this object with a zero length string sets the virtual router name to its default value.</p>                                                                                                                                                                                                                                                                                                        |

| Table/Group | Supported Variables | Comments                                                                            |
|-------------|---------------------|-------------------------------------------------------------------------------------|
|             |                     | The default value for etsysSyslogServerVirtualRouterName is VR-Mgmt.<br>Read-create |

| Table/Group                | Supported Variables              | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

If etsysSyslogServerSeverity is implemented read-only, and this value is changed, it should affect the syslog message severity level that will be used to filter all syslog messages as soon as it is practical.<br>This parameter value is maintained across system reboots.<br>etsysSyslogServerDefaultSeverity value is debug(8).<br>Read-only |

The mapping between Syslog MIB severity (for example, etsysSyslogServerSeverity) and ExtremeXOS severity is not one-to-one as ExtremeXOS does not support “emergency” and “alert” severity; and Syslog MIB does not support “debug-data”, “debug-verbose” and “debug-summary” severity.

The following table shows the mapping between the two:

| etsysSyslogServerSeverity  | ExtremeXOS Syslog Severity              |
|----------------------------|-----------------------------------------|
| emergency, alert, critical | critical                                |
| Error                      | error                                   |
| Warning                    | warning                                 |
| Notice                     | notice                                  |
| Info                       | info                                    |
| debug                      | debug-data,debug-verbose, debug-summary |

## ENTERASYS-VLAN-AUTHORIZATION-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group                       | Supported Variables | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysVlanAuthorizationEnable      | All objects         | The enable/disable state for the VLAN authorization feature. When disabled, no modifications to the VLAN attributes related to packet switching should be enforced.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| etsysVlanAuthorizationTable       | All objects         | Extensions to the table that contains information about every port that is associated with this transparent bridge.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| etsysVlanAuthorizationEntry       | All objects         | A list of extensions that support the management of proprietary features for each port of a transparent bridge. This is indexed by dotIdBasePort.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| etsysVlanAuthorizationStatus      | All objects         | The enabled/disabled status for the application of VLAN authorization on this port, if disabled, the information returned in the VLAN-Tunnel-Type from the authentication will not be applied to the port (although it should be represented in this table).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| etsysVlanAuthorizationAdminEgress | All objects         | Controls the modification of the current vlan egress list (of the vlan returned in the VLAN-Tunnel-Type, and reported by etsysVlanAuthorizationVlanID) upon successful authentication in the following manner: none(1) No egress manipulation will be made. tagged(2) The authenticating port will be added to the current egress for the VLAN-ID returned. untagged(3) The authenticating port will be added to the current untagged egress for the VLAN-ID returned. dynamic(4) The authenticating port will use information returned in the authentication response to modify the current egress lists. This value is supported only if the device supports a mechanism through which the egress status may be returned through the RADIUS response. Should etsysVlanAuthorizationEnable become disabled, etsysVlanAuthorizationStatus become disabled for a port, or should etsysVlanAuthorizationVlanID become 0 or 4095, all effect on the port egress MUST be removed. |

| Table/Group                      | Supported Variables | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------------|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysVlanAuthorizationOperEgress | All objects         | Reports the current state of modification to the current vlan egress list (of the vlan returned in the VLAN-Tunnel-Type) upon successful authentication, if etsysVlanAuthorizationStatus is enabled, in the following manner:<br>none(1) No egress manipulation will be made.<br>tagged(2) The authenticating port will be added to the current egress for the VLAN-ID returned.<br>untagged(3) The authenticating port will be added to the current untagged egress for the VLAN-ID returned. The purpose of this leaf is to report, specifically when etsysVlanAuthorizationAdminEgress has been set to dynamic(4), the currently enforced egress modification. If the port is unauthenticated, or no VLAN-ID has been applied, this leaf should return none(1). |
| etsysVlanAuthorizationVlanID     | All objects         | The 12 bit VLAN identifier for a given port, used to override the PVID of the given port, obtained as a result of an authentication. A value of zero indicates that there is no authenticated VLAN ID for the given port. Should a port become unauthenticated this value MUST be returned to zero. A value of 4095 indicates that a the port has been authenticated, but that the VLAN returned could not be applied to the port (possibly because of resource constraints or misconfiguration). In this instance, the original PVID should still be applied. Should the feature become disabled or the session terminate, all effect on the Port VLAN ID MUST be removed.                                                                                        |
| etsysVlanAuthorizationGroup      | All objects         | A collection of objects relating to VLAN Authorization.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## EXTREME-AUTOPROVISION-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group                | Supported Variables | Comments                                                      |
|----------------------------|---------------------|---------------------------------------------------------------|
| extremeAutoProvisionConfig |                     | Enables or disables the Auto Provision feature on the switch. |

The following traps can be generated.

| Trap                       | Notification Objects               | Comments                                                                                                                                                                                    |
|----------------------------|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeAutoProvisionStatus |                                    | This trap reports the auto provision result (success/failed). It contains the attributes it received from the <i>DHCP (Dynamic Host Configuration Protocol)</i> server.                     |
|                            | extremeAutoProvisionResult         | Result of the Auto provision.                                                                                                                                                               |
|                            | extremeAutoProvisionIpAddress      | The IP address received from the DHCP server for this interface.                                                                                                                            |
|                            | extremeAutoProvisionGateway        | The gateway address received from the DHCP server for this interface.                                                                                                                       |
|                            | extremeAutoProvisionTFTPServer     | The IP address of the TFTP server received from the DHCP server.                                                                                                                            |
|                            | extremeAutoProvisionConfigFileName | The configuration file name received from the DHCP server which the auto-provision enabled switch will download from the TFTP server and apply. It can use either the cfg or xsf extension. |

## EXTREME-CFM-MIB

The ExtremeCFM MIB provides information about the Connectivity Fault Management (CFM) Group. This is an extension to IEEE8021- CFM-MIB.

The following tables, groups, and variables are supported in this MIB.

| Table/Group                   | Supported Variables           | Comments                                                                                                                                                                                 |
|-------------------------------|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeCfmGroup               | ExtremeCfmGroupOperStatus     | This is a textual convention which, indicates the operational status of a group associated with a MEP on a port of an association in a given domain.                                     |
| extremeCfmGroupNextIndexTable |                               | This object contains an unused value for extremeCfmGroupIndex in the extremeCfmGroupTable, or a zero to indicate that none exists.                                                       |
|                               | extremeCfmGroupNextIndexEntry | The conceptual row of extremeCfmGroupNextIndexTable. Not accessible.                                                                                                                     |
|                               | extremeCfmGroupNextIndex      | Value used as the index of the Group table entries, for this Maintenance association End Point Identifier when the management entity wants to create a new row in that table. Read only. |

| Table/Group               | Supported Variables       | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeCfmGroupTable      |                           | Includes configuration objects and operations for the Group function, mainly used by the registered clients like <i>ERPS (Ethernet Ring Protection Switching)</i> , <i>EAPS (Extreme Automatic Protection Switching)</i> to know link detection failure through CFM. Each row in the table represents a Group for the defined MEP.                                                                                                                                           |
|                           | extremeCfmGroupEntry      | This is a complex index with four indices to access any row in extremeCfmGroupTable. The first three are Maintenance Domain, MaNet, and MEP indices. The fourth index is the specific Group on the selected MEP.<br>Not accessible.                                                                                                                                                                                                                                          |
|                           | extremeCfmGroupName       | The name of a CFM group. Group name must be alpha-numeric.                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                           | extremeCfmGroupStatus     | Whether the group is operational or not. Ready only.                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                           | extremeCfmMepIfIndex      | Interface index of the interface, either a bridge port, or an aggregated IEEE 802.1 link within a bridge port, to which the MEP and hence the group is attached.<br>Upon a restart of the system, the system, if necessary, changes the value of this variable so that it indexes the entry in the interface table with the same value of ifAlias that it indexed before the system restart. If no such entry exists, then the system sets this variable to 0.<br>Read only. |
|                           | extremeCfmGroupRemoteMEPs | Lists the Remote MEPs associated with a group. Not all Remote MEPs of an MA may be associated with a group. Ready only.                                                                                                                                                                                                                                                                                                                                                      |
|                           | extremeCfmGroupClients    | Lists all the registered clients with a group. The clients are informed with link failure or recovery through group status notifications. Ready only.                                                                                                                                                                                                                                                                                                                        |
|                           | extremeCfmGroupRowStatus  | The status of the row. All columns must have a valid value before a row can be activated.                                                                                                                                                                                                                                                                                                                                                                                    |
| extremeCfmGroupMepDbTable |                           | Maintains information about other MEPs in that group.                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Table/Group                      | Supported Variables           | Comments                                                                                                                                         |
|----------------------------------|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
|                                  | extremeCfmGroupMepDbEntry     | Complex index including Maintenance Domain, MaNet, MEP and Group indices along with RMEP ID to identify a row in this table.<br>Not accessible.  |
|                                  | extremeCfmGroupMepDbRMepld    | Maintenance association End Point Identifier of a remote MEP whose information from the group MEP database is to be returned.<br>Not accessible. |
|                                  | extremeCfmGroupMepDbRowStatus | The status of the row. All columns must have a valid value before a row can be activated.                                                        |
| extremeCfmGroupStatusDownUpAlarm | extremeCfmGroupStatus         | A notification (DownUpAlarm) is sent to the management entity with the OID of the group that has detected the status change.                     |

## EXTREME-CLEARFLOW-MIB

This MIB defines the following Extreme-specific CLEAR-Flow traps generated by Extreme Networks devices.

| Trap                                     | Comments                                          |
|------------------------------------------|---------------------------------------------------|
| extremeClearflowMessage                  | CLEAR-Flow message trap.                          |
| The varbinds supported in this trap are: |                                                   |
| extremeClearflowMsgId                    | User-defined message ID.                          |
| extremeClearflowMsg                      | User-defined message.                             |
| extremeClearflowPolicyName               | Policy file name.                                 |
| extremeClearflowRuleName                 | Rule name which triggered this message.           |
| extremeClearflowRuleValue                | Calculated rule value.                            |
| extremeClearflowRuleThreshold            | Rule threshold value.                             |
| extremeClearflowRuleInterval             | Rule sampling and evaluation interval.            |
| extremeClearflowVlanName                 | <u>VLAN</u> name on which this policy is applied. |
| extremeClearflowPortName                 | Port name on which this policy is applied.        |

## EXTREME-EAPS-MIB

Managed objects for EAPS MIB are defined proprietary on ExtremeXOS.

Table 175 lists the existing traps supported in this MIB.

**Table 175: EAPS MIB Traps**

| Trap                               | Varbinds                                                                                                                                                                                             | Comments                                                                                   |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------|
| extremeEapsStateChange             | extremeEapsName,<br>extremeEapsMode,<br>extremeEapsPrevState,<br>extremeEapsState,<br>extremeEapsFailedFlag,<br>extremeEapsPrimaryStatus<br>extremeEapsSecondaryStatus                               | Send on Master/Transit Nodes                                                               |
| extremeEapsLastStatusChangeTime    | extremeEapsLastStatusChange<br>extremeEapsStatusTrapCount                                                                                                                                            | Send on Master/Transit Nodes. General indication of a status change using 10 second timer. |
| extremeEapsPortStatusChange        | extremeEapsName,<br>extremeEapsPrimaryStatus<br>extremeEapsSecondaryStatus<br>extremeEapsLastStatusChange                                                                                            | Send on Master/Transit Nodes                                                               |
| extremeEapsConfigChange            | extremeLastConfigurationChange                                                                                                                                                                       | 30 second granularity Send on Master/Transit Nodes                                         |
| extremeEapsSharedPortStateChange   | extremeEapsSharedPortIfIndex<br>extremeEapsSharedPortLinkId<br>extremeEapsSharedPortState<br>extremeEapsSharedPortNbrStatus<br>extremeEapsSharedPortRootBlockerStatus<br>extremeEapsLastStatusChange | Send on Controller/Partner Nodes                                                           |
| extremeEapsRootBlockerStatusChange | extremeEapsSharedPortIfIndex<br>extremeEapsSharedPortRootBlockerStatus<br>extremeEapsSharedPortRootBlockerId<br>extremeEapsLastStatusChange                                                          | Send on Controller/Partner Nodes                                                           |

Table 176 lists the MIB entries.

**Table 176: EAPS MIB Entries**

| MIB Variable                | Description                                                                                                                                                                                                                                                                                                                         |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeEapsLastStatusChange | Time gets updated for any of the following changes... extremeEapsState, extremeEapsSharedPortState, extremeEapsSharedPortSegmentStatus, extremeEapsFailedFlag, extremeEapsPrimaryStatus, extremeEapsSecondaryStatus, extremeEapsSharedPortNbrStatus, extremeEapsSharedPortRootBlockerStatus, extremeEapsSharedPortSegmentFailedFlag |
| extremeEapsStatusTrapCount  | Indicates the number of status traps sent out since the switch booted. Status traps include extremeEapsStateChange, extremeEapsPortStatusChange, extremeEapsSharedPortStateChange, extremeEapsRootBlockerStatusChange                                                                                                               |

## EXTREME-EDP-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group             | Supported Variables | Comments                                                                                |
|-------------------------|---------------------|-----------------------------------------------------------------------------------------|
| extremeEdpTable         | All objects         | This table contains <i>EDP (Extreme Discovery Protocol)</i> information of this device. |
| extremeEdpNeighborTable | All objects         | This table contains EDP neighbor information.                                           |
| extremeEdpPortTable     | All objects         |                                                                                         |

## EXTREME-ENTITY-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group           | Supported Variable           | Comments                                                                                                               |
|-----------------------|------------------------------|------------------------------------------------------------------------------------------------------------------------|
| extremeEntityFRUTable | entPhysicalIndex             | A table containing information about each FRU based on the Entity MIB.                                                 |
|                       | extremeEntityFRUStartTime    | First recorded start time.                                                                                             |
|                       | extremeEntityFRUOdometer     | Number of time units in service.                                                                                       |
|                       | extremeEntityFRUOdometerUnit | Time unit used to represent value reported by extremeEntityFRUOdometer. Depends on the underlying hardware capability. |

## EXTREME-ERPS-MIB

Managed objects for *ERPS* MIB are defined proprietary on ExtremeXOS. Groups and tables are implemented as read only.

The following tables, groups, and variables are supported in this MIB.

| Table/Group                   | Supported Variables | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeErpsProtectedVlanTable | All objects         | Contains the grouping of set of protected VLANs.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| extremeErpsRingTable          | All objects         | Contains information for each ERPS ring present in the switch.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| extremeErpsStatsTable         | All objects         | Contains statistics information for each of the ring present in the switch.                                                                                                                                                                                                                                                                                                                                                                                                             |
| extremeErpsGlobalInfo         |                     | Contains the information of ERPS configured globally in the switch.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| extremeErpsNotification       |                     | Contains two types of traps: extremeErpsStateChangeTrap and extremeErpsFailureTrap. extremeErpsStateChangeTrap is generated on the following events: <ul style="list-style-type: none"> <li>Local SF is received for the ring.</li> <li>Local Clear SF is received for the ring.</li> <li>Remote failure is detected on this ring.</li> <li>Remote failure is cleared on this ring.</li> <li>Force Switch is issued for a ring.</li> <li>Manual Switch is issued for a ring.</li> </ul> |

## EXTREME-ESRP-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group                    | Supported Variables | Comments                                                                         |
|--------------------------------|---------------------|----------------------------------------------------------------------------------|
| extremeEsrpDomainTable         | All objects         | This table contains information for domains on this device.                      |
| extremeEsrpDomainMemberTable   | All objects         | This table contains information for member VLANs of the ESRP domain.             |
| extremeEsrpDomainNeighborTable | All objects         | This table contains neighbor router information for ESRP domains on this device. |
| extremeEsrpDomainAwareTable    | All objects         | This table contains ESRP aware information for this device.                      |

| Table/Group                 | Supported Variables          | Comments                                                                                               |
|-----------------------------|------------------------------|--------------------------------------------------------------------------------------------------------|
| extremeEsrpDomainStatsTable | All objects                  | This table contains statistics on ESRP hello packets exchanged and ESRP state changes for this device. |
| extremeEsrpNotifications    | extremeEsrpDomainStateChange | Signifies ESRP state change.                                                                           |

## EXTREME-FDB-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group                  | Supported Variables       | Comments                                                                                                                                                                                                 |
|------------------------------|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeFdbIpFdbTable         | All objects               | Supports <i>SNMP</i> get and get next operations only.                                                                                                                                                   |
| extremeFdbPermFdbTable       | All objects               |                                                                                                                                                                                                          |
| extremeFdbMacExosFdbTable    | extremeFdbMacExosFdbEntry | A table that contains information about the hardware MAC <i>FDB</i> ( <i>forwarding database</i> ) table. Supported only on switches running ExtremeXOS. Supports SNMP get and get next operations only. |
| extremeFdbMacFdbCounterTable | All objects               | Supports SNMP get and get next operations only.                                                                                                                                                          |

| Trap                   | Comments                                                                                          |
|------------------------|---------------------------------------------------------------------------------------------------|
| extremeMACTrackingAdd  | The specified MAC address was added to the FDB on the mentioned port and VLAN.                    |
| extremeMACTrackingDel  | The specified MAC address was deleted from the FDB on the mentioned port and VLAN.                |
| extremeMACTrackingMove | The specified MAC address was moved from the previous port to the new port on the specified VLAN. |

## EXTREME-MAC-AUTH-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group               | Supported Variables           | Comments                                                                                                     |
|---------------------------|-------------------------------|--------------------------------------------------------------------------------------------------------------|
| extremeMacAuthClientTable | All objects                   | This table contains client authentication based on the source MAC address of the traffic received on a port. |
| ExtremeMacAuthClientEntry |                               | An entry in the MAC authentication table. Each entry represents a MAC authentication client                  |
|                           | extremeMacAuthClientAddresses | The MAC address of the client.                                                                               |

| Table/Group | Supported Variables                | Comments                                                                  |
|-------------|------------------------------------|---------------------------------------------------------------------------|
|             | extremeMacAuthClientInitialize     | Remove the entry for the client from extremeMacAuthClientTable.           |
|             | extremeMacAuthClientReauthenticate | Re-authenticate the client on all ports on which the client is connected. |

## EXTREME MLAG MIB

The following tables, groups, and variables are supported in this MIB.

### Note

EXTREME MLAG MIB objects such as extremeMlagLocalAddrType, extremeMlagLocalIP, extremeMlagAlternateLocalAddrType, extremeMlagAlternateLocalIP are defined with a maximum access of read-create and are populated automatically based on MLAG peer info.

| Table/Group          | Supported Variables      | Comments                                                                                                                                                                                                                                                                         |
|----------------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeMlagPeerTable |                          | This table contains MLAG peer entries. This table contains a MLAG peer switch association structure, associates an MLAG peer structure with an MLAG peer switch IP address. Displays User configured items, MLAG peer switch state, MLAG port count and health-check statistics. |
|                      | extremeMlagPeerName      | Read-create<br>The name of the MLAG Peer switch. MLAG Peer names must be alphanumeric and must start with an alpha character.                                                                                                                                                    |
|                      | extremeMlagPeerVlan      | Read-only<br>The name of the VLAN through which the MLAG Peer can be reached.                                                                                                                                                                                                    |
|                      | extremeMlagPeerVR        | Read-create<br>The name of the VR with which the MLAG peer VLAN is associated with.                                                                                                                                                                                              |
|                      | extremeMlagLocalAddrType | Read-create<br>The IP address type of the extremeMlagLocalIP object.                                                                                                                                                                                                             |
|                      | extremeMlagLocalIP       | Read-create<br>Local Switch IPAddress of ISC connection.                                                                                                                                                                                                                         |
|                      | extremeMlagPeerAddrType  | Read-create<br>The IP address type of the extremeMlagPeerIP object.                                                                                                                                                                                                              |
|                      | extremeMlagPeerIP        | Read-create<br>MLAG peer IP address for the ISC. The specified IP address must be contained within an existing direct route.                                                                                                                                                     |

| Table/Group | Supported Variables             | Comments                                                                                                                                                                                                                                                                                                                                                            |
|-------------|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | extremeMlagPeerPortCount        | Read-only<br>Number of MLAG Ports associated with this MLAG peer                                                                                                                                                                                                                                                                                                    |
|             | extremeMlagPeerCheckPointStatus | Read-only<br>Checkpointing Status of this MLAG peer                                                                                                                                                                                                                                                                                                                 |
|             | extremeMlagPeerRxHellos         | Read-only<br>Number of Hellos received from the peer                                                                                                                                                                                                                                                                                                                |
|             | extremeMlagPeerRxCheckpointMsgs | Read-only<br>Number of Checkpoint Messages received from the peer                                                                                                                                                                                                                                                                                                   |
|             | extremeMlagPeerHelloErrors      | Read-only<br>Number of Hello Error Messages                                                                                                                                                                                                                                                                                                                         |
|             | extremeMlagPeerHelloTimeouts    | Read-only<br>Number of Hello Timeout Messages                                                                                                                                                                                                                                                                                                                       |
|             | extremeMlagPeerUptime           | Read-only<br>Specifies the time that the Connectivity with the peer is up                                                                                                                                                                                                                                                                                           |

|                      | extremeMlagPeerCheckpointAuthKey | Read-create<br>The authentication key to be used for checkpoint connection to the peer. Recommended to be of size 12-24 per RFC 3562. This object will return a blank string of minimum length when queried.                                                                                                                                                                                                                                                                                                                          |
| extremeMlagPortTable |                                  | This table contains Mlag port entries<br>Binds a local port or LAG port to an MLAG port uniquely identified by the MLAG Id value. Once the MLAG group binding is made, any change to load sharing on MLAG ports is disallowed. Displays User configured items, MLAG peer switch state, port count and health-check statistics.<br><br><b>Note:</b> To create a row in the extremeMlagPortTable, extremeMlagPortId and extremeMlagPortPeer should be specified in the SNMP SET request in addition to extremeMlagPortLocalPortIfIndex. |
|                      | extremeMlagPortLocalPortIfIndex  | Read-create<br>The ifIndex of the local member port of the MLAG port. The specified port ifIndex may be a single port or the master port of a load share port but should not be a load share member port.                                                                                                                                                                                                                                                                                                                             |
|                      | extremeMlagPortId                | Read-create<br>The identifier which is used to identify the MLAG port                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                      | extremeMlagPortPeer              | Read-create<br>This object identifies the MLAG peer switch with which this port is associated                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                      | extremeMlagPortLocalLinkStatus   | Read-only<br>Local MLAG Port Status, that can be Active/Disabled/Ready/Port not present. It reflects the status of entire LAG when LAG is used in conjunction with MLAG.                                                                                                                                                                                                                                                                                                                                                              |
|                      | extremeMlagPortRemoteLinkStatus  | Read-only<br>Remote MLAG Port Status, which can be Up(1) - One or more links are active on the remote switch or<br>Down(2)- No links are active on the remote switch or<br>N/A(3) - The peer has not communicated link state for this MLAG group.<br>It reflects the status of entire LAG when LAG is used in conjunction with MLAG.                                                                                                                                                                                                  |
|                      | extremeMlagPortPeerState         | Read-only<br>MLAG Peer Switch State, up/down                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Table/Group | Supported Variables              | Comments                                                                                                                                                                                                                                                                                                                                   |
|-------------|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | extremeMlagPortLocalFailures     | Read-only<br>Gives the number of ports that are down in the local MLAG port.                                                                                                                                                                                                                                                               |
|             | extremeMlagPortRemoteFailures    | Read-only<br>Gives number of ports that are down in the remote MLAG port                                                                                                                                                                                                                                                                   |
|             | extremeMlagPortRowStatus         | Read-create<br>The status of this entry.                                                                                                                                                                                                                                                                                                   |
|             | extremeMlagConvergenceControl    | Read-write<br>This object specifies if an ACL can be used on an MLAG port to achieve faster convergence. If an ACL is used, better convergence times can be achieved irrespective of the number of FDB entries present on the MLAG port. The second time can be chosen when convergence time is not an issue and ACLs are to be preserved. |
|             | extremeMlagReloadDelayInterval   | Read-write<br>Time Interval in seconds that is used to delay the enabling of MLAG ports during startup. This is used to allow convergence of protocols and for reachability of MLAG peer.                                                                                                                                                  |
|             | extremeMlagReloadDelayEnable     | Read-write<br>Setting this object to true will enable the reload delay feature. Enabling reload delay will delay enabling of MLAG ports during startup to allow convergence of protocols and for reachability of MLAG peer.                                                                                                                |
|             | extremeMlagLinkupIsolationEnable | Read-write<br>Setting this object to true will isolate MLAG ports from sending traffic to local ISC port during link-up transition until remote ISC port is configured.                                                                                                                                                                    |
|             | extremeMlagPeerUp                | This trap is sent when the MLAG peer comes up.                                                                                                                                                                                                                                                                                             |
|             | extremeMlagPeerDown              | This notification is sent when health check messages are not received from the peer MLAG switch for 3 times the configured hello interval.                                                                                                                                                                                                 |
|             | extremeMlagAltPathUp             | This notification is sent when the ISC goes down and the alternate path to MLAG peer comes up.                                                                                                                                                                                                                                             |
|             | extremeMlagAltPathDown           | This notification is sent when the alternate path to MLAG peer is down. This can happen when either alternate path or remote peer is down or the ISC link has come up.                                                                                                                                                                     |

## EXTREME-MPLS-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group              | Supported Variables                | Comments                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeMplsNotifications | extremepwUpDownNotificationEnable  | If this object is set to true (1), then it enables the emission of pwUp and pwDown notifications; otherwise these notifications are not emitted.                                                                                                                                                                                                         |
|                          | extremepwDeletedNotificationEnable | If this object is set to true (1), then it enables the emission of pwDeleted notification; otherwise this notification is not emitted.                                                                                                                                                                                                                   |
|                          | pwNotificationMaxRate              | This variable indicates the maximum number of notifications issued per second. If events occur more rapidly, the implementation may simply fail to emit these notifications during that period, or might queue them until an appropriate time. A value of 0 means no throttling is applied and events might be notified at the rate at which they occur. |
|                          | extremepwNotificationPwIndex       | This variable indicates the index of the PW that either went up, down, or was deleted as reported by the corresponding notification.                                                                                                                                                                                                                     |
|                          | extremepwNotificationPwOperStatus  | This variable is used to report the value of pwOperStatus in pwTable (RFC 5601) associated with the PW that went up or down.                                                                                                                                                                                                                             |
|                          | extremepwNotificationPeerAddrType  | Denotes the address type of the peer node.                                                                                                                                                                                                                                                                                                               |
|                          | extremepwNotificationPeerAddr      | This object contains the value of the peer node address.                                                                                                                                                                                                                                                                                                 |
|                          | extremeMplsNotifTunnelIndex        | Uniquely identifies a set of tunnel instances between a pair of ingress and egress LSRs. Contains part of the index of a TE tunnel that underwent state change. The same tunnel can also be looked up in the TE MIB.                                                                                                                                     |
|                          | extremeMplsNotifTunnelInstance     | Uniquely identifies a particular instance of a tunnel between a pair of ingress and egress LSRs.                                                                                                                                                                                                                                                         |
|                          | extremeMplsNotifTunnelIngressLSRId | Identity of the ingress LSR associated with this tunnel instance.                                                                                                                                                                                                                                                                                        |
|                          | extremeMplsNotifTunnelEgressLSRId  | Identity of the egress LSR associated with this tunnel instance.                                                                                                                                                                                                                                                                                         |
|                          | extremeMplsNotifTunnelAdminStatus  | Reports the desired operational status of this tunnel.                                                                                                                                                                                                                                                                                                   |

| Table/Group | Supported Variables                         | Comments                                                                                                                                                                                                                                                                                                                                                              |
|-------------|---------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | extremeMplsNotifTunnelOperStatus            | Reports the actual operational status of this tunnel, which is typically but not limited to, a function of the state of individual segments of this tunnel.                                                                                                                                                                                                           |
|             | extremeMplsNotifLdpEntityLdpId              | The LDP identifier. This is the primary index to identify a row in the mplsLdpEntityTable (RFC 3815).                                                                                                                                                                                                                                                                 |
|             | extremeMplsNotifLdpEntityIndex              | This index is used as a secondary index to uniquely identify a row in the mplsLdpEntityTable (RFC 3815). This object is meaningful to some, but not all, LDP implementations.                                                                                                                                                                                         |
|             | extremeMplsNotifLdpPeerLdpId                | The LDP identifier of this LDP Peer.                                                                                                                                                                                                                                                                                                                                  |
|             | extremeMplsNotifLdpSessionState             | The current state of the session, all of the states 1 to 5 are based on the state machine for session negotiation behavior.                                                                                                                                                                                                                                           |
|             | extremeMplsNotifLdpSessionDiscontinuityTime | The initial value of this object is the value of sysUpTime when the entry was created in this table. Subsequent notifications report the time when the session between a given entity and peer goes away or a new session is established.                                                                                                                             |
|             | extremeVplsNotifConfigIndex                 | Unique index for the conceptual row identifying a VPLS service in the vplsConfigTable.                                                                                                                                                                                                                                                                                |
|             | extremeVplsNotifConfigVpnId                 | This object indicates the IEEE 802-1990 VPN ID of the associated VPLS service. This object has the same value as vplsConfigVpnId in the vplsConfigTable for an index value equal to extremeVplsNotifConfigIndex sent in the notification.                                                                                                                             |
|             | extremeVplsNotifConfigAdminStatus           | The administrative state of the VPLS service. This object has the same value as vplsConfigAdminStatus in the vplsConfigTable for an index value equal to extremeVplsNotifConfigIndex sent in the notification.                                                                                                                                                        |
|             | extremeVplsNotifStatusOperStatus            | The current operational state of this VPLS service. A value of up (1) indicates that all PWs for this VPLS are up and the attachment circuit is up. A value of degraded (2) indicates that at least one PW for this VPLS is up and the attachment circuit is up. A value of down (3) indicates that all PWs for this VPLS are down or the attachment circuit is down. |

| Table/Group            | Supported Variables               | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | extremePwStatusChange             | This notification is generated when the pwOperStatus object for a pseudowire transitions from up (1) to down (2) or from down (2) to up (1).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|                        | extremePwDeleted                  | This notification is generated when a PW has been deleted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                        | extremeMplsTunnelStatusChange     | This notification is generated when the mplsTunnelOperStatus object for a TE-LSP transitions from up (1) to down (2) or from down (2) to up (1). This new state is indicated by the included value of mplsTunnelOperStatus.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                        | extremeMplsLdpSessionStatusChange | This notification is generated when the value of 'mplsLdpSessionState' (RFC3815) enters or leaves the operational (5) state.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|                        | extremeVplsStatusChange           | This notification is generated to inform recipients of the state of the VPLS.<br>When all PWs in this VPLS are up or ready and the attachment circuit is up, extremeVplsNotifStatusOperStatus is set to vplsOperStatusUp (1) in the notification.<br>When at least one PW in this VPLS is up or ready and the attachment circuit is up, extremeVplsNotifStatusOperStatus is set to vplsOperStatusDegraded (2) in the notification.<br>When all PWs in this VPLS are down or the attachment circuit is down, extremeVplsNotifStatusOperStatus is set to vplsOperStatusDown (3) in the notification.<br>Once a notification has been sent with vplsOperStatusDegraded (2), no further notification will be sent until extremeVplsNotifStatusOperStatus transitions to vplsOperStatusUp (1) or vplsOperStatusDown (3). |
| extremeVplsConfigTable |                                   | This table specifies information for configuring and monitoring VPLS.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                        | extremeVplsConfigEntry            | A row in this table represents a VPLS in a packet network. It is indexed by extremeVplsConfigIndex, which uniquely identifies a single VPLS.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| ExtremeVplsConfigEntry | extremeVplsConfigIndex            | Unique index for the conceptual row identifying a VPLS service.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                        | extremeVplsConfigRedunType        | This variable indicates the redundancy type for this VPLS. Redundancy states can be None, <i>EAPS</i> , <i>ESRP</i> ( <i>Extreme Standby Router Protocol</i> ) and <i>STP</i> ( <i>Spanning Tree Protocol</i> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Table/Group            | Supported Variables         | Comments                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | extremeVplsConfigEAPSStatus | This variable indicates the EAPS redundancy status for this VPLS. It displays Protected if the VLAN is protected, else Not Protected. EAPS status displays the following values: Waiting—if waiting on EAPS status.Connected—if EAPS ring status is connected to VLAN. PW is not installed in this state.Disconnected—if EAPS ring state is disconnected. PW is installed in this state.Unknown—if EAPS is not found. |
|                        | extremeVplsConfigESRPState  | This variable indicates the ESRP redundancy state for this VPLS. ESRP states can have two values: master and slave. PW is installed only when ESRP is in the master state.                                                                                                                                                                                                                                            |
| extremeVplsStatusTable |                             | This table specifies information for configuring and monitoring VPLS.                                                                                                                                                                                                                                                                                                                                                 |
|                        | extremeVplsStatusEntry      | A row in this table represents a VPLS in a packet network. It is indexed by extremeVplsConfigIndex, which uniquely identifies a single VPLS.                                                                                                                                                                                                                                                                          |
|                        | extremeVplsStatusIndex      | Unique index for the conceptual row identifying a VPLS service.                                                                                                                                                                                                                                                                                                                                                       |
|                        | extremeVplsOperStatus       | This variable indicates the VPLS operation status. This is different from the VPLS PW status shown in the standard MIB. Supported values are: Up—all PWs are in the Up or Ready state.Degraded—At least one PW is in the Up or Ready state.Down—None of the PWs are in Up or Ready state.                                                                                                                             |
| extremeVplsPeerTable   |                             | This table provides information for monitoring VPLS peer entries.                                                                                                                                                                                                                                                                                                                                                     |
|                        | extremeVplsPeerEntry        | This entry contains information for all the peers belonging to a particular VPLS.                                                                                                                                                                                                                                                                                                                                     |
|                        | extremeVplsIndex            | Unique index for the conceptual row identifying a VPLS service.                                                                                                                                                                                                                                                                                                                                                       |
|                        | extremeVplsPwBindIndex      | Secondary Index for the conceptual row identifying a PW within the PwEntry which must match an entry from the PW-STD-MIB's PwTable, which represents an already-provisioned PW that is then associated with this VPLS instance.                                                                                                                                                                                       |
|                        | extremePwInstalled          | Boolean true or false, indicating if PW is installed.                                                                                                                                                                                                                                                                                                                                                                 |

| Table/Group | Supported Variables     | Comments                                                                                                                                                                                                                      |
|-------------|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | extremePwMode           | The peer mode of this PW. It indicates its current mode and the mode of the switch it is connected to. It can have the following values: Core-to-core, Core-to-Spoke, and Spoke-to-Core.                                      |
|             | extremePwConfiguredRole | The configured role of this PW. It applies only in the case the PWMode is Core-to-core. In this case, the configured role can either be Primary or Secondary. For all the other PW modes, the configured role does not apply. |

The following traps can be generated:

| Trap                    | Comments                                                                                                                             |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| pwStatusChange          | This notification is generated when the pwOperStatus object for a PW transitions from up (1) to down (2) or from down (2) to up (1). |
| pwDeleted               | This notification is generated when a PW has been deleted.                                                                           |
| extremeMPLSTrapsEnable  | MPLS trap status. If enabled then all the MPLS related traps are sent out.                                                           |
| extremeL2VpnTrapsEnable | L2VPN trap status. If enabled then all the L2VPN related traps are sent out.                                                         |

## EXTREME-MPLS-TE-MIB

The following tables, groups, and variables are supported in this MIB:

| Table/Group            | Supported Variables      | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeMplsTunnelTable | mplsTunnelIndex          | The mplsTunnelTable (see RFC3812) allows new MPLS tunnels to be created between an LSR and a remote endpoint, and existing tunnels to be reconfigured or removed. Note that only point-to-point tunnel segments are supported, although multipoint-to-point and point-to-multipoint connections are supported by an LSR acting as a cross-connect. Each MPLS tunnel can thus have one out-segment originating at this LSR and/or one in-segment terminating at this LSR. Extreme Networks MPLS implementation allows tunnel instances with a common endpoint to be grouped at the ingress LSR to provide redundancy. The role of each tunnel in the group must be configured and is indicated by extremeMplsTunnelRedundancyType. |
|                        | mplsTunnelInstance       | Uniquely identifies a particular instance of a tunnel between a pair of ingress and egress LSRs. It is useful to identify multiple instances of tunnels for the purposes of backup and parallel tunnels.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                        | mplsTunnelIngressLSRId   | Identity of the ingress LSR associated with this tunnel instance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                        | mplsTunnelEgressLSRId    | Identity of the egress LSR associated with this tunnel instance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                        | mplsTunnelRedundancyType | Identifies the tunnel redundancy type associated with this tunnel instance. A value of primary (1) or secondary (2) MAY be assigned by the network administrator or by an <i>SNMP</i> manager at the time of setting up the tunnel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Table/Group | Supported Variables        | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | mplsTunnelRedundancyStatus | Indicates the actual redundancy status of this tunnel. When the status is active, the tunnel is the preferred tunnel in the group.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|             | mplsTunnelTransportStatus  | Indicates the type of traffic the tunnel group can be used for sending.<br>When the status is allowAllIp (0), IP traffic destined for all IPv4 routes is allowed over any tunnel in the group marked active. When the status is allowAssignedIpOnly (1), IP traffic destined only for IPv4 static routes that have been explicitly configured to use this tunnel group is allowed. When the status is allowAllLayer 2Vpn (2), Layer 2 VPN traffic for all Layer 2 VPNs is allowed over any tunnel in the group marked active. When the status is allowAssignedLayer 2VpnOnly (3), Layer 2 VPN traffic destined only for PWs that have been explicitly configured to use this tunnel group are allowed. |

## EXTREME-OSPF-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group               | Supported Variables | Comments                                                                                                           |
|---------------------------|---------------------|--------------------------------------------------------------------------------------------------------------------|
| extremeOspfInterfaceTable | All objects         | This table contains Extreme Networks specific information about <i>OSPF (Open Shortest Path First)</i> interfaces. |

## EXTREME-PoE-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group                           | Supported Variables | Comments                         |
|---------------------------------------|---------------------|----------------------------------|
| extremePethSystemAdminEnable          |                     | Objects are supported read-only. |
| extremePethSystemDisconnectPrecedence |                     |                                  |
| extremePethSystemUsageThreshold       |                     |                                  |
| extremePethSystemPowerSupplyMode      |                     |                                  |
| extremePethPseSlotTable               | All objects         |                                  |
| extremePethPsePortTable               | All objects         |                                  |

## EXTREME-PORT-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group                | Supported Variables                | Comments                                                                                                                                                                                                                                                 |
|----------------------------|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremePortLoadshareTable  | All objects                        | Not supported.                                                                                                                                                                                                                                           |
| extremePortSummitlinkTable | All objects                        | Not supported.                                                                                                                                                                                                                                           |
| extremePortLoadshare2Table | extremePortLoadshare2Entry         | A table of bindings between a master port and its load-sharing slaves. Create/delete entries here to add/delete a port to/from a load-sharing group. Default is empty table. There are restrictions on what row creates will be accepted by each device. |
|                            | extremePortLoadshare2MasterIfIndex | The if Index value which identifies the port controlling a load-sharing group of ports that includes extremePortLoadshareSlaveIfIndex.                                                                                                                   |
|                            | extremePortLoadshare2SlaveIfIndex  | The if Index value which identifies the port which is a member of a load-sharing group controlled by extremePortLoadshare2MasterIfIndex.                                                                                                                 |
|                            | extremePortLoadshare2Algorithm     | This value identifies the load sharing algorithm to be used for this group of load shared ports.                                                                                                                                                         |
|                            | extremePortLoadshare2Status        | The row status variable, used according to row installation and removal conventions.                                                                                                                                                                     |
|                            | extremePortLoadshare2MinLinks      | The minimum active links that must be up in order trunk to remain up.                                                                                                                                                                                    |
| extremePortRateShapeTable  | All objects                        | Not supported                                                                                                                                                                                                                                            |

| Table/Group                       | Supported Variables            | Comments                                                                                                                                                                 |
|-----------------------------------|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremePortUtilizationTable       | extremePortUtilizationEntry    | Global <i>QoS (Quality of Service)</i> profiles are defined in the extremeQosProfileTable. This table contains a list of ports for which certain QoS parms are reported. |
|                                   | extremePortUtilizationAvgTxBw  | The reported average bandwidth in the transmit direction. When displayed, it shows as an integer value. For example, 99.99% is displayed as 9999.                        |
|                                   | extremePortUtilizationAvgRxBw  | The reported average bandwidth in the receive direction. When displayed, it shows as an integer value. For example, 99.99% is displayed as 9999.                         |
|                                   | extremePortUtilizationPeakTxBw | The reported peak bandwidth in the transmit direction. When displayed it shows as an integer value. For example, 99.99% is displayed as 9999.                            |
|                                   | extremePortUtilizationPeakRxBw | The reported peak bandwidth in the receive direction. When displayed it shows as an integer value. For example, 99.99% is displayed as 9999.                             |
| extremePortInfoTable              | All objects                    | Not supported.                                                                                                                                                           |
| extremePortXenpakVendorTable      | All objects                    | Not supported.                                                                                                                                                           |
| extremePortIngressStatsPortTable  | All objects                    | Not supported.                                                                                                                                                           |
| extremePortIngressStatsQueueTable | All objects                    | Not supported.                                                                                                                                                           |
| extremePortEgressRateLimitTable   | All objects                    | Not supported.                                                                                                                                                           |
| extremeWiredClientTable           | All objects                    | Not supported.                                                                                                                                                           |

| Table/Group                     | Supported Variables               | Comments                                                                                                                                          |
|---------------------------------|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| extremePortUtilizationExtnTable | extremePortUtilizationExtnEntry   | Global QoS profiles are defined in the extremeQosProfileTable. This table contains a list of ports for which certain QoS parameters are reported. |
|                                 | extremePortUtilizationAvgTxPkts   | The reported number of average packets in the transmit direction per second.                                                                      |
|                                 | extremePortUtilizationAvgRxPkts   | The reported number of average packets in the receive direction per second.                                                                       |
|                                 | extremePortUtilizationPeakTxPkts  | The reported number of peak packets in the transmit direction per second.                                                                         |
|                                 | extremePortUtilizationPeakRxPkts  | The reported number of peak packets in the receive direction per second.                                                                          |
|                                 | extremePortUtilizationAvgTxBytes  | The reported number of average bytes in the transmit direction per second.                                                                        |
|                                 | extremePortUtilizationAvgRxBytes  | The reported number of average bytes in the receive direction per second.                                                                         |
|                                 | extremePortUtilizationPeakTxBytes | The reported number of peak bytes in the transmit direction per second.                                                                           |
|                                 | extremePortUtilizationPeakRxBytes | The reported number of peak bytes in the receive direction per second.                                                                            |

| Table/Group              | Supported Variables      | Comments                                                             |
|--------------------------|--------------------------|----------------------------------------------------------------------|
| extremePortQosStatsTable | extremePortQosStatsEntry | This table lists Ports QoS information for either ingress or egress. |
|                          | extremePortQosIngress    | Indicates whether the port is in ingress/egress.                     |
|                          | extremePortQP0TxBytes    | The number of QoS 0 bytes that gets transmitted from this port.      |
|                          | extremePortQP0TxPkts     | The number of QoS 0 packets that gets transmitted from this port.    |
|                          | extremePortQP1TxBytes    | The number of QoS 1 bytes that gets transmitted from this port.      |
|                          | extremePortQP1TxPkts     | The number of QoS 1 packets that gets transmitted from this port.    |
|                          | extremePortQP2TxBytes    | The number of QoS 2 bytes that gets transmitted from this port.      |
|                          | extremePortQP2TxPkts     | The number of QoS 2 packets that gets transmitted from this port.    |
|                          | extremePortQP3TxBytes    | The number of QoS 3 bytes that gets transmitted from this port.      |
|                          | extremePortQP3TxPkts     | The number of QoS 3 packets that gets transmitted from this port.    |
|                          | extremePortQP4TxBytes    | The number of QoS 4 bytes that gets transmitted from this port.      |
|                          | extremePortQP4TxPkts     | The number of QoS 4 packets that gets transmitted from this port.    |
|                          | extremePortQP5TxBytes    | The number of QoS 5 bytes that gets transmitted from this port.      |
|                          | extremePortQP5TxPkts     | The number of QoS 5 packets that gets transmitted from this port.    |
|                          | extremePortQP6TxBytes    | The number of QoS 6 bytes that gets transmitted from this port.      |
|                          | extremePortQP6TxPkts     | The number of QoS 6 packets that gets transmitted from this port.    |
|                          | extremePortQP7TxBytes    | The number of QoS 7 bytes that gets transmitted from this port.      |
|                          | extremePortQP7TxPkts     | The number of QoS 7 packets that gets transmitted from this port.    |

| Table/Group                        | Supported Variables                | Comments                                                                                                                |
|------------------------------------|------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| extremePortMauTable                | All objects                        | Port Optics Status Table. extremePortMauTable is not supported. Use the ifMauTable (MAU-MIB) to get optics information. |
| extremePortCongestionStatsTable    | extremePortCongestionStatsEntry    | This table lists ports congestion information.                                                                          |
|                                    | extremePortCongDropPkts            | The number of packets dropped due to congestion on this port.                                                           |
| extremePortQosCongestionStatsTable | extremePortQosCongestionStatsEntry | This table lists ports per QoS congestion information.                                                                  |
|                                    | extremePortQP0CongPkts             | The number of QoS 0 packets that got dropped due to congestion on this port.                                            |
|                                    | extremePortQP1CongPkts             | The number of QoS 1 packets that got dropped due to congestion on this port.                                            |
|                                    | extremePortQP2CongPkts             | The number of QoS 2 packets that got dropped due to congestion on this port.                                            |
|                                    | extremePortQP3CongPkts             | The number of QoS 3 packets that got dropped due to congestion on this port.                                            |
|                                    | extremePortQP4CongPkts             | The number of QoS 4 packets that got dropped due to congestion on this port.                                            |
|                                    | extremePortQP5CongPkts             | The number of QoS 5 packets that got dropped due to congestion on this port.                                            |
|                                    | extremePortQP6CongPkts             | The number of QoS 6 packets that got dropped due to congestion on this port.                                            |
|                                    | extremePortQP7CongPkts             | The number of QoS 7 packets that got dropped due to congestion on this port.                                            |

| Table/Group            | Supported Variables        | Comments                                                                                                                                |
|------------------------|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| extremePortConfigTable |                            | Not-accessible.<br>This table lists port entries with information including auto negotiation, configured port speed, and duplex.        |
|                        | extremePortConfigEntry     | Not-accessible.<br>An individual Port Information Entry with information including auto negotiation, configured port speed, and duplex. |
|                        | extremePortAutoNegotiation | Read-write access.<br>Indicates whether the port is operating auto negotiation mode.                                                    |
|                        | extremePortAdminSpeed      | Read-write access.<br>The configured speed of the port. The current actual speed of the port can be determined from ifSpeed             |
|                        | extremePortDuplex          | Read-write access.<br>Indicates whether the port is operating in half- duplex, full- duplex, or auto negotiation mode.                  |
|                        | extremePortMedium          | Read-write access.<br>Medium-specific attributes for combination ports.                                                                 |

The following traps can be generated:

| Trap                          | Comments                                                                                                                                                                                                                                                                                              |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremePortMauChangeTrap      | This trap is sent whenever a MAU is inserted or removed. When the MAU is inserted, the value of extremePortMauStatus is 'inserted' and extremePortMauType indicates the type of the MAU inserted. If MAU is removed, the value of extremePortMauStatus is empty and the type of the MAU will be NONE. |
| extremeRateLimitExceededAlarm | This notification indicates the first time a poll of a rate-limited port has a non-zero counter.                                                                                                                                                                                                      |

## Pseudowire LSP Sharing MIB

By implementing the tables in PW LSP sharing MIB, the SNMP manager is able to observe the transmit packet counters over each LSP that is configured for used by the PW, and aggregated transmit and receive packet counters over PW itself. It consist three tables:

- extremePwPerfTable
- extremePwLspOutboundMappingTable
- extremePwLspPerfTable

There are no standard MIB tables and scalars objects that can be used for Pseudo Wire LSP Sharing. MIB table and object defined here are Extreme Networks proprietary. These three table are implemented in code/ l3protocol/mpls/src/extrememplsMib.my.

A new SNMP MIB object is introduced for PW LSP Load Sharing: extremePwObjects OBJECT IDENTIFIER ::= { extremeMplsMIB 5 }

#### *extremePwPerfTable*

This table contains the aggregated transmit and receive packet counters for in-service PWs.

| MIB Object         | Description                                 | Variable Type | Support Status |
|--------------------|---------------------------------------------|---------------|----------------|
| pwPerfInPackets    | Receive packet counter per PW               | Read          | Supported      |
| pwPerfInBytes      | Receive packet counter in bytes per PW      | Read          | Supported      |
| pwPerfOutPackets   | Transmit packet counters per PW             | Read          | Supported      |
| pwPerfOutBytes     | Transmit packet counter in bytes per PW     | Read          | Supported      |
| pwPerfInHCPackets  | Receive high capacity packet counter per PW | Read          | Supported      |
| pwPerfInHCBytes    | Receive packet counter in bytes per PW      | Read          | Supported      |
| pwPerfOutHCPackets | Transmit packet counters per PW             | Read          | Supported      |
| pwPerfOutHCBytes   | Transmit packet counter in bytes per PW     | Read          | Supported      |

#### *extremePwLspOutboundMappingTable*

This table provides the mapping between PWs and LSPs by providing an LSP index. LSP indexes are assigned uniquely for each PW. Entries in this table indicate that an LSP is being used by an in-service PW. An SNMP notification will be sent when an entry is added or deleted.

| MIB Object              | Description                                                                        | Variable Type | Support Status |
|-------------------------|------------------------------------------------------------------------------------|---------------|----------------|
| lspIndex                | LSP index per LSP used by the PW. It is only unique per PW peer.                   | Index         | Supported      |
| pwLspOutboundLsrXclndex | Corresponding entry in the <i>MPLS (Multiprotocol Label Switching)-LSR-STD-MIB</i> | Read          | Supported      |
| pwLspOutboundTunnelndex | Corresponding RSVP-TE tunnel index based on LSP index used by the PW               | Read          | Supported      |

| MIB Object                   | Description                                                                                                                                                                 | Variable Type | Support Status |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|----------------|
| pwLspOutboundTunnelInstance  | Corresponding RSVP-TE tunnel instance based on LSP index used by the PW                                                                                                     | Read          | Supported      |
| pwLspOutboundTunnelLclLSR    | Corresponding RSVP-TE tunnel ingress LSR ID based on LSP index used by the PW                                                                                               | Read          | Supported      |
| pwLspOutboundTunnelPeerLSR   | Corresponding RSVP-TE tunnel egress LSR ID based on LSP index used by the PW                                                                                                | Read          | Supported      |
| pwLspOutboundTunnelTypeInUse | LSP Type used by the PW. mplsTe value (MIB definition is 1) is being used for RSVP-TE LSPs, and mplsNonTe value (MIB definition is 2) is being used for Static or LDP LSPs. | Read          | Supported      |

#### *extremePwLspPerfTable*

This table contains the transmit packet and byte counters for traffic sent over a specific PW using a specific LSP.

| MIB Object            | Description                                                           | Variable Type | Support Status |
|-----------------------|-----------------------------------------------------------------------|---------------|----------------|
| pwLspPerfOutPackets   | Receive packet counter per LSP used by the PW.                        | Index         | Supported      |
| pwLspPerfOutBytes     | Receive packet counter in bytes per LSP used by the PW.               | Read          | Supported      |
| pwLspPerfOutHCPackets | Receive high capacity packet counter per LSP used by the PW.          | Read          | Supported      |
| pwLspPerfOutHCBytes   | Receive high capacity packet counter in bytes per LSP used by the PW. | Read          | Supported      |

## EXTREME-QOS-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group             | Supported Variables         | Comments                                                                                                                                                                                                                                                           |
|-------------------------|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeQosProfileTable  | extremeQosProfileIndex      | An index that uniquely identifies an entry in the <i>QoS</i> table.                                                                                                                                                                                                |
|                         | extremeQosProfileName       | A unique QoS profile name.                                                                                                                                                                                                                                         |
|                         | extremeQosProfileMinBw      | The minimum percentage of bandwidth that this queue requires. The switch is required to provide the minimum amount of bandwidth to the queue. The lowest possible value is 0%.                                                                                     |
|                         | extremeQosProfileMaxBw      | The maximum percentage of bandwidth that this queue is permitted to use.                                                                                                                                                                                           |
|                         | extremeQosProfilePriority   | The level of priority at which this queue will be serviced by the switch.                                                                                                                                                                                          |
|                         | extremeQosProfileRowStatus  | The status of the extremeQosProfile entry. This object can be set to:<br>active (1)createAndGo (4)createAndWait(5)destroy (6)<br>The following values may be read:<br>active<br>(1)notInService(2)notReady (3)                                                     |
| extremeIqosProfileTable | extremeIqosProfileIndex     | The ExtremeXOS software does not support global QoS profile settings in CLI; it supports per port settings only. Walks of this table display the default values with which the ports are initialized.                                                              |
|                         | extremeIqosProfileName      | A unique ingress QoS profile name.                                                                                                                                                                                                                                 |
|                         | extremeIqosProfileMinBwType | The type of the current minimum bandwidth setting. A value of 1 signifies that the minimum bandwidth value is a percentage of the configurable port bandwidth. A value of 2 or 3 signifies a guaranteed minimum available bandwidth in Kbps or Mbps, respectively. |

| Table/Group            | Supported Variables        | Comments                                                                                                                                                                                                                                                                                       |
|------------------------|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | extremeQosProfileMinBw     | The guaranteed minimum bandwidth for this queue, expressed as either a percentage or a specific bandwidth value, as specified by the value of extremeQosProfileMinBwType.                                                                                                                      |
|                        | extremeQosProfileMaxBwType | The type of the current maximum bandwidth setting. A value of 1 signifies that the maximum bandwidth value is a percentage of the configurable port bandwidth. A value of 2 or 3 signifies a maximum allowed bandwidth in Kbps or Mbps, respectively.                                          |
|                        | extremeQosProfileMaxBw     | The maximum allowed input bandwidth for this queue, expressed as either a percentage or a specific bandwidth value, as specified by the value of extremeQosProfileMaxBwType.                                                                                                                   |
|                        | extremeQosProfileRED       | The random early drop threshold. When the input queue fill ratio exceeds this percentage, frames start to drop randomly with a linear increasing drop probability as the queue fill count approaches the maximum queue size. A value of 100 indicates that this feature is currently disabled. |
|                        | extremeQosProfileMaxBuf    | The percentage of the total ingress queue size to use. Lower values can be used to reduce the maximum latency through this queue, but with potentially greater loss with bursty traffic.                                                                                                       |
| extremePerPortQosTable | extremePerPortQosIndex     | The value of this variable is the same as the value of extremeQosProfileIndex of the QoS profile which is overridden (for the port specified by ifIndex) by the definition in this table.                                                                                                      |
|                        | extremePerPortQosMinBw     | The minimum percentage of bandwidth that this queue on the specified port requires. The switch is required to provide the minimum amount of bandwidth to the queue. The lowest possible value is 0%.                                                                                           |

| Table/Group                   | Supported Variables                    | Comments                                                                                                                                                                                                                                                                                               |
|-------------------------------|----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                               | extremePerPortQosMaxBw                 | The maximum percentage of bandwidth that this queue on the specified port is permitted to use.                                                                                                                                                                                                         |
|                               | extremePerPortQosPriority              | The level of priority at which this queue will be serviced by the switch.                                                                                                                                                                                                                              |
|                               | extremePerPortQosRowStatus             | The status of the extremePerPortQos entry. This object can be set to active (1) and createAndGo (4). The following value may be read: active (1). Note that a destroy (6) is not supported. A row will only be deleted from this table when the QoS profile indicated in that row is changed globally. |
| extremeQosByVlanMapping Table | extremeVlanIfIndex                     | Shows mapping of <u>VLAN</u> to queues for untagged packets. For tagged packets, the vpri field determines which queue the packet should be using.                                                                                                                                                     |
|                               | extremeQosByVlanMappingQosProfileIndex | Value of extremeQosProfileIndex that uniquely identifies a QoS profile entry in an extremeQosProfileTable. This indicates the QoS to be given to traffic for this VLAN in the absence of any other more specific configuration information for this traffic.                                           |

## EXTREME-RMON-MIB

The following tables, groups, and variables are supported in this MIB

| Table/Group         | Supported Variables           | Comments                                |
|---------------------|-------------------------------|-----------------------------------------|
| extremeRtStatsTable | extremeRtStatsIndex           | All objects are supported as read-only. |
|                     | extremeRtStatsIntervalStart   |                                         |
|                     | extremeRtStatsCRCAAlignErrors |                                         |
|                     | extremeRtStatsUndersizePkts   |                                         |
|                     | extremeRtStatsOversizePkts    |                                         |
|                     | extremeRtStatsFragments       |                                         |
|                     | extremeRtStatsJabbers         |                                         |
|                     | extremeRtStatsCollisions      |                                         |

| Table/Group | Supported Variables       | Comments |
|-------------|---------------------------|----------|
|             | extremeRtStatsTotalErrors |          |
|             | extremeRtStatsUtilization |          |

## EXTREME-PVLAN-MIB

Two MIB tables allow for GET/SET operations to view and configure ExtremeXOS PVLAN objects. The first is a PVLAN name table with PVLAN name as the index, and the second is the PVLAN subscriber table with PVLAN name, member VLAN type, and Subscriber VlanIfIndex as the index. Functionality includes supporting the current set of PVLAN CLI configuration options.

*PVLAN Table (extremePvlanTable)*

| extremePvlanName (index) | extremePvlanVrName | extremePvlanNetworkVlanIfIndex |
|--------------------------|--------------------|--------------------------------|
| DisplayString            | DisplayString      | InterfaceIndexOrZero           |
| p1                       | VR-Default14       | 14                             |
| foo                      | VR-Cust1           | 0                              |

*PVLAN Subscriber Table (extremePvlanSubscriberTable)*

| extremePvlanName (index) | extremePvlanSubscriberVlanIfIndex (index) | extremePvlanSubscriberType | extremePvlanSubscriberLoopBackPortIfIndex |
|--------------------------|-------------------------------------------|----------------------------|-------------------------------------------|
| DisplayString            | InterfaceIndex                            | Integer                    | InterfaceIndexOrZero                      |
| foo                      | 9                                         | PVLAN_ISOLATED(2)          | 0                                         |
| foo                      | 12                                        | PVLAN_ISOLATED(2)          | 1002                                      |
| p1                       | 1                                         | PVLAN_ISOLATED(2)          | 0                                         |
| p1                       | 6                                         | PVLAN_NON_ISOLATED(1)      | 1004                                      |
| p1                       | 8                                         | PVLAN_ISOLATED(2)          | 1010                                      |
| p1                       | 10                                        | PVLAN_NON_ISOLATED(1)      | 0                                         |

RowStatus is defined as: active(1), createAndGo(4), destroy(6)

## EXTREME-SNMPv3-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group               | Supported Variables                   | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeTargetAddrExtTable | extremeTargetAddrExtIgnoreMPModel     | The value of the snmpTargetParamsMPModel object in the snmpTargetParamsTable is ignored while determining the version of the trap/notification to be sent. When a trap-receiver is created through the RMON trapDestTable or from the CLI command 'configure snmp add trapreceiver ...', the value of this object is set to TRUE for the corresponding entry in this table.                                                                                                                                                                                                                                                                                                                                                                                               |
|                           | extremeTargetAddrExtStandardMode      | When this object is set to TRUE, the management target is treated as a 'standard mode' one, in that any Extreme Networks specific extra varbinds present in a standards-based trap/notification is not sent to this management target. Only the varbinds defined in the standard are sent.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|                           | extremeTargetAddrExtTrapDestIndex     | This object contains the value of the trapDestIndex in the corresponding entry of the RMON trapDestTable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                           | extremeTargetAddrExtUseEventCommunity | This object is used only when sending RMON alarms as SNMPv3 traps. When it is set to TRUE and an RMON risingAlarm or fallingAlarm is being sent for an event, then the eventCommunity in the RMON event table is compared to the snmpTargetAddrName in the snmpTargetAddrTable. The alarm is sent to the target only when the two are the same. This behavior is exhibited only when the snmpTargetParamsMPModel corresponding to the target indicates an SNMPv3 trap. For SNMPv1/v2c traps, the community in the RMON trapDestTable is used for the comparison, which is the regular method, as per the standards. When this object is set to FALSE, then the RMON alarm (if being sent as an SNMPv3 trap) is sent without using the event community for any comparison. |

| Table/Group                 | Supported Variables           | Comments                                                                                                                                                                          |
|-----------------------------|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                             | extremeTargetAddrExtTrapSrcIp | This object contains the source IP address from which traps have to be sent out. If this object is assigned an IP address that does not belong to the switch, an error is thrown. |
|                             | extremeTargetAddrExtVrName    | This object contains the VR name through which the <i>SNMP</i> Traps are being sent out.                                                                                          |
| extremeUsm3DESPrivProtocol  |                               | Supported from ExtremeXOS 12.3                                                                                                                                                    |
| extremeUsmAesCfb192Protocol |                               | Supported from ExtremeXOS 12.3                                                                                                                                                    |
| extremeUsmAesCfb256Protocol |                               | Supported from ExtremeXOS 12.3                                                                                                                                                    |

## EXTREME-STP-EXTENSIONS-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group             | Supported Variables             | Comments                                                                                                                              |
|-------------------------|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| extremeStpDomainTable   | All objects                     | This table contains <i>STP</i> information per STP domain.                                                                            |
|                         | extremeStpDomainStpdDescription | The description associated with this STP domain.                                                                                      |
| extremeStpPortTable     | All objects                     | This table contains port-specific information per STP domain.                                                                         |
| extremeStpVlanPortTable | All objects                     | This table contains information of the ports belonging to a STP domain on a per <i>VLAN</i> basis.                                    |
| extremeStpNotifications | extremeStpEdgePortLoopDetected  | This is a trap that would be sent when a loop has been detected on the network login edge safeguard port (the port will be disabled). |

## EXTREME-STPNOTIFICATIONS-MIB

This MIB defines the following Extreme-specific *STP* Notifications trap generated by Extreme Networks devices.

| Trap                           | Comments                                                                                         |
|--------------------------------|--------------------------------------------------------------------------------------------------|
| extremeStpEdgePortLoopDetected | A loop has been detected on the network login edge safeguard port and the port will be disabled. |

## EXTREME-SYSTEM-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group | Supported Variables            | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | extremeSaveConfiguration       | When this object is set, the device copies the contents of the configuration database to a buffer and saves it to the persistent store specified by the value of the object. The save is performed asynchronously, and the <i>SNMP</i> agent continues to respond to both gets and sets while the save is taking place. A network management application may use the extremeSaveStatus object to determine when the asynchronous save operation has completed. |
|             | extremeSaveStatus              | This object returns the status of a save operation invoked by setting the extremeSaveConfiguration object. A network management application can read this object to determine that a save operation has completed.                                                                                                                                                                                                                                             |
|             | extremeCurrentConfigInUse      | Shows which NVRAM configuration store was used at last boot.                                                                                                                                                                                                                                                                                                                                                                                                   |
|             | extremeConfigToUseOnReboot     | Controls which NVRAM configuration store will be used on next reboot.                                                                                                                                                                                                                                                                                                                                                                                          |
|             | extremeOverTemperatureAlarm    | Alarm status of overtemperature sensor in device enclosure.                                                                                                                                                                                                                                                                                                                                                                                                    |
|             | extremePrimaryPowerOperational | Not supported. Always returns True.                                                                                                                                                                                                                                                                                                                                                                                                                            |
|             | extremePowerStatus             | Not supported. Always returns presentOK.                                                                                                                                                                                                                                                                                                                                                                                                                       |
|             | extremePowerAlarm              | Not supported. Always returns False.                                                                                                                                                                                                                                                                                                                                                                                                                           |
|             | extremeRedundantPowerStatus    | Not supported. Always returns presentOK.                                                                                                                                                                                                                                                                                                                                                                                                                       |
|             | extremeRedundantPowerAlarm     | Not supported. Always returns presentOK.                                                                                                                                                                                                                                                                                                                                                                                                                       |
|             | extremeInputPowerVoltage       | Contains the input voltage of the latest power-supply to power-on in a system with multiple power-supplies.                                                                                                                                                                                                                                                                                                                                                    |

| Table/Group           | Supported Variables            | Comments                                                                                                |
|-----------------------|--------------------------------|---------------------------------------------------------------------------------------------------------|
|                       | extremePrimarySoftwareRev      | This value indicates the revision number of the software image on the primary partition.                |
|                       | extremeSecondarySoftwareRev    | This value indicates the revision number of the software image on the secondary partition.              |
|                       | ExtremeImageToUseOnReboot      | This value indicates the partition where the software image is located and to be used on the next boot. |
|                       | extremeSystemID                | This represents the system ID of a switch.                                                              |
|                       | extremeSystemBoardID           | Not supported.                                                                                          |
|                       | extremeSystemLeftBoardID       |                                                                                                         |
|                       | extremeSystemRightBoardID      |                                                                                                         |
|                       | extremeRmonEnable              |                                                                                                         |
|                       | extremeBootROMVersion          | Returns information for the current MSM only.                                                           |
|                       | extremeDot1dTpFdbTableEnable   | Not supported.                                                                                          |
|                       | extremeHealthCheckErrorType    |                                                                                                         |
|                       | extremeHealthCheckAction       |                                                                                                         |
|                       | extremeHealthCheckMaxRetries   |                                                                                                         |
|                       | extremeCpuUtilRisingThreshold  |                                                                                                         |
|                       | extremeCpuTaskUtilPair         |                                                                                                         |
|                       | extremeCpuAggregateUtilization |                                                                                                         |
|                       | extremeCpuUtilRisingThreshold  |                                                                                                         |
|                       | extremeAuthFailSrcAddr         |                                                                                                         |
|                       | extremeCpuTransmitPriority     |                                                                                                         |
|                       | extremeImageBooted             |                                                                                                         |
| extremeFanStatusTable | extremeFanStatusEntry          | Operational status of all internal cooling fans.                                                        |
|                       | extremeFanNumber               | Identifier of cooling fan, numbered from the front and/or left side of device.                          |
|                       | extremeFanOperational          | Operational status of a cooling fan.                                                                    |

| Table/Group                        | Supported Variables                             | Comments                                                                                                                                        |
|------------------------------------|-------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
|                                    | extremeFanEntPhysicalIndex                      | The entity index for this fan entity in the entityPhysicalTable table of the entity MIB.                                                        |
|                                    | extremeFanSpeed                                 | The speed (RPM) of a cooling fan in the fantray.                                                                                                |
| extremeCpuTaskTable                | All objects                                     | Not supported.                                                                                                                                  |
| extremeCpuTask2Table               | All objects                                     | Not supported.                                                                                                                                  |
| extremeSlotTable                   | All objects                                     | Cards are currently not configurable via SNMP.                                                                                                  |
| extremePowerSupplyEntPhysicalIndex | extremePowerSupplyEntPhysicalIndex              | The entity index for this psu entity in the entityPhysicalTable of the entity MIB.                                                              |
| extremePowerSupplyNumber           | extremePowerSupplyNumber                        | Power supply number.                                                                                                                            |
| extremePowerSupplySerialNumber     | extremePowerSupplySerialNumber                  | The serial number of the power supply unit.                                                                                                     |
| extremePowerSupplySource           | extremePowerSupplySource                        | The power supply unit input source.                                                                                                             |
| extremePowerSupplyTable            | extremePowerSupplyStatus                        | Status of the power supply.                                                                                                                     |
|                                    | extremePowerSupplyInputVoltage                  | Input voltage of the power supply.                                                                                                              |
|                                    | extremePowerSupplyFan1Speed                     | The speed of Fan-1 in the power supply unit.                                                                                                    |
|                                    | extremePowerSupplyFan2Speed                     | The speed of Fan-2 in the power supply unit.                                                                                                    |
|                                    | extremePowerSupplyInputPowerUsage               | Input power usage for the given psu slot. The value 0 in this field indicates the power usage is not supported or that there is a read failure. |
|                                    | extremePowerMonSupplyNumOutput                  | Number of output sensors in the power supply unit.                                                                                              |
|                                    | extremePowerSupplyInputPowerUsageUnitMultiplier | The magnitude of watts for the usage value in extremePowerSupplyInputPowerUsage.                                                                |
| extremePowerSupplyOutputPowerTable | extremePowerSupplyIndex                         | Power supply unit slot index.                                                                                                                   |
|                                    | extremePowerSupplyOutputSensorIdx               | Power supply Sensor index.                                                                                                                      |

| Table/Group                    | Supported Variables                    | Comments                                                                                                                                                                                          |
|--------------------------------|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                | extremePowerSupplyOutputVoltage        | Output voltage per sensor for the current PSU slot number. A zero (0) in this field indicates that the PSU does not support output voltage reading or else there is an output voltage read error. |
|                                | extremePowerSupplyOutputCurrent        | Output current per sensor for the current PSU slot number. A zero (0) in this field indicates that the PSU does not support output current reading or else there is an output current read error. |
|                                | extremePowerSupplyOutputUnitMultiplier | The magnitude of volts and amps for the usage value in extremePowerSupplyOutputVoltage and extremePowerSupplyOutputCurrent.                                                                       |
| extremePowerSupplyUsageTable   | extremeSlotIndex                       | Slot number in the stack-based system.                                                                                                                                                            |
|                                | extremePowerSupplyUsageValue           | Power usage of the particular slot in the stack. The power usage is measured in milliwatts.                                                                                                       |
|                                | extremePowerSupplyUnitMultiplier       | The magnitude of watts for the usage value in extremePowerSupplyUsageValue.                                                                                                                       |
| extremeSystemPowerUsage        | extremeSystemPowerUsageValue           | The current power usage of the system. In stack mode, this variable tells the total power usage of the entire system.                                                                             |
|                                | extremeSystemPowerUsageUnitMultiplier  | The magnitude of watts for the usage value in extremeSystemPowerUsageValue.                                                                                                                       |
| extremeSystemPowerMonitorTable | extremeSystemPowerMonitorIndex1        | Reserved. Can be used for future expansion. Currently set to zero.                                                                                                                                |

| Table/Group                         | Supported Variables                                                                      | Comments                                                                                                                                                                              |
|-------------------------------------|------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                     | extremeSystemPowerMonitorPollInterval                                                    | Configure how often input power is measured. It is configured in seconds with a default value of 60 seconds. If zero (0) is configured, then the input power measurement is disabled. |
|                                     | extremeSystemPowerMonitorReportChanges                                                   | Configure report-changes. Has none or log or trap or log-and-trap, with a default of none.                                                                                            |
|                                     | extremeSystemPowerMonitorChangeThreshold                                                 | Configure the input power change threshold to initiate report-changes action. By default 2 watts is configured. This field is configured in watts.                                    |
| extremeSystemPowerUsageNotification | sysUpTime, sysDescr, extremeSystemPowerUsageValue, extremeSystemPowerUsageUnitMultiplier | Whenever the power usage is increased/decreased by the configured threshold value, then the power usage trap is generated if the trap is enabled.                                     |
| extremeImageTable                   | extremeImageNumber                                                                       | This table contains image information for all images installed on the device. extremeImageNumber values are not compatible with EW releases. Current image has value 3 instead of 0.  |
|                                     | extremeMajorVersion                                                                      | This is the first number within the software image version number which consists of 4 numbers separated by a period.                                                                  |
|                                     | extremeMinorVersion                                                                      | This is the second number within the software image version number.                                                                                                                   |
|                                     | extremeBuildNumber                                                                       | This is the fourth number within the software image version number.                                                                                                                   |
|                                     | extremeTechnologyReleaseNumber                                                           | The technology release version. This value is zero for all but TR releases.                                                                                                           |
|                                     | extremeSustainingReleaseNumber                                                           | The sustaining release number for the ExtremeXOS version.                                                                                                                             |

| Table/Group                       | Supported Variables         | Comments                                                                                                                                                                              |
|-----------------------------------|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                   | extremeBranchRevisionNumber | This is the branch from where the software image was built.                                                                                                                           |
|                                   | extremeImageType            | This is the software image type (for example, ExtremeXOS core, ExtremeXOS module, ExtremeXOS firmware).                                                                               |
|                                   | extremeImageDescription     | Description of image contains image version, including major version, submajor version, minor version, build version, build branch, build-master login, and build date.               |
|                                   | extremePatchVersion         | The ExtremeXOS release patch version. This is the third number within the software image version number.                                                                              |
| extremeImageFeatureTable          | extremeImageFeatureEntry    | A table containing information about the software features.                                                                                                                           |
|                                   | extremeImageFeatureNumber   | A unique integer identifying the particular software image. This indicates the partition on which the image is loaded:<br>0—Current partition1—Primary partition2—Secondary partition |
|                                   | extremeImageSshCapability   | Indicates whether image has SSH capability:<br>1=nossh—shown by default when the SSH license is not enabled.2=ssh—shown when the SSH license is enabled.                              |
|                                   | extremeImageUAACapability   | Not supported.                                                                                                                                                                        |
| extremeCpuMonitorInterval         |                             | This value determines how frequent CPU usage will be monitored.                                                                                                                       |
| extremeCpuMonitorTotalUtilization |                             | This value indicates the total CPU utilization.                                                                                                                                       |
| extremeCpuMonitorTable            |                             | This value indicates the total CPU utilization.                                                                                                                                       |
|                                   | extremeCpuMonitorSlotId     | This value indicates the slot ID where the CPU is being monitored.                                                                                                                    |

| Table/Group                  | Supported Variables                      | Comments                                                                 |
|------------------------------|------------------------------------------|--------------------------------------------------------------------------|
|                              | extremeCpuMonitorProcessName             | This value indicates the process name for the process being monitored.   |
|                              | extremeCpuMonitorProcessId               | This value indicates the process ID.                                     |
|                              | extremeCpuMonitorProcessState            | This value indicates the current state of the process.                   |
|                              | extremeCpuMonitorUtilization5secs        | This value indicates the CPU utilization in the past 5 seconds.          |
|                              | extremeCpuMonitorUtilization10secs       | This value indicates the CPU utilization in the past 10 seconds.         |
|                              | extremeCpuMonitorUtilization30secs       | This value indicates the CPU utilization in the past 30 seconds.         |
|                              | extremeCpuMonitorUtilization1min         | This value indicates the CPU utilization in the past 1 minute.           |
|                              | extremeCpuMonitorUtilization5mins        | This value indicates the CPU utilization in the past 5 minutes.          |
|                              | extremeCpuMonitorUtilization30mins       | This value indicates the CPU utilization in the past 30 minutes.         |
|                              | extremeCpuMonitorUtilization1hour        | This value indicates the CPU utilization in the past 1 hour.             |
|                              | extremeCpuMonitorUserTime                | This value indicates the CPU usage under User Mode.                      |
|                              | extremeCpuMonitorSystemTime              | This value indicates the CPU usage under system mode.                    |
| extremeCpuMonitorSystemTable |                                          | This table contains CPU monitoring information for all system processes. |
|                              | extremeCpuMonitorSystemSlotId            | This value indicates the slot ID where the CPU is being monitored.       |
|                              | extremeCpuMonitorSystemUtilization5secs  | This value indicates the CPU utilization in the past 5 seconds.          |
|                              | extremeCpuMonitorSystemUtilization10secs | This value indicates the CPU utilization in the past 10 seconds.         |

| Table/Group                     | Supported Variables                      | Comments                                                                                    |
|---------------------------------|------------------------------------------|---------------------------------------------------------------------------------------------|
|                                 | extremeCpuMonitorSystemUtilization30secs | This value indicates the CPU utilization in the past 30 seconds.                            |
|                                 | extremeCpuMonitorSystemUtilization1min   | This value indicates the CPU utilization in the past 1 minute.                              |
|                                 | extremeCpuMonitorSystemUtilization5mins  | This value indicates the CPU utilization in the past 5 minutes.                             |
|                                 | extremeCpuMonitorSystemUtilization30mins | This value indicates the CPU utilization in the past 30 minutes.                            |
|                                 | extremeCpuMonitorSystemUtilization1hour  | This value indicates the CPU utilization in the past 1 hour.                                |
|                                 | extremeCpuMonitorSystemMaxUtilization    | This value indicates the maximum CPU utilization so far.                                    |
| extremeMemoryMonitorSystemTable |                                          | This table contains system-level memory monitor information.                                |
|                                 | extremeMemoryMonitorSystemSlotId         | This value indicates the slot ID where the memory is being monitored.                       |
|                                 | extremeMemoryMonitorSystemTotal          | This value indicates the total memory installed on the switch.                              |
|                                 | extremeMemoryMonitorSystemFree           | This value indicates the amount of memory that is free.                                     |
|                                 | extremeMemoryMonitorSystemUsage          | This value indicates the amount of memory consumed for kernel code.                         |
|                                 | extremeMemoryMonitorUserUsage            | This value indicates the amount of memory consumed by user processes as well as the kernel. |
| extremeMemoryMonitorTable       |                                          | This table contains memory monitor information for each user process.                       |
|                                 | extremeMemoryMonitorSlotId               | This value indicates the slot ID where the memory is being monitored.                       |
|                                 | extremeMemoryMonitorProcessName          | This value indicates the name of the process being monitored.                               |

| Table/Group | Supported Variables                     | Comments                                                                       |
|-------------|-----------------------------------------|--------------------------------------------------------------------------------|
|             | extremeMemoryMonitorUsage               | This value indicates the amount of memory being consumed by this user process. |
|             | extremeMemoryMonitorLimit               | Not supported.                                                                 |
|             | extremeMemoryMonitorZone                |                                                                                |
|             | extremeMemoryMonitorGreenZoneCount      |                                                                                |
|             | extremeMemoryMonitorYellowZoneCount     |                                                                                |
|             | extremeMemoryMonitorOrangeZoneCount     |                                                                                |
|             | extremeMemoryMonitorRedZoneCount        |                                                                                |
|             | extremeMemoryMonitorGreenZoneThreshold  |                                                                                |
|             | extremeMemoryMonitorYellowZoneThreshold |                                                                                |
|             | extremeMemoryMonitorOrangeZoneThreshold |                                                                                |
|             | extremeMemoryMonitorRedZoneThreshold    |                                                                                |

## EXTREME-TRAP-MIB

This MIB defines the following Extreme-specific SNMPv1 traps generated by Extreme Networks devices.

| Trap                       | Comments                                                                                                                                                                                                                               |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeOverheat            | The on-board temperature sensor has reported an overheat condition. The system shuts down until the unit has sufficiently cooled such that operation can begin again. A cold start trap is issued when the unit has come back on line. |
| extremeFanfailed           | One or more of the cooling fans inside the device has failed. A fanOK trap will be sent once the fan has attained normal operation.                                                                                                    |
| extremeFanOK               | A fan has transitioned out of a failure state and is now operating correctly.                                                                                                                                                          |
| extremeInvalidLoginAttempt | A user attempted to log into the console or by telnet but was refused access due to an incorrect username or password.                                                                                                                 |
| extremePowerSupplyGood     | One or more previously bad sources of power to this agent has come back to life without causing an agent restart.                                                                                                                      |
| extremePowerSupplyFail     | One or more sources of power to this agent has failed. Presumably a redundant power-supply has taken over.                                                                                                                             |
| extremeEdpNeighborAdded    | This node discovers a new neighbor through <i>EDP</i> .                                                                                                                                                                                |

| Trap                      | Comments                                                                                                                                                |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeEdpNeighborRemoved | No EDP updates are received from this neighbor within the configured timeout period and this neighbor entry is aged out by the device.                  |
| extremeModuleStateChanged | Signifies that the value of the extremeSlotModuleState for the specified extremeSlotNumber has changed. Traps are reported only for significant states. |

## EXTREME-TRAPPOLL-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group                   | Supported Variables                     | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------|-----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                               | extremeSmartTrapFlushInstanceTableIndex | This object acts as a flush control for the extremeSmartTrapInstanceTable. Setting this object can flush the matching entries from the extremeSmartTrapInstanceTable based on certain rules as defined in the MIB.                                                                                                                                                                                                                                                                                                                                         |
| extremeSmartTrapRulesTable    |                                         | The entries created in the extremeSmartTrapRulesTable define the rules that are used to generate Extreme smart traps. The object extremeSmartTrapRulesDesiredOID supports OID values whose prefix are among the following:<br>ipAddrTable, ifMauTable, extremeSlotTable, extremeVlanGroup, extremeVirtualGroup, extremeVlanProtocolTable, extremeVlanProtocolVlanTable, extremeVlanOpaqueTable, extremeStpDomainTable, extremeStpPortTable, extremeStpVlanPortTable, pethPsePortTable, extremePethSystem, extremePethPseSlotTable, extremePethPsePortTable |
| extremeSmartTrapInstanceTable |                                         | extremeSmartTrapInstanceTable is a read-only table that stores the information about which variables have changed according to rules defined in the extremeSmartTrapRulesTable.                                                                                                                                                                                                                                                                                                                                                                            |

## EXTREME-V2TRAP-MIB

This MIB defines the following Extreme-specific SNMPv2c traps generated by Extreme Networks devices.

| Trap                               | Comments                                                                                                                                |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| extremeHealthCheckFailed           | CPU HealthCheck has failed.                                                                                                             |
| extremeBgpM2PrefixReachedThreshold | This notification is generated when the number of prefixes received over this peer session reaches the threshold limit.                 |
| extremeBgpM2PrefixMaxExceeded      | This notification is generated when the number of prefixes received over this peer session reaches the maximum configured limit.        |
| extremeEapsStateChange             | Send on master/transit nodes.                                                                                                           |
| extremeEapsFailTimerExpFlagSet     | This notification is generated when the <i>EAPS</i> domain fail timer expires for the first time, while its state is not in Fail state. |

| Trap                               | Comments                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeEapsFailTimerExpFlagClear   | This notification is generated when the EAPS domain fail timer expired flag is cleared.                                                                                                                                                                                                                                                                                            |
| extremeEapsLinkDownRingComplete    | If a transit is in link-down state, and it receives a Health-Check-Pdu from the master indicating the ring is complete, there is some problem with the transit switch that has issued this trap message.                                                                                                                                                                           |
| extremeEapsLastStatusChangeTime    | Sent on master/transit nodes. Provides a general indication of a status change using a 10 second timer.                                                                                                                                                                                                                                                                            |
| extremeEapsPortStatusChange        | Sent on master/transit nodes.                                                                                                                                                                                                                                                                                                                                                      |
| extremeEapsConfigChange            | Sent on master/transit nodes. This trap has a granularity of 30 seconds.                                                                                                                                                                                                                                                                                                           |
| extremeEapsSharedPortStateChange   | Sent on controller/partner nodes.                                                                                                                                                                                                                                                                                                                                                  |
| extremeEapsRootBlockerStatusChange |                                                                                                                                                                                                                                                                                                                                                                                    |
| extremeNMSInventoryChanged         | These traps are not generated by the ExtremeXOS <a href="#">SNMP</a> agent but by the Ridgeline NMS.                                                                                                                                                                                                                                                                               |
| extremeNMSTopologyChanged          |                                                                                                                                                                                                                                                                                                                                                                                    |
| extremeOverheatNormal              | An overheat (return to) normal notification indicates that the on-board tempature sensor has reported a temperature that has returned to within the normal operating range from having been in an overheat (or overcold) condition. The temperature of the unit has sufficiently cooled to be below the maximum (or warmed to be above the minimum) of the normal operating range. |

## EXTREME-VLAN-MIB

The following tables, groups, and variables are supported in this MIB.

### Note

SNMP Set operations are not allowed for "Mgmt" and "Default" VLANs.

| Table/Group         | Supported Variables             | Comments                                                                                                                                                                                                                                                      |
|---------------------|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeVirtualGroup | extremeNextAvailableVirtIfIndex |                                                                                                                                                                                                                                                               |
| extremeVlanIfTable  | extremeVlanIfIndex              | While creating a new row in the extremeVlanIfTable, the value of the object extremeVlanIfDescr must be specified.<br>For all tables in this MIB that contain objects with RowStatus semantics, the only values supported are: {active, createAndGo, destroy}. |
|                     | extremeVlanIfDescr              | This is a description of the VLAN interface.                                                                                                                                                                                                                  |

| Table/Group                     | Supported Variables           | Comments                                                                                                                                                                                                                                                                                        |
|---------------------------------|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                 | extremeVlanIfType             | The VLAN interface type.                                                                                                                                                                                                                                                                        |
|                                 | extremeVlanIfGlobalIdentifier | Not supported.                                                                                                                                                                                                                                                                                  |
|                                 | extremeVlanIfStatus           | The status column for this VLAN interface.<br>This object can be set to: active (1); createAndGo (4); createAndWait (5); destroy (6). The following values may be read: active (1); notInService (2); notReady (3).                                                                             |
|                                 | extremeVlanIfIgnoreStpFlag    | Not supported.                                                                                                                                                                                                                                                                                  |
|                                 | extremeVlanIfIgnoreBpduFlag   | Not supported.                                                                                                                                                                                                                                                                                  |
|                                 | extremeVlanIfLoopbackModeFlag | Setting this object to true causes loopback mode to be enabled on this VLAN.                                                                                                                                                                                                                    |
|                                 | extremeVlanIfVlanId           | The VLAN ID of this VLAN.                                                                                                                                                                                                                                                                       |

| extremeVMFTPServerTable | extremeVMFTPServerEntry   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                         | extremeVMFTPServerType    | The type of the FTP server. The backup server is contacted if the primary fails to respond.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                         | extremeVMFTPAddrType      | The IP type of IP address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                         | extremeVMFTPServer        | The IP address of the FTP server used for transferring various management files.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                         | extremeVMFTPSynchInterval | The time in minutes between automatic synchronization attempts. A value of 0 indicates that automatic synchronizations are not performed. Note that each switch does not perform a synchronization at exactly the time configured, but varies the synchronization interval between 3/4 and 5/4 of the configured interval. This avoids the situation where all switches in a network attempt a synchronization at exactly the same moment. Automatic synchronization is disabled by default, and requests to enable them are rejected until the FTP server information (IPv4 or IPv6 address, username, and password) is configured. |
|                         | extremeVMFTPRowStatus     | There can only be two entries in this table, one each for primary and secondary FTP servers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                         | extremeVMFTPPathName      | The FTP server directory name for the policies to be synchronized. A value of '/pub' is used by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|                         | extremeVMFTPUsername      | A valid username on the FTP server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                         | extremeVMFTPPassword      | The password associated with the FTP user. This object returns a zero length string when queried.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| extremeVMGeneral        | extremeVMFTPPolicyDir     | The server directory name for the policies to be synchronized. A value of '/' is used by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                         | extremeVMLastSynch        | The timestamp of the most recent synchronization attempt.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Table/Group              | Supported Variables                  | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | extremeVMLastSynchStatus             | The result of the most recent synchronization attempt: success (1)—indicates that the synchronization completed successfully; accessDenied (2)—The username and password were not accepted by the server; serverTimeout (3)—Could not establish a file transfer session with the configured server; serverNotConfigured (4)—The server configuration is not complete.                                                                            |
|                          | extremeVMSynchAdminState             | Triggers a synchronization cycle on demand. A synchronization automatically downloads new or updated policies as well as delete policies to match those on the server: idle (1) is returned whenever this object is read; synchronizeNow (2) triggers an immediate synchronization, and is reflected in extremeVMSynchOperState. Attempts to set this variable to synchronizeNow (2) are rejected if a synchronization is currently in progress. |
|                          | extremeVMSynchOperState              | Indicates if a synchronization is in progress, either on-demand or automatic.                                                                                                                                                                                                                                                                                                                                                                    |
|                          | extremeVMTrackingEnabled             | The virtual machine (VM) tracking feature is disabled by default and can be enabled using this object.                                                                                                                                                                                                                                                                                                                                           |
|                          | extremeVMPortConfigTable             | Configures the VM features on each port.                                                                                                                                                                                                                                                                                                                                                                                                         |
| extremeVMPortConfigEntry |                                      | An entry in the table for VM features on each port.                                                                                                                                                                                                                                                                                                                                                                                              |
|                          | extremeVMPortConfigIfIndex           | The value of ifIndex of a physical port capable of supporting the VM tracking features.                                                                                                                                                                                                                                                                                                                                                          |
|                          | extremeVMPortConfigVMTrackingEnabled | Enables the VM tracking feature on a port. The VM tracking feature is disabled by default.                                                                                                                                                                                                                                                                                                                                                       |
| extremeVMVPPTable        |                                      | This table contains port policies contained within this switch. Port policies come in two variants: network and local. Network policies are downloaded from the FTP server; local policies reside only within a single switch.                                                                                                                                                                                                                   |

| Table/Group           | Supported Variables            | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeVMVPPEntry     |                                | An entry in the table of VM policy information of this device. This table is populated with two sets of policies, those downloaded from the policy server and those defined locally on this switch.                                                                                                                                                                                                                                                                                                                                                   |
|                       | extremeVMVPPType               | The type of the port policy. Network port policies are obtained from a central policy store. Local policies are specific to this particular switch.                                                                                                                                                                                                                                                                                                                                                                                                   |
|                       | extremeVMVPPName               | The name of the port VPP. VPP names must be alpha-numeric and must start with an alpha character.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                       | extremeVMVPPControl            | Performs the requested operation on this policy. synchronizeNow (1) downloads a copy of the policy from the FTP server. (Network policies only). This object returns noOperation (2) if read.                                                                                                                                                                                                                                                                                                                                                         |
|                       | extremeVMVPPRowStatus          | Only local VPPs can be created or deleted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| extremeVMMappingTable |                                | This table contains the mapping of port policies to VM MAC addresses.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                       | extremeVMMappingEntry          | An entry in the table of VM information of this device.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                       | extremeVMMappingType           | The type of mapping for this entry. A local mapping exists only on this specific switch. A network mapping is one obtained through a download of a mapping file.                                                                                                                                                                                                                                                                                                                                                                                      |
|                       | extremeVMMappingMAC            | The MAC address associated with the VM. Note that a VM can have multiple MAC addresses.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                       | extremeVMMappingIngressVPPName | The ingress policy associated with the VM/MAC address. Note that this may refer to a policy without a corresponding entry in the extremeVMVPPTable if a network policy mapping refers to a non-existent policy. This indicates an error in the policy mapping file that is consulted if network authentication fails.<br>When creating an entry in this table, this name must refer to an existing, valid, local policy. The creation of a mapping to a network policy is not permitted. Those mappings must be created at the central policy server. |

|                          | extremeVMMappingEgressVPPName | The egress policy associated with the VM/MAC address. Note that this might refer to a policy without a corresponding entry in the extremeVMVPPTable if a network policy mapping refers to a non-existent policy. This indicates an error in the policy mapping file that is consulted if network authentication fails.<br>When creating an entry in this table, this name must refer to an existing, valid, local policy. The creation of a mapping to a network policy is not permitted. Those mappings must be created at the central policy server.                                                                                                          |
|                          | extremeVMMappingStatus        | Indicates the virtual port profile mapping status:<br>vppValid (1)—A VPP mapped to this VM MAC address does not have any policies associated with it (or) all the policies associated with this VPP can be applied (policy validation is success). Policy validation will happen only when this VM MAC is detected.vppMissing (2)—This value is applicable only for network VM if the specified VPP name was missing.vppInvalid (3)—One of the policies mapped to VPP cannot be applied (policy validation failed) because the policy file contains one or more errors that prevent it from being applied.vppNotMapped (4)—The VM does not have any VPP mapped. |
|                          | extremeVMMappingRowStatus     | Only local policies can be created or deleted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                          |                               | The virtual port profile associated with the VM MAC address. When creating an entry in this table, this name must refer to an existing, valid, local profile. The creation of a mapping to a network profile is not permitted. Those mappings must be created at the central policy server.                                                                                                                                                                                                                                                                                                                                                                     |
| extremeVMVPP2PolicyTable |                               | This table contains the mapping of a VPP to individual policies.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| extremeVMVPP2PolicyEntry |                               | An individual mapping of VPP to policy.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| extremeVMDetected      | extremeVMDetectedNumber         | The number of VMs detected on this switch.                                                                                                                                                                                                                                                                                                                                           |
| extremeVMDetectedTable |                                 | This table contains the currently detected VMs on this switch.                                                                                                                                                                                                                                                                                                                       |
| extremeVMDetectedEntry |                                 | An entry in the table of VM information of this device.                                                                                                                                                                                                                                                                                                                              |
|                        | extremeVMDetectedMAC            | The MAC address associated with the VM. Note that a VM can have multiple MAC addresses.                                                                                                                                                                                                                                                                                              |
|                        | extremeVMDetectedVMName         | The name of the VM. Note that a VM authenticated locally might not have a name.                                                                                                                                                                                                                                                                                                      |
|                        | extremeVMDetectedIngressVPPName | The name of the policy applied (or attempted to apply) to this VM.                                                                                                                                                                                                                                                                                                                   |
|                        | extremeVMDetectedEgressVPPName  | The name of the policy applied (or attempted to apply) to this VM.                                                                                                                                                                                                                                                                                                                   |
|                        | extremeVMDetectedIfIndex        | The value of ifIndex on which this VM was detected.                                                                                                                                                                                                                                                                                                                                  |
|                        | extremeVMDetectedAdminStatus    | The administrative status of the VM authentication. Setting this variable to authenticating (1) will force the re-authentication of the VM. This variable always returns idle (2) when read.                                                                                                                                                                                         |
|                        | extremeVMDetectedOperStatus     | The authentication status of the VM: authenticating (1)—an authentication is currently in progressauthenticatedNetwork (2)—the VM has been authenticated by a network sourceauthenticatedLocally (3)—the VM has been authenticated by the local databasedenied (4)—the VM was explicitly deniedentrynotAuthenticated (5)—the authentication process timed out or was never attempted |

| Table/Group             | Supported Variables             | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                         | extremeVMDetectedResultIngress  | Indicates the result of a VM entry into the network. Only the two values below will be returned at any point of time:<br>policyApplied (1)—All the ingress policies in the VPP were successfully applied to the port.policyNotApplied (2) - One of the ingress policies in the VPP was not applied to the port. If this value is returned then refer to the extremeVMDetectedIngErrPolicies object for list of failed ingress policies. |
|                         | extremeVMDetectedResultEgress   | Indicates the result of a VM entry into the network. Only the two values below will be returned at any point of time:<br>policyApplied (1) - All the egress policies in the VPP were successfully applied to the port.policyNotApplied (2) - One of the egress policies in the VPP was not applied to the port. If this value is returned then refer to the extremeVMDetectedEgrErrPolicies object for list of failed egress policies.  |
|                         | extremeVMDetectedIngErrPolicies | Displays the list of failed ingress policies.                                                                                                                                                                                                                                                                                                                                                                                           |
|                         | extremeVMDetectedEgrErrPolicies | Displays the list of failed egress policies.                                                                                                                                                                                                                                                                                                                                                                                            |
|                         | extremeVMDetectedVPPName        | The name of the VPP applied (or attempted to apply) to this VM.                                                                                                                                                                                                                                                                                                                                                                         |
|                         | extremeVMDetectedVPPResult      | Indicates the result of a VPP associated with a VM MAC:<br>vppMapped (1)—indicates that the named VPP was mapped.vppNotMapped (2)—indicates that the no VPP was mapped.vppInvalid (3)—indicates that the VPP mapped was invalid.vppMissing (4)—indicates that the VPP mapped was missing                                                                                                                                                |
| extremeVMVPPDetailTable |                                 | This table contains the mapping of a VPP to individual policies.                                                                                                                                                                                                                                                                                                                                                                        |
| extremeVMVPPDetailEntry |                                 | A set of mappings from a VPP to one or more policies.                                                                                                                                                                                                                                                                                                                                                                                   |
|                         | extremeVMVPPDetailVPPName       | The name of the VPP.                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                         | extremeVMVPPDetailDirection     | The direction in which the policy is applied.                                                                                                                                                                                                                                                                                                                                                                                           |
|                         | extremeVMVPPDetailType          | The type of policy.                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Table/Group           | Supported Variables          | Comments                                    |
|-----------------------|------------------------------|---------------------------------------------|
|                       | extremeVMVPPDetailOrder      | The order in which this policy is executed. |
|                       | extremeVMVPPDetailPolicyName | The name of the local policy                |
|                       | extremeVMVPPDetailRowStatus  | The row status for this mapping.            |
| extremeVMVPPSynchType |                              | Indicates the type of policy                |

The following traps can be generated.

| Trap                        | Notification Objects    | Comments                                                                                                   |
|-----------------------------|-------------------------|------------------------------------------------------------------------------------------------------------|
| extremeVMNotificationPrefix | extremeVMVPPSyncFailed  | A synchronization attempt failed.                                                                          |
|                             | extremeVMVPPInvalid     | A VPP definition is invalid, indicating it cannot be applied to a port.                                    |
|                             | extremeVMMapped         | This notification is generated whenever a MAC address is manually mapped to a local policy.                |
|                             | extremeVMUnMapped       | This notification is generated whenever a MAC address is manually unmapped to a local policy.              |
|                             | extremeVMDetectResult   | This notification is generated after a VM is detected on a port and reflects the result of that operation. |
|                             | extremeVMUnDetectResult | This notification is generated after a VM is undetected (removed) from a port.                             |

## MIB Support Details

The following sections describe the MIB support provided by the ExtremeXOS *SNMP* agent residing on Extreme Networks devices running ExtremeXOS:

Where applicable, these sections note how the implementation differs from the standards, or from the private MIBs.

### Note

Only entries for the default VR are supported.

ExtremeXOS software supports only the following “Row status” in the MIBs:

- Create and Go
- Active
- Destroy

The standard MIBs are described in the following sections.

## ETMONSERVICEABILITYTRAP

The following tables, groups, and variables are supported in this MIB.

| Table/Group                   | Supported Variables | Comments                                                                                                                                                                                                                 |
|-------------------------------|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etmonServiceabilityTrapPrefix | noMoreMemory        | Status = current.<br>"Memory full, No more memory. System memory is depleted."                                                                                                                                           |
|                               | asyncQGrowing       | Status = current.<br>"async queue is growing. Logged messages in switch will provide more information related to growing async queue. MIB have limitation to provide all the information related to growing sync queue." |

## IEEE 802.1AB (LLDP-MIB)

All tables and variables of this MIB are supported.

## IEEE 802.1AB (LLDP-EXT-DOT1-MIB)

All tables and variables of this MIB are supported.

## IEEE 802.1AB (LLDP-EXT-DOT3-MIB)

All tables and variables of this MIB are supported.

## IEEE 802.1AG (CFM MIB)

This MIB contains objects for the 802.1ag protocol.

The following tables, groups, and variables are supported in this MIB.

| Table/Group      | Supported Variables | Comments                                                              |
|------------------|---------------------|-----------------------------------------------------------------------|
| dot1agCfmMdTable | dot1agCfmMdIndex    | The index to the Maintenance Domain (MD) table.                       |
|                  | dot1agCfmMdFormat   | Supported as read only. The type (and thereby format) of the MD name. |
|                  | dot1agCfmMdName     | Supported as read only. The MD name.                                  |
|                  | dot1agCfmMdMdLevel  | Supported as read only. The MD Level.                                 |

| Table/Group               | Supported Variables        | Comments                                                                                                                                                                                                           |
|---------------------------|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                           | dot1agCfmMdMhfCreation     | Enumerated value indicating whether the management entity can create MHFs (MIP Half Function) for this MD. Supported as read only. Configuration in CLI is not supported. The defMHFdefault (2) value is returned. |
|                           | dot1agCfmMdMhfIdPermission | Supported as read only. Configuration in CLI is not supported. The sendIdChassisManage (4) value is returned.                                                                                                      |
|                           | dot1agCfmMdMaNextIndex     | Value to be used as the index of the Maintenance Association (MA) table entries.                                                                                                                                   |
|                           | dot1agCfmMdRowStatus       | The status of the row. The writable columns in a row cannot be changed if the row is active. All columns must have a valid value before a row can be activated.                                                    |
| dot1agCfmMdTableNextIndex | dot1agCfmMdTableNextIndex  | An unused value for dot1agCfmMdIndex that is used as the MD index for the next newly created domain.                                                                                                               |
| dot1agCfmMaNetTable       | dot1agCfmMdIndex           | MD index.                                                                                                                                                                                                          |
|                           | dot1agCfmMaIndex           | Index of the MA table. dot1agCfmMdMaNextIndex needs to be inspected to find an available index for row-creation.                                                                                                   |
|                           | dot1agCfmMaNetFormat       | Supported as read only. The type of the MA name.                                                                                                                                                                   |
|                           | dot1agCfmMaNetName         | Supported as read only. MA name.                                                                                                                                                                                   |
|                           | dot1agCfmMaNetCcmlInterval | Supported as read only. Transmission interval between CCMs to be used by all MEPs in the MA.                                                                                                                       |
|                           | dot1agCfmMaNetRowStatus    | The status of the row. The writable columns in a row cannot be changed if the row is active. All columns must have a valid value before a row can be activated.                                                    |
| dot1agCfmMepTable         | dot1agCfmMdIndex           | MD Index.                                                                                                                                                                                                          |
|                           | dot1agCfmMaIndex           | MA Index.                                                                                                                                                                                                          |

| Table/Group | Supported Variables        | Comments                                                                                                                                                                                                |
|-------------|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | dot1agCfmMepIdentifier     | A small integer, unique over a given MA identifying a specific MA end point.                                                                                                                            |
|             | dot1agCfmMepIfIndex        | Supported as read only. Interface index of the interface bridge port.                                                                                                                                   |
|             | dot1agCfmMepDirection      | Supported as read only. The direction in which the MEP faces on the bridge port.                                                                                                                        |
|             | dot1agCfmMepPrimaryVid     | Supported as read only. VID of the MEP.                                                                                                                                                                 |
|             | dot1agCfmMepActive         | Supported as read only. Administrative state of the MEP.                                                                                                                                                |
|             | dot1agCfmMepFngState       | Current state of the MEP Fault Notification Generator State Machine. Can have any one of the following values:fngReset (1)fngDefect (2)fngReportDefect (3)fngDefectReported (4)fngDefectClearing (5)    |
|             | dot1agCfmMepCciEnabled     | Supported as read only. If set to true, the MEP will generate CCM.                                                                                                                                      |
|             | dot1agCfmMepCcmltmPriority | Supported as read only. The priority value for CCMs and LTMs transmitted by the MEP. Configuration in CLI is not supported. Default value 0 is returned.                                                |
|             | dot1agCfmMepMacAddress     | MAC address of the MEP. In Extreme Networks switches, the MAC is returned.                                                                                                                              |
|             | dot1agCfmMepLowPrDef       | Supported as read only. An integer value specifying the lowest priority defect that is allowed to generate a Fault Alarm. Configuration in CLI is not supported. Default VLAN macRemErrXon is returned. |
|             | dot1agCfmMepFngAlarmTime   | Supported as read only. The time that defects must be present before a Fault Alarm is issued. Configuration in CLI is not supported. Default value 2.5 seconds is returned.                             |

| Table/Group | Supported Variables             | Comments                                                                                                                                                                  |
|-------------|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | dot1agCfmMepFngResetTime        | Supported as read only. The time that defects must be absent before resetting a Fault Alarm. Configuration in CLI is not supported. Default value 10 seconds is returned. |
|             | dot1agCfmMepHighestPrDefect     | The highest priority defect that has been present. Possible values are:none (0)defRDICCM (1)defMACstatus (2)defRemoteCCM (3)defErrorCCM (4)defXconCCM (5)                 |
|             | dot1agCfmMepDefects             | Error condition to be sent. The conditions can be any one of the following:bDefRDICCM (0)bDefMACstatus (1)bDefRemoteCCM (2)bDefErrorCCM (3)bDefXconCCM (4)                |
|             | dot1agCfmMepErrorCcmLastFailure | The last-received CCM that triggered a DefErrorCCM fault.                                                                                                                 |
|             | dot1agCfmMepXconCcmLastFailure  | The last-received CCM that triggered a DefXconCCM fault.                                                                                                                  |
|             | dot1agCfmMepCcmSequenceErrors   | The total number of out-of-sequence CCMs received from all remote MEPs.                                                                                                   |
|             | dot1agCfmMepCciSentCcms         | The total number of Continuity Check messages transmitted.                                                                                                                |
|             | dot1agCfmMepNextLbmTransId      | Next sequence number/ transaction identifier to be sent in a Loopback message.                                                                                            |
|             | dot1agCfmMepLbrIn               | The total number of valid, in-order Loopback Replies received.                                                                                                            |
|             | dot1agCfmMepLbrInOutOfOrder     | The total number of valid, out-of-order Loopback Replies received.                                                                                                        |
|             | dot1agCfmMepLbrBadMsdu          | The total number of LBRs received whose mac_service_data_unit did not match (except for the OpCode) that of the corresponding LBM.                                        |
|             | dot1agCfmMepLtmNextSeqNumber    | Next transaction identifier/ sequence number to be sent in a Linktrace message.                                                                                           |

| Table/Group | Supported Variables                    | Comments                                                                                                                                                         |
|-------------|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | dot1agCfmMepUnexpLtrIn                 | The total number of unexpected LTRs received.                                                                                                                    |
|             | dot1agCfmMepLbrOut                     | The total number of Loopback Replies transmitted.                                                                                                                |
|             | dot1agCfmMepTransmitLbmStatus          | Supported as read only. A Boolean flag set to true by the bridge port to indicate that another LBM may be transmitted.                                           |
|             | dot1agCfmMepTransmitLbmDestMac Address | Supported as read only. The target MAC address field to be transmitted.                                                                                          |
|             | dot1agCfmMepTransmitLbmDestMepId       | Supported as read only. To transmit the LBM, destMEPID need not be given.                                                                                        |
|             | dot1agCfmMepTransmitLbmDestIsMepId     | Supported as read only. This always returns FALSE.                                                                                                               |
|             | dot1agCfmMepTransmitLbmMessages        | Supported as read only. The number of Loopback messages to be transmitted.                                                                                       |
|             | dot1agCfmMepTransmitLbmDataTlv         | Supported as read only. An arbitrary amount of data to be included in the Data TLV if the Data TLV is selected to be sent. This returns 0.                       |
|             | dot1agCfmMepTransmitLbmVlanPriority    | Priority. A three-bit value to be used in the VLAN tag, if present in the transmitted frame. Configuration in CLI is not supported. Default value 0 is returned. |
|             | dot1agCfmMepTransmitLbmVlanDropEnable  | Not supported. Returns FALSE.                                                                                                                                    |
|             | dot1agCfmMepTransmitLbmResultOK        | Indicates the result of the operation linked with MEP active state.                                                                                              |
|             | dot1agCfmMepTransmitLbmSeqNumber       | The Loopback Transaction Identifier of the first LBM (to be) sent. The value returned is undefined if dot1agCfmMepTransmitLbmResultOK is false.                  |
|             | dot1agCfmMepTransmitLtmStatus          | Supported as read only. A Boolean flag set to true by the bridge port to indicate that another LTM may be transmitted.                                           |

| Table/Group         | Supported Variables                     | Comments                                                                                                                                                        |
|---------------------|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                     | dot1agCfmMepTransmitLtmFlags            | Supported as read only. The flags field for LTMs transmitted by the MEP. Currently, useFDBOnly (0) is supported.                                                |
|                     | dot1agCfmMepTransmitLtmTargetMacAddress | Supported as read only. The target MAC address field to be transmitted.                                                                                         |
|                     | dot1agCfmMepTransmitLtmTargetMepId      | Not supported. To transmit the LTM destMEPID need not be given. Value 0 is returned.                                                                            |
|                     | dot1agCfmMepTransmitLtmTargetIsMepId    | Not supported. This always returns FALSE.                                                                                                                       |
|                     | dot1agCfmMepTransmitLtmTtl              | Supported as read only. The LTM TTL field.                                                                                                                      |
|                     | dot1agCfmMepTransmitLtmResult           | Supported as read only. Indicates the result of the operation. Linked with MEP active state.                                                                    |
|                     | dot1agCfmMepTransmitLtmSeqNumber        | The LTM transaction identifier.                                                                                                                                 |
|                     | dot1agCfmMepTransmitLtmEgressIdentifier | Supported as read only. Identifies the MEP Linktrace Initiator that is originating or the Linktrace Responder that is forwarding this LTM.                      |
|                     | dot1agCfmMepRowStatus                   | The status of the row. The writable columns in a row cannot be changed if the row is active. All columns must have a valid value before a row can be activated. |
| dot1agCfmMepDbTable | dot1agCfmMdIndex                        | MD Index.                                                                                                                                                       |
|                     | dot1agCfmMaIndex                        | MA Index.                                                                                                                                                       |
|                     | dot1agCfmMepIdentifier                  | MA end point identifier.                                                                                                                                        |
|                     | dot1agCfmMepDbRMepIdentifier            | Maintenance association end point identifier of a remote MEP whose information from the MEP database is to be returned.                                         |
|                     | dot1agCfmMepDbRMepState                 | The operational state of the remote MEP IFF state machines. The state can be any one of the following:rMepIdle (1)rMepStart (2)rMepFailed (3)rMepOk (4)         |

| Table/Group       | Supported Variables              | Comments                                                                                                                                                                                                                                                    |
|-------------------|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                   | dot1agCfmMepDbRMepFailedOkTime   | The time (SysUpTime) at which the IFF remote MEP state machine last entered either the RMEP_FAILED or RMEP_OK state.                                                                                                                                        |
|                   | dot1agCfmMepDbMacAddress         | The MAC address of the remote MEP.                                                                                                                                                                                                                          |
|                   | dot1agCfmMepDbRdi                | State of the RDI bit in the last received CCM.                                                                                                                                                                                                              |
|                   | dot1agCfmMepDbPortStatusTlv      | An enumerated value of the Port status TLV received in the last CCM from the remote MEP or the default value. The value is one of the following:psNoPortStateTLV (0)psBlocked (1)psUp (2)                                                                   |
|                   | dot1agCfmMepDbInterfaceStatusTlv | An enumerated value of the Interface status TLV received in the last CCM from the remote MEP. The value can be one of the following:isNoInterfaceStatusTlv (0)isUp (1)isDown (2)isTesting (3)isUnknown (4)isDormant (5)isNotPresent (6)isLowerLayerDown (7) |
|                   | dot1agCfmMepDbChassisIdSubtype   | networkAddress (5) is returned if senderIDTLV is received.                                                                                                                                                                                                  |
|                   | dot1agCfmMepDbChassisId          | The first octet contains the IANA Address Family Numbers enumeration value for the specific address type, and octets 2 through N contain the network address value in network byte order.                                                                   |
|                   | dot1agCfmMepDbManAddressDomain   | Not supported. Value zero is returned.                                                                                                                                                                                                                      |
|                   | dot1agCfmMepDbManAddress         | Not supported. Value zero is returned.                                                                                                                                                                                                                      |
| dot1agCfmLtrTable | dot1agCfmMdIndex                 | MD Index.                                                                                                                                                                                                                                                   |
|                   | dot1agCfmMaIndex                 | MA Index.                                                                                                                                                                                                                                                   |
|                   | dot1agCfmMepIdentifier           | MA end point identifier.                                                                                                                                                                                                                                    |
|                   | dot1agCfmLtrSeqNumber            | Transaction identifier/sequence number returned by a previous transmit linktrace message command.                                                                                                                                                           |

| Table/Group | Supported Variables              | Comments                                                                                                                                                                                  |
|-------------|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | dot1agCfmLtrReceiveOrder         | An index to distinguish among multiple LTRs with the same LTR Transaction Identifier field value.                                                                                         |
|             | dot1agCfmLtrTtl                  | TTL field value for a returned LTR.                                                                                                                                                       |
|             | dot1agCfmLtrForwarded            | Indicates if a LTM was forwarded by the responding MP.                                                                                                                                    |
|             | dot1agCfmLtrTerminalMep          | Not supported. Value FALSE is returned.                                                                                                                                                   |
|             | dot1agCfmLtrLastEgressIdentifier | An octet field holding the Last Egress Identifier returned in the LTR Egress Identifier TLV of the LTR.                                                                                   |
|             | dot1agCfmLtrNextEgressIdentifier | An octet field holding the Next Egress Identifier returned in the LTR Egress Identifier TLV of the LTR.                                                                                   |
|             | dot1agCfmLtrRelay                | Value returned in the Relay Action field.                                                                                                                                                 |
|             | dot1agCfmLtrChassisIdSubtype     | networkAddress (5) is returned if senderIDTLV is received.                                                                                                                                |
|             | dot1agCfmLtrChassisId            | The first octet contains the IANA Address Family Numbers enumeration value for the specific address type, and octets 2 through N contain the network address value in network byte order. |
|             | dot1agCfmLtrManAddressDomain     | Not supported. Value zero is returned.                                                                                                                                                    |
|             | dot1agCfmLtrManAddress           | Not supported. Value zero is returned.                                                                                                                                                    |
|             | dot1agCfmLtrIngress              | The value returned in the Ingress Action Field of the LTM.                                                                                                                                |
|             | dot1agCfmLtrIngressMac           | MAC address returned in the ingress MAC address field.                                                                                                                                    |
|             | dot1agCfmLtrIngressPortIdSubtype | interfaceName (5) is returned if present.                                                                                                                                                 |

| Table/Group             | Supported Variables                 | Comments                                                                                                                                                                                                  |
|-------------------------|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                         | dot1agCfmLtrIngressPortId           | interfaceName (5), then the octet string identifies a particular instance of the ifName object. If the particular ifName object does not contain any values, another port identifier type should be used. |
|                         | dot1agCfmLtrEgress                  | The value returned in the Egress Action Field of the LTM.                                                                                                                                                 |
|                         | dot1agCfmLtrEgressMac               | MAC address returned in the egress MAC address field.                                                                                                                                                     |
|                         | dot1agCfmLtrEgressPortIdSubtype     | interfaceName (5) is returned if present.                                                                                                                                                                 |
|                         | dot1agCfmLtrEgressPortId            | interfaceName (5), then the octet string identifies a particular instance of the ifName object. If the particular ifName object does not contain any values, another port identifier type should be used. |
|                         | dot1agCfmLtrOrganizationSpecificTlv | All organization specific TLVs returned in the LTR.                                                                                                                                                       |
| dot1agCfmStackTable     | dot1agCfmStackIfIndex               | Index object. This object represents the bridge port or aggregated port on which MEPs or MHFs might be configured.                                                                                        |
|                         | dot1agCfmStackVlanIdOrNone          | Index object. VLAN ID to which the MP is attached.                                                                                                                                                        |
|                         | dot1agCfmStackMdLevel               | Index object. MD Level of the Maintenance Point.                                                                                                                                                          |
|                         | dot1agCfmStackDirection             | Index object. Direction in which the MP faces on the bridge port.                                                                                                                                         |
|                         | dot1agCfmStackMdIndex               | The index of the MD in the dot1agCfmMdTable to which the MP is associated.                                                                                                                                |
|                         | dot1agCfmStackMaIndex               | The index of the MA in the dot1agCfmMaNetTable and dot1agCfmMaCompTable to which the MP is associated.                                                                                                    |
|                         | dot1agCfmStackMepId                 | If an MEP is configured, the MEP ID.                                                                                                                                                                      |
|                         | dot1agCfmStackMacAddress            | MAC address of the MP.                                                                                                                                                                                    |
| dot1agCfmMaMepListTable | dot1agCfmMdIndex                    | MD Index.                                                                                                                                                                                                 |

| Table/Group                        | Supported Variables          | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| dot1agCfmFaultAlarm (NOTIFICATION) | dot1agCfmMepHighestPrDefect  | A MEP has a persistent defect condition. A notification (fault alarm) is sent to the management entity with the OID of the MEP that has detected the fault. The management entity receiving the notification can identify the system from the network source address of the notification, and can identify the MEP reporting the defect by the indices in the OID of the dot1agCfmMepHighestPrDefect variable in the notification: dot1agCfmMdIndex—Also the index of the MEPs.MD table entry (dot1agCfmMdTable).dot1agCfmMaIndex—Also an index (with the MD table index) of the MEP's MA network table entry (dot1agCfmMaNetTable), and (with the MD table index and component ID) of the MEP's MA component table entry.dot1agCfmMepIdentifier—MEP Identifier and final index into the MEP table (dot1agCfmMepTable). |
| extremeCfmMibConformance           |                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| dot1agCfmMaCompTable               |                              | Not supported                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| dot1agCfmDefaultMdTable            |                              | Not supported                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## IEEE8021-PAE-MIB

This MIB contains objects for the 802.1X protocol draft D10 of the 802.1X standard.

The following tables, groups, and variables are supported in this MIB.

| Table/Group                | Supported Variables | Comments                                                                                                                             |
|----------------------------|---------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| dot1xPaeSystemAuthControl  |                     |                                                                                                                                      |
| dot1xPaePortTable          | All objects         |                                                                                                                                      |
| dot1xAuthConfigTable       | Not supported       | In lieu of these tables, Extreme Networks supports the per-station based versions which are present in the IEEE8021X-EXTENSIONS-MIB. |
| dot1xAuthStatsTable        | Not supported       |                                                                                                                                      |
| dot1xAuthDiagTable         | Not supported       | This table has been deprecated in the drafts subsequent to the 2001 version of the 802.1X standard.                                  |
| dot1xAuthSessionStatsTable | Not supported       |                                                                                                                                      |
| dot1xSuppConfigTable       | None                | These tables are not applicable to the switch since they are for a supplicant.                                                       |
| dot1xSuppStatsTable        | None                |                                                                                                                                      |

## IEEE8021X-EXTENSIONS-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group           | Supported Variables | Comments |
|-----------------------|---------------------|----------|
| dot1xAuthStationTable | All objects         |          |
| dot1xAuthConfigTable  | All objects         |          |
| dot1xAuthStatsTable   | All objects         |          |

## ISIS-MIB (draft-ietf-isis-wg-mib-10.txt)

The following tables, groups, and variables are supported in this MIB.

| Table/Group  | Supported Variables     | Comments                                                                      |
|--------------|-------------------------|-------------------------------------------------------------------------------|
| IsisSysTable | isisSysInstance         |                                                                               |
|              | isisSysVersion          |                                                                               |
|              | isisSysType             |                                                                               |
|              | isisSysID               |                                                                               |
|              | isisSysMaxPathSplits    | Unsupported object. Always returns MIB default value if one exists for a GET. |
|              | isisSysMaxLSPGenInt     | Unsupported object. Always returns MIB default value if one exists for a GET. |
|              | isisSysMaxAreaAddresses | Unsupported object. Always returns MIB default value if one exists for a GET. |

| Table/Group          | Supported Variables          | Comments                                                                      |
|----------------------|------------------------------|-------------------------------------------------------------------------------|
|                      | isisSysPollESHHelloRate      | Unsupported object. Always returns MIB default value if one exists for a GET. |
|                      | isisSysWaitTime              | Unsupported object. Always returns MIB default value if one exists for a GET. |
|                      | isisSysAdminState            |                                                                               |
|                      | isisSysLogAdjacencyChanges   | Unsupported object. Always returns MIB default value if one exists for a GET. |
|                      | isisSysNextCircIndex         |                                                                               |
|                      | isisSysL2toL1Leaking         | Unsupported object. Always returns MIB default value if one exists for a GET. |
|                      | isisSysMaxAge                |                                                                               |
|                      | isisSysReceiveLSPBufferSize  | Unsupported object. Always returns MIB default value if one exists for a GET. |
|                      | isisSysExistState            | Only state destroy (6) is supported.                                          |
| isisSysLevelTable    | isisSysLevelIndex            |                                                                               |
|                      | isisSysLevelOrigLSPBuffSize  | Unsupported object. Always returns MIB default value if one exists for a GET. |
|                      | isisSysLevelMinLSPGenInt     | Supported isisSysLevelMinLSPGenInt range is 1 - 120 (MIB is 1 - 65535).       |
|                      | isisSysLevelOverloadState    |                                                                               |
|                      | isisSysLevelSetOverload      |                                                                               |
|                      | isisSysLevelSetOverloadUntil |                                                                               |
|                      | isisSysLevelMetricStyle      |                                                                               |

## OSPFv3-MIB (draft-ietf-ospf-ospfv3-mib-10)

All tables and variables of this MIB are supported.

### Note

*SNMP*.SET requests for *OSPFv3 (Open Shortest Path First version 3)* MIB objects are not supported.

## PIM-MIB (draft-ietf-pim-mib-v2-01.txt)

This MIB is superset of RFC 2934.

## SNMPv3 MIBs

The ExtremeXOS *SNMP* stack fully supports the SNMPv3 protocol and therefore implements the MIBs in the SNMPv3 RFCs.

Specifically, the MIBs in following RFCs are fully supported:

- RFC 2576—Coexistence between Version 1, Version 2, and Version 3 of the Internet-standard Network Management Framework
- RFC 3410—Introduction and Applicability Statements for Internet-Standard Management Framework
- RFC 3411—An Architecture for Describing Simple Network Management Protocol (SNMP) Management Frameworks
- RFC 3412—Message Processing and Dispatching for the Simple Network Management Protocol (SNMP)
- RFC 3413—Simple Network Management Protocol (SNMP) Applications.
- RFC 3414—User-based Security Model (USM) for version 3 of the Simple Network Management Protocol (SNMPv3)
- RFC 3415—View-based Access Control Model (VACM) for the Simple Network Management Protocol (SNMP)
- RFC 3826—The Advanced Encryption Standard (AES) Cipher Algorithm in the SNMP User-based Security Model

## RFC 1213 (MIB-II)

The following tables, groups, and variables are supported in this MIB.

| Table/Group          | Supported Variables | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| ipRouteTable         | All objects         | Supported as read only. Routes are indexed by prefix only.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| ipNetToMediaTable    | All objects         | context support is available for the ipNetToMediaTable in MIB-2. In order to retrieve entries in various VRs for ipNetToMediaTable in MIB-2, VRs can be mentioned as contexts. For example, to get the entries in <u>VR-Mgmt</u> , the following net-snmp query needs to be used:<br><pre>snmpwalk -v3 -n "VR-Mgmt" -u &lt;v3username&gt; -a md5 -a &lt;v3user- authentication password&gt; &lt;deviceIpAddress/Hostname&gt; ipNetToMediaTable</pre> Here -n has the context value of "VR-Mgmt". If no context is specified in the <u>SNMP</u> query, then only the entries in the <u>VR-Default</u> are shown. |
| ICMP group           | All objects         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## RFC 1215

This MIB defines an SMI for SNMPv1 traps, and some traps themselves.

Of these, the following are supported.

| Traps                 | Comments                                                                                                                                                                                                |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| coldStart             |                                                                                                                                                                                                         |
| warmStart             |                                                                                                                                                                                                         |
| authenticationFailure | The authentication failure trap will have additional extreme proprietary varbinds (extremeAuthFailSrcAddr, extremeAuthFailSrcAddressType , extremeAuthFailSrcAddress, extremeAuthFailSrcAddressVrName ) |
| linkDown              |                                                                                                                                                                                                         |
| linkUp                |                                                                                                                                                                                                         |

## RFC 1493 (BRIDGE-MIB) and draft-ietf-bridge-rstpmib-03.txt

The BRIDGE-MIB has been augmented with draft-ietf-bridge-rstpmib-03.txt for 802.1w support.

Objects below that are defined in the latter are marked as such.

| Table/Group             | Supported Variables    | Comments                                                                                                      |
|-------------------------|------------------------|---------------------------------------------------------------------------------------------------------------|
| dot1dBase group scalars | dot1dBaseBridgeAddress |                                                                                                               |
|                         | dot1dBaseNumPorts      | This object returns the number of ports in <i>STP</i> domain s0, not the total number of ports on the switch. |
|                         | dot1dBaseType          |                                                                                                               |

| Table/Group            | Supported Variables                                                                               | Comments                                                                                                                                                                                                                                                                                                                                                               |
|------------------------|---------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dot1dBasePortTable     | dot1dBasePort<br>dot1dBasePortIfIndex<br>dot1dBasePortCircuit<br>dot1dBasePortMtuExceededDiscards | dot1BasePort is supported and returns the port number.<br>dot1dBasePortIfIndex is supported.<br>dot1dBasePortCircuit always has the value { 0 0 } since there is a one to one correspondence between a physical port and its ifIndex.<br>dot1dBasePortMtuExceededDiscards is supported and value can be checked if packets exceeds MTU configured on particular ports. |
| dot1dStp group scalars | dot1dStpProtocolSpecification                                                                     | Values for these objects will be returned for the STP domain s0 only. For other domains, see the EXTREME-STPEXTENSTIONS-MIB.                                                                                                                                                                                                                                           |

| STP Traps            | newRoot                  |                                                                                                                                                                                                                                                                                                                              |
|                      | topologyChange           |                                                                                                                                                                                                                                                                                                                              |
| dot1dTpFdbTable      | Supported                | The object dot1dTpFdbTable displays ports and <i>FDB</i> MAC addresses. They include both the static and dynamic FDB entries on the switch. The MIB does not provide a way to identify the <i>VLAN</i> on which the entry was learned. The port numbers are assumed to be 1 to 128 on Slot 1, and 128 to 255 on Slot 2, etc. |
| dot1dTpPortTable     | Supported                |                                                                                                                                                                                                                                                                                                                              |
| dot1dStatic group    | Supported                |                                                                                                                                                                                                                                                                                                                              |
|                      | Dot1dStaticAllowedToGoTo | Not supported                                                                                                                                                                                                                                                                                                                |

## RFC 4363 (P-BRIDGE-MIB)

The following tables, groups, and variables are supported in this MIB.

| Table/Group                  | Supported Variables                    | Comments                                                                                                                                                                                                                                                       |
|------------------------------|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dot1dPortCapabilitiesTable   | dot1dDeviceCapabilities.               | A table that contains capabilities information about every port that is associated with this bridge.<br>Read-only.                                                                                                                                             |
| dot1dDeviceCapabilities      | Bit 0 (dot1dExtendedFilteringServices) | Denotes the multicast address filtering capability by GMRP. ExtremeXOS does not support this, and returns 0 always.                                                                                                                                            |
|                              | Bit 1 (dot1dTrafficClasses)            | Denotes switch capability on user priority mapping for multiple traffic classes. ExtremeXOS supports this, and always returns 1.                                                                                                                               |
|                              | Bit 2 (dot1qStaticEntryIndividualPort) | Denotes switch capability on Static unicast/multicast address support for all/particular port. ExtremeXOS does not support this, and returns 0 always.                                                                                                         |
|                              | Bit 3 (dot1qIVLCapable)                | Denotes switch capability on Independent VLAN Learning (IVL). ExtremeXOS supports this, and always returns 1.                                                                                                                                                  |
|                              | Bit 4 (dot1qSVLCapable)                | Denotes switch capability on Shared VLAN Learning (SVL). ExtremeXOS does not support this, and returns 0 always.                                                                                                                                               |
|                              | Bit 5 (dot1qHybridCapable)             | Denotes switch capability to support both IVL and SVL. ExtremeXOS does not support this, and returns 0 always.                                                                                                                                                 |
|                              | Bit 6 (dot1qConfigurablePvidTagging)   | Denotes whether the switch supports the ability to override the default PVID setting and its egress status (VLAN-Tagged or Untagged) on each port. ExtremeXOS supports this, and always returns 1.                                                             |
|                              | Bit 7 (dot1dLocalVlanCapable)          | Denotes whether the switch supports multiple local vlans. ExtremeXOS supports this, and always returns 1.                                                                                                                                                      |
| dot1dPortDefaultUserPriority |                                        | The default ingress User Priority for this port. This only has effect on media, such as Ethernet, that do not support native User Priority. The value of this object MUST be retained across reinitializations of the management system.<br>Read-write access. |

## RFC 4363 (Q-BRIDGE-MIB)

The following tables, groups, and variables are supported in this MIB.

| Table/Group                                    | Supported Variables    | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------------------------------|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RFC 4363<br>dot1qBasegroup<br>Read-only access | dot1qVlanVersionNumber | The version number of IEEE 802.1Q that this device supports.<br>Read-only access.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                                                | dot1qMaxVlanId         | The maximum IEEE 802.1Q <u>VLAN-ID</u> that this device supports.<br>Read-only access.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                                                | dot1qMaxSupportedVlans | The maximum number of IEEE 802.1Q VLANs that this device supports.<br>Read-only access.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|                                                | dot1qNumVlans          | The current number of IEEE 802.1Q VLANs that are configured in this device.<br>Read-only access.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                                                | dot1qGvrpStatus        | The administrative status requested by management for GVRP. The value enabled (1) indicates that GVRP should be enabled on this device, on all ports for which it has not been specifically disabled. When disabled (2), GVRP is disabled on all ports, and all GVRP packets is forwarded transparently. This object affects all GVRP Applicant and Registrar state machines. A transition from disabled (2) to enabled (1) causes a reset of all GVRP state machines on all ports. The value of this object MUST be retained across reinitializations of the management system.<br>Read-write access. |

## RFC 1724 (RIPv2-MIB)

The following tables, groups, and variables are supported in this MIB.

| Table/Group     | Supported Variables    | Comments |
|-----------------|------------------------|----------|
| rip2Globals     | rip2GlobalRouteChanges |          |
|                 | rip2GlobalQueries      |          |
| rip2IfStatTable | All objects            |          |

| Table/Group     | Supported Variables | Comments |
|-----------------|---------------------|----------|
| rip2IfConfTable | All objects         |          |
| rip2PeerTable   | Not supported       |          |

## RFC 1757 (RMON-MIB)

The following tables, groups, and variables are supported in this MIB.

| Table/Group         | Supported Variables                        | Comments |
|---------------------|--------------------------------------------|----------|
| etherStatsTable     | All objects, except etherStatsDropEvents   |          |
| historyControlTable | All objects                                |          |
| etherHistoryTable   | All objects, except etherHistoryDropEvents |          |
| alarmTable          | All objects                                |          |
| eventTable          | All objects                                |          |
| logTable            | All objects                                |          |

## RFC 1850 (OSPF-MIB)

The following tables, groups, and variables are supported in this MIB.

| Table/Group            | Supported Variables | Comments |
|------------------------|---------------------|----------|
| ospfGeneralGroup       | All objects         |          |
| ospfAreaTable          | All objects         |          |
| ospfStubAreaTable      | All objects         |          |
| ospfLsdbTable          | All objects         |          |
| ospfAreaRangeTable     | All objects         |          |
| ospfHostTable          | All objects         |          |
| ospfIfTable            | All objects         |          |
| ospfIfMetricTable      | All objects         |          |
| ospfVirtIfTable        | All objects         |          |
| ospfNbrTable           | All objects         |          |
| ospfVirtNbrTable       | All objects         |          |
| ospfExtLsdbTable       | All objects         |          |
| ospfAreaAggregateTable | All objects         |          |
| ospfTrap               | All traps           |          |

## RFC 2021 (RMON2-MIB)

The following tables, groups, and variables are supported in this MIB.

| Table/Group   | Supported Variables | Comments |
|---------------|---------------------|----------|
|               | probeCapabilities   |          |
|               | probeSoftwareRev    |          |
|               | probeHardwareRev    |          |
|               | probeDateTime       |          |
|               | probeResetControl   |          |
| trapDestTable | All objects         |          |

## RFC 2233 (IF-MIB)

The following tables, groups, and variables are supported in this MIB.

| Table/Group | Supported Variables        | Comments                                                                                                                  |
|-------------|----------------------------|---------------------------------------------------------------------------------------------------------------------------|
|             | IfNumber                   |                                                                                                                           |
| ifTable     | ifIndex                    | The ifIndex for ports is calculated as ((slot * 1000) + port). For VLANs, the ifIndex starts from 1000001.                |
|             | ifDescr                    |                                                                                                                           |
|             | ifType                     | Only the following values are supported: {other, ethernetCsmacd, softwareLoopback, propVirtual}                           |
|             | ifMtu                      |                                                                                                                           |
|             | ifSpeed                    |                                                                                                                           |
|             | ifPhysAddress              |                                                                                                                           |
|             | ifAdminStatus              | The testing state is not supported.                                                                                       |
|             | ifOperStatus               |                                                                                                                           |
|             | ifLastChange               |                                                                                                                           |
|             | ifInOctets                 | Updated every time queries this counter.                                                                                  |
|             | ifInUcastPkts              | Updated every time SNMP queries this counter.                                                                             |
|             | ifInNUcastPkts(deprecated) | Though deprecated, this object returns a value if the system keeps a count. Updated every time SNMP queries this counter. |
|             | ifInDiscards               | No count is kept of this object, so it always returns 0.                                                                  |

Also, only entries for physical ports appear in it.                                                                                                                                                                                         |
| snmpTraps         | linkDown                    |                                                                                                                                                                                                                                                                                          |
|                   | linkUp                      |                                                                                                                                                                                                                                                                                          |

## RFC 2465 (IPV6 MIB)

The following tables, groups, and variables are supported in this MIB.

| Table/Group           | Supported Variables                   | Comments |
|-----------------------|---------------------------------------|----------|
| ipv6Forwarding        | All objects                           |          |
| ipv6DefaultHopLimit   | All objects                           |          |
| ipv6Interfaces        | All objects                           |          |
| ipv6IfTableLastChange | All objects                           |          |
| ipv6IfTable           | All objects except ipv6IfEffectiveMtu |          |
| ipv6IfStatsTable      | All objects                           |          |
| ipv6AddrPrefixTable   | All objects                           |          |
| ipv6AddrTable         | All objects                           |          |
| ipv6RouteNumber       | All objects                           |          |
| ipv6DiscardedRoutes   | All objects                           |          |

| Table/Group         | Supported Variables | Comments |
|---------------------|---------------------|----------|
| ipv6RouteTable      | All objects         |          |
| ipv6NetToMediaTable | All objects         |          |

## RFC 2466 (IPV6 ICMP MIB)

The following tables, groups, and variables are supported in this MIB.

| Table/Group   | Supported Variables | Comments |
|---------------|---------------------|----------|
| ipv6IcmpTable | All objects         |          |

## RFC 2613 (SMON)

The following tables, groups, and variables are supported in this MIB.

| Table/Group               | Supported Variables            | Comments                                                                                                                                                                                                                                                        |
|---------------------------|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| smonVlanStatsControlTable | smonVlanStatsControlIndex      | A unique arbitrary index for this smonVlanStatsControlEntry.                                                                                                                                                                                                    |
|                           | smonVlanStatsControlDataSource | The source of data for this set of <u>VLAN</u> statistics. This object MAY NOT be modified if the associated smonVlanStatsControlStatus object is equal to active (1).                                                                                          |
|                           | smonVlanStatsControlCreateTime | The value of sysUpTime when this control entry was last activated. This object allows a management station to detect deletion and recreation cycles between polls.                                                                                              |
|                           | smonVlanStatsControlOwner      | Administratively assigned named of the owner of this entry. It usually defines the entity that created this entry and is therefore using the resources assigned to it, though there is no enforcement mechanism, nor assurance that rows created are ever used. |
|                           | smonVlanStatsControlStatus     | The status of this row. An entry MAY NOT exist in the active state unless all objects in the entry have an appropriate value. If this object is not equal to active (1), all associated entries in the smonVlanIdStatsTable SHALL be deleted.                   |

| Table/Group          | Supported Variables                 | Comments                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| smonVlanIdStatsTable | smonVlanIdStatsId                   | The unique identifier of the VLAN monitored for this specific statistics collection. Tagged packets match the VID for the range between 1 and 4094. An external RMON probe MAY detect VID=0 on an Inter Switch Link, in which case the packet belongs to a VLAN determined by the PVID of the ingress port. The VLAN to which such a packet belongs can be determined only by a RMON probe internal to the switch. |
|                      | smonVlanIdStatsTotalPkts            | The total number of packets counted on this VLAN.                                                                                                                                                                                                                                                                                                                                                                  |
|                      | smonVlanIdStatsTotalOverflowPkts    | The number of times the associated smonVlanIdStatsTotalPkts counter has overflowed.                                                                                                                                                                                                                                                                                                                                |
|                      | smonVlanIdStatsTotalHCPkts          | The total number of packets counted on this VLAN.                                                                                                                                                                                                                                                                                                                                                                  |
|                      | smonVlanIdStatsTotalOctets          | The total number of octets counted on this VLAN.                                                                                                                                                                                                                                                                                                                                                                   |
|                      | smonVlanIdStatsTotalOverflowOctets  | The number of times the associated smonVlanIdStatsTotalOctets counter has overflowed.                                                                                                                                                                                                                                                                                                                              |
|                      | smonVlanIdStatsTotalHCOctets        | The total number of octets counted on this VLAN.                                                                                                                                                                                                                                                                                                                                                                   |
|                      | smonVlanIdStatsNUcastOverflowOctets | The number of times the associated smonVlanIdStatsNUcastOctets counter has overflowed.                                                                                                                                                                                                                                                                                                                             |
|                      | smonVlanIdStatsCreateTime           | The value of sysUpTime when this entry was last activated. This object allows a management station to detect deletion and recreation cycles between polls.                                                                                                                                                                                                                                                         |
| dataSourceDapsTable  | dataSourceCapsObject                | Defines an object that can be a SMON data source or a source or a destination for a port copy operation.                                                                                                                                                                                                                                                                                                           |
|                      | dataSourceRmonCaps                  | General attributes of the specified dataSource. Note that these are static attributes, which SHOULD NOT be adjusted because of current resources or configuration.                                                                                                                                                                                                                                                 |
|                      | dataSourceCopyCaps                  | PortCopy function capabilities of the specified dataSource. Note that these are static capabilities, which SHOULD NOT be adjusted because of current resources or configuration.                                                                                                                                                                                                                                   |

| Table/Group         | Supported Variables    | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                     | dataSourceCapsIfIndex  | This object contains the ifIndex value of the ifEntry associated with this smonDataSource. The agent MUST create 'propVirtual' ifEntries for each dataSourceCapsEntry of type VLAN or entPhysicalEntry.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| portCopyConfigTable | portCopySource         | The ifIndex of the source which has all packets redirected to the destination as defined by portCopyDest.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                     | portCopyDest           | Defines the ifIndex destination for the copy operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|                     | portCopyDestDropEvents | The total number of events in which port copy packets were dropped by the switch at the destination port due to lack of resources. Note that this number is not necessarily the number of packets dropped; it is just the number of times this condition has been detected. A single dropped event counter is maintained for each portCopyDest. Thus all instances associated with a given portCopyDest will have the same portCopyDestDropEvents value. The value for this field is "0" (zero) due to hardware limitation.                                                                                                                                                                                                                                                                                                                                                                                         |
|                     | portCopyDirection      | This object affects the way traffic is copied from a switch source port, for the indicated port copy operation. If this object has the value copyRxOnly (1), then only traffic received on the indicated source port will be copied to the indicated destination port. If this object has the value copyTxOnly (2), then only traffic transmitted out the indicated source port will be copied to the indicated destination port. If this object has the value copyBoth (3), then all traffic received or transmitted on the indicated source port will be copied to the indicated destination port. The creation and deletion of instances of this object is controlled by the portCopyRowStatus object. Note that there is no guarantee that changes in the value of this object performed while the associated portCopyRowStatus object is equal to active will not cause traffic discontinuities in the packet. |

| Table/Group               | Supported Variables | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                           | portCopyStatus      | Defines the status of the port copy entry. In order to configure a source to destination portCopy relationship, both source and destination interfaces MUST be present as an ifEntry in the ifTable and their respective ifAdminStatus and ifOperStatus values must be equal to up (1). If the value of any of those two objects changes after the portCopyEntry is activated, portCopyStatus transitions to notReady (3).<br>The capability of an interface to be source or destination of a port copy operation is described by the copySourcePort (0) and copyDestPort (1) bits in dataSourceCopyCaps. Those bits should be appropriately set by the agent, in order to allow for a portCopyEntry to be created. |
| smonPrioStatsControlTable |                     | Not supported due to hardware limitations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| smonPrioStatsTable        |                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## RFC 2665 (EtherLike-MIB)

The following tables, groups, and variables are supported in this MIB.

| Table/Group    | Supported Variables                | Comments      |
|----------------|------------------------------------|---------------|
| Dot3StatsTable | dot3StatsIndex                     |               |
|                | dot3StatsAlignmentErrors           |               |
|                | dot3StatsFCSErrors                 |               |
|                | dot3StatsSingleCollisionFrames     |               |
|                | dot3StatsMultipleCollisionFrames   |               |
|                | dot3StatsSQETestErrors             | Not supported |
|                | dot3StatsDeferredTransmissions     |               |
|                | dot3StatsLateCollisions            |               |
|                | dot3StatsExcessiveCollisions       |               |
|                | dot3StatsInternalMacTransmitErrors |               |
|                | dot3StatsCarrierSenseErrors        | Not supported |
|                | dot3StatsFrameTooLongs             |               |
|                | dot3StatsInternalMacReceiveErrors  |               |
|                | dot3StatsSymbolErrors              | Not supported |
|                | dot3StatsEtherChipSet              |               |

| Table/Group      | Supported Variables   | Comments      |
|------------------|-----------------------|---------------|
|                  | dot3StatsDuplexStatus |               |
| dot3CollTable    | dot3CollCount         |               |
|                  | dot3CollFrequencies   |               |
| dot3ControlTable |                       | Not supported |
| dot3PauseTable   |                       | Not supported |

*Other Unsupported Tables and Nodes in EtherLike MIB:*

dot3ControlTable, dot3PauseTable, dot3Tests – all nodes under this, dot3Errors, etherConformance, etherGroups, etherCompliance, dot3Compliance. RFC 1657 (Definitions of Managed Objects for the Fourth Version of the BGP-4 using SMIv2).

All tables and variables of this MIB are supported with read-only access.

## RFC 2668 (MAU-MIB)

The following tables, groups, and variables are supported in this MIB.

| Table/Group       | Supported Variables | Comments                                                       |
|-------------------|---------------------|----------------------------------------------------------------|
| ifMauTable        | All objects         |                                                                |
| ifJackTable       | All objects         |                                                                |
| ifMauAutoNegTable | All objects         | Setting auto-negotiation through <u>SNMP</u> is not supported. |

The following new Extreme proprietary MAU types have been added to the ifMauType textual convention:

```

extremeMauType1000BaseWDMHD OBJECT IDENTIFIER
 ::= { extremeMauType 7 }
 "Gigabit WDM, half duplex"

extremeMauType1000BaseWDMFD OBJECT IDENTIFIER
 ::= { extremeMauType 8 }
 "Gigabit WDM, full duplex"

extremeMauType1000BaseLX70HD OBJECT IDENTIFIER
 ::= { extremeMauType 9 }
 "Gigabit LX70, half duplex"

extremeMauType1000BaseLX70FD OBJECT IDENTIFIER
 ::= { extremeMauType 10 }
 "Gigabit LX70, full duplex"

```

```
extremeMauType1000BaseZXHD OBJECT IDENTIFIER
 ::= { extremeMauType 11 }
 "Gigabit ZX, half duplex"
extremeMauType1000BaseZXFD OBJECT IDENTIFIER
 ::= { extremeMauType 12 }
 "Gigabit ZX, full duplex"
extremeMauType1000BaseLX100HD OBJECT IDENTIFIER
 ::= { extremeMauType 13 }
 "Gigabit LX100, half duplex"
extremeMauType1000BaseLX100FD OBJECT IDENTIFIER
 ::= { extremeMauType 14 }
 "Gigabit LX100, full duplex"
extremeMauType10GBaseCX4 OBJECT IDENTIFIER
 ::= { extremeMauType 15 }
 "10 Gigabit CX4"
extremeMauType10GBaseZR OBJECT IDENTIFIER
 ::= { extremeMauType 16 }
 "10 Gigabit ZR"
extremeMauType10GBaseDWDM OBJECT IDENTIFIER
 ::= { extremeMauType 17 }
 "10 Gigabit DWDM"
extremeMauType10GBaseCX OBJECT IDENTIFIER
 ::= { extremeMauType 18 }
 "10 Gigabit CX - SFP+ twin coax cable"
extremeMauType10GBaseT OBJECT IDENTIFIER
 ::= { extremeMauType 19 }
 "10 Gigabit BaseT"
extremeMauType40G OBJECT IDENTIFIER
 ::= { extremeMauType 20 }
 "40 Gigabit interface"
```

Corresponding MAU Type List Bits values have been added:

```

extreme_ifMauTypeListBits_b1000baseWDMHD -- 64
extreme_ifMauTypeListBits_b1000baseWDMFD -- 65
extreme_ifMauTypeListBits_b1000baseLX70HD -- 66
extreme_ifMauTypeListBits_b1000baseLX70FD -- 67
extreme_ifMauTypeListBits_b1000baseZXHD -- 68
extreme_ifMauTypeListBits_b1000baseZXFD -- 69

```

The following standards-based additions have been made as a 'Work in Progress', as per draft-ietf-hubmib-mau-mib-v3-02.txt:

A new enumeration 'fiberLC(14)' for the JackType textual convention.

New MAU types:

```

dot3MauType10GigBaseX OBJECT-IDENTITY
 STATUS current
 DESCRIPTION "X PCS/PMA (per 802.3 section 48), unknown PMD."
 ::= { dot3MauType 31 }

dot3MauType10GigBaseLX4 OBJECT-IDENTITY
 STATUS current
 DESCRIPTION "X fiber over WDM optics (per 802.3 section 53)"
 ::= { dot3MauType 32 }

dot3MauType10GigBaseR OBJECT-IDENTITY
 STATUS current
 DESCRIPTION "R PCS/PMA (per 802.3 section 49), unknown PMD."
 ::= { dot3MauType 33 }

dot3MauType10GigBaseER OBJECT-IDENTITY
 STATUS current
 DESCRIPTION "R fiber over 1550 nm optics (per 802.3 section 52)"
 ::= { dot3MauType 34 }

dot3MauType10GigBaseLR OBJECT-IDENTITY
 STATUS current
 DESCRIPTION "R fiber over 1310 nm optics (per 802.3 section 52)"
 ::= { dot3MauType 35 }

```

```

dot3MauType10GigBaseSR OBJECT-IDENTITY
 STATUS current
 DESCRIPTION "R fiber over 850 nm optics (per 802.3 section 52)"
 ::= { dot3MauType 36 }
dot3MauType10GigBaseW OBJECT-IDENTITY
 STATUS current
 DESCRIPTION "W PCS/PMA (per 802.3 section 49 and 50), unknown PMD."
 ::= { dot3MauType 37 }
dot3MauType10GigBaseEW OBJECT-IDENTITY
 STATUS current
 DESCRIPTION "W fiber over 1550 nm optics (per 802.3 section 52)"
 ::= { dot3MauType 38 }
dot3MauType10GigBaseLW OBJECT-IDENTITY
 STATUS current
 DESCRIPTION "W fiber over 1310 nm optics (per 802.3 section 52)"
 ::= { dot3MauType 39 }
dot3MauType10GigBaseSW OBJECT-IDENTITY
 STATUS current
 DESCRIPTION "W fiber over 850 nm optics (per 802.3 section 52)"
 ::= { dot3MauType 40 }

```

Corresponding new Mau Type List bit values:

|                      | vrrpNotificationCntl     |                                                                                                                                                                                                                   |
| vrrpStatistics       | vrrpRouterChecksumErrors |                                                                                                                                                                                                                   |
|                      | vrrpRouterVersionErrors  |                                                                                                                                                                                                                   |
|                      | vrrpRouterVrldErrors     |                                                                                                                                                                                                                   |
| vrrpOperTable        | All objects              | Creation of a new row or modifying an existing row requires vrrpOperAdminState to be set to down; otherwise any kind of set will fail on this table.<br>vrrpOperAuthType does not support ipAuthenticationHeader. |
| vrrpAssolpAddrTable  | All objects              |                                                                                                                                                                                                                   |
| vrrpRouterStatsTable | All objects              |                                                                                                                                                                                                                   |
| vrrpNotifications    | vrrpTrapNewMaster        |                                                                                                                                                                                                                   |
|                      | vrrpTrapAuthFailure      |                                                                                                                                                                                                                   |

## RFC-3433 (Entity Sensor MIB)

The Entity Sensor MIB contains a single entitySensorValueGroup that contains objects for representing values and status of the SFP/QSFP.

| Table/Group            | Supported Variables         | Comments                                                                                |
|------------------------|-----------------------------|-----------------------------------------------------------------------------------------|
| entitySensorValueGroup | entPhySensorType            | An integer that defines the type of data units for the sensor.<br>Read-only.            |
|                        | enetPhySensorScale          | An integer representing the data scaling factor for the sensor.<br>Read-only.           |
|                        | entPhySensorPrecision       | An integer representing the number of decimal places of sensor precision.<br>Read-only. |
|                        | entPhySensorValue           | An integer representing the sensor value.<br>Read-only.                                 |
|                        | entPhyOperStatus            | Operational status of the sensor.                                                       |
|                        | entPhySensorUnitsDisplay    | Text description of data units used in entPhySensorValue.<br>Read-only.                 |
|                        | entPhySensorValueTimeStamp  | Value of sysUpTime at the time the status and value was last obtained.<br>Read-only.    |
|                        | entPhySensorValueUpdateRate | Frequency that the agent updates the associated entPhySensorValue.<br>Read-only.        |

### *entPhySensorType*

The entPhySensorType object is an integer that defines the sensor as one of the following types: Value

| Value | Sensor Type |
|-------|-------------|
| 1     | Other       |
| 2     | Unknown     |
| 3     | voltsAC     |
| 4     | voltsDC     |
| 5     | Amperes     |
| 6     | Watts       |
| 7     | Hertz       |
| 8     | Celsius     |
| 9     | percentRH   |
| 10    | Rpm         |
| 11    | Cmm         |
| 12    | thruthvalue |

The following sensor types are used for the digital diagnostic monitoring data.

| Sensor          | Sensor Type |
|-----------------|-------------|
| Temperature     | Celsius     |
| VCC             | voltsDC     |
| Tx Bias Current | Amperes     |
| Rx Power        | Watts       |
| Tx Power        | Watts       |

Power measurements may be represented as decibels (dB). If this is the case, the sensor type is defined as "other" and the units of measurement are determined using entPhySensorUnitsDisplay.

#### *entPhySensorScale*

The entPhySensorScale object is an integer that defines the scale of the sensor as one of the following.

| Value | Sensor Scale |
|-------|--------------|
| 1     | Yocto        |
| 2     | Zepto        |
| 3     | Atto         |
| 4     | femto        |
| 5     | Pico         |
| 6     | nano         |
| 7     | micro        |
| 8     | milli        |
| 9     | units        |
| 10    | Kilo         |
| 11    | mega         |
| 12    | giga         |
| 13    | tera         |
| 14    | Exa          |
| 15    | peta         |
| 16    | zetta        |
| 17    | yotta        |

#### *entPhySensorPrecision*

This object defines the sensor precision range.

A value in the range 1 to 9, represents the number of decimal places in the fractional part of an associated entPhySensorValue fixed-point number. A value in the range -8 to -1, represents the number of accurate digits in the associated entPhySensorValue fixed-point number. The value zero indicates the associated entPhySensorValue object is not a fixed-point number.

*entPhySensorValue*

The entPhySensorValue object is the value of the sensor.

*entPhySensorOperStatus*

The entPhySensorOperStatus object is an integer that defines the operating status of the sensor as one of the following.

| Value | Sensor Status  |
|-------|----------------|
| 1     | Ok             |
| 2     | Unavailable    |
| 3     | Nonoperational |

Ports without a populated transceiver or one that is unreachable due to i2c bus errors, etc. are designated “nonoperational”. Ports populated with a transceiver that does not support digital diagnostic monitoring are designated “unavailable.”

*entPhySensorUnitsDisplay*

The entPhySensorUnitsDisplay object is a textual description of the data units that should be used in the display of entPhySensorValue.

*entPhySensorValueTimeStamp*

The entPhySensorValueTimeStamp object is the value of sysUpTime at the time the status and/or value of this sensor were last obtained.

*entPhySensorValueUpdateRate*

The entPhySensorValueUpdateRate object is an indication of the frequency that the agent updates the associated entPhySensorValue object, represented in milliseconds.

## RFC 3621 (PoE-MIB)

The following tables, groups, and variables are supported in this MIB.

| Table/Group       | Supported Variables               | Comments                             |
|-------------------|-----------------------------------|--------------------------------------|
| pethPsePortTable  | All objects                       | Objects in this table are read-only. |
| pethMainPseTable  | All objects                       | Objects in this table are read-only. |
| pethNotifications | pethPsePortOnOffNotification      |                                      |
|                   | pethMainPowerUsageOnNotification  |                                      |
|                   | pethMainPowerUsageOffNotification |                                      |

## RFC-4133 (ENTITY MIB)

For RFC-4133, the entityPhysicalGroup contains a single table, entityPhysicalTable, to identify physical system components. The following table lists the objects that are supported.

| Table/Group             | Description                                                                                       | Comments       |
|-------------------------|---------------------------------------------------------------------------------------------------|----------------|
| entPhysicalIndex        | The arbitrarily assigned index for the table                                                      | Not-accessible |
| entPhysicalDescr        | Text description of the sensor.                                                                   | Read-only      |
| entPhysicalVendorType   | Specified OID used to identify enterprise-wide type/version/model.                                | Read-only      |
| entPhysicalContainedIn  | The entPhysicalIndex of the parent device. For SFP sensors, this is the corresponding port index. | Read-only      |
| entPhysicalClass        | Integer that defines the general device type. SFP sensors are of class "sensor (8)".              | Read-only      |
| entPhysicalParentRelPos | Relative position of the parent device.                                                           | Read-only      |
| entPhysicalModuleIName  | Text String of the model information stored in the SFP/QSFP.                                      | Read-only      |
| entPhysicalSerialNum    | Text String of the serial number information stored in the SFP/QSFP.                              | Read-only      |
| entPhysicalMfgName      | Manufacture Name of the SFP/QSFP, "Extreme Networks".                                             | Read-only      |

## RFC 5601 (PW-STD-MIB)

The following tables, groups, and variables are supported in this MIB.

All tables and variables of this MIB are supported as read only. The comments here are abbreviated versions of the description in the RFC documentation.

| Table/Group | Supported Variables | Comments                                                                                                                                                                                                                                                                      |
|-------------|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pwTable     | pwIndex             | A unique index for the conceptual row identifying a PW within this table.                                                                                                                                                                                                     |
|             | pwPeerAddr          | This object contains the value of the peer node address of the PW/PE maintenance protocol entity. This object should contain a value of all zeroes if not applicable (pwPeerAddrType is 'unknown').                                                                           |
|             | pwID                | Pseudowire identifier. If the pwOwner object is pwIdFecSignaling or I2tpControlProtocol, then this object is signaled in the outgoing PW ID field within the Virtual Circuit FEC Element. For other values of pwOwner, this object is not signaled and it can be set to zero. |
|             | pwLocalCapabAdvert  | If a maintenance protocol is used, it indicates the capabilities the local node will advertise to the peer.                                                                                                                                                                   |

| Table/Group         | Supported Variables | Comments                                                                                                                                                                                                                                              |
|---------------------|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                     | pwRemoteGroupID     | This object is obtained from the Group ID field as received through the maintenance protocol used for PW setup. Value of zero is reported if not used. Value of 0xFFFFFFFF is used if the object is yet to be defined by the PW maintenance protocol. |
|                     | pwOutboundLabel     | The PW label used in the outbound direction (i.e., toward the PSN). It might be set manually if pwOwner is 'manual'; otherwise, it is set automatically.                                                                                              |
|                     | pwInboundLabel      | The PW label used in the inbound direction (i.e., packets received from the PSN). It may be set manually if pwOwner is 'manual'; otherwise, it is set automatically.                                                                                  |
|                     | pwCreateTime        | The value of sysUpTime at the time this PW was created.                                                                                                                                                                                               |
|                     | pwUpTime            | Specifies the time since last change of pwOperStatus to Up (1).                                                                                                                                                                                       |
|                     | pwLastChange        | The value of sysUpTime at the time the PW entered its current operational state. If the current state was entered prior to the last re-initialization of the local network management subsystem, then this object contains a zero value.              |
|                     | pwAdminStatus       | The desired operational status of this PW. This object can be set at any time.                                                                                                                                                                        |
|                     | pwOperStatus        | This object indicates the operational status of the PW; it does not reflect the status of the Customer Edge (CE) bound interface.                                                                                                                     |
|                     | pwLocalStatus       | Indicates the status of the PW in the local node.                                                                                                                                                                                                     |
|                     | pwRemoteStatus      | Indicates the status of the PW as was advertised by the remote.                                                                                                                                                                                       |
|                     | pwRowStatus         | For creating, modifying, and deleting this row. This object can be changed at any time.                                                                                                                                                               |
|                     | pwOamEnable         | This variable indicates if OAM is enabled for this PW. It can be changed at any time.                                                                                                                                                                 |
| pwIndexMappingTable | All objects         | This table enables the reverse mapping of the unique PWid parameters [peer IP, PW type, and PW ID] and the pwIndex. The table is not applicable for PWs created manually or by using the generalized FEC.                                             |

## RFC 5602 (PW-MPLS-STD-MIB)

The following tables, groups, and variables are supported in this MIB.

All tables and variables of this MIB are supported as read only. The comments here are abbreviated versions of the description in the RFC documentation.

| Table/Group         | Supported Variables       | Comments                                                                                                                                                                                                                                                       |
|---------------------|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pwMplsTable         | pwIndex                   | This table controls MPLS-specific parameters when the PW is going to be carried over MPLS PSN.                                                                                                                                                                 |
|                     | pwMplsMplsType            | This object is set by the operator to indicate the outer tunnel types, if existing.                                                                                                                                                                            |
|                     | pwMplsTtl                 | This object is set by the operator to indicate the PW TTL value to be used on the PW shim label.                                                                                                                                                               |
|                     | pwMplsLocalLdpID          | The LDP identifier of the LDP entity that creates this PW in the local node.                                                                                                                                                                                   |
|                     | pwMplsLocalLdpEntityIndex | The local node LDP Entity Index of the LDP entity creating this PW.                                                                                                                                                                                            |
|                     | pwMplsPeerLdpID           | The peer LDP identifier of the LDP session. This object should return the value zero if LDP is not used or if the value is not yet known.                                                                                                                      |
| pwMplsOutboundTable | All objects               | This table reports and configures the current outbound MPLS tunnels (i.e., toward the PSN) or the physical interface in the case of a PW label only that carries the PW traffic. It also reports the current outer tunnel and LSP that forward the PW traffic. |

## RFC 5603 (PW-ENET-STD-MIB)

The following tables, groups, and variables are supported in this MIB.

All tables and variables of this MIB are supported as read only. The comments here are abbreviated versions of the description in the RFC documentation.

| Table/Group | Supported Variables | Comments                                                                                                                                 |
|-------------|---------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| pwEnetTable | pwIndex             | This table contains the index to the Ethernet tables associated with this Ethernet PW, the <u>VLAN</u> configuration, and the VLAN mode. |
|             | pwEnetPwInstance    | If multiple rows are mapped to the same PW, this index is used to uniquely identify the individual row.                                  |
|             | pwEnetPwVlan        | This object defines the (service-delimiting) VLAN field value on the PW.                                                                 |
|             | pwEnetVlanMode      | This object indicates the mode of VLAN handling between the port or the virtual port associated with the PW and the PW encapsulation.    |
|             | pwEnetPortVlan      | This object defines if the mapping between the original port (physical port or VPLS virtual port) to the PW is VLAN based or not.        |

| Table/Group | Supported Variables | Comments                                                                                                                                                                                                                                 |
|-------------|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | pwEnetPortIfIndex   | This object is used to specify the ifIndex of the Ethernet port associated with this PW for point-to-point Ethernet service, or the ifIndex of the virtual interface of the VPLS instance associated with the PW if the service is VPLS. |
|             | pwEnetRowStatus     | This object enables creating, deleting, and modifying this row.                                                                                                                                                                          |

## RFC 5643

A subset of the traps in RFC 5643 are supported.

## RFC 6933 (ENTITY-MIB)

The following tables, groups, and variables are supported in this MIB.

| Table/Group         | Supported Variables    | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| entityPhysicalTable | entPhysicalIndex       | The index for this entry.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                     | entPhysicalDescr       | A textual description of physical entity. This object should contain a string that identifies the manufacturer's name for the physical entity and should be set to a distinct value for each version or model of the physical entity.                                                                                                                                                                                                                                                                                                                        |
|                     | entPhysicalVendorType  | An indication of the vendor-specific hardware type of the physical entity. Note that this is different from the definition of MIB-II's sysObjectID. An agent should set this object to an enterprise-specific registration identifier value indicating the specific equipment type in detail. The associated instance of entPhysicalClass is used to indicate the general type of hardware device. If no vendor-specific registration identifier exists for this physical entity, or the value is unknown by this agent, then the value { 0 0 } is returned. |
|                     | entPhysicalContainedIn | The value of entPhysicalIndex for the physical entity that 'contains' this physical entity. A value of zero indicates this physical entity is not contained in any other physical entity. Note that the set of 'containment' relationships define a strict hierarchy; that is, recursion is not allowed. In the event that a physical entity is contained by more than one physical entity (e.g., double-wide modules), this object should identify the containing entity with the lowest value of entPhysicalIndex.                                         |

| Table/Group | Supported Variables     | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | entPhysicalClass        | An indication of the general hardware type of the physical entity. An agent should set this object to the standard enumeration value that most accurately indicates the general class of the physical entity, or the primary class if there is more than one entity. If no appropriate standard registration identifier exists for this physical entity, then the value 'other(1)' is returned. If the value is unknown by this agent, then the value 'unknown(2)' is returned.                                                                                                                                                                                                                                                       |
|             | entPhysicalParentRelPos | An indication of the relative position of this 'child' component among all its 'sibling' components. Sibling components are defined as entPhysicalEntries that share the same instance values of each of the entPhysicalContainedIn and entPhysicalClass objects.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|             | entPhysicalName         | The textual name of the physical entity. The value of this object should be the name of the component as assigned by the local device and should be suitable for use in commands entered at the device's 'console'. This might be a text name (e.g., 'console') or a simple component number (e.g., port or module number, such as '1'), depending on the physical component naming syntax of the device. If there is no local name, or if this object is otherwise not applicable, then this object contains a zero-length string. Note that the value of entPhysicalName for two physical entities will be the same in the event that the console interface does not distinguish between them, e.g., slot-1 and the card in slot-1. |
|             | entPhysicalHardwareRev  | The vendor-specific hardware revision string for the physical entity. The preferred value is the hardware revision identifier actually printed on the component itself (if present). Note that if revision information is stored internally in a non-printable (e.g., binary) format, then the agent must convert such information to a printable format in an implementation-specific manner. If no specific hardware revision string is associated with the physical component, or if this information is unknown to the agent, then this object will contain a zero-length string.                                                                                                                                                 |

| Table/Group | Supported Variables    | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | entPhysicalFirmwareRev | The vendor-specific firmware revision string for the physical entity. Note that if revision information is stored internally in a non-printable (e.g., binary) format, then the agent must convert such information to a printable format in an implementation-specific manner. If no specific firmware programs are associated with the physical component, or if this information is unknown to the agent, then this object will contain a zero-length string. |
|             | entPhysicalSoftwareRev | The vendor-specific software revision string for the physical entity. Note that if revision information is stored internally in a non-printable (e.g., binary) format, then the agent must convert such information to a printable format in an implementation-specific manner. If no specific software programs are associated with the physical component, or if this information is unknown to the agent, then this object will contain a zero-length string. |

| Table/Group | Supported Variables  | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | entPhysicalSerialNum | <p>The vendor-specific serial number string for the physical entity. The preferred value is the serial number string actually printed on the component itself (if present). On the first instantiation of a physical entity, the value of entPhysicalSerialNum associated with that entity is set to the correct vendor-assigned serial number, if this information is available to the agent. If a serial number is unknown or non-existent, the entPhysicalSerialNum will be set to a zero-length string instead. Note that implementations that can correctly identify the serial numbers of all installed physical entities do not need to provide write access to the entPhysicalSerialNum object. Agents that cannot provide non-volatile storage for the entPhysicalSerialNum strings are not required to implement write access for this object. Not every physical component will have a serial number, or even need one. Physical entities for which the associated value of the entPhysicalFRU object is equal to 'false(2)' (e.g., the repeater ports within a repeater module) do not need their own unique serial numbers. An agent does not have to provide write access for such entities and may return a zero-length string. If write access is implemented for an instance of entPhysicalSerialNum and a value is written into the instance, the agent must retain the supplied value in the entPhysicalSerialNum instance (associated with the same physical entity) for as long as that entity remains instantiated. This includes instantiations across all re-initializations/reboots of the network management system, including those resulting in a change of the physical entity's entPhysicalIndex value.</p> |
|             | entPhysicalMfgName   | <p>The name of the manufacturer of this physical component. The preferred value is the manufacturer name string actually printed on the component itself (if present). Note that comparisons between instances of the entPhysicalModelName, entPhysicalFirmwareRev, entPhysicalSoftwareRev, and the entPhysicalSerialNum objects are only meaningful amongst entPhysicalEntries with the same value of entPhysicalMfgName. If the manufacturer name string associated with the physical component is unknown to the agent, then this object will contain a zero-length string.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Table/Group | Supported Variables  | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | entPhysicalModelName | The vendor-specific model name identifier string associated with this physical component. The preferred value is the customer-visible part number, which may be printed on the component itself. If the model name string associated with the physical component is unknown to the agent, then this object will contain a zero-length string.                                                                                                                                                                                                                                                                      |
|             | entPhysicalAlias     | Not supported.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|             | entPhysicalAssetID   | Not supported.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|             | entPhysicalIsFRU     | This object indicates whether or not this physical entity is considered a 'field replaceable unit' by the vendor. If this object contains the value 'true(1)', then this entPhysicalEntry identifies a field replaceable unit. For all entPhysicalEntries that represent components permanently contained within a field replaceable unit, the value 'false(2)' should be returned for this object.                                                                                                                                                                                                                |
|             | entPhysicalMfgDate   | This object contains the date of manufacturing of the managed entity. If the manufacturing date is unknown or not supported, the object is not instantiated. The special value '0000000000000000'H may also be returned in this case.                                                                                                                                                                                                                                                                                                                                                                              |
|             | entPhysicalUris      | This object contains identification information about the physical entity. The object contains URIs; therefore, the syntax of this object must conform to RFC 3986. Multiple URIs may be present and are separated by white space characters. Leading and trailing white space characters are ignored. If no URI identification information is known about the physical entity, the object is not instantiated. A zero-length octet string may also be returned in this case.<br><br><b>Note:</b> This object has read-write permission, but is implemented with read-only mode. Write operation is not supported. |
|             | entPhysicalUUID      | This object contains identification information about the physical entity. The object contains a Universally Unique Identifier, the syntax of this object must conform to RFC 4122, Section 4.1. A zero-length octet string is returned if no UUID information is known.                                                                                                                                                                                                                                                                                                                                           |

| Table/Group   | Supported Variables       | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | entAliasMappingIdentifier | The value of this object identifies a particular conceptual row associated with the indicated entPhysicalIndex and entLogicalIndex pair. Because only physical ports are modeled in this table, only entries that represent interfaces or ports are allowed. If an ifEntry exists on behalf of a particular physical port, then this object should identify the associated ifEntry. For repeater ports, the appropriate row in the 'rptrPortGroupTable' should be identified instead.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|               | entPhysicalChildIndex     | The value of entPhysicalIndex for the contained physical entity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|               | entConfigChange           | An entConfigChange notification is generated when the value of entLastChangeTime changes. It can be utilized by an NMS to trigger logical/physical entity table maintenance polls. An agent should not generate more than one entConfigChange 'notification-event' in a given time interval (five seconds is the suggested default). A 'notification-event' is the transmission of a single trap or inform PDU to a list of notification destinations. If additional configuration changes occur within the throttling period, then notification-events for these changes should be suppressed by the agent until the current throttling period expires. At the end of a throttling period, one notification-event should be generated if any configuration changes occurred since the start of the throttling period. In such a case, another throttling period is started right away. An NMS should periodically check the value of entLastChangeTime to detect any missed entConfigChange notification-events. |
| entityGeneral | entLastChangeTime         | The value of sysUpTime at the time a conceptual row is created, modified, or deleted in any of these tables: <ul style="list-style-type: none"> <li>entPhysicalTable</li> <li>entLogicalTable</li> <li>entLPMappingTable</li> <li>entAliasMappingTable</li> <li>entPhysicalContainsTable</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## VPLS-MIB (draft-ietf-l2vpn-vpls-mib-02.txt)

The following tables, groups, and variables are supported in this MIB.

All tables and variables of this MIB are supported as read only. The comments here are abbreviated versions of the description in the RFC documentation.

| Table/Group     | Supported Variables   | Comments                                                                                                                                                              |
|-----------------|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| vplsConfigTable | vplsConfigIndex       | Unique index for the conceptual row identifying a VPLS service.                                                                                                       |
|                 | vplsConfigName        | A textual name of the VPLS. If there is no local name, or this object is otherwise not applicable, then this object MUST contain a zero-length octet string.          |
|                 | vplsConfigAdminStatus | The desired administrative state of the VPLS service.                                                                                                                 |
|                 | vplsConfigRowStatus   | For creating, modifying, and deleting this row.                                                                                                                       |
|                 | vplsConfigMtu         | The value of this object specifies the MTU of this vpls instance.                                                                                                     |
|                 | vplsConfigVpnId       | This object indicates the IEEE 802-1990 VPN ID of the associated VPLS service.                                                                                        |
| vplsStatusTable | All objects           | This table provides information for monitoring VPLS.                                                                                                                  |
| vplsPwBindTable | vplsConfigIndex       | This table provides an association between a VPLS service and the corresponding PWs. A service can have more than one PW association. PWs are defined in the pwTable. |
|                 | vplsPwBindIndex       |                                                                                                                                                                       |
|                 | vplsPwBindType        | The value of this object indicates whether the PW binding is of type mesh or spoke.                                                                                   |
|                 | vplsPwBindRowStatus   | For creating, modifying, and deleting this row.                                                                                                                       |

# Glossary

---

## **AAA**

Authentication, Authorization, and Accounting is a system in IP-based networking to control which computer resources specific users can access and to keep track of the activity of specific users over the network.

## **ACL**

An Access Control List is a mechanism for filtering packets at the hardware level. Packets can be classified by characteristics such as the source or destination MAC, IP address, IP type, or QoS queue. Once classified, the packets can be forwarded, counted, queued, or dropped.

## **ad hoc mode**

An 802.11 networking framework in which devices or stations communicate directly with each other, without the use of an AP.

## **ARP**

Address Resolution Protocol is part of the TCP/IP suite used to dynamically associate a device's physical address (MAC address) with its logical address (IP address). The system broadcasts an ARP request, containing the IP address, and the device with that IP address sends back its MAC address so that traffic can be transmitted.

## **AS**

In OSPF, an Autonomous System is a connected segment of a network topology that consists of a collection of subnetworks (with hosts attached) interconnected by a set of routes. The subnetworks and the routers are expected to be under the control of a single administration. Within an AS, routers may use one or more interior routing protocols and sometimes several sets of metrics. An AS is expected to present to other autonomous systems an appearance of a coherent interior routing plan and a consistent picture of the destinations reachable through the AS. An AS is identified by a unique 16-bit number.

## **ATM**

Asynchronous Transmission Mode is a start/stop transmission in which each character is preceded by a start signal and followed by one or more stop signals. A variable time interval can exist between characters. ATM is the preferred technology for the transfer of images.

## **BGP**

Border Gateway Protocol is a router protocol in the IP suite designed to exchange network reachability information with BGP systems in other autonomous systems. You use a fully meshed configuration with BGP.

BGP provides routing updates that include a network number, a list of ASs that the routing information passed through, and a list of other path attributes. BGP works with cost metrics to choose the best

available path; it sends updated router information only when one host has detected a change, and only the affected part of the routing table is sent.

BGP communicates within one AS using Interior BGP (IBGP) because BGP does not work well with IGP. Thus the routers inside the AS maintain two routing tables: one for the IGP and one for IBGP. BGP uses exterior BGP (EBGP) between different autonomous systems.

## **BPDU**

In STP, a Bridge Protocol Data Unit is a packet that initiates communication between devices. BPDU packets contain information on ports, addresses, priorities, and costs and they ensure that the data ends up where it was intended to go. BPDU messages are exchanged across bridges to detect loops in a network topology. The loops are then removed by shutting down selected bridge interfaces and placing redundant switch ports in a backup, or blocked, state.

## **bridge**

In conventional networking terms, bridging is a Layer 2 function that passes frames between two network segments; these segments have a common network layer address. The bridged frames pass only to those segments connected at a Layer 2 level, which is called a broadcast domain (or VLAN). You must use Layer 3 routing to pass frames between broadcast domains (VLANs).

In wireless technology, bridging refers to forwarding and receiving data between radio interfaces on APs or between clients on the same radio. So, bridged traffic can be forwarded from one AP to another AP without having to pass through the switch on the wired network.

## **BSS**

Basic Service Set is a wireless topology consisting of one access point connected to a wired network and a set of wireless devices. Also called an infrastructure network. See also [\*IBSS \(Independent Basic Service Set\)\*](#).

## **CCM**

In CFM, Connectivity Check Messages are frames transmitted periodically by a MEP to ensure connectivity across the maintenance entities to which the transmitting MEP belongs. The CCMs contain a unique ID for the specified domain. Because a failure to receive a CCM indicates a connectivity fault in the network, CCMs proactively check for network connectivity.

## **CEP**

Customer Edge Port, also known as Selective Q-in-Q or C-tagged Service Interface, is a role that is configured in software as a CEP VMAN port, and connects a VMAN to specific CVLANs based on the CVLAN CVID. The CNP role, which is configured as an untagged VMAN port, connects a VMAN to all other port traffic that is not already mapped to the port CEP role.

## **CFM**

Connectivity Fault Management allows an ISP to proactively detect faults in the network for each customer service instance individually and separately. CFM comprises capabilities for detecting, verifying, and isolating connectivity failures in virtual bridged LANs.

## **Chalet**

Chalet is a web-based user interface for setting up and viewing information about a switch, removing the need to enter common commands individually in the CLI.

**CHAP**

Challenge-Handshake Authentication Protocol is one of the two main authentication protocols used to verify a user's name and password for PPP Internet connections. CHAP is more secure because it performs a three-way handshake during the initial link establishment between the home and remote machines. It can also repeat the authentication anytime after the link has been established.

**CIST root port**

In an NSTO environment, the port on the CIST regional root bridge that connects to the CIST root bridge is the CIST root port. The CIST root port is the master port for all MSTIs in that MSTP region, and it is the only port that connects the entire region to the CIST root bridge.

**CLI**

Command Line Interface. The CLI provides an environment to issue commands to monitor and manage switches and wireless appliances.

**CoS**

Class of Service specifies the service level for the classified traffic type.

**Data Center Connect**

DCC, formerly known as DCM (Data Center Manager), is a data center fabric management and automation tool that improves the efficiency of managing a large virtual and physical network. DCC provides an integrated view of the server, storage, and networking operations, removing the need to use multiple tools and management systems. DCC automates VM assignment, allocates appropriate network resources, and applies individual policies to various data objects in the switching fabric (reducing VM sprawl). Learn more about DCC at <http://www.extremenetworks.com/product/data-center-connect/>.

**DCB**

Data Center Bridging is a set of IEEE 802.1Q extensions to standard Ethernet, that provide an operational framework for unifying Local Area Networks (LAN), Storage Area Networks (SAN) and Inter-Process Communication (IPC) traffic between switches and endpoints onto a single transport layer.

**DHCP**

Dynamic Host Configuration Protocol allows network administrators to centrally manage and automate the assignment of IP addresses on the corporate network. DHCP sends a new IP address when a computer is plugged into a different place in the network. The protocol supports static or dynamic IP addresses and can dynamically reconfigure networks in which there are more computers than there are available IP addresses.

**DoS attack**

Denial of Service attacks occur when a critical network or computing resource is overwhelmed so that legitimate requests for service cannot succeed. In its simplest form, a DoS attack is indistinguishable from normal heavy traffic. ExtremeXOS software has configurable parameters that allow you to defeat DoS attacks.

**DSCP**

Differentiated Services Code Point is a field in the header of IP packets that is used for packet classification purposes.

**DSSS**

Direct-Sequence Spread Spectrum is a transmission technology used in Local Area Wireless Network (LAWN) transmissions where a data signal at the sending station is combined with a higher data rate bit sequence, or chipping code, that divides the user data according to a spreading ratio. The chipping code is a redundant bit pattern for each bit that is transmitted, which increases the signal's resistance to interference. If one or more bits in the pattern are damaged during transmission, the original data can be recovered due to the redundancy of the transmission. (Compare with [\*FHSS \(Frequency-Hopping Spread Spectrum\)\*](#).)

**EAP-TLS/EAP-TTLS**

EAP-TLS Extensible Authentication Protocol - Transport Layer Security. A general protocol for authentication that also supports multiple authentication methods, such as token cards, Kerberos, one-time passwords, certificates, public key authentication and smart cards.

IEEE 802.1x specifies how EAP should be encapsulated in LAN frames.

In wireless communications using EAP, a user requests connection to a WLAN through an access point, which then requests the identity of the user and transmits that identity to an authentication server such as RADIUS. The server asks the access point for proof of identity, which the access point gets from the user and then sends back to the server to complete the authentication.

EAP-TLS provides for certificate-based and mutual authentication of the client and the network. It relies on client-side and server-side certificates to perform authentication and can be used to dynamically generate user-based and session-based WEP keys.

EAP-TTLS (Tunneled Transport Layer Security) is an extension of EAP-TLS to provide certificate-based, mutual authentication of the client and network through an encrypted tunnel, as well as to generate dynamic, per-user, per-session WEP keys. Unlike EAP-TLS, EAP-TTLS requires only server-side certificates.

(See also [\*PEAP \(Protected Extensible Authentication Protocol\)\*](#).)

**EAPS**

Extreme Automatic Protection Switching is an Extreme Networks-proprietary version of the Ethernet Automatic Protection Switching protocol that prevents looping Layer 2 of the network. This feature is discussed in RFC 3619.

**ECMP**

Equal Cost Multi Paths is a routing algorithm that distributes network traffic across multiple high-bandwidth OSPF, BGP, IS-IS, and static routes to increase performance. The Extreme Networks implementation supports multiple equal cost paths between points and divides traffic evenly among the available paths.

**edge safeguard**

Loop prevention and detection on an edge port configured for RSTP. Configuring edge safeguard on RSTP edge ports can prevent accidental or deliberate misconfigurations (loops) resulting from connecting two edge ports together or from connecting a hub or other non-STP switch to an edge port. Edge safeguard also limits the impact of broadcast storms that might occur on edge ports. This advanced loop prevention mechanism improves network resiliency but does not interfere with the rapid convergence of edge ports.

**EDP**

Extreme Discovery Protocol is a protocol used to gather topology information about neighboring Extreme Networks switches.

**ELRP**

Extreme Loop Recovery Protocol is an Extreme Networks-proprietary protocol that allows you to detect Layer 2 loops.

**ERPS**

Ethernet Ring Protection Switching provides fast protection and recovery switching for Ethernet traffic in a ring topology. It also ensures that the Ethernet layer remains loop-free. It is defined in ITU/T G.8032.

**ESRP**

Extreme Standby Router Protocol is an Extreme Networks-proprietary protocol that provides redundant Layer 2 and routing services to users.

**ESRP group**

An ESRP group runs multiple instances of ESRP within the same VLAN (or broadcast domain). To provide redundancy at each tier, use a pair of ESRP switches on the group. See [\*ESRP \(Extreme Standby Router Protocol\)\*](#).

**event**

Any type of occurrence on a switch that could generate a log message or require an action. For more, see [\*syslog\*](#).

**Extreme Management Center**

Extreme Management Center (Management Center), formerly Netsight™, is a web-based control interface that provides centralized visibility into your network. Management Center reaches beyond ports, VLANs, and SSIDs and provides detailed control of individual users, applications, and protocols. When coupled with wireless and Identity & Access Management products, Management Center becomes the central location for monitoring and managing all the components in the infrastructure. Learn more about Management Center at <http://www.extremenetworks.com/product/management-center/>.

**ExtremeAnalytics**

ExtremeAnalytics™, formerly Purview™, is a network powered application analytics and optimization solution that captures and analyzes context-based application traffic to deliver meaningful intelligence about applications, users, locations, and devices. ExtremeAnalytics provides data to show how applications are being used. This can be used to better understand customer behavior on the network, identify the level of user engagement, and assure business application delivery to optimize the user experience. The software also provides visibility into network and application performance allowing IT to pinpoint and resolve performance issues in the infrastructure whether they are caused by the network, application, or server. Learn more about ExtremeAnalytics at <http://www.extremenetworks.com/product/extremeanalytics/>.

**ExtremeCloud Appliance**

The ExtremeCloud Appliance, the newest addition to the Smart OmniEdge portfolio, is a next generation orchestration application offering all the mobility services required for modern unified access deployments. The ExtremeCloud Appliance extends the simplified workflows of the ExtremeCloud public cloud application to on-prem/private cloud deployments.

The ExtremeCloud Appliance includes comprehensive critical network services for wireless and wired connectivity, wireless device secure onboarding, distributed and centralized data paths, role-based access control through the Application Layer, integrated location services, and IoT device onboarding through a single platform.

Built on architecture with the latest technology, the embedded operating system supports application containers that enable future expansion of value added applications for the unified access edge. Learn more about ExtremeCloud Appliance at <https://www.extremenetworks.com/product/extremecloud-appliance/>.

### **ExtremeCloud**

ExtremeCloud is a cloud-based network management Software as a Service (SaaS) tool. ExtremeCloud allows you to manage users, wired and wireless devices, and applications on corporate and guest networks. You can control the user experience with smarter edges – including managing QoS, call admission control, secure access policies, rate limiting, multicast, filtering, and traffic forwarding, all from an intuitive web interface. Learn more about ExtremeCloud at <http://www.extremenetworks.com/product/extremecloud/>.

### **ExtremeControl**

ExtremeControl, formerly Extreme Access Control™ (EAC), is a set of management software tools that use information gathered by a hardware engine to control policy to all devices on the network. The software allows you to automate and secure access for all devices on the network from a central dashboard, making it easier to roll out security and identity policies across the wired and wireless network. Learn more about ExtremeControl at <https://www.extremenetworks.com/product/extremecontrol/>.

### **ExtremeSwitching**

ExtremeSwitching is the family of products comprising different switch types: **Modular** (X8 and 8000 series [formerly BlackDiamond] and S and K series switches); **Stackable** (X-series and A, B, C, and 7100 series switches); **Standalone** (SSA, X430, and D, 200, 800, and ISW series); and **Mobile Backhaul** (E4G). Learn more about ExtremeSwitching at <http://www.extremenetworks.com/products/switching-routing/>.

### **ExtremeWireless**

ExtremeWireless products and solutions offer high-density WiFi access, connecting your organization with employees, partners, and customers everywhere they go. The family of wireless products and solutions includes APs, wireless appliances, and software. Learn more about ExtremeWireless at <http://www.extremenetworks.com/products/wireless/>.

### **ExtremeXOS**

ExtremeXOS, a modular switch operating system, is designed from the ground up to meet the needs of large cloud and private data centers, service providers, converged enterprise edge networks, and everything in between. Based on a resilient architecture and protocols, ExtremeXOS supports network virtualization and standards-based SDN capabilities like VXLAN gateway and OpenStack Cloud orchestration. ExtremeXOS also supports comprehensive role-based policy. Learn more about ExtremeXOS at <http://www.extremenetworks.com/product/extremexos-network-operating-system/>.

### **FDB**

The switch maintains a database of all MAC address received on all of its ports and uses this information to decide whether a frame should be forwarded or filtered. Each forwarding database (FDB) entry

consists of the MAC address of the sending device, an identifier for the port on which the frame was received, and an identifier for the VLAN to which the device belongs. Frames destined for devices that are not currently in the FDB are flooded to all members of the VLAN. For some types of entries, you configure the time it takes for the specific entry to age out of the FDB.

**FHSS**

Frequency-Hopping Spread Spectrum is a transmission technology used in Local Area Wireless Network (LAWN) transmissions where the data signal is modulated with a narrowband carrier signal that 'hops' in a random but predictable sequence from frequency to frequency as a function of time over a wide band of frequencies. This technique reduces interference. If synchronized properly, a single logical channel is maintained. (Compare with [\*DSSS \(Direct-Sequence Spread Spectrum\)\*](#).)

**gratuitous ARP**

When a host sends an ARP request to resolve its own IP address, it is called gratuitous ARP.

**IBSS**

An IBSS is the 802.11 term for an ad hoc network. See [\*ad hoc mode\*](#).

**ICMP**

Internet Control Message Protocol is the part of the TCP/IP protocol that allows generation of error messages, test packets, and operating messages. For example, the ping command allows you to send ICMP echo messages to a remote IP device to test for connectivity. ICMP also supports traceroute, which identifies intermediate hops between a given source and destination.

**IGMP**

Hosts use Internet Group Management Protocol to inform local routers of their membership in multicast groups. Multicasting allows one computer on the Internet to send content to multiple other computers that have identified themselves as interested in receiving the originating computer's content. When all hosts leave a group, the router no longer forwards packets that arrive for the multicast group.

**IGP**

Interior Gateway Protocol refers to any protocol used to exchange routing information within an AS. Examples of Internet IGPs include RIP and OSPF.

**LAG**

A Link Aggregation Group is the logical high-bandwidth link that results from grouping multiple network links in link aggregation (or load sharing). You can configure static LAGs or dynamic LAGs (using the LACP).

**LLDP**

Link Layer Discovery Protocol conforms to IEEE 802.1ab and is a neighbor discovery protocol. Each LLDP-enabled device transmits information to its neighbors, including chassis and port identification, system name and description, VLAN names, and other selected networking information. The protocol also specifies timing intervals in order to ensure current information is being transmitted and received.

**LSA**

A Link State Advertisement is a broadcast packet used by link state protocols, such as OSPF. The LSA contains information about neighbors and path costs and is used by the receiving router to maintain a routing table.

## **LSDB**

In OSPF, a Link State Database is a database of information about the link state of the network. Two neighboring routers consider themselves to be adjacent only if their LSDBs are synchronized. All routing information is exchanged only between adjacent routers.

## **MD5**

Message-Digest algorithm is a hash function that is commonly used to generate a 128-bit hash value. It was designed by Ron Rivest in 1991. MD5 is officially defined in RFC 1321 - The MD5 Message-Digest Algorithm.

## **MEP**

In MEP, a Maintenance End Point is an end point for a single domain, or maintenance association. The MEP may be either an UP MEP or a DOWN MEP.

## **MIB**

Management Information Bases make up a database of information (for example, traffic statistics and port settings) that the switch makes available to network management systems. MIB names identify objects that can be managed in a network and contain information about the objects. MIBs provide a means to configure a network device and obtain network statistics gathered by the device. Standard, minimal MIBs have been defined, and vendors often have private enterprise MIBs.

## **MIC**

Message Integrity Check (or Code), also called 'Michael', is part of WPA and TKIP. The MIC is an additional 8-byte code inserted before the standard 4-byte ICV appended in by standard WEP to the 802.11 message. This greatly increases the difficulty in carrying out forgery attacks. Both integrity check mechanisms are calculated by the receiver and compared against the values sent by the sender in the frame. If the values match, there is assurance that the message has not been tampered with.

## **MLAG**

The Multi-switch Link Aggregation Group feature allows users to combine ports on two switches to form a single logical connection to another network device. The other network device can be either a server or a switch that is separately configured with a regular LAG (or appropriate server port teaming) to form the port aggregation.

## **MPLS**

Multiprotocol Label Switching speeds up network traffic. When forwarding packets, the Layer 2 (Switching) label is used to avoid complex destination lookups in the routing table. MPLS uses Label Switched Paths (LSPs) to establish the network path. The packet will be labeled so that service providers can decide the best way to keep traffic flowing. The Multiprotocol Label Switching Transport Profile (MPLS-TP) extensions to MPLS are designed to meet service provider requirements and are used as a network layer technology in transport networks. MPLS-TP gives service providers a reliable packet-based technology that is based on circuit-based transport networking. MPLS-TP is expected to be a low cost level 2 technology (if the limited profile is implemented in isolation) that will provide QoS, end-to-end OAM and protection switching.

## **MSDP**

Multicast Source Discovery Protocol is used to connect multiple multicast routing domains. MSDP advertises multicast sources across Protocol Independent Multicast-Sparse Mode (PIM-SM) multicast

domains or Rendezvous Points (RPs). In turn, these RPs run MSDP over TCP to discover multicast sources in other domains.

**MSTI**

Multiple Spanning Tree Instances control the topology inside an MSTP region. An MSTI is a spanning tree domain that operates within a region and is bounded by that region; and MSTI does not exchange BPDUs or send notifications to other regions. You can map multiple VLANs to an MSTI; however, each VLAN can belong to only one MSTI. You can configure up to 64 MSTIs in an MSTP region.

**MSTP**

Multiple Spanning Tree Protocol, based on IEEE 802.1Q-2003 (formerly known as IEEE 892.1s), allows you to bundle multiple VLANs into one STP topology, which also provides enhanced loop protection and better scaling. MSTP uses RSTP as the converging algorithm and is compatible with legacy STP protocols.

**NetLogin**

Network login provides extra security to the network by assigning addresses only to those users who are properly authenticated. You can use web-based, MAC-based, or IEEE 802.1X-based authentication with network login. The two modes of operation are campus mode and ISP mode.

**netmask**

A netmask is a string of 0s and 1s that mask, or screen out, the network part of an IP address, so that only the host computer part of the address remains. A frequently-used netmask is 255.255.255.0, used for a Class C subnet (one with up to 255 host computers). The ".0" in the netmask allows the specific host computer address to be visible.

**OSPF**

An interior gateway routing protocol for TCP/IP networks, Open Shortest Path First uses a link state routing algorithm that calculates routes for packets based on a number of factors, including least hops, speed of transmission lines, and congestion delays. You can also configure certain cost metrics for the algorithm. This protocol is more efficient and scalable than vector-distance routing protocols. OSPF features include least-cost routing, ECMP routing, and load balancing. Although OSPF requires CPU power and memory space, it results in smaller, less frequent router table updates throughout the network. This protocol is more efficient and scalable than vector-distance routing protocols.

**OSPFv3**

Open Shortest Path First version 3 is one of the routing protocols used with IPV6 and is similar to OSPF.

**PEAP**

Protected Extensible Authentication Protocol is an IETF draft standard to authenticate wireless LAN clients without requiring them to have certificates. In PEAP authentication, first the user authenticates the authentication server, then the authentication server authenticates the user. If the first phase is successful, the user is then authenticated over the SSL tunnel created in phase one using EAP-Generic Token Card (EAP-GTC) or Microsoft Challenged Handshake Protocol Version 2 (MSCHAP V2). (See also [EAP-TLS/EAP-TTLS](#).)

**PoE**

The Power over Ethernet standard (IEEE 802.3af) defines how power can be provided to network devices over existing Ethernet connections, eliminating the need for additional external power supplies.

## **QoS**

Quality of Service is a technique that is used to manage network resources and guarantee a bandwidth relationship between individual applications or protocols. A communications network transports a multitude of applications and data, including high-quality video and delay-sensitive data such as real-time voice. Networks must provide secure, predictable, measurable, and sometimes guaranteed services. Achieving the required QoS becomes the secret to a successful end-to-end business solution.

## **RADIUS**

RADIUS is a client/server protocol and software that enables remote access servers to communicate with a central server to authenticate dial-in users and authorize their access to the requested system or service. RADIUS allows a company to maintain user profiles in a central database that all remote servers can share. It provides better security, allowing a company to set up a policy that can be applied at a single administered network point. With RADIUS, you can track usage for billing and for keeping network statistics.

## **rate limiting**

In QoS, rate limiting is the process of restricting traffic to a peak rate (PR).

## **rate shaping**

In QoS, rate shaping is the process of reshaping traffic throughput to give preference to higher priority traffic or to buffer traffic until forwarding resources become available.

## **RIP**

This IGP vector-distance routing protocol is part of the TCP/IP suite and maintains tables of all known destinations and the number of hops required to reach each. Using Routing Information Protocol, routers periodically exchange entire routing tables. RIP is suitable for use only as an IGP.

## **RIPng**

Routing Information Protocol Next Generation is one of the routing protocols used with IPv6 and is similar to RIP.

## **RSTP**

Rapid Spanning Tree Protocol, described in IEEE 802.1w, is an enhanced version of STP that provides faster convergence. The Extreme Networks implementation of RSTP allows seamless interoperability with legacy STP.

## **segment**

In Ethernet networks, a section of a network that is bounded by bridges, routers, or switches. Dividing a LAN segment into multiple smaller segments is one of the most common ways of increasing available bandwidth on the LAN.

## **SNMP**

Simple Network Management Protocol is a standard that uses a common software agent to remotely monitor and set network configuration and runtime parameters. SNMP operates in a multivendor environment, and the agent uses MIBs, which define what information is available from any manageable network device. You can also set traps using SNMP, which send notifications of network events to the system log.

## **SNTP**

Simple Network Time Protocol is used to synchronize the system clocks throughout the network. An extension of NTP, SNTP can usually operate with a single server and allows for IPv6 addressing.

**SSH**

Secure Shell, sometimes known as Secure Socket Shell, is a UNIX-based command interface and protocol of securely gaining access to a remote computer. With SSH commands, both ends of the client/server connection are authenticated using a digital certificate, and passwords are protected by being encrypted. At Extreme Networks, the SSH is a separate software module, which must be downloaded separately. (SSH is bundled with SSL in the software module.)

**SSL**

Secure Socket Layer is a protocol for transmitting private documents using the Internet. SSL works by using a public key to encrypt data that is transferred over the SSL connection. SSL uses the public-and-private key encryption system, which includes the use of a digital certificate.

**STP**

Spanning Tree Protocol, defined in IEEE 802.1d, used to eliminate redundant data paths and to increase network efficiency. STP allows a network to have a topology that contains physical loops; it operates in bridges and switches. STP opens certain paths to create a tree topology, thereby preventing packets from looping endlessly on the network. To establish path redundancy, STP creates a tree that spans all of the switches in an extended network, forcing redundant paths into a standby, or blocked, state.

STP allows only one active path at a time between any two network devices (this prevents the loops) but establishes the redundant links as a backup if the initial link should fail. If STP costs change, or if one network segment in the STP becomes unreachable, the spanning tree algorithm reconfigures the STP topology and re-establishes the link by activating the standby path.

**STPD**

Spanning Tree Domain is an STP instance that contains one or more VLANs. The switch can run multiple STPDs, and each STPD has its own root bridge and active path. In the Extreme Networks implementation of STPD, each domain has a carrier VLAN (for carrying STP information) and one or more protected VLANs (for carrying the data).

**syslog**

A protocol used for the transmission of event notification messages across networks, originally developed on the University of California Berkeley Software Distribution (BSD) TCP/IP system implementations, and now embedded in many other operating systems and networked devices. A device generates a messages, a relay receives and forwards the messages, and a collector (a syslog server) receives the messages without relaying them.

syslog uses the UDP as its underlying transport layer mechanism. The UDP port that has been assigned to syslog is 514. (RFC 3164)

**UDP**

User Datagram Protocol is an efficient but unreliable, connectionless protocol that is layered over IP (as is TCP). Application programs must supplement the protocol to provide error processing and retransmitting data. UDP is an OSI Layer 4 protocol.

**virtual router**

In the Extreme Networks implementations, virtual routers allow a single physical switch to be split into multiple virtual routers. Each virtual router has its own IP address and maintains a separate logical

forwarding table. Each virtual router also serves as a configuration domain. The identity of the virtual router you are working in currently displays in the prompt line of the CLI. The virtual routers discussed in relation to Extreme Networks switches themselves are not the same as the virtual router in VRRP.

In VRRP, the virtual router is identified by a virtual router (VRID) and an IP address. A router running VRRP can participate in one or more virtual routers. The VRRP virtual router spans more than one physical router, which allows multiple routers to provide redundant services to users.

### **VLAN**

The term VLAN is used to refer to a collection of devices that communicate as if they are on the same physical LAN. Any set of ports (including all ports on the switch) is considered a VLAN. LAN segments are not restricted by the hardware that physically connects them. The segments are defined by flexible user groups you create with the CLI.

### **VMAN**

In ExtremeXOS software, Virtual MANs are a bi-directional virtual data connection that creates a private path through the public network. One VMAN is completely isolated from other VMANs; the encapsulation allows the VMAN traffic to be switched over Layer 2 infrastructure. You implement VMAN using an additional 892.1Q tag and a configurable EtherType; this feature is also known as Q-in-Q switching.

### **VR-Control**

This virtual router is part of the embedded system in Extreme Networks switches. VR-Control is used for internal communications between all the modules and subsystems in the switch. It has no ports, and you cannot assign any ports to it. It also cannot be associated with VLANs or routing protocols. (Referred to as VR-1 in earlier ExtremeXOS software versions.)

### **VR-Default**

This virtual router is part of the embedded system in Extreme Networks switches. VR-Default is the default VR on the system. All data ports in the switch are assigned to this VR by default; you can add and delete ports from this VR. Likewise, VR-Default contains the default VLAN. Although you cannot delete the default VLAN from VR-Default, you can add and delete any user-created VLANs. One instance of each routing protocol is spawned for this VR, and they cannot be deleted. (Referred to as VR-2 in earlier ExtremeXOS software versions.)

### **VR-Mgmt**

This virtual router is part of the embedded system in Extreme Networks switches. VR-Mgmt enables remote management stations to access the switch through Telnet, SSH, or SNMP sessions; and it owns the management port. The management port cannot be deleted from this VR, and no other ports can be added. The Mgmt VLAN is created VR-Mgmt, and it cannot be deleted; you cannot add or delete any other VLANs or any routing protocols to this VR. (Referred to as VR-0 in earlier ExtremeXOS software versions.)

### **VRRP**

The Virtual Router Redundancy Protocol specifies an election protocol that dynamically assigns responsibility for a virtual router to one of the VRRP routers on a LAN. The VRRP router controlling the IP address(es) associated with a virtual router is called the master router, and forwards packets sent to these IP addresses. The election process provides dynamic failover in the forwarding responsibility should the master router become unavailable. In case the master router fails, the virtual IP address is mapped to a backup router's IP address; this backup becomes the master router. This allows any of the

virtual router IP addresses on the LAN to be used as the default first-hop router by end-hosts. The advantage gained from using VRRP is a higher availability default path without requiring configuration of dynamic routing or router discovery protocols on every host. VRRP is defined in RFC 2338.

## **VXLAN**

VXLAN is a network virtualization technology that leverages existing Layer 3 infrastructures to create tenant overlay networks. VXLAN addresses the requirements of a multi-tenant data center network infrastructure by:

- Increasing virtual network scalability to 16 million instances. This allows for tenant VLAN (Virtual LAN) isolation whereby multiple tenants can manage their own VLAN/VMAN and MAC address spaces.
- Adding an encapsulation that effectively hides VM MAC addresses from the physical network that results in physical networking devices to have smaller MAC and IP table sizes.
- Allowing for Layer 2 adjacency across IP networks by which DC network operators protect their investment in their current infrastructure. Additionally operators can distribute traffic loads across links efficiently using Layer 3 ECMP.

## **WLAN**

Wireless Local Area Network.

## **XNV**

Extreme Network Virtualization is an ExtremeXOS feature that enables the software to support VM port movement, port configuration, and inventory on network switches.
