ExtremeXOS® User Guide

for Version 32.4

Table of Contents

Introduction to the ExtremeXOS® User Guide

This guide is intended for use by network administrators who are responsible for installing and setting up network equipment. In addition to comprehensive conceptual information about each feature of our software, you will also find detailed configuration material, helpful examples, and troubleshooting information. Also included are supported platforms and recommended best practices for optimal software performance.

➡ **Important**
Release 31.6 introduced new names for the network operating systems running on Universal platforms. ExtremeXOS (EXOS) was renamed to Switch Engine and VSP Operating SystemSoftware (VOSS) was renamed to Fabric Engine. This document covers non-Universal platforms only. Switch Engine Universal platform documentation can be found at https://www.extremenetworks.com/support/documentation/ under "Switch Engine" product.

📓 **Note**
If the information in the release notes shipped with your switch differs from the information in this guide, follow the release notes.

Conventions

To help you better understand the information presented in this guide, the following topics describe the formatting conventions used for notes, text, and other elements.

Text Conventions

Unless otherwise noted, information in this document applies to all supported environments for the products in question. Exceptions, like command keywords associated with a specific software version, are identified in the text.

When a feature, function, or operation pertains to a specific hardware product, the product name is used. When features, functions, and operations are the same across an

entire product family, such as ExtremeSwitching switches or SLX routers, the product is referred to as *the switch* or *the router*.

Table 1: Notes and warnings

Icon	Notice type	Alerts you to...
	Tip	Helpful tips and notices for using the product
	Note	Useful information or instructions
	Important	Important features or instructions
	Caution	Risk of personal injury, system damage, or loss of data
	Warning	Risk of severe personal injury

Table 2: Text

Convention	Description
`screen displays`	This typeface indicates command syntax, or represents information as it is displayed on the screen.
The words *enter* and *type*	When you see the word *enter* in this guide, you must type something, and then press the Return or Enter key. Do not press the Return or Enter key when an instruction simply says *type*.
Key names	Key names are written in boldface, for example **Ctrl** or **Esc**. If you must press two or more keys simultaneously, the key names are linked with a plus sign (+). Example: Press **Ctrl**+**Alt**+**Del**
Words in italicized type	Italics emphasize a point or denote new terms at the place where they are defined in the text. Italics are also used when referring to publication titles.
NEW!	New information. In a PDF, this is searchable text.

Table 3: Command syntax

Convention	Description
bold text	Bold text indicates command names, keywords, and command options.
italic text	Italic text indicates variable content.
[ ]	Syntax components displayed within square brackets are optional. Default responses to system prompts are enclosed in square brackets.
{ **x** | **y** | **z** }	A choice of required parameters is enclosed in curly brackets separated by vertical bars. You must select one of the options.
x | **y**	A vertical bar separates mutually exclusive elements.
< >	Nonprinting characters, such as passwords, are enclosed in angle brackets.
…	Repeat the previous element, for example, *member*[*member*...].
\	In command examples, the backslash indicates a "soft" line break. When a backslash separates two lines of a command input, enter the entire command at the prompt without the backslash.

VLAN Option Formatting in Commands

For commands with a `vlan_list` option, the input into this option must not contain spaces.

Example

The `enable stpd auto-bind` command `vlan_list` input should be entered as:

```
enable stpd "s0" auto-bind vlan 10,20-30
```

Not as:

```
enable stpd "s0" auto-bind vlan 10, 20-30
```

Platform-Dependent Conventions

Unless otherwise noted, all information applies to all platforms supported by Switch Engine software, which are the following:

- ExtremeSwitching® switches
- SummitStack™

When a feature or feature implementation applies to specific platforms, the specific platform is noted in the heading for the section describing that implementation in the Switch Engine command documentation (see the Extreme Documentation page at www.extremenetworks.com/documentation/). In many cases, although the command

is available on all platforms, each platform uses specific keywords. These keywords specific to each platform are shown in the Syntax Description and discussed in the Usage Guidelines sections.

Terminology

When features, functionality, or operation is specific to a device family, such as ExtremeSwitching, the family name is used. Explanations about features and operations that are the same across all product families simply refer to the product as the *device*.

Open Source Declarations

Some software files have been licensed under certain open source licenses. More information is available at: www.extremenetworks.com/support/policies/open-source-declaration/.

Send Feedback

The Information Development team at Extreme Networks has made every effort to ensure that this document is accurate, complete, and easy to use. We strive to improve

our documentation to help you in your work, so we want to hear from you. We welcome all feedback, but we especially want to know about:

- Content errors, or confusing or conflicting information.
- Improvements that would help you find relevant information.
- Broken links or usability issues.

To send feedback, do either of the following:

- Access the feedback form at https://www.extremenetworks.com/documentation-feedback/.
- Email us at documentation@extremenetworks.com.

Provide the publication title, part number, and as much detail as possible, including the topic heading and page number if applicable, as well as your suggestions for improvement.

Help and Support

If you require assistance, contact Extreme Networks using one of the following methods:

Extreme Portal

Search the GTAC (Global Technical Assistance Center) knowledge base; manage support cases and service contracts; download software; and obtain product licensing, training, and certifications.

The Hub

A forum for Extreme Networks customers to connect with one another, answer questions, and share ideas and feedback. This community is monitored by Extreme Networks employees, but is not intended to replace specific guidance from GTAC.

Call GTAC

For immediate support: (800) 998 2408 (toll-free in U.S. and Canada) or 1 (408) 579 2826. For the support phone number in your country, visit: www.extremenetworks.com/support/contact

Before contacting Extreme Networks for technical support, have the following information ready:

- Your Extreme Networks service contract number, or serial numbers for all involved Extreme Networks products
- A description of the failure
- A description of any actions already taken to resolve the problem
- A description of your network environment (such as layout, cable type, other relevant environmental information)
- Network load at the time of trouble (if known)
- The device history (for example, if you have returned the device before, or if this is a recurring problem)
- Any related RMA (Return Material Authorization) numbers

Subscribe to Product Announcements

You can subscribe to email notifications for product and software release announcements, Field Notices, and Vulnerability Notices.

1. Go to The Hub.
2. In the list of categories, expand the **Product Announcements** list.
3. Select a product for which you would like to receive notifications.
4. Select **Subscribe**.
5. To select additional products, return to the **Product Announcements** list and repeat steps 3 and 4.

You can modify your product selections or unsubscribe at any time.

Getting Started

The Getting Started chapter is intended to help you learn about your ExtremeXOS software. Information about your product, software version requirements and navigation, common commands, and password management, along with other helpful software orientation information can be found in this chapter.

Product Overview

This table lists the Extreme Networks products that run the ExtremeXOS software.

Release 32.1 removes support for the X670-G2, X690, X870, and X620t/p (copper) switches.

SummitStack	All ExtremeSwitching family switches, except X435.

Software Required

For information about which software version is required for each hardware switch model, see *ExtremeXOS and Switch Engine Software Support*.

The features available on each switch are determined by the installed feature license and optional feature packs. For more information, see the *ExtremeXOS 32.4 Feature License Requirements* document.

ExtremeCloud™ IQ Agent Support

ExtremeXOS provides support for ExtremeCloud IQ. Currently, device discovery, basic monitoring, and visibility into homogenous stacking are supported. ExtremeXOS also has the ability to configure an optional user-defined virtual router (VR) and address of the server for ExtremeCloud IQ agent to connect to. These values are used instead of any auto-detected values.

In addition, users can configure the IQ Agent HTTP Proxy server IP and port, and define the username and password, if required.

To configure a server VR or address, use the following command:

```
configure iqagent server [vr [[vr-name | none] | vr_name vlan vlan-
name]] | none] | ipaddress [fqdn | ip_address| none]]
```

ExtremeCloud IQ supports BGP Auto-peering (see).

To configure the HTTP proxy, use the following command:

```
configure iqagent http-proxy [ipaddress [fqdn | ip_address] port
port_number | user user_name password [encrypted encrypted_password |
password] | none]
```

You can enable or disable the IQ Agent with the following commands:

➡️ **Important**
Disabling IQ Agent prevents all access to ExtremeCloud IQ. Any current activity with ExtremeCloud IQ, including remote SSH sessions, are disconnected immediately. Re-enabling IQ Agent can only occur by using the enable command by either console or Telnet or SSH access. Disabling IQ Agent deactivates automatic DHCP access on VLAN Mgmt, which is required for Zero-Touch Provisioning (ZTP).

```
enable iqagent
```

```
disable iqagent
```

To view information about IQ Agent, use the following command:

```
show iqagent discovery
```

For more information about ExtremeCloud IQ, go to https://www.extremenetworks.com/support/documentation/extremecloud-iq/.

Table 5: Supported Platforms

Switch Series	Switch Models
ExtremeSwitching X435	X435-8T-4S X435-8P-4S X435-8P-2T-W X435-24T-4S X435-24P-4S
ExtremeSwitching X440-G2	X440-G2-24P-10GE4 X440-G2-48P-10GE4 X440-G2-12T-10GE4 X440-G2-12P-10GE4 X440-G2-24T-10GE4 X440-G2-48T-10GE4
ExtremeSwitching X450-G2	X450-G2-24P-10GE X450-G2-48P-10GE X450-G2-24P-GE4 X450-G2-48P-GE4
ExtremeSwitching X460-G2	X460-G2-24P-10GE4 X460-G2-48P-10GE4 X460-G2-16MP-32P-10GE4 X460-G2-24P-48HP-10GE4
ExtremeSwitching X465	X465-48P X465-24MU-24W X465-24W X465-48W X465-24MU

IQ Agent and ExtremeCloud IQ Communication

After the IQ Agent is enabled, communication forms between the IQ Agent and extremecloudiq.com by secure HTTPS communication using destination TCP port 443. Communication between the IQ Agent and ExtremeCloud IQ occurs every 30 seconds, which includes check-in to ExtremeCloud IQ for actions, and includes CPU, memory, FDB information, Syslog, and ports statistics information. Note that data plane traffic is not sent to ExtremeCloud IQ by the IQ Agent.

Note that Telnet and SSH do not permit access to 'hivemanager' account, which the IQ Agent creates for its own purpose and uses it for all cloud-initiated SSH connections through local host, so logging on to this account through Telnet or SSH is not allowed.

IQ Agents use SNMPv2 (enabled only for internal requests) to monitor the status of the switch.

Distributed Denial of Service Support for IQ Agent

Distributed Denial of Service (DDoS) support for IQ Agent installs a filter on HTTPS L4 ports to set a CPU queue (QoS 5) that separates IQ Agent traffic from other IP exceptions. This new ACL redirects TCP traffic with source port 443 (default HTTPS port) to CPU queue 5. The IQ Agent system ACL is installed or uninstalled along with the L3 Unicast Miss (L3UCMiss) filter.

Automation of this feature is only supported on the ExtremeSwitching X695 series switch.

You can manually install the ACL to redirect IQ Agent traffic to CPU queue 5 on smaller switches with 8 ACL slices (for example, X440-G2, X435, X620) by running the following command:

```
# configure access-list iqagent.pol any

iqagent.pol:
entry iqagent_cpu5 {
  if {
    protocol tcp;
    source-port 443;
  } then {
    traffic-queue cpu_q_5;
  }
}
```

Simple Switch Configuration with Chalet

Chalet is a web-based user interface for setting up and viewing information about a switch. Chalet removes the need to know and remember commands in a CLI environment. Viewable on desktop and mobile with a quick login and intuitive navigation, Chalet features an Quick Setup mode for configuring a switch in a few simple steps. Basic data surrounding port utilization, power, and Quality of Service (QoS) are available, and more advanced users can configure multiple VLANs, create Access Control Lists (ACLs), and configure Audio Video Bridging (AVB).

Chalet is packaged with ExtremeXOS release 15.7.1 and later for all platforms, so there's nothing extra to download or install. Chalet can be launched in any modern web browser and does not depend on any outside resources to work, including Java Applets, Adobe Flash, or dedicated mobile applications.

Chalet helps you interact with the switch outside of a CLI environment and allows you to easily:

- Configure the switch for the first time without the use of a console cable.
- Configure MLAG between two peers.
- Create and upload files to and from the switch.
- Install software images and modules directly on the switch.
- View status and details of the switch and its slots and ports.
- Analyze power efficiency of power supplies, fans, and PoE ports.
- Create VLANs and ACL policies.
- Enable and disable multiple features, including QoS, AVB, auto-negotiation, and flooding.
- View recent system events.
- View device topology (stacked switches only).
- Manage users, including defining global and individual security policies.

For instructions about setting up, logging in, configuring, and monitoring your switch, see *Switch Configuration with Chalet for ExtremeXOS 21.x and 22.x*.

Switch Configuration Using VLAN ID (VID)

Referring to a *VLAN (Virtual LAN)* by VID and specifying lists of VIDs is a useful shortcut that can greatly reduce the number of commands required to configure the switch.

For example consider a scenario where two ports should be added to four tagged VLANs. Previously, this required four commands:

- configure vlan red add ports 2, 10 tagged
- configure vlan blue add ports 2, 10 tagged
- configure vlan green add ports 2, 10 tagged
- configure vlan orange add ports 2, 10 tagged

Assuming the tags for the VLANs are 100, 200, 300, 400 respectively this configuration can be accomplished with a single command:

- configure vlan 100,200,300,400 add ports 2, 10 tagged

> **Note**
> commands enhanced with VID list support operate in a "best effort" fashion. If one of the VIDs in a VID list do not exist the command is still executed for all of the VIDs in the list that do exist. No error or warning is displayed for the invalid VIDs unless all of the specified VIDs are in valid.

Zero Touch Provisioning (Auto Configuration)

Zero Touch Provisioning (ZTP) enables switches "just out of the box" to automatically gain a management IP address and configuration without serial cables and manual configuration. ZTP provides:

- Management port IP connectivity using an IPv4 link-local IP address.
- DHCP client to contact a *DHCP (Dynamic Host Configuration Protocol)* server for:
  - Assigned IP address
  - ExtremeXOS image update
  - Configuration or script file
  - Extreme Management Center (formerly, NetSight) trap address

> **Note**
> ZTP works on both tagged and untagged VLANs.

> **Note**
> ZTP+ supports stacking mode, but ZTP does not.

IPv4 Link-Local Address

Link-Local addressing (subnet `169.254.x.x`) allows a host device to automatically and predictably derive a non-routable IP address for IP communication over Ethernet links.

By configuring the Ethernet management port "just out of the box" with an IP address, a user can connect a laptop directly to the management Ethernet port. If the laptop is not configured with a fixed IP address, it tries to get an IP address from a DHCP server. If it cannot, it assigns its own Link-Local address putting the switch and the laptop on the same subnet. The laptop can then use Telnet or a web browser to access the switch removing the need for the serial cable.

> **Note**
> The ExtremeSwitching X435-8T-4S, X435-8P-4S, and X435-8P-2T-W do not have dedicated management ports. You can use front panel ports for management connectivity for these switches.

The IPv4 address format is used to make it simple for a user to determine the switch's IP address. The formula is to use the lower 2 bytes of the MAC address as the last two numbers in the Link-Local IPv4 address.

- MAC address: `00:04:96:97:E9:EE`
- Link-Local IP address: `169.254.233.238` or `0xa9fee9ee`

Web browsers accept a hexadecimal value as an IPv4 address. (Microsoft IE displays the URL with the number dot notation `169.254.233.239`.)

The web URL is `http://0xa9fee9ee` or just `0xa9fee9ee`

The user documentation directs the customer to access the web browser by typing `0xa9fe` followed by the last two number/letter groups in the MAC address found on the switch label. No hexadecimal translation is required.

With this information, you can connect the Ethernet port directly from a laptop to this switch using the temporary Link-Local address. You can communicate via web or Telnet to perform the initial switch configuration, if needed, and no longer needs a serial cable to configure a switch.

DHCP Parameters

If a DHCP server is available, ZTP tries to contact it alternating between the default *VLAN* and the management Ethernet port. The DHCP server can provide:

- IP Address
- Gateway
- option43 parameters
- Options 66 and 67 on page 19

If an IP address is provided by a DHCP server on the management port, it replaces the Link-Local management IPv4 address.

If a TFTP server IP address is provided along with the name of a config file, ZTP downloads the config file to the switch. The switch reboots to activate the config file.

For .xos image files, ZTP executes the `download image` command to update the switch software. The switch does not reboot after the download image command completes.

Option 43

Option 43 processing does not require an NMS. If a switch receives option43 as part of the DHCP response, it uses the TFTP protocol to transfer files from the specified TFTP server IP address.

Option43 parameters may contain:

- TFTP Server to Contact
- Config file to be loaded or script to be run (.xsf or .py)
- Policy files (.pol)
- ExtremeXOS image file to be downloaded (.xos)
- ExtremeXOS XMOD file to be downloaded (.xmod)
- *SNMP (Simple Network Management Protocol)* trap receiver address for Extreme MIB traps

Multiple file names may be specified in option43. The file names can be either relative path names or a full URL with the IP address of the TFTP server. If relative path names are specified, the TFTP IP address is also required.

File name examples assuming a TFTP server is present with the IP address 10.10.10.1:

- `exos/summitX-15.7.1.1.xos` (specify the IP address in sub-option 100)
- `tftp://10.10.10.1/exos/summitX-15.7.1.1.xos` (sub-option 100 is not required)

Once all of the files specified in option43 have been transferred to the switch, the switch reboots.

Following is a sample Linux DHCP configuration:

```
option space EXTREME;
option EXTREME.tftp-server-ip code 100 = ip-address;
option EXTREME.config-file-name code 101 = text;
option EXTREME.snmp-trap-ip code 102 = ip-address;
class "Edge-without-POE" {
match if (option vendor-class-identifier = "XSummit");
vendor-option-space EXTREME;
option EXTREME.tftp-server-ip 10.120.89.80;
option EXTREME.config-file-name "XSummit_edge.cfg";
option EXTREME.snmp-trap-ip 10.120.91.89;
}
class "Edge-SummitX-POE" {
match if (option vendor-class-identifier = "XSummit");
vendor-option-space EXTREME;
option EXTREME.tftp-server-ip 10.120.89.80;
option EXTREME.config-file-name "xSummit_edge.xsf";
option EXTREME.snmp-trap-ip 10.120.91.89;
}
subnet 10.127.8.0  netmask 255.255.255.0 {
option routers                  10.127.8.254;
option domain-name-servers      10.127.8.1;
option subnet-mask              255.255.255.0;
pool {
deny dynamic bootp clients;
range 10.127.8.170 10.127.8.190;
allow members of "Edge-without-POE";
allow members of "Edge-SummitX-POE";
}
}
```

Options 66 and 67

Starting with ExtremeXOS 30.6, option 66 and option 67 are supported, which provide TFTP server and `bootpfilename` for cases when option 43 is not available for ZTP.

> **Note**
> TFTPservername from option 66 is only considered when the DHCP header contains option 52 in DHCPOFFER or DHCPACK messages, or when there is no servername in the DHCP header.

Options 66 and 67 are received as DHCP options in a DHCP response by ExtremeXOS.

- Option 66 is used to identify the TFTP server with details of TFTP server IP address.
- Option 67 provides the `bootpfilename` details, which are downloaded to ExtremeXOS from the TFTP server IP address, and ExtremeXOS is rebooted after

the download is successful. The `bootpfilename` can be of any image type (`.xos` or `.xmod`) or configuration file (`.xsf` or `.py`).

If option 43 is not present, then ExtremeXOS looks for the TFTP server IP address and bootp file name in options 66 and 67 to load the configurations or update the new image. If option 43, and options 66 and 67 are present, option 43 has higher precedence.

ExtremeXOS Image Update

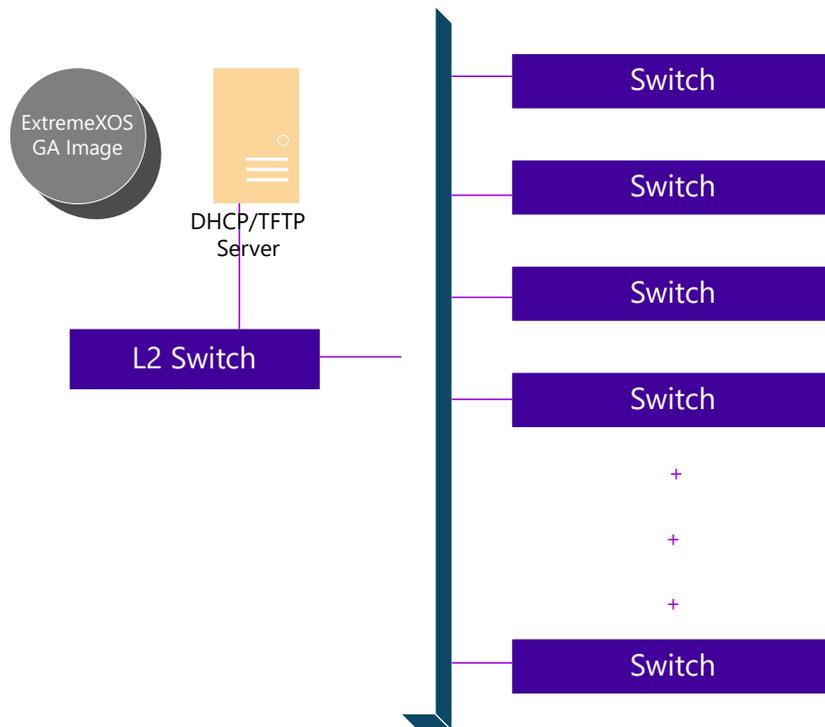
Using ZTP, you can setup a DHCP/TFTP server and connect switches directly to it, possibly via a Layer 2 switch. Switches can then update themselves with an ExtremeXOS generally available software image before being installed into a live network. Figure 1 shows one possible method of upgrading switches by connecting them to a Layer 2 switch. This approach upgrades the switches before being deployed into a network.


Figure 1: ZTP DHCP/TFTP Server Setup

Identifying an Auto Provision Enabled Switch

A switch enabled with auto provision can be identified by the following:

- A warning message for the console and each Telnet session is displayed as follows:
  ```
  Note:  This switch has Auto-Provision enabled to obtain configuration remotely.
  Commands should be limited to:
  show auto-provision
  show log
  ```

```
Any changes to this configuration will be discarded at the next reboot if auto
provisioning sends a ".cfg" file.
```
- The shell prompt displays: `(auto-provision) SummitX #`
- The status appears in the `show auto-provision` command.

Auto-provisioning Process

The auto-provisioning process is first initiated through the default _VLAN_ (bound to _VR-Default_).

After three unsuccessful attempts to reach the network, the switch waits for 15 seconds before it switches over to the Mgmt VLAN (bound to _VR-Mgmt_). It continues this process until it reaches the network.

Delay in the auto-provisioning process results from the following configuration problems:
- The _DHCP_ server may not be reachable.
- The configuration file has an invalid file extension. Only .cfg or .xsf is accepted.
- The TFTP server is unreachable.
- The configuration file name does not exist in the TFTP server.

You can use the `show log` command to view the exact problem reported.

An _SNMP_ trap is sent out for these conditions when the SNMP-Trap-IP code (code 102) is configured in the DHCP server. The SNMP trap is not sent out when the DHCP server is unreachable.

When these conditions occur, the switch continues to retry to reach the network and remains in an "In Progress" state.

When there is a system error or internal problem, the switch moves to an auto-provision "Failed" state. The switch does not retry the auto-provisioning process once it has reached the "Failed" state.

Once the network is reached, the switch receives and configures the IP address and the gateway. The switch then executes the configuration file (.cfg or .xsf file), sends the trap to inform the user of the successful auto-provisioning (only when the SNMP-Trap-IP code, code 102, is configured), and reboots for the new configuration to take effect.

Following is the mandatory DHCP option configuration used for auto provision to work:

Standard Option:
- IP address
- Subnet mask
- Gateway

Option 60:
- Vendor identifier option

Option 43:

- TFTP server IP address
- Configuration file name

DHCP option:

- SNMP trap receiver IP address

> **Note**
> The file uploaded to the TFTP server using the upload configuration command is an .xsf file extension configuration. An .cfg file extension configuration is created using the tftp put command.
>
> Configuration changes made to the switch when auto provisioning is in progress will be appended if auto provisioning uses an .xsf file extension configuration, and it will be discarded if auto provisioning uses a .cfg file extension configuration.

Auto-provisioning Configuration

- Auto provisioning is enabled by default. It can be restarted by clearing the switches configuration using `unconfigure switch {`**`all`** `|` **`erase`** `[`**`all`** `|` **`nvram`**`]}` with the **`all`** and rebooting the switch.

> **Note**
> Auto provisioning is not enabled on the _VLAN_ (Mgmt or Default) if the IP address is already configured.

- To disable auto provision, use the following command:

  ```
  disable auto-provision
  ```

  When the `disable auto-provision` command is issued, the following message is displayed:

  ```
  This setting will take effect at the next reboot of this switch.
  ```

- To display the current state of auto provision on the switch, use the following command:

  ```
  show auto-provision
  ```

Cloning Switches

ExtremeXOS switches provide a script called `clone.py` that allows you to clone one switch's setup to another switch in the following scenarios:

- **Within a stack** (see Cloning within a Stack on page 24)
- **Standalone to standalone** (see Cloning Standalone to Standalone on page 25)
- **Standalone to stack** (see Cloning from Standalone to a Stack on page 27)
- **Standalone to USB** (see Copying One Switch's Configuration to Another Switch Using USB Zero Touch Provisioning (ZTP) on page 30)

The `clone.py` script copies the following:

- All content under:
    - `/boot`
    - `/exos`
    - `/alt/boot`
    - `/alt/exos`
    - (optionally) `/usr/local/cfg`
- Specific NVRAM contents:
    - Boot selector
    - CLI banner
    - Failsafe username,password, and action

Limitations

- Requires ExtremeXOS 30.3 or later.
- Cloning to a standalone switch using a stacking master as the source does not make the standalone switch a stacking master. The configuration cloned from a stacking master to the standalone switch is ignored by ExtremeXOS.
- ONIE to non-ONIE or non-ONIE to ONIE cloning cannot be performed.

  Most of the newer ExtremeSwitching series switches (X465, X695 , X590) use the Open Network Install Environment (ONIE) bootloader. All other ExtremeSwitching series switches do not use ONIE.
- Clone application does not connect through VR-USER.
- Synchronize cannot be done for mixed stacking. All nodes in the stack must be the same platform.
- If the clone master is started and stopped, the dirty bit is set.

Supported Platforms

Cloning is supported on all switches.

Using Clone.py

To run `clone.py` to copy the current switch, use the following command:

```
run script clone.py master
```

To stop `clone.py`, use the following command:

```
run script clone.py stop
```

To show if `clone.py` is running and display the version number, use the following command:

```
run script clone.py show
```

Cloning within a Stack

To clone within a stack, you can either:

- Run the `synchronize {`**`slot`** `slotid}` command, which invokes the `clone.py` script. You can only clone one slot/switch at a time. For more information, see synchronize in the *ExtremeXOS 32.4 Command Reference Guide*.
- Run the `clone.py` script directly, which allows you to specify multiple slots/switches. If more than one slot is specified, the master is cloned to each slot one at a time.

To clone within a stack by running the `clone.py` script directly, on the master switch, enter the command:

`run script clone.py` **`slot`** `slotlist`

Where `slotlist` can be any number of valid slot positions separated with commas, or **`all`**. For example, `run script clone.py slot 1,2,3`

The following appears on the master switch:

```
+++++++++++++++++++++++++++++++++++++++++++++++++++++++
+                   C A U T I O N                     +
+   Cloning will erase all contents on these slots:   +
+                  1,3,4,5,6,7,8                       +
+     The switch contents of this stacking master     +
+     will replace the contents of these switches     +

Cloning Standalone to Standalone

There are two common cases where you might want to clone from one switch to another:

Scenario 1: You want to have a reference ExtremeXOS image and configuration for your network. New switches can clone from the master switch, getting an exact copy as the beginning switch configuration that you can then modify as needed.

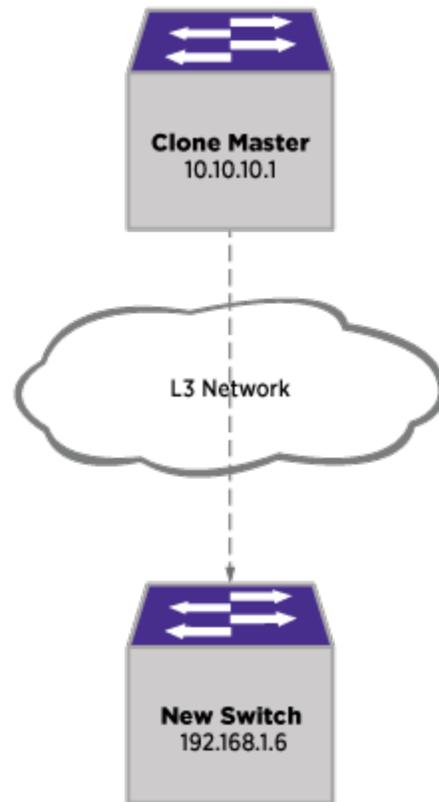
Scenario 2: You receive a large shipment of switches and want to configure one switch the way you want it, and then replicate that for all of the new switches. `Clone.py` is run on the clone master and the new switches can use _DHCP_ to get a new address, and then copy from the clone master. The new switches must have an IP address and must be able to connect with the IP address of the clone master. Either a front panel port or the management port can be used. `Clone.py` tries both VR-Mgmt and VR-Default to connect with the IP address of the clone master.


Figure 2: Cloning from Standalone Switch to Another Standalone Switch

To clone from standalone to standalone:

1. On the master switch, run the command `run script clone.py` **`master`**. The following appears:

   ```
   # run script clone.py master
   clone.py is started as cloning master
   Use "stop" option to stop cloning master services
   ```

2. On the new switch (target), run the command `run script clone.py` **`from`** `ipaddress`. Where `ipaddress` is the IP address of the master switch. The following appears:

   ```
   # run script clone.py from 10.68.65.81
   ++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++
   +                          C A U T I O N                              +
   +     Cloning will replace the EXOS partitions and configuration      +
   +   on this switch with the contents of the master switch 10.68.65.81 +

Cloning from Standalone to a Stack

You can easily add or replace a switch in a stack using the `clone.py` script.

When cloning to become a stacking member, additional NVRAM attributes are copied:

- Stacking enabled
- Stack MAC address
- Slot number—either provided or derived from the stacking master
- Switch's master-capable status—using the **-m** option when running `clone.py` sets the standalone switch to be master-capable.

> **Note**
> Cloning to a standalone switch using a stacking master as the source does not make the standalone switch a stacking master. The configuration cloned from a stacking master to the standalone switch is ignored by ExtremeXOS.

To clone from a standalone to a stack:

1. On the stack master, run the command `run script clone.py master`. The following appears:

   ```
   clone.py is started as cloning master
   Use "stop" option to stop cloning master services
   ```

2. Ensure that the standalone switch has an IP address or DHCP. See Zero Touch Provisioning (Auto Configuration) on page 17.

3. On the standalone switch, configure the switch's stacking-support options so that stacking connectivity is ready once the switch becomes stacking enabled. Run the command `enable stacking-support`.

   > **Important**
   > You must perform this step before cloning the standalone switch. If the switch is cloned as a stacking standby switch, console login and configuration options require contacting a stack master for user authentication. If the stacking links are not configured correctly, then only failsafe login is available.

4. On the standalone switch, confirm that the stacking links are configured correctly. Run the command `show stacking`. The following should appear (see bold text):

```
# show stacking
Stack Topology is a Ring
This node is not in an Active Topology
Node MAC Address    Slot  Stack State  Role      Flags
-----------------   ----  -----------  -------   ---
*00:04:96:98:94:d3  -     Disabled     Master    --- <-This is the standalone switch
 00:04:96:98:87:3a  4     Active       Standby   --O
 0e:00:00:00:00:85  5     Active       Standby   --O
 00:04:96:98:87:54  6     Active       Standby   --O
 0e:00:00:00:00:84  7     Active       Standby   --O
 00:04:96:14:0b:03  8     Active       Backup    --O
 00:04:96:14:0b:04  1     Active       Standby   --O
 0e:00:00:00:00:83  2     Active       Master    --O
* - Indicates this node
Flags:  (C) Candidate for this active topology, (A) Active Node
        (O) node may be in Other active topology
```

5. On the standalone switch, run the command `run script clone.py` **from** *ipaddress* **-s** *STACKING_SLOT*-**M**, where:

   - *ipaddress* is the IP address of the stack master.

   - *STACKING_SLOT* is the slot number. Use 0 (zero) to have the switch given the lowest available slot number.

   - **-M** enable this switch to be master-capable.

   The following appears:

```
# run script clone.py from 10.68.69.94 -s 0
++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++
+                             C A U T I O N                                  +
+        Cloning will replace the EXOS partitions and configuration          +
+     on this switch with the contents of the master switch 10.68.69.94      +
+                                                                            +
+                             STACKING                                       +
+     You have requested this switch to be cloned to stack 10.68.69.94       +
+         Switches have a variety of stacking cabling options. See:          +
+                                                                            +
+                     configure stacking-support ...                         +
+                                 and                                        +

Copying One Switch's Configuration to Another Switch Using USB Zero Touch Provisioning (ZTP)

You can copy one switch's configuration (ExtremeXOS image, configuration files, scripts) to another switch using USB Zero Touch Provisioning (ZTP).

Insert a USB drive with the desired configuration files on it into an unconfigured switch (does not need to be connected to the network), and the unconfigured switch automatically searches for the files and deploys them. The switch auto detects the USB drive at bootup or while ExtremeXOS is running.

Criteria for USB Zero Touch Provisioning

The following is required for USB Zero Touch Provisioning (ZTP) to work:
- The receiving switch must be running ExtremeXOS 30.3 or later.
- The USB drive must be formatted with FAT32.
- The receiving switch must be unconfigured.
- The receiving switch must be compatible with the source switch for ExtremeXOS image files (suffix .xos).
- The following conditions must <u>not</u> be present:
  - Stacking enabled.
  - Default.xsf is present.
  - Autoexec.xsf is present.

USB Zero Touch Provisioning File Types

Table 6 shows all of the USB Zero Touch Provisioning (ZTP) files types. With the exception of xos<serial-number>.cln files, file names must start with "ztp" (not case sensitive) to be recognized by USB ZTP.

ZTP searches for files on the USB drive in a specific order. Once a file of a higher precedence is detected, lower precedence files are not searched for.

Table 6: ZTP File Types

Order of Precedence	File Name	Description	Created by	Notes
1	`ztp.cln`	Complete image of the switch.	Created by `clone.py` application with `usb` option.	-
2	`xos<serial-number>…cln`			-
3	`ztp.lst`	Output of zip, tar, or plain text file.	Created by WinZip or `tar` on a computer and saved to the USB drive with a file name `ztp.lst`.	For zip or tar, include all of the files from the source switch you want installed on the receiving switch in this file. USB ZTP extracts the files from this compressed file, and then looks for any ztp.xsf or ztp.py scripts, and then runs them. For plain text file, list all of the file names from the source switch you want installed on the receiving switch in the plain text file, and then include all of these files on the USB drive. USB ZTP looks for any ztp.xsf or ztp.py scripts, and then runs them.
4 **Note:** USB ZTP looks for each of these optional file types. If a file is not present, USB ZTP continues to look for any of these other optional files.	`ztp.xos`	ExtremeXOS image	N/A	Installed on the inactive partition.
	`ztp.xmod`	ExtremeXOS XMOD image		
	`ztp.cfg`	ExtremeXOS configuration		Copied to `primary.cfg`.
	`ztp.xsf`	Script		Run using the `load script ztp.xsf` command.
	`ztp.py`	Script		Run using the `run script ztp.py` command.

Using USB Zero Touch Provisioning

To use USB Zero Touch Provisioning (ZTP):

1. Gather the files that you need from the source switch by using one of the following methods:

   - Run the command:
     ```
     run script clone.py usb -o
     ```

     Use the **-e** option if you want to only clone the ExtremeXOS partitions and not copy the switch configuration:
     ```
     run script clone.py usb -o -e
     ```

     The following appears:

     ```
     ++++++++++++++++++++++++++++++++++++++++++++++++++++++++++
     +   Clone EXOS partitions on this switch to the file:   +
     +   /usr/local/ext/xos1405G-00125_2017-01-21_1757.cln   +
     ++++++++++++++++++++++++++++++++++++++++++++++++++++++++++
     Do you want to continue cloning? [y/N]: y
     ..................................
     -rwxr-xr-x    1 root      root     453981696 Jan 21 17:58 /usr/local/ext/
     xos1405G-00125_2017-01-21_1757.cln

      1K-blocks      Used Available Use%
         7958912    443428   7515484   6%

     ************************
     *   Cloning COMPLETE   *
     ************************
     ```

     Skip Step 2 on page 32.
   - Use `tar` or WinZip to create a compressed file containing all of the files from the source switch, and then rename it `ztp.lst`.
   - Create a plain text file with a list of all of the file names from the source switch, and then reaname it `ztp.lst`.
   - Select `.xos`, `.xmod`, `.cfg`, `.xsf`, and `.py` files as needed, and then append "ztp" (not case sensitive) to the beginning of each file name.

2. Copy the necessary file(s) dependant on which method you used) to the USB drive:

   - `ztp.lst` (compressed file).
   - `ztp.lst` (plain text list), plus the files listed in `ztp.lst`.
   - ExtremeXOS image, configuration, and script files, as needed.

3. Ensure that the receiving switch is unconfigured—either "just out-of-the-box" or run `unconfigure switch {`**all** | **erase** [**all** | **nvram**]`}`.

4. Insert the USB drive in the receiving switch.

   - If you used `clone.py`, run the command `run script clone.py` **usb -i** *filename* **-e**, where **-i** enables the copying from the source switch, **-e** only copies the ExtremeXOS partitions (not the switch configuration), and *filename*

is the name of the file created from running the `clone.py` script on the original switch. The file is in the format: `xos`*`serialnumber_date`*`.cln`, where

- `xos`—constant identifying that this file was created from ExtremeXOS.
- *`serialnumber`*—the serial number of the switch used to create the clone image file.
- *`date`*—the date and time the clone image file was created.
- `.cln` – file suffix indicating this file was created by `clone.py`.

> **Note**
> Use the command `run script clone.py` **`usb -v`** *`filename`* to view the ExtremeXOS versions that are in the file. For example:
>
> ```
> # run script clone.py usb -v xos1405G-00125_2017-01-21_1757.cln
> File: /usr/local/ext/xos1405G-00125_2017-01-21_1757.cln
> Contains:
> EXOS: 22.2.0.38
> EXOS: 22.3.0.7
> ```

For example:

```
run script clone.py usb -i xos1405G-00125_2017-01-21_1757.cln
```

The following appears:

```
++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++
+                       C A U T I O N                             +
+   Cloning will replace the EXOS partitions and configuration    +
+        on this switch with the contents of the usb file         +
+       /usr/local/ext/xos1405G-00125_2017-01-21_1757.cln         +
++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++
Do you want to continue cloning? [y/N]: y
DO NOT REMOVE POWER or REBOOT the switch until the operation is COMPLETE
Switch will reboot when cloning is COMPLETE

Transferring /usr/local/cfg directory
...
Transferring inactive EXOS partition
...........
Transferring active EXOS partition
..............
****************************
*   USB Cloning COMPLETE   *
****************************
...reboot: Restarting system
```

- If you did not use `clone.py` (the file is named `ztp`), the cloning starts automatically.

Files found on the USB drive are processed in the following order:

- `ztp.xos` is installed to the inactive partition
- `ztp.xmod` is installed in the inactive parttion

◦ `ztp.cfg` is copied to primary.cfg

> **Note**
> When a configuration file is present, some processing is deferred until after reboot by using the ExtremeXOS `autoexec.xsf` capability. The deferred actions are:
> - **Configuration files**—`autoexec.xsf` issues a `use configuration` command, since ExtremeXOS does not recognize `.cfg` file unless the file is present at bootup.
> - **Script files**—Since script files are likely to modify the configuration, scripts are processed after implementing the configuration (`.cfg`) by `autoexec.xsf`.
> - **Save**—the last action of `autoexec.xsf` is to save.
> - **Remove autoexec.xsf**—`autoexec.xsf` file is automatically removed after it is processed for USB ZTP.

◦ `ztp.xsf` is run using the `load script ztp.xsf` command
◦ `ztp.py` is run using the `run script ztp.py` command

If the switch supports it, during the USB ZTP process the front panel LEDs display a flashing pattern instead of the usual link activity. If a stacking slot seven-segment display is available and the hardware supports it, the switch scrolls the letters "U S b". When USB ZTP finishes, the LEDs resume their normal behavior.

Logging in to the Switch

Perform the following tasks to log in to the switch.

1. The initial login prompt appears as follows:

   `(Pending-AAA) login:`

   At this point, the failsafe account is now available, but the normal AAA login security is not. (For additional information on using the failsafe account, refer to Failsafe Accounts on page 58.)

2. Wait for the following message to appear:

   `Authentication Service (AAA) on the master node is now available for login.`

   At this point, the normal AAA login security is available.

3. Press **[Enter]**.

   Whether or not you press **[Enter]**, after you see the logon prompt, you can perform a normal logon. (See Default Accounts on page 56.)

   The following prompt appears: `login`

After you have successfully logged on, the following information about successful and unsuccessful logons appears:

```
There have been 26 successful logins since last reboot and 0 failed logins since last
successful login
Last Successful Login was on: Thu Apr 23 17:16:08 2020
```

Understanding the Command Syntax

This section describes the steps to take when you enter a command.

Software command syntax is described in detail in the *ExtremeXOS 32.4 Command Reference Guide*. Some commands are also included in this guide in order to describe how to use OS software features. However, only a subset of commands are described here, and in some cases only a subset of the options that a command supports. You should consider the *ExtremeXOS 32.4 Command Reference Guide* as the definitive source for information on commands.

You can enter configuration commands at the # prompt. At the > prompt, you can enter only monitoring commands, not configuration commands. When you log in as admin (which has read and write access), you see the # prompt. When you log in as user (which has only read access), you will see the > prompt. When the switch is booting up, you may see the > command prompt. When the bootup process is complete, the # prompt is displayed.

When you enter a command at the prompt, ensure that you have the appropriate privilege level.

Most configuration commands require you to have the administrator privilege level. For more information on setting CLI privilege levels, see the `create account`, `configure account`, and `configure account [`**all** `| ` *name*`]` **privilege** `[`**admin** `| ` **user**`]` commands.

Using the CLI

This section describes how to use the CLI to issue commands.

1. At the prompt, enter the command name.
   If the command does not include a parameter or values, skip to step 3. If the command requires more information, continue to step 2.
2. If the command includes a parameter, enter the parameter name and values.
   The value part of the command specifies how you want the parameter to be set. Values include numerics, strings, or addresses, depending on the parameter.
3. After entering the complete command, press **[Enter]**.

   > **Note**
   > If an asterisk (*) appears in front of the command line prompt, it indicates that you have pending configuration changes that have not been saved. For more information on saving configuration changes, see Software Upgrade and Boot Options on page 1958.

Syntax Helper

The CLI has a built-in syntax helper. If you are unsure of the complete syntax for a particular command, enter as much of the command as possible, and then press:

- **[Tab]**— Auto-completes the command if there is a unique match. If there is a partial match, auto-completes to the nearest match, and then lists the available options.

- **?**—provides a list of options for the entered command.

If you enter an invalid command, the syntax helper notifies you of your error, and indicates where the error is located.

If the command is one where the next option is a named component (such as a *VLAN*, access profile, or route map), the syntax helper also lists any currently configured names that might be used as the next option. In situations where this list is very long, the syntax helper lists only one line of names, followed by an ellipsis (...) to indicate that there are more names that can be displayed.

CLI File Name Completion

When entering a command, at the point where a file name could be entered, press **[Tab]** or **?** to display an alphabetically sorted list of possible file names. You can also type part of the file name to display a filtered list of file names matching what you have typed so far.

The following commands support this behavior:

- cd *directory_name*

- configure access-list *aclname* [**any** | **ports** *port_list* | **vlan** *vlan_name*] {**ingress** | **egress**}

- configure ip-security dhcp-bindings storage filename *name*

- configure snmp access-profile [*access_profile* {**readonly** | **readwrite**} | [[**add** *rule*] [**first** | [[**before** | **after**] *previous_rule*]]] | **delete** *rule* | **none**]

- configure ssh2 access-profile [*access_profile* | [[**add** *rule*] [**first** | [[**before** | **after**] *previous_rule*]]] | **delete** *rule* | **none**]

- configure telnet access-profile [*access_profile* | [[**add** *rule*] [**first** | [[**before** | **after**] *previous_rule*]]] | **delete** *rule* | **none**]

- configure vlan *vlan_name* **udp-profile** [*profilename* | **none**]

- cp *old_name new_name*

- create process *name* executable *exe* {start [**auto** | **on-demand**]} {**node** *node*} {*vr vr-name*} {**description** *description*} {*arg1* {*arg2* { *arg3* { *arg4* { *arg5* { *arg6* { *arg7* { *arg8* { *arg9* }}}}}}}}}

- create process *name* **python-module** *python-module* {**start** [**auto** | **on-demand**]} {**node** *node*} {**vr** *vr-name*} {**description** *description*} {*arg1* {*arg2* {*arg3* {*arg4* {*arg5* {*arg6* {*arg7* {*arg8* {*arg9*}}}}}}}}}

- edit policy *filename*

- enable license file *filename*

- enable ssh2 {**access-profile** [*access_profile* | **none**]} {**port** *tcp_port_number*} {**vr** [*vr_name* | **all** | **default**]}

- load script *filename* {**arg1**} {**arg2**} ... {**arg9**}

- ls *file_name*

- mkdir *directory_name*

- mv *old_name new_name*

- scp2 {**cipher** *cipher*} {**mac** *mac*} {**compression** [**on** | **off**]} {**port** *portnum*} {**vr** *vr_name*} *user* [*hostname* | *ipaddress*]:*remote_file local_file*

- show ssl {[**trusted-ca** | **ocsp-signature-ca**] [*file_name* | **all**]} {**manufacturing**}{**certificate** | **detail**}

- tftp [**ip-address** | **host-name**] { **-v** *vr_name* } { **-b** *block_size* } [**-g** | **-p**] [**-l** *local-file* { **-r** *remote-file* } | **-r** *remote-file* { **-l** *local-file* }]

- tftp get [**ip-address** | **host-name**] { **vr** *vr_name* } { **block-size** *block_size* } *remote-file local-file*} {**force-overwrite**}

- tftp put [*ip-address* | *host-name*] {**vr** *vr_name*} {**block-size** *block_size*}*local-file* { *remote-file*}

- rm *file_name*

- rmdir *directory_name*

- run script *filename* {**arg1**} {**arg2**} **...** {**arg9**}

- unconfigure ssl certificate [**trusted-ca** | **ocsp-signature-ca**] [*file_name* | **all**]

Object Names

You must provide all named components within a category of the switch configuration (such as *VLAN*) a unique *object name*.

Object names must begin with an alphabetical character, and may contain alphanumeric characters and underscores (_), but they cannot contain spaces. The maximum allowed length for a name is 32 characters. User-created object names for the following modules are not case-sensitive: access list, account, *CFM (Connectivity Fault Management)*, *EAPS (Extreme Automatic Protection Switching)*, *ESRP (Extreme Standby Router Protocol)*, flow-redirect, meter, *MSDP (Multicast Source Discovery Protocol)*, Network Login, PVLAN, protocol, *SNMP*, SSHD2, STP, tunnel, UPM, *VLAN*, VMAN, etc.

Object names can be reused across categories (for example, *STPD (Spanning Tree Domain)* and VLAN names). If the software encounters any ambiguity in the components within your command, it generates a message requesting that you clarify the object you specified.

> **Note**
> If you use the same name across categories, we recommend that you specify the identifying keyword as well as the actual name. If you do not use the keyword, the system may return an error message.

Reserved Keywords

Keywords such as **vlan**, **stp**, and other second-level keywords are reserved and you cannot use them as object names. This restriction only applies to the specific word e.g (**vlan**); you can use expanded versions e.g (**vlan2**) of the word.

A complete list of the reserved keywords for ExtremeXOS 12.4.2 and later software is displayed in Table 7. Any keyword that is not on this list can be used as an object name.

> **Note**
> The list of reserved keywords is not exhaustive, and more will be added as new features are added. A failure to create an object with the following error means that the keyword is reserved:
>
> "Name cannot be a reserved keyword."

Abbreviated Syntax

Abbreviated syntax is the shortest unambiguous allowable abbreviation of a command or parameter. Typically, this is the first three letters of the command.

When using abbreviated syntax, you must enter enough characters to make the command unambiguous and distinguishable to the switch. If you do not enter enough letters to allow the switch to determine which command you mean, the syntax helper provides a list of the options based on the portion of the command you have entered.

Command Shortcuts

Components are typically named using the `create` command. When you enter a command to configure a named component, you do not need to use the keyword of the component.

> **Note**
> True only for some named components.

For example, you can create a _VLAN_.

1. Enter a VLAN name:

   ```
   create vlan engineering
   ```

   After you have created the name for the VLAN, you can eliminate the keyword **vlan** from all other commands that require the name to be entered.

2. Enter the shortcut.

   ```
   configure engineering delete port 1:3,4:6
   ```

Command Aliases

You can create aliases to execute any ExtremeXOS command, including any options, arguments, and redirection.

For example, you can create an alias called "download" to substitute for "`download image 102.3.10.5`". Now you can now simply type "download" and then the image file name to download your ExtremeXOS image from the 102.3.10.5 location, instead of typing `download image 102.3.10.5` *`image_name`*.

> **Important**
>
> Aliases are only available in the shell session in which they are created. When you exit the shell your aliases are lost. To create persistent aliases, you need to add the aliases to the script `exshrc.xsf` that you must create using the VI editor and save in the `/usr/local/cfg` folder.
>
> For more information about the `exshrc.xsf` script, see ExtremeXOS Shell RC Script on page 440. For information about managing files on the switch, see Using the ExtremeXOS File System on page 138.

To be recognized, the alias must be the first word in the command string typed at the prompt. Substitution does not occur if the alias name string occurs anywhere else.

Auto-completion works for aliases much as it does for ExtremeXOS commands (see Syntax Helper on page 35).

Limitations

- Arguments cannot occur in the middle of alias commands. For example, you cannot create an alias "set_vlan_ip" for the command `configure` **`vlan`** *`vlan_name`* **`ipaddress`** *`ip_address`* where you specify the VLAN name as an argument. This is because aliases work through direct textual substitution.
- Aliases cannot be chained together. For example, if you create an alias "sh" for `show version` and another alias "ps" for `process`, then entering `sh ps` at the prompt is not equivalent to entering "`show version process`".
- You cannot tab-complete commands when creating an alias by using the `alias` command.
- Aliases cannot be created for the current shell session using UPM scripts or Python scripts.
- Tab completion does not work for commands given inside the aliases.

Usage

To create an alias, use the command `alias` *`alias_name command`*

To view a list of current aliases, use the command `alias` (with no other arguments).

To display the command that will be substituted for *`alias_name`*, use the command `alias` *`alias_name`*.

To delete aliases, use the command `unalias`.

Command Line Interface (CLI) History Expansion

The history expansion character '!' can be used to specify a command from the history that is substituted into the command line. All occurrences of the form "!n:w" in the command are replaced with the w'th word from the n'th line in the command history. Specification of the word is optional.

For example, if the command history is as follows:

1. show vlan
2. create vlan vlan_1
3. show ports

You can type `configure vlan !2:2 ipaddress 10.0.0.1` to configure the IP address of vlan_1. Or type `!1` to run the command `show vlan`.

You can also use negative values for n to refer backward through the history. `!-1` refers to the previous command executed, which in the preceding example is `show ports`. To execute a command that was typed two commands back, use `!-2`. You can use negative values for w to refer to the first (1+|w|) words from the selected line in history.

For example, `!2:-1` gives you the first 1+|-1|=2 words from line 2 of the history (in this example, `create vlan`).

This feature is disabled by default.

Supported Platforms

CLI history expansion is available on all ExtremeSwitching platforms.

Configuring CLI History Expansion

To enable CLI history expansion, use the following command:

`enable` **`cli history expansion`** `{`**`session`** `|` **`permanent`**`}`

To disable CLI history expansion, use the following command:

`disable` **`cli history expansion`** `{`**`session`** `|` **`permanent`**`}`

To view the status of CLI history expansion, use the following command:

`show switch management`

CLI History Lookup

You can find and re-execute CLI commands from the history.

To find a previously entered command:

1. Press **CTRL** + **R**. The prompt changes to `reverse-i-search`.

2. Start typing any part of the desired command. The CLI shows matching commands from the history. If there are multiple matches, press **CTRL** + **R** again to view additional matches.
3. To use the recovered command:
   - To execute the command with <u>no changes</u>, press **ENTER**.
   - To modify the command at the <u>searched word</u>, press **ESC** to place the command in the prompt with the cursor on the searched word.
   - To modify the command from the <u>end</u> of the command, press **CTRL** + **E** to place the command in the prompt with the cursor at the end of the command.

Support for Revising CLI Commands

ExtremeXOS has evolved and incorporated many new features over time. During this development, CLI keywords have been introduced that are not logically organized or do not conform to the CLI format standards. ExtremeXOS30.3 and later provides the infrastructure capability to manage the reorganization and removal of CLI commands with the goal of providing clearer CLI organization and improved usability.

The following command manages how old keywords that have been moved and redefined appear in the CLI:

`configure` **cli moved-keywords** [**hide** | **show** {**no-help**}]. Choices made in this command appear in the output of the `show management` command. The following

table explains the configure command options, how they impact CLI behavior, and how these choices appear in the `show switch management` command.

Moved Command Option	CLI Impact	Show Switch Management Command Display
`hide`	Moved commands do not appear in the CLI. • The removed keyword no longer appears as an option when using **TAB** or **?** for syntax suggestion and completion (see Syntax Helper on page 35). • Removed commands continue to run, provided the syntax is correct.	**Hidden**
`show`	Moved commands appear in the CLI. • The removed keyword appears as an option when using **TAB** or **?** for syntax suggestion and completion (see Syntax Helper on page 35). Help text indicates the new preferred syntax. • Removed commands continue to execute, provided the syntax is correct, but a message appears prompting you to use the preferred new syntax.	**Displayed with Help**
`no-help`	Moved commands appear in the CLI. • The removed keyword appears as an option when using **TAB** or **?** for syntax suggestion and completion (see Syntax Helper on page 35). Help text does not indicate the new preferred syntax. • Removed commands continue to execute, provided the syntax is correct. No message appears prompting you to use the preferred new syntax.	**Displayed with No Help**

Symbols

You may see a variety of symbols shown as part of the command syntax.

These symbols explain how to enter the command, and you do not type them as part of the command itself. Table 8 summarizes command syntax symbols you may see throughout this guide.

> **Note**
> ExtremeXOS software does not support the ampersand (&), left angle bracket (<), or right angle bracket (>), because they are reserved characters with special meaning in XML.

Table 8: Command Syntax Symbols

Symbol	Description
square brackets [ ]	Enclose a required value or list of required arguments. One or more values or arguments can be specified. For example, in the syntax `disable port [port_list	all]` you must specify either specific ports or all for all ports when entering the command. Do not type the square brackets.
vertical bar |	Separates mutually exclusive items in a list, one of which must be entered. For example, in the syntax `configure snmp add community [readonly	readwrite]` `alphanumeric_string` you must specify either the read or write community string in the command. Do not type the vertical bar.
braces { }	Enclose an optional value or a list of optional arguments. One or more values or arguments can be specified. For example, in the syntax `reboot {time month day year hour min sec } {cancel}` `{msm slot_id} {slot slot-number	node-address node-` `address	stack-topology {as-standby} }` You can specify either a particular date and time combination, or the keyword **cancel** to cancel a previously scheduled reboot. (In this command, if you do not specify an argument, the command will prompt, asking if you want to reboot the switch now.) Do not type the braces.

Port Numbering

The operating system software runs on stand-alone switches.

> **Note**
> The keyword **all** acts on all possible ports; it continues on all ports even if one port in the sequence fails.

Stand-alone Switch Numerical Ranges

On ExtremeSwitching switches, the port number is simply noted by the physical port number.

Separate the port numbers by a dash to enter a range of contiguous numbers, and separate the numbers by a comma to enter a range of non-contiguous numbers:

- x-y—Specifies a contiguous series of ports on a stand-alone switch.
- x,y—Specifies a non-contiguous series of ports on a stand-alone switch.
- x-y,a,d—Specifies a contiguous series of ports and a non-contiguous series of ports on a stand-alone switch.

SummitStack Numerical Ranges

On SummitStack switches, the port number is a combination of the slot number and the port number.

The nomenclature for the port number is as follows: `slot:port`

For example, if there is a switch in slot 2 of the stack with a total of four ports, the following ports are valid:

- 2:1
- 2:2
- 2:3
- 2:4

You can also use wildcard combinations (*) to specify port combinations.

The following wildcard combinations are allowed:

- slot:*—Specifies all ports on a particular switch in the stack.
- slot:x-slot:y—Specifies a contiguous series of ports on a range of switches in the stack.
- slot:x-y—Specifies a contiguous series of ports on a particular switch in the stack.
- slota:x-slotb:y—Specifies a contiguous series of ports on a SummitStack node and end on another node.

Assigning Slot:Port Notation on Standalone Switches

You can configure a standalone system as a slotted system, which allows for commands which had 'slot' arguments to be visible and take in a valid slot number of '1', along with any port arguments specified in 'slot':'port' notation. In turn, any command output would specify 'slot' information and ports displayed in 'slot':'port' notation.

To assign slot:port notation to a standalone switch, use the following command:

configure **system ports notation** [**slot:port** | **slot/port**]

The CLI prompt for the switch changes to show that you have changed it to slot:port notation. For example:

```
Slot-1 X460G2-24t-10G4.1
```

Line-Editing Keys

Table 9 on page 47 describes the line-editing keys available using the CLI.

Table 9: Line-Editing Keys

Key(s)	Description
Left arrow or **[Ctrl] + B**	Moves the cursor one character to the left.
Right arrow or **[Ctrl] + F**	Moves the cursor one character to the right.
[Ctrl] + H or Backspace	Deletes character to left of cursor and shifts remainder of line to left.
[Ctrl] + D	Deletes character under cursor and shifts remainder of line to left.
[Ctrl] + K	Deletes characters from under cursor to end of line.
[Insert]	Toggles on and off. When toggled on, inserts text and shifts previous text to right.
[Ctrl] + A	Moves cursor to first character in line.
[Ctrl] + E	Moves cursor to last character in line.
[Ctrl] + L	Clears screen and moves cursor to beginning of line.
[Ctrl] + P or Up arrow	Displays previous command in command history buffer and places cursor at end of command.
[Ctrl] + N or Down arrow	Displays next command in command history buffer and places cursor at end of command.
[Ctrl] + U	Clears all characters typed from cursor to beginning of line.
[Ctrl] + W	Deletes previous word.
[Ctrl] + C	Interrupts the current CLI command execution.

Viewing Command History (Journal)

The operating system retains a list of the most recently executed CLI commands (journal). The journal retains as many as 200 commands along with the timestamp and user name. Commands are saved even after logging off, rebooting, or switch crashes.

To view the list of recent CLI commands, use the command `show cli journal`.

To configure command list size, use the command `configure cli` **`journal size`** `size`.

To view the currently configured command list size, use the command `show switch management`.

To remove the list, use either of the following commands: `unconfigure switch all` or `unconfigure switch erase all`.

Limitations

- Commands executed using North Bound interfaces (For example: _SNMP_, Extreme Management Center, web) are not supported.
- The command `show cli journal` is not checkpointed in backup slot.

Common Commands

This section discusses common commands you can use to manage the switch.

Commands specific to a particular feature may also be described in other chapters of this guide. For a detailed description of the commands and their options, see the _ExtremeXOS 32.4 Command Reference Guide_.

Table 10: Common Commands

Command	Description
`clear session [history	sessId	all]`	Terminates a Telnet or SSH2 session from the switch.
`configure account`	Configures a user account password. Passwords can have a minimum of 0 character and can have a maximum of 32 characters. Passwords are case-sensitive. User names are not case-sensitive.
`configure banner`	Configures the banner string. You can configure a banner to be displayed before login or after login.You can enter up to 24 rows of 79-column text that is displayed before the login prompt of each session.
`configure ports port_list {medium [copper	fiber]} auto off speed speed duplex [half	full]`	Manually configures the port speed and duplex setting of one or more ports on a switch.
`configure ssh2 key {pregenerated}`	Generates the SSH2 host key.
`configure sys-recovery-level [all	none]`	Configures a recovery option for instances where an exception occurs in ExtremeXOS software.
`configure time month day year hour min sec`	Configures the system date and time. The format is as follows:`mm dd yyyy hh mm ss` The time uses a 24-hour clock format. You cannot set the year earlier than 2003 or past 2036.
`configure timezone`	Configures the time zone information to the configured offset from GMT time. The format of **GMT_offset** is ± minutes from GMT time. The **autodst** and **noautodst** options enable and disable automatic Daylight Saving Time change based on the North American standard. Additional options are described in the _ExtremeXOS 32.4 Command Reference Guide_

Table 10: Common Commands (continued)

Command	Description
`configure [{ `**`vlan`**`} `*`vlan_name`* `| `**`vlan`**` `*`vlan_id`* `] `**`ipaddress`**` [`*`ipaddress`*` {`*`ipNetmask`*`} | `**`ipv6-link-local`**` | {`**`eui64`**`} `*`ipv6_address_mask`*`]`	Configures an IP address and subnet mask for a _VLAN_.
`create account`	Creates a user account. This command is available to admin-level users and to users with _RADIUS (Remote Authentication Dial In User Service)_ command authorization. The username is between 1 and 32 characters and is not case-sensitive. The password is between 0 and 32 characters and is case-sensitive. For user names, only alphanumeric, dash (-), and underscore (_) characters may be used. Any text after a hashtag (#) in a password is ignored. It has to be enclosed in "<double quotes>" if the hashtag is to be made part of the special character password.
`create vlan [{ `**`vlan`**`} `*`vlan_name`* `| `**`vlan`**` `*`vlan_list`* `] {`**`description`**` `*`vlan-description`*`} {`**`vr`**` `*`name`*`}`	Creates a VLAN.
`delete account `*`name`*	Deletes a user account.
`delete [{ `**`vlan`**`} `*`vlan_name`* ` | `**`vlan`**` `*`vlan_list`*`]`	Deletes a VLAN.
`disable bootp vlan [`*`vlan`*` | `**`all`**`]`	Disables BOOTP for one or more VLANs.
`disable cli prompting`	Disables CLI prompting for the session.
`disable cli config-logging`	Disables logging of CLI commands to the Syslog.
`disable cli paging`	Disables pausing of the screen display when a show command output reaches the end of the page.
`disable cli idle-timeout`	Disables the timer that disconnects all sessions. After being disabled, console sessions remain open until the switch is rebooted or until you log off. Telnet sessions remain open until you close the Telnet client. SSH2 sessions time out after 61 minutes of inactivity.
`disable port [`*`port_list`*` | `**`all`**`]`	Disables one or more ports on the switch.
`disable ssh2`	Disables SSH2 access to the switch.
`disable telnet`	Disables Telnet access to the switch.
`enable bootp vlan [`*`vlan`*` | `**`all`**`]`	Enables BOOTP for one or more VLANs.
`enable cli config-logging`	Enables the logging of CLI configuration commands to the Syslog for auditing purposes. The default setting is disabled.

Table 10: Common Commands (continued)

Command	Description
`enable cli paging`	Enables pausing of the screen display when show command output reaches the end of the page. The default setting is enabled.
`enable cli idle-timeout`	Enables a timer that disconnects all sessions (Telnet, SSH2, and console) after 20 minutes of inactivity. The default setting is enabled.
`enable license {`**`software`**`}` `key`	Enables a particular software feature license. Specify `key` as a 10 or 14 digit hexadecimal value. The command `unconfigure switch {all}` does not clear licensing information. This license cannot be disabled once it is enabled on the switch.
`enable ssh2 {`**`access-profile`** `[`*`access_profile`* `|` **`none`**`]} {`**`port`** *`tcp_port_number`*`} {`**`vr`** `[`*`vr_name`* `|` **`all`** `|` **`default`**`]}`	Enables SSH2 sessions. By default, SSH2 is disabled. When enabled, SSH2 uses TCP port number 22.
`enable telnet`	Enables Telnet access to the switch. By default, Telnet uses TCP port number 23.
`history`	Displays the commands entered on the switch.
`show banner {`**`after-login`** `|` **`before-login`**`}`	Displays the user-configured banner.
`unconfigure switch {`**`all`**`}` or `unconfigure switch erase` **`all`** `|` **`nvram`**	Resets all switch parameters (with the exception of defined user accounts, and date and time information) to the factory defaults. If you specify the keyword **all**, the switch erases the currently selected configuration image in flash memory and reboots. As a result, all parameters are reset to default settings.

Using Safe Defaults Mode

When you take your switch from the box and set it up for the first time, you set the safe defaults mode. You should use the safe defaults mode, which disables Telnet, *STP (Spanning Tree Protocol)*, and *SNMP*. All ports are enabled in the factory default setting; you can choose to have all unconfigured ports disabled on reboot using the interactive questions. Also, *STPD* s0 is enabled on the default *VLAN*; you have the option to disable STPD in safe defaults mode.

After you connect to the console port of the switch, or after you run `unconfigure switch {all}` or `configure switch safe-default-script`, you can change management access to your device to enhance security.

1. Connect the console and log in to the switch.
   ```
   This switch currently has some management methods enabled for convenience reasons.
   Please answer these questions about the security settings you would like to use.
   You may quit and accept the default settings by entering 'q' at any time.

   Would you like to activate VOSS? [y/N/q]
   ```

2. You are prompted to select your network operating system: ExtremeXOS (default) or VOSS:
   • For ExtremeXOS, type `N`.
   • For VOSS, type `y`.

   ```
   !!!!  NOTE: Spanning Tree default changed in ExtremeXOS 22.2  !!!!

   Multiple Spanning Tree Protocol (MSTP) is enabled by default to prevent
   broadcast storms

   Would you like to disable MSTP? [y/N/q]:
   ```

3. Type `y` (to disable) or `n` (to enable) *MSTP (Multiple Spanning Tree Protocol)*.
   ```
   The switch offers an enhanced security mode. Would you like to read more,
   and have the choice to enable this enhanced security mode? [y/N/q]:
   ```

   If you select "no," go to 5 on page 51.

4. If you select "yes," the following appears:
   ```
   Enhanced security mode configures the following defaults:

           * Disable Telnet server.
           * Disable HTTP server.
           * Disable SNMP server.
           * Remove all factory default login accounts.
           * Force creation of a new admin (read-write) account.
           * Lockout accounts for 5 minutes after 3 consecutive login failures.
           * Plaintext password entry will not be allowed.
           * Generate an event when the logging memory buffer exceeds 90% of capacity.
           * Only admin privilege accounts are permitted to run "show log".
           * Only admin privilege accounts are permitted to run "show diagnostics".

   Would you like to use this enhanced security mode? [Y/n/q]:
   ```

   If you select "yes," enhanced security mode is enabled. Go to step 9 on page 52.

5. If you select "no," you are prompted to disable Telnet:
   ```
   Telnet is enabled by default. Telnet is unencrypted and has been the target of
   security exploits in the past.

   Would you like to disable Telnet? [y/N/q]:
   ```

6. You are prompted to enable SNMPv1/v2c:
   ```
   SNMP access is disabled by default.
   SNMPv1/v2c uses no encryption, SNMPv3 can be configured to eliminate this problem.
   Would you like to enable SNMPv1/v2c? [y/N/q]: Yes
   ```

7. You are prompted to set up the community string:
   ```
   SNMP community string is a text string that is used to authenticate SNMPv1/v2c
   messages.
   ```

```
It is required for managing the switch using SNMPv1/v2c.
Would you like to configure a read-only and read-write community string? [Y/n/q]: Yes

Read-only community string:
Re-enter read-only community string:
Read-write community string:
Re-enter read-write community string:
```

8. You are prompted to enable SNMPv3:

```
Would you like to enable SNMPv3? [y/N/q]: Yes

SNMPv3 uses usernames/passwords to authenticate and encrypt SNMP messages.
Would you like to create an SNMPv3 user? [Y/n/q]: Yes

User name: admin
Authentication password:
Reenter authentication password:
Privacy password:
Reenter privacy password:

SNMPv3 user 'admin' was created with authentication protocol SHA and privacy protocol
AES-128.
```

9. Reboot the switch.

Adjusting Bootup Time

There are two menu timeout periods that you can adjust to impact the bootup time for X465, X590, and X695 series switches:

- BIOS autoboot timeout
- Boot menu timeout

Changing the BIOS Autoboot Timeout

To change the BIOS autoboot timeout period:

1. Connect to the switch console.
2. Reboot the switch.
3. When the first BIOS boot messages ("Version", "BIOS Date" etc.) appear, press the **DEL** key several times. This stops the bootup process and displays the BIOS menus.
4. Use the **left/right** arrow keys to select the **Boot** tab.
5. Change the **Setup Prompt Timeout** as desired. To reduce the bootup time as much as possible, change the value to 1. This is the smallest possible value.
6. Press **F4**, and then **ENTER** to save the changes.

Changing the Boot Menu Timeout

To change the boot menu timeout, use the command configure switch **boot-menu delay** [**default** | *seconds*].

To view the current setting for boot menu timeout, use the command show switch **boot-menu**.

Configuring Management Access

Account Access Levels

By default, the software supports two roles for login sessions: administrative (or "admin" privilege having "write" permission) and non-administrative (or "user" privilege having "read-only" permission).

To change a user's account-level privileges to be administrative or non-administrative, use the command `configure account` [**all** | *name*] **privilege** [**admin** | **user**]. Any sessions that are currently logged in with the account specified are cleared and therefore forced to login again with the new privilege.

In addition to the account-level privileges, you can optionally use an external *RADIUS* server to provide CLI command authorization checking for each command. For more information on RADIUS, see Security on page 1085.

> **Note**
> CLI commands are sent to the RADIUS server unencrypted. Sensitive information entered into the CLI could be seen by either internal or external third parties.

User Accounts

A user-level account has viewing access to all manageable parameters. Users cannot access:

- User account database
- *SNMP* community strings

An account with a user-level privilege can use the `ping` command to test device reachability and change the password assigned to the account name.

If you have logged on with user privileges, the command line prompt ends with a (>) sign. For example: `X460G2-48t-G4.3 >`

Administrator Accounts

Administrator-level accounts can view and change all switch parameters.

With this privilege level, you can also add and delete users, as well as change the password associated with any account name. To erase the password, use the `unconfigure switch all` command.

An administrator can disconnect a management session that has been established by way of a Telnet connection. If this occurs, the user logged on through the Telnet connection is notified that the session has been terminated.

If you log on with administrator privileges, the command line prompt ends with a pound or hash (#) sign.

For example: `X460G2-48t-G4.3 #`

Lawful Intercept Account

The Lawful Intercept account can log in to a session and execute lawful intercept commands on the switch. The commands provide for configuration consists of dynamic ACLs and a mirror-to port to direct traffic to a separate device for analysis. The lawful intercept login session, session-related events, and the ACLs and mirror instance are not visible to, or modifiable by, any other user (administrative or otherwise).

No lawful intercept configuration is saved in the configuration file, and it must be reconfigured in the case of a system reboot.

Other important feature information:

- An administrative user can create and delete a single local account having the lawful intercept privilege and user privileges, but not administrative privileges, and can set its initial password.
- The lawful intercept user is required to change the password (for the single lawful intercept-privileged account) upon logging in for the first time.
- The password for the lawful intercept account can only be changed by the lawful intercept user and cannot be changed by an administrative user.
- The `show accounts` command displays the existence of the lawful intercept account, but does not display any related statistics.
- The `show configuration` command does not display the lawful intercept account.
- The `show session {{detail} {sessID}} {history}` command does not display any lawful intercept user information. The EMS events normally associated with logging in and out are suppressed, and do not occur relative to logging in and out of the lawful intercept account.
- The EMS events normally associated with the `enable cli config-logging` command are suppressed, and do not occur relative to a lawful intercept user session.
- The lawful intercept user can create and delete non-permanent dynamic ACLs with the mirror action only. The lawful intercept user cannot create or delete any other ACLs.
- The `show access-list` command does not display any Lawful Intercept user-created ACLs to a non-lawful intercept user.
- The lawful intercept user-created ACLs are not accessible for any use by a non-lawful intercept user (specifically through the `configure access-list add` or `configure access-list delete` commands).
- The lawful intercept user can only create or delete one (non-permanent) mirror instance with which to bind the lawful intercept user-created ACLs and specify the mirror-to port.

Configure Banners

You can add a banner to give users helpful information before or after logging in.

- To add a banner to your switch, use the following command:

  ```
  configure banner {after-login | { before-login } { acknowledge } |
  before-login {acknowledge} save-to-configuration}
  ```

  When using **before-login**, you have to select the **save-to-configuration** option so that the change is saved to the configuration file to have it show up in output of the show configuration {*module-name*} {**detail**} command.

  When you use the **acknowledge** option, users must press a key to get the login prompt.

  When no options are specified, the command configures a banner for a CLI session that appears before login. A CLI banner can have a maximum size of 24 rows with 79 columns of text.

- To clear a configured banner, use the following command:

  ```
  unconfigure banner { after-login | before-login } command.
  ```

- To disable the acknowledgment feature (which forces the user to press a key before the login screen appears), use the following command omitting the **acknowledge** option:

  ```
  configure banner {after-login | { before-login } { acknowledge } |
  before-login {acknowledge} save-to-configuration}
  ```

- To display the banners that are configured on the switch, use the following command:

  ```
  show banner { after-login | before-login }
  ```

Startup Screen and Prompt Text

Once you log into the switch, the system displays the startup screen.

```
login: admin
password:

ExtremeXOS
Copyright (C) 1996-2023 Extreme Networks.
All rights reserved.
This product is protected by one or more US
patents listed at
http://www.extremenetworks.com/patents
along with their foreign counterparts.
===============================================================================

Press the <tab> or '?' key at any time for completions.
Remember to save your configuration changes.

* <switchname>.1 #
```

You must have an administrator-level account to change the text of the prompt. The prompt text is taken from the *SNMP* sysname setting.

The number that follows the period after the switch name indicates the sequential line of the specific command or line for this CLI session.

If an asterisk (*) appears in front of the command line prompt, it indicates that you have outstanding configuration changes that have not been saved.

For example: `* 5420F-48P-4XE.1 #`

If you have logged on with administrator capabilities, the command line prompt ends with a (#) sign.

For example: `5420F-48P-4XE.1 #`

If you have logged on with user capabilities, the command line prompt ends with a (>) sign.

For example: `5420F-48P-4XE.1 >`

Default Accounts

By default, the switch is configured with two accounts. ExtremeXOS 15.7.1 added the ability to disable all default accounts ("admin" and "user").

Table 11: Default Accounts

Account Name	Access Level
admin	This user can access and change all manageable parameters. However, the user may not delete all admin accounts.
user	This user can view (but not change) all manageable parameters, with the following exceptions: • This user cannot view the user account database. • This user cannot view the _SNMP_ community strings.

Creating Management Accounts

An account can be disabled or enabled locally using read/write access. Even all administrative privileged accounts and user privileged accounts can be disabled. Lawful-Intercept account will be disabled under user privileged option. When all administrative accounts will be disabled locally, a warning will be shown to use failsafe account, if necessary.

1. Log in to the switch as admin.
2. At the password prompt, press **[Enter]**, or enter the password that you have configured for the admin account.

3. Run the `create account` [**admin** | **user** | **lawful-intercept**] *account-name* {**encrypted** *encrypted_password* | *password*} command to add a new user.

   If you do not specify a password or the keyword **encrypted**, you are prompted for one. Passwords are case-sensitive.

   > ⚠️ **Caution**
   > Using the **encrypted** option incorrectly can result in being locked out of your switch account. For more information about the **encrypted** option, see create account.

   If you do not want a password associated with the specified account, press **[Enter]** twice.

   User-created account names are not case-sensitive.

Viewing Accounts

You can view all accounts. To view the accounts that have been created, you must have administrator privileges. Run the `show accounts` command.

Deleting an Account

You can remove accounts that should no longer exist, but you must have administrator privileges. To delete an account, run the `delete account` command.

Authenticating Management Sessions through the Local Database

You can use a local database on each switch to authenticate management sessions. An account can be disabled or enabled locally using read/write access. Even all administrative privileged accounts and user privileged accounts can be disabled. Lawful-Intercept account will be disabled under user privileged option. When all administrative accounts will be disabled locally, a warning will be shown to use failsafe account, if necessary.

This enable/disable command affects the following North Bound Interfaces (NBIs) in mgmt-access realm:

- console
- TELNET
- SSH
- HTTP
- XML

The local database stores user names and passwords and helps to ensure that any configuration changes to the switch can be done only by authorized users.

You can increase authentication security using Secure Shell 2 (SSH2). SSH2 provides encryption for management sessions. For information about SSH2, see Secure Shell 2 on page 1193.

Failsafe Accounts

The failsafe account is last possible method to access your switch.

This account is never displayed by the `show accounts` command, but it is always present on the switch. To display whether the user configured a username and password for the failsafe account, or to show the configured connection-type access restrictions, use the following command: `show failsafe-account` .

The failsafe account has admin access level.

To configure the account name and password for the failsafe account, use the following command:

```
configure failsafe-account {[deny | permit] [all | control | serial |
ssh {vr vr-name} | telnet {vr vr-name}]}
```

When you use the command with no parameters, you are prompted for the failsafe account name and prompted twice to specify the password for the account.

For example:

```
# configure failsafe-account
enter failsafe user name: blue5green
enter failsafe password:
enter password again:
```

When you use the command with the permit or deny parameter, the connection-type access restrictions are altered as specified. For example:

```
# configure failsafe-account deny all
# configure failsafe-account permit serial
```

The failsafe account is immediately saved to NVRAM. On a SummitStack, the failsafe account is saved in the NVRAM of every node in the active topology.

> **Note**
> On a SummitStack, when the `synchronize stacking {node-address node-address | slot slot-number }` command is used, the failsafe account is transferred from the current node to the specified nodes in the stack topology.

You do not need to provide the existing failsafe account information to change it.

> **Note**
> The information that you use to configure the failsafe account cannot be recovered by Extreme Networks. Technical support cannot retrieve passwords or account names for this account. Protect this information carefully.

Accessing the Switch using Failsafe Account

You can access your switch using the failsafe account.

1. Connect to the switch using one of the (configured) permitted connection types.

2. At the switch login prompt, carefully enter the failsafe account name.

   If you enter an erroneous account name, you cannot re-enter the correct name. In that case, press **[Enter]** until you get a login prompt and then try again.

3. When prompted, enter the password.

Managing Passwords

When you first access the switch, you have a default account.

You configure a password for your default account. As you create other accounts (see Creating Management Accounts on page 56), you configure passwords for those accounts.

The software allows you to apply additional security to the passwords. You can enforce a specific format and minimum length for the password. Additionally, you can age out the password, prevent a user from employing a previously used password, and lock users out of the account after three consecutive failed login attempts.

You can change the password to an encrypted password after you create an account.

Applying a Password to the Default Account

Default accounts do not have passwords assigned to them. Passwords can have a minimum of zero and a maximum of 32 characters. (If you specify the format of passwords using the `configure account password-policy char-validation` command, the minimum is eight characters.)

> **Note**
> Passwords are case-sensitive. User-created account names are not case-sensitive.

1. Log in to the switch using the name admin or user.
2. At the password prompt, press **[Enter]**.
3. Add a default admin password of green to the admin account or blue to the user account.

   ```
   configure account admin green
   configure account user blue
   ```

> **Note**
> If you forget your password while logged out of the CLI, you can use the bootloader to reinstall a default switch configuration, which allows access to the switch without a password. Note that this process reconfigures all switch settings back to the initial default configuration.

Applying Security to Passwords

You can increase the security of your system by enforcing password restrictions, which will make it more difficult for unauthorized users to access your system. You can specify

that each password must include at least two characters of each of the following four character types:

- Upper-case A-Z
- Lower-case a-z
- 0-9
- !, @, #, $, %, ^, *, (,)

You can enforce a minimum length for the password, and set a maximum and minimum time limit, after which the password will not be accepted.

By default, the system terminates a session after the user makes three consecutive failed logon attempts and the account is locked for 15 minutes.

The user may then start another session (which would also terminate after three consecutive failed logon attempts). To increase security, you can lock users out of the system entirely after three failed consecutive logon attempts.

After the user's account is locked out (using the configure account password-policy lockout-on-login-failures command), it must be re-enabled by an administrator.

- To set character requirements for the password, use the following command:

  configure account [**all** | *name*] **password-policy char-validation** [**none** | **all-char-groups**]

- To configure the number of characters in a revised password that must be changed from an existing password.

  configure account [**all** |*name*] **password-policy min-different-characters** [*count*]

- To set a minimum length for the password, use the following command:

  configure account [**all** | *name*] **password-policy min-length** [*num_characters* | **none**]

- To age out the password after a specified time, use the following command:

  configure account [**all** | *name*] **password-policy max-age** [*num_days* | **none**]

- To configure a minimum password lifespan, use the following command:

  configure account [**all** | *name*] **password-policy min-age** [*num_days* | **none**]

- To block users from employing previously used passwords, use the following command:

  configure account [**all** | *name*] **password-policy history** [*num_passwords* | **none**]

- To disable an account after three consecutive failed logon attempts, use the following command:

  `configure account [`**`all`**` | `*`name`*`] `**`password-policy lockout-on-login-`**
  `failures`` [`**`on`**` | `**`off`**`]`

  > **Note**
  > If you are not working on SSH, you can configure the number of failed
  > logons that trigger lockout, using the `configure cli max-failed-logins`
  > *num-of-logins* command. (This command also sets the number of failed
  > logons that terminate the particular session.)

- To re-enable a locked-out account, use the following command:

  `clear account [`**`all`**` | `*`name`*`] `**`lockout`**

  Selecting the **`all`** option affects the setting of all existing and future new accounts.

- To view account settings, use the following command:

  `show accounts password-policy`

Hash Algorithm for Account Passwords

SHA-256 is hash for local passwords. This hash is visible in both the XML config file (.cfg) and ASCII (.xsf). All existing users (created with older software) are still recognized and their MD5 (Message-Digest algorithm 5) hashes can be verified.

However, if a new user is created or a password is changed, it will use the SHA-256 hash. After a downgrade, older software will not be able to validate users with the SHA-256 hash. Upgrading will not automatically change the hash for existing users.

Removal of Cleartext Passwords

All passwords, secrets, or keys are not shown in the clear. The software does not emit those passwords in any commands or display them as part of the device configuration.

A new mode of operation for the CLI requires prompting (with no echo) for all passwords, secrets, or keys. The command `configure cli password prompting-only` controls this mode.

Each CLI command with password arguments is modified to use the new mode (designated with flags="prompting-only" in the CLI syntax attribute specification). Then prompting must be handled by that command.

Timed Lockout

This feature includes the option to disable an account for a configurable period of time after consecutive failed logins. After the configured duration elapses a disabled account is re-enabled automatically. The configurable period of lockout time ranges from 1 minute to 1 hour. The configurable number of the consecutive failed attempts ranges from 1 to 10.

The intent is to ensure the box is not ever completely locked out.

This feature augments this behavior in two ways:

- The failsafe account can now be locked out provided that the lockout is timed.
- All admin accounts can now be locked out provided that at least one is timed.

The feature applies to Telnet/SSH/Console/Https/Http.

Displaying Passwords

To display the accounts and any applied password security, use the following command:

- To display accounts and passwords, use the following command:

    ```
    show accounts password-policy
    ```

- To display which accounts can be locked out, use the following command:

    ```
    show accounts
    ```

Accessing an Active Node in a SummitStack

You can access any active node in a SummitStack from any other active node in the active topology by running:

```
telnet slot slot-number {no-auto-login}
```

You are <u>not</u> prompted for your username or password. You are logged in to the same account (with corresponding rights) with which you accessed the originating slot.

DNS Cache Resolver and Analytics Engine Overview

The Domain Name System (DNS) cache resolver feature implements a cache of DNS queries on the switch, so that repeated queries can be handled directly by the switch, rather than by repeatedly forwarding the requests to the DNS servers, which consumes time and network resources.

The DNS analytics engine analyzes the DNS queries (IPv4 and IPv6) from all connected clients and keeps track of received DNS queries from clients, and domains accessed along with time stamps. By using the cache and analytics, audits can be performed on the details of queries coming from clients, which allows for threat mitigation.

To provide GDPR compliance, DNS analytics provides a mechanism to restrict the collection of DNS analytics of a protected client. When you configure the client IP address subnet in the protected list, DNS queries from configured protected clients are erased from the analytics database and future queries are not stored.

Supported Platforms

All ExtremeSwitching platforms.

Limitations

- TCP DNS queries are not cached.
- The DNS cache feature and the L7 DNS feature in ONEPolicy should not be enabled at the same time.
- Checkpointing is not supported in a stack or a MLAG setup for DNS caching.
- IPv6 DNS queries are not cached.
- DNS cache feature should not be enabled on VXLAN tenant VLANs.

Using DNS Cache Resolver

Checkpointing is not supported in a stack or a MLAG setup for DNS caching.

Enabling/Disabling DNS Cache

To enable DNS cache, use the following command:

```
enable dns cache {{vlan} vlan_name | {vr} vr_name}
```

To disable DNS cache, use the following command:

```
disable dns cache {{vlan} vlan_name | {vr} vr_name}
```

Clearing the DNS Cache

To clear DNS cache entries, use the following command:

```
clear dns cache
```

Configuring DNS Cache

To add or delete DNS name servers, use the following command:

```
configure dns cache [add | delete ] name-server ip_address {{vr}
vr_name}
```

Showing DNS Cache Information

To show DNS cache entries, use the following command:

```
show dns cache {current} {detail}
```

To show DNS cache status (enabled or disabled), use the following command:

```
show dns cache configuration {{vlan} vlan_name | {vr} vr_name}
```

To show the current DNS name servers, use the following command:

```
show dns cache name-server
```

Using DNS Cache Analytics

In a stack, DNS analytics provides chcekpointing of data collected by the master node to the backup node. Similarly, analyzed data of VLANs, which are spanning across MLAG nodes are checkpointed.

Enabling/Disabling DNS Analytics

To enable DNS analytics, use the following command:

```
enable dns cache analytics {{vr} vr_name}
```

To disable DNS analytics, use the following command:

```
disable dns cache analytics {{vr} vr_name}
```

Clearing DNS Analytics

To clear the DNS analytics entries, use the following command:

```
clear dns cache analytics entries {{vr} vr_name}
```

Configuring DNS Analytics

To configure the timeout of entries or maximum number of entries for DNS analytics, use the following command:

```
configure dns cache analytics [{timeout minutes} {max-entries
max_entries}]
```

To configure the protected client list for the DNS cache analytics, use the following command:

```
configure dns cache analytics [add | delete]protected-client [client_ip
netmask | ipNetmask] {{vr} vr_name}
```

Showing DNS Analytics Information

To show the DNS analytics status (enabled or disabled) and the configured maximum entries and timeout period, use the following command:

```
show dns cache analytics configuration {{vr} vr_name}
```

To show the DNS analytics protected client list, use the following command:

```
show dns cache analytics protected-client {{vr} vr_name}
```

To show DNS queries received from clients, use the following command:

```
show dns cache analytics statistics {client client_ip domain
domain_name } {detail} {{vr} vr_name}}
```

Domain Name System (DNS) Security Extension

DNSSEC validates DNS replies and cache DNSSEC data. When forwarding DNS queries, dnsmasq requests the DNSSEC records needed to validate the replies. The replies are validated, and the result returned as the Authenticated Data bit in the DNS packet. In addition, the DNSSEC records are stored in the cache, making validation by clients more efficient. Note that validation by clients is the most secure DNSSEC mode, but for clients unable to do validation, use of the AD bit set by dnsmasq is useful, provided that the network between the dnsmasq server and the client is trusted. The nameservers upstream of dnsmasq must be DNSSEC-capable—that is, capable of returning DNSSEC records with data. If they are not, dnsmasq is not able to determine the trusted status of answers, and this means that DNS service is entirely broken

Configuring DNSSEC

To enable DNSSEC, use the following command:

```
enable dns cache {dnssec}
```

To disable DNSSEC, use the following command:

```
disable dns cache {dnssec}
```

To show DNSSEC status, use the following command:

```
show dns cache configuration {{vlan} vlan_name | {vr} vr_name}
```

Domain Name Service Client Services

The Domain Name Service (DNS) client augments the following commands to allow them to accept either IP addresses or host names.

- telnet
- download bootrom
- download image
- ping
- traceroute
- configure radius server client-ip
- configure tacacs server client-ip
- create cfm domain dns md-level

The DNS client can resolve host names to both IPv4 and IPv6 addresses. In addition, you can use the nslookup utility to return the IP address of a host name.

Use the following command to specify up to eight DNS servers for use by the DNS client:

```
configure dns-client add
```

Use the following command to specify a default domain for use when a host name is used without a domain.

```
configure dns-client default-domain
```

For example, if you specify the domain xyz-inc.com as the default domain, then a command such as `ping accounting1` is taken as if it had been entered `ping accounting1.xyz-inc.com`.

Checking Basic Connectivity

To check basic connectivity to your switch, use the `ping` and `traceroute` commands.

Ping

The ping command enables you to send _ICMP (Internet Control Message Protocol)_ echo messages to a remote IP device.

The ping command is available for both the user and administrator privilege levels.

```
ping {vr vr-name} {continuous|count|dont-fragment|interval|start-size|
tos|ttl|udp} {mac|mpls|ipv4|ipv6} {from|with}
```

Table 12: Ping Command Parameters

Parameter	Description
count	Specifies the number of ping requests to send.
start-size	Specifies the size, in bytes, of the packet to be sent, or the starting size if incremental packets are to be sent.
continuous	Specifies that UDP or ICMP echo messages are to be sent continuously. This option can be interrupted by pressing **[Ctrl] + C**.
end-size	Specifies an end size for packets to be sent.
udp	Specifies that the ping request should use UDP instead of ICMP.
dont-fragment	Sets the IP to not fragment the bit.
ttl	Sets the TTL value.
tos	Sets the TOS value.
interval	Sets the time interval between sending out ping requests.
vrid	Specifies the _virtual router (VR)_ name to use for sending out the echo message. If not specified, _VR-Default_ is used. **Note:** User-created VRs are supported only on the platforms listed for this feature in the _ExtremeXOS 32.4 Feature License Requirements_ document.
ipv4	Specifies IPv4 transport.

Table 12: Ping Command Parameters (continued)

Parameter	Description
ipv6	Specifies IPv6 transport. **Note:** If you are contacting an IPv6 link local address, you must specify the *VLAN* you are sending the message from: `ping ipv6 link-local address %vlan_name host .`
host	Specifies a host name or IP address (either v4 or v6).
from	Uses the specified source address. If not specified, the address of the transmitting interface is used.
with record-route	Sets the traceroute information.

If a ping request fails, the switch stops sending the request after three attempts. Press **[Ctrl]** + **[C]** to interrupt a ping request earlier. The statistics are tabulated after the ping is interrupted or stops.

Use the ipv6 variable to ping an IPv6 host by generating an ICMPv6 echo request message and sending the message to the specified address. If you are contacting an IPv6 link local address, you must specify the VLAN that you are sending the message from, as shown in the following example (you must include the % sign):

```
ping ipv6 link-local address %vlan_name host
```

Traceroute

The `traceroute` command enables you to trace the path between the switch and a destination endstation.

```
traceroute {vr vrid} {ipv4 host} {ipv6 host} {ttl number} {from from}
{[port port] | icmp}
```

vr

The name of the *VR*.

ipv4/ipv6

The transport.

from

Uses the specified source address in the *ICMP* packet. If not specified, the address of the transmitting interface is used.

host

The host of the destination endstation. To use the hostname, you must first configure DNS.

ttl

Configures the switch to trace the hops until the time-to-live has been exceeded for the switch.

port

Uses the specified UDP port number.

icmp

Uses ICMP echo messages to trace the routed path.

Displaying Switch Information

You can display basic information about the switch by running the `show switch` command.

Filtering the Output of Show Commands

The output from many show commands can be long and complicated, sometimes containing more information than you need. You can filter the output from a show command to suit your needs using a restricted version of a UNIX/Linux feature that uses a "pipe" character to direct the output of one command to be used as input for the next command.

You can include or exclude show command output that matches your specified text pattern. You can also exclude all output until a line matches the pattern, and then include all output beginning with that line.

Most show commands can be filtered, but a few, for example, `show tech-support`, do not allow filtering.

To filter show command output, use the following command:

show *specific show command syntax* | [[**begin** | **exclude** | **grep** | **include**] { **ignore-case** } *regexp* { | **count** } | **count**]

show *specific show command syntax*	Specify the show command followed by the vertical bar (|) or pipe character. For example, `show ports`.
include	Display the lines that match the regular expression.
exclude	Do not display the lines that match the regular expression.
begin	Display all the lines starting with the first line that matches the regular expression.
grep	Display the lines that match the regular expression.
ignore-case	Ignore case distinctions in both the output and the regular expression.
count	Display the number of lines after the filtered output.
count	Display the number of lines after the output.
regexp	The text pattern (regular expression) to match (case-sensitive), enclosed by quotation marks.

If the specified show command outputs a refreshed display, filtering the show command terminates the display without refreshing and a message appears stating this.

Table 13 shows a summary of special characters.

Table 13: Definition of Regular Expression Characters

Operator Type	Examples	Description
Literal characters match a character exactly	a A y 6 % @	Letters, digits and many special characters match exactly
	\$ \^ \+ \\ \?	Precede other special characters with a \ to cancel their regex special meaning
	\n \t \r	Literal new line, tab, return
Anchors and assertions	^	Starts with
	$	Ends with
Character groups any one character from the group	[aAeEiou]	Any character listed from [to]
	[^aAeEiou]	Any character except aAeEio or u
	[a-fA-F0-9]	Any hex character (0 to 9 or a to f)
	.	Any character at all
Counts apply to previous element	+	One or more ("some")
	*	Zero or more ("perhaps some")
	?	Zero or one ("perhaps a")
Alternation	|	Either, or

Flow control

The following example display the status of "flow control" on the ports of a switch:

```
show ports 1-2 information detail | include "(Port|Flow Control)"
```

The output is similar to the following:

```
Port: 1
          Flow Control:   Rx-Pause: Enabled        Tx-Pause: Disabled
Priority Flow Control: Disabled

Port: 2
          Flow Control:   Rx-Pause: Enabled        Tx-Pause: Disabled
Priority Flow Control: Disabled
```

Automate Running Show Commands

This feature runs the integrated Python script `watch.py` to run a specified show command periodically and display the output accordingly. In the script, CLI paging is disabled so that user input is not needed, and CLI refreshing is disabled so that the keyword "no-refresh" is not needed in auto-refreshing commands.

To run a specified show command, use the following command:

`watch` *command* {**difference**} {**count** *count*} {**interval** *interval*}.

Example

The following example runs the show ports command for port 11 runs 15 times with an interval of 30 seconds:

```
# watch "show ports 11 statistics port-number no-refresh" count 15 interval 30
Port       Link        Tx Pkt       Tx Byte      Rx Pkt       Rx Byte      Rx Pkt       Rx
Pkt        Tx Pkt      Tx Pkt

           State       Count        Count        Count        Count        Bcast
Mcast      Bcast       Mcast

========= ===== =========== =========== =========== =========== =========== ===========

```

Managing the Switch

This chapter provides information about how to use your ExtremeXOS switch. Included you will find information about the ExtremeXOS Shell, system redundancy, power supply management, user authentication, Telnet, and hitless failover support, as well as *SNMP (Simple Network Management Protocol)* and *SNTP (Simple Network Time Protocol)* usage information.

ExtremeXOS Switch Management Overview

This chapter describes how to use the operating system to manage the switch. It also provides details on how to perform the following various basic switch functions:

- Access the command line interface (CLI) by connecting a terminal (or workstation with terminal-emulation software) to the console port.
- Access the switch remotely using TCP/IP through one of the switch ports, or through the dedicated 10/100 unshielded twisted pair (UTP) Ethernet management port. Remote access includes:
  - Telnet using the CLI interface
  - Secure Shell (SSH2) using the CLI interface
  - *SNMP* access using Ridgeline™ or another SNMP manager

- Download software updates and upgrades. For more information, see Software Upgrade and Boot Options on page 1958.

The switch supports the following number of concurrent user sessions:

- One console session
- Eight shell sessions
- Eight Telnet sessions
- Eight Trivial File Transfer Protocol (TFTP) sessions
- Eight SSH2 sessions
- Six XML sessions

Understanding the Operating System Shell

When you log in to the operating system from a terminal, a shell prompt is displayed.

At the prompt, input the commands you want to execute on the switch. After the switch processes and executes a command, the results are displayed on your terminal.

The shell supports ANSI, VT100, and XTERM terminal emulation and adjusts to the correct terminal type and window size. In addition, the shell supports UNIX-style page view for page-by-page command output capability.

By default, up to eight active shell sessions can access the switch concurrently; however, you can change the number of simultaneous, active shell sessions supported by the switch. You can configure up to 16 active shell sessions. Configurable shell sessions include both Telnet and SSH connections (not console CLI connections). If only eight active shell sessions can access the switch, a combination of eight Telnet and SSH connections can access the switch even though Telnet and SSH each support eight connections. For example, if you have six Telnet sessions and two SSH sessions, no one else can access the switch until a connection is terminated or you access the switch through the console.

If you configure a new limit, only new incoming shell sessions are affected. If you decrease the limit and the current number of sessions already exceeds the new maximum, the switch refuses only new incoming connections until the number of shell session drops below the new limit. Already connected shell sessions are not disconnected as a result of decreasing the limit.

Configure the number of shell sessions accepted by the switch, use the following command:

```
configure cli max-sessions
```

For more information about the line-editing keys that you can use with the ExtremXOS shell, see Line-Editing Keys on page 47.

Using the Console Interface

You can access the switch as needed through the command line interface.

The switch is accessible using the following connectors:

- Summit switches: 9-pin, RS-232 ports.

On a stand-alone switch, the console port is located on the front panel.

> **Note**
> For more information on the console port pinouts, see the *hardware installation guide* for your switch.

After the connection is established, you will see the switch prompt and can now log in.

Using the 10/100 or 10/100/1000 Ethernet Management Port

The ExtremeSwitching switches provide a dedicated 10/100 Mbps or 10/100/1000 Mbps Ethernet management port. This port provides dedicated remote access to the switch using TCP/IP. It supports the following management methods:

- Telnet/SSH2 using the CLI interface
- *SNMP* access using Extreme Management Center, Ridgeline or another SNMP manager

The switch uses the Ethernet management port only for host operation, not for switching or routing. The TCP/IP configuration for the management port is done using the same syntax as used for *VLAN (Virtual LAN)* configuration. The VLAN management comes preconfigured with only the management port as a member. The management port is a member of the *virtual router (VR) VR-Mgmt*.

> **Note**
> The ExtremeSwitching X435-8T-4S, X435-8P-4S, and X435-8P-2T-W do not have dedicated management ports. You can use front panel ports for management connectivity for these switches.

On a SummitStack, the master node is accessed using the management port primary IP address for other platforms. The primary IP address is acquired by the backup node when it becomes the master node due to a failover. You can also directly access any node in the stack using its alternate IP address if the node's management port is connected to your network.

- To configure the IP address and subnet mask for the VLAN mgmt, use the following command:

  ```
  configure vlan mgmt ipaddress ip_address /subnet_mask
  ```

- To configure the default gateway (you must specify VR-Mgmt for the management port and VLAN mgmt), use the following command:

  ```
  configure iproute add default gateway { metric } {multicast |
  multicast-only | unicast | unicast-only} {vr vrname}
  ```

  The following example configuration sets the management port IP address to 192.168.1.50, mask length of 25, and configures the gateway to use 192.168.1.1:

  ```
  configure vlan mgmt ipaddress 192.168.1.50/25
  configure iproute add default 192.168.1.1 vr vr-mgmt
  ```

For more information see Logging into a Stack on page 183.

Managing the Switch with Bluetooth Devices

You can manage the ExtremeSwitching X465 series switch using Bluetooth with mobile devices or laptops. Bluetooth is enabled by default.

Supported Platforms

Switch: ExtremeSwitching X465 series switch.

Adapters: Dongles with a common Bluetooth controller (Cypress CY20702). Vendors with CY20702 pluggable and CC&C (USB-BT-400).

Limitations

- Stacking with Bluetooth is not supported. Currently, access to a slot connected with a Bluetooth device is supported, but other slots cannot be accessed.
- No security procedures are initiated for Bluetooth connectivity.
- Only a specific list of Bluetooth dongles is supported.
- Only one Bluetooth adapter is enabled per card. Other adapters will be in powered off state.

Using Bluetooth

Bluetooth users/clients can access switches using either the global IP address or link local IP address. The Bluetooth interface is assigned with the global IP address (192.168.1.1/24 or 172.16.1.1/24). DHCP server runs on the Bluetooth interface. This is mainly to serve Bluetooth clients with DHCP support. After a Bluetooth connection is established, all Bluetooth clients are allocated IP addresses from this pool (192.168.1.2–192.168.1.20 or 172.16.1.1–172.16.1.20). For Bluetooth clients that do not support DHCP, you can use the link local IP address for accessing the switch. Range is 169.254.1.1–169.254.1.8.

To set up a Bluetooth device to manage a switch:

1. Insert a supported dongle into the USB port of the switch.
2. If needed (Bluetooth is enabled by default), ensure that Bluetooth capability, discovery, and pairing are all enabled. using the following command:

   ```
   enable switch bluetooth {discovery | pairing }
   ```

   You can check Bluetooth status using the show **switch bluetooth** [**statistics** | **inventory**] command.
3. If needed, enable Bluetooth on the desired Bluetooth device (phone or laptop).
4. To initiate pairing, do one of the following:
   - Press and hold the **mode** button for approximately 5 seconds.
   - Press the pairing button on the dongle.

The Bluetooth Status LED blinks green while pairing is in progress, and then becomes solid green when Bluetooth is connected.

Bluetooth Commands

To enable Bluetooth capabilities, use the following command:

```
enable switch bluetooth {discovery | pairing }
```

To disable Bluetooth capabilities, use the following command:

```
disable switch bluetooth {discovery | pairing }
```

To clear Bluetooth devices, use the following command:

```
clear switch bluetooth device [all | address]
```

To show Bluetooth information, use the following command:

```
show switch bluetooth [statistics | inventory]
```

Using ExtremeCloud IQ - Site Engine to Manage the Network

ExtremeCloud IQ - Site Engine is a powerful yet easy-to-use application suite that facilitates the management of a network of Extreme Networks switches, as well as selected third-party switches.

This product offers a comprehensive set of network management tools that are easy to use from a client workstation running client software, or from a workstation configured with a web browser and the Java plug-in.

Authenticating Users

There are three methods to authenticate users who log in to the switch: *RADIUS (Remote Authentication Dial In User Service)* client, TACACS+, and a local database of accounts and passwords.

> **Note**
> You cannot configure RADIUS and TACACS+ at the same time.

RADIUS Client

Remote Authentication Dial In User Service (*RADIUS*, RFC 2865) is a mechanism for authenticating and centrally administrating access to network nodes.

The ExtremeXOS RADIUS client implementation allows authentication for Telnet or console access to the switch. For detailed information about RADIUS and configuring a RADIUS client, see Security on page 1085.

TACACS+

Terminal Access Controller Access Control System Plus (TACACS+) is a mechanism for providing authentication, authorization, and accounting on a central server, similar in function to the *RADIUS* client.

The ExtremeXOS version of TACACS+ is used to authenticate prospective users who are attempting to administer the switch. TACACS+ is used to communicate between the switch and an authentication database.

For detailed information about TACACS+ and configuring TACACS+, see Security on page 1085.

Management Accounts

ExtremeXOS supports two levels of management accounts (local database of accounts and passwords): user and administrator.

A user level account can view but not change all manageable parameters, with the exception of the user account database and *SNMP* community strings. An administrator level account can view and change all manageable parameters.

For detailed information about configuring management accounts, see Configuring Management Access on page 53.

Using Telnet

The operating system supports the Telnet Protocol based on RFC 854.

Telnet allows interactive remote access to a device and is based on a client/server model. The operating system uses Telnet to connect to other devices from the switch (client) and to allow incoming connections for switch management using the CLI (server).

Starting the Telnet Client

Ensure that the IP parameters described in Configuring Switch IP Parameters on page 78 are set up and then start an outgoing Telnet session.

Telnet is enabled and uses *VR-Mgmt* by default.

> **Note**
> Maximize the Telnet screen so that it correctly displays screens that automatically update.

1. Use Telnet to establish a connection to the switch.

2. Specify the IP address or host name of the device that you want to connect to.

   Check the user manual supplied with the Telnet facility if you are unsure of how to do this.

   After the connection is established, you see the switch prompt and you can log in. The same is true if you use the switch to connect to another host. From the CLI, you must specify the IP address or host name of the device that you want to connect to.

3. If the host is accessible and you are allowed access, you may log in.

For more information about using the Telnet client on the switch, see Connect to Another Host Using Telnet on page 78.

About the Telnet Server

Any workstation with a Telnet facility should be able to communicate with the switch over a TCP/IP network using VT100 terminal emulation.

Up to eight active Telnet sessions can access the switch concurrently. If you enable the idle timer using the `enable cli idle-timeout` command, the Telnet connection times out after 20 minutes of inactivity by default. If a connection to a Telnet session is lost inadvertently, the switch terminates the session within two hours.

The switch accepts IPv6 connections.

For information about the Telnet server on the switch, see the following sections:

- Configuring Telnet Access to the Switch on page 81
- Disconnecting a Telnet Session on page 82

Connect to Another Host Using Telnet

You can Telnet from the current CLI session to another host. For more information see Starting the Telnet Client on page 77.

Run `telnet {`**`vr`** `vr_name} [host_name | remote_ip] {port} .`

User-created VRs are supported only on the platforms listed for this feature in the *ExtremeXOS 32.4 Feature License Requirements* document.

If the TCP port number is not specified, the Telnet session defaults to port 23. If the *VR* name is not specified, the Telnet session defaults to *VR-Mgmt*. Only VT100 emulation is supported.

Configuring Switch IP Parameters

To manage the switch by way of a Telnet connection or by using an *SNMP* Network Manager, you must first configure the switch IP parameters.

Using a BOOTP or DHCP Server

The switch contains a BOOTP and *DHCP (Dynamic Host Configuration Protocol)* client, so if you have a BOOTP or DHCP server in your IP network, you can have it assign IP

addresses to the switch. This is more likely to be desirable on the switch's _VLAN_ mgmt than it is on any other VLANs.

If you are using IP and you have a Bootstrap Protocol (BOOTP) server set up correctly on your network, you must provide the following information to the BOOTP server:

• Switch Media Access Control (MAC) address, found on the rear label of the switch
• IP address
• Subnet address mask (optional)

The switch does not retain IP addresses assigned by BOOTP or DHCP through a power cycle, even if the configuration has been saved. To retain the IP address through a power cycle, you must configure the IP address of the VLAN using the CLI or Telnet.

If you need the switch's MAC address to configure your BOOTP or DHCP server, you can find it on the rear label of the switch. Note that all VLANs configured to use BOOTP or DHCP use the same MAC address to get their IP address, so you cannot configure the BOOTP or DHCP server to assign multiple specific IP addresses to a switch depending solely on the MAC address.

• To enable the BOOTP or DHCP client per VLAN, use the following command:

  ```
  enable bootp vlan [ vlan_name | all]
  enable dhcp vlan [ vlan_name | all]
  ```

• To disable the BOOTP or DHCP client per VLAN, use the following command:

  ```
  disable bootp vlan [ vlan_name | all]
  ```

  ```
  disable dhcp vlan [ vlan_name | all]
  ```

• To view the current state of the BOOTP or DHCP client, use the following command:

  ```
  show dhcp-client state
  ```

> **Note**
> The ExtremeXOS DHCP client will discard the DHCP OFFER if the lease time is less than or equal to two seconds.

Manually Configuring the IP Settings

If you are using IP without a BOOTP server, you must enter the IP parameters for the switch in order for the _SNMP_ Network Manager or Telnet software to communicate with the device.

1. Assign IP parameters to the switch.
   a. Log in to the switch with administrator privileges using the console interface.
   b. Assign an IP address and subnet mask to a _VLAN_.

c. The switch comes configured with a default VLAN named default. To use Telnet or an SNMP Network Manager, you must have at least one VLAN on the switch, and that VLAN must be assigned an IP address and subnet mask. IP addresses are always assigned to each VLAN. The switch can be assigned multiple IP addresses (one for each VLAN).

> **Note**
> For information on creating and configuring VLANs, see VLANs on page 583.

2. Manually configure the IP settings.

   a. Connect a terminal or workstation running terminal emulation software to the console port, as detailed in Using the Console Interface on page 73.

   b. At your terminal, press **[Enter]** one or more times until you see the login prompt.

   c. At the login prompt, enter your user name and password. The user name is not case-sensitive; the password is case-sensitive. Ensure that you have entered a user name and password with administrator privileges.

   If you are logging in for the first time, use the default user name *admin* to log in with administrator privileges. For example: `login: admin`

   Administrator capabilities enable you to access all switch functions. The default user names have no passwords assigned.

   If you have been assigned a user name and password with administrator privileges, enter them at the login prompt.

   d. Enter the password when prompted.

   When you have successfully logged in to the switch, the command line prompt displays the name of the switch.

   e. Assign an IP address and subnetwork mask for the default VLAN by using the following command:

   `configure {`**`vlan`**`}` *`vlan_name`* **`ipaddress`** `[`*`ipaddress`* `{`*`ipNetmask`*`} |` **`ipv6-link-local`** `| {`**`eui64`**`}` *`ipv6_address_mask`*`]`

   For example:
   ```
   configure vlan default ipaddress 123.45.67.8 255.255.255.0
   ```
   The changes take effect immediately.

   > **Note**
   > As a general rule, when configuring any IP addresses for the switch, you can express a subnet mask by using dotted decimal notation or by using classless inter domain routing notation (CIDR). CIDR uses a forward slash plus the number of bits in the subnet mask. Using CIDR notation, the command identical to the previous example is: `configure vlan default ipaddress 123.45.67.8/24.`

3. Configure the default route for the switch using the following command:

   configure iproute add default *gateway* {*metric*} {**multicast | multicast-only | unicast | unicast-only**} {**vr** *vrname*}

   For example:
   ```
   configure iproute add default 123.45.67.1
   ```

4. Save your configuration changes so that they will be in effect after the next switch reboot.

   If you want to save your changes to the currently booted configuration, use the following command: save

   ExtremeXOS allows you to select or create a configuration file name of your choice to save the configuration to.

   a. If you want to save your changes to an existing or new configuration file, use the following command:

      save configuration {**primary** | **secondary** | *existing-config* | *new-config*}

5. When you are finished using the facility, log out of the switch by typing: logout or quit.

Configuring Telnet Access to the Switch

By default, Telnet services are enabled on the switch and all virtual routers listen for incoming Telnet requests. The switch accepts IPv6 connections.

User-created VRs are supported only on the platforms listed for this feature in the *ExtremeXOS 32.4 Feature License Requirements* document.

The safe defaults mode runs an interactive script that allows you to enable or disable *SNMP*, Telnet, and switch ports. When you set up your switch for the first time, you must connect to the console port to access the switch. After logging in to the switch, you will enter into the safe defaults mode. Although SNMP, Telnet, and switch ports are enabled by default, the script prompts you to confirm those settings.

If you choose to keep the default setting for Telnet—the default setting is enabled—the switch returns the following interactive script:

```
Since you have chosen less secure management methods, please remember to increase the
security of your network by taking the following actions:
* change your admin password
* change your SNMP public and private strings
* consider using SNMPv3 to secure network management traffic
```

For more detailed information about safe defaults mode, see Using Safe Defaults Mode on page 50.

- To configure the *VR* from which you receive a Telnet request, use the following command:

  configure telnet vr [**all** | **default** | *vr_name*]

- To change the default, use the following command:

  configure telnet port [*portno* | **default**]

The range for the port number is 1–65535. The following TCP port numbers are reserved and cannot be used for Telnet connections: 22, 80, and 1023. If you attempt to configure a reserved port, the switch displays an error message.

Viewing Telnet Information

To display the status of Telnet, including the current TCP port, the *VR* used to establish a Telnet session, and whether ACLs are controlling Telnet access, run the `show switch management` command.

Disabling and Enabling Telnet

> **Note**
> You must be logged in as an administrator to configure the virtual router(s) used by Telnet and to enable or disable Telnet.

- You can choose to disable Telnet by using the following command:

  ```
  disable telnet
  ```

- To re-enable Telnet on the switch, use the following command:

  ```
  enable telnet
  ```

Disconnecting a Telnet Session

A person with an administrator level account can disconnect a Telnet management session.

1. Log in to the switch with administrator privileges.
2. Determine the session number of the session you want to terminate.

   ```
   show session {{detail} {sessID}} {history}
   ```
3. Terminate the session.

   ```
   clear session [history |sessId | all]
   ```

The user logged in by way of the Telnet connection is notified that the session has been terminated.

Access Profile Logging for Telnet

By default, Telnet services are enabled on the switch.

The access profile logging feature allows you to use an *ACL (Access Control List)* policy file or dynamic ACL rules to control access to Telnet services on the switch. When access profile logging is enabled for Telnet, the switch logs messages and increments counters when packets are denied access to Telnet. No messages are logged for permitted access.

You can manage Telnet access using one (not both) of the following methods:

- Create and apply an ACL policy file.
- Define and apply individual ACL rules.

One advantage of ACL policy files is that you can copy the file and use it on other switches. One advantage to applying individual ACL rules is that you can enter the rules at the CLI command prompt, which can be easier than opening, editing, and saving a policy file.

ACL Match Conditions and Actions

The ACLs section describes how to create *ACL* policies and rules using match conditions and actions. Access profile logging supports the following match conditions and actions:

- Match conditions
  - Source-address—IPv4 and IPv6
- Actions
  - Permit
  - Deny

If the ACL is created with more match conditions or actions, only those listed above are used for validating the packets. All other conditions and actions are ignored.

The source-address field allows you to identify an IPv4 address, IPv6 address, or subnet mask for which access is either permitted or denied.

If the Telnet traffic does not match any of the rules, the default behavior is deny.

Limitations

Access profile logging for Telnet has the following limitations:

- Either policy files or *ACL* rules can be associated with Telnet, but not both at the same time.
- Only source-address match is supported.
- Access-lists that are associated with one or more applications cannot be directly deleted. They must be unconfigured from the application first and then deleted from the CLI.
- Default counter support is added only for ACL rules and not for policy files.

Managing ACL Policies for Telnet

The ACLs section describes how to create *ACL* policy files.

1. To configure Telnet to use an ACL policy, use the following command:

```
configure telnet access-profile profile_name
```

2. To configure Telnet to remove a previously configured ACL policy, use the following command:

```
configure telnet access-profile none
```

> **Note**
> Do not also apply the policy to the access list. Applying a policy to both an access profile and an access list is neither necessary nor recommended.

Managing ACL Rules for Telnet

Before you can assign an *ACL* rule to Telnet, you must create a dynamic ACL rule as described in ACLs.

1. To add or delete a rule for Telnet access, use the following command:

   ```
   configure telnet access-profile [ access_profile | [[add rule ] [first
   | [[before | after] previous_rule]]] | delete rule | none ]
   ```

2. To display the access-list permit and deny statistics for an application, use the following command:

   ```
   show access-list counters process [snmp | telnet | ssh2 | http]
   ```

Misconfiguration Error Messages

The following messages can appear during configuration of policies or rules for the *SNMP* service:

`Rule <rule> is already applied`	A rule with the same name is already applied to this service.
`Please remove the policy <policy> already configured, and then add rule <rule>`	A policy file is already associated with the service. You must remove the policy before you can add a rule.
`Rule <previous_rule> is not already applied`	The specified rule has not been applied to the service, so you cannot add a rule in relation to that rule.
`Rule <rule> is not applied`	The specified rule has not been applied to the service, so you cannot remove the rule from the service.
`Error: Please remove previously configured rule(s) before configuring policy <policy>`	A policy or one or more *ACL* rules are configured for the service. You must delete the remove the policy or rules from the service before you can add a policy.

Sample ACL Policies

The following are sample policies that you can apply to restrict Telnet access.

In the following example named MyAccessProfile.pol, the switch permits connections from the subnet 10.203.133.0 /24 and denies connections from all other addresses:

```
MyAccessProfile.pol
entry  AllowTheseSubnets {
    if  {
        source-address 10.203.133.0 /24;
    } then {
        permit;
    }
}
```

In the following example named MyAccessProfile.pol, the switch permits connections from the subnets 10.203.133.0 /24 or 10.203.135.0/24 and denies connections from all other addresses:

```
MyAccessProfile.pol
entry  AllowTheseSubnets {
    if match any {
```

```
        source-address 10.203.133.0 /24;
        source-address 10.203.135.0 /24;
    } then {
        permit;
    }
}
```

In the following example named MyAccessProfile_2.pol, the switch does not permit connections from the subnet 10.203.133.0 /24 but accepts connections from all other addresses:

```
MyAccessProfile_2.pol
entry dontAllowTheseSubnets {
    if {
        source-address 10.203.133.0 /24;
    } then {
        deny;
    }
}
entry  AllowTheRest {
    if  {
        ; #none specified
    } then {
        permit;
    }
}
```

In the following example named MyAccessProfile_2.pol, the switch does not permit connections from the subnets 10.203.133.0/24 or 10.203.135.0 /24 but accepts connections from all other addresses:

```
MyAccessProfile_2.pol
entry dontAllowTheseSubnets {
    if match any {
        source-address 10.203.133.0 /24;
        source-address 10.203.135.0 /24;
    } then {
        deny;
    }
}
entry  AllowTheRest {
    if  {
        ; #none specified
    } then {
        permit;
    }
}
```

Using Secure Shell 2

Secure Shell 2 (SSH2) is a feature of the software that allows you to encrypt session data between a network administrator using SSH2 client software and the switch or send encrypted data from the switch to an SSH2 client on a remote system. Configuration, image, public key, and policy files can be transferred to the switch using the Secure Copy Protocol 2 (SCP2).

The SSH2 switch application works with the following clients: Putty, SSH2 (version 2.x or later) from SSH Communication Security, and OpenSSH (version 2.5 or later).

The switch accepts IPv6 connections.

Up to eight active SSH2 sessions can run on the switch concurrently. If you enable the idle timer using the `enable cli idle-timeout` command, the SSH2 connection times out after 20 minutes of inactivity by default. If you disable the idle timer using the `disable cli idle-timeout` command, the SSH2 connection times out after 60 minutes of inactivity, by default. You can modify the timeout value using the command `configure ssh2 idletimeout <minutes>` where <minutes> can be from 1 to 240 . For more information, refer to the `help` command for `configure ssh2 idletimeout`. If a connection to an SSH2 session is lost inadvertently, the switch terminates the session within 60 minutes.

For detailed information about SSH2, see Security on page 1085.

Access Profile Logging for SSH2

The access profile logging feature allows you to use an _ACL_ policy file or dynamic ACL rules to control access to SSH2 services on the switch.

When access profile logging is enabled for SSH2, the switch logs messages and increments counters when packets are denied access to SSH2. No messages are logged for permitted access.

You can manage SSH2 access using one (not both) of the following methods:

- Create and apply an ACL policy file
- Define and apply individual ACL rules

One advantage of ACL policy files is that you can copy the file and use it on other switches. One advantage to applying individual ACL rules is that you can enter the rules at the CLI command prompt, which can be easier than opening, editing, and saving a policy file.

ACL Match Conditions and Actions

The ACLs section describes how to create _ACL_ policies and rules using match conditions and actions. Access profile logging supports the following match conditions and actions:

- Match conditions
    ◦ Source-address—IPv4 and IPv6
- Actions
    ◦ Permit
    ◦ Deny

If the ACL is created with more match conditions or actions, only those listed above are used for validating the packets. All other conditions and actions are ignored.

The source-address field allows you to identify an IPv4 address, IPv6 address, or subnet mask for which access is either permitted or denied.

If the Telnet traffic does not match any of the rules, the default behavior is deny.

Limitations

Access profile logging for SSH2 has the following limitations:

- Either policy files or ACLs can be associated with SSH2, but not both at the same time.
- Only source-address match is supported.
- Access-lists that are associated with one or more applications cannot be directly deleted. They must be unconfigured from the application first and then deleted from the CLI.
- Default counter support is added only for dynamic ACL rules and not for policy files.

Managing ACL Policies for SSH2

The ACLs section describes how to create ACL policy files.

- To configure SSH2 to use an ACL policy, use the following command:

  ```
  configure ssh2 access-profile profile_name
  ```

- To configure SSH2 to remove a previously configured ACL policy, use the following command:

  ```
  configure ssh2 access-profile none
  ```

Managing ACL Rules for SSH2

Before you can assign an ACL rule to SSH, you must create a dynamic ACL rule as described in ACLs.

- To add or delete a rule for SSH2 access, use the following command:

  ```
  configure ssh2 access-profile [ access_profile | [[add rule ] [first |
  [[before | after] previous_rule]]] | delete rule | none ]
  ```

- To display the access-list permit and deny statistics for an application, use the following command:

  ```
  show access-list counters process [snmp | telnet | ssh2 | http]
  ```

Misconfiguration Error Messages

The following messages can appear during configuration of policies or rules for the SNMP service:

`Rule <rule> is already applied`	A rule with the same name is already applied to this service.
`Please remove the policy <policy> already configured, and then add rule <rule>`	A policy file is already associated with the service. You must remove the policy before you can add a rule.
`Rule <previous_rule> is not already applied`	The specified rule has not been applied to the service, so you cannot add a rule in relation to that rule.
`Rule <rule> is not applied`	The specified rule has not been applied to the service, so you cannot remove the rule from the service.
`Error: Please remove previously configured rule(s) before configuring policy <policy>`	A policy or one or more ACL rules are configured for the service. You must delete the remove the policy or rules from the service before you can add a policy.

Using the Trivial File Transfer Protocol

ExtremeXOS supports the Trivial File Transfer Protocol (TFTP) based on RFC 1350.

TFTP is a method used to transfer files from one network device to another. The ExtremeXOS TFTP client is a command line application used to contact an external TFTP server on the network. For example, ExtremeXOS uses TFTP to download software image files, switch configuration files, and ACLs from a server on the network to the switch.

Up to eight active TFTP sessions can run on the switch concurrently.

We recommend using a TFTP server that supports blocksize negotiation (as described in RFC 2348, TFTP Blocksize Option), to enable faster file downloads and larger file downloads.

> **Note**
> For better functionality, minimum block-size of 64 bytes is recommended.

For additional information about TFTP, see the following chapters:

- For information about downloading software image files, BootROM files, and switch configurations, see Software Upgrade and Boot Options on page 1958.
- For information about downloading *ACL* (and other) policy files, see Policy Manager.
- For information about using TFTP to transfer files to and from the switch, see Managing the Switch on page 72.
- For information about configuring core dump files and transferring the core dump files stored on your switch, see Troubleshooting on page 1986

TFTP Block-size Configuration

ExtremeXOS supports the TFTP client block-size option configuration based on RFC 2348, which can range from 8 octets to 65000 octets. The block-size refers to data octets and does not include TFTP header. This feature added the user configuration option for data bock-size:

- in the generic commands that are used for downloading/uploading image/configuration/log/core file etc.
- ranging from 24 bytes to 65000 bytes, taking into consideration the local/remote file name size and the current busy box TFTP client support limits.
- to support larger TFTP data packets exceeding normal MTU especially on a front-panel port in case of in-band management, enable jumbo frames on that port. Please refer "Jumbo Frames" for the usage and its functional restrictions that affect TFTP data packet transfers.

If you do not specify block-size, the default is 1400 bytes.

Connecting to Another Host Using TFTP

You can TFTP from the current CLI session to another host to transfer files.

1. Run the `tftp` command:

   tftp [**ip-address** | **host-name**] { **-v** *vr_name* } { **-b** *block_size* } [**-g** | **-p**] [**-l** *local-file* { **-r** *remote-file* } | **-r** *remote-file* { **-l** *local-file* }]

   > **Note**
   > User-created VRs are supported only on the platforms listed for this feature in the *ExtremeXOS 32.4 Feature License Requirements* document.

   The TFTP session defaults to port 69. If you do not specify a *VR*, *VR-Mgmt* is used.

   For example, to connect to a remote TFTP server with an IP address of 10.123.45.67 and "get" or retrieve an ExtremeXOS configuration file named `XOS1.cfg` from that host, use the following command:

   ```
   tftp 10.123.45.67 -g -r XOS1.cfg
   ```

   When you "get" the file through TFTP, the switch saves the file.

2. To view the files you retrieved, run the `ls` command at the command prompt.

   In addition to the `tftp` command, the following two commands are available for transferring files to and from the switch:

   tftp get [**ip-address** | **host-name**] { **vr** *vr_name* } { **block-size** *block_size* } *remote-file local-file*} {**force-overwrite**}

   By default, if you transfer a file with a name that already exists on the system, the switch prompts you to overwrite the existing file. For more information, see the `tftp get` command.

Understanding System Redundancy

If you configure two master-capable nodes in a SummitStack, one assumes the role of primary (also called "master") and the other assumes the role of backup.

The primary node provides all of the switch management functions including running the bridging and routing protocols, and configuring the switch. The primary node also synchronizes the backup node in case it needs to take over the management functions if the primary node fails.

For SummitStack, a node can be a redundant primary node if it has been configured to be master-capable.

To configure master capability on one or all nodes in a SummitStack, use one of the following commands:

configure stacking [**node-address** *node-address* | **slot** *slot-number*] **alternate-ip-address** [*ipaddress netmask* | *ipNetmask*] *gateway*
configure stacking redundancy [**none** | **minimal** | **maximal**]

Node Election

Node election is based on leader election between master-capable nodes present in a SummitStack.

By default, the SummitStack node in slot 1 has primary status. Each node uses health information about itself together with a user configured priority value to compute its node role election priority. Nodes exchange their node role election priorities. During the node election process, the node with the highest node role election priority becomes the master or primary node, and the node with the second highest node role election priority becomes the backup node. All other nodes (if any) remain in STANDBY state.

The primary node runs the switch management functions, and the backup node is fully prepared to become the primary node if the primary fails. In SummitStack, nodes that remain in STANDBY state (called Standby nodes) program their port hardware based on instructions received from the primary. Standby nodes configured to be master-capable elect a new backup node from among themselves after a failover has occurred.

Determining the Primary Node

The following parameters determine the primary node:

Node state

The node state must be STANDBY to participate in leader election and be selected as primary. If the node is in the INIT, DOWN, or FAIL states, it cannot participate in leader election. For more information about the node states, see Viewing Node Status on page 93.

Configuration priority

This is a user assigned priority. The configured priority is compared only after the node meets the minimum thresholds in each category for it to be healthy. Required processes and devices must not fail.

Software health

This represents the percent of processes available.

Health of secondary hardware components

This represents the health of the switch components, such as power supplies, fans, and so forth.

Slot ID

The slot number configured on a stack node.

Configuring the Node Priority on a SummitStack

If you do not configure any priorities, slot 1 has the highest priority, slot 2 the second highest priority, and so forth in order of increasing slot number. You may also use the factory assigned MAC address as the node-address value. By default the priority is "automatic" and the node-pri value is any number between 1 and 100. The higher the value, the higher the priority.

Configure the priority of a node in a SummitStack using the following command:

```
configure stacking {node-address node-address | slot slot-number}
priority [node-pri | automatic]
```

Relinquishing Primary Status

Before relinquishing primary status and initiating failover, review the section Synchronizing Nodes on page 1982 to confirm that your platform and both installed MSMs/MMs or master-capable nodes are running software that supports the `synchronize` command.

You can cause the primary to failover to the backup, thereby relinquishing its primary status.

1. Use the `show switch {detail}` command on the primary or the backup node to confirm that the nodes are synchronized and have identical software and switch configurations before failover.

   A node may not be synchronized because checkpointing did not occur, incompatible software is running on the primary and backup, or the backup is down.

   If the nodes are not synchronized and both nodes are running a version of ExtremeXOS that supports synchronization, proceed to step 2.

   If the nodes are synchronized, proceed to step 3 on page 91.

   The output displays the status of the nodes, with the primary node showing MASTER and the backup node showing BACKUP (InSync).

2. If the nodes are not synchronized because of incompatible software, use the `synchronize` command to ensure that the backup has the same software in flash as the primary.

   The `synchronize` command:

   - Reboots the backup node to prepare it for synchronizing with the primary node.
   - Copies both the primary and secondary software images.
   - Copies both the primary and secondary configurations.
   - Reboots the backup node after replication is complete.

   After you confirm the nodes are synchronized, proceed to step 3.

3. If the nodes are synchronized, use the `run failover {force}` command to initiate failover from the primary node to the backup node.

   The backup node then becomes the primary node and the original primary node reboots.

Replicating Data Between Nodes

ExtremeXOS replicates configuration and run-time information between the primary node and the backup node so that the system can recover if the primary fails. This method of replicating data is known as checkpointing. Checkpointing is the process of automatically copying the active state from the primary to the backup, which allows for state recovery if the primary fails.

Replicating data consists of the following three steps:

- Configuration synchronization—Relays current and saved configuration information from the primary to the backup.

- Bulk checkpoint—Ensures that each individual application running on the system is synchronized with the backup.
- Dynamic checkpoint—Checkpoints any new state changes from the primary to the backup.

To monitor the checkpointing status, use the following command:

```
show checkpoint-data {process}
```

Data is not replicated from the primary to the standby nodes.

Relaying Configuration Information

To facilitate a failover from the primary node to the backup node, the primary transfers its active configuration to the backup.

Relaying configuration information is the first level of checkpointing . During the initial switch boot-up, the primary's configuration takes effect. During the initialization of a node, its configuration is read from the local flash. After the primary and backup nodes have been elected, the primary transfers its current active configuration to the backup. After the primary and backup nodes are synchronized, any configuration change you make to the primary is relayed to the backup and incorporated into the backup's configuration copy.

> **Note**
> To ensure that all of the configuration commands in the backup's flash are updated, issue the **save** command after you make any changes. On a SummitStack, the save configuration command will normally save the primary node's configuration file to all active nodes in the SummitStack.

If a failover occurs, the backup node continues to use the primary's active configuration. If the backup determines that it does not have the primary's active configuration because a run-time synchronization did not happen, the switch or SummitStack reboots. Because the backup always uses the primary's active configuration, the active configuration remains in effect regardless of the number of failovers.

> **Note**
> If you issue the `reboot` command before you save your configuration changes, the switch prompts you to save your changes. To keep your configuration changes, save them before you reboot the switch.

Bulk Checkpointing

Bulk checkpointing causes the master and backup run-time states to be synchronized. Since ExtremeXOS runs a series of applications, an application starts checkpointing only after all of the applications it depends on have transferred their run-time states to the backup node.

After one application completes bulk checkpointing, the next application proceeds with its bulk checkpointing.

- To monitor the checkpointing status, use the `show checkpoint-data {process}` command.

- To see if bulk checkpointing is complete (that is, to see if the backup node is fully synchronized [in sync] with the master node), use the `show switch {detail}` command.

If a failover occurs before bulk checkpointing is complete, the SummitStack reboots. However, once bulk checkpointing is complete, failover is possible without a SummitStack reboot.

Dynamic Checkpointing

After an application transfers its saved state to the backup node, dynamic checkpointing requires that any new configuration information or state changes that occur on the primary be immediately relayed to the backup.

This ensures that the backup has the most up-to-date and accurate information.

Viewing Checkpoint Statistics

View and check the status of one or more processes being copied from the primary to the backup node.

Run `show checkpoint-data {process}`.

This command is also helpful in debugging synchronization problems that occur at run time.

The output displays, in percentages, the amount of copying completed by each process and the traffic statistics between the process on both the primary and the backup nodes.

Viewing Node Status

ExtremeXOS allows you to view node statistical information. Each node in a stackable switch in a SummitStack installed in your system is self-sufficient and runs the ExtremeXOS management applications. By reviewing this output, you can see the general health of the system along with other node parameters.

Run `show node {detail}`.

In a SummitStack, the `show stacking` command shows the node roles of active nodes.

Node Status Collected

Table 14 provides descriptions of node states.

Table 14: Node States

Node State	Description
BACKUP	In the backup state, this node becomes the primary node if the primary fails or enters the DOWN state. The backup node also receives the checkpoint state data from the primary.
DOWN	In the down state, the node is not available to participate in leader election. The node enters this state during any user action, other than a failure, that makes the node unavailable for management. Examples of user actions are: • Upgrading the softwareRebooting the system using the `reboot` command. • Initiating a failover using the `run failover` command. • Synchronizing the node software and configuration in non-volatile storage using the `synchronize` command.
FAIL	In the fail state, the node has failed and needs to be restarted or repaired. The node reaches this state if the system has a hardware or software failure.
INIT	In the initial state, the node is being initialized. A node stays in this state when it is coming up and remains in this state until it has been fully initialized. Being fully initialized means that all of the hardware has been initialized correctly and there are no diagnostic faults.
MASTER	In the primary (master) state, the node is responsible for all switch management functions.
STANDBY	In the standby state, leader election occurs—the primary and backup nodes are elected. The priority of the node is only significant in the standby state. In SummitStack, there can be more than two master-capable nodes. All such nodes that do not get elected either master or backup remain in standby state.

Understanding Hitless Failover Support

SummitStack node has customer ports that are under the control of its single central processor. In a SummitStack, failure of the primary node results in all ports that require that node's processor for normal operation going down. The remaining SummitStack nodes' ports continue to function normally.

As described in the section Understanding System Redundancy on page 89, if you configure at least two master-capable nodes in a SummitStack, one assumes the role of primary and the other assumes the role of backup.

The primary node provides all of the switch management functions including bringing up and programming the other (standby) nodes in the SummitStack, running the bridging and routing protocols, and configuring the switch. The primary node also

synchronizes the backup node in case it needs to take over the management functions if the primary node fails.

The configuration is one of the most important pieces of information checkpointed to the backup node. Each component of the system needs to checkpoint whatever runtime data is necessary to allow the backup node to take over as the primary node if a failover occurs, including the protocols and the hardware-dependent layers. For more information about checkpointing data and relaying configuration information, see Replicating Data Between Nodes on page 91.

Not all protocols support hitless failover. Layer 3 forwarding tables are maintained for pre-existing flows, but subsequent behavior depends on the routing protocols used. Static Layer 3 configurations and routes are hitless. You must configure *OSPF (Open Shortest Path First)* graceful restart for OSPF routes to be maintained, and you must configure *BGP (Border Gateway Protocol)* graceful restart for BGP routes to be maintained. For more information about OSPF, see OSPF on page 1662 and for more information about BGP, see BGP on page 1717. For routing protocols that do not support hitless failover, the new primary node removes and re-adds the routes.

Protocol Support for Hitless Failover

Table 15 summarizes the protocol support for hitless failover. Unless otherwise noted, the behavior is the same for all switches.

If a protocol indicates support for hitless failover, additional information is also available in that particular chapter. For example, for information about network login support of hitless failover, see Network Login on page 897.

Table 15: Protocol Support for Hitless Failover

Protocol	Behavior	Hitless
Bootstrap Protocol Relay	All bootprelay statistics (including option 82 statistics) are available on the backup node also	Yes
BGP	If you configure BGP graceful restart, by default the route manager does not delete BGP routes until 120 seconds after failover occurs. There is no traffic interruption. However, after BGP comes up after restart, BGP re-establishes sessions with its neighbors and relearns routes from all of them. This causes an increase in control traffic onto the network. If you do not configure graceful restart, the route manager deletes all BGP routes 1 second after the failover occurs, which results in a traffic interruption in addition to the increased control traffic.	Yes

Table 15: Protocol Support for Hitless Failover (continued)

Protocol	Behavior	Hitless
Connectivity Fault Management (IEEE 802.1ag)	An ExtremeXOS process running on the master node should continuously send the MEP state changes to the backup. Replicating the protocol packets from an master node to a backup may be a huge overhead if CCMs are to be initiated/received in the CPU and if the CCM interval is in the order of milliseconds. RMEP timeout does not occur on a remote node during the hitless failover. RMEP expiry time on the new master node in case of double failures, when the RMEP expiry timer is already in progress, is as follows: RMEP Expiry Time = elapsed expiry time on the master node + 3.5 * ccmIntervaltime + master node convergence time.	Yes
Dynamic Host Configuration Protocol client	The IP addresses learned on all _DHCP_ enabled VLANs are retained on the backup node after failover.	Yes
Dynamic Host Configuration Protocol server	A DHCP server continues to maintain the IP addresses assigned to various clients and the lease times even after failover. When a failover happens, all the clients work as earlier.	Yes
EAPS (Extreme Automatic Protection Switching)	The primary node replicates all EAPS BPDUs to the backup, which allows the backup to be aware of the state of the EAPS domain. Since both primary and backup nodes receive EAPS BPDUs, each node maintains equivalent EAPS states. By knowing the state of the EAPS domain, the EAPS process running on the backup node can quickly recover after a primary node failover. Although both primary and backup nodes receive EAPS BPDUs, only the primary transmits EAPS BPDUs to neighboring switches and actively participates in EAPS.	Yes
EDP (Extreme Discovery Protocol)	EDP does not checkpoint protocol data units (PDUs) or states, so the backup node does not have the neighbor's information. If the backup node becomes the primary node, and starts receiving PDUs, the new primary learns about its neighbors.	No

Table 15: Protocol Support for Hitless Failover (continued)

Protocol	Behavior	Hitless
Extreme Loop Recovery Protocol (ELRP)	If you use ELRP as a standalone tool, hitless failover support is not needed since you initiate the loop detection. If you use ELRP in conjunction with *ESRP (Extreme Standby Router Protocol)*, ELRP does not interfere with the hitless failover support provided by ESRP. Although there is no hitless failover support in ELRP itself, ELRP does not affect the network behavior if a failover occurs.	No
Extreme Standby Router Protocol (ESRP)	If failover occurs on the ESRP MASTER switch, it sends a hello packet with the HOLD bit set. On receiving this packet, the ESRP SLAVE switch freezes all further state transitions. The MASTER switch keeps sending hellos with the HOLD bit set on every hello interval. When the MASTER is done with its failover, it sends another hello with the HOLD bit reset. The SLAVE switch resumes normal processing. (If no packet is received with the HOLD bit reset, the SLAVE timeouts after a certain time interval and resumes normal processing.) Failover on the ESRP SLAVE switch is of no importance because it is the SLAVE switch.	Yes
Intermediate System-Intermediate System (IS-IS)	If you configure IS-IS graceful restart, there is no traffic interruption. However, after IS-IS comes up after restart, IS-IS re-establishes sessions with its neighbors and relearns Link State Packets (LSPs) from all of the neighbors. This causes an increase in network control traffic. If you do not configure graceful restart, the route manager deletes all IS-IS routes one second after the failover occurs, which results in a traffic interruption and increased control traffic. IS-IS for IPv6 does not support hitless restart .	IS-IS (IPv4) Yes IS-IS (IPv6) No
Link Aggregation Control Protocol (LACP)	If the backup node becomes the primary node, there is no traffic disruption.	Yes
LLDP (Link Layer Discovery Protocol)	LLDP is more of a tool than a protocol, so there is no hitless failover support. LLDP is similar to EDP, but there is also a MIB interface to query the information learned. After a failover, it takes 30 seconds or greater before the MIB database is fully populated again.	No

Table 15: Protocol Support for Hitless Failover (continued)

Protocol	Behavior	Hitless
MSDP (Multicast Source Discovery Protocol)	If the master node fails, the MSDP process loses all state information and the backup node becomes active. However, the failover from the master to the backup causes MSDP to lose all state information and dynamic data, so it is not a hitless failover.	No
MLAG (Multi-switch Link Aggregation Group)	All MLAG user configuration is executed on both master and backup nodes. Both nodes open listening health-check and checkpoint listening sockets on the respective well-known ports. All _FDB (forwarding database)_ entries and IPMC group/cache information that were received through ISC checkpointing is synchronized to the backup node. After failover, the TCP session, which is handled by the failed master, tears down and there is a new session with the MLAG peer switch. After the failover, the FDB & McMgr processes trigger bulk checkpointing of all its entries to the MLAG peer upon receiving ISC up notification.	Yes

Table 15: Protocol Support for Hitless Failover (continued)

Protocol	Behavior	Hitless
Network Login	802.1X Authentication—Authenticated clients continue to remain authenticated after failover. However, one second after failover, all authenticated clients are forced to re-authenticate themselves. Information about unauthenticated clients is not checkpointed, so any such clients that were in the process of being authenticated at the instant of failover must go through the authentication process again from the beginning after failover. MAC-Based Authentication—Authenticated clients continue to remain authenticated after failover so the failover is transparent to them. Information about unauthenticated clients is not checkpointed so any such clients that were in the process of being authenticated at the instant of failover must go through the authentication process again from the beginning after failover. In the case of MAC-Based authentication, the authentication process is very short with only a single packet being sent to the switch so it is expected to be transparent to the client stations. Web-Based Authentication—Web-based Netlogin users continue to be authenticated after a failover.	Yes Yes Yes
OSPF	If you configure OSPF graceful restart, there is no traffic interruption. However, after OSPF comes up after restart, OSPF re-establishes sessions with its neighbors and relearns Link State Advertisements (LSAs) from all of the neighbors. This causes an increase in control traffic onto the network. If you do not configure graceful restart, the route manager deletes all OSPF routes one second after the failover occurs, which results in a traffic interruption in addition to the increased control traffic.	Yes

Table 15: Protocol Support for Hitless Failover (continued)

Protocol	Behavior	Hitless
OSPFv3 (Open Shortest Path First version 3)	If you configure OSPFv3 graceful restart, there is no traffic interruption. However, after OSPFv3 comes up after restart, OSPFv3 re-establishes sessions with its neighbors and relearns Link State Advertisements (LSAs) from all of the neighbors. If you do not configure graceful restart, the route manager deletes all OSPFv3 routes after failover occurs, which results in a traffic interruption in addition to the increased control traffic.	Yes
PoE (Power over Ethernet)	The PoE configuration is checkpointed to the backup node. This ensures that, if the backup takes over, all ports currently powered stay powered after the failover and the configured power policies are still in place.	Yes
Protocol Independent Multicast (PIM)	After a failover, all hardware and software caches are cleared and learning from the hardware is restarted. This causes a traffic interruption since it is the same as if the switch rebooted for all Layer 3 multicast traffic.	No
RIP (Routing Information Protocol)	RIP does not support graceful restart, so the route manager deletes all RIP routes one second after the failover occurs. This results in a traffic interruption as well as an increase in control traffic as RIP re-establishes its database.	No
RIPng (Routing Information Protocol Next Generation)	RIPng does not support graceful restart, so the route manager deletes all RIPng routes one second after the failover occurs. This results in a traffic interruption. After RIPng comes up on the new primary node, it relearns the routes from its neighbors. This causes an increase in control traffic onto the network.	No
Simple Network Time Protocol Client	*SNTP* client will keep the backup node updated about the last server from which a valid update was received, the time at which the last update was received, whether the SNTP time is currently good or not and all other statistics.	Yes

Table 15: Protocol Support for Hitless Failover (continued)

Protocol	Behavior	Hitless
STP (Spanning Tree Protocol)	STP supports hitless failover including catastrophic failure of the primary node without interruption. There should be no discernible network event external to the switch. The protocol runs in lock step on both master and backup nodes and the backup node is a hot spare that can take over at any time with no impact on the network.	Yes
VRRP (Virtual Router Redundancy Protocol)	VRRP supports hitless failover. The primary node replicates VRRP PDUs to the backup, which allows the primary and backup nodes to run VRRP in parallel. Although both nodes receive VRRP PDUs, only the primary transmits VRRP PDUs to neighboring switches and participates in VRRP.	Yes

Hitless Failover Caveats

This section describes the caveats for hitless failover.

Check the latest version of the ExtremeXOS release notes for additional information.

Caveats for a SummitStack

The following describes the hitless failover caveats for a SummitStack:

- All customer ports and the stacking links connected to the failed primary node will go down. In the recommended stack ring configuration, the stack becomes a daisy chain until the failed node restarts or is replaced.
- A brief traffic interruption (less than 50 milliseconds) can occur when the traffic on the ring is rerouted because the active topology becomes a daisy chain.
- Since the SummitStack can contain more than two master-capable nodes, it is possible to immediately elect a new backup node. If a new backup node is elected, when the original primary node restarts, it will become a standby node.
- To simulate the behavior of a chassis, a MAC address of one of the nodes is designated as the seed to form a stack MAC address. When a failover occurs, the SummitStack continues to be identified with this address.
- During an _OSPF_ graceful restart, the SummitStack successfully restores the original link state database only if the OSPF network remains stable during the restart period. If the failed primary node provided interfaces to OSPF networks, the link state database restoration is prematurely terminated, and reconvergence occurs in the OSPF network due to the failover. See OSPF on page 1662 for a description of OSPF and the graceful restart function.
- During a _BGP_ graceful restart, the SummitStack successfully restores the BGP routing table only if the BGP network remains stable during the restart period. If a receiving speaker detected the need for a routing change due to the failure of

links on the failed primary node, it deletes any previous updates it received from the restarting speaker (the SummitStack) before the restart occurred. Consequently, reconvergence occurs in the BGP network due to the failover. See BGP on page 1717 for a description of BGP and its graceful restart function.

Understanding Power Supply Management

Using Power Supplies

On ExtremeSwitching switches, ExtremeXOS reports when the PSU has power or has failed.

The ExtremeSwitching switches support an internal power supply with a range of 90V to 240V AC power as well as an external redundant power supply. The Extreme Networks External Power System (EPS) allows you to add a redundant power supply to the ExtremeSwitching switches to protect against a power supply failure. The EPS consists of a tray or module that holds the EPS power supplies.

> **Note**
> When an EPS-T tray with two EPS-160 PSUs is connected to a ExtremeSwitching switch, the internal power supply will show as failed.

On non-*PoE* ExtremeSwitching switches, if you experience an internal PSU failure and do not have an external PSU installed, the switch powers down. If you experience a PSU failure and have an external PSU installed, the switch uses the external PSU to maintain power to the switch.

On PoE ExtremeSwitching switches, there are specific power budget requirements and configurations associated with PoE that are not described in this section. The PoE ExtremeSwitching switches respond to internal and external PSU failures based on your PoE configurations. For more information about configuring PoE on the ExtremeSwitching PoE switches, see PoE on page 510.

For more information about ExtremeSwitching switches and EPS, see the hardware documentation listed in Related Publications on page 8.

Using Power Supplies--SummitStack Only

Since the nodes have their own power supplies and since they cannot be shared, management is the same as it is for standalone ExtremeSwitching switches.

The only difference is that the power management commands have been centralized so that they can be issued from the primary node.

Displaying Power Supply Information

Display the status of the currently installed power supplies on all switches.

1. Run `show power {`*`ps_num`*`} {`**`detail`**`}`.

   The **detail** option of this command shows power usage parameters on stacking and standalone ExtremeSwitching switches.
2. To view the system power status and the amount of available and required power, use the following command:

   `show power budget`
3. To display the status of the currently installed power supply controllers, use the following command:

   `show power {`*`ps_num`*`}`

Using the Network Time Protocol

Network Time Protocol (NTP) is used for synchronizing time on devices across a network with variable latency (time delay).

NTP provides a coordinated Universal Time Clock (UTC), the primary time standard by which the world regulates clocks and time. UTC is used by devices that rely on having a highly accurate, universally accepted time, and can synchronize computer clock times to a fraction of a millisecond. In a networked environment, having a universal time can be crucial. For example, the stock exchange and air traffic control use NTP to ensure accurate, timely data.

NTP uses a hierarchical, semi-layered system of levels of clock sources called a *stratum*. Each stratum is assigned a layer number starting with 0 (zero), with 0 meaning the least amount of delay. The stratum number defines the distance, or number of NTP hops away, from the reference clock. The lower the number, the closer the switch is to the reference clock. The stratum also serves to prevent cyclical dependencies in the hierarchy.

SNTP, as the name would suggest, is a simplified version of NTP that uses the same protocol, but without many of the complex synchronization algorithms used by NTP. SNTP is suited for use in smaller, less complex networks. For more information about SNTP see the section, .

> **Note**
> When NTP is enabled, it is not recommended to update the time manually.

Limitations

The Extreme Networks implementation of NTP includes the following limitations:

- *SNTP* cannot be enabled at the same time NTP is enabled.
- The NTP multicast delivery mechanism is not supported.
- The NTP autokey security mechanism is not supported.
- The broadcast client option cannot be enabled on a per-*VLAN* basis.

- NTP authentication can be enabled globally. It cannot be enabled per VR.
- VRF is not supported.

VR Configuration Support

Starting with ExtremeXOS 22.2, NTP can be configured over multiple VRs.

To enable NTP on a VR, use the following command:

```
enable ntp vr vr_name
```

> **Note**
> If VR is not specified, command is executed in current VR context and enables NTP for that VR alone.

To configure NTP over VLANs, use the following command:

```
enable ntp vlan vlan-name [broadcast-server | key keyid]
```

To configure NTP in all VLANs for a VR, use the following command:

```
enable ntp vr vr_name
```

The VR configuration can be seen in `show ntp {{vr}vr_name}` command output.

Configuring the NTP Server/Client

An NTP server provides clock information to NTP or _SNTP_ clients. You can configure an NTP server as an NTP client to receive clock information from more reliable external NTP servers or a local clock. You can also build a hierarchical time distribution topology by using TCP/IP. The switch can work as both an NTP client and server at the same time to build a hierarchical clock distribution tree. This hierarchical structure eliminates the need for a centralized clock server and provides a highly available clock tree with minimal network load and overhead.

- To configure an NTP server, use the following command:
  ```
  configure ntp [server | peer] add [ip_address | host_name] {key keyid}
  {option [burst | initial-burst]} {{vr} vr_name}
  ```
- To delete an NTP server, use the following command:
  ```
  configure ntp [server | peer] delete [ip_address | host_name]
  ```
- To display NTP server information, use the following commands:
  ```
  show ntp server
  ```

With scaled configuration, NTP takes more time to apply the configuration, since it involves system calls to apply the configuration.

Configuring Restrict Lists

You can configure a restrict list to deny/permit a particular host or network. The following limitations apply:

- You cannot add an NTP server to the restrict list. When the NTP server is added, the server IP address is added as the system restrict list with the action "permit".
- If an NTP is enabled on a _VLAN_, that VLAN IP address/network cannot be added as restrict list entry.

To create or delete a restrict list, use the following command:

```
configure ntp restrict-list [add | delete] network {mask} [permit |
deny] {{vr} vr_name}
```

To show the NTP access list of the current system based on the source IP address blocks, use the following command:

```
show ntp restrict-list {user | system} {{vr}vr_name}
```

Managing NTP Peer Support

An NTP peer is a member of a group of NTP servers. Normally, an NTP peer is used to synchronize clock information among a group of servers that serve as mutual backups for each other. Typically, core switches are configured as NTP peers, and an NTP server is configured as a core switch to an NTP client, aggregation switch, or edge switch. An NTP client can choose the most reliable clock from all servers that have a peer relationship with the client.

- To configure an NTP peer, use the following command:

  ```
  configure ntp [server | peer] add [ip_address | host_name] {key keyid}
  {option [burst | initial-burst]} {{vr} vr_name}
  ```
- To delete an NTP peer, use the following command:

  ```
  configure ntp [server | peer] delete [ip_address | host_name]
  ```
- To display an NTP peer, use the following command:

  ```
  show ntp
  show ntp association [{ip_address} | {host_name}] {{vr} vr_name}
  show ntp association [{ip_address} | {host_name}] statistics
  {{vr}vr_name}
  show ntp sys-info
  ```

Managing NTP Local Clock Support

A local clock serves as backup to distribute clock information internally when reliable external clock sources are not reachable. Assign a higher stratum value to the local clock to ensure that it is not selected when an external reliable clock source with a lower stratum number exists.

- To configure a local clock, use the following command:

  ```
  configure ntp local-clock stratum stratum_number
  ```

- To delete a local clock, use the following command:
  ```
  configure ntp local-clock none
  ```

Managing NTP Broadcast Server Support

An NTP broadcast server sends periodic time updates to a broadcast address in a LAN. When a broadcast client is configured for NTP, that client can receive time information from the broadcasted NTP packets. Using broadcast packets can greatly reduce the NTP traffic on a network, especially in a network with many NTP clients.

To ensure that NTP broadcast clients get clock information from the correct NTP broadcast servers, with minimized risks from malicious NTP broadcast attacks, configure RSA Data Security, Inc. *MD5 (Message-Digest algorithm 5)* Message-Digest Algorithm authentication on both the NTP broadcast server and NTP clients.

- To configure an NTP broadcast server over a *VLAN* where NTP broadcast service is provided, use the following command:
  ```
  enable ntp {vlan} vlan-name broadcast-server {key keyid}
  ```
- To delete an NTP broadcast server over a VLAN where NTP broadcast service is enabled, use the following command:
  ```
  disable ntp {vlan} vlan-name broadcast-server
  ```
- To display an NTP broadcast server, use the following command:
  ```
  show ntp server
  show ntp vlan {{vr} vr_name}
  ```

Managing NTP Broadcast Client Support

An NTP client listens for NTP packets from an NTP broadcast server. To listen for network broadcast messages, enable an NTP broadcast client. This option is global (it cannot be enabled on a per-*VLAN* basis).

- To configure an NTP broadcast client, use the following command:
  ```
  enable ntp broadcast-client {{vr} vr_name}
  ```
- To delete an NTP broadcast client, use the following command:
  ```
  disable ntp broadcast-client {{vr} vr_name}
  ```
- To display an NTP broadcast client, use the following command:
  ```
  show ntp {{vr}vr_name}
  ```

Managing NTP Authentication

To prevent false time information from unauthorized servers, enable NTP authentication to allow an authenticated server and client to exchange time information. The currently supported authentication methods are the RSA Data Security, Inc. *MD5* Message-Digest Algorithm and SHA-256.

When FIPS mode is enabled, Network Time Protocol (NTP) uses OpenSSL Federal Information Processing Standards (FIPS) library and supports only FIPS-compliant algorithms for authentication (SHA-256 authentication only). MD5 key configuration

support is not available when FIPS mode is enabled, and existing MD5 key configurations are removed when FIPS mode comes into effect. For more information about FIPS mode, see Federal Information Processing Standards (FIPS) Mode on page 1088.

First, enable NTP authentication globally on the switch. Then create an NTP authentication key configured as trusted, to check the encryption key against the key on the receiving device before an NTP packet is sent. After configuration is complete, an NTP server, peer, and broadcast server can use NTP authenticated service.

- To enable or disable NTP authentication globally on the switch, use the following command:

```
enable ntp authentication
disable ntp authentication
```

- To create or delete an RSA Data Security, Inc. MD5 Message-Digest Algorithm key for NTP authentication, use the following command:

```
create ntp key keyid [md5 | sha256] {encrypted encrypted_key_string |
key_string}
delete ntp key [keyid | all]
```

- To configure an RSA Data Security, Inc. MD5 Message-Digest Algorithm key as trusted or not trusted, use the following command:

```
configure ntp key keyid [trusted | not-trusted]
```

- To display RSA Data Security, Inc. MD5 Message-Digest Algorithm authentication, use the following command:

```
show ntp key
```

- To display NTP authentication, use the following command:

```
show ntp sys-info
```

    If NTP authentication is enabled, then "Authentication" flag is set in "System Flags" output.

Showing NTP Information

To display the global NTP status of the switch, use the command:

```
show ntp
```

To display the current system status based on the most reliable clock server or NTP server, use the following command:

```
show ntp sys-info
```

To display NTP *VLAN* configurations, use the command:

```
show ntp vlan {{vr} vr_name}
```

To display NTP VR configurations, use the command:

```
show ntp {{vr}vr_name}
```

To display all of the NTP clock source information, from a statically configured server, peer, or broadcast server:

```
show ntp association [{ip_address} | {host_name}] {{vr} vr_name}
```

NTP Configuration Example

In the example shown in Figure 3, SW#1 synchronizes its clock from the 0-3.us.pool.ntp.org timer server, and provides the synchronized clock information to SW#2 as a unicast message, and to SW#3 as a broadcast message.

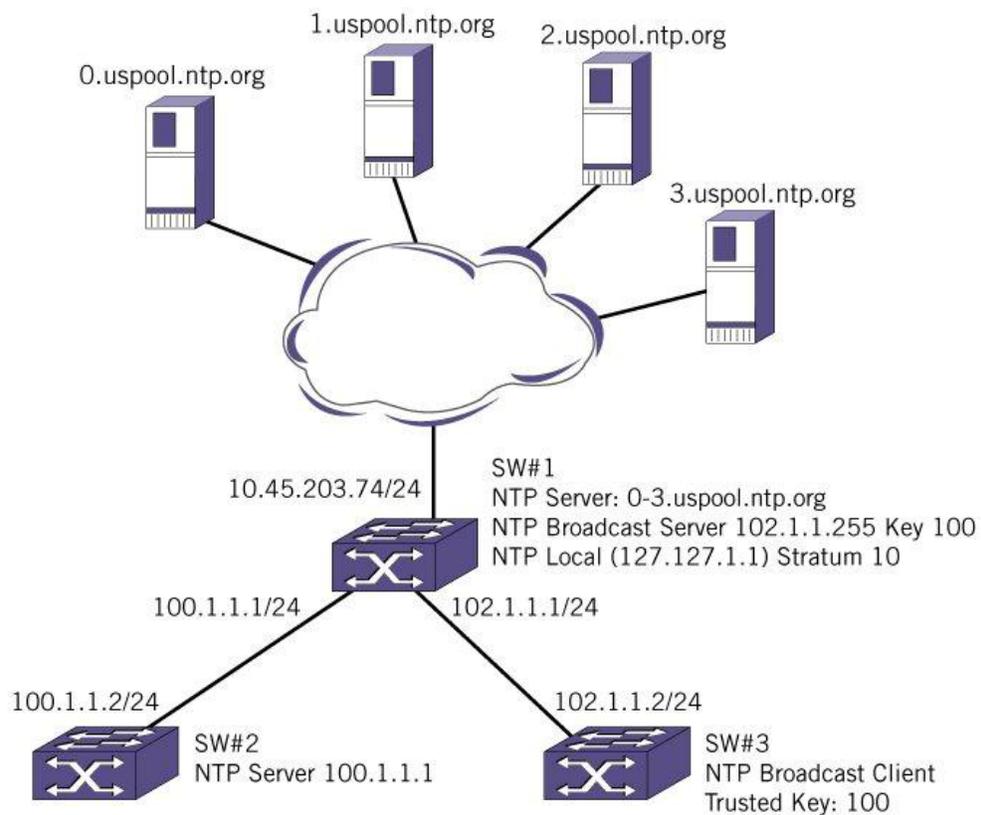
SW#2 configures SW#1 as a time server using a normal unicast message. It also has a local clock (127.127.1.1) with a stratum level of 10. SW#3 is configured as broadcast client without specific server information. For security purposes, SW#2 and SW#3 use RSA Data Security, Inc. *MD5* Message-Digest Algorithm authentication with a key index of 100.


Figure 3: NTP Configuration Example

SW#1 Configuration

```
create vlan internet
create vlan toSW2
create vlan toSW3
config vlan internet add port 1
config vlan toSW2 add port 2
config vlan toSW3 add port 3
config vlan internet ipaddress 10.45.203.74/24
```

```
config vlan toSW2 ipaddress 100.1.1.1/24
config vlan toSW3 ipaddress 102.1.1.1/24
config iproute add default 10.45.203.1 vr vr-default
enable ntp
create ntp key 100  md5 EXTREME
config ntp key 100 trusted
enable ntp vlan internet
enable ntp vlan toSW2
enable ntp vlan toSW3
enable ntp vlan toSW3 broadcast-server key 100
config ntp server add 0.us.pool.ntp.org
config ntp server add 1.us.pool.ntp.org
config ntp server add 2.us.pool.ntp.org
config ntp server add 3.us.pool.ntp.org
config ntp local-clock stratum 10
```

SW#2 Configuration

```
create vlan toSW1
config vlan toSW1 add port 1
config vlan toSW1 ipaddress 100.1.1.2/24
enable ntp
enable ntp vlan toSW1
config ntp server add 100.1.1.1
```

SW#3 Configuration

```
create vlan toSW1
config vlan toSW1 add port 1
config vlan toSW1 ipaddress 102.1.1.2/24
enable ntp
enable ntp broadcast-client
create ntp key 100 md5 EXTREME
config ntp key 100 trusted
enable ntp vlan toSW1
```

NTP Configuration Example over Multiple VRs

Switch SW#1 Configuration

```
create vlan v2 -- in vr VR-Mgmt
create vlan v5 -- in vr VR-Default
create vlan v3 -- in vr test (user-VR)
create vlan v6 -- in vr test (user-VR)
config vlan v2 ipaddress 10.127.7.33/24
config vlan v5 ipaddress 5.1.1.5/24
config vlan v3 ipaddress 10.127.7.60/24
config vlan v5 add port <port towards SW#2>
config vlan v6 add port <port towards SW#3>
config vlan v2 add port <port connected to reach reference clock>
config vlan v3 add port <port connected to reach reference clock>
enable ntp vr test
enable ntp vr VR-Default
enable ntp vr VR-Mgmt
enable ntp vlan v3
enable ntp vlan v6
enable ntp vlan v2
enable ntp vlan v5
enable ntp vlan Mgmt
configure ntp server add 128.138.140.44 initial-burst vr VR-Default
configure ntp server add 128.138.141.172 initial-burst vr VR-Default
configure ntp server add 129.6.15.28 initial-burst vr test
configure ntp server add 129.6.15.29 initial-burst vr test
```

```
configure ntp server add 129.6.15.30 initial-burst vr test
configure ntp server add 2.us.pool.ntp.org initial-burst vr test
configure ntp server add 204.152.184.72 initial-burst vr VR-Mgmt
configure ntp server add 24.56.178.140 initial-burst vr VR-Default
configure ntp server add 64.113.32.5 initial-burst vr VR-Default
configure ntp server add 66.199.22.67 initial-burst vr VR-Mgmt
configure ntp server add 98.175.203.200 initial-burst vr VR-Mgmt
```

SW#2 Configuration

```
create vlan v5 -- in vr VR-Default
config vlan v5 add port <port towards SW#1>
config vlan v5 ipaddress 5.1.1.6/24
enable ntp vr VR-Default
enable ntp vlan v5
configure ntp server add 5.1.1.5 initial-burst vr VR-Default
```

SW#3 Configuration

```
create vlan v6 -- in vr test (user-VR)
config vlan v6 ipaddress 6.1.1.7/24
config vlan v6 add port <port towards SW#1>
enable ntp vr test
enable ntp vlan v6
configure ntp server add 6.1.1.6 initial-burst vr test
```

Using the Simple Network Management Protocol

Any network manager program running the *SNMP* can manage the switch if the Management Information Base (MIB) is installed correctly on the management station.

Each network manager program provides its own user interface to the management facilities.

> **Note**
> When using a network manager program to create a *VLAN*, we do not support the SNMP createAndWait operation. To create a VLAN with SNMP, use the createAndGo operation.
> createAndGo is one of six values in the RowStatus column of SMIv2 tables. createAndGo is supplied by a manager wishing to create a new instance of a conceptual row and have its status automatically set to active in order to make it available for use by the managed device

The following sections describe how to get started if you want to use an SNMP manager. It assumes you are already familiar with SNMP management.

> **Note**
> Perform a save operation if you make any configurations using SNMP mibs. If you do not save, some of the configurations may not survive when you reboot.

Enabling and Disabling SNMPv1/v2c and SNMPv3

ExtremeXOS can concurrently support SNMPv1/v2c and SNMPv3. The default is that both types of *SNMP* are disabled. Network managers can access the device with either SNMPv1/v2c methods or SNMPv3.

- To allow support for all SNMP access, or SNMPv1/v2c access only, or SNMPv3 access only, use the following command:

  `enable snmp access {`**`snmp-v1v2c`** `|` **`snmpv3`**`}`

- To prevent support for all SNMP access, or SNMPv1/v2c access only, or SNMPv3 access only, use the following command:

  `disable snmp access {`**`snmp-v1v2c`** `|` **`snmpv3`**`}`

Most of the commands that support SNMPv1/v2c use the keyword **`snmp`**; most of the commands that support SNMPv3 use the keyword **`snmpv3`**.

After a switch reboot, all slots must be in the "Operational" state before SNMP can manage and access the slots. To verify the current state of the slot, use the `show slot` command.

Understanding Safe Defaults Mode and SNMP

The safe defaults mode runs an interactive script that allows you to enable or disable *SNMP*, Telnet, and switch ports.

When you set up your switch for the first time, you must connect to the console port to access the switch. After logging in to the switch, you enter safe defaults mode. Although Telnet and switch ports are enabled by default, the script prompts you to confirm those settings or disable them.

SNMP is disabled by default. If you choose to enable SNMP, the switch follows the interactive script asking you if you want to enable SNMPv1/v2c and/or SNMPv3.

For more detailed information about safe defaults mode, see .

Enabling and Disabling SNMP Access on Virtual Routers

Beginning with ExtremeXOS 12.4.2 software, you can enable and disable *SNMP* access on any or all VRs. By default, SNMP access is enabled on all VRs.

When SNMP access is disabled on a VR, incoming SNMP requests are dropped and the following message is logged:

`SNMP is currently disabled on VR <vr_name> Hence dropping the SNMP requests on this VR.`

SNMP access for a VR has global SNMP status that includes all SNMPv1v2c, SNMPv3 default users and default group status. However, trap receiver configuration and trap enabling/disabling are independent of global SNMP access and are still forwarded on a VR that is disabled for SNMP access.

- Enable SNMP access on a VR:

  `enable snmp access vr [`*`vr_name`* `|` **`all`**`]`

- Disable SNMP access on a VR, use the following command:

  `disable snmp access vr [`*`vr_name`*` | `**`all`**`]`

- Display the SNMP configuration and statistics on a VR:

  `show snmp {`**`vr`**`} `*`vr_name`*

Accessing Switch Agents

To access the _SNMP_ agent residing in the switch, at least one _VLAN_ must have an assigned IP address. ExtremeXOS supports either IPv4 or IPv6 addresses to manage the switch.

By default, SNMP access and SNMPv1/v2c traps are enabled. SNMP access and SNMP traps can be disabled and enabled independently—you can disable SNMP access but still allow SNMP traps to be sent, or vice versa.

Return-to-Normal SNMP Notifications

This feature implements two new _SNMP_ notifications that indicate that an alert condition has "returned-to-normal". The first notification addresses CPU utilization. Currently, ExtremeXOS allows you to monitor the CPU utilization and history for all of the processes running on the switch. When this function is enabled, a CPU threshold value is used to flag a process in the system that has exceeded the threshold. A SNMP notification is generated for processes exceeding that threshold. When a process' cpu utilization falls back below the configured threshold, this feature adds support to generated a new "return-to-normal" notification.

The second notification is a "return-to-normal" message that corresponds to a previously generated overheat notification. The overheat notification indicates that the on board temperature sensor has reported a overheat condition. When the on board temperature sensor reports the clearing of an overheat condition, the new "return-to-normal" notification is generated.

Supported MIBs

Standard MIBs supported by the switch. In addition to private MIBs, the switch supports the standard MIBs listed in Supported Standards, Protocols, and MIBs on page 2017.

Configuring SNMPv1/v2c Settings

The following SNMPv1/v2c parameters can be configured on the switch:

- **Authorized trap receivers**—An authorized trap receiver can be one or more network management stations on your network. The switch sends SNMPv1/v2c traps to all configured trap receivers. You can specify a community string and UDP port individually for each trap receiver. All community strings must also be added to the switch using the `configure snmp add community` command.

To configure a trap receiver on a switch, use the following command:

> **Note**
> It is recommended to use a different community name for the trap receiver
> and other _SNMP_ read/write operations.

```
configure snmp add trapreceiver [ip_address | ipv6_address] community
[[hex hex_community_name] | community_name] {port port_number} {from
[src_ip_address | src_ipv6_address]} {vr vr_name} {mode trap_mode}
```

To configure the notification type (trap/inform), use the following command
specifying trap as the type:

```
configure snmpv3 add notify [[hex hex_notify_name] | notify_name] tag
[[hex hex_tag] | tag] {type [trap | inform]}{volatile}
```

To delete a trap receiver on a switch, use the following command:

```
configure snmp delete trapreceiver [[ip_address | ipv6_address]
{port_number} | all]
```

Entries in the trap receiver list can also be created, modified, and deleted using the
RMON2 trapDestTable MIB table, as described in RFC 2021.

- SNMP INFORM—SNMP INFORM allows for confirmation of a message delivery.
  When an SNMP manager receives an INFORM message from an SNMP agent, it
  sends a confirmation response back to the agent. If the message has not been
  received and therefore no response is returned, the INFORM message is resent. You
  can configure the number of attempts to make and the interval between attempts.

  To configure the notification type (trap/inform), use the following command
  specifying inform as the type:

```
configure snmpv3 add notify [[hex hex_notify_name] | notify_name] tag
[[hex hex_tag] | tag] {type [trap | inform]}{volatile}
```

  To configure the number of SNMP INFORM notification retries, use the following
  command:

```
configure snmpv3 target-addr [[hex hex_addr_name] | addr_name] retry
retry_count
```

  To configure the SNMP INFORM timeout interval, use the following command:

```
configure snmpv3 target-addr [[hex hex_addr_name] | addr_name] timeout
timeout_val
```

- Community strings—The community strings allow a simple method of
  authentication between the switch and the remote network manager. There are two
  types of community strings on the switch:
  - Read community strings provide read-only access to the switch.
  - Read-write community strings provide read- and-write access to the switch.

  To store and display the SNMP community string in encrypted format, use the
  following command:

```
configure snmpv3 add community [[hex hex_community_index] |
community_index] [encrypted name community_name | name [[hex
hex_community_name] | community_name] {store-encrypted} ] user
[[hex hex_user_name] | user_name] {tag [[hex transport_tag] |
transport_tag]]} {volatile}
```

> **Note**
> SNMP community string name can contain special characters.

- **System contact** (optional)—The system contact is a text field that enables you to enter the name of the person(s) responsible for managing the switch.
- **System name** (optional)—The system name enables you to enter a name that you have assigned to this switch. The default name is the model name of the switch (for example, BD-1.2).
- **System location** (optional)—Using the system location field, you can enter the location of the switch.

Displaying SNMP Settings

To view _SNMP_ settings configured on the switch, use the following command:

```
show switch management
```

This command displays the following information:

- Enable/disable state for Telnet and SNMP access
- Login statistics
- Enable/disable state for idle timeouts
- Maximum number of CLI sessions
- SNMP community strings
- SNMP notification type (trap or INFORM)
- SNMP trap receiver list
- SNMP trap receiver source IP address
- SNMP statistics counter
- SSH access state (enabled/disabled).
- CLI configuration logging
- SNMP access states of v1, v2c disabled and v3 enabled
- Enable/disable state for Remote Monitoring (RMON)
- Access-profile usage configured via ACLs for additional Telnet, SSH2 security, SNMP, and HTTP(s)
- CLI scripting settings
- Enable/disable state
- Error message setting
- Persistence mode
- Dropped SNMP packet counter

ExtremeXOS SNMP Notification Log

SNMP traps and informs are two methods that an Network Element (NE) uses to notify an NMS about an autonomous events that occur on the NE. SNMP traps are unacknowledged notifications, while SNMP informs are acknowledged by the recipient (typically a management station). Sometimes SNMP notifications sent by an NE fail to be received by the management station. Typically, when a failure clears, the management station will re-sync its view of the NE state with the actual NE state.

Re-syncs are costly because the management station has to read the entire state of the NE, even if the changes in the state of the NE during the downtime are minimal. To reduce the need a full re-sync, ExtremeXOS adds a notification log to the NE. The log is populated with notifications sent by the NE to management stations. After a network or management station failure, the management station can read the log to see what events occurred during the downtime, thus eliminating the need for a full re-sync.

SNMP Notification Logs Overview

This feature offers users, or a management station, the ability to define multiple *SNMP* notification logs that keep track of the SNMP notifications (either an SNMP trap, or an SNMP inform) sent by the NE to management stations. A notification log has a name and a notification filter profile associated with it. The name is used to uniquely identify the log, and the filter profile defines which notifications generated by the NE are added to the log, and which notifications are not.

A log is also associated with the security credentials (SNMP user name, SNMP security model, and SNMP security level) that are used to create the log. Notifications that are added to a log are restricted to the notifications that can be accessed using these security credentials. You can also create a default log (a null-named log). The default log does not have security credentials associated with it, so it does not implement any access checks.

A notification log is limited in the number of notifications that it can store by a global entry limit, and a log entry limit, both of which can be changed. The global entry limit specifies the number of notifications that are present in all logs combined, while the log entry limit specifies the number of entries that are present for a specific log. You can also let the system manage the log entry limit, in which case the log can use all available free space within the limit specified by the global entry limit.

You can also enable aging of log entries by configuring an age-out period for them. When enabled, log entries that are older than the specified period are removed from the log.

The information stored in a log for each notification entry includes the following:

- The value of system up time at which the notification was generated.
- The date and time at which the notification was generated.
- The context for the notification.
- The object ID of the notification.
- The list of var-binds that is present in the notification.

After the SNMP agent is restarted, the value of system up time when the notification was generated is reset to 0 for all entries that are present in the log. This serves as an indication to log viewers that the SNMP agent restarted.

Enabling and Disabling SNMP Notification Logs

To enable SNMP notification logging, create an entry in nlmConfigLogTable. After you create an entry, you can control the administrative status of the entry through both nlmConfigLogAdminStatus and nlmConfigLogEntryStatus MIB objects. You can view the operational status of the log using the nlmConfigLogOperStatus MIB object. You must associate an existing filter profile with the log for it to become operational.

Log Size Limits

You can set the maximum number of notification that can be logged at both the system level, and the individual log level. These limits are controlled through the nlmConfigGlobalEntryLimit and nlmConfigLogEntryLimit MIB objects, respectively. The sum of the values of nlmConfigLogEntryLimit for all entries cannot exceed nlmConfigGlobalEntryLimit.

If you try to set the value of nlmConfigLogEntryLimit so the sum of the values of nlmConfigLogEntryLimit for all entries exceeds the nlmConfigGlobalEntryLimit, the set operation is rejected. Similarly if you try to reduce the value of nlmConfigGlobalEntryLimit so that sum of the values of the nlmConfigLogEntryLimit for all entries exceeds the new value for nlmConfigGlobalEntryLimit, the operation is rejected. You can also set the nlmConfigLogEntryLimit to 0 (system-managed). If the entry limit for a log is set to 0, the log can use all available free space within the limit specified by nlmConfigGlobalEntryLimit.

Aging

You can specify an age limit in minutes for notifications in the log through the nlmConfigGlobalAgeOut MIB object. When a notification entry grows older than the specified age limit, the notification entry is deleted. You can disable aging of log entries by setting the value of this object to 0.

Access Control

When a named log is enabled moving the nlmConfigLogEntryStatus object of the log to the active state, the NE associates the security credentials used to perform that operation with the log. A notification may be added to the log only if the notification and the var-binds in the notification can be accessed using these security credentials. Access control does not apply to the default log (null-named log). The default log is not associated with any security credentials, so notifications are added to the default log without any access control restrictions.

Benefits and Limitations

Benefits

The ExtremeXOS *SNMP* Notification Log feature has the following benefits:
- Ability to create multiple SNMP notification logs.
- Ability to restrict SNMP notifications that are added to a log.

- Ability to age log entries.
- Ability to limit the maximum number of entries in a log.
- Ability to control the feature through both CLI and SNMP.

Limitations

- No capability to query log entries by time duration (for example, list log entries from the last hour).
- The notification log name "default" is reserved to represent the default log in CLI. You cannot create a notification log with the name "default".
- Aging out of entries may occur sooner, or later, than the global age out period that you specify if the current time of the NE is changed.
- Notification log statistics (but not entries) are lost on a restart of the SNMP Master process.
- Notification log statistics (but not entries) are lost on failover.
- Notification log entries and statistics are lost if the NE is rebooted.

Logging Operation

This section discusses operation of the notification-log feature when a notification is generated by the NE.

Logging

When a notification is generated by a NE, it is added to each log that exists in nlmConfigLogTable and satisfies the following conditions:

- The notification log is enabled and active.
- The security credentials associated with the log permit acces to the notification and all the var-binds contained in the notification. This condition does not apply to the default log as it is not associated with any security credentials.
- The filter associated with the log exists and is active and does not filter out the notification.

Before adding a notification to a log, the NE makes sure that the log size limits are not exceeded by this addition in the following manner:

- For system managed logs (i.e. nlmConfigLogEntryLimit is set to 0):
  ◦ If the total number of entries in all logs combined is equal to the global entry limit (nlmConfigGlobalEntryLimit), then the oldest entry from the system managed log with the largest number of entries is removed before adding the new notification to the log.

- For logs with user defined size limits (i.e. nlmConfigLogEntryLimit is set to a value greater than 0):
  ◦ If the number of entries in the log is equal to the entry limit of the log (nlmConfigLogEntryLimit), the oldest notification is removed from the log before adding the new notification to the log.
  ◦ If the number of entries in the log is less than the entry limit of the log (nlmConfigLogEntryLimit), but the total number of entries in all logs combined is

equal to the global entry limit (nlmConfigGlobalEntryLimit), then the oldest entry from the system managed log with the largest number of entries is removed before adding the new notification to the log.

Aging

Periodically (every minute), the notification log module calculates the difference between the current time and the time the notification entry is added to a log for each notification entry in each log. If the time difference is greater than the global age out period, the entry is removed from the log. Aging in this manner imposes a limitation that entries may be aged out sooner or later than the actual global age out period if the current time of the NE is changed (for example, to DST changes). Implementing age out accurately consumes 4 additional bytes of memory per notification entry.

Statistics

In ExtremeXOS Release 15.5, the following *SNMP* Notification Logs statistics are available:

- Total number of notifications that have been logged since the NE last restarted.
- Total number of notifications that have been removed due to size constraints since the NE last restarted.
- Per log number of notifications logged since the NE last restarted.
- Per log number of notifications removed due to size constraints since the NE last restarted.

Configuration Examples

The following sections provide various examples of the SNMP Notification Log feature.

Log all notifications

The following example illustrates how to log all notifications sent by a switch, and retain them for as long as possible. However, to reduce memory usage, you might want to limit the number of notifications in all logs to 5000 entries:

```
configure snmp notification-log global-entry-limit 5000
```

Disable aging of notification entries.

```
configure snmp notification-log global-age-out none
```

Create the default log. Because you want to log all notifications, the default log can be used instead of a named log, because it does not impose any security checks.

```
configure snmp add notification-log default
```

Create a filter that accepts all notifications.

```
configure snmpv3 add filter "all" subtree 1 type included
```

Attach the filter to the log.

```
configure snmp notification-log "default" filter-profile-name "all"
```

View the configuration, status and entries of the default log.

```
show snmp notification-log "default"
```

View entry number 1 of the default log in detail.

```
show snmp notification-log "default" entry 1
```

Log all notifications using security

The following example illustrates how to log all notifications that are visible to the SNMP user "monitor" when using the security mode 'USM', and the security level 'privacy'.

Create the log and associate it with the security credentials of the user "monitor".

```
configure snmp add notification-log "monitor-log" user "monitor" sec-model usm sec-level
priv
```

Create a filter including only all traps.

```
configure snmpv3 add filter "all" subtree 1 type included
```

Attach the filter to the log.

```
configure snmp notification-log "monitor-log" filter-profile-name "all"
```

View the configuration, status and entries of "monitor-log".

```
show snmp notification-log "monitor-log"
```

View entry number 1 of "monitor-log" log in detail.

```
show snmp notification-log "monitor-log" entry 1
```

NMS logs all link status change notifications

The following example illustrates the configuration for when an NMS wants to log all link status change notifications. The NMS queries the log every hour, and wants to age out the log entries every two hours. Additionally, to ensure that link status events are not replaced by other events, the NMS wants to reserve 1000 entries for this log.

- Create a notification filter profile including both linkUp and linkDown OIDs.
```
snmpNotifyFilterMask.11."link-status".1.3.6.1.6.3.1.1.5.3 = ''H
snmpNotifyFilterType.11."link-status".1.3.6.1.6.3.1.1.5.3 = include
snmpNotifyFilterStorageType.11."link-status".1.3.6.1.6.3.1.1.5.3 = nonVolatile
snmpNotifyFilterRowStatus.11."link-status".1.3.6.1.6.3.1.1.5.3 = createAndGo
snmpNotifyFilterMask.11."link-status".1.3.6.1.6.3.1.1.5.4 = ''H
snmpNotifyFilterType.11."link-status".1.3.6.1.6.3.1.1.5.4 = include
snmpNotifyFilterStorageType.11."link-status".1.3.6.1.6.3.1.1.5.4 = nonVolatile
snmpNotifyFilterRowStatus.11."link-status".1.3.6.1.6.3.1.1.5.4 = createAndGo
```

- Create a named log for link status notifications, attach the profile created above, and set its entry limit to 1000. The SNMP operation of creating this entry must be performed using security credentials that have access to the linkUp and linkDown notifications.
```
nlmConfigLogFilterName.5."links" = "link-status"
nlmConfigLogEntryLimit.5."links" = 1000
nlmConfigLogAdminStatus.5."links" = enabled
nlmConfigLogStorageType.5."links" = nonVolatile
nlmConfigLogEntryStatus.5."links" = createAndGo
```

- Set the global age-out to 120 minutes.
  ```
  nlmConfigGlobalAgeOut.0 = 120
  ```
- To view the log contents, the NMS must query nlmLogTable and nlmLogVariableTable.

SNMPv3

SNMPv3 is an enhanced standard for *SNMP* that improves the security and privacy of SNMP access to managed devices and provides sophisticated control of access to the device MIB. The prior standard versions of SNMP, SNMPv1, and SNMPv2c, provided no privacy and little security.

> **Note**
> If you downgrade from ExtremeXOS 15.6 to a lower version, the SNMPv3 users do not work if the configuration was saved in 15.6. The SNMPv3 users must be manually created again.

The following RFCs provide the foundation for the Extreme Networks implementation of SNMPv3:

- RFC 3410, Introduction to version 3 of the Internet-standard Network Management Framework, provides an overview of SNMPv3.
- RFC 3411, An Architecture for Describing SNMP Management Frameworks, talks about SNMP architecture, especially the architecture for security and administration.
- RFC 3412, Message Processing and Dispatching for the Simple Network Management Protocol (SNMP), talks about the message processing models and dispatching that can be a part of an SNMP engine.
- RFC 3413, SNMPv3 Applications, talks about the different types of applications that can be associated with an SNMPv3 engine.
- RFC 3414, The User-Based Security Model for Version 3 of the Simple Network Management Protocol (SNMPv3), describes the User-Based Security Model (USM).
- RFC 3415, View-based Access Control Model (VACM) for the Simple Network Management Protocol (SNMP), talks about VACM as a way to access the MIB.
- RFC 3826, The Advanced Encryption Standard (AES) Cipher Algorithm in the SNMP User-based Security Model.

> **Note**
> 3DES, AES 192 and AES 256 bit encryption are proprietary implementations and may not work with some SNMP Managers.

The SNMPv3 standards for network management were driven primarily by the need for greater security and access control. The new standards use a modular design and model management information by cleanly defining a message processing (MP) subsystem, a security subsystem, and an access control subsystem.

The MP subsystem helps identify the MP model to be used when processing a received Protocol Data Unit (PDU), which are the packets used by SNMP for communication.

The MP layer helps in implementing a multilingual agent, so that various versions of SNMP can coexist simultaneously in the same network.

The security subsystem features the use of various authentication and privacy protocols with various timeliness checking and engine clock synchronization schemes.

SNMPv3 is designed to be secure against:

- Modification of information, where an in-transit message is altered.
- Masquerades, where an unauthorized entity assumes the identity of an authorized entity.
- Message stream modification, where packets are delayed and/or replayed.
- Disclosure, where packet exchanges are sniffed (examined) and information is learned about the contents.

The access control subsystem provides the ability to configure whether access to a managed object in a local MIB is allowed for a remote principal. The access control scheme allows you to define access policies based on MIB views, groups, and multiple security levels.

In addition, the SNMPv3 target and notification MIBs provide a more procedural approach for generating and filtering of notifications.

SNMPv3 objects are stored in non-volatile memory unless specifically assigned to volatile storage. Objects defined as permanent cannot be deleted.

> **Note**
> In SNMPv3, many objects can be identified by a human-readable string or by a string of hexadecimal octets. In many commands, you can use either a character string, or a colon-separated string of hexadecimal octets to specify objects. To indicate hexadecimal octets, use the keyword hex in the command.

Message Processing

A particular network manager may require messages that conform to a particular version of _SNMP_. The choice of the SNMPv1, SNMPv2c, or SNMPv3 MP model can be configured for each network manager as its target address is configured. The selection of the MP model is configured with the **mp-model** keyword in the following command:

```
configure snmpv3 add target-params [[hex hex_param_name] |
param_name ]user [[hex hex_user_name] | user_name] mp-model [snmpv1 |
snmpv2c | snmpv3] sec-model [snmpv1 | snmpv2c | usm] {sec-level [noauth
| authnopriv | priv]} {volatile}
```

SNMPv3 Security

In SNMPv3 the User-Based Security Model (USM) for _SNMP_ was introduced. USM deals with security related aspects like authentication, encryption of SNMP messages, and defining users and their various access security levels. This standard also encompasses protection against message delay and message replay.

USM Timeliness Mechanisms

>An Extreme Networks switch has one SNMPv3 engine, identified by its snmpEngineID. The first four octets are fixed to 80:00:07:7C, which represents the Extreme Networks vendor ID. By default, the additional octets for the snmpEngineID are generated from the device MAC address.

>Every SNMPv3 engine necessarily maintains two objects: SNMPEngineBoots, which is the number of reboots the agent has experienced and SNMPEngineTime, which is the local time since the engine reboot. The engine has a local copy of these objects and the latestReceivedEngineTime for every authoritative engine it wants to communicate with. Comparing these objects with the values received in messages and then applying certain rules to decide upon the message validity accomplish protection against message delay or message replay.

>In a SummitStack, the MAC address chosen for the snmpEngineID is the configured stack MAC address.

Configuring USM Timeliness Mechanism

>Configure the snmpEngineID and SNMPEngineBoots from the command line. The snmpEngineID can be configured from the command line, but when the snmpEngineID is changed, default users revert back to their original passwords/keys, and non-default users are removed from the device.

>SNMPEngineBoots can be set to any desired value but will latch on its maximum, 2147483647.

>1. To set the snmpEngineID, use the following command:

>   ```
>   configure snmpv3 engine-id hex_engine_id
>   ```

>2. To set the SNMPEngineBoots, use the following command:

>   ```
>   configure snmpv3 engine-boots (1-2147483647)
>   ```

Users, Groups, and Security

>SNMPv3 controls access and security using the concepts of users, groups, security models, and security levels.

>Users are created by specifying a user name. Depending on whether the user will be using authentication and/or privacy, you would also specify an authentication protocol (RSA Data Security, Inc. *MD5* Message-Digest Algorithm or SHA) with password or key, and/or privacy (DES, 3DES, AES) password or key.

Managing Users

>Users are created by specifying a user name. Enabling the SNMPv3 default-user access allows an end user to access the MIBs using SNMPv3 default-user.By disabling default-users access, the end-user is not able to access the switch/MIBs using SNMPv3 default-user.

>• To create a user, use the following command:

>   ```
>   configure snmpv3 add user [[hex hex_user_name] | user_name]
>   {authentication [md5 | sha] [hex hex_auth_password | auth_password]}
>   ```

```
{privacy {des | 3des | aes {128 | 192 | 256}} [[hex hex_priv_password]
| priv_password]} }{volatile}
```

A number of default users are initially available. These user names are: admin, initial, initialmd5, initialsha, initialmd5Priv, initialshaPriv. The default password for admin is *password*. For the other default users, the default password is the user name.

- To display information about a user, or all users, use the following command:

```
show snmpv3 user {[[hex hex_user_name] | user_name]}
```

- To delete a user, use the following command:

```
configure snmpv3 delete user [all | [[hex hex_user_name] | user_name]
{engine-id engine_id}]
```

> **Note**
> The SNMPv3 specifications describe the concept of a security name. In the ExtremeXOS implementation, the user name and security name are identical. In this manual, both terms are used to refer to the same thing.

Managing Groups

Groups are used to manage access for the MIB. You use groups to define the security model, the security level, and the portion of the MIB that members of the group can read or write.

The security model and security level are discussed in Security Models and Levels on page 124. The view names associated with a group define a subset of the MIB (subtree) that can be accessed by members of the group. The read view defines the subtree that can be read, write view defines the subtree that can be written to, and notify view defines the subtree that notifications can originate from. MIB views are discussed in Setting SNMPv3 MIB Access Control on page 125.

A number of default groups are already defined. These groups are: admin, initial, v1v2c_ro, v1v2c_rw.

Enabling SNMPv3 default-group access activates the access to an SNMPv3 default group and the user- created SNMPv3-user part of default group.

Disabling SNMPv3 default-group access removes access to default-users and user-created users who are part of the default-group.

The user-created authenticated SNMPv3 users (who are part of a user-created group) are able to access the switch.

- To underscore the access function of groups, groups are defined using the following command:

```
configure snmpv3 add access [[hex hex_group_name] | group_name] {sec-
model [snmpv1 | snmpv2c | usm]} {sec-level [noauth | authnopriv |
priv]} {read-view [[hex hex_read_view_name] | read_view_name]} {write-
```

       view [[**hex** *hex_write_view_name*]] | *write_view_name*]} {**notify-view**
       [[**hex** *hex_notify_view_nam*]] | *notify_view_name*]} {**volatile**}

- To display information about the access configuration of a group or all groups, use the following command:

       show snmpv3 access {[[**hex** *hex_group_name*] | *group_name*]}

- To enable default-group, use the following command:

       enable snmpv3 **default-group**

- To disable a default-group, use the following command:

       disable snmpv3 **default-group**

- To associate users with groups, use the following command:

       configure snmpv3 add group [[**hex** *hex_group_name*] | *group_name*] **user**
       [[**hex** *hex_user_name*] | *user_name*] {**sec-model** [**snmpv1**| **snmpv2c** | **usm**]}
       {**volatile**}

- To show which users are associated with a group, use the following command:

       show snmpv3 group {[[**hex** *hex_group_name*] | *group_name*] {**user** [[**hex**
       hex_user_name] | *user_name*]}}

- To delete a group, use the following command:

       configure snmpv3 delete access [**all-non-defaults** | {[[**hex**
       hex_group_name] | *group_name*] {**sec-model** [**snmpv1** | **snmpv2c** | **usm**] **sec-**
       level [**noauth** | **authnopriv** | **priv**]}}]

       When you delete a group, you do not remove the association between the group and users of the group.

- To delete the association between a user and a group, use the following command:

       configure snmpv3 delete group {[[**hex** *hex_group_name*] | *group_name*]}
       user [**all-non-defaults** | {[[**hex** *hex_user_name*] | *user_name*] {**sec-model**
       [**snmpv1**|**snmpv2c**|**usm**]}}]

Security Models and Levels

For compatibility, SNMPv3 supports three security models:

- SNMPv1—no security
- SNMPv2c—community strings-based security
- SNMPv3—USM security

The default is USM. You can select the security model based on your network manager.

The three security levels supported by USM are:

- noAuthnoPriv—No authentication, no privacy. This is the case with existing SNMPv1/v2c agents.
- AuthnoPriv—Authentication, no privacy. Messages are tested only for authentication.
- AuthPriv—Authentication, privacy. This represents the highest level of security and requires every message exchange to pass the authentication and encryption tests.

When a user is created, an authentication method is selected, and the authentication and privacy passwords or keys are entered.

When RSA Data Security, Inc. _MD5_ Message-Digest Algorithm authentication is specified, HMAC-MD5-96 is used to achieve authentication with a 16-octet key, which generates a 128-bit authorization code. This authorization code is inserted in the msgAuthenticationParameters field of SNMPv3 PDUs when the security level is specified as either AuthnoPriv or AuthPriv. Specifying SHA authentication uses the HMAC-SHA protocol with a 20-octet key for authentication.

For privacy, the user can select any one of the following supported privacy protocols: DES, 3DES, AES 128/192/256. In the case of DES, a 16-octet key is provided as input to DES-CBS encryption protocol which generates an encrypted PDU to be transmitted. DES uses bytes 1-7 to make a 56 bit key. This key (encrypted itself) is placed in msgPrivacyParameters of SNMPv3 PDUs when the security level is specified as AuthPriv.

The _SNMP_ Context Name should be set to the _VR_ name for which the information is requested. If the Context Name is not set the switch will retrieve the information for "_VR-Default_". If the SNMP request is targeted for the protocols running per _VR_ (see Adding and Deleting Routing Protocols on page 732), then the contextName should be set to the exact virtual-Router for which the information is requested. List of protocols running per Virtual Router:

- _BGP_
- _OSPF_
- PIM
- _RIP_
- _OSPFv3_
- RIPNG
- _MPLS (Multiprotocol Label Switching)_
- ISIS

Setting SNMPv3 MIB Access Control

SNMPv3 provides a fine-grained mechanism for defining which parts of the MIB can be accessed. This is referred to as the View-Based Access Control Model (VACM).

MIB views represent the basic building blocks of VACM. They are used to define a subset of the information in the MIB. Access to read, to write, and to generate notifications is based on the relationship between a MIB view and an access group. The users of the access group can then read, write, or receive notifications from the part of the MIB defined in the MIB view as configured in the access group.

A view name, a MIB subtree/mask, and an inclusion or exclusion define every MIB view. For example, there is a System group defined under the MIB-2 tree. The Object Identifier (OID) for MIB-2 is 1.3.6.1.2, and the System group is defined as MIB-2.1.1, or directly as 1.3.6.1.2.1.1.

When you create the MIB view, you can choose to include the MIB subtree/mask or to exclude the MIB subtree/mask.

In addition to the user-created MIB views, there are three default views: defaultUserView, defaultAdminView, and defaultNotifyView.

MIB views that are used by security groups cannot be deleted.

• To define a MIB view which includes only the System group, use the following subtree/mask combination:
  1.3.6.1.2.1.1/1.1.1.1.1.1.1.0

  The mask can also be expressed in hex notation (used in the ExtremeXOS CLI):

  1.3.6.1.2.1.1/fe

• To define a view that includes the entire MIB-2, use the following subtree/mask:
  1.3.6.1.2.1.1/1.1.1.1.1.0.0.0

  which, in the CLI, is:

  1.3.6.1.2.1.1/f8

• To create a MIB view, use the following command:
  ```
  configure snmpv3 add mib-view [[hex hex_view_name] | view_name]
  subtree object_identifier {subtree_mask} {type [included | excluded]}
  {volatile}
  ```

  After the view has been created, you can repeatedly use the `configure snmpv3 add mib-view` command to include and/or exclude MIB subtree/mask combinations to precisely define the items you want to control access to.

• To show MIB views, use the following command:
  ```
  show snmpv3 mib-view {[[hex hex_view_name] | view_name] {subtree
  object_identifier}}
  ```

• To delete a MIB view, use the following command:
  ```
  configure snmpv3 delete mib-view [all-non-defaults | {[[hex
  hex_view_name] | view_name] {subtree object_identifier}}]
  ```

SNMPv3 Notification

SNMPv3 can use either SNMPv1 traps or SNMPv2c notifications to send information from an agent to the network manager.

The terms *trap* and *notification* are used interchangeably in this context. Notifications are messages sent from an agent to the network manager, typically in response to some state change on the agent system. With SNMPv3, you can define precisely which traps you want sent, to which receiver by defining filter profiles to use for the notification receivers.

To configure notifications, you configure a target address for the target that receives the notification, a target parameters name, and a list of notification tags. The target parameters specify the security and MP models to use for the notifications to the target. The target parameters name also points to the filter profile used to filter the notifications. Finally, the notification tags are added to a notification table so that any target addresses using that tag will receive notifications.

Configuring Target Addresses

A target address is similar to the earlier concept of a trap receiver.

- To configure a target address, use the following command:

```
configure snmpv3 add target-addr [[hex hex_addr_name] | addr_name]
param [[hex hex_param_name] |param_name ] ipaddress [ ip_address
| ipv4-with-mask ip_and_tmask ] | [ ipv6_address | ipv6-with-mask
ipv6_and_tmask ]] {transport-port port_number} {from [src_ip_address
| src_ipv6_address]} {vr vr_name} {tag-list [tag_list | hex
hex_tag_list]} {volatile}
```

In configuring the target address you supply an address name that identifies the target address, a parameters name that indicates the MP model and security for the messages sent to that target address, and the IP address and port for the receiver. The parameters name also is used to indicate the filter profile used for notifications.

The **from** option sets the source IP address in the notification packets.

The **tag-list** option allows you to associate a list of tags with the target address. The tag defaultNotify is set by default.

- To display target addresses, use the following command:

```
show snmpv3 target-addr {[[hex hex_addr_name] | addr_name]}
```

- To delete a single target address or all target addresses, use the following command:

```
configure snmpv3 delete target-addr [{[[hex hex_addr_name] |
addr_name]} | all]
```

Managing Notification Tags

When you create a target address, either you associate a list of notification tags with the target or by default, the defaultNotify tag is associated with the target. When the system generates notifications, only those targets associated with tags currently in the standard MIB table, called snmpNotifyTable, are notified.

> **Note**
> This notification entry can be deleted via CLI and also via MIB. If this is deleted, then this can result in the traps not being sent for trap receivers which do not have the tag-list value mentioned explicitly.

- To add an entry to the table, use the following command:

```
configure snmpv3 add notify [[hex hex_notify_name] | notify_name] tag
[[hex hex_tag] | tag] {type [trap | inform]}{volatile}
```

Any targets associated with tags in the snmpNotifyTable are notified, based on the filter profile associated with the target.

- To display the notifications that are set, use the following command:

```
show snmpv3 notify {[[hex hex_notify_name] | notify_name]}
```

- To delete an entry from the snmpNotifyTable, use the following command:

```
configure snmpv3 delete notify [{[[hex hex_notify_name] |
notify_name]} | all-non-defaults]
```

Configuring Notifications

Because the target parameters name points to a number of objects used for notifications, configure the target parameter name entry first.

You can then configure the target address, filter profiles and filters, and any necessary notification tags.

Access Profile Logging for SNMP

The access profile logging feature allows you to use an *ACL* policy file or dynamic ACL rules to control access to *SNMP* services on the switch.

When access profile logging is enabled for SNMP, the switch logs messages and increments counters when packets are denied access to SNMP. No messages are logged for permitted access.

You can manage SNMP access using one (not both) of the following methods:

- Create and apply an ACL policy file.
- Define and apply individual ACL rules.

One advantage of ACL policy files is that you can copy the file and use it on other switches. One advantage to applying individual ACL rules is that you can enter the rules at the CLI command prompt, which can be easier than opening, editing, and saving a policy file.

ACL Match Conditions and Actions

The ACLs section describes how to create *ACL* policies and rules using match conditions and actions. Access profile logging supports the following match conditions and actions:

- Match conditions
  - Source-address—IPv4 and IPv6
- Actions
  - Permit
  - Deny

If the ACL is created with more match conditions or actions, only those listed above are used for validating the packets. All other conditions and actions are ignored.

The source-address field allows you to identify an IPv4 address, IPv6 address, or subnet mask for which access is either permitted or denied.

If the *SNMP* traffic does not match any of the rules, the default behavior is deny.

Limitations

Access profile logging for _SNMP_ has the following limitations:

- Either policy files or _ACL_ rules can be associated with SNMP, but not both at the same time.
- Only source-address match is supported.
- Access-lists that are associated with one or more applications (SNMP or Telnet, for example) cannot be directly deleted. They must be unconfigured from the application first and then deleted from the CLI.
- Default counter support is added only for ACL rules and not for policy files.

Managing ACL Policies for SNMP

The ACLs section describes how to create _ACL_ policy files.

- Configure _SNMP_ to use an ACL policy using one of the following commands:

```
configure snmp access-profile profile_name
configure snmp access-profile profile_name readonly
configure snmp access-profile profile_name readwrite
```

  By default, SNMP supports the **readwrite** option. However, you can specify the **readonly** or **readwrite** option to change the current configuration.

- To configure SNMP to remove a previously configured ACL policy, use the following command:

```
configure snmp access-profile none
```

Managing ACL Rules for SNMP

Before you can assign an _ACL_ rule to SNMP, you must create a dynamic ACL rule as described in ACLs.

- To add or delete a rule for _SNMP_ access, use the following command:

```
configure snmp access-profile [ access_profile {readonly | readwrite}
| [[add rule ] [first | [[before | after] previous_rule]]] | delete
rule | none ]
```

- To display the access-list permit and deny statistics for an application, use the following command:

```
show access-list counters process [snmp | telnet | ssh2 | http]
```

Misconfiguration Error Messages

The following messages can appear during configuration of policies or rules for the _SNMP_ service:

`Rule <rule> is already applied`	A rule with the same name is already applied to this service.
`Please remove the policy <policy> already configured, and then add rule <rule>`	A policy file is already associated with the service. You must remove the policy before you can add a rule.
`Rule <previous_rule> is not already applied`	The specified rule has not been applied to the service, so you cannot add a rule in relation to that rule.

`Rule <rule> is not applied`	The specified rule has not been applied to the service, so you cannot remove the rule from the service.
`Error: Please remove previously configured rule(s) before configuring policy <policy>`	A policy or one or more _ACL_ rules are configured for the service. You must delete the remove the policy or rules from the service before you can add a policy.

Using the Simple Network Time Protocol

ExtremeXOS supports the client portion of the _SNTP_ Version 3 based on _RFC4330_.

SNTP can be used by the switch to update and synchronize its internal clock from a Network Time Protocol (NTP) server. After SNTP has been enabled, the switch sends out a periodic query to the indicated NTP server, or the switch listens to broadcast NTP updates. In addition, the switch supports the configured setting for Greenwich Mean time (GMT) offset and the use of Daylight Saving Time.

Configuring and Using SNTP

To use _SNTP_:

1. Identify the host(s) that are configured as NTP server(s). Additionally, identify the preferred method for obtaining NTP updates. The options are for the NTP server to send out broadcasts, or for switches using NTP to query the NTP server(s) directly. A combination of both methods is possible. You must identify the method that should be used for the switch being configured.
2. Configure the Greenwich Mean Time (GMT) offset and Daylight Saving Time preference. The command syntax to configure GMT offset and usage of Daylight Saving Time is as follows:

   ```
   configure timezone {name tz_name} GMT_offset {autodst {name
   dst_timezone_ID} {dst_offset} begins [every floatingday | on
   absoluteday] {at time_of_day_hour time_of_day_minutes} {ends
   [every floatingday | on absoluteday] {at time_of_day_hour
   time_of_day_minutes}}}
   ```

   By default beginning in 2007, Daylight Saving Time is assumed to begin on the second Sunday in March at 2:00 AM, and end the first Sunday in November at 2:00 AM and to be offset from standard time by one hour.

   a. If this is the case in your time zone, you can set up automatic daylight saving adjustment with the command:

   ```
   configure timezone GMT_offset autodst
   ```

   b. If your time zone uses starting and ending dates and times that differ from the default, you can specify the starting and ending date and time in terms of a floating day, as follows:

   ```
   configure timezone name MET 60 autodst name MDT begins every last sunday march
   at 1 30 ends every last sunday october at 1 30
   ```

c. You can also specify a specific date and time, as shown in the following command:

```
configure timezone name NZST 720 autodst name NZDT 60 begins every first sunday
october
at 2 00 ends on 3 16 2004 at 2 00
```

The optional time zone IDs are used to identify the time zone in display commands such as `show switch {detail}`.

Table 16 describes the time zone command options in detail.

Table 16: Time Zone Configuration Command Options

tz_name	Specifies an optional name for this timezone specification. May be up to six characters in length. The default is an empty string.
GMT_offset	Specifies a Greenwich Mean Time (GMT) offset, in + or - minutes.
autodst	Enables automatic Daylight Saving Time.
dst_timezone_ID	Specifies an optional name for this Daylight Saving Time specification. May be up to six characters in length. The default is an empty string.
dst_offset	Specifies an offset from standard time, in minutes. Value is from 1–60. The default is 60 minutes.
floatingday	Specifies the day, week, and month of the year to begin or end Daylight Saving Time each year. Format is *week day month* where: • *week* is specified as [first | second | third | fourth | last] • *day* is specified as [sunday | monday | tuesday | wednesday | thursday | friday | saturday] • *month* is specified as [january | february | march | april | may | june | july | august | september | october | november | december] Default for beginning is second sunday march; default for ending is first sunday november.
absoluteday	Specifies a specific day of a specific year on which to begin or end DST. Format is *month day year* where: • *month* is specified as 1–12 • *day* is specified as 1–31 • *year* is specified as 1970–2035 The year must be the same for the begin and end dates.
time_of_day_hour	Specifies the time of day to begin or end Daylight Saving Time. May be specified as an hour (0–23). The default is 2.
time_of_day_minutes	Specify the minute to begin or end Daylight Saving Time. May be specified as a minute (0–59).
noautodst	Disables automatic Daylight Saving Time.

3. Automatic Daylight Saving Time changes can be enabled or disabled.

The default setting is enabled. To disable automatic Daylight Saving Time, use the command:

```
configure timezone {name tz_name} GMT_offset noautodst
```

4. Enable the SNTP client using the following command:

   ```
   enable sntp-client
   ```

   After SNTP has been enabled, the switch sends out a periodic query to the NTP servers defined in the next step (if configured) or listens to broadcast NTP updates from the network. The network time information is automatically saved into the onboard real-time clock.

5. If you would like this switch to use a directed query to the NTP server, configure the switch to use the NTP server(s). An NTP server can be an IPv4 address or an IPv6 address or a hostname. If the switch listens to NTP broadcasts, skip this step. To configure the switch to use a directed query, use the following command:

   ```
   configure sntp-client [primary | secondary] host-name-or-ip {vr
   vr_name}
   ```

   The following two examples use an IPv6 address as an NTP server and a hostname as an NTP server:

   ```
   configure sntp-client primary fd98:d3e2:f0fe:0:54ae:34ff:fecc:892
   configure sntp-client primary ntpserver.mydomain.com
   ```

   NTP queries are first sent to the primary server. If the primary server does not respond within one second, or if it is not synchronized, the switch queries the secondary server (if one is configured). If the switch cannot obtain the time, it restarts the query process. Otherwise, the switch waits for the sntp-client update interval before querying again.

6. Optionally, the interval for which the SNTP client updates the real-time clock of the switch can be changed using the following command:

   ```
   configure sntp-client update-interval update-interval
   ```

   The default sntp-client update-interval value is 64 seconds.

7. Verify the configuration.

   a. ```show sntp-client```

      This command provides configuration and statistics associated with SNTP and its connectivity to the NTP server.

   b. ```show switch {detail}```

      This command indicates the GMT offset, the Daylight Saving Time configuration and status, and the current local time.

NTP updates are distributed using GMT time.

To properly display the local time in logs and other time-stamp information, the switch should be configured with the appropriate GMT offset to GMT based on geographical location.

GMT Offsets

lists offsets for GMT.

Table 17: Greenwich Mean Time Offsets

GMT Offset in Hours	GMT Offset in Minutes	Common Time Zone References	Cities
+0:00	+0	GMT - Greenwich Mean UT or UTC - Universal (Coordinated) WET - Western European	London, England; Dublin, Ireland; Edinburgh, Scotland; Lisbon, Portugal; Reykjavik, Iceland; Casablanca, Morocco
-1:00	-60	WAT - West Africa	Cape Verde Islands
-2:00	-120	AT - Azores	Azores
-3:00	-180		Brasilia, Brazil; Buenos Aires, Argentina; Georgetown, Guyana
-4:00	-240	AST - Atlantic Standard	Caracas; La Paz
-5:00	-300	EST - Eastern Standard	Bogota, Columbia; Lima, Peru; New York, NY, Trevor City, MI USA
-6:00	-360	CST - Central Standard	Mexico City, Mexico
-7:00	-420	MST - Mountain Standard	Saskatchewan, Canada
-8:00	-480	PST - Pacific Standard	Los Angeles, CA, Santa Clara, CA, Seattle, WA USA
-9:00	-540	YST - Yukon Standard	
-10:00	-600	AHST - Alaska-Hawaii Standard CAT - Central Alaska HST - Hawaii Standard	
-11:00	-660	NT - Nome	
-12:00	-720	IDLW - International Date Line West	
+1:00	+60	CET - Central European FWT - French Winter MET - Middle European MEWT - Middle European Winter SWT - Swedish Winter	Paris France; Berlin, Germany; Amsterdam, The Netherlands; Brussels, Belgium; Vienna, Austria; Madrid, Spain; Rome, Italy; Bern, Switzerland; Stockholm, Sweden; Oslo, Norway
+ 2:00	+120	EET - Eastern European, Russia Zone 1	Athens, Greece; Helsinki, Finland; Istanbul, Turkey; Jerusalem, Israel; Harare, Zimbabwe
+3:00	+180	BT - Baghdad, Russia Zone 2	Kuwait; Nairobi, Kenya; Riyadh, Saudi Arabia; Moscow, Russia; Tehran, Iran
+4:00	+240	ZP4 - Russia Zone 3	Abu Dhabi, UAE; Muscat; Tblisi; Volgograd; Kabul

Table 17: Greenwich Mean Time Offsets (continued)

GMT Offset in Hours	GMT Offset in Minutes	Common Time Zone References	Cities
+5:00	+300	ZP5 - Russia Zone 4	
+5:30	+330	IST - India Standard Time	New Delhi, Pune, Allahabad, India
+6:00	+360	ZP6 - Russia Zone 5	
+7:00	+420	WAST - West Australian Standard	
+8:00	+480	CCT - China Coast, Russia Zone 7	
+9:00	+540	JST - Japan Standard, Russia Zone 8	
+10:00	+600	EAST - East Australian Standard GST - Guam Standard Russia Zone 9	
+11:00	+660		
+12:00	+720	IDLE - International Date Line East NZST - New Zealand Standard NZT - New Zealand	Wellington, New Zealand; Fiji, Marshall Islands
+13:00	+780	PHOT-Phoenix Island Time	Kanton Island
+14:00	+840	LINT-Line Islands Time	Kiritimati

SNTP Example

In this example, the switch queries a specific NTP server and a backup NTP server.

The switch is located in Cupertino, California, and an update occurs every 20 minutes. The commands to configure the switch are as follows:

```
configure timezone -480 autodst
configure sntp-client update-interval 1200
enable sntp-client
configure sntp-client primary 10.0.1.1
configure sntp-client secondary 10.0.1.2
```

Access Profile Logging for HTTP/HTTPS

The access profile logging feature allows you to use dynamic _ACL_ rules to control access to Hypertext Transfer Protocol (HTTP) services on the switch.

When access profile logging is enabled for HTTP, the switch logs messages and increments counters when packets are denied access to HTTP. No messages are logged for permitted access.

> **Note**
> For more information on ExtremeXOS software support for HTTP, see Hypertext Transfer Protocol on page 1193.

You can manage HTTP access using one (not both) of the following methods:

- Create and apply an ACL policy file
- Define and apply individual ACL rules

One advantage of ACL policy files is that you can copy the file and use it on other switches. One advantage to applying individual ACL rules is that you can enter the rules at the CLI command prompt, which can be easier than opening, editing, and saving a policy file.

ACL Match Conditions and Actions

The ACLs section describes how to create *ACL* policies and rules using match conditions and actions. Access profile logging supports the following match conditions and actions:

- Match conditions
  - Source-address—IPv4 and IPv6
- Actions
  - Permit
  - Deny

If the ACL is created with more match conditions or actions, only those listed above are used for validating the packets. All other conditions and actions are ignored.

The source-address field allows you to identify an IPv4 address, IPv6 address, or subnet mask for which access is either permitted or denied.

If the HTTP traffic does not match any of the rules, the default behavior is deny.

Limitations

Access profile logging for HTTP/HTTPS has the following limitations:

- Policy file support is not available for HTTP and HTTPS.
- Only source-address match is supported.
- Access-lists that are associated with one or more applications cannot be directly deleted. They must be unconfigured from the application first and then deleted from the CLI.

Managing ACL Rules for HTTP

Before you can assign an *ACL* rule to HTTP, you must create a dynamic ACL rule as described in ACLs.

- To add or delete a rule for HTTP access, use the following command:

  `configure web http access-profile [[[**add** *rule* ] [**first** | [[**before** | **after**] *previous_rule*]]] | **delete** *rule* | **none** ]`

- To display the access-list permit and deny statistics for an application, use the following command:

  `show access-list counters process [**snmp** | **telnet** | **ssh2** | **http**]`

Misconfiguration Error Messages

The following messages can appear during configuration of policies or rules for the *SNMP* service:

`Rule <rule> is already applied`	A rule with the same name is already applied to this service.
`Please remove the policy <policy> already configured, and then add rule <rule>`	A policy file is already associated with the service. You must remove the policy before you can add a rule.
`Rule <previous_rule> is not already applied`	The specified rule has not been applied to the service, so you cannot add a rule in relation to that rule.
`Rule <rule> is not applied`	The specified rule has not been applied to the service, so you cannot remove the rule from the service.
`Error: Please remove previously configured rule(s) before configuring policy <policy>`	A policy or one or more *ACL* rules are configured for the service. You must delete the remove the policy or rules from the service before you can add a policy.

Managing the ExtremeXOS Software

The ExtremeXOS software platform is a distributed software architecture.

The distributed architecture consists of separate binary images organized into discrete software modules with messaging between them. The software and system infrastructure subsystem form the basic framework of how the ExtremeXOS applications interact with each other, including the system startup sequence, memory allocation, and error events handling. Redundancy and data replication is a built-in mechanism of ExtremeXOS. The system infrastructure provides basic redundancy support and libraries for all of the ExtremeXOS applications.

> **Note**
> For information about downloading and upgrading a new software image, saving configuration changes, and upgrading the BootROM, see Software Upgrade and Boot Options on page 1958.

Like any advanced operating system, ExtremeXOS gives you the tools to manage your switch and create your network configurations.

With the introduction of ExtremeXOS, the following enhancements and functionality have been added to the switch operating system:

- File system administration
- Configuration file management
- Process control
- Memory protection

File system administration

With the enhanced file system, you can move, copy, and delete files from the switch. The file system structure allows you to keep, save, rename, and maintain multiple copies of configuration files on the switch. In addition, you can manage other entities of the switch such as policies and access control lists (ACLs).

Configuration file management

With the enhanced configuration file management, you can oversee and manage multiple configuration files on your switch. In addition, you can upload, download, modify, and name configuration files used by the switch.

Process control

With process control, you can stop and start processes, restart failed processes, and update the software for a specific process or set of processes.

Memory protection

With memory protection, each function can be bundled into a single application module running as a memory protected process under real-time scheduling. In essence, ExtremeXOS protects each process from every other process in the system. If one process experiences a memory fault, that process cannot affect the memory space of another process.

The following sections describe in more detail how to manage the ExtremeXOS software.

Using the ExtremeXOS File System

The file system in ExtremeXOS is the structure by which files are organized, stored, and named.

The switch can store multiple user-defined configuration and policy files, each with its own name. Using a series of commands, you can manage the files on your system. For example, you can rename or copy a configuration file on the switch, display a comprehensive list of the configuration and policy files on the switch, or delete a policy file from the switch.

> **Note**
> File names are case-sensitive. For information on file name restrictions, see the specific command in the *ExtremeXOS 32.4 Command Reference Guide*.

You can also download configuration and policy files from the switch to a network Trivial File Transfer Protocol (TFTP) server using TFTP. For detailed information about downloading switch configurations, see Software Upgrade and Boot Options on page 1958. For detailed information about downloading policies and ACLs, see ACLs on page 781.

With guidance from Extreme Networks Technical Support personnel, you can configure the switch to capture core dump files, which contain debugging information that is useful in troubleshooting situations. For more information about configuring core dump files and managing the core dump files stored on your switch, see Understanding Core Dump Messages on page 1971.

File are stored at:
- USB: `/usr/local/ext`
- Internal memory: `/usr/local/tmp`
- Home directory: `/usr/local/cfg`

The command `ls` without specifying the path returns results for just the home directory.

By default, core dumps are stored in the internal memory space (`/usr/local/tmp`), so to see them, run the command `ls /usr/local/tmp`.

List Files

```
# ls /usr/local/tmp
-rw-r--r-- 1 root root 7429 Sep 22 16:19 core.nvram.1
-rw-r--r-- 1 root root 7100 Sep 28 08:40 core.nvram.2
drwxrwxrwx 2 root root 1024 Sep 28 08:43 dhcp
-rw-rw-rw- 1 root root 1072 Sep 28 08:43 trigger_log_slot1.txt
```

TFTP Files

```
# tftp put 10.6.48.39 /usr/local/tmp/core.nvram.1 mmitchell/core.nvram.1
Uploading core.nvram.1 to 10.6.48.39 ... done!
```

Copy Files

```
# cp /usr/local/tmp/core.nvram.1 core.copy
Copy 'core.nvram.1' from '/usr/local/tmp' to '/usr/local/cfg/core.copy'? (y/N)
```

Move Files

```
# mv /usr/local/tmp/core.nvram.1 core.moveToHome
Move 'core.nvram.1' from '/usr/local/tmp' to '/usr/local/cfg/core.moveToHome'? (y/N)
```

Moving or Renaming Files on the Switch

You can move or rename an existing configuration, policy, or if configured, core dump file in the system.

XML-formatted configuration files have a .cfg file extension. The switch runs only .cfg files. ASCII-formatted configuration files have an .xsf file extension. See Uploading ASCII-Formatted Configuration Files on page 1976 for more information. Policy files have a .pol file extension.

When you rename a file, make sure the it uses the same file extension as the original file. If you change the file extensions, the file may be unrecognized by the system. For example, if you have an existing configuration file named test.cfg, the new filename must include the .cfg extension.

1. Run the `mv` command.

   ```
   # mv test.cfg megset.cfg
   Rename config test.cfg to config megtest.cfg on switch? (y/n)
   ```

2. Enter `y` to rename the file on your system. Enter `n` to cancel this process and keep the existing filename.

   If you attempt to rename an active configuration file (the configuration currently selected the boot the switch), the switch displays an error similar to the following:
   ```
   Error: Cannot rename current selected active configuration.
   ```

For more information about configuring core dump files and managing the core dump files stored on your switch, see Understanding Core Dump Messages on page 1971.

Copying Files on the Switch

The copy function allows you to make a copy of an existing file before you alter or edit the file. By making a copy, you can easily go back to the original file if needed.

XML-formatted configuration files have a .cfg file extension. The switch runs only .cfg files. ASCII-formatted configuration files have an .xsf file extension. See Uploading ASCII-Formatted Configuration Files on page 1976 for more information. Policy files have a .pol file extension.

When you copy a configuration or policy file from the system, make sure you specify the appropriate file extension. For example, if you want to copy a policy file, specify the filename and .pol.

1. Copy an existing configuration or policy file on your switch using the `cp` command.

   ```
   cp test.cfg test1.cfg
   Copy config test.cfg to config test1.cfg on switch? (y/n)
   ```

2. Enter `y` to copy the file. Enter `n` to cancel this process and not copy the file.

   When you enter `y`, the switch copies the file with the new name and keeps a backup of the original file with the original name. After the switch copies the file, use the `ls` command to display a complete list of files.

   > **Note**
   > If you make a copy of a file, such as a core dump file, you can easily compare new information with the old file if needed.

For more information about configuring the storage of core dump files, see Understanding Core Dump Messages on page 1971.

Displaying Files on the Switch

You can display a list of the configuration, policy, or if configured, core dump files stored on your switch by running the command `ls {file_name}`.

When you do not specify a parameter, this command lists all of the files in the current directory stored on your switch.

If you do specify a parameter, you can refer to a specific directory to view all of the files in that directory.

Output from this command includes the file size, date and time the file was last modified, and the file name.

For more information about configuring core dump files and managing the core dump files stored on your switch, see Understanding Core Dump Messages on page 1971.

Transferring Files to and from the Switch

TFTP allows you to transfer files between a TFTP server and the following switch storage areas: local file system, internal memory card, compact flash card, and USB 2.0 storage device.

- Download a file from a TFTP server to the switch, using the `tftp` or `tftp get` commands.

  ```
  tftp [ ip-address | host-name ] { -v vr_name } [ -g ] [ { -l local-
  file | } { -r remote-file } | { -r remote-file } { -l local-file } ]
  tftp get [ ip-address | host-name] { vr vr_name } remote-file {local-
  file} {force-overwrite}
  ```

  > **Note**
  > By default, if you transfer a file with a name that already exists on the system, the switch prompts you to overwrite the existing file. For more information, see the `tftp get` command.

- Download a file from a universal resource locator (URL), using the following command:

  ```
  download [url url {vr vrname} | image [active | inactive] [[hostname |
  ipaddress] filename {{vr} vrname} {block-size block_size}] {partition}
  {install {reboot}}
  ```

  The `download url` command supports the following file types: `cfg`, `lic`, `lst`, `pol`, `py`, `voss`, `xmod`, `xos`, `xsf`, and `xtr`.

  The `download image` commands supports the following file types: `voss`, `xmod`, `xos`, and `xtr`.

- To upload a file from the switch to a TFTP server, use the `tftp` or `tftp put` commands:

  ```
  tftp [ ip-address | host-name ] { -v vr_name } [ -p ] [ { -l local-
  file | } { -r remote-file } | { -r remote-file } { -l local-file } ]
  tftp put [ ip-address | host-name] {vr vr_name} local-file { remote-
  file}
  ```

For detailed information about downloading software image files, BootROM files, and switch configurations, see Software Upgrade and Boot Options on page 1958. For more information about configuring core dump files and managing the core dump files stored on your switch, see Understanding Core Dump Messages on page 1971.

Deleting Files from the Switch

You can delete a configuration, policy, or if configured, core dump file from your system by running the `rm file_name` command.

When you delete a configuration or policy file from the system, make sure you specify the appropriate file extension. For example, when you want to delete a policy file, specify the filename and .pol. After you delete a file, it is unavailable to the system.

When you delete a file from the switch, a message similar to the following appears:

```
Remove testpolicy.pol from switch? (y/n)
```

Enter `y` to remove the file from your system. Enter `n` to cancel the process and keep the file on your system.

If you attempt to delete an active configuration file (the configuration currently selected to boot the switch), the switch displays an error similar to the following:

```
Error: Cannot remove current selected active configuration.
```

For more information about configuring core dump files and managing the core dump files stored on your switch, see Understanding Core Dump Messages on page 1971.

Managing the Configuration File

The configuration is the customized set of parameters that you have selected to run on the switch. Table 18 describes some of the key areas of configuration file management in ExtremeXOS.

Table 18: Configuration File Management

Task	Behavior
Configuration file database	ExtremeXOS supports saving a configuration file into any named file and supports more than two saved configurations. For example, you can download a configuration file from a network TFTP server and save that file as primary, secondary, or with a user-defined name. You also select where to save the configuration: primary or secondary partition, or another space.
Downloading configuration files	ExtremeXOS uses the `tftp` and `tftp get` commands to download configuration files from the network TFTP server to the switch. For more information about downloading configuration files, see Using TFTP to Download the Configuration on page 1980.
Uploading configuration files	ExtremeXOS uses the `tftp` and `tftp put` commands to upload configuration files from the switch to the network TFTP server. For more information about uploading configuration files, see Using TFTP to Upload the Configuration on page 1979.

Table 18: Configuration File Management (continued)

Task	Behavior
Managing configuration files, including listing, copying, deleting, and renaming	The following commands allow you to manage configuration files: • `ls`: Lists all of the configuration files in the system. • `cp`: Makes a copy of an existing configuration file in the system. • `rm`: Removes/deletes an existing configuration file from the system. • `mv`: Renames an existing configuration file.
Configuration file types	• XML-formatted configuration file • ASCII-formatted configuration file
XML-formatted configuration file	ExtremeXOS configuration files are saved in Extensible Markup Language (XML) format. Use the `show configuration` command to view on the CLI your currently running switch configuration.
ASCII-formatted configuration file	You can upload your current configuration in ASCII format to a network TFTP server. The uploaded ASCII file retains the CLI format. To view your configuration in ASCII format, save the configuration with the .xsf file extension (known as the XOS CLI script file). This saves the XML-based configuration in an ASCII format readable by a text editor. ExtremeXOS uses the `upload configuration` command to upload the ASCII-formatted configuration file from the switch to the network TFTP server. ExtremeXOS uses the `tftp` and `tftp get` commands to download configuration files from the network TFTP server to the switch. For more information about ASCII-formatted configuration files, see Uploading ASCII-Formatted Configuration Files on page 1976.
XML configuration mode	Indicated by (xml) at the front of the switch prompt. Do not use; instead, run `disable cli xml-mode` to disable this mode.
Displaying configuration files	You can also see a complete list of configuration files by entering the `ls` command followed by the **[Tab]** key.

For more information about saving, uploading, and downloading configuration files, see Save the Configuration on page 1978.

Managing ExtremeXOS Processes

ExtremeXOS consists of a number of cooperating processes running on the switch. With process control, under certain conditions, you can stop and start processes, restart failed processes, examine information about the processes, and update the software for a specific process or set of processes.

Displaying Process Information

To display process information, use the following command:

```
show process {name} {detail} {description} {slot slotid}
```

Stopping Processes

If recommended by Extreme Networks Technical Support personnel, you can stop a running process. You can also use a single command to stop and restart a running process during a software upgrade on the switch.

By using the single command, there is less process disruption and it takes less time to stop and restart the process.

- To stop a running process, use the following command:

```
terminate process name [forceful | graceful]
```

In a SummitStack:

```
terminate process name [forceful | graceful] {slot slot}
```

Where the following is true:

name	Specifies the name of the process to terminate. You can terminate the following processes: bgp, eaps, exsshd, isis, lldp, netLogin, netTools, ntp, ospf, ospfv3, snmpMaster,snmpSubagent, telnetd, thttpd, tftpd, vrrp, and xmld.
forceful	Specifies a forceful termination.
graceful	Specifies a graceful termination.

> **Note**
> Do not terminate a process that was installed since the last reboot unless you have saved your configuration. If you have installed a software module and you terminate the newly installed process without saving your configuration, your module may not be loaded when you attempt to restart the process with the `start process` command.

- To preserve a process's configuration during a terminate and (re)start cycle, save your switch configuration before terminating the process. Do not save the configuration or change the configuration during the process terminate and re(start) cycle. If you save the configuration after terminating a process, and before the process (re)starts, the configuration for that process is lost.
- To stop and restart a process during a software upgrade, use the following command:

```
restart process [class cname | name {msm slot}]
```

Where the following is true:

cname	Specifies the name of the process to restart. With this parameter, you can terminate and restart all instances of the process associated with a specific routing protocol on all VRs.You can restart the *OSPF (Open Shortest Path First)* routing protocol and associated processes.
name	Specifies the name of the process to terminate and restart. You can use this command with the following processes: bgp, eaps, exsshd, isis, lldp, netLogin, netTools, ntp, ospf, ospfv3, snmp Subagent, snmpMaster, telnetd, thttpd, tftpd, vrrp, and xmld.
slot	On a SummitStack, specifies the node's slot number. The number is a value from 1 to 8.

Starting Processes

- To start a process, use the following command:

  ```
  start process name {msm slot}
  ```

  In a SummitStack:

  ```
  start process name {slot slot}
  ```

  Where the following is true:

name	Specifies the name of the process to start. You can start the following processes: bgp, eaps exsshd, isis, lldp, netLogin, netTools, ospf, snmpMaster, snmpSubagent, telnetd, thttpd, tftpd, vrrp, xmld
slot	On a SummitStack, specifies the node's slot number. The number is a value from 1 to 8.

```
Error: Process telnetd already exists!
```

> **Note**
> After you stop a process, do not change the configuration on the switch until you start the process again. A new process loads the configuration that was saved prior to stopping the process. Changes made between a process termination and a process start are lost, and error messages can result when you start the new process.

As described in the section, Stopping Processes on page 144, you can use a single command, rather than multiple commands, to stop and restart a running process.

- Stop and restart a process during a software upgrade.

  ```
  restart process [class cname | name {msm slot}]
  ```

  In a SummitStack:

  ```
  restart process [class cname | name {slot slot}]
  ```

  For more detailed information, see Stopping Processes on page 144.

Creating Processes

The following commands allow you to add a process. The process can be a C executable compiled using the C-based SDK or a Python module. You upload it to /usr/local/cfg using the normal mechanisms (for example, TFTP).

To create a C-executable process, use the command:

```
create process name executable exe {start [auto | on-demand]} {node
node} {vr vr-name} {description description} {arg1 {arg2 { arg3 { arg4
{ arg5 { arg6 { arg7 { arg8 { arg9 }}}}}}}}}
```

To create a Python module, use the command:

```
create process name python-module python-module {start [auto | on-
demand]} {node node} {vr vr-name} {description description} {arg1 {arg2
{arg3 {arg4 {arg5 {arg6 {arg7 {arg8 {arg9}}}}}}}}}
```

Understanding Process Control Groups

Processes running in ExtremeXOS are grouped into "Vital" (ExtremeXOS) and "Other" (non-ExtremeXOS) process control groups. The "Vital" (ExtremeXOS) group includes all the ExtremeXOS infrastructure, network services, protocols, configuration and network management processes. The "Other" (non-ExtremeXOS) groups include all the processes created through CLI, and scripts executed in ExtremeXOS shell. Both these groups are capped with memory and CPU limits as a percentage of the total available memory and CPU resources in the system. Both groups get a guaranteed share of memory and CPU access up to that limit.

A user-created process automatically is classified as being in the "Other" group. The "Vital" group has, by default, 95% of the system memory and 90% of the system CPU resources. In contrast, the "Other" group has a default memory limit of 5% and a default CPU limit of 10%, both configurable to a certain extent through CLI. This provides a level of segregation where processes in one group cannot significantly impact processes running in another group.

To manage the CPU and memory usage for the "Other" (non-ExtremeXOS) group, use the following commands:

> **Note**
> Increasing the memory or CPU limit of the "Other" group impacts the total available memory or CPU resources of the "EXOS" group. These commands need to be used with careful consideration of the resource requirements in real-time.

- `configure process group other cpu-limit cpu_limit`
- `configure process group other memory-limit memory_limit`

When these commands are issued, the CPU and memory limits for the "EXOS" (ExtremeXOS) group are changed as well.

To clear the user-configured memory and CPU limits and restore default settings, use the following command:

```
unconfigure process group
```

To clear the memory- and CPU-related statistics of "Vital" and/or "Other" groups, use the following command:

```
clear process group statistics {vital | other}
```

To show the configured settings and statistics for the process control groups, use the following command:

```
show process group {[vital | other]}
```

Understanding Memory Protection

ExtremeXOS provides memory management capabilities. Each process in ExtremeXOS runs in a protected memory space. This infrastructure prevents one process from overwriting or corrupting the memory space of another process. For example, if one process experiences a loop condition, is under some type of attack, or is experiencing some type of problem, that process cannot take over or overwrite another processes' memory space.

Memory protection increases the robustness of the system. By isolating and having separate memory space for each individual process, you can more easily identify the process or processes that experience a problem.

To display the current system memory and that of the specified process, use the following command: `show memory process name {slot slotid}`

Where the following is true:
- *name*: Specifies the name of the process.
- **slot**: On a SummitStack, specifies the slot number of the target node. The number is a value from 1 to 8.

Reading the Output

The `show memory process` command displays the following information in a tabular format:
- System memory information (both total and free).
- Current memory used by the individual processes.

The current memory statistics for the individual process also includes the following:
- For SummitStacks, the slot number.
- The name of the process.

Viewing System Memory

You can also use the `show memory {`**`slot slotid`**`}` command to view the system memory and the memory used by the individual processes, even for all processes on all MSMs/MMs installed in modular switches. The **slot** parameter is available only on modular switches and SummitStack.

In general, the *free* memory count for a switch decreases when one or more running processes experiences an increase in memory usage. If you have not made any system configuration changes, and you observe a continued decrease in free memory, this might indicate a memory leak.

The information from these commands may be useful for your technical support representative if you experience a problem.

The following is sample truncated output from an ExtremeSwitching switch:

```
CPU Utilization Statistics - Monitored every 25 seconds
----------------------------------------------------------------------
Process           5    10   30   1    5    30   1     Max        Total
                 secs secs secs min  mins mins hour            User/System
                 util util util util util util util   util     CPU Usage
                 (%)  (%)  (%)  (%)  (%)  (%)  (%)     (%)        (secs)

Configuring Stacked Switches

A stack consists of a group of up to eight switches that are connected to form a ring. The stack offers the combined port capacity of the individual switches. But it operates as if it were a single switch, making network administration easier.

Stacking is facilitated by the SummitStack feature – part of the ExtremeXOS Edge license.

This chapter contains information about configuring a stack, maintaining the stack configuration, and troubleshooting.

For descriptions of the supported configurations for stacking, considerations for planning a stack, and instructions for setting up the hardware, see the *Stacking* chapter in the *hardware installation guide* for your switch. We recommend that you read that chapter before installing the switches that will make up the stack.

Introduction to Stacking

Using the SummitStack feature—part of the ExtremeXOS Edge license—a stack can combine switches from different series, provided that every switch in the stack:

- Runs in the same partition (primary or secondary).
- Runs the same version of ExtremeXOS.
- Includes support for stacking.

> **Note**
> The ExtremeSwitching X435 series switches do not support stacking.

The stack operates as if it were a single switch with a single IP address and a single point of authentication. One switch – called the primary switch – is responsible for running network protocols and managing the stack. The primary runs ExtremeXOS software and maintains all the software tables for all the switches in the stack.

All switches in the stack, including the primary switch, are called nodes. Figure 4 shows four nodes in a stack, connected to each other by SummitStack cables.

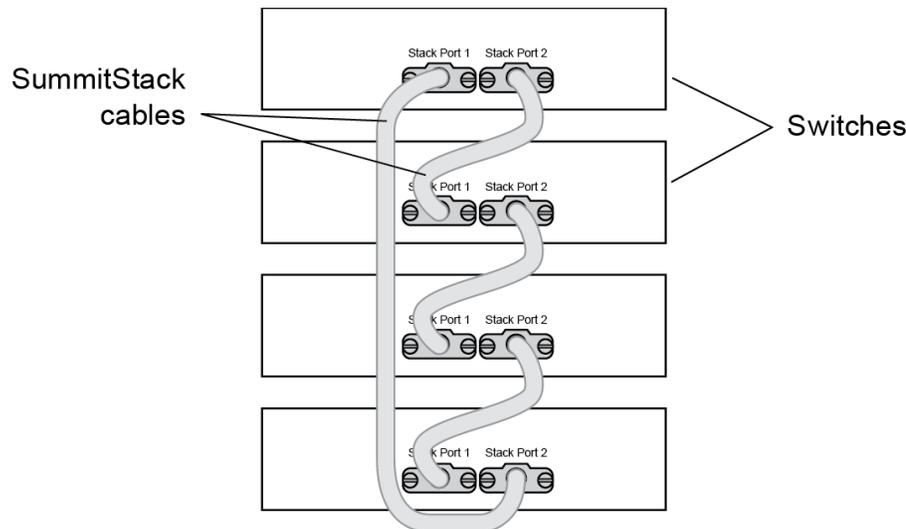
All connections between stack ports must be directly between switches. A stacking connection cannot pass through a third device, for example a Virtual Port Extender or an LRM/MACsec Adapter.


Figure 4: Switches Connected to Form a Stack
The following sections introduce you to the basic principles of stacking and provide recommendations for creating stacks.

More information to answer your questions about stacking and help you plan your configuration is available on the Extreme Networks GTAC Knowledge Base.

Build Basic Stacks

A stack can be created in either of two ways:

- In *native stacking*, switches are connected using either designated Ethernet data ports or dedicated stacking connectors.
- In *alternate stacking*, switches are connected using 10-Gbps Ethernet data ports that have been configured for stacking. These ports are located either on the switch itself or on option cards installed on either the front or the rear of the switch.

When planning and building your stack, be sure to follow port compatibility and cabling recommendations as described in this chapter.

Slot Numbers in Stacks

A switch stack can be thought of as a virtual chassis. Each switch (node) operates as if it were occupying a slot in a chassis and is controlled by the primary. The high-speed stacking links function like the backplane links of a chassis.

Each switch in the stack is assigned a "slot number" during the initial software configuration of the stack. Starting at the switch with the console connection, numbers are assigned in numerical order following the physical path of the connected stacking

cables. For example, if you follow the cabling recommendations presented in and configure a vertical stack from the console on the switch at the top of the physical stack, the switches will be assigned slot numbers 1 through 8 from the top down.

The top half of the number blinks if the switch is the primary, and the bottom half blinks if it is the backup. If the LED is steadily lit, the switch is a standby. If the LED is off the switch is not configured as a member of a stack.

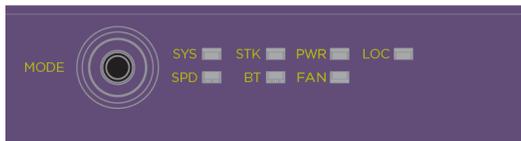
The Mode button is used to cycle through three display modes for the port LEDs. After two presses of the Mode button, the port LEDs will enter the STK Display Mode, indicated by the STK LED. STK mode is used to indicate slot presence and slot number via the first eight port LEDs.


Figure 5: Mode Button with SRK LED Example

The LED is steady green if the link is OK, blinking green if traffic is present, and off if no signal is present.

A quick way to verify that the cable connections match the software configuration is to check the stack number indicator on each switch. If the slot numbers do not line up in the order you arranged the switches, this might indicate that the stacking cable setup differs from what you intended when you configured the software. In this case, reconnect the cables in the correct order and perform the software configuration again.

Primary/Backup Switch Redundancy

When your stack is operational, one switch is the primary switch, responsible for running network protocols and managing the stack.

To provide recovery in case of a break in the stack connections, you can configure redundancy by designating a backup switch to take over as primary if the primary switch fails. When you perform the initial software configuration of the stack, the "easy setup" configuration option automatically configures redundancy, with slot 1 as the primary and slot 2 as the backup. You can also configure additional switches as "primary-capable," meaning they can become a stack primary in case the initial backup switch fails.

When assigning the primary and backup roles in mixed stacks, consider the feature scalability and the speed of each switch model. The easy setup configuration process selects primary and backup switches based on capability and speed. The following list shows the capabilities based on the ability to cross stack with other switch families. The most capable switches are shown at the top of each list:

1. ExtremeSwitching X460-G2 (most capable)
2. ExtremeSwitching X450-G2

3. ExtremeSwitching X440-G2 and X620

1. ExtremeSwitching X590 and X695
2. ExtremeSwitching X465

For example, in a stack that combines X460-G2 switches with other switch models, an X460-G2 switch might provide more memory and more features than other switches in the stack. Consider these differences when selecting a primary node, selecting a backup node, and configuring failover operation.

> **Note**
> Assign the primary and backup roles to switches from the same series. For example, if the primary node is an X460-G2 switch, the backup node should also be an X460-G2 switch.

When easy setup compares two switches that have the same capability, the lower slot number takes precedence.

Follow the same ranking hierarchy when you plan the physical placement of the switches in the stack.

SummitStack Topologies

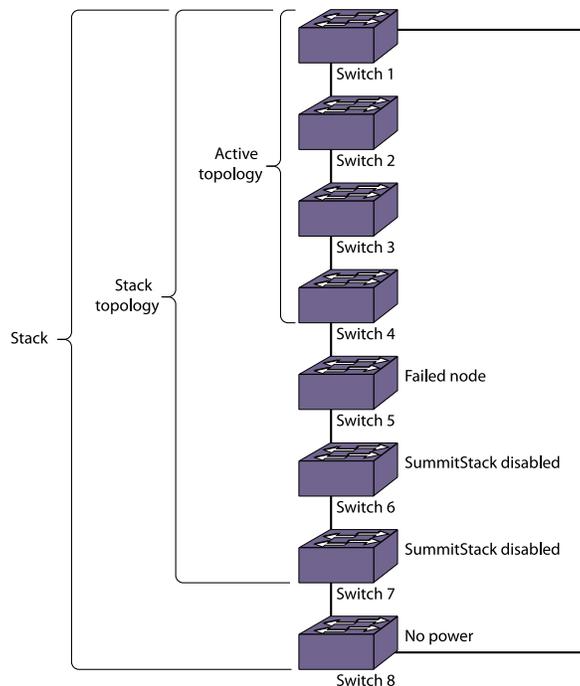
Figure 6 presents a graphical representation of a stack and some of the terms that describe stack conditions.


Figure 6: Example of a Stack, Showing the Active Topology and the Stack Topology

A stack is the collection of all switches, or nodes, that are cabled together to form one virtual switch using the Switch Engine SummitStack feature.

The maximum cable length supported between switches depends on the types of switches in your stack, the installed option cards, and the configured stacking ports. For more information, see .

A stack topology is the set of contiguous nodes that are powered up and communicating with each other. In the example shown, Switch 8 is not part of the stack topology because it is not powered up.

An active topology is the set of contiguous nodes that are active. An active node is powered up, is configured for stack operation, and is communicating with the other active nodes.

Switch 5 in the example has failed, stacking is disabled on Switches 6 and 7, and Switch 8 has no power. As a result, the active topology includes Switches 1 through 4 only.

For more information about SummitStack terminology, see SummitStack Terms on page 159.

Ring Topology: Recommended for Stacking

SummitStack nodes should be connected to each other in a ring topology. In a ring topology, one link is used to connect to a node and the other link is used to connect to another node. The result forms a physical ring connection. This topology is highly recommended for normal operation.

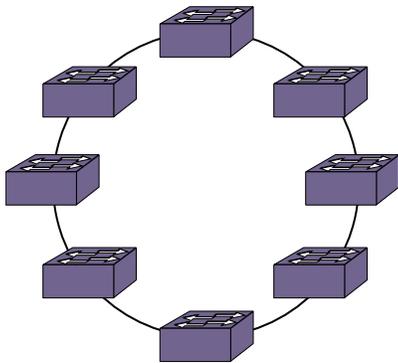
Figure 7 represents a maximal ring topology of eight active nodes.


Figure 7: Graphical Representation of a Ring Topology

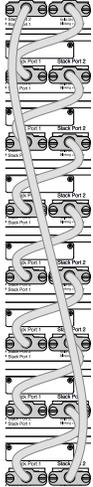
Figure 8 shows what the same ring topology would look in actual practice. Each switch in the rack is connected to the switch above it and the switch below it. To complete the ring, a longer cable connects Switch 1 with Switch 8.


Figure 8: Switches Connected to Each Other in a Ring Topology

Note that, while a physical ring connection may be present, a ring active topology exists only when all nodes in the stack are active.

Daisy Chain Topology: Not Recommended for Stacking

Stackable switches can be connected in a daisy-chain topology. This is a ring topology with one of the links disconnected, inoperative, or disabled. A daisy chain can be created when a link fails or a node reboots in a ring topology, but the daisy chain topology is not recommended for normal operation.

We strongly recommend that your stack nodes be connected in a ring topology, not a daisy-chain topology, for normal operation.

In Figure 9, the nodes delineated as the active topology are operating in a daisy-chain configuration, even though there is physically a ring connection in the stack.

Figure 9: Daisy-Chain Topology

You might need to use a daisy chain topology while adding a new node, removing a node, or joining two stacks.

If you are using a daisy chain topology, the possibility of a dual master condition increases. Before you create a daisy chain topology, read Managing a Dual Primary Situation on page 213.

Using Ethernet Ports for Stacking (SummitStack-V Feature)

On many Extreme Networks switches, you can reconfigure one or two 10-Gbps Ethernet data ports to operate as stacking ports.

This feature, known as *SummitStack-V* or *alternate stacking*, means that you can use less expensive cables to connect the switches in a stack. Because copper and fiber Ethernet ports support longer cable distances, you can also extend the physical distance between stack nodes – connecting, for example, switches on different floors in a building or in different buildings on a campus.

The SummitStack-V feature means that you can stack switches that have no dedicated (or *native*) stacking ports but that do have at least two Ethernet ports. The ports can be configured to support either data communications or stacking. When configured to support stacking, they are called alternate stacking ports to distinguish them from the native stacking ports that use custom cables.

A single stack can use both native stacking ports and alternate stacking ports. On one switch, for example, you can use a native stacking port to connect to a switch in the

same rack, and you can use an alternate stacking port to connect to a switch on a
different floor.

> **Note**
> When you connect distant nodes using alternate stacking ports, be sure to run
> the cables over physically different pathways to reduce the likelihood of a cut
> affecting multiple links.

On each switch model, only specific data ports can be used as alternate stacking ports.
The alternate stacking ports must be 10-Gbps Ethernet ports, either on the front panel
of the switch or on installed port option cards or versatile interface modules at the
rear of the switch. Switch models that do not have native stacking ports can still use
alternate stacking if they have 10-Gbps Ethernet ports.

Alternate stacking ports on different switches must be directly connected, with no
intervening switch connections. This is because alternate stacking ports use the
proprietary ExtremeXOS protocol for stacking, not the standard Ethernet protocol.

Table 19 lists the data ports that can be used as native and alternate stacking ports for
each switch model.

When the stacking-support option is enabled (with the `enable stacking-support`
command), data communication stops on the physical data ports that are designated
for alternate stacking. Then, when stacking is enabled (with the `enable stacking`
command), those ports – listed in the Alternate Stacking Ports column of Table 19 –
operate as stacking ports.

Table 19: Native and Alternate Stacking Ports

Switch Model	Type or location of Native Stacking Ports	Alternate Stacking Ports	Location of Alternate Stacking Ports
X440-G2-12t-10GE4 X440-G2-12p-10GE4	Fixed (front panel)	15,16	Front panel
X440-G2-24t-10GE4 X440-G2-24p-10GE4 X440-G2-24x-10GE4 X440-G2-24t-10GE4-DC	Fixed (rear panel)	27,28	Rear panel

X620-16x	None	15,16	Front panel
X695-48Y-8C	61, 62	None	Front panel

Available Stacking Methods

Each ExtremeSwitching switch model can use various methods of stacking.

Table 20 shows the switch models that can participate in each stacking method.

Table 20: SummitStacking by Stacking Method

Stacking Method	Speed per Link (HDX)	Cable Type and Lengths	Switch Models
SummitStack	10 Gbps	0.5 m, 1.5 m, 3.0 m, 5.0 m, 20Gb Stacking Cable	ExtremeSwitching X460-G2 (using VIM-2SS)
SummitStack-V	10 Gbps	0.5 m - 40 km SFP+ (with SR, LR, and ER)	ExtremeSwitching X440-G2 ExtremeSwitching X450-G2 (10G models) ExtremeSwitching X460-G2 (1G models with VIM-2x) ExtremeSwitching X460-G2 (10G models) ExtremeSwitching X620
SummitStack-V84	21 Gbps	0.5 m - 5 m QSFP+ passive copper	ExtremeSwitching X450-G2 (rear panel 21G stacking ports)

Table 20: SummitStacking by Stacking Method (continued)

Stacking Method	Speed per Link (HDX)	Cable Type and Lengths	Switch Models
SummitStack-V160	40 Gbps	0.5 m - 40 kM QSFP+ only	ExtremeSwitching X460-G2 (VIM-2q) * ExtremeSwitching X590 (ports 29, 33) * ExtremeSwitching X465 (ports S1 and S2) * ExtremeSwitching X695 (ports 61, 62) **Note:** * The X465, X590, and X695 can stack with each other, but not with other V160-capable switches.
SummitStack-V400	106 Gbps	0.5 m - 100 m QSFP28 only	ExtremeSwitching X590 (ports 29,33) ExtremeSwitching X695 (61, 62)
SummitStack-V400 Alternative Configuration	100 Gbps	V400 Alternative Configuration is required when using specific fiber cables. This mode sets the stack ports to 100G, enables pre-emphasis, and FEC (clause_91). • QSFP28 SR4 • QSFP28 LR4 • QSFP28 CWDM4 • QSFP28 PSM4 • QxQ AOC cable - 5m • QxQ AOC cable - 7m • QxQ AOC cable - 10m • QxQ AOC cable - 20m	ExtremeSwitching X590 (ports 29,33) ExtremeSwitching X695 (ports 61, 62)

For more details about the stacking methods that are available for each switch series, see the hardware installation guide for your switch.

> **Note**
> Because all switches in the stack must run the same version of ExtremeXOS, it is not possible to stack switches that require ExtremeXOS version 21, for example the X440-G2 and the X620, with switches that are incompatible with ExtremeXOS version 21, for example the X440 and the X460.

SummitStack Terms

Table 21 describes the terms used for the SummitStack feature. These terms are listed in the recommended reading sequence.

Table 21: List of Stacking Terms

Term	Description
Stackable switch	An ExtremeSwitching switch that provides two stacking ports and can participate in a stack.
Stacking port	A physical interface of a stackable switch that is used to allow the connection of a stacking link. Stacking ports are point-to-point links that are dedicated for the purpose of forming a stack.
Native stacking	A stacking configuration in which stack members are connected using either designated Ethernet data ports or dedicated stacking connectors.
Alternate stacking	A stacking configuration in which stack members are connected using 10-Gbps Ethernet data ports that have been configured for stacking. These ports are located either on the switch itself or on option cards installed on the rear of the switch.
Stacking link	A cable that connects a stacking port of one stackable switch to a stacking port of another stackable switch, plus the stacking ports themselves.
Node	A switch that runs the ExtremeXOS operating system and is part of a stack. Synonymous with *stackable switch*.
Stack	A set of stackable switches and their connected stacking links made with the intentions that: (1) all switches are reachable through their common connections; (2) a single stackable switch can manage the entire stack; and (3) configurable entities such as VLANs and link trunk groups can have members on multiple stackable switches. A stack consists of all connected nodes regardless of the state of the nodes.
Stack topology	A contiguously connected set of nodes in a stack that are currently communicating with one another. All nodes that appear in the `show stacking` command display are present in the stack topology.
Stack path	A data path that is formed over the stacking links for the purpose of determining the set of nodes that are present in the stack topology and their locations in the stack. Every node is always present in a stack path whether or not stacking is enabled on the node.
Control path	A data path that is formed over the stacking links that is dedicated to carrying control traffic, such as commands to program hardware or software image data for software upgrade. A node must join the control path to fully operate in the stack. A node that is disabled for stacking does not join the control path, but does communicate over the stack path.

Table 21: List of Stacking Terms (continued)

Term	Description
Active node	A node that has joined the control path. The active node can forward the control path messages or can process them. It can also forward data traffic. Only an active node can appear as a card inserted into a slot when the `show slot {slot {detail}	detail }` command is executed on the primary node of the stack.
Active topology	A contiguous set of active nodes in a stack topology plus the set of stacking links that connect them. When an active topology consists of more than one node, each node in the active topology is directly and physically connected to at least one other node in the active topology. Thus, the active topology is a set of physically contiguous active nodes within a stack topology.
Candidate node	A node that is a potential member of an active topology, or an active node that is already a member of an active topology. A candidate node may or may not be an active mode – that is, it may or may not have joined the control path.
Node role	The role that each active node plays in the stack – either primary, backup, or standby.
Primary node	The node that is elected as the primary node in the stack. The primary node runs all of the configured control protocols such as OSPF (Open Shortest Path First), RIP (Routing Information Protocol), Spanning Tree, and EAPS (Extreme Automatic Protection Switching). The primary node controls all of its own data ports as well as all data ports on the backup and standby nodes. To accomplish this, the primary node issues specific programming commands over the control path to the backup and standby nodes.
Backup node	The node assigned to take over the role of primary if the primary node fails. The primary node keeps the backup node's databases synchronized with its own databases in preparation for such an event. If and when the primary node fails, the backup node becomes the primary node and begins operating with the databases it has previously received. In this way, all other nodes in the stack can continue operating.
Standby node	A node that is prepared to become a backup node in the event that the backup node becomes the primary node. When a backup node becomes a primary node, the new primary node synchronizes all of its databases to the new backup node. When a node operates in a standby role, most databases are not synchronized – except those few that directly relate to hardware programming.

Table 21: List of Stacking Terms (continued)

Term	Description
Acquired node	A standby or backup node that is acquired by a primary node. This means that the primary node has used its databases to program the hardware of the standby or backup node. The standby or backup node has acted as a hardware programming proxy, accepting the instructions of the primary node to do so. An acquired backup node maintains the databases needed to reflect why the hardware is programmed as it is. However, a standby node does not. An acquired node can be re-acquired (without a reboot) by the backup node only when the backup node becomes the primary node, and only when both the backup and standby nodes were already acquired by the same primary node at the time of its failure.
Data ports	The set of ports on a stackable switch that are available for connection to your data networks. Such ports can be members of a user-configured VLAN or trunk group. They can be used for Layer 2 and 3 forwarding of user data traffic, for mirroring, or other features you can configure. Data ports are different from stacking ports.
Failover	The process of changing the backup node to the primary node when the original primary node has failed. When a primary node fails, if a backup node is present, and if that node has completed its initial synchronization with the primary node, then the backup node assumes the role of primary node. The standby nodes continue their operation and their data ports do not fail.
Hitless failover	A failover in which all data ports in the stack, except those of the failing primary node, continue normal operation when the primary node fails.
Node address	The unique MAC address that is factory-assigned to each node.
Node role election	The process that determines the role for each node. The election takes place during initial stack startup and elects one primary node and one backup node. An election also takes place after a primary node failover, when a new backup node is elected from the remaining standby nodes.
Node role election priority	A priority assigned to each node, to be used in node role election. The node with the highest node role election priority during a role election becomes the primary node. The node with the second highest node role election priority becomes the backup.
Operational node	A node that has achieved operational state as a card in a slot. The operational state can be displayed using the `show slot {`*`slot`* `{`**`detail`**`} |` **`detail`** `}`command.
System uptime	The amount of time that has passed since the last node role election. You can display the system uptime by entering the `show switch {`**`detail`** `}` command on the primary node.

Table 21: List of Stacking Terms (continued)

Term	Description
Stack segment	A collection of nodes that form a stack topology. The term is useful when a stack is severed. Each severed portion of the stack is referred to as a stack segment.
Stack state	A state assigned by the stack to a node. You can display the stack state by entering the `show stacking` command.
Easy Setup	A procedure that automatically configures the essential stacking parameters on every node for initial stack deployment, and then automatically reboots the stack to put the parameters into effect. The choice to run Easy Setup is offered when you run the `enable stacking {`**`node-address`** *`node-address`*`}` command and the essential stacking parameters are unconfigured or inconsistent. It can also be invoked directly by running the `configure stacking easy-setup` command.

Preparing to Configure a Stack

The following topics contain background information to help you configure your stack so that it functions as effectively as possible:

- Stacking Node Roles, Redundancy, and Failover on page 162
- Stack Configuration Parameters, Configuration Files, and Port Numbering on page 163
- QoS in Stacking on page 164
- Stacking Link Overcommitment on page 166
- Log Messages from Stack Nodes on page 166

Stacking Node Roles, Redundancy, and Failover

ExtremeXOS supports control plane redundancy and hitless failover.

A stack supports control plane redundancy and hitless failover. Hitless failover is supported to the extent that the failing master node and all of its ports are operationally lost, including the loss of supplied power on any *PoE (Power over Ethernet)* ports that the node provided, but all other nodes and their provided ports continue to operate. After the failover, the backup node becomes the master node.

At failover time, a new backup node is selected from the remaining standby nodes that are configured to be master capable. All operational databases are then synchronized from the new master node to the new backup node. Another hitless failover is possible only after the initial synchronization to the new backup node has completed. This can be seen using the `show switch {`**`detail`**`}` command on the master node and noting that the new backup node is In Sync.

When a backup node transitions to the master node role, it activates the Management IP interface that is common to the whole stack. If you have correctly configured an alternate management IP address, the IP address remains reachable.

When a standby node is acquired by a master node, the standby node learns the identity of its backup node. The master node synchronizes a minimal subset of its databases with the standby nodes.

When a standby node loses contact with both its acquiring master and backup nodes, it reboots.

A master node that detects the loss of an acquired standby node indicates that the slot the standby node occupied is now empty and flushes its dynamic databases of all information previously learned about the lost standby node.

A backup node restarts if the backup node has not completed its initial synchronization with the master node before the master node is lost. When a backup node transitions to the master node role and detects that the master node has not already synchronized a minimal subset of its databases with a standby node, the standby node is restarted.

Reboot or Failure of a Non-Master Node

If a backup node fails, a standby node configured as master-capable is elected as the new backup. This new backup node is then synchronized to the databases of the master node.

For all non-master nodes, a node that reboots or is power-cycled loses all of its connections to all networks for the duration of the reboot cycle. Any *PoE* ports that were providing power prior to the event do not supply power.

When a non-master node fails, the master node marks the related slot as Empty. All other nodes exclude the failed node from the control path and any customer-configured VLANs, trunk group ports, mirroring ports, and so forth.

Stack Configuration Parameters, Configuration Files, and Port Numbering

The stacking configurations are stored in the NVRAM of each node. Some of these configurations take effect only during the next node restart.

Table 22: Stacking Configuration Items, Time of Effect, and Default Value

Configuration Item	Takes Effect	Default Value
Stacking Mode	at boot time	Disabled
Slot Number	at boot time	1
Master-Capable	at boot time	Yes
License Restriction	at boot time	Not configured
Priority	at the next master election	Automatic
Alternate IP Address	immediately	Not configured
Stack MAC	at boot time	Not configured

Stacking parameters, such as mode, slot number, etc., can be configured from a single unit in the stack topology. You can change the stacking-specific configuration even when a node is not in stacking mode, but is connected to the stack. The target node

for the configuration must be powered on and running a version of ExtremeXOS that supports stacking. Further, the node need not be in stacking mode and can be in any node role.

Most ExtremeXOS configuration parameters are not stored in NVRAM, but are instead stored in a configuration file. Configurations stored in NVRAM are those that are needed when the configuration file is not available. The configuration file chosen for the stack is the one selected on the master node that is first elected after a stack restart.

The data (non-stacking) port numbers, in the existing configuration files (which were created when not in stacking mode), are simple integer quantities. On a stack, the data port numbers are expressed as slot:port; where the slot is an integer representing the slot and port is an integer representing the port. For example, 1:2. The configuration file contains an indication that it was created on a stackable switch in stacking mode. The indication is the stacking platform ID. Thus, when in stacking mode, the ports are referenced in the configuration file with the slot:port notation and when not in stacking mode, the ports are referenced as simple integers.

When a standalone switch is configured for stacking, after reboot the non-slotted configuration is converted to a single slot (slot = 1) configuration (all port numbers and port ranges are prepended with "1:"). The configuration is not automatically saved. You must save the configuration to overwrite the existing `primary.cfg`, `secondary.cfg`, or custom named file.

QoS in Stacking

Each stack uses _QoS (Quality of Service)_ on the stacking links to prioritize the following traffic within the stack:

- Stack topology control packets
- ExtremeXOS control packets
- Data packets

For stack performance and reliability, the priority of control packets is elevated over that of data packets.

This is done to prevent control packet loss and avoid the timed retries that can lower performance. It is also done to prevent unneeded stack topology changes that can occur if enough stack topology information packets are lost. For these reasons, the SummitStack feature reserves one QoS profile to provide higher priority to control packets. The following sections describe the differences in QoS while using it in stack.

QoS Profile Restrictions

In stacking mode, CoS level 6 (hardware queue 6) is reserved for stacking, so you cannot create quality profile QP7.

Because QP7 cannot be created, you cannot use hardware queue 6 to assign CoS level 6 to a packet. However, you can assign packets received with 802.1p priority 6 to a _QoS_

profile using the technique described in Processing of Packets Received With 802.1p Priority 6 on page 165

> **Note**
> This restriction is applicable only when the stackable switch is operating in stacking mode.

QoS Scheduler Operation

In stacking mode, the *QoS* scheduler operation is different for the stacking ports and the data ports.

The scheduler for the data ports operates the same as for standalone ExtremeSwitching switches and is managed with the following command:

```
configure qosscheduler [default |strict-priority | weighted-round-robin
| weighteddeficit- round-robin]
```

The scheduler for the stacking ports is defined by the software when the stack is configured, and it cannot be modified. For all switches, the scheduler is set to strict-priority for the stacking ports, and meters are used to elevate the queue 6 priority above the priority of the other queues. This is the only scheduling method for stack ports.

Processing of Packets Received With 802.1p Priority 6

By default, 802.1p examination is turned on.

Priority 7 is mapped to *QoS* profile QP8, and priorities 6 through 0 are mapped to QoS profile QP1. You can create other QoS profiles and can change this mapping as needed. Since you cannot create QP7 in stacking mode, 802.1p examination always maps packets with priority 6 to other QoS levels. However, you can use an *ACL (Access Control List)* rule entry to set the 802.1p egress value to 6 without affecting the QoS profile assignment as shown in this example:

```
entry VoIPinSummitStack { if { IP-TOS 46; } then { replace-dot1p-value 6; } }
```

Effects on 802.1p Examination

You can turn off 802.1p examination.

When stacking is enabled, the examination remains turned on for priority 6. However, the examination happens at a lower precedence than that of all other traffic groupings.

The mapping you have configured for priority 6 remains in effect, and changes accordingly if you subsequently change the mapping.

When stacking is not enabled, all 802.1p examination is disabled when the feature is turned off.

Effects on DiffServ Examination

When DiffServ examination and 802.1p examination are both turned off, the 802.1p examination for packets arriving at 802.1p priority level 6 remains on at the lowered precedence.

In addition, the examination is adjusted to apply to all packets. The actual priority levels that are used for such packets are the defaults (QP1), or the values last configured using the following command:

```
configure dot1p type dot1p_priority {qosprofile} qosprofile
```

Effects on Port QoS and VLAN QoS

Port *QoS* and *VLAN (Virtual LAN)* QoS have a higher precedence than the 802.1p priority examination performed when the 802.1p examination feature is turned off, and is therefore unaffected.

Stacking Link Overcommitment

The stack is formed by each node supplying a pair of full-duplex, logical stacking ports. Each node can operate on a stack with full duplex throughput up to the limits found in the *hardware installation guide* for your switch.

Even though two links are available, the links might not be fully utilized. For example, suppose there is a ring of eight nodes and the nodes are numbered clockwise from 1 to 8. The stacking port limit in this example is 10 Gbps in each direction for a total stack throughput of 20 Gbps for each port, or 40 Gbps total. Suppose node 1 wants to send 10 Gbps of unicast traffic to each of node 2 and node 3. The shortest path topology forces all traffic from node 1 over the link to node 2. Traffic from node 1 to node 3 passes through node 2. Thus, there is only 10 Gbps link available. However, if node 1 wanted to send 10 Gbps to node 2 and node 8, there would be 20 Gbps available because both links connected to node 1 would be used.

In a ring of eight nodes, between any two nodes, only one link is used. If the devices provide 48 1-Gbps Ethernet ports, the overcommitment ratio between two such nodes is approximately 5:1.

Log Messages from Stack Nodes

Each node can generate log messages through the usual logging mechanism.

On backup and standby nodes, a log target and related filter is automatically installed. The log target is the master node. The filter allows all messages that have a log level of warning, error, or critical to be saved in the log file of the master node.

If the master node changes, the log target is updated on all the remaining nodes. You can also log in to any node in the active topology and see the complete log of the node.

Configuring a Stack

Before configuring a new stack, do the following:

- Ensure that every switch, or node, in the stack is running on the same partition (primary or secondary). To find this information for any node, issue the command `show switch` and look for the `Image Booted` field in the output.

- Ensure that every switch in the stack is running the same version *and patch level* of ExtremeXOS. To find this information for any node, issue the command `show switch` and look for the `Primary Ver` or `Secondary Ver` field in the output.

- If necessary, enable switch license levels or configure license level restrictions for the nodes in the stack.
  - To understand how licensing works in stacked switches, see Managing Licenses on a Stack on page 185.
  - To enable a license on a node, see Software Upgrade and Boot Options on page 1958.
  - To restrict the license level for one or more nodes in a stack, see Restricting a Switch License Level on page 186.

- We recommend that you save the configuration for each switch that will participate in the stack, so that you can reinstate the configuration after the switch is no longer needed in the stack.

> **Note**
> New switches are primary-capable by default.

Because stacks can consist of switches of different series and different models, ExtremeXOS does not restrict configuration settings based on the capabilities of any particular node in the stack. Therefore, you are responsible for ensuring that your configuration settings are appropriate for all switches in the stack.

Follow these steps to configure a new stack. Some of the steps include references where you can find additional information.

1. Physically connect the switches (stack nodes) using their stacking ports or alternate stacking ports.

   Instructions for physically setting up the stack are provided in the *hardware installation guide* for your switch.

   > **Note**
   > If your stack includes X460-G2 switches, you must first install the versatile interface modules (VIMs) that you plan to use.

2. Power on the switches.

3. On each switch, issue the command `enable stacking-support`.

   This command configures the switch so that it is capable of being added to a stack. It is not the same as `enable stacking`, which you will use later to build the stack.

   > **Note**
   > You do not need to enable stacking support on the ExtremeSwitching X450-G2 and X465 series switches, since these switches have dedicated stacking ports that are always enabled.

4. Ensure that all of the cabled stacking ports are enabled for stacking:

   a. On each node, issue the command `show ports x,y`, where *x* and *y* are the port numbers.

      In the output, `port state = E` means a port is enabled.

   b. For any ports that are *not* enabled, issue the command `enable ports x,y`, where *x* and *y* are the port numbers.

   c. If you enabled ports on any switches, reboot those switches.

      Save the configuration files.

5. Configure all switches in the stack that will use the SummitStack-V, SummitStack-V160, SummitStack-V320, SummitStack-V400, or *MPLS (Multiprotocol Label Switching)* features.

   > **Note**
   > If the stack will use MPLS, only the following switch types can act as primary and backup: Extreme Switching X460-G2; X465, X590, or X695.

   a. Configure switches that will use alternate stacking ports as described in Using Ethernet Ports for Stacking (SummitStack-V Feature) on page 155.

   b. Reboot the switches whose configurations you changed.

6. Log in, using the console port, to the switch that will be the primary.

7. Issue the command `show stacking stack-ports` to verify that the stacking ports are properly connected.

   All of the ports should show a state of `Operational`.

   In the following example, two of the ports are not in an `Operational` state, which means they are not connected properly.

```
* switch1 # show stacking stack-ports
Stack Topology is a Ring
Slot Port Select Node MAC Address   Port State   Flags Speed
---- ---- ------ ----------------- ----------- ----- -----
*-    1    27      00:04:96:9c:e4:39 Operational C-      10G
*-    2    28      00:04:96:9c:e4:39 Operational CB      10G
 -    1    27      00:04:96:9b:c1:34 Operational CB      10G
 -    2    28      00:04:96:9b:c1:34 Operational C-      10G
 -    1    15      00:04:96:9e:5c:76 Link Down   C-      10G
 -    2    16      00:04:96:9e:5c:76 No-Neighbor C-      10G
 -    1    15      00:04:96:9c:53:b6 Operational C-      10G
 -    2    16      00:04:96:9c:53:b6 Operational C-      10G
* - Indicates this node
Flags:  (C) Control path is active, (B) Port is Blocked
```

When a port displays a state other than `Operational`, use the following tips to troubleshoot:

- If the state displays as `Link Down`, check the port's physical connections.
- Verify that the port is using the same stacking technology, for example SummitStack-V160, as the rest of the ports in the stack.

8. Verify that all nodes in the stack have stacking disabled.

   Note that, even though you enabled stacking-support in step 3 on page 168, it is necessary that stacking be *disabled* before the stack is actually built.

   a. Issue the command `show stacking configuration`.

      For example:

```
* switch1 # show stacking configuration
Stack MAC in use: <none>
Node               Slot         Alternate           Alternate
MAC Address        Cfg Cur Prio Mgmt IP / Mask      Gateway         Flags     Lic
------------------ --- --- ---- ------------------ --------------- --------- ---
*00:04:96:9c:e4:39 1   -   Auto <none>             <none>          -c-----Nn --
 00:04:96:9b:c1:34 1   -   Auto <none>             <none>          -c-----Nn --
 00:04:96:9e:5c:76 1   -   Auto <none>             <none>          -c-----Nn --
 00:04:96:9c:53:b6 1   -   Auto <none>             <none>          -c-----Nn --
* - Indicates this node
Flags:  (C) master-Capable in use, (c) master-capable is configured,
        (E) Stacking is currently Enabled, (e) Stacking is configured Enabled,
        (M) Stack MAC in use, (m) Stack MACs configured and in use are the same,
        (i) Stack MACs configured and in use are not the same or unknown,
        (N) Enhanced protocol is in use, (n) Enhanced protocol is configured,
        (-) Not in use or not configured
License level restrictions: (C) Core, (A) Advanced edge, or (E) Edge in use,
        (c) Core, (a) Advanced edge, or (e) Edge configured,
        (-) Not in use or not configured
```

   b. If a node is enabled for stacking (shown by a capital letter `E` in the Flags column), issue the command `disable stacking node-address` *mac_address* for that node.

      Then reboot the switch.

9. From the node that will be the primary, issue the command `enable stacking`.

   The following prompt displays:

```
X440G2-24t-10G4.4 # enable stacking
You have not yet configured all required stacking parameters.
Would you like to perform an easy setup for stacking operation? (y/N)
```

10. Enter `y` to proceed with Easy Setup (strongly recommended), or enter `n` to configure the stack manually.

- When you enter `y` for Easy Setup, you are prompted to confirm your choice:

```
Executing "configure stacking easy-setup" command...
For every node in the 4-node stack, this command will:
- enable stacking
- configure a stack MAC address
- choose and configure a slot number (this node will be assigned to slot 1)
- configure redundancy to minimal (slot 1 will be the master node)
- configure the stacking protocol to enhanced
Upon completion, the stack will automatically be rebooted into the new
configuration.
Warning: If stacking is already configured, this command will alter that
```

```
configuration.
Do you wish to proceed? (y/N)
```

Enter `y` again to confirm. All of the switches reboot automatically and form a stack in which one switch is the primary, one is the backup, and the rest are standby nodes. Easy Setup configures all other required stacking parameters for every switch in the stack.

- If you forgo Easy Setup by entering `n` in response to the prompt (not recommended), you will need to configure the stack manually. Instead of continuing with step 11, follow the steps in Manually Configuring a Stack on page 170.

11. Verify the configuration, following the instructions in Verifying the Configuration on page 176.

12. Save the ExtremeXOS configuration to every active node in the stack.

On the primary node, issue the command `save configuration` *`config_name`*, where *`config_name`* is a descriptive name for this configuration.

The stacking-specific configuration parameters are saved in a file called *`config_name`*`.cfg` to the NVRAM of each node.

The stack is ready to use.

Manually Configuring a Stack

We recommend that you configure your stack using Easy Setup, as described in step 9 on page 169.

However, instead of running Easy Setup, you can configure the stack parameters manually. After performing step 1 on page 167 through step 9 on page 169, perform the following steps as needed:

1. Reboot the switch that will be the master.
2. Optionally, assign slot numbers to all switches in the stack.

   See Configuring Slot Numbers on page 171.
3. Configure node priorities on each slot.

   When the stack boots up, the node priority determines which node will be the master and which node will be the backup. Node priorities can be from 1 to 99, the lowest numbered slot having the highest priority.

   See Configuring the Primary, Backup, and Standby Roles on page 172.
4. Disable master capability for any nodes that you do not want to become master nodes.

   See Configuring Master-Capability on page 197.
5. Assign a MAC address to the stack.

   See Assigning a MAC Address to a Stack on page 174.
6. Optionally, configure a failsafe account for the stack.

   See Failsafe Accounts on page 58.

7. Optionally, set a command prompt for the stack.

    Issue the command `configure snmp sysName stack_name`.

    If you do not define your own command prompt, the default command prompt looks similar to

    `* Slot-6 Stack.9 #`, where:

    - `*` indicates a changed and unsaved ExtremeXOS configuration
    - 9 is a sequence number indicating the 9th command to be entered since login
    - # indicates that your are logged into the master node (other nodes display the > symbol)

8. When you have performed all desired configuration steps, reboot the stack.

9. Verify the configuration, following the instructions in Verifying the Configuration on page 176.

10. Save the ExtremeXOS configuration to every active node in the stack.

    On the primary node, issue the command `save configuration config_name`, where `config_name` is a descriptive name for this configuration.

    The stacking-specific configuration parameters are saved in a file called `config_name.cfg` to the NVRAM of each node.

Configuring Slot Numbers

When you configure a stack manually, each node in the stack must be assigned a unique slot number. You can assign the slot number only through configuration; the stack does not dynamically assign a slot number. The available slot numbers are 1 through 8. You can specify a slot number for each node manually, or you can have the system assign the slot numbers using a single command.

> **Note**
> Slot numbers take effect only after a restart. If you change a slot number, the unit continues to operate with the slot number it was last restarted with.

- To manually add a slot number to a node, use the following command:

  `configure stacking node-address mac_address slot-number slot_number`

  where `mac_address` is the node's MAC address.

- To configure the system to choose slot numbers for all nodes, enter the command:

  `configure stacking slot-number automatic`

  Automatic slot number assignment is performed in the order of appearance of the nodes in the `show stacking` display. In the case of a ring topology, the first node in the display is the intended master node into which you have logged in.

- To view current slot number assignments, regardless of whether they were assigned manually or automatically, use either the `show stacking` or the `show stacking configuration` command.

    You can find examples of these commands and their output in Verifying the Configuration on page 176.

    📝 **Note**
    A node that boots in standalone mode does not use a slot number.

Configuring the Primary, Backup, and Standby Roles

Each stack has a primary node, and it might have a backup node and multiple standby nodes. Each switch's role is determined by its priority.

The role of each stack node is determined by, in order of precedence:

- The switch model number.
- The configured priority value (a higher value means the switch has higher priority).
- The slot number in the stack (slot 1 is the primary, slot 2 is the backup).
- The setting of the `master-capability` option (see Configuring Master-Capability on page 197).

Some switch models have greater CPU processing capability, more memory, and support additional features – thus making them more suitable for the role of primary node.

To support the additional capabilities in a stack that includes multiple switch models, the most capable switch automatically becomes the primary node. When choosing a switch to act as a backup node, a switch with the same capability as the primary node should be chosen.

The following list shows which switch models can cross stack with each other. Within each list, the relative ranking is shown with the most capable switches placed at the top of the list:

1. ExtremeSwitching X460-G2 (most capable)*
2. ExtremeSwitching X450-G2*
3. ExtremeSwitching X440-G2 and X620*
4. ExtremeSwitching X590 and X695**
5. ExtremeSwitching X465**

* - Cross stack group 1. Switches in this group cannot cross stack with switches in group 2.

** - Cross stack group 2. Switches in this group cannot cross stack with switches in group 1.

If the stack configuration includes switches that are more capable than others, the stack will try to select the most-capable backup node.

If a switch with reduced capabilities serves as the backup node for a switch with greater capabilities, that switch might not be able to support the stack as a primary node if a failover occurs (for example, the less-capable switch might not have enough processing power or table space to run efficiently as the primary node). If your configuration needs to support automatic failover, we recommend that if a stack contains mixed model numbers, one of the following configurations should be used:

- Identical, most-capable switches available to become the primary and backup nodes.
- The primary-capability option is turned off for all less-capable switches.

When all primary-capable nodes in a stack have the same model number, the node with the highest node role election priority becomes the primary as a result of the first node role election, and the node with the second highest node role election priority becomes the backup node. All other nodes become standby nodes. See Node Election on page 90 for more information.

During subsequent node role elections that occur when a primary node fails, the node priority configuration helps determine the node that becomes the replacement backup node.

Node priority configuration takes effect at the next node role election. A change in node priority configuration does not cause a new election. Once an active topology has elected a primary node, that node retains the primary node role until it fails or loses a dual primary resolution.

You can configure one of the following election priority algorithms:

- Priority algorithm: If any node has a numeric priority value configured. Use the `configure stacking priority` command to configure priority values for the nodes in the stack.
- Automatic algorithm: If all nodes participating in node role election have the automatic priority value configured.

The priority algorithm is selected if any node has a numeric priority value configured. You can specify an integer priority value between 1 and 100. The higher the value, the greater the node role election priority. For example, the command `configure stacking slot 2 priority 10` assigns a priority of 10 to the switch in slot 2.

If any node participating in a role election has a priority value configured, all nodes use the priority algorithm. A node configured with the automatic algorithm uses a priority value of zero (the lowest priority) in the priority algorithm if another node has a priority value configured.

The automatic algorithm is selected if no node participating in a role election has a numeric priority value configured. In automatic mode, the stack determines the highest role election priority based on factors such as available processing power, maintenance level of ExtremeXOS, and so forth.

In both algorithms, if the highest computed node role election priority is shared among multiple nodes, the slot number is used to adjust the node role election priority. A numerically lower slot number results in a higher role election priority than

a numerically higher slot number. If you want to use the slot number as the sole determining factor in node role election priority calculation, you should configure every node with the same priority value, rather than using the automatic algorithm.

> **Note**
> The automatic priority algorithm may change in future ExtremeXOS releases.

Nodes that are configured as not primary-capable do not participate in node role election. Priority configuration is not relevant on such nodes.

A dual primary resolution does not use the configured node priority in most cases. Instead, it uses the oldest time that a node became a primary in the current active topology.

Assigning a MAC Address to a Stack

Each stack must use a single MAC address. When the master node fails over to the backup node, the backup node must continue to use the same MAC address that the master node was using.

Each stackable switch is assigned a single unique MAC address during production. By default, no stack MAC address is configured. You can choose any node to supply its factory assigned MAC address to form the stack MAC address.

> **Note**
> This task is not necessary when you configure the stack using Easy Setup. With Easy Setup, the MAC address is assigned by default.

When you assign a MAC address to a stack, one of the stackable switches is designated as the node whose factory-assigned MAC address is used to form the stack MAC address. Once this is done, all nodes receive and store this formed MAC address in their own NVRAM. Whenever the stack boots up, this MAC address is used, regardless of which node is the master.

When new nodes are added to the stack, the new nodes must be configured with the stack MAC address. The easiest way to do this is to use the `synchronize stacking` {**node-address** *node_address* | **slot** *slot_number*} command.

Before being stored as the stack MAC address, the chosen node's factory-assigned MAC address is converted to a locally administered MAC address. This prevents duplicate MAC address problems which lead to dual master conditions. The chosen MAC address is put into effect only at node boot time. If the address needs to be changed on a single node, rebooting that node results in usage of the same address stack-wide.

If you do not configure the stack MAC address or it is not the same on all nodes, a warning message appears in the log.

Each node operates with whatever address is available: the configured stack MAC address or the node's factory-assigned MAC address. If a master node fails over to the backup node, and the backup node's address is different than the one the former master node was using, the address is inconsistent with the addresses programmed

into the packet forwarding hardware. The MAC address related to the management IP address changes to the one in use by the new master, but no gratuitous ARP requests are sent. In this case, it takes some time for hosts on the management network to flush the related ARP entry.

> **Note**
> If the node whose MAC address is chosen was removed from the stack with the intention of using the node elsewhere in the network, and that node is selected to supply the stack MAC in its new stack, the stack MAC of the original stack must be reconfigured to prevent a duplicate MAC address in the network.

To assign a MAC address to a stack, follow these steps.

1. Use the `show stacking configuration` command to display the stack MAC address configuration.

```
Slot-1 stack.3 # show stacking configuration
Stack MAC in use: 02:04:96:9c:e4:39
Node              Slot        Alternate           Alternate
MAC Address       Cfg Cur Prio Mgmt IP / Mask     Gateway         Flags     Lic
----------------- --- --- ---- ----------------- --------------- --------- ---
*00:04:96:9c:e4:39 1   1   Auto <none>            <none>          CcEeMm-Nn --
 00:04:96:9b:c1:34 2   2   Auto <none>            <none>          CcEeMm-Nn --
 00:04:96:9e:5c:76 3   3   Auto <none>            <none>          --EeMm-Nn --
 00:04:96:9c:53:b6 4   4   Auto <none>            <none>          --EeMm-Nn --
* - Indicates this node
Flags:  (C) master-Capable in use, (c) master-capable is configured,
        (E) Stacking is currently Enabled, (e) Stacking is configured Enabled,
        (M) Stack MAC in use, (m) Stack MACs configured and in use are the same,
        (i) Stack MACs configured and in use are not the same or unknown,
        (N) Enhanced protocol is in use, (n) Enhanced protocol is configured,
        (-) Not in use or not configured
License level restrictions: (C) Core, (A) Advanced edge, or (E) Edge in use,
        (c) Core, (a) Advanced edge, or (e) Edge configured,
        (-) Not in use or not configured
```

The MAC Address column displays the factory MAC address for the node. The stack MAC address configuration information appears in the last three positions of the Flags column. As shown in the key at the bottom of the command display, the stack MAC configuration is displayed with the letters capital M, lower-case m, and lower-case i. If the flags read ---, the stack MAC address needs to be configured. If the flags read Mm-, the stack MAC address is already configured and in use.

2. To configure the stack to use the MAC address of the master node, follow these steps:

   a. Log in to the master node.
   b. Issue the command `configure stacking mac-address`.

c. To verify that the command executed properly, enter the command `show stacking`.

   The Flags column should show `--i`, indicating that the stack MAC is configured but is not in use. After you restart the stack, the `i` will no longer appear in the Flags column.

d. To verify that the stack MAC is configured consistently, enter the command `show stacking detail`.

   Verify that all of the stack MAC addresses are the same.

3. To configure the stack to use a MAC address from a non-master node, log in to the master console and enter the command `configure stacking {`**node-address** *node-address* | **slot** *slot-number*} **mac-address** .

   For example:
   ```
   Slot-1 stack.4 # configure stacking slot 2 mac-address
   This command will take effect at the next reboot of the specified node(s).
   ```
   The stack is configured to use the MAC address of the node in slot 2.

4. Reboot the stack.

5. Verify the new stack MAC address using the command `show stacking configuration`.

   For example:
   ```
   Slot-1 stack.5 # show stacking configuration
   Stack MAC in use: 02:04:96:9b:c1:34

   Node               Slot          Alternate          Alternate
   MAC Address        Cfg Cur Prio Mgmt IP / Mask      Gateway        Flags     Lic
   ----------------- --- --- ---- ----------------- --------------- -------- ---
   *00:04:96:9c:e4:39 1   1   Auto <none>            <none>          CcEeMm-Nn --
    00:04:96:9b:c1:34 2   2   Auto <none>            <none>          CcEeMm-Nn --
    00:04:96:9e:5c:76 3   3   Auto <none>            <none>          --EeMm-Nn --
    00:04:96:9c:53:b6 4   4   Auto <none>            <none>          --EeMm-Nn --
   * - Indicates this node
   ```

Verifying the Configuration

To verify that your stack is configured as you intended, log into the master node and issue any or all of the following commands.

- show stacking on page 177
- show stacking configuration on page 177
- show slot on page 178
- show stacking detail on page 178
- show stacking stack-ports on page 179

These commands are also helpful when debugging problems with your stack.

> **Note**
> The examples in the following sections show a stack consisting of four X440-G2 switches.

show stacking

The `show stacking` command displays the stack topology along with each node's slot number, state, and role (master, backup, or standby).

```
Slot-1 Stack.1 # show stacking
Stack Topology is a Ring
Active Topology is a Ring
Node MAC Address    Slot   Stack State   Role      Flags
-----------------   ----   ----------    -------   ---
*00:04:96:9c:e4:39  1      Active         Master   CA-
00:04:96:9b:c1:34   2      Active         Backup   CA-
00:04:96:9e:5c:76   3      Active         Standby  CA-
00:04:96:9c:53:b6   4      Active         Standby  CA-
* - Indicates this node
Flags:  (C) Candidate for this active topology, (A) Active Node
        (O) node may be in Other active topology
```

In the command output, note that:

- The asterisk (*) that precedes the node MAC address indicates the node to which you are logged in. The node MAC address is the address that is factory assigned to the stackable switch.
- The slot number shown is the number currently in use by the related node. Because slot number configuration only takes effect during node initialization, a change in configured value alone does not cause a change to the slot number in use.
- If a node role has not yet been determined, the node role indicates <none>. In a ring topology, the node on which this command is executed is always the first node displayed. In a daisy chain, the ends of the daisy chain are the first and last nodes displayed.
- Even though the stack topology could be a ring, the active topology could be a daisy chain because it does not contain every node in the stack topology.
- If the node on which this command is being executed is not active, the stacking topology is replaced with a line similar to this one:
  ```
  This node is not in an Active Topology.
  ```
- It is possible for a node to be in stabilizing or waiting state and still be in the active topology.

show stacking configuration

The `show stacking configuration` command displays a summary of the stacking configuration for all nodes in the stack.

```
Slot-1 Stack.3 # show stacking configuration
Stack MAC in use: 02:04:96:9c:e4:39
Node               Slot        Alternate         Alternate
MAC Address        Cfg Cur Prio Mgmt IP / Mask   Gateway        Flags      Lic
-----------------  --- --- ---- ----------------- --------------- --------- ---
*00:04:96:9c:e4:39 1   1   Auto <none>               <none>          CcEeMm-Nn --
00:04:96:9b:c1:34  2   2   Auto <none>               <none>          CcEeMm-Nn --
00:04:96:9e:5c:76  3   3   Auto <none>               <none>          --EeMm-Nn --
00:04:96:9c:53:b6  4   4   Auto <none>               <none>          --EeMm-Nn --
* - Indicates this node
Flags:  (C) master-Capable in use, (c) master-capable is configured,
        (E) Stacking is currently Enabled, (e) Stacking is configured Enabled,
        (M) Stack MAC in use, (m) Stack MACs configured and in use are the same,
```

```
        (i) Stack MACs configured and in use are not the same or unknown,
        (N) Enhanced protocol is in use, (n) Enhanced protocol is configured,
        (-) Not in use or not configured
License level restrictions: (C) Core, (A) Advanced edge, or (E) Edge in use,
        (c) Core, (a) Advanced edge, or (e) Edge configured,
        (-) Not in use or not configured
```

In the command output, note especially the values in the **Flags** column:

- All nodes should have the `Ee`, `Mm`, and `Nn` flags active.
- Additionally, the master and backup nodes should have the `Cc` flags active.

(The meanings of the flags are displayed at the bottom of the table in the command output.)

show slot

The `show slot` command shows the states of the nodes as they move from the empty to operational state.

```
Slot-1 Stack.2 # show slot
Slots    Type                    Configured          State       Ports
-----------------------------------------------------------------
Slot-1   X440G2-24t-10G4                             Operational  28
Slot-2   X440G2-24x-10G4                             Operational  28
Slot-3   X440G2-12p-10G4                             Operational  16
Slot-4   X440G2-12t-10G4                             Operational  16
Slot-5                                               Empty         0
Slot-6                                               Empty         0
Slot-7                                               Empty         0
Slot-8                                               Empty         0
```

show stacking detail

The `show stacking {`**node-address** *node_address* `|` **slot** *slot_number*`}` **detail** command displays a full report about a particular node.

```
Slot-1 Stack.33 # show stacking slot 1 detail
Stacking Node 00:04:96:26:6b:ec information:
Current:
Stacking : Enabled
Role : Master
Priority : Automatic
Slot number : 1
Stack state : Active
Master capable? : Yes
Stacking protocol : Enhanced
License level restriction : <none>
In active topology? : Yes
Factory MAC address : 00:04:96:26:6b:ec
Stack MAC address : 02:04:96:26:6b:ec
Alternate IP address : <none>
Alternate gateway : <none>
Stack Port 1:
State : Operational
Blocked? : No
Control path active? : Yes
Selection : Alternate (23)
Stack Port 2:
State : Operational
Blocked? : Yes
```

```
Control path active? : Yes
Selection : Native
Configured:
Stacking : Enabled
Master capable? : Yes
Slot number : 1
Stack MAC address : 02:04:96:26:6b:ec
Stacking protocol : Enhanced
License level restriction : <none>
Stack Port 1:
Selection : Alternate (23)
Stack Port 2:
Selection : Native
```

In the command output, note that:

- If you issue `show stacking detail` without a *node-address* or *slot* parameter, the output is generated for all nodes in the stack topology.
- The *slot* parameter is available only in stacking mode. The *node-address* parameter is always available.
- Current information represents stacking states and configured values that are currently in effect. Configured information is that which takes effect at node reboot only.
- The node's role can be Master, Backup, Standby, or none.
- License level restrictions are Edge, Advanced Edge/Base, or Core/Premier.

show stacking stack-ports

The `show stacking stack-ports` command displays the states of each stacking port in the stack. This information can help you verify that all ports are properly connected and operational.

```
Slot-1 Stack.5 # show stacking stack-ports
Stack Topology is a Ring
Slot Port Select Node MAC Address  Port State  Flags Speed
---- ---- ------ ----------------- ----------- ----- -----
*1   1    27      00:04:96:9c:e4:39 Operational C-      10G
*1   2    28      00:04:96:9c:e4:39 Operational CB      10G
2    1    27     00:04:96:9b:c1:34 Operational CB      10G
2    2    28     00:04:96:9b:c1:34 Operational C-      10G
3    1    15     00:04:96:9e:5c:76 Operational C-      10G
3    2    16     00:04:96:9e:5c:76 Operational C-      10G
4    1    15     00:04:96:9c:53:b6 Operational C-      10G
4    2    16     00:04:96:9c:53:b6 Operational C-      10G
* - Indicates this node
Flags:  (C) Control path is active, (B) Port is Blocked
```

In the command output, a state other than `Operational` indicates a potential problem. Check the physical connections and the software configuration for the ports in question. For more information, see Troubleshooting a Stack on page 212.

Using the X465 Mode Button to Automatically Stack

The **mode** button is a front-panel button used to select alternate front-panel LED display modes that convey additional port and stacking information. On the

ExtremeSwitching X465 series switch, this button can be used to initiate automatic stacking.

Automatic stacking using the **mode** button feature is aimed at zero-touch customers who want to deploy stacking in remote sites. You can ship switches to remote sites and have a local (non-technical) installer mount the switches in the rack, attach the power cables, and connect the stacking cables. The installer can then press the **Mode** button to initiate the automatic stacking sequence. After stacking is complete, the switches can be provisioned and managed remotely using a cloud connection.

You can stack 1 to 8 nodes. If you have only a single node in the stack, stacking occurs in a daisy-chain topology. If there is more than a single node in the stack topology, the stack is connected as a ring. If a ring is not detected, the automatic stacking sequence does not run when you presses the **Mode** button.

You can build a stack a node at a time by initiating automatic stacking on one switch that, after rebooting, becomes the primary node. Attaching nodes subsequently causes those nodes to join the stack.

> **Important**
>
> To use automatic stacking, each switch must have the factory default configuration. If any of the switches do not have the factory configuration (directly out of the shipping box), remove any configuration and restore the factory defaults by running the command `unconfigure switch {`**`all`**` | `**`erase`**` [`**`all`**` | `**`nvram`**`]}` with the **`all`** option.
>
> License level and ExtremeXOS version mismatches are automatically reconciled. However, license mismatches due to installing feature licenses cannot be resolved automatically. The applicable node is left in the failed state.

To use automatic stacking, all switches must:

- Have the same license level.
- Be running ExtremeXOS 30.3 or later.

  If the primary node is running a newer version of ExtremeXOS than the nodes, the nodes are upgraded to the newer ExtremeXOS version.

- Not have an Extended Edge Switching topology.

To begin automatic stacking:

1. Remove the switches from their boxes and mount the desired number of switches in the desired locations. For information about physically setting up switches, see the *ExtremeSwitching Quick Reference Guide* for the switch series.
2. Attach the stacking cables to form a ring between the switches (see Ring Topology: Recommended for Stacking on page 153).
3. Attach the power cables to each switch, and then plug them into a power source.
4. Wait for all switches to boot (approximately 2 minutes).

5. Verify that there is **LINK UP** on all stack ports by checking the stack port LEDs.

> **Note**
> A single node stack (no cabling) will not have a lit LED.

6. On the switch that is going to be the stack primary, push the **Mode** button twice and verify that the **STK** LED is solid green.
7. Press and hold the **Mode** button for at least 5 seconds.

AFter releasing the **Mode** button (following the final step), the front panel port LEDs (on the primary node) flash in an alternating pattern followed by a delayed reboot of all of the switches. The LEDs flash for approximately 15 seconds prior to reboot. After the reboot completes, the switches are stacked.

If the front panel port LEDs on the primary node do *not* flash (flashing LEDs indicate that automatic stacking has been initiated), try the following:

- Check the cabling for correct ring topology, and fix as needed (see Ring Topology: Recommended for Stacking on page 153).
- Check that the stack port **LINK UP** LEDs are lit (see step 5 on page 181).

> **Note**
> A single node stack (no cabling) will not have a lit LED.

If you can verify that both the cabling and the **LINK UP** LEDs are lit, then further troubleshooting requires accessing the switch with a console or by cloud access to check the switch's error log.

Using a USB Flash Drive to Automatically Stack

A USB flash drive can be used for auto-stacking on switches with or without a **mode** button.

You can stack 1 to 8 nodes. If you have only a single node in the stack, stacking occurs in a daisy-chain topology. If there is more than a single node in the stack topology, the stack is connected as a ring. If a ring is not detected, the automatic stacking sequence does not run when you insert the USB flash drive.

You can build a stack one node at a time by initiating automatic stacking on one switch that, after rebooting, becomes the primary node. Attaching nodes subsequently causes those nodes to join the stack.

> **Important**
>
> To use automatic stacking, each switch must have the factory default configuration. If any of the switches do not have the factory configuration (directly out of the shipping box), remove any configuration and restore the factory defaults by running the command `unconfigure switch {`**`all`** `|` **`erase`** `[`**`all`** `|` **`nvram`**`]}` with the **`all`** option.
>
> License level and ExtremeXOS version mismatches are automatically reconciled. However, license mismatches due to installing feature licenses cannot be resolved automatically. The applicable node is left in the failed state.

To use automatic stacking, all switches must:

- Have the same license level.
- Be running ExtremeXOS 31.4 or later.

  If the primary node is running a newer version of ExtremeXOS than the nodes, the nodes are upgraded to the newer ExtremeXOS version.
- Not have an Extended Edge Switching topology.

To begin automatic stacking:

1. Remove the switches from their boxes and mount the desired number of switches in the desired locations. For information about physically setting up switches, see *ExtremeSwitching Quick Reference Guide* for the switch series.
2. Attach the stacking cables to form a ring between the switches (see Ring Topology: Recommended for Stacking on page 153).
3. Attach the power cables to each switch, and then plug them into a power source.
4. Wait for all switches to boot (approximately 2 minutes).
5. Verify that there is **LINK UP** on all stack ports by checking the stack port LEDs.

> **Note**
>
> A single node stack (no cabling) will not have a lit LED.

6. On the switch that is going to be the stack primary, insert the USB flash drive.

The USB flash drive must contain a file named "autoStackingMasterNode," which invokes the auto-stacking logic. The front panel port LEDs (on the primary node) flash in an alternating pattern followed by a delayed reboot of all of the switches. The LEDs flash for approximately 15 seconds prior to reboot. After the reboot completes, the switches are stacked.

> **Note**
>
> The delay for auto-stacking can be up to 5 minutes.

If the front panel port LEDs on the primary node do *not* flash within the 5 minute timeout period (flashing LEDs indicate that automatic stacking has been initiated), try the following:

- Check the cabling for correct ring topology, and fix as needed (see Ring Topology: Recommended for Stacking on page 153).
- Check that the stack port **LINK UP** LEDs are lit.

> **Note**
> A single node stack (no cabling) will not have a lit LED.

If you can verify that both the cabling and the **LINK UP** LEDs are lit, then further troubleshooting requires accessing the switch with a console or by cloud access to check the switch's error log.

Managing an Operational Stack

The following topics describe common tasks for logging into an operational stack and managing it.

Logging into a Stack

You can log into any node in a stack, but you can control more stack features when you log into the master. The following guidelines describe the options available to you when you log into different nodes:

- On master nodes, all features supported by the switch license operate correctly.
- On backup nodes, most show commands show correct data for the active stack. For example, `show vlan {`**`virtual-router`** *`vr-name`*`}` shows all configured VLANs.
- On all non-master nodes, most of the configuration commands are rejected. However, the failsafe account, enable license, and stacking configuration commands work on any node.
- On standby nodes, most show commands do not show correct data for the current stack operation. However, the `show switch {`**`detail`**`}`, `show licenses`, and all `show stacking` commands show correct data.
- If a node is connected to the stack and stacking is not enabled, you can still configure stacking features on that node.

The login security that is configured on the master node applies when logging into any node in the active topology. This includes any active node that is present in a slot. A node that is disabled for stacking is its own master, and uses its own security configuration.

You can log in to a SummitStack node using the following methods:

- Console connection to any node
- Management connection to the master

- Management connection to a standby node
- Telnet session over the stack from any active node to any other node in the same active topology

Logging in Through the Console Port

You can use the console port on any switch to manage the stack.

If you connect to the master node, you can configure and manage the stack. If you connect to a non-master node, you can view node status and configure only a few options from the node to which you are connected. However, you can use the Telnet feature to connect to another node and manage that node as if you were connected to it (see Logging Into a Node From Another Node on page 184).

Logging in from the Management Network

The management network is an Ethernet network to which the management port of each switch connects.

The primary management IP address is assigned to the master node. You can use a terminal emulation program and this IP address to connect to the master for configuration and management.

The alternate management IP addresses allow you to connect to individual nodes from your management network. During normal operation, you connect to the stack using the primary management IP address. However, if the stack is split, you can use the alternate management IP address to connect to the other half of the stack. For more information, see Configuring an Alternate IP Address and Gateway on page 192.

After you log in to a master or standby node through the management network, you can Telnet to any other node and control that node as if you were directly connected to it. For more information, see Logging Into a Node From Another Node on page 184.

Logging Into a Node From Another Node

You may log into any node in the active topology from any other node in the same active topology. If you do not know the slot number of the node to which you want to connect, enter the `show slot` command. You can Telnet to any switch that appears in the `show slot` command display.

> **Note**
> If the node to which you want to connect does not appear in the `show slot {slot {detail} | detail }` command display, you can connect to the node through the its console port or management port.

You have the most control over the stack when you log in to the master.

1. Determine which node is the master using the command `show stacking`.
2. Telnet to another node using the command `telnet slot slot-number `.

   The switches must be active in the stack for this command to function.

You are <u>not</u> prompted for your username or password. You are logged in to the same account (with corresponding rights) with which you accessed the originating slot.

When the Telnet program accepts a connection from another node in the stack, it performs security validation. The master node validates all login security information (except for the failsafe account), regardless of the node into which you are attempting to establish a login. If you are not able to log in using your user credentials, use the failsafe account to log in.

Managing Licenses on a Stack

The SummitStack feature is not licensed separately. You can use the SummitStack feature with a Base or Premier license.

The rules for licensing are as follows:

- The effective license level of all master-capable nodes must be the same.
- If you set a license level for the stack, then each node must be at that license level or higher.
- If you do not set a license level for the stack, the license level the stack uses is the effective license level of the node that is elected master at startup.

> **Note**
> If the stack is using a certain license level, and you attempt to add a master-capable node that is using a lower level license, the node does not become operational. In response to the `show slot {`*slot* `{`**detail**`} |` **detail** `}` command, the node displays as Failed with a License Mismatch reason.

- Master-capable nodes continuously monitor the effective license level of the master node.
- Nodes with higher license levels than other nodes can be restricted to operate at a lower or effective license level.

Viewing Switch Licenses and License Restrictions

1. To view the current license information for the stack, log into that master node and enter the `show licenses {[`*slot slot* `|`**all**`]} {`**detail**`}` command with the **all** option.

   The command displays information similar to the following:
   ```
   # show licenses slot all
    Slot Enabled License          Effective License        Feature Packs
    ---- ----------------------- ----------------------- -----------------------
    1    Base                    Base                     None
    2    Premier                 Base                     MACsec
   ```

   The Enabled License Level is the purchased license level. This is the maximum level at which this node can operate without purchasing a license level upgrade.

   The Effective License Level is the operating license level. If a license level restriction is configured for this node, the effective license level may be lower than the enabled

license level. All master-capable switches must be operated at the same effective license level.

Feature Packs shows which feature packs are installed on that node.

2. On the master node, run `show stacking configuration` to view the license level restrictions configured for all nodes in a stack.

```
Slot-1 stack.2 # show stacking configuration
Stack MAC in use: 02:04:96:9c:e4:39
Node               Slot        Alternate          Alternate
MAC Address        Cfg Cur Prio Mgmt IP / Mask     Gateway         Flags     Lic
------------------ --- --- ---- ----------------- --------------- --------- ---
*00:04:96:9c:e4:39 1   1   Auto <none>           <none>          CcEeMm-Nn --
 00:04:96:9b:c1:34 2   2   Auto <none>           <none>          CcEeMm-Nn --
 00:04:96:9e:5c:76 3   3   Auto <none>           <none>          --EeMm-Nn --
 00:04:96:9c:53:b6 4   4   Auto <none>           <none>          --EeMm-Nn -e
* - Indicates this node
Flags:  (C) master-Capable in use, (c) master-capable is configured,
        (E) Stacking is currently Enabled, (e) Stacking is configured Enabled,
        (M) Stack MAC in use, (m) Stack MACs configured and in use are the same,
        (i) Stack MACs configured and in use are not the same or unknown,
        (N) Enhanced protocol is in use, (n) Enhanced protocol is configured,
        (-) Not in use or not configured
License level restrictions: (B) Base, or (P) Premier in use,
        (b) Base, or (p) Premier configured,
        (-) Not in use or not configured
```

License level restrictions appear in the **Lic** column. The license level restriction in use appears first, represented by a capital letter as shown in the display legend. The configured license level restriction appears second, represented by a lower-case letter. When the letters in the Lic column are different, for example `-e` or `Ae`, the node is configured with a different license level restriction than the one that is currently in use.

To put the configured license level restriction into effect, you must reboot the node.

Enabling a Switch License

All nodes must have a purchased license level at least equal to the license level of the master node in order to become operational in the stack. The purchased license level of a node can be enabled only after you log in to that node.

For instructions on enabling a license on a node, see Software Upgrade and Boot Options on page 1958.

Restricting a Switch License Level

If the master-capable nodes in a stack have different license levels and you want to operate a stack at the minimum license level, you can apply a license level restriction. The restriction is stored in the NVRAM of each master-capable node. It forces the node to reduce its license level below its purchased level at node restart time for the life of the restart. This reduced license level is called the effective license level and can be displayed by entering the `show licenses` command on the node you want to evaluate.

To restrict a master-capable node to operate at a license level that is lower than the one purchased for the node, use the command:

```
configure stacking {node-address node-address | slot slot-number}
license-level license_restriction.
```

In the following example, node 7 is restricted to operate at the Edge license level:

```
Slot-1 Stack.3 # configure stacking slot 7 license-level edge
This command will take effect at the next reboot of the specified node(s).
```

You must reboot the master-capable node for the command to take effect.

The command restricts the specified node to operate at the specified license level. The specified license level must match the effective license level of all master-capable nodes in the stack. To avoid stack reboots when future license level upgrades are purchased, during initial deployment you should purchase the same license level for every master-capable node in the stack, and the license level restriction should not be configured.

Upgrading Stack Licenses

You can purchase license level upgrades for ExtremeSwitching switches. All master-capable switches in a stack must run the same license level. If the license you want to run is not available for a specific switch, you cannot use that switch and that license level as a master-capable switch. For example, if you want to upgrade to the core license, your master-capable nodes must be switches that support the core license.

> **Note**
> For information about which switches support which licenses, see the *ExtremeXOS 32.4 Feature License Requirements* document. That document also lists which switches support the SummitStack feature.

To upgrade the licenses for the switches in a stack, follow these steps.

1. Log in to the master node.
2. Enter the `show stacking` command and note the role (master, backup, or standby) of each node in the stack.
3. Enter the `show stacking configuration` command and note any nodes that are configured with a license level restriction.
   See Viewing Switch Licenses and License Restrictions on page 185 for more information.
4. Install the required license level in each master-capable node (backup and standby nodes) by logging into each node (`telnet slot slot-number`) and entering the command:
   `enable license {software} key`
5. Enter the license key given to you by Extreme Networks when you purchased the upgrade.
6. Use the commands in Step 4 to install the required license level on the master node.
7. If any nodes are configured with a license level restriction that is lower than the intended operating license level of the stack, log into the master node and remove the stack license level restriction using the command:
   `unconfigure stacking license-level`

   This command removes the restriction on all nodes.

8. If you removed a license level restriction, reboot the stack to put the license level restriction removal into effect using the command:
   `reboot {[`**`time`** `mon day year hour min sec] |` **`cancel`**`} {`**`slot`** `slot-number |` **`node-address`** `node-address |` **`stack-topology`** `{`**`as-standby`**`}}`

9. Verify that all master-capable nodes are operating at the intended license level. On the master node, run `show licenses` and `show slot {slot {`**`detail`**`} |` **`detail`** `}`.

   If no slot shows as Failed, then all master-capable nodes are operating at the effective license level shown for the master node.

Upgrading ExtremeXOS on a Stack

The following topics describe how to upgrade the ExtremeXOS software and the bootrom on the switches in a stack.

Stack Rolling Software Upgrade

A Stack Rolling Software Upgrade (Rolling Upgrade) enables a stack to continue functioning during a software upgrade. The benefit of a Rolling Upgrade is minimal impact to the devices connected via a LAG or other multi-homing technologies that allow a device to be simultaneously connected to different stack nodes. Performing a Rolling Upgrade does not change the current method of installing software, only how the stack is rebooted.

The Rolling Upgrade process reboots all the Standby nodes, reboots the Backup node, and then initiates a failover to make the old Backup node the new Primary. The failover results in the old Primary node rebooting. Since the selected software version on each node is the newer, upgraded software version, after each node reboots, they will run the new software version.

Performing a Rolling Upgrade on page 188 contains steps on initiating a Rolling Upgrade.

Performing a Rolling Upgrade

To begin a Rolling Upgrade, all nodes in the stack must have the same selected software version.

Complete these steps to perform a Rolling Upgrade.

> **Note**
> Performing a Rolling Upgrade does not change the current method of installing software, only how the stack is rebooted.

1. Download the software image using the **`download`** command.
2. Install the image (if not already completed in the previous step) using the **`install`** command.
3. Reboot the stack using the **`reboot`** command, specifying the `reboot rolling` option.

A failover is performed to complete the upgrade.

If a Rolling Upgrade fails, the nodes in the stack will likely be in different stages of the rolling upgrade process. Any nodes that have started the reboot process will be running the newer software version. Nodes that did not begin rebooting will still be running the older software. The stack should not be left in this condition for an extended period of time.

Possible remedies include:

- Reverting a Rolling Upgrade on page 189
- Finishing a Rolling Upgrade on page 190

Reverting a Rolling Upgrade

To revert an upgrade, the Rolling Upgrade process is performed in reverse order by completing the following steps:

1. Determine which partition is currently selected on each node by entering the **show slot detail** command.

    The **include** keyword can be used to simplify the output. In the following example, the Backup and both Standy nodes have been rebooted and are running the newer software version:

    ```
    # show slot detail | include "information|Image|State|ver:"
    Slot-1 information:
         State:              Operational
         Current State:      MASTER
         Image Selected:     primary
         Image Booted:       secondary
         Primary ver:        31.3.1.22
         Secondary ver:      31.3.0.106
    Slot-2 information:
         State:              Operational
         Current State:      BACKUP (In Sync)
         Image Selected:     primary
         Image Booted:       primary
         Primary ver:        31.3.1.22
         Secondary ver:      31.3.0.106
    Slot-3 information:
         State:              Operational
         Current State:      STANDBY
         Image Selected:     primary
         Image Booted:       primary
         Primary ver:        31.3.1.22
         Secondary ver:      31.3.0.106
    Slot-4 information:
         State:              Operational
         Current State:      STANDBY
         Image Selected:     primary
         Image Booted:       primary
         Primary ver:        31.3.1.22
         Secondary ver:      31.3.0.106
    ```

2. Change the selected software partition to the old version on all nodes by entering the **use image secondary** command.

3. When all nodes have the old software version selected, reboot each node running the new software version, starting with the Backup node first.

   When the Backup node reboots, it should go back to "In-Sync" with the Primary node.

   > **Note**
   >
   > After each reboot, allow a few minutes for the network to converge before proceeding.

4. Reboot any Standby nodes individually, ensuring that the rebooted node is operational before moving on to the next node.

When all nodes are running the old software version, the upgrade is reverted. At this point, all nodes should have both their selected and booted partitions set to the partition that contains the old software version.

Finishing a Rolling Upgrade

To manually finish an upgrade and continue rebooting nodes that were not rebooted, complete the following steps:

1. Determine which partition was booted for each node by entering the `show slot detail` command.

   The `include` keyword can be used to simplify the output. In the following example, only one of the Stanby nodes (Slot-3) was rebooted and is running the newer software version:

   ```
   # show slot detail | include "information|Image|State|ver:"
   Slot-1 information:
         State:               Operational
         Current State:       MASTER
         Image Selected:      primary
         Image Booted:        secondary
         Primary ver:         31.3.1.22
         Secondary ver:       31.3.0.106
   Slot-2 information:
         State:               Operational
         Current State:       BACKUP (In Sync)
         Image Selected:      primary
         Image Booted:        secondary
         Primary ver:         31.3.1.22
         Secondary ver:       31.3.0.106
   Slot-3 information:
         State:               Operational
         Current State:       STANDBY
         Image Selected:      primary
         Image Booted:        primary
         Primary ver:         31.3.1.22
         Secondary ver:       31.3.0.106
   Slot-4 information:
         State:               Operational
         Current State:       STANDBY
         Image Selected:      primary
         Image Booted:        secondary
         Primary ver:         31.3.1.22
         Secondary ver:       31.3.0.106
   ```

2. Reboot any Standby nodes running the old software version individually, ensuring that the rebooted node is operational before moving on to the next node.

3. When all the Standby nodes are running the new software version and the network has converged, reboot the Backup node and allow it to go back "In-Sync" with the Primary node.

> **Note**
> After each reboot, allow a few minutes for the network to converge before proceeding.

4. Failover control of the stack from the Primary node to the Backup node by entering the `run failover` command.

When all nodes are running the newer software version, the upgrade is finished. At this point, all nodes should have both their selected and booted partitions set to the partition that contains the newer software version.

Upgrading the Software on all Active Nodes

You can centrally upgrade the software on all active nodes in a stack. To upgrade all nodes in the stack, all nodes must be running an ExtremeXOS release that supports stacking (ExtremeXOS release 12.0 or later).

> **Note**
> You cannot automatically update a switch running ExtremeXOS 30.2 or earlier to ExtremeXOS 30.3 or later due to a file system compatibility issue. If you are inserting a switch that has ExtremeXOS 30.2 or earlier, prior to inserting the switch into the stack topology, you need to manually upgrade the switch with the following procedure.

Hitless upgrade is not supported in a stack, except during a Stack Rolling Software Upgrade.

1. To download and install a new image, the active partitions (primary or secondary) of all non-master nodes must match the active partition of the master node.

   a. To determine the active partition selected on all nodes and the ExtremeXOS versions installed in each partition, use the `show slot {`*`slot`* `{`**`detail`**`} | ` **`detail`** `}` command with the **`detail`** option. If the node being upgraded is running on the primary partition, then the new image is downloaded and installed on the secondary partition.

   b. If the active partition is different on some nodes, the action you take depends on what is stored in both partitions:

      If both primary and secondary partitions have the same ExtremeXOS release, you may use the following commands to cause a node to use the same active image as the rest of the stack:

      `use image {`**`primary`** `| ` **`secondary`**`} slot ` *`slot-number`*
      `reboot slot ` *`slot-number`*

2. Download a new ExtremeXOS software release and install it on all nodes on the active topology using the command: `download [`**`url`** *`url`* `{`**`vr`** *`vrname`*`} | image [`**`active`** `| ` **`inactive`**`] [[`*`hostname`* `| ` *`ipaddress`*`] ` *`filename`* `{{`**`vr`**`} ` *`vrname`*`} {`**`block-size`** *`block_size`*`}] {`*`partition`*`} {`**`install`** `{`**`reboot`**`}}`

3. Restart all nodes in the new release using `reboot` `{[`**`time`** `mon day year hour min sec]` `|` **`cancel`**`}` `{`**`slot`** `slot-number}` `|` **`node-address`** `node-address` `|` **`stack-topology`** `{`**`as-standby`**`}` `|` **`all`**`}` `|` **`rolling`**`}`

Upgrading the Software on a Single Node

To upgrade the software on a single active node:

1. Enter the following commands to download an image to a node:

   `download image [[`*`hostname`* `|` *`ipaddress`*`]` *`filename`* `{{`**`vr`**`}` *`vrname`*`}` `{`**`block-size`** `block_size}]` `{partition}` `{`**`install`** `{`**`reboot`**`}}`

   `use image {`**`partition`**`}` `[`**`primary`** `|` **`secondary`**`]` `slot` *`slotid`*

   `reboot slot` *`slot number`*

   The slot number is the one in use by the active node that is to be upgraded. Be sure that you keep the same image versions on all the other nodes as you have on the master node.

   Alternatively, if your master node has the same image versions in its partitions that you want installed in the node to be upgraded, you can use the command `synchronize` `{`**`slot`** `slotid}` to upgrade both images and select the desired image.

2. You can upgrade the image on an active node even if the node shows as Failed when using the `show slot` command.

Upgrading the Bootrom

The SummitStack feature does not require a bootrom upgrade. You should not upgrade the bootrom of any node unless there are specific reasons to do so. However, the SummitStack feature does allow centralized bootrom upgrade.

You can download and install the bootrom to a specific slot using the slot parameter. The slot parameter is available only on stackable switches in the active stack topology. For information on upgrading the bootrom, see Software Upgrade and Boot Options on page 1958.

If you do not provide a slot number, the stack attempts to download the bootrom image and install it on all stackable switches in the active topology.

Configuring an Alternate IP Address and Gateway

The stack has a primary IP address and subnetwork. These values are assigned using the `configure vlan mgmt ipaddress` command. There can also be static or default routes associated with the stack.

For each node in the stack, you can configure an alternate management IP address, subnetwork mask, and default gateway. The alternate IP address is restricted to being a member of the primary IP subnetwork that is configured on the management *VLAN*, and thus the alternate IP subnetwork must exactly match the primary IP management subnetwork. A subnetwork match is exact if the subnetwork portion of the IP addresses

match exactly. For example, 10.11.12.1/24 and 10.11.12.2/24 are an exact subnetwork match (because both represent the subnet 10.11.12.0/24).

Standby nodes always install their configured alternate management IP address and gateway on the management interface. A standby node does not have the ability to verify whether the configured alternate IP address matches the primary management IP subnetwork of the stack.

The backup and master nodes have the ability to verify the configured alternate IP address. The master and backup nodes compare the primary IP subnetwork information to the alternate IP subnetwork. If there is a match, the backup node installs the primary IP management subnetwork's default routes and installs only the alternate management IP address (not the primary IP address). The master node installs both the configured management subnetwork with specific IP address and the alternate IP address. In this case, the alternate gateway is not used, expecting that primary management routes are configured or will be configured. In either case, if the alternate IP subnetwork does not match the configured management subnetwork, the alternate IP address is not installed on the management interface.

Each node in the stack normally installs its alternate IP address on the management subnetwork. When an ARP request for the alternate IP address is satisfied, the stackable switch supplies its factory-assigned MAC address and not the stack MAC address. Only the master node installs the primary IP address. An ARP request for the configured management IP address returns the configured stacking MAC address. Because of the above behavior, all nodes are reachable over their management ports even during a dual master condition. The VLAN used is the management VLAN (VID 4095) and is untagged.

The alternate gateway is only installed on a master or backup node when the primary management IP subnetwork is not configured. Once the primary IP subnetwork is installed, the alternate gateway is removed. The alternate gateway is always installed on a standby node.

If a dual master condition occurs because a stack has been severed, the alternate IP addresses and associated MAC addresses are unique, and it is possible to use telnet or ssh to reach any node. Any node on the segment with the incorrect master can then be used to reboot the entire stack segment into standby mode if you want to rejoin the stack segments later.

If a node is operating in stacking mode, the alternate management IP address configuration takes effect immediately.

> **Note**
> Only IPv4 alternate management IP addresses are supported in this release.

To configure an alternate IP address and gateway, follow these steps.

1. View the alternate IP address configuration using the `show stacking configuration` command:
   ```
   Slot-1 stack.3 # show stacking configuration
   Stack MAC in use: 02:04:96:9c:e4:39
   Node              Slot          Alternate          Alternate
   ```

```
MAC Address        Cfg Cur Prio Mgmt IP / Mask     Gateway         Flags     Lic
------------------ --- --- ---- ----------------- --------------- --------- ---
*00:04:96:9c:e4:39 1   1   Auto <none>            <none>          CcEeMm-Nn --
 00:04:96:9b:c1:34 2   2   Auto <none>            <none>          CcEeMm-Nn --
 00:04:96:9e:5c:76 3   3   Auto <none>            <none>          --EeMm-Nn --
 00:04:96:9c:53:b6 4   4   Auto <none>            <none>          --EeMm-Nn --
* - Indicates this node
Flags:  (C) master-Capable in use, (c) master-capable is configured,
        (E) Stacking is currently Enabled, (e) Stacking is configured Enabled,
        (M) Stack MAC in use, (m) Stack MACs configured and in use are the same,
        (i) Stack MACs configured and in use are not the same or unknown,
        (N) Enhanced protocol is in use, (n) Enhanced protocol is configured,
        (-) Not in use or not configured
License level restrictions: (C) Core, (A) Advanced edge, or (E) Edge in use,
        (c) Core, (a) Advanced edge, or (e) Edge configured,
        (-) Not in use or not configured
```

In the preceding example, no alternate IP address or alternate gateway is configured.

2. If you have a continuous block of IP addresses to assign to the stack, enter the `configure stacking alternate-ip-address [`*`ipaddress netmask`* `|` *`ipNetmask`*`]` *`gateway`* **`automatic`** command.

For example:

```
Slot-1 Stack.4 # configure stacking alternate-ip-address 10.127.4.131/24 10.127.4.254
automatic
Slot-1 Stack.5 # show stacking configuration
Stack MAC in use: 02:04:96:9c:e4:39
Node               Slot        Alternate         Alternate
MAC Address        Cfg Cur Prio Mgmt IP / Mask     Gateway         Flags     Lic
------------------ --- --- ---- ----------------- --------------- --------- ---
*00:04:96:9c:e4:39 1   1   Auto 10.127.4.131/24    10.127.4.254    CcEeMm-Nn --
 00:04:96:9b:c1:34 2   2   Auto 10.127.4.132/24    10.127.4.254    CcEeMm-Nn --
 00:04:96:9e:5c:76 3   3   Auto 10.127.4.133/24    10.127.4.254    --EeMm-Nn --
 00:04:96:9c:53:b6 4   4   Auto 10.127.4.134/24    10.127.4.254    --EeMm-Nn --
* - Indicates this node
```

3. If you do not have a continuous block of IP addresses for the stack, assign an alternate IP address and gateway to each node using the `configure stacking` [**`node-address`** *`node-address`* | **`slot`** *`slot_number`*] **`alternate-ip-address`** [*`ipaddress netmask`* | *`ipNetmask`*] *`gateway`* command.

For example:
```
Slot-1 Stack.6 # configure stacking slot 4 alternate-ip-address 10.127.4.139/24
10.127.4.254
```

> **Note**
> If you try to assign an alternate IP address and gateway to a node that is already configured with these parameters, an error message appears. To remove an existing configuration so you can change the alternate IP address and gateway, enter the `unconfigure stacking` {**`node-address`** *`node_address`* | **`slot`** *`slot_number`*} **`alternate-ip-address`** command.

4. Enter the `show stacking configuration` command to verify that the alternate IP address and gateway is configured as intended for each node.

```
Slot-1 Stack.7 # show stacking configuration
Stack MAC in use: 02:04:96:9c:e4:39
```

```
Node             Slot        Alternate          Alternate
MAC Address      Cfg Cur Prio Mgmt IP / Mask     Gateway          Flags      Lic
----------------- --- --- ---- ----------------- --------------- --------- ---
*00:04:96:9c:e4:39 1   1   Auto 10.127.4.131/24   10.127.4.254    CcEeMm-Nn --
 00:04:96:9b:c1:34 2   2   Auto 10.127.4.132/24   10.127.4.254    CcEeMm-Nn --
 00:04:96:9e:5c:76 3   3   Auto 10.127.4.133/24   10.127.4.254    --EeMm-Nn --
 00:04:96:9c:53:b6 4   4   Auto 10.127.4.139/24   10.127.4.254    --EeMm-Nn --
* - Indicates this node
```

Viewing the Alternate IP Address

To view the alternate IP address for a node, run `show vlan mgmt` or `show ipconfig mgmt`.

show vlan mgmt Command

The `show vlan mgmt` command shows the alternate management IP address as applied to the management _VLAN_ on the local unit. This allows you to see how the configured alternate management IP address has been applied.

The `show vlan mgmt` command displays the following information:

```
Slot-1 Stack.1 # show vlan "Mgmt"
VLAN Interface with name Mgmt created by user
    Admin State:        Enabled    Tagging:   802.1Q Tag 4095
    Description:        Management VLAN
    Virtual router:     VR-Mgmt
    IPv4 Forwarding:    Disabled
    IPv4 MC Forwarding: Disabled
    IPv6 Forwarding:    Disabled
    IPv6 MC Forwarding: Disabled
    IPv6:               None
    STPD:               None
    Protocol:           Match all unfiltered protocols
    Loopback:           Disabled
    NetLogin:           Disabled
    OpenFlow:           Disabled
    QosProfile:         None configured
    Flood Rate Limit QosProfile:      None configured
    Ports:   1.          (Number of active ports=1)
     Untag: Mgmt-port on Mgmt-1 is active
```

For the management VLAN, a secondary address cannot be configured and so the Secondary IP line does not appear.

The Alternate IP line shows one of the following:

- The configured alternate management IP address if it has been activated.
- <none> if it has not been configured.
- Mismatch if it has been configured but does not exactly match the Primary IP subnet.

show ipconfig mgmt Command

The `show ipconfig mgmt` command shows the configured alternate management IP address as applied to the management _VLAN_ on the local unit. This allows you to see how the configured alternate management IP address has been applied.

The Multinetted VLAN indication always appears as NO. The alternate IP address is restricted to the same subnet as the primary subnet configured for the management IP interface. As a result, only a single subnet is used with the possibility of multiple station addresses. Further, you cannot configure a secondary IP address on the management VLAN.

The `show ipconfig mgmt` command displays the following information:

```
Slot1 Stack.36 # show ipconfig MgmtRouter Interface on VLAN Mgmt is enabled and up.
inet 10.66.4.74/24  broadcast 10.66.4.255  Mtu 1500
Alternate IP Address: 10.66.4.75/24
Flags:
AddrMaskRly  NO       BOOTP Host  NO    DirBcstHwFwd  NO      Fwd Bcast  NO
IgnoreBcast  NO       IP Fwding  NO     IPmc Fwd  NO          Multinetted VLAN  NO
IRDP Advert  NO       SendParam YES     SendPortUn YES        Send Redir YES
SendTimxceed YES      SendUnreach YES   TimeStampRly  NO      VRRP  NO
```

For the management VLAN, a secondary address cannot be configured and so the Secondary IP line does not appear.

The Alternate IP Address line shows one of the following:

- The configured alternate management IP address if it has been activated.
- <none> if it has not been configured.
- Mismatch if it has been configured but does not exactly match the Primary IP subnet.

Viewing Stacking Port Statistics

To view the status of any stacking port, run any of the following variations:

```
show ports stack-ports stacking-port-list utilization {bandwidth | bytes
| packets}
show ports {stack-ports stacking-port-list | port_list} statistics
{norefresh}
show ports {port_list | stack-ports stacking-port-list} rxerrors
{norefresh}
show ports {stack-ports stacking-port-list | port_list} txerrors
{norefresh}
```

The commands accept stacking port ranges that span multiple nodes. For example, both *port-list* and *stacking-port-list* might be expressed as 1:1-3:2.

There are no stacking port configuration options.

See *ExtremeXOS 32.4 Command Reference Guide* for details about these commands.

> **Note**
> There is no way to disable a stacking port. Stacking ports are always enabled.

Configuring Master-Capability

Each node is configurable to be master-capable or not. This means that a node can either be allowed to take on any node role, or be restricted to executing the standby node role only. The default is that a node can take on any role. The restriction is used to avoid the dual master condition. A master-capability configuration change takes effect at the next restart.

You can configure one or more nodes to be allowed to operate either as a master or a backup.

The `configure stacking master-capability` command allows you to set the master-capability of specific nodes, while configure stacking redundancy allows you to set the master-capability on all nodes in the stack.

The commands do not allow you to disable master-capability on all nodes in a stack topology.

> **Note**
>
> If the entire stack is restarted in stacking mode without any node having master capability, you need to know the failsafe account and password to log into any node in the stack. If you do not know the failsafe account information, you might need to rescue the stack. See Rescuing a Stack that has No Primary-Capable Node on page 217.

You can use any of the following commands to configure the master-capability:

- `configure stacking [`**`node-address`** `node_address |` **`slot`** `slot_number]` **`master-capability`** `[`**`on`** `|` **`off`**`]`
- `configure stacking redundancy [`**`none`** `|` **`minimal`** `|` **`maximal`**`]`

Rebooting a Stack

You can reboot a stack by entering the command `reboot` from the master. You can:

- Reboot all the nodes in the stack topology by entering the `reboot` command from a master node login session.
- Reboot a specific node by entering the `reboot node-address` *node-address* command.
- Reboot all nodes in the active topology by entering the `reboot stack-topology` command.
- Move a node to a standby node.
- Reboot the stack topology so that every node comes up in standby role.
- Reboot an active node from another active node by entering the `reboot slot` *slot-number* command.
- Reboot the stack by rolling through each node individually, allowing multi-homed devices to remain connected through the reboot by entering the `reboot` **`rolling`** command.

Changing the Stack Configuration

The following topics describe common tasks for changing the configuration of a stack that was defined previously.

Automatically Adding or Replacing Nodes in a Stack

You can easily automatically add or replace nodes in an existing stack.

> **Important**
> You can only replace a switch with the same switch model, or with a model from the same switch series (family) with the same number of ports, but a different port type. For example, you can replace an ExtremeSwitching X450-G2-24t-10GE4 with an ExtremeSwitching X450-G2-24p-10GE4 (24t → 24p).

Connecting a new node to a stack automatically triggers the following tasks in a stack:

- **Adds New Nodes**—When a new switch is connected to a stack, the switch is automatically:

  1. Configured with the proper stacking support parameters needed to bring up either native or alternate stack ports. This automatic configuration (auto-discovery) is supported on ExtremeSwitching X440-G2, X450-G2, and X460-G2 series switches beginning in ExtremeXOS 30.3. Switches other than the ones listed above require that you configure stacking support on the stacking ports manually.
  2. Assigned the lowest available slot number.
  3. Set as stacking master-capability if the stack has only one master-capable switch (the master itself) and the switch is directly connected to the current stack master. Otherwise, the new switch is not made master-capable.
  4. Assigned the stack MAC address.
  5. Rebooted, which then causes the new node to join the stack.

- **Incompatible ExtremeXOS Check**—Checks for and resolves incompatible ExtremeXOS software versions of stack nodes. If the new switch is running an incompatible version, the version is reconciled by running the `synchronize {`**`slot`** *`slotid`*`}` command for that switch causing the new switch to align with the stack master.

  > **Note**
  > You cannot automatically update a switch running ExtremeXOS 30.2 or earlier to ExtremeXOS 30.3 or later due to a file system compatibility issue. If a switch has ExtremeXOS 30.2 or earlier, prior to inserting the switch into the stack topology, you need to manually upgrade the switch (see Upgrading the Software on all Active Nodes on page 191).

- **License Mismatch Check**—Checks for and resolves software license mismatches between all master-capable nodes. The following command is issued: `configure`

`stacking {`**`node-address`** `node-address | `**`slot`** `slot-number}` **`license-level`** `license_restriction`.

> **Note**
>
> License mismatches due to installing feature licenses cannot be resolved automatically. The node is left in the failed state.

To start automatic node replacement:

1. Prepare the replacement node:

   a. If the replacement switch is not out of the shipping box, remove any configuration and restore the factory defaults by running the command `unconfigure switch {`**`all`** `| `**`erase`** `[`**`all`** `| `**`nvram`**`]}` with the **all** option.

   b. If the replacement switch is going to be the backup node, check for feature license mismatches between it and the master by running `show licenses {[`*slot slot* `|`**`all`**`]} {`**`detail`**`}` on both switches. Install licenses as needed to the replacement node by running the command `enable license {`**`software`**`} [`*key* `]` or;

      `install license` **`file`** *filename* `for universal platforms.`

   c. Power down the replacement switch.

2. Remove the current node from the stack.

3. If you are changing to a different port type (for example, 24t → 24p):

   a. On the master, run the command `configure slot` *slot* **`module`** *module_type* , and change the **module_type** as applicable.

   b. Save the configuration (`save configuration {`**`primary`** `| `**`secondary`** `| `*existing-config | new-config*`}`).

4. Physically connect the new switch to the stack, and power it up. For information about cabling, see the *hardware installation guide* for your switch.

5. Configure the switch port and speed for stack communication on the connected port of the new node for ExtremeSwitching X465, X590, X620, X695 series switches by running the command `configure stacking-support` **`stack-port`** `[`*stack-ports* `| `**`all`**`]` **`selection`** `[`**`native`** `{`**`V40`** `| `**`V80`** `| `**`V160`** `| `**`V200`** `| `**`V320`** `| `**`V400`** `{`**`alternative-configuration`** `| `**`help`**`}} | `**`alternate`**`]`.

   For ExtremeSwitching X460-G2, X450-G2, X440-G2 series switches, the auto-discovery feature automatically turns on stacking support for the connected port.

Platform	Stacking Mode	Supported Ports	Stacking Method	Port Speed
X460-G2	Native	VIM-2Q	V160	40G
		VIM-2SS	–	10G
	Alternate	VIM-2X	–	10G
		Front panel	–	10G

Platform	Stacking Mode	Supported Ports	Stacking Method	Port Speed
X440-G2	Alternate	Front/rear panel	–	10G
X450-G2	Alternate	Front panel	-	10G

Important

The auto-discovery feature takes between 5 and 10 minutes to complete. During this time, the new node is rebooted twice, and if an image upgrade is required, it is rebooted a third time.

To determine that the auto-discovery feature has finished adding the node to the stack, on the master run the command `show slot {`*`slot`* `{`**`detail`**`}` | **`detail`** `}` without the **`detail`** options. When auto-discovery is finished, the slot appears in the output as "Operational". If the node appears as "Failed", run the command `show slot {`*`slot`* `{`**`detail`**`}` | **`detail`** `}`, specifying the slot and using the **`detail`** option to see why the node has failed to join the stack. The most likely problem is that there is a feature license mismatch. To resolve this, re-run the procedure ensuring that you complete Step 1b.

Note

Auto-discovery is enabled by default. To turn on or off auto-discovery, use the following command: `configure` **`stacking-support auto-discovery`** [**`disable`** | **`enable`**].

To manually add or replace a node, see Manually Adding Nodes to a Stack on page 200.

Manually Adding Nodes to a Stack

Tip

For an easier, automatic way to add or replace a node, see Automatically Adding or Replacing Nodes in a Stack on page 198.

Adding a new switch, or node, to an active stack topology is similar to bringing up a new stack.

Note

If the node being added is actually a replacement node for one that was previously removed, see Replacing a Node with the Same Switch Type on page 202 or Replacing a Node with a Different Switch Type on page 204.

Note

If the stack will use MPLS, only the following switch types can act as primary and backup: Extreme Switching X460-G2; X465, X590, and X695.

Review the general and model-specific configuration guidelines for the node you are installing. These guidelines are described in the *hardware installation guide* for your switch.

The examples in the following procedure assume that your current stack has four nodes and you are adding a new node at slot 5.

To manually add a node to a stack:

1. Before connecting the new node to the stack, prepare it as follows:

    a. Turn off stacking auto-discovery by using the following command:

    configure **stacking-support auto-discovery** [**disable** | **enable**]

    b. With the power off, install any required option cards as described in the *hardware installation guide* for your switch.

    c. Power on the new node.

    d. Use the `show switch` command to verify that the new node's software is compatible with the stack:

    -   The new node must run the same ExtremeXOS version as the stack. Install the correct version if necessary.

    -   The ExtremeXOS software must be booted on the same image (primary or secondary) as the stack. If the new node is booted on a different image, change the image before you continue.

    e. Use the `enable stacking` command to enable stacking. Then decline the Easy Setup option.

    f. Configure a unique slot number for the new node (see Configuring Slot Numbers on page 171).

    Select the lowest slot number that is not already in use in the stack. In the following example, the new node has MAC address 00:04:96:26:6c:92 and is assigned to slot 5.

    ```
    Switch.3 # configure stacking node-address 00:04:96:26:6c:92 slot-number 5
    This command will take effect at the next reboot of the specified node(s).
    ```

    g. Configure the node's primary-capability to correspond to the role it should have in the stack (see Configuring Master-Capability on page 197).

    h. If the new node will operate as a primary-capable node, use the `show licenses` command to verify that the enabled license level is at the same level as the primary-capable nodes in the stack.

    If necessary, configure the license-level restriction of the new node to be same as the other primary-capable nodes in the stack (see Managing Licenses on a Stack on page 185).

    i. Configure the node role priority to correspond to the priority it should have in the stack (see Configuring the Primary, Backup, and Standby Roles on page 172).

    j. Configure an alternate IP address and gateway (see Configuring an Alternate IP Address and Gateway on page 192).

    k. If the new node will use the SummitStack-V feature, configure the alternate stacking ports as described in Using Ethernet Ports for Stacking (SummitStack-V Feature) on page 155.

2. Connect the stacking cables to the new node.

   The connections should be made such that the new node appears in the natural position in the stack and in the slot. The following example adds a new node that becomes slot 5.

   • Break the connection between slot 4 port 2 and slot 1 port 1.

   • Connect slot 5 port 1 (the new node) to slot 4 port 2.

   • Connect slot 5 port 2 (the new node) to slot 1 port 1.

   For more information about cabling, see the *hardware installation guide* for your switch.

3. Reboot the new node.

4. At the stack primary node, enter the command `synchronize stacking node-address` *node-address*.

5. Reboot the new node by entering the command `reboot node-address` *node-address*].

6. (Optional) Run the `show stacking` and `show slot` commands, as shown in the following example, to verify that the configuration is what you want.

```
Slot-1 Stack.1 # show stacking
Stack Topology is a Ring
Active Topology is a Ring
Node MAC Address    Slot  Stack State  Role     Flags
-----------------   ----  -----------  -------  ---
*00:04:96:9c:e4:39  1     Active       Master   CA-
00:04:96:9b:c1:34   2     Active       Backup   CA-
00:04:96:9e:5c:76   3     Active       Standby  CA-
00:04:96:9c:53:b6   4     Active       Standby  CA-
00:04:96:26:6c:92   5     Active       Standby  CA-
* - Indicates this node
Flags:  (C) Candidate for this active topology, (A) Active Node
        (O) node may be in Other active topology

Slot-1 Stack.2 # show slot
Slots    Type                    Configured        State        Ports
----------------------------------------------------------------------
Slot-1   X440G2-24t-10G4                           Operational   28
Slot-2   X440G2-24x-10G4                           Operational   28
Slot-3   X440G2-12p-10G4                           Operational   16
Slot-4   X440G2-12t-10G4                           Operational   16
Slot-5   X440G2-12t-10G4                           Operational   16
Slot-6                                             Empty          0
Slot-7                                             Empty          0
Slot-8                                             Empty          0
```

Replacing a Node with the Same Switch Type

> **Tip**
> For an easier, automatic way to add/replace a node, see Automatically Adding or Replacing Nodes in a Stack on page 198.

When you replace a node with the same switch type, for example when you replace an X460-G2-48t-10GE4 switch with another X460-G2-48t-10GE4 switch, you can continue to use the same stack configuration.

If you are replacing a node with a different switch type, you must change the stack configuration before the new node can operate. Follow the procedure in Replacing a Node with a Different Switch Type on page 204.

> **Note**
> If the stack will use *MPLS*, only the following switch types can act as primary and backup: Extreme Switching X460-G2, X465, X590, X695.

To replace a node with an identical switch type, follow these steps:

1. Use the `show switch`, `show licenses`, and `show stacking configuration` commands to display configuration information for the node that is being replaced.

   Note the following attributes of the node you are replacing:
   - ExtremeXOS software version
   - Partition on which the switch is booted
   - Effective license level for the stack
   - Slot number
   - primary-capable feature configuration
   - Node priority
   - Alternate gateway IP address
2. Remove the stacking cables from the node that is being replaced.
3. Replace the node with another switch of the same type.
4. Before connecting the new (replacement) switch to the stack, prepare the switch as follows:
   a. Review the attributes needed for the node you are installing, as listed in step 1.
   b. With the power off, install any required option cards as described in the *hardware installation guide* for your switch.
   c. Power on the new node.
   d. Use the `show switch` command to verify that the new node's software is compatible with the stack:

      - The new node must run the same ExtremeXOS version as the stack. Install the correct version if necessary.
      - The ExtremeXOS software must be booted on the same image (primary or secondary) as the stack. If the new node is booted on a different image, change the image before you continue.
   e. Use the `enable stacking` command to enable stacking. Then decline the Easy Setup option.
   f. Configure the slot number for the new node using the slot number noted in step 1. For more information, see Configuring Slot Numbers on page 171.
   g. Configure the node's primary-capability to correspond to the role it should have in the stack (see Configuring Master-Capability on page 197).

h. If the new node will operate as a primary-capable node, use the `show licenses` command to verify that the enabled license level is at the same level as the primary-capable nodes in the stack.

   If necessary, configure the license-level restriction of the new node to be same as the other primary-capable nodes in the stack (see Managing Licenses on a Stack on page 185).

i. Configure the node role priority to correspond to the priority it should have in the stack (see Configuring the Primary, Backup, and Standby Roles on page 172).

j. Configure an alternate IP address and gateway (see Configuring an Alternate IP Address and Gateway on page 192).

k. If the new node will use the SummitStack-V feature, configure the alternate stacking ports as described in Using Ethernet Ports for Stacking (SummitStack-V Feature) on page 155.

5. Connect the stacking cables and reboot the node. The new node will join the stack topology.

   For cabling instructions, see the *hardware installation guide* for your switch.

6. At the stack primary node, enter `synchronize stacking`.

> **Note**
> If the primary node was replaced, log into another stack node before entering this command.

7. Reboot the new node by entering the command: `reboot slot [`*slot-number* `|` **node-address** *node-address*`]`.

> **Note**
> If the primary node was replaced, reboot the stack by entering the reboot command at the primary node.

8. (Optional) Run the `show stacking configuration` command and verify that the configuration is what you want.

> **Note**
> To verify that the new node became operational, enter the `show slot {`*slot* `{`**detail**`} |` **detail** `}` command. If the slot shows a Mismatch state, the node was replaced with a different type of switch (see Replacing a Node with a Different Switch Type on page 204).

Replacing a Node with a Different Switch Type

> **Tip**
> For an easier, automatic way to add/replace a node, see Automatically Adding or Replacing Nodes in a Stack on page 198.

When you replace a node with a different switch type, you cannot continue to use the same stack configuration. The slot configuration for the replaced node must change to reflect the new switch type.

> **Note**
> If you are replacing a node with the same switch type, you can continue to use the existing stack configuration. For more information, see Replacing a Node with the Same Switch Type on page 202.

To replace a node with a different switch type, follow these steps:

1. Use the `show switch`, `show licenses`, and `show stacking configuration` commands to display configuration information for the node to be replaced.

   Note the following about the node you are replacing:
   - ExtremeXOS software version
   - Partition on which the switch is booted
   - Effective license level for the stack
   - Slot number
   - Master-capable feature configuration
   - Node priority
   - Alternate gateway IP address

2. Enter the `unconfigure slot` *slot* command to remove the configuration for the node to be replaced.

   All configuration parameters (except for the related node's NVRAM-based configurations such as stacking parameters, image to be used, and failsafe account) for the slot are erased.

3. Remove the stacking cables from the node that is being replaced.

4. Add the new node to the stack following the procedure in Manually Adding Nodes to a Stack on page 200.

Merging Two Stacks

You can join or merge two stacks to create one larger stack. However, the maximum number of nodes in an active topology is eight.

The operation performed when two stack segments are joined together depends on the following factors:
- Whether a slot number is duplicated
- Whether both stacks have master nodes
- The states of the nodes in each stack

If the nodes are configured with stacking enabled, one of the following occurs:
- If two segments are joined, both have operational masters, and at least one of the nodes in one of the stacks duplicates a slot number of a node in the other stack, the join is allowed. The link that has just connected the two stacks shows as Inhibited. This prevents accidental stack joins. In this condition, the nodes on the joined segment can still be reconfigured centrally for stacking.
- If two segments are joined, both have operational masters, and all nodes have assigned slot numbers that are unique in both stacks, the dual master situation is automatically resolved.

- If two segments are joined, there are no duplicate slot numbers, one of the segments has a master and a backup node, and the other segment does not have either a master or a backup node, the nodes in this segment are acquired by the master node. These nodes become standby nodes in the stack.

The nodes that are not configured for stacking do not attempt to join the active topology but join the stack anyway.

Any nodes enabled for stacking that are isolated between nodes (that are not enabled for stacking) attempt to form an isolated active topology.

If one of the nodes that is not configured for stacking is then configured for stacking and restarted, the behavior is as if two active stacks were joined.

Example: Merging Two Stacks

This example demonstrates how to join two stacks, named StackA and StackB. Each stack contains two switches (nodes), and the joined stack contains four nodes.

In the steps that follow, the nodes are referred to as A1, A2, B1, and B2, as shown in this table:

Table 23: Example Node Names in Stacks Being Merged

Node Name	Original Stack	Original Slot	MAC Address
A1	StackA	1	00:04:96:9c:e4:39
A2	StackA	2	00:04:96:9b:c1:34
B1	StackB	1	00:04:96:9e:5c:76
B2	StackB	2	00:04:96:9c:53:b6

Here are displays taken from the original StackA:

Slot-8                                             Empty          0
```

1. Form the new stack. Assuming both stacks are rings, break one link in each stack as follows:

   Note
   Refer to Table 23 for a guide to the switch (node) names used in the following steps.

   a. For StackA, break the link between node A1 port 1 and node A2 port 2.
   b. For StackB, break the link between node B1 port 1 and node B2 port 2.

2. Connect the broken links between the two stacks to form a ring as follows:

   a. Connect node A2 port 2 to node B1 port 1.
   b. Connect node B2 port 2 to node A1 port 1.

   Because both stacks are active stacks and have duplicate slot numbers, the links between the two stacks are in Inhibited state.

3. Assume that the master node of stackA is to be the master node of the joined stack. Log into the intended master node. (This is node A1.)

4. Verify the details of the new stack using the following commands:

   ```
   show stacking
   show stacking configuration
   show stacking stack-ports
   ```

   ```
   Slot-1 Stack.1 # show stacking
   Stack Topology is a Ring
   Active Topology is a Daisy-Chain
   Node MAC Address     Slot   Stack State   Role      Flags

 2   2    28       00:04:96:9b:c1:34 Inhibited    --     10G
 1   1    15       00:04:96:9e:5c:76 Inhibited    --     10G
 1   2    16       00:04:96:9e:5c:76 Operational C-     10G
 2   1    15       00:04:96:9c:53:b6 Operational C-     10G
 2   2    16       00:04:96:9c:53:b6 Inhibited    --     10G
* - Indicates this node
Flags:  (C) Control path is active, (B) Port is
Blocked                                          Empty           0
```

5. Configure the nodes so that they all have unique slot numbers.

   See Configuring Slot Numbers on page 171.

6. Configure the stack MAC address using the `configure stacking mac-address` command.

   See Assigning a MAC Address to a Stack on page 174.

7. Optionally, use the `configure stacking redundancy minimal` command to ensure that only slots 1 and 2 are master-capable.

8. Optionally, configure new alternate IP addresses for nodes from the original StackB.

   See Configuring an Alternate IP Address and Gateway on page 192.

9. For master-capable nodes, configure a license restriction to be the minimum of the two original values on all master-capable nodes.

   Alternatively, you may purchase license upgrades from Extreme if necessary. In this case, use the command: `configure stacking license-level edge`

10. Either reboot the entire stack topology using the `reboot stack-topology` command, or individually reboot the two nodes that formerly were in StackB.

   Using the nodes in this example, the latter requires the following commands:
   ```
   reboot node 00:04:96:9e:5c:76
   reboot node 00:04:96:9c:53:b6
   ```

   Reboot the nodes in this order: standby nodes first, backup node next, and master node last. Because none of these nodes is master-capable, there is no temporary dual master situation as a result of these separate node reboots.

11. When the rebooted nodes come back up, run the following commands to see the resulting stack.

You can verify that the joined stack came up as expected – that is, all nodes have unique slot numbers, a common stack MAC address, and so forth:

```
Slot-1 Stack.15 # show stacking
Stack Topology is a Ring
Active Topology is a Ring
Node MAC Address    Slot  Stack State  Role     Flags
-----------------   ----  -----------  -------  ---

Flags:  (C) Control path is active, (B) Port is Blocked

Slot-1 Stack.18 # show slot
Slots    Type                Configured           State       Ports
----------------------------------------------------------------------
Slot-1   switch_model                             Operational   28
Slot-2   switch_model                             Operational   28
Slot-3   switch_model                             Operational   16
Slot-4   switch_model                             Operational   16
Slot-5                                            Empty          0
Slot-6                                            Empty          0
```

```
Slot-7                                                    Empty        0
Slot-8                                                    Empty        0
```

12. Configure the new slots in VLANs, IP subnetworks, and so forth as required.

Removing a Node from a Stack

To remove a node from a stack, follow these steps:

1. Determine if the target node to be removed is using the SummitStack-V feature by issuing the `show stacking stack-ports` command.

   Examine the Select column to see whether the target node is using alternate (non-native) stacking ports.

2. If the target node is using alternate stacking ports, do the following:

   a. Log into the target node and issue the command: `unconfigure stacking-support`

   b. Log out of the target node.

   > **Note**
   > Do not reboot the target node at this time.

3. Log into the master node.

4. Delete the target node stacking configuration by entering the following command:

   `unconfigure stacking {`**`node-address`** *`node_address`* `|` **`slot`** *`slot_number`*`}`

5. Reboot the target node by entering the following command:

   `reboot [`**`node`** *`node-address`* `|` **`slot`** *`slot-number`*`]`

   When the node reboots, it detects that the configuration file selected is a stacking configuration file (see Stack Configuration Parameters, Configuration Files, and Port Numbering on page 163). It de-selects the configuration file and uses the factory defaults.

6. Disconnect the node from the stack, and redeploy it as needed.

Dismantling a Stack

To dismantle a stack and use the ExtremeSwitching switches in standalone mode, do the following:

1. Issue the `show stacking stack-ports` command to see if any nodes in the stack are using alternate stacking ports.

   In the following example, the switches in slots 1 and 2 have 24 data ports, and the switches in slots 3 and 4 have 12 data ports. The numbers in the **Select** column show that all ports in this stack are alternate stacking ports, not regular data ports.

```
Slot-1 Stack.5 # show stacking stack-ports
Stack Topology is a Ring
Slot Port Select Node MAC Address  Port State  Flags Speed
---- ---- ------ ---------------- ----------- ----- -----
*1   1    27       00:04:96:9c:e4:39 Operational C-      10G
*1   2    28       00:04:96:9c:e4:39 Operational CB      10G
 2   1    27       00:04:96:9b:c1:34 Operational CB      10G
 2   2    28       00:04:96:9b:c1:34 Operational C-      10G
 3   1    15       00:04:96:9e:5c:76 Operational C-      10G
```

```
3   2    16      00:04:96:9e:5c:76 Operational C-      10G
4   1    15      00:04:96:9c:53:b6 Operational C-      10G
4   2    16      00:04:96:9c:53:b6 Operational C-      10G
* - Indicates this node
Flags:  (C) Control path is active, (B) Port is Blocked
```

2. For every non-master node in the stack that is using alternate stacking ports, log into the node and issue the `unconfigure stacking-support` command.

   Do not reboot any of the switches.

   If step 1 showed that no alternate stacking ports are in use, skip this step.

   > **Note**
   > - This command resets the ports so that they are no longer dedicated for use as stacking ports.
   > - It is not necessary to unconfigure stacking-support on the master node.
   > - If a node is a member of the active topology, you can log in to other nodes using the `telnet slot` *slot-number* {**no-auto-login**} command. Otherwise, you need access to the node's console port, or you need to log in through a management network.

3. Log into the master node and issue the `unconfigure switch all` command.

   After this command is entered, the configuration file is deselected, all stacking parameters are reset to factory defaults, and all nodes in the active topology reboot. In effect, this sets all nodes back to the factory default configuration, thus allowing each switch to be redeployed individually.

4. Restore the saved configuration for each switch, if applicable.

Troubleshooting a Stack

Use this section to diagnose and troubleshoot problems with your stacked switches.

The `show stacking`, `show stacking configuration`, `show stacking-support`, and `show stacking stack-ports` commands can help you identify switches and stack ports that are improperly configured, not properly cabled, or powered down.

The commands can help you spot common problems like the following.

Incorrect ExtremeXOSSoftware Version

If a node appears in the stack as expected but does not appear to be operating as configured, use the `show slot` {*slot* {**detail**} | **detail** } command to see if there is a license mismatch or if the node is running an incorrect ExtremeXOS software version. For more information, see Managing Licenses on a Stack on page 185.

Stacking Not Enabled

If the `show stacking` command displays the status as Disabled for any node in the stack, use the `enable stacking` {**node-address** *node-address*} command, with

`node-address` as the disabled node address, to enable stacking on that node. You can issue the command from the master node, and you can reboot the disabled node from the master node to activate the slot number configuration.

Choice of Master Node

If the switch with the highest priority was not elected master, it might be because the stack nodes were powered up at different times. Reboot all nodes in the stack simultaneously.

The following topics contain information for troubleshooting problems related to the choice of the master node:

- Managing a Dual Primary Situation on page 213
- Connecting to a Stack with No Primary on page 216
- Rescuing a Stack that has No Primary-Capable Node on page 217

Choice of Backup and Standby Nodes

About five minutes after a master node takes control of the stack, you might see one of the following messages:

```
Warning: The Backup stack node is not as powerful or as capable
as the Master stack node. This configuration is not recommended
for successful use of the failover feature.
Notice: There are Standby stack nodes which are more powerful and more capable
than the Master and/or Backup stack nodes. This configuration is not recommended
for optimal stack performance. We recommend that you reconfigure the stacking
master-capability and/or priority parameters to allow the higher performing and
more capable nodes to become Master and/or Backup stack nodes.
```

In each case, to optimize your use of the failover feature, follow the guidelines in Configuring the Primary, Backup, and Standby Roles on page 172.

Loss of Saved Files

Note that saved files (backup configurations, script, etc.) are lost on a node that becomes a non-master when implementing stacking. Disabling or deleting the stacking configuration does not restore the files.

Refer to the following topics for help with troubleshooting other problems in your stack.

Managing a Dual Primary Situation

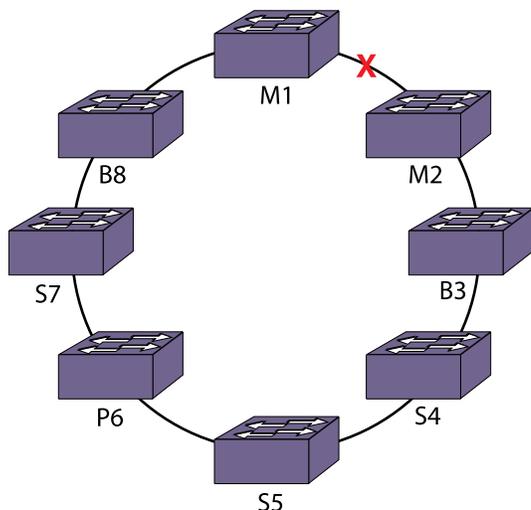
If a daisy chain is broken, or if a ring is broken in two places, it is possible to form two separate active stack topologies. This results in a dual primary situation, as shown in the following example .


Figure 10: Example of a Split Stack that Results in a Dual Primary Situation

P6	Node 6 is powered off
M	Primary nodes
B	Backup nodes
S	Standby nodes
X	Indicates the broken link

In the example, a link was broken while a node in the ring was powered off. The broken link formerly connected the original primary (M1) and backup (M2) nodes of a single active topology.

All nodes in the stack except the powered-off node are in the active topology and all nodes are configured to be primary-capable. Nodes 1, 7 and 8 form an active topology and nodes 2, 3, 4, and 5 form another active topology. Node M2 immediately transitions from backup to primary node role. Nodes B8 and B3 are elected in their respective active topologies as backup nodes.

If the backup node is on one stack and the primary node is on the other, the backup node becomes a primary node because the situation is similar to that of primary failure. Because both stacks are configured to operate as a single stack, there is confusion in your networks. For example, all of the switch's configured IP addresses appear to be duplicated. The management IP address also appears to be duplicated since that address applies to the entire original stack.

To help mitigate the dual primary problem, you can configure primary-capability so as to prevent some nodes in the stack from operating in backup or primary node roles. In addition, you can force all nodes in the (broken) stack topology to restart and come up as not primary-capable for the life of that restart. The `save configuration {`**primary** | **secondary** | *existing-config* | *new-config*`}` command saves the configuration on all nodes in the active topology.

Standby nodes that exist in a severed stack segment that does not contain either the original primary or backup node do not attempt to become the primary node. Instead,

these nodes reboot. After rebooting, however, a primary election process occurs among the nodes on this broken segment, resulting in a dual primary situation.

Dual primary conditions are also possible when two non-adjacent nodes in a ring or a single (middle) node in a daisy chain reboot.

For a period of time, a rebooting node does not advertise itself to its neighbors, resulting in temporary stacking link failures. This can cause node isolation, and the nodes that are isolated perform as a severed stack segment depending on the circumstances of the severance:

- If the backup node is on the broken portion, it becomes a (dual) primary.
- If the backup node is on the same portion as the primary, all nodes on the (other) broken portion reboot.

When the rebooting nodes have sufficiently recovered, or when a severed stack is rejoined, the dual primary condition is resolved, resulting in the reboot of one of the primary nodes. All standby and backup nodes that had been acquired by the losing primary node also reboot.

You can avoid a dual primary possibility during configuration by:

- Configuring the stack in a ring topology.
- Avoiding having too many primary-capable nodes when configuring larger stacks.
- Placing the primary-capable nodes that provide stack redundancy in such a way that broken stacking links are unlikely.

Eliminating a Dual Master Situation Manually

To eliminate the dual master situation, you need to know all the nodes that are supposed to be in the stack. You might lose the management connectivity to the master node because the other master node duplicates the stack's primary management IP address and stack MAC address.

> **Note**
> The following procedure is necessary only if you cannot reconnect the severed link in a timely manner. If you can reconnect, the dual master condition resolves itself. The formerly broken portion of the stack reboots and the nodes come up as standby nodes.

1. If you lose the management connectivity, log into the master node using its alternate management IP address.
2. Use the `show stacking` command to determine which nodes have been lost from the stack.

   You should already know which nodes are expected to be part of the stack.
3. Log into any node in the severed segment you want to deactivate, either through its console port or through the management interface using the alternate management IP address.
4. Issue the `show stacking` command to find out whether the broken segment has indeed elected a new master node.

5. Using the `reboot stack-topology as-standby` command, reboot the broken segment.

   This forces all nodes in the segment to come up as standby nodes.

   If you have unsaved configuration changes, take care when selecting the stack segment to be rebooted. You should reboot the segment that has the smaller System UpTime.

   If you know the node that was master of the unbroken stack, you can reboot the stack segment that does not contain this master node. Otherwise, determine the System UpTime shown by each master node.

   If the System UpTimes of both masters are the same, you can reboot either segment without loss of unsaved configuration changes. If the System UpTimes of both masters differ, you must reboot the segment with the smaller System UpTime.

Automatic Resolution of the Dual Master Situation

When two stack segments are connected together and no slot number is duplicated on either segment, it is assumed that this is a severed stack rejoin.

It is possible that each stack segment has its own master. Resolution of the dual master situation should generally be in favor of the original stack segment's master node. This is because the original stack segment may still retain the unsaved configuration. If the severed segment was restarted before electing a new master node, the unsaved configuration is lost on that segment.

The master election is done using the System UpTime. The master election process collects the System UpTime information of the nodes. If a failover occurs, the System UpTime is inherited by the new master node, and the new master node continues to increase it as time passes. Thus the System UpTime is the time since a master was first elected on a segment. When the stack is broken and both master and backup nodes are on the same segment, the severed segment always has the smaller System UpTime.

If a stack severance results in the master and backup nodes being on different segments, both have the same System UpTime. In this case, the master is elected using the normal node role election method.

Connecting to a Stack with No Primary

If an entire stack has no primary node because the stack has been rebooted in standby only mode, you can log in to a node by using the failsafe account.

If a new node has been added to the stack since the stack failsafe account was configured, logging in to that node requires knowledge of the failsafe account information that is already configured into that node's NVRAM.

If you do not know the failsafe account and you still want to log in to the stack, you have to:

1. Join the stack to another segment that has a primary node to which the you have access.

2. Manually restart the stack to clear the as-standby condition if the reboot stack-topology as-standby command was previously used.
3. Use the procedure described in Rescuing a Stack that has No Primary-Capable Node on page 217.

Rescuing a Stack that has No Primary-Capable Node

It is possible for all nodes in a stack to have primary-capability set to OFF. For example, if a stack was operating with no redundancy (for example, with one primary-capable node) and the primary node failed, all other nodes in the stack restart as standby nodes and there is no primary node.

Another example is the case where you dismantle a stack before using the `unconfigure stacking` command or the `unconfigure switch all` command. In this case, the individual switches are configured for stacking, are not primary-capable, and are isolated from a stack primary.

In this situation, the only security information available is the failsafe account. If you know the failsafe user name and password, you can log into any node and reconfigure primary-capability or redundancy. However, if you do not know the failsafe account information, there is another way you can change the configuration.

The procedure described here generally is not needed if another primary-capable node is expected to rejoin the stack. If this procedure is used, it is possible that the new primary will duplicate the primary that is expected to rejoin later.

To assign a new primary-capable node, follow these steps.

1. At the login prompt, enter the following special login ID exactly as displayed below (all uppercase letters) and press **[Enter]**:

   `REBOOT AS PRIMARY-CAPABLE`

   The following message appears:
   `Node reboot initiated with primary-capability turned on.`

   This node then sets an internal indicator that is preserved across the reboot. While restarting, the node notices and resets this indicator, ignores the node primary-capability configuration, and becomes a primary node.

   The special login ID described here is available only if all of the following conditions are met:

   • The node supports the SummitStack feature.
   • Stacking mode is active on the node.
   • All nodes in the active topology have primary-capability turned off.
   • There is no primary node in the active topology.

   If the above conditions are met, five minutes after starting the node and every five minutes after that, the following message displays on the console:

   ```
   Warning: the stack has no Primary node and all active nodes are operating
   with primary-capability turned off. If you wish to reconfigure, you may log
   in using the failsafe account. Alternatively, you may use the special login
   REBOOT AS PRIMARY-CAPABLE with no password to force a reboot of a node with
   primary-capability temporarily turned on.
   ```

   Using the special login ID does not alter the primary-capability configuration permanently. If you restart a node that has been restarted with the special login ID, that node restarts using its configured primary-capability, unless you again use the special login ID to restart.

   When a node has been rebooted using the special login ID, it becomes a primary node. While the node is a primary, the special login ID is not recognized, even though the entire stack is still configured as not primary-capable. To get the special login ID to be recognized, the node must be rebooted again.

2. If a node was intentionally separated from the stack without first being unconfigured, its security configuration might be unusable. In this case, perform the following steps:

   a. Connect to the node's console port.
   b. Reboot the node using the special `REBOOT AS PRIMARY-CAPABLE` login ID described in step 1.
   c. During the reboot, enter the bootrom program by waiting until you see the message `Starting Default Bootloader ...` and then pressing and holding the space bar until the bootrom prompt displays.
   d. Force the switch to boot up with a default configuration by entering the following commands at the bootrom prompt:

   ```
   config none
   boot
   ```

The switch boots up in stacking mode operating as a primary-capable switch. You can then log in using the default admin account with no password.

Daisy Chain

If you issue the **show stacking** command and see that the stack topology is a daisy chain, we strongly recommend that you reconfigure the stack to use a ring topology.

Here is a sample CLI output from **show stacking** showing that the stack is in a daisy chain.

```
 # show stacking
Stack Topology is a Daisy-Chain
This node is not in an Active Topology
Node MAC Address      Slot  Stack State  Role      Flags
------------------    ----  -----------  -------   ---
*00:04:96:7d:fc:9a     -    Disabled      Master   ---
```

To solve a daisy-chain problem, follow these steps:

1. Ensure that all stack cables are properly seated and that the Link LED is illuminated on each stack port.
2. Ensure that each stack node meets the following conditions:
    *   All nodes must have ExtremeXOS running on the **same partition.**
    *   All nodes must be running the **same ExtremeXOS version.**
    *   All nodes must have the **same license level.**
3. Wait for all stack nodes to finish booting and get through AAA login.
4. Enter `show stacking` to verify that all stack nodes are connected in a ring topology.
5. Check that the stacking port LEDs show as active on all nodes.
6. Reconnect the stacking cables.

Broken Stack (Isolated Nodes)

When a stack setup is not properly unconfigured before the stacking cables are removed, former stack nodes can become isolated.

A common symptom of this problem is that either or both ends of a stacking link show that the state is No Neighbor. This can mean that the port at either end is configured incorrectly. Some configuration errors can produce the No Neighbor state at one end and the Link Down state at the other end.

Here is an example of how an isolated node would look when you log in to it:

```
 (pending-AAA) login:
Warning: the stack has no Master node and all active nodes are operating with
master-capability turned off. If you wish to reconfigure, you may log in using
the failsafe account. Alternatively, you may use the special login
REBOOT AS MASTER-CAPABLE
with no password to force a reboot of a node with master-capability temporarily
turned on.
```

If the `show stacking` command shows the stack state for a slot as Active with the "O" flag set, the node associated with that slot might be isolated from the rest of the stack by a failed node.

To fix an isolated node problem, follow these steps:

1. Verify the physical connections between each port and the rest of the stack.
2. Following the prompt in the sample console session, log in by entering `reboot as master-capable`

   The switch reboots as a master-capable switch.
3. Enter `unconfigure stacking` to unconfigure the stack.

   This command takes effect only once. If the switch is powered off or rebooted you must reissue the **reboot as master-capable** command.

The switch is now available for use in a new stack.

Failed Stack

Even if the **enable stacking** command executes without any warnings or prompts, it is still possible for a stack to fail.

When a stack fails, verify that all of the following conditions are met.

- All nodes must have ExtremeXOS running on the **same partition.**
- All nodes must be running the **same ExtremeXOS version.**
- All nodes must have the **same license level.**

A common sign of a failed stack is one of the non-master nodes being stuck at `(pending-AAA)` for more than five minutes. You can attempt to communicate with the master node (the switch on which the stack was enabled) and determine what went wrong by checking the state of each slot in the stack, as shown in this example CLI session:

```
Slot-1 Stack.1 # show slot
Slots    Type              Configured State    Ports
----------------------------------------------------------
Slot-1   switch_model      Operational          50
Slot-2   switch_model      Failed               26
Slot-3   Empty 0
Slot-4   Empty 0
Slot-5   Empty 0
Slot-6   Empty 0
Slot-7   Empty 0
Slot-8   Empty 0
```

In this example, Slot-2 is in the failed state. To determine why it failed, enter the `show slot` command – in this example, `show slot 2` – to get detailed information about the state of the failed slot:

```
Slot-1 Stack.1 # show slot 2
Slot-2 information:
State: Failed
Download %: 0
Last Error: License Mismatch
Restart count: 1 (limit 5)
```

```
Serial number: N/A(0) N/A(0)
Hw Module Type: switch_model
Configured Type:
Ports available: 26
Recovery Mode: Reset
Node MAC: 00:00:00:00:00:00
Current State: FAIL (License Mismatch)
Image Selected:
Image Booted:
Primary ver:
Secondary ver:
Config Selected: NONE
```

In this example, the highlighted line in the output reveals the cause of the failure: a license mismatch in Slot-2.

Failed Stack Node

If the `show stacking` command shows the stack state for a slot as Failed, check the following things:

- Does the `show stacking stack-ports` command show a port state as Inhibited? If so, the problem might be a duplicate slot number. If more than one node is using the same slot number, change the slot number on one of the affected nodes to a unique slot number.
- Is the affected node isolated by other nodes for which the stack state is listed as Disabled? If so, you need to enable stacking on the disabled nodes.
- Enter the show slot detail command. If the command displays License Mismatch, either upgrade the node license, or configure a license level restriction so that all master-capable nodes are at the same effective license level.
- Enter the `show slot detail` command. If the command displays `Incompatible EXOS Version`, log into the master node and use the `synchronize slot` command to update the failed node.

License Mismatch

A stack might have a failed node even though the **show licenses** command shows that all nodes are running the same license and/or feature packs.

To fix a license mismatch, do the following:

1. At the master node's console, enter `show slot` *slot_number* repeatedly until you find the slot node that is failing.

   > **Note**
   > When you are creating a stack, a blinking orange MGMT light usually indicates a license mismatch on a master-capable standby node.

2. Enter `unconfigure stacking` at the master node to unconfigure the stack.

3. After making a connection to the failed switch's slot, update the license information for that node:

   a. Run `clear license [{`**`software`**`} |` **`port-speed`**`]` command without the **`software`** or **`port-speed`** keywords.

      Select **revoke**.

   b. Enter `reboot`

   c. Obtain the correct license information for the failed switch, then enter `#` `enable license` *`license_key`* (where *`license_key`* has the format *xxxx-xxxx-xxxx-xxxx-xxxx*).

      For more information about licensing for stack nodes, see Managing Licenses on a Stack on page 185.

4. Enter `show stacking` and `enable stacking` to re-enable the stack.

> **Note**
> Only those switches that are master-capable require compatible licenses be installed.

Stacking Link Failure

A stacking link is said to be failed when one of the following happens:

- The stacking link is physically disconnected.
- The neighbor on a link stops transmitting topology information.
- The link goes down while a node restarts or when it is powered off.

Based on the stacking topology, the stack behavior changes.

Ring Topology

All traffic paths that were directed through the failed link are redirected. All nodes converge on the new (daisy chain) topology that results from the link break. The Topology Protocol that determines the stack topology immediately informs other nodes that a link has failed. Each node starts the process of redirecting traffic paths.

Daisy Chain

A stacking link failure means a severed stack. The Topology Protocol reports the loss of all nodes in the severed portion. Depending on master capability configuration and the original location of the backup node, the severed portion may or may not elect a new master node. If it does, the dual master condition may be in effect.

The `show slot {`*`slot`* `{`**`detail`**`} |` **`detail`** `}` command displays the slots that contain active nodes that are in the severed portion as Empty.

Understanding Stacking Traps

Every stack generates traps that provide status information about switches and stacking ports.

The stack routinely generates the following traps:

- `extremeStackMemberStatusChanged`
- `extremeStackMemberSlotId`: the slot ID
- `extremeStackMemberOperStatus`: the slot state of the switch

When an overheat condition is detected on an active node, the stack generates the following trap when the node reaches a steady state:

- `extremeStackMemberOverheat`

When a member is added to or deleted from the stack, or any time the status of a stacking port changes, the change is indicated by means of the following traps:

- `extremeStackingPortStatusChanged`
- `IfIndex`: Interface Index of the port
- `extremeStackingPortRemoteMac`: MAC Address of the remote switch attached to this port
- `extremeStackingPortLinkSpeed`: the port's link speed, for example, 100, or 1000 Mbps
- `extremeStackingPortLinkStatus`: the status of the link

Configuring Slots and Ports on a Switch

This chapter describes the processes for enabling, disabling and configuring individual and multiple ports and displaying port statistics.

Configuring Ports on a Switch

> **Note**
> A port can belong to multiple virtual routers (VRs). See Virtual Routers on page 723 for more information on VRs.

Port Numbering

ExtremeXOS runs on stand-alone and SummitStack switches, and the port numbering scheme is slightly different on each.

Stand-alone Switch Numerical Ranges

On a standalone switch, the port number is simply noted by the physical port number, as shown below:

```
5
```

Separate the port numbers by a dash to enter a range of contiguous numbers, and separate the numbers by a comma to enter a range of noncontiguous numbers:

- x-y: Specifies a contiguous series of ports on a stand-alone switch
- x,y: Specifies a noncontiguous series of ports on a stand-alone switch
- x-y,a,d: Specifies a contiguous series of ports and a series of noncontiguous ports on a stand-alone switch

SummitStack Numerical Ranges

On SummitStack, the port number is a combination of the slot number and the port number. The nomenclature for the port number is as follows:

```
slot:port
```

For example, if the second switch in a SummitStack has four ports, the following ports are valid:

- 2:1
- 2:2
- 2:3
- 2:4

You can also use wildcard combinations (*) to specify multiple port combinations.

The following wildcard combinations are allowed:

- slot:*: Specifies all ports on a stack node.
- slot:x-slot:y: Specifies a contiguous series of ports on multiple stack nodes.
- slot:x-y: Specifies a contiguous series of ports on a particular stack node.
- slota:x-slotb:y: Specifies a contiguous series of ports that begin on one stack node and end on another stack node.

Enabling and Disabling Switch Ports

By default, all ports are enabled. You have the flexibility to receive or not to receive *SNMP (Simple Network Management Protocol)* trap messages when a port transitions between up and down.

- To enable or disable one or more ports on a switch, use the following commands:

  ```
  enable port [port_list | all]
  disable port [port_list | all]
  ```

  For example, to disable slot 7, ports 3, 5, and 12 through 15 on a SummitStack, enter:

  ```
  disable port 7:3,7:5,7:12-7:15
  ```

- To receive these SNMP trap messages, use the following command:

  `enable snmp traps port-up-down ports [`*`port_list`*` | `**`all`**`]`

- To stop receiving these messages, use the following command:

  `disable snmp traps port-up-down ports [`*`port_list`*` | `**`all`**`]`

Refer to Displaying Port Information on page 311 for information on displaying link status.

Configuring Switch Port Speed and Duplex Setting

> **Note**
>
> For information about displaying port speed, duplex, auto-negotiation, and flow control settings, see Displaying Port Information on page 311.

ExtremeXOS supports the following port types:

- 2.5 GBASE-T ports.
- 5 GBASE-T ports.
- 10 GBASE-T ports.
- 10 Gbps ports.
- 25 Gbps.
- 40 Gbps ports.
- 50 Gbps.
- 100 Gbps ports.
- 10/100/1000 Mbps copper ports.
- 10/100/1000 SFPs.
- 10/100/1000 Mbps copper ports with *PoE (Power over Ethernet)*—only on the following ExtremeSwitching switches:
  - X450-G2-24P and X450-G2-48P
  - X460-G2-24P and X460-G2-48P
  - X435-8P-4S, X435-24P-4S, and X435-8P-2T-W
  - X440-G2-48P, X440-G2-24P, and X440-G2-12P
  - X465-24W, X465-48W, X465-48P, and X465i-48W
- 1 Gbps small form factor pluggable (SFP) fiber ports.
- 100 FX SFPs, which must have their speed configured to 100 Mbps.

- 10 Gbps stacking ports.
- 10 Gbps small Form Factor pluggable+ (SFP+) fiber ports. These should be configured to 10 Gbps auto off if an SFP+ optic is inserted; they should be configured to 1G auto on (or auto off) if 1G SFP optic is inserted.

> **Note**
> Stacking ports always use the same type of connector and copper PHY, which are built in to the ExtremeSwitching switches. You cannot configure stacking port parameters such as port speed, duplex, and link fault signal. You also cannot configure data port features such as VLANs and link aggregation.

Auto-negotiation determines the port speed and duplex setting for each port (except 10 and 40 Gbps ports). You can manually configure the duplex setting and the speed of 10/100/1000 Mbps ports.

The 10/100/1000 Mbps ports can connect to either 10BASE-T, 100BASE-T, or 1000BASE-T networks. By default, the ports autonegotiate port speed. You can also configure each port for a particular speed (either 10 Mbps or 100 Mbps).

> **Note**
> With auto-negotiation turned off, you cannot set the speed to 1000 Mbps.

In general, SFP gigabit Ethernet ports are statically set to 1 Gbps, and their speed cannot be modified.

However, there are two SFPs supported by Extreme that can have a configured speed:

- 100 FX SFPs, which must have their speed configured to 100 Mbps.
- 100FX/1000LX SFPs, which can be configured at either speed.

The 10 Gbps ports always run at full duplex and 10 Gbps. The 40 Gbps ports always run at full duplex and 40 Gbps.

ExtremeXOS allows you to specify the medium as copper or fiber when configuring ExtremeSwitching switches with combination ports. If the medium is not specified for combination ports then the configuration is applied to the current primary medium. The current primary medium is displayed in the Media Primary column of the `show ports configuration` command output.

> **Note**
> For switches that do not support half-duplex, the copper switch ports must have auto-negotiation disabled and full duplex enabled when connecting 10/100/1000 Mbps devices that do not autonegotiate. If the switch attempts and fails to auto negotiate with its partner, it will fail to link up. A non-negotiating connected device must also be manually configured for full duplex or packet loss and port errors will occur each time it detects a collision.

> **Note**
> Beginning in version 32.4, Auto-negotiation defaults to ON for SFP28, QSFP+, and QSFP28 ports (25G/40G/50G/100G).

To configure port speed and duplex setting , use the following command:

```
configure ports port_list {medium [copper | fiber]} auto off speed speed
duplex [half | full]
```

To configure the system to autonegotiate, use the following command:

```
configure ports port_list {medium [copper|fiber]} auto on {[{speed
speed} {duplex [half | full]}] | [{duplex [half | full]} {speed speed}]}
```

> **Note**
> The keyword medium is used to select the configuration medium for combination ports. If port_list contains any non-combination ports, the command is rejected.

ExtremeXOS does not support turning off auto-negotiation on the management port.

Support for Auto-negotiation on Various Ports

The following table lists the support for auto-negotiation, speed, and duplex setting for the various types of ports.

Port	Auto-negotiation	Speed	Duplex
100 Gbps	Off (default) On	100,000 Mbps	Full duplex
10 Gbps	Off	10,000 Mbps	Full duplex
40 Gbps	On	40,000 Mbps	Full duplex
1 Gbps fiber SFP	On (default) Off	1,000 Mbps	Full duplex
100 FX SFP	On (default) Off	100 Mbps	Full duplex
10/100/1,000 Mbps	On (default) Off	10 and 100 Mbps 1,000 Mbps	Full/half duplex Full/half duplex
10/100 Mbps	On (default) Off	10 Mbps 100 Mbps	Full/half duplex Full/half duplex
100/1000/2.5 Gbps	On (default) Off	100 and 1,000 Mbps 2,500 Mbps	Full/half duplex Full/half duplex
100/1,000/2.5/5 Gbps	On (default) Off	100, 1000, and 2,500 Mbps 5,000 Mbps	Full duplex Full duplex
25 Gpbs **Note:** Supported with X465 VIM5-4YE; not supported with VIM5-4Y and VIM5-2Y.	Off (default) On	25,000 Mbps	Full duplex

Port	Auto-negotiation	Speed	Duplex
10 Gbps SFP+	Off	10,000 Mbps	Full duplex
50 Gbps	Off (default) On	50,000 Mbps	Full duplex

> **Note**
> For ExtremeSwitching X695 series switches, auto-negotiation is not supported at 1G and 10G ports.

> **Note**
> The following products do not support half-duplex operation: ExtremeSwitching X450-G2 and X460-G2 (excluding the X460-G2-24p-24hp-10GE4 and X460-G2-24t-24ht-10GE4 models), and ExtremeSwitching X465-24MU.

Flow control on Gigabit Ethernet ports is enabled or disabled as part of auto-negotiation (see IEEE 802.3x). If auto-negotiation is set to Off on the ports, flow control is disabled. When auto-negotiation is On, flow control is enabled.

With Extreme Networks devices, the 1 Gbps ports and the 10 Gbps ports implement flow control as follows:

- 1 Gbps ports:
  - Auto-negotiation enabled
    - Advertise support for pause frames
    - Respond to pause frames
  - Auto-negotiation disabled
    - Do not advertise support for pause frames
    - Do not respond to pause frames
- 10 Gbps ports:
  - Auto-negotiation always disabled
  - Do not advertise support for pause frames
  - Respond to pause frames

> **Note**
> When 1G SFP optics are inserted into 10 GBps ports, you must configure auto-negotiation "on" with 1G speed.

Support for IEEE Forward Error Correction (FEC)

ExtremeXOS allows you to enable IEEE Forward Error Correction (FEC) Clause 91 or Clause 74 (exclusively) on a per-port basis regardless of speed/type.

FEC gives the receiver the ability to correct errors without requiring a reverse channel to request retransmission of data, but at the cost of a fixed, higher forward channel bandwidth. Some devices require this to interoperate.

FEC is only available on ExtremeSwitching X465 (supported on VIM5-4YE; not supported on VIM5-4Y and VIM5-2Y), X695, and X590 ports.

To enable/disable FEC, use the following commands:

```
configure ports port_list forward-error-correction [off | on [cl74 |
cl91]]
```

To show FEC status, use the following commands:

```
show port port_list forward-error-correction {refresh | no-refresh }
port-number
```

```
show port {mgmt |port_list | tag tag} information {detail}
```

Configuring Extended Port Description

ExtremeXOS provides a configurable per-port "display-string" parameter that is displayed on each of the `show port` CLI commands, exposed through the _SNMP_ ifAlias element, and accessible via the XML port.xsd API. This existing field is enhanced to allow up to 255 characters with much less stringent syntax limitations. Some characters are still not permitted, as they have special meanings. These characters include the following: <, >, ?, &. This new field is accessible through the `show port info detail` command, and is also accessible through the SNMP ifAlias object of IfXTable from IF-MIB (RFC 2233), and the XML API.

You can always configure a 255-character-long string regardless of the configured value of ifAlias size. Its value only affects the SNMP behavior.

Use the following commands to configure up to 255 characters associated with a port:

```
config port port_list description-string string
```

Use the following command to unconfigure the description-string setting:

```
unconfig port port_list description-string
```

Use the following command to control the accessible string size (default 64, per MIB) for the SNMP ifAlias object:

```
config snmp ifmib ifalias size [default | extended]
```

If you choose extended size option, the following warning will be displayed:

```
Warning: Changing the size to [extended] requires the use of increased 255 chars long
ifAlias object of ifXtable from IF-MIB(RFC 2233)
```

Port Groups

Port groups allow you to define ports by similar functionality or role. You can create port groups and use them to configure QoS profiles, ingress meters and flood rate-limiters for ports that share the same role. QoS commands that use port groups are updated

automatically if the ports group is removed or if ports are added or removed from the group.

In addition, ExtremeCloud IQ - Site Engine can create and manipulate port groups through the CoS MIB using SNMP. These groups are used to configure the ExtremeCloud IQ - Site Engine-specified CoS resources that are mapped to QoS profiles, ingress meters, and flood rate-limiters. Since the ExtremeCloud IQ - Site Engine CoS feature is port group-oriented, ExtremeXOS QoS entities (QoS profiles, ingress meter, and flood rate-limiting) that are configured on a per-port basis are not exposed through the CoS MIB using SNMP.

To create port groups, use the following command:

```
create ports group port_group
```

To delete port groups, use the following command:

```
delete ports group port_group
```

To add/delete ports from a port group, use the following command:

```
configure ports {group} port_group [[ add | delete ] port_list ]
```

To show port group information, use the following command:

```
show ports group {port_group}
```

Partitioning High Bandwidth Ports

The 40G ports on ExtremeSwitching X465 (with VIM5-2Q) and X590 series switches can be partitioned into 4x10G and 1x40G modes. Also, the 100G ports on the X590 and X695 can be partitioned into 1x100G, 2x50G, 4x25G, 4x10G, 1x40G.

Additionally, on ExtremeSwitching X465 (with VIM5-4Y/4YE/2Y) and X695 switches, the 25G ports can be partitioned into 10G.

> **Note**
> This partition allows all ports to be converted either as 10G or as 25G and not both. To partition the 25G ports, apply the **4x10** option in the following command to:
> * X465: first VIM port (port 25 on 24-port models, and port 49 on 48-port models).
> * X695: ports: 1–48.

To partition the ports, enter the following command:

```
configure ports [port_list | all] partition [1x100G | 1x40G | 2x50G |
4x10G | 4x25G]
```

> **Note**
> Because of the nature of these ports at the physical layer level, the 10G side
> may show a remote or local linkup.

Flow Control

IEEE 802.3x Flow Control

With autonegotiation enabled, ExtremeSwitching switches advertise the ability to
support pause frames.

This includes receiving, reacting to (stopping transmission), and transmitting pause
frames. However, the switch does not actually transmit pause frames unless it is
configured to do so, as described below.

IEEE 802.3x flow control provides the ability to configure different modes in the default
behaviors. Ports can be configured to transmit pause frames when congestion is
detected, and the behavior of reacting to received pause frames can be disabled.

TX

You can configure ports to transmit link-layer pause frames upon detecting congestion.
The goal of IEEE 802.3x is to backpressure the ultimate traffic source to eliminate or
significantly reduce the amount of traffic loss through the network. This is also called
lossless switching mode.

The following limitations apply to the TX flow control feature:
- Flow control is applied on an ingress port basis, which means that a single stream
  ingressing a port and destined to a congested port can stop the transmission of
  other data streams ingressing the same port that are destined to other ports.
- High volume packets destined to the CPU can cause flow control to trigger. This
  includes protocol packets such as, *EDP (Extreme Discovery Protocol)*, *EAPS (Extreme
  Automatic Protection Switching)*, *VRRP (Virtual Router Redundancy Protocol)*, and
  OSPF (Open Shortest Path First).
- When flow control is applied to the fabric ports, there can be a performance
  limitation. For example, a single 1G port being congested could backpressure a high-
  speed fabric port and reduce its effective throughput significantly.

To configure a port to allow the transmission of IEEE 802.3x pause frames, use the
following command:

```
enable flow-control tx-pause ports port_list|all
```

> **Note**
> To enable TX flow-control, RX flow-control must first be enabled. If you attempt
> to enable TX flow-control with RX flow-control disabled, an error message is
> displayed.

To configure a port to return to the default behavior of not transmitting pause frames, use the following command:

```
disable flow-control tx-pause ports
```

RX

You can configure the switch to disable the default behavior of responding to received pause frames. Disabling rx-pause processing avoids dropping packets in the switch and allows for better overall network performance in some scenarios where protocols such as TCP handle the retransmission of dropped packets by the remote partner.

To configure a port to disable the processing of IEEE 802.3x pause frames, use the following command:

```
disable flow-control rx-pause ports port-list | all
```

> **Note**
> To disable RX flow-control, TX flow-control must first be disabled. If you attempt to disable RX flow-control with TX flow-control enabled, an error message is displayed.

To configure a port to return to the default behavior of enabling the processing of pause frames, use the following command:

```
enable flow-control rx-pause ports port-list | all
```

IEEE 802.1Qbb Priority Flow Control

Priority flow control (PFC) as defined in the IEEE 802.1Qbb standard is an extension of IEEE 802.3x flow control, which is discussed in IEEE 802.3x Flow Control on page 232.

When buffer congestion is detected, IEEE 802.3x flow control allows the communicating device to pause all traffic on the port, whereas IEEE 802.1Qbb allows the device to pause just a portion of the traffic while allowing other traffic on the same port to continue.

For PFC, when an ingress port detects congestion, it generates a MAC control packet to the connected partner with an indication of which traffic priority to pause and an associated time for the pause to remain in effect. The recipient of the PFC packet then stops transmission on the priority indicated in the control packet and starts a timer indicating when traffic can resume.

Traffic can resume in two ways:
- On the transmitting side, when the timer expires, traffic on that priority can resume.
- On the receiving side, once congestion is relieved, another PFC packet is generated to un-pause the priority so that traffic can resume.

Limitations

The following limitations are associated with this feature:
- PFC must be explicitly configured by the user.

- In order to support the signaling of congestion across the fabric, an enhanced fabric mode is required. This enhanced mode is not available on some older models of Summits (see the following supported platforms section). Also, this enhanced mode reduces the effective bandwidth on the fabric by a small amount (less than 5%).
- The fabric flow control packets take up some small amount of bandwidth on the fabric ports.

Supported Platforms

PFC is currently supported only on 10G ports and on specific models of the following newer platforms indicated by the part number:

- ExtremeSwitching X450-G2 switches: 1G, 10G ports
- ExtremeSwitching X460-G2 switches: 1G, 2.5G, 10G, 40G ports
- ExtremeSwitching X465 switches: all ports
- ExtremeSwitching X590 switches: all ports
- ExtremeSwitching X620 switches: all ports
- ExtremeSwitching X695 switches: all ports

To verify that your switch supports PFC, use the `show version` command. If you attempt to enable PFC on unsupported ports, an error message is displayed. (See Abnormal Configuration Examples on page 237.)

Setting the Priorities

Priority is established for reception of PFC packets with a *QoS (Quality of Service)* profile value on the ExtremeXOS switch and for transmission with a priority value added to the PFC packet.

- QoS profile—Ingress traffic is associated with a QoS profile for assignment to one of eight hardware queues in the system that define how the traffic flows with respect to bandwidth, priority, and other parameters. By default, there are two QoS profiles (QP1 and QP8) defined in these supported platforms and PFC works with this default. To segregate the ingress traffic with more granularity, you will want to define other QoS profiles. The traffic that will be paused on reception of the PFC packet is associated with the hardware queue of the QoS profile that you specify.

    The QoS profile is also used to configure the fabric ports.
- Priority—When the hardware transmits a PFC packet, it uses the priority bits in the *VLAN (Virtual LAN)* header on the ingress packet to determine the priority to pause, if the ingress packet is tagged. You can specify this transmit priority independently from the QoS profile to associate it with the reception of a PFC packet thus giving flexibility in the configuration of the network. For untagged ingress packets, the hardware queue determines the priority in the transmitted PFC packet. (For additional information, see QoS Profiles on page 877.

It is suggested that the priority in the VLAN header match the QoS profile priority when traffic ingresses at the edge of the network so that the traffic can be more easily controlled as it traverses through the network.

Fabric Port Configuration

This feature also configures the fabric between ingress and egress ports to optimize PFC behavior.

When the ingress and egress ports are located on separate nodes in a SummitStack, note that some older systems do not support the enhanced fabric mode required for PFC.

If any other ExtremeSwitching switch attempts to join the stack after the initial configuration of PFC, it is not allowed to join.

If your situation does not respond well to having flow control enabled on the fabric links, you can turn off flow control in the fabric by using the following command:

```
configure forwarding flow-control fabric [auto | off]
```

Configuring Priority Flow Control

With PFC, it is expected that both RX and TX be enabled or disabled.

- To enable PFC, use the following command:

  ```
  enable flow-control [tx-pause {priority priority} | rx-pause
  {qosprofile qosprofile}] ports [all | port_list]
  ```

- To disable PFC, use the following command:

  ```
  disable flow-control [tx-pause {priority priority} | rx-pause
  {qosprofile qosprofile}] ports [all | port_list]
  ```

Example

The network needs to transport FCoE (Fiber Channel over Ethernet) traffic which is intermixed with other more typical LAN traffic on the same Ethernet network. FCoE needs a lossless transport and PFC can be used to enable this. You define *QoS* profiles for all eight traffic priorities. At the network level, it is decided that FCoE traffic will be assigned to priority 3 (which corresponds to QP4) and the remaining traffic is assigned to one or more other priorities. For this example, it is also assumed that the priority bits in the incoming packets are also 3.

One mechanism that can be used for this classification is the use of Access Control Lists (ACLs) that match on the FCoE ethertypes (0x8906 and 0x8914) using the ethernet-type qualifier with an action of QoS profile QP4 for both rules. Other traffic can be classified to other priorities. Once this configuration is applied, FCoE is now separated from the other Ethernet traffic and is assigned a priority of 3 through the switch.

PFC is enabled at the ports that will see FCoE traffic, in this case, ports 1:1, 2:3, and 6:5.

Since FCoE is assigned to QP4, you would enable the receive PFC for QoS profile to be QP4 and, in this example, would also enable PFC with a transmit priority of 3. The enable commands would then read as follows:

```
enable flow-control tx-pause priority 3 ports 1:1,2:3,6:5
enable flow-control rx-pause qosprofile qp4 ports 1:1,2:3,6:5
```

The `show port flow-control rx-pause no-refresh` command displays the following information. With the no-refresh option the display shows the following information:

```
# show ports 1,5,9 flow-control rx-pauses no-refresh
Flow Control Frames Received
Port   Pause    PFC0    PFC1    PFC2    PFC3    PFC4    PFC5    PFC6    PFC7
       Rcvs    Rcvs    Rcvs    Rcvs    Rcvs    Rcvs    Rcvs    Rcvs    Rcvs
================================================================================
1         -       -       -       - 1234567 1234567       - 1234567       -
5         -       -       -       - 1234567 1234567       - 1234567       -
16:104 1234567    -       -       -       -       -       -       -       -
================================================================================
">" Name truncated, "-" rx-pause not enabled, "." Counter not available
```

Without the no-refresh option the display refreshes until interrupted by the console operator pressing `Escape`:

```
# show ports 1,5,9 flow-control rx-pauses
Flow Control Frame Monitor                     Sat Aug 18 19:35:12 2012
Port   Pause    PFC0    PFC1    PFC2    PFC3    PFC4    PFC5    PFC6    PFC7
       Rcvs    Rcvs    Rcvs    Rcvs    Rcvs    Rcvs    Rcvs    Rcvs    Rcvs
================================================================================
1         -       -       -       - 1234567 1234567       - 1234567       -
5         -       -       -       - 1234567 1234567       - 1234567       -
16:104 1234567    -       -       -       -       -       -       -       -
================================================================================
">" Name truncated, "-" rx-pause not enabled, "." Counter not available
Spacebar->Toggle screen 0->Clear counters U->Pageup D->Pagedown ESC->exit
```

The new `show port flow-control tx-pause no-refresh` CLI command displays the following information. With the no-refresh option the display shows the following information:

```
# show ports 1,5,9 flow-control tx-pauses no-refresh
Flow Control Frames Transmitted
Port   Pause    PFC0    PFC1    PFC2    PFC3    PFC4    PFC5    PFC6    PFC7
       Xmts    Xmts    Xmts    Xmts    Xmts    Xmts    Xmts    Xmts    Xmts
================================================================================
1         -       -       -       - 1234567 1234567       - 1234567       -
5         -       -       -       - 1234567 1234567       - 1234567       -
16:104 1234567    -       -       -       -       -       -       -       -
================================================================================
">" Name truncated, "-" tx-pause not enabled, "." Counter not available
```

Without the no-refresh option the display refreshes until interrupted by the console operator pressing the escape key:

```
# show ports 1,5,9 flow-control tx-pauses
Flow Control Frame Monitor Sat Aug 18 19:35:12 2012
Port   Pause    PFC0    PFC1    PFC2    PFC3    PFC4    PFC5    PFC6    PFC7
       Xmts    Xmts    Xmts    Xmts    Xmts    Xmts    Xmts    Xmts    Xmts
================================================================================
1         -       -       -       - 1234567 1234567       - 1234567       -
5         -       -       -       - 1234567 1234567       - 1234567       -
16:104 1234567    -       -       -       -       -       -       -       -
================================================================================
">" Name truncated, "-" tx-pause not enabled, "." Counter not available
Spacebar->Toggle screen 0->Clear counters U->Pageup D->Pagedown ESC->exit
```

Once this configuration is complete, if a switch ingress port detects congestion, it will send PFC packets to the remote link partner and will respond to PFC packets from the remote link partner by stopping transmit.

Abnormal Configuration Examples

Examples of abnormal configuration scenarios.

- If you attempt to configure PFC on a port that does not support it, an error message similar to the following is issued and you will be informed that PFC cannot be configured on that port:

```
enable flow-control tx-pause priority 3 port 1:1
Error: Port 1:1 does not support Priority Flow Control.
```

- When PFC is enabled on a port, IEEE 802.3x will be disabled. If, after enabling PFC, you try to modify RX or TX pause parameters, an error message similar to the following will be issued explaining the dependency on PFC configuration:

```
BD8810.1# enable flow-control tx-pause port 1:1
Error: Priority Flow Control is currently enabled on port 1:1 and is mutually
exclusive with TX and RX pause configuration. TX and RX pause configuration cannot be
done until PFC is disabled on this port.
```

Turning off Autonegotiation on a Gigabit Ethernet Port

In certain interoperability situations, you need to turn autonegotiation off on a fiber gigabit Ethernet port. Although a gigabit Ethernet port runs only at full duplex, you must specify the duplex setting. The 10 Gbps ports do not autonegotiate; they always run at full duplex and 10 Gbps speed.

Running Link Fault Signal

The 10 Gbps ports support the Link Fault Signal (LFS) function. This function, which is always enabled, monitors the 10 Gbps ports and indicates either a remote fault or a local fault. The system then stops transmitting or receiving traffic from that link. After the fault has been alleviated, the system puts the link back up and the traffic automatically resumes.

The Extreme Networks implementation of LFS conforms to the IEEE standard 802.3ae-2002.

> **Note**
> To display the part number of the switch in a SummitStack, use the `show slot` *slot_number* command.

Although the physical link remains up, all Layer 2 and above traffic stops.

The system sends LinkDown and LinkUp traps when these events occur. Additionally, the system writes one or more information messages to the syslog, as shown in the following example:

```
09/09/2004 14:59:08.03 <Info:vlan.dbg.info> MSM-A: Port 4:3 link up at
10 Gbps speed and full-duplex
09/09/2004 14:59:08.02 <Info:hal.sys.info> MSM-A: 4:3 - remote fault recovered.
09/09/2004 14:59:05.56 <Info:vlan.dbg.info> MSM-A: Port 4:3 link down
due to remote fault
```

```
09/09/2004 14:59:05.56 <Info:hal.sys.info> MSM-A: 4:3 - remote fault.
09/09/2004 15:14:12.22 <Info:hal.sys.info> MSM-A: 4:3 - local fault
recovered.
09/09/2004 15:14:11.35 <Info:vlan.dbg.info> MSM-A: Port 4:3 link up at
10 Gbps speed and full-duplex
09/09/2004 15:13:33.56 <Info:vlan.dbg.info> MSM-A: Port 4:3 link down
due to local fault
09/09/2004 15:13:33.56 <Info:hal.sys.info> MSM-A: 4:3 - local fault.
09/09/2004 15:13:33.49 <Info:vlan.dbg.info> MSM-A: Port 4:3 link down
due to local fault
```

On ExtremeSwitching switches, after disabling the 10 Gbps ports, the following message appears in the Syslog:

```
08/26/2008 06:05:29.29 Port 1 link down - Local fault
```

> **Note**
> A link down or up event may trigger Spanning Tree Protocol topology changes or transitions.

Turn off Autopolarity

The autopolarity feature allows the system to detect and respond to the Ethernet cable type (straight-through or crossover cable) used to make the connection to the switch port or an endstation.

This feature applies only to the 10/100/1000 BASE-T ports on the switch and copper medium on ExtremeSwitching combination ports.

When the autopolarity feature is enabled, the system causes the Ethernet link to come up regardless of the cable type connected to the port. When the autopolarity feature is disabled, you need a crossover cable to connect other networking equipment and a straight-through cable to connect to endstations. The autopolarity feature is enabled by default.

Under certain conditions, you might opt to turn autopolarity off on one or more ports.

- To disable or enable autopolarity detection, use the following command:

  configure ports *port_list* **auto-polarity** [**off** | **on**]

  Where the following is true:
  - port_list—Specifies one or more ports on the switch
  - off—Disables the autopolarity detection feature on the specified ports
  - on—Enables the autopolarity detection feature on the specified ports

  The following example turns autopolarity off for ports 5 to 7 on an ExtremeSwitching switch:

  ```
  configure ports 5-7 auto-polarity off
  ```

- When autopolarity is disabled on one or more Ethernet ports, you can verify that status using the command:

  show port information detail

IPFIX

IP Flow Information Export protocol

The IP Flow Information Export (IPFIX) protocol (created by the IETF) is a standard way to capture information about traffic flows passing through network elements in a data network.

The protocol consists of a metering process, an exporting process, and a collecting process. This section discusses the metering and exporting processes; the collecting process is not defined by the standard and therefore is outside the scope of this document. The IPFIX protocol is a rival, but complementary, protocol to sFlow.

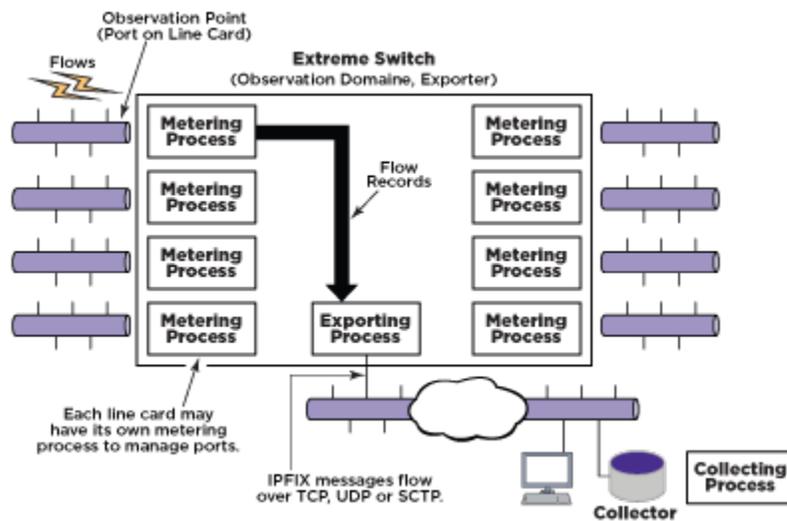
The Extreme Networks switch contains various metering processes that gather information about flows through different ports, or observation points, on the switch. This information includes: the ingress and egress interfaces, the link state, IPFIX state, flow count, byte count, packet count, flow record count and premature exports. The metering process then sends the information to the exporting process in the switch which handles communication, using TCP, UDP, or SCTP transport protocols, over the network to a collecting process.


Figure 11: IPFIX Processes

Limitations

- The flow key definition is limited to the L2, L3, and L4 header fields the hardware provides.
- IPFIX is supported on ExtremeSwitching X460-G2 only. The IPFIX flow count is limited to is 4K flows—2K for ingress and 2K for egress.

Enabling IPFIX

- To enable IPFIX on a port and provide a check to ensure that the port being enabled has hardware support for IPFIX, use the following command:
  ```
  enable ip-fix ports [port_list | all] {ipv4 | ipv6 | non-ip |
  all_traffic}
  ```

If the port does not support IPFIX, an error message is displayed.

- To disable an enabled port, use the following command:

  ```
  disable ip-fix ports [port_list | all]
  ```

- To enable or disable IPFIX globally and override an individual port enable, use the following command:

  ```
  [enable | disable] ip-fix
  ```

Configuring IPFIX Flow Key Masks

Flow keys define what data in the packet header identifies a unique flow to the hardware. On each port, there is a flow key for IPv4, IPv6, and non-IP traffic type data. Following are the flow keys together with the size of the field:

IPv4:
- Source IP Address (32)
- Destination IP Address (32)
- L4 Source Port (16)
- L4 Destination Port (16)
- L4 Protocol (8)
- TOS (DSCP +ECN) (8)

IPv6:
- Source IP Address (128)
- Destination IP Address (128)
- L4 Source Port (16)
- L4 Destination Port (16)
- Next Header (8)
- IPv6 Flow Label (20)
- TOS (DSCP +ECN) (8)

Non-IP:
- Source MAC Address (48)
- Destination MAC Address (48)
- *VLAN* ID (12)
- VLAN Priority (3)
- Ethertype (16)
- VLAN Tagged (1)

By default, IPFIX uses all the above listed flow keys and all bits. You can override this on a global basis and specify exactly which keys to use. The template that specifies the structure of the information that is communicated from the exporter to the collector will then contain only those specified keys.

To specify the flow keys to use for each of the three traffic types, use the following commands:

```
configure ip-fix flow-key ipv4 {src-ip} {src-port} {dest-ip} {dest-port}
{protocol} {tos}
```

```
configure ip-fix flow-key ipv6 {src-ip} {src-port} {dest-ip} {dest-port}
{next-hdr} {tos} {flow-label}
```

```
configure ip-fix flow-key nonip {src-mac} {dest-mac} {ethertype} {vlan-
id} {priority} {tagged}
```

To reset to the all keys default, use the following command:

```
unconfigure ip-fix flow-key
```

You can then define masks for the IPv4 and IPv6 source and destination address fields on a per port basis.

Use the following commands: `configure ip-fix ports port_list **flow-key [ipv6|ipv4] mask** [**source** | **destination**] **ipaddress** value`

Example

You can use the flow keys and masks to minimize the information sent to the collector and aggregate certain types of flows.

A common use of the non-default values may be to see all traffic from a user only instead of each individual flow. For example, in the case of IPv4:

```
configure ip-fix flow-key ipv4 src-ip dest-ip
```

Then, by configuring the mask on a port, the aggregation could be further restricted to meter only individual subnets.

For example, with a 255.255.255.0 mask:

```
configure ip-fix ports 3:1 flow-key ipv4 mask source ipaddress 255.255.255.0
configure ip-fix ports 3:1 flow-key ipv4 mask destination ipaddress 255.255.255.0
```

To unconfigure the masks, use the following command:

```
unconfigure ip-fix ports port_list flow-key mask
```

Configuring IPFIX Parameters on a Port

These are optional commands; when not configured, the defaults are used.
- To configure whether to meter on ingress and/or egress ports, use the following command:

```
configure ip-fix ports port_list [ingress | egress | ingress-and-
egress]
```

(The default is ingress.)
- To configure whether to meter all, dropped only, or non-dropped only records, use the following command:

```
configure ip-fix ports port_list record [all | dropped-only | non-
dropped]
```

(The default is all.)

- To unconfigure these IPFIX settings on a port or group of ports, use the following command:

```
unconfigure ip-fix ports port_list
```

This restores the configuration to the defaults for those ports. It does not enable or disable IPFIX.

Configuring Domain IDs

Observation points are aggregated into observation domains. The entire switch operates as one domain. The IPFIX protocol contains an observation domain ID in the flow records that are sent to the collector. The collector can use the domain to correlate records to their origin. How this field is used is up to a given collector.

- To configure a domain ID, use the following command:

```
configure ip-fix domain domain_id
```

Configuring a Collector

To export flow records using the IPFIX protocol, you must first configure a collector. Only a single collector is allowed. You can specify the source IP address and VR to use when sending from the switch to a given collector. When not specified, the system defaults to the switch IP address the traffic exits.

- To specify the Source IP address to be used in IPFIX packets, use the following command:

```
configure ip-fix source ip-address ipaddress {vr vrname}
```

- To reset back to the default of using the switch IP, use the following command:

```
unconfigure ip-fix source ip-address
```

- To specify the IP address, port number, transport protocol and VR for a collector, use the following command:

```
configure ip-fix ip-address ipaddress {protocol [sctp | tcp | udp]}
{L4-port portno} {vr vrname}
```

- To unconfigure this, use the following command:

```
unconfigure ip-fix ip-address
```

Unconfiguring IPFIX

- To unconfigure IPFIX completely, use the following command. This removes all port and collector configuration and disables IPFIX on all ports.

```
unconfigure ip-fix
```

Displaying IPFIX Information

You can view information about IPFIX information on ports.

- To display the global state, the collector information and the ports that are enabled for IPFIX, use the following command:

```
show ip-fix
```

- To display information about per port metering, use the following command:

```
show ports {port_list} ip-fix {[no-refresh | port-number | refresh] }
```

- To show whether IPFIX is enabled on a specific port together with port IPFIX configuration, use the following command:

```
show port { port_list } information {detail}
```

Configuring Switching Mode—Cut-through Switching

Default Switching Mode

All platforms use store-and-forward by default. The platforms are also capable of supporting cut-through forwarding to reduce latency. Store-and-forward switching requires the complete receipt of a packet prior to transmitting it out the interface. The packet is stored in its entirety in packet memory and can be validated via the frame CRC by the switch prior to forwarding it to the next hop.

Cut-through switching allows the switch to begin transmitting a packet before its entire contents have been received thereby reducing the overall forwarding latency for large packet sizes.

Cut-through forwarding mode is supported on 10G, 25G, 40G, 50G, and 100G ports on the ExtremeSwitching X695 series switch.

The following limitations apply to the cut-through switching feature:

- Error packets may be forwarded when using cut-through mode. These packets need to be detected and discarded by one of the downstream switches, routers, or the ultimate end station.

In some circumstances, store-and-forward is automatically used. Following are examples:

- Cut-through mode cannot be achieved when switching a packet internally from a low-speed front-panel port (1G or 10G) to a higher-speed fabric port. In this case, store-and-forward switching will automatically be used. However, cut-through switching can be used when switching between equal speed ports or from 100-G or less to 40G ports or from 50G or less to 25G or 10G ports.
- Store-and-forward is used for packets that are switched to multiple egress ports in scenarios such as *VLAN* flooding and multicast.
- Store-and-forward is used whenever the egress interface is congested including when *QoS* rate shaping is in effect.

Configuring Switching Mode

You can change or view the default switching mode.

- To configure the switching mode, use the following command:

```
configure forwarding switching-mode [cut-through | store-and-forward]
```

- To display the switching mode settings, use the following command:

```
show forwarding configuration
```

DWDM Optics Support

DWDM stands for "dense wavelength division multiplexing." Extreme Networks DWDM optics can be tuned to transmit on different "channels" (wavelengths), as needed.

Limitations

This feature has the following limitations:

- Support exists only for Extreme Networks certified SFP+ modules.
- It can take 500-1000 ms to stabilize the channel after DWDM channel configuration is completed, meaning that the port loses its data transmission capability for that time frame. Links are dropped until the channel is stabilized. However, this is expected behavior when the physical medium is changed.
- When a tunable dense wavelength division multiplexing (TDWDM) SFP+ module is inserted, the software configures the default channel or the configured channel based on the existing configuration, and the link is likely to be dropped during this process.

Configuring DWDM

- To configure DWDM specific channels on the port(s), use the following command:
  ```
  configure port all | port_list dwdm channel channel_number
  ```
- To configure the DWDM default channel 21 on the port(s), use the following command:
  ```
  configure port all | port_list dwdm channel none
  ```

Displaying DWDM

- To display DWDM configuration, use the following command
  ```
  show ports {mgmt | port_list | tag tag} configuration {no-refresh}
  show port {mgmt | port_list | tag tag} information {detail}
  ```
- To display the channel scheme for mapping the DWDM wavelengths, use the following command
  ```
  show dwdm channel-map { channel_first { - channel_last } } {port port_num}
  ```

Configuring Digital Diagnostic Monitoring Interface (DDMI)

DDMI provides critical system information about the installed optical modules. DDMI is enabled by default.

To enable or disable DDMI, use the following command:

```
configure ports [port_list | all] ddmi [on | off]
```

To view DDMI information, use the following commands:

```
show ports {port_list | tag tag} transceiver information
```

```
show ports {port_list | tag tag} transceiver information detail
```

Jumbo Frames

Jumbo frames are Ethernet frames that are larger than 1522 bytes, including four bytes used for the cyclic redundancy check (CRC).

Extreme products support switching and routing of jumbo frames at wire-speed on all ports. The configuration for jumbo frames is saved across reboots of the switch.

Jumbo frames are used between endstations that support larger frame sizes for more efficient transfers of bulk data. Both endstations involved in the transfer must be capable of supporting jumbo frames. The switch only performs IP fragmentation, or participates in maximum transmission unit (MTU) negotiation on behalf of devices that support jumbo frames.

Guidelines for Jumbo Frames

You need jumbo frames when running the Extreme Networks VMAN implementation. With SummitStack or ExtremeSwitching series switches, you can enable and disable jumbo frames on individual ports before configuring VMANs. For more information on configuring VMANs, refer to VLANs on page 583.

Jumbo frame support is available on ExtremeSwitching series switches that are operating in a SummitStack. For information about displaying jumbo frame status, see Displaying Port Information on page 311.

Enabling Jumbo Frames

> **Note**
> Some network interface cards (NICs) have a configured maximum MTU size that does not include the additional 4 bytes of CRC. Ensure that the NIC maximum MTU size is at or below the maximum MTU size configured on the switch. Frames that are larger than the MTU size configured on the switch are dropped at the ingress port.

To enable jumbo frame support, enable jumbo frames on the desired ports:

- To set the maximum jumbo frame size, use the following command:

```
configure jumbo-frame-size framesize
```

The jumbo frame size range is 1,523 to 9,216. This value describes the maximum size of the frame in transit (on the wire), and includes 4 bytes of CRC.

> **Note**
> For Tagged Packets, the maximum frame size supported is 9,220 bytes, which includes 4 bytes of cyclic redundancy check (CRC), plus another 4 bytes.

- To set the MTU size for the _VLAN_, use the following command:

  `configure ip-mtu` _mtu_ **vlan** _vlan_name_

- Next, enable support on the physical ports that will carry jumbo frames using the following command:

  `enable jumbo-frame ports [`**all** `|` _port_list_`]`

  You can enable or disable jumbo frames for individual ports before configuring the VMANs.

Path MTU Discovery

Using path MTU discovery, a source host assumes that the path MTU is the MTU of the first hop (which is known). The host sends all datagrams on that path with the "don't fragment" (DF) bit set which restricts fragmentation. If any of the datagrams must be fragmented by an Extreme switch along the path, the Extreme switch discards the datagrams and returns an _ICMP (Internet Control Message Protocol)_ Destination Unreachable message to the sending host, with a code meaning "fragmentation needed and DF set." When the source host receives the message (sometimes called a "Datagram Too Big" message), the source host reduces its assumed path MTU and retransmits the datagrams.

The path MTU discovery process ends when one of the following is true:

- The source host sets the path MTU low enough that its datagrams can be delivered without fragmentation.
- The source host does not set the DF bit in the datagram headers.

If it is willing to have datagrams fragmented, a source host can choose not to set the DF bit in datagram headers. Normally, the host continues to set DF in all datagrams, so that if the route changes and the new path MTU is lower, the host can perform path MTU discovery again.

IP Fragmentation with Jumbo Frames

ExtremeSwitching series switches support fragmentation of IP packets. The above support is included whether or not the switches are present in a SummitStack.

ExtremeXOS supports the fragmenting of IP packets. If an IP packet originates in a local network that allows large packets and those packets traverse a network that limits packets to a smaller size, the packets are fragmented instead of discarded.

This feature is designed to be used in conjunction with jumbo frames. Frames that are fragmented are not processed at wire-speed within the switch fabric.

> **Note**
> Jumbo frame-to-jumbo frame fragmentation is not supported. Only jumbo frame-to-normal frame fragmentation is supported.

1. Enable jumbo frames on the incoming port.
2. Add the port to a _VLAN_.

3. Assign an IP address to the VLAN.
4. Enable ipforwarding on the VLAN.
5. Set the MTU size for the VLAN.

    ```
    configure ip-mtu mtu vlan vlan_name
    ```

    The ip-mtu value ranges between 1500 and 9194, with 1500 the default. However, CLI will allow the maximum limit up to 9216 considering port configuration such as tagging which influences L2 Header size. But the values greater than 9194 may lead to packet loss and hence not recommended.

    > **Note**
    > To set the MTU size greater than 1500, all ports in the VLAN must have jumbo frames enabled.

Link Aggregation on the Switch

The link aggregation (also known as load sharing) feature allows you to increase bandwidth and availability by using a group of ports to carry traffic in parallel between switches.

Load sharing, link aggregation, and trunking are terms that have been used interchangeably in Extreme Networks documentation to refer to the same feature, which allows multiple physical ports to be aggregated into one logical port, or *LAG (Link Aggregation Group)*. Refer to IEEE 802.1AX for more information on this feature. The advantages to link aggregation include an increase in bandwidth and link redundancy.

Link Aggregation Overview

Link aggregation, or load sharing, is disabled by default. Load sharing allows the switch to use multiple ports as a single logical port, or *LAG*.

> **Note**
> All ports in a LAG must be running at the same speed and duplex setting. Each port can belong to only one LAG.

For example, VLANs see the LAG as a single logical port. And, although you can only reference the master port of a LAG to a *STPD (Spanning Tree Domain)*, all the ports of the LAG actually belong to the specified STPD.

If a port in a load-sharing group (or LAG) fails, traffic is redistributed to the remaining ports in the LAG. If the failed port becomes active again, traffic is redistributed to include that port.

> **Note**
> Load sharing must be enabled on both ends of the link, or a network loop may result.

Link aggregation is most useful when:

- The egress bandwidth of traffic exceeds the capacity of a single link.
- Multiple links are used for network resiliency.

In both situations, the aggregation of separate physical links into a single logical link multiplies total link bandwidth in addition to providing resiliency against individual link failures.

The software supports control protocols across the LAGs, both static and dynamic. If you add the protocols (for example, *EAPS*, *ESRP (Extreme Standby Router Protocol)*, and so forth) to the port and then create a LAG on that port, you may experience a slight interruption in the protocol operation. To seamlessly add or delete bandwidth when running control protocols, we recommend that you create a LAG consisting of only one port. Then add your protocols to that port and add other ports as needed.

Configurable Per Slot LAG Member Port Distribution

Rather than distribute to all active members in a *LAG*, you have two options to specify a subset of the active member ports as eligible for distribution on a per slot basis: "local slot distribution" and "distribution port lists". The specific choice of configuration is described in the command line syntax as a **distribution-mode**. The choice of distribution mode is configurable per LAG. You may dynamically switch between distribution modes using the `configure sharing` **distribution-mode** command.

Local Slot Distribution

The "local-slot" distribution mode restricts distribution of unicast packets to the active LAG members on the same slot where the packet was received. If no active LAG members are present on the slot where the packet was received, all active LAG member ports are included in the distribution algorithm. The "local-slot" distribution mode is useful for reducing the fabric bandwidth load of a switch. Reducing fabric bandwidth may be especially important for a SummitStack, which has significantly less fabric (inter-slot) bandwidth available in comparison to chassis switches. In many SummitStack hardware configurations, the "local-slot" distribution mode may reduce the switching latency of some flows distributed to a LAG.

Distribution Port Lists

The "port-lists" distribution mode configures one or more LAG member ports to be eligible for unicast LAG distribution on each slot in a switch. If a slot does not have a distribution port list configured or if none of the configured member ports is active in the LAG, all active member ports are eligible for unicast distribution. The use of the "port-lists" distribution mode should be taken into consideration when adding ports to a LAG with the configure sharing command. Any newly added port on a LAG is not available for unicast distribution unless it is also added to the distribution port list of at least one slot.

Limitations

The distribution modes affect only the distribution of known unicast packets on a LAG. Non-unicast packets are distributed among all active members of a LAG.

Link Aggregation and Software-Controlled Redundant Ports

If you are configuring software-controlled redundant ports and link aggregation together, the following rules apply:

- You must unconfigure the software-controlled redundant ports before either configuring or unconfiguring load sharing.
- The entire *LAG* must go down before the software-controlled redundant port takes effect.

Dynamic Versus Static Load Sharing

ExtremeXOS software supports two broad categories of load sharing, or link aggregation.

Dynamic Load Sharing

Dynamic load sharing includes the Link Aggregation Control Protocol (LACP) and Health Check Link Aggregation. The Link Aggregation Control Protocol is used to dynamically determine if link aggregation is possible and then to automatically configure the aggregation. LACP is part of the IEEE 802.1AX standard and allows the switch to dynamically reconfigure the *LAG*s. The LAG is enabled only when LACP detects that the remote device is also using LACP and is able to join the LAG. Health Check Link Aggregation is used to create a link aggregation group that monitors a particular TCP/IP address and TCP port.

Static Load Sharing

Static load sharing is a grouping of ports specifically configured to load share. The switch ports at each end must be specifically configured as part of a load-sharing group.

> **Note**
> The platform-related load sharing algorithms apply to LACP (as well as static load sharing).

Load-Sharing Algorithms

Load-sharing, or link aggregation, algorithms select an egress link for each packet forwarded to egress the *LAG*.

The ExtremeXOS software supports the following types of load sharing algorithms:
- Address based—The egress link is chosen based on packet contents (see Address-Based Load Sharing on page 250).
- Port-based—The egress link is chosen based on the key assigned to the ingress port (see Port-Based Load Sharing on page 252).

ExtremeXOS provides multiple addressed-based algorithms. For some types of traffic, the algorithm is fixed and cannot be changed. For other types of traffic, you can

configure an algorithm. Algorithm selection is not intended for use in predictive traffic engineering.

> **Note**
> Always reference the master logical port of the load-sharing group when configuring or viewing _VLAN_s. VLANs configured to use other ports in the LAG will have those ports deleted from the VLAN when link aggregation is enabled.

Address-Based Load Sharing

All ExtremeXOS platforms support address-based load sharing.

The following are the types of traffic to which addressed-based algorithms apply and the traffic components used to select egress links:

- IPv4 and IPv6 packets—Load sharing is based on the configured options supported on each platform:
  - L2 algorithm—Layer 2 source and destination MAC addresses. Available on SummitStack and all ExtremeSwitching series switches.
  - L3 algorithm—Layer 3 source and destination IP addresses. Available on ExtremeSwitching series switches and SummitStack.
  - L3_L4 algorithm—Layer 3 and Layer 4, the combined source and destination IP addresses and source and destination TCP and UDP port numbers. Available on ExtremeSwitching series switches.
- Non-IP traffic—The source and destination MAC addresses.

Link Aggregation Standard and Custom Algorithms

All ExtremeSwitching switches and stacks support address-based load sharing.

There are two types of algorithms:

- Standard algorithms.
- Custom algorithms, which offer additional options, including the ability to evaluate IP address information from the inner header of an IP-in-IP or GRE tunnel packet.

Standard Algorithms

The following are the types of traffic to which standard addressed-based algorithms apply and the traffic components used to select egress links:

- Layer 2 frames, Unknown unicast packet and non-IP traffic—The source and destination MAC addresses.
- IPv4 and IPv6 packets—Load sharing is based on the configured options supported on each platform:
  - L2 algorithm—Layer 2 source and destination MAC addresses.
  - L3 algorithm—Layer 3 source and destination IP addresses.
  - L3_L4 algorithm—Layer 3 and Layer 4, the combined source and destination IP addresses and source and destination TCP and UDP port numbers.
- _MPLS (Multiprotocol Label Switching)_ packets—The source and destination MAC addresses.

Custom Algorithms

The following are the types of traffic to which custom addressed-based algorithms apply and the traffic components used to select egress links:

- Non-IP Layer 2—Uses the _VLAN_ ID, the source and destination MAC addresses, and the ethertype.
- IPv4 packets—Uses IP address information from an IP header, or for tunneled packets, the custom algorithm always uses the inner header of an IP-in-IP or GRE tunnel packet. The configuration options are:
  - The source and destination IPv4 addresses and Layer 4 port numbers (default)
  - The source IP address only,
  - The destination IP address only
  - The source and destination IP addresses
- IPv6 packets—Uses the source and destination IPv6 addresses and Layer 4 port numbers.
- MPLS packets—Uses the top, second, and reserved labels and the source and destination IP addresses.

> **Note**
>
> In a switch having at least one _LAG_ group with custom algorithm, the egress port for unknown unicast packets across all LAG groups in switch will be decided based on Layer 3 source and destination IP address.

The following command allows you to enable load sharing and select either a standard algorithm or specify that you want to use a custom algorithm:

```
enable sharing port grouping port_list {algorithm [address-based {L2 |
L3 | L3_L4 | custom} | port-based }]} {lacp | health-check}
```

If you choose the **custom** option when you enable load sharing, you can use the following command to select a custom load sharing algorithm:

```
configure sharing address-based custom [ipv4 [source-only | destination-
only | source-and-destination] | hash-algorithm [xor | crc-16 | crc-32
[lower | upper]]]
```

The **hash-algorithm** option controls how the source information (such as an IP address) is used to select the egress port. The **xor** hash algorithm guarantees that the same egress port is selected for traffic distribution based on a pair of IP addresses, Layer 4 ports, or both, regardless of which is the source and which is the destination.

Hash polarization can be prevented by choosing different load sharing algorithms on neighboring switches in different layers. This approach may not be viable in some situations. For example, the network may require the capabilities of the "custom" algorithm for all LAGs in the network. Another approach to varying the load sharing algorithm among neighboring switches would be to use different hashing algorithms of the "custom" algorithm on different switches. For example, some switches could be configured to use "crc-32 upper" algorithm and some configured to use the "crc-16" algorithm.

To change the algorithm for a previously created LAG, use the command:

```
configure sharing master_port algorithm [address-based [L2 | L3 | L3_L4
| custom] | port-based].
```

> **Note**
> Use of the *ACL (Access Control List)* redirect-port-no-sharing *port* action overrides any load-sharing algorithm hash that is generated based on the lookup results. For more information about this action, see LAG Port Selection on page 846.

Another strategy for preventing hash polarization is to configure different hash seed values that are used by the CRC versions of the custom algorithms on the LAG switches. With different hash seeds used on neighboring switches, hash polarization can be prevented while maintaining otherwise identical distribution algorithms.

To set a random hash seed value, use the command:

```
configure sharing address-based custom hash-seed [seed | switch-mac-
address]
```

By using the **switch-mac-address** option for the hash seed value, identical load sharing algorithms may be used on all of the LAGs in the network while automatically preventing hash polarization.

Prior to supporting configuring the hash seed (ExtremeXOS 30.1), the default value of the hash seed was 0x7F2193EA. You can restore the legacy default behavior for the hash seed by explicitly configuring this legacy value.

Port-Based Load Sharing

A port-based load sharing key is used to determine the index of the selected aggregator port where the list of aggregator ports is organized as an array sorted by increasing front panel port number with a zero-based index. The index of the selected aggregator port is equal to the key value module of the number of ports in the aggregator.

> **Note**
> This feature is supported on all ExtremeSwitching Universal platforms.

index = key value % N

where N = the number of ports in the aggregator

The resulting behavior is that ports with a key value of 0 distribute to the lowest numbered port in an aggregator, ports with a key value of 1 distribute to the second lowest numbered port in an aggregator, etc.

Example

A port-based load sharing group contains aggregator ports 2,4,6 and 8. If the zero-based load sharing key 7 is assigned to port 1, then traffic received on port 1 and forwarded to the group will be transmitted on port 8 according to the following calculation:

7 (key) modulo 4 (number of ports in the aggregator) = 3 (index), which corresponds to port 8 which has zero-based index 3 in the sorted array of aggregator ports as shown in Table 24:

Table 24: Aggregator Ports Array

Index	Keys	Member port
0	0, 4, 8, 12	2
1	1, 5, 9, 13	4
2	2, 6, 10, 14	6
3	3, 7, 11, 15	8

Port-based Load Sharing Limitations

When considering the selection of a _LAG_ algorithm, even distribution over member ports is usually the goal. Full utilization of the LAG's bandwidth requires even distribution. In the absence of even distribution, a single member port may become oversubscribed while other member ports are undersubscribed resulting in traffic loss when the LAG, viewed as an aggregate of member ports, is undersubscribed. LAGs distribute best when the diversity of flows destined for the LAG is large relative to the number of ports in the aggregator. For example, when many thousands of L2 flows are destined to a LAG using the "L2" algorithm, distribution on the LAG is typically good (even). Since the number of ports which will switch to a LAG is unlikely to be much larger (orders of magnitude) than the number of ports in the aggregator, extra care may be required from a network administrator when configuring and/or provisioning a switch using port-based LAGs.

LAG Member Port Distribution Modes

As of ExtremeXOS 21.1, two different configuration options are available for specifying subsets of active member ports as eligible for distribution. Both of these options specify a subset of the active member ports on a per slot basis. The specific choice of configuration is described in the CLI as a "distribution-mode". The choice of distribution mode is configurable per _LAG_.

The distribution modes below affect only the distribution of known unicast packets on a LAG. Non-unicast packets are distributed among all active members of a LAG.

Local Slot Distribution

The "local-slot" distribution mode restricts distribution of unicast packets to the active LAG members on the same slot where the packet was received. If no active LAG members are present on the slot where the packet was received, all active LAG member ports are included in the distribution algorithm.

The "local-slot" distribution mode may be specified during LAG creation with the `configure sharing` _`port`_ `slot` _`slot`_ `distribution-list [`_`port_list`_ `| add` _`port_list`_ `|` **`all`**`]` CLI command. It may also be configured dynamically with the "configure sharing" command. This distribution mode is self-configuring in the sense that no configuration is required other than the specification of the "local-slot"

distribution mode. Addition or deletion of LAG member ports via the `configure`
`sharing` *port* `slot` *slot* `distribution-list` [*port_list* | `add` *port_list* |
all] command is automatically handled.

The "local-slot" distribution mode is useful for reducing the fabric bandwidth load of a
switch.

In many SummitStack hardware configurations, the "local-slot" distribution mode will
minimize the switching latency of packets distributed to a LAG. Note that some
modules may not provide the minimum possible latency due to the details of the
switch's fabric connections. Some ExtremeSwitching switches have more than one
switching ASIC and "local-slot" distribution may still involve inter-ASIC switching
through local fabric links.

Distribution Port Lists

The "port-lists" distribution mode provides the ability to configure one or more LAG
member ports to be eligible for unicast LAG distribution on each slot in the switch.
If a slot does not have a distribution port list configured or if none of the configured
member ports is active in the LAG, then all active member ports are eligible for unicast
distribution.

The "port-lists" distribution mode may be specified during LAG creation with the
`configure sharing` *port* `slot` *slot* `distribution-list` [*port_list* | `add`
port_list | **all**] CLI command. It may also be configured dynamically with the
`configure sharing` *port* `slot` *slot* `distribution-list` [*port_list* | `add`
port_list | **all**]command. The use of the "port-lists" distribution mode should be
taken into consideration when adding ports to a LAG with the "configure sharing" CLI
command. Any newly added port on a LAG will not be available for unicast distribution
unless it is also added to the distribution port list of at least one slot.

LACP

You can run the Link Aggregation Control Protocol (LACP) on Extreme Networks
devices. LACP enables dynamic load sharing and hot standby for link aggregation links,
in accordance with the IEEE 802.3ad standard. All third-party devices supporting LACP
run with Extreme Networks devices.

The addition of LACP provides the following enhancements to static load sharing, or
link aggregation:
- Automatic configuration
- Rapid configuration and reconfiguration
- Deterministic behavior
- Low risk of duplication or misordering

After you enable load-sharing, the LACP protocol is enabled by default. You configure
dynamic link aggregation by first assigning a primary, or logical, port to the group, or
LAG and then specifying the other ports you want in the LAG.

LACP, using an automatically generated key, determines which links can aggregate. Each link can belong to only one LAG. LACP determines which links are available. The communicating systems negotiate priority for controlling the actions of the entire trunk (LAG), using LACP, based on the lowest system MAC number. You can override this automatic prioritization by configuring the system priority for each LAG.

After you enable and configure LACP, the system sends PDUs (LACPDUs) on the LAG ports. The LACPDUs inform the remote system of the identity of the sending system, the automatically generated key of the link, and the desired aggregation capabilities of the link. If a key from a particular system on a given link matches a key from that system on another link, those links are aggregatable. After the remote system exchanges LACPDUs with the LAG, the system determines the status of the ports and whether to send traffic on which ports.

Among those ports deemed aggregatable by LACP, the system uses those ports with the lowest port number as active ports; the remaining ports aggregatable to that LAG are put into standby status. Should an active link fail, the standby ports become active, also according to the lowest port number. (See Configuring LACP on page 263 for the number of active and standby LACP links supported per platform.)

All ports configured in a LAG begin in an unselected state. Based on the LACPDUs exchanged with the remote link, those ports that have a matching key are moved into a selected state. If there is no matching key, the ports in the LAG remain in the unselected state.

However,if more ports in the LAG are selected than the aggregator can handle because of the system hardware, those ports that fall out of the hardware's capability are moved into standby state. The lowest numbered ports are the first to be automatically added to the aggregator; the rest go to standby. As the name implies, these ports are available to join the aggregator if one of the selected ports should go offline.

You can configure the port priority to ensure the order that ports join the aggregator. However, that port must first be added to the LAG before you can configure the LACP settings. Again, if more than one port is configured with the same priority, the lowest-numbered port joins the aggregator first.

After the ports in the LAG move into the selected state, LACP uses the mux portion of the protocol to determine which ports join the aggregator and can collect and distribute traffic. A few seconds after a port is selected, it moves into the mux state of waiting, and then into the mux state of attached. The attached ports then send their own LACP sync messages announcing that they are ready to receive traffic.

The protocol keeps sending and receiving LACPDUs until both sides of the link have echoed back each other's information; the ends of the link are then considered synchronized. After the sync messages match up on each end, that port is moved into the aggregator (into the mux state of collecting-distributing) and is able to collect and distribute traffic.

The protocol then enables the aggregated link for traffic and monitors the status of the links for changes that may require reconfiguration. For example, if one of the links in a LAG goes down and there are standby links in that LAG, LACP automatically moves

the standby port into selected mode and that port begins collecting and distributing traffic.

The marker protocol portion of LACP ensures that all traffic on a link has been received in the order in which it was sent and is used when links must be dynamically moved between aggregation groups. The Extreme Networks LACP implementation responds to marker frames but does not initiate these frames.

> **Note**
> Always verify the LACP configuration by issuing the `show ports sharing` command; look for the ports specified as being in the aggregator. You can also display the aggregator count by issuing the `show lacp lag` command.

You can configure additional parameters for the LACP protocol and the system sends certain _SNMP_ traps in conjunction with LACP. The system sends a trap when a member port is added to or deleted from an aggregator.

The system now detects and blocks loopbacks; that is, the system does not allow a pair of ports that are in the same LAG but are connected to one another by the same link to select the same aggregator. If a loopback condition exists between two ports, they cannot aggregate. Ports with the same MAC address and the same admin key cannot aggregate; ports with the same MAC address and a different admin key can belong to the same LAG.

The system sends an error message if a LAG port is configured and up but still not attached to the aggregator or in operation within 60 seconds. Use the `show lacp member-port` _port_ `detail` command to display the churn on both sides of the link. If the churn value is shown as True in the display, check your LACP configuration. The issue may be either on your end or on the partner link, but you should check your configuration. The display shows as True until the aggregator forms, and then it changes to False.

A LAG port moves to expired and then to the defaulted state when it fails to receive an LACPDU from its partner for a specified time. You can configure this timeout value as long, which is 90 seconds, or short, which is three seconds; the default is long. (In ExtremeXOS 11.3, the timeout value is not configurable and is set as long, or 90 seconds.) Use the `show lacp lag` _group-id_ `detail` command to display the timeout value for the LAG.

There are two LACP activity modes: active and passive. In LACP active mode, the switch periodically sends LACPDUs; in passive mode, the switch sends LACPDUs only when it receives one from the other end of the link. The default is active mode. (In ExtremeXOS 11.3, the mode is not configurable; it is always active mode.) Use the `show lacp lag` _group-id_ `detail` command to display the LACP mode for the LAG.

> **Note**
> One side of the link must be in active mode in order to pass traffic. If you configure your side in the passive mode, ensure that the partner link is in LACP active mode.

A LAG port moves into a defaulted state after the timeout value expires with no LACPDUs received for the other side of the link. You can configure whether you want this defaulted LAG port removed from the aggregator or added back into the aggregator. If you configure the LAG to remove ports that move into the default state, those ports are removed from the aggregator and the port state is set to Unselected. The default configuration for defaulted ports is to be removed, or deleted, from the aggregator. (In ExtremeXOS version 11.3, defaulted ports in the LAG are always removed from the aggregator; this is not configurable.)

> **Note**
> To force the LACP trunk to behave like a static sharing trunk, use the
> `configure sharing` *port* **`lacp defaulted-state-action`** [**`add`** | **`delete`**]
> command to add ports to the aggregator.

If you configure the LAG to add the defaulted port into the aggregator, the system takes inventory of the number of ports currently in the aggregator. If there are fewer ports in the aggregator than the maximum number allowed, the system adds the defaulted port to the aggregator (port set to selected and collecting-distributing). If the aggregator has the maximum ports, the system adds the defaulted port to the standby list (port set to standby). Use the `show lacp lag` *group-id* {**`detail`**} command to display the defaulted action set for the LAG.

> **Note**
> If the defaulted port is assigned to standby, that port automatically has a lower priority than any other port in the LAG (including those already in standby).

LACP Fallback

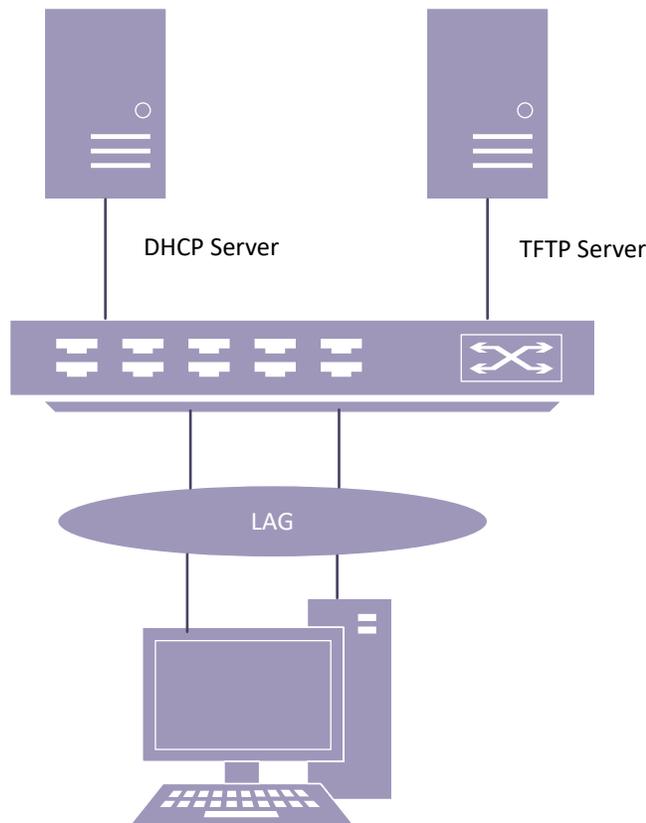
Preboot Execution Environment (PXE) is a client/server environment that allows workstations to boot from the server before their full operating system is running. PXE images are too small to take advantage of LACP functionality, and therefore it is up to the administrator to statically configure the switch for correct connectivity. This also means that after the full operating is fully running the switch needs to be reconfigured back for LACP. The LACP fallback feature introduced in ExtremeXOS 21.1 allows for this process to be automated.


Figure 12: LACP Fallback

The LACP fallback feature allows you to select a single port which will be automatically added to the aggregator if LACP PDUs are not seen on any of the member ports within a specified period of time. If LACP PDUs are exchanged before this timeout expires, then the aggregator is formed using traditional means. If LACP PDUs are not received, then an active port with the lowest priority level is automatically added to the aggregator (enters fallback state). If ports have the same priority value then the lowest port number on the lowest slot number is chosen.

The selected port stays in fallback mode until fallback is disabled or until LACP PDUs start being received on any of the member ports, at which point the old aggregator is removed and a new one is selected based on information propagated in the LACP PDUs. The new fallback port may also be reelected if the existing fallback port changes state; such as port priority change, link bounce, or port enable/disable.

> **Note**
> In an *MLAG (Multi-switch Link Aggregation Group)* environment, fallback port selection occurs only on the LACP master switch.

Link Aggregation Minimum Active Links

The _LAG_ Minimum Links feature allows you to configure a value for the minimum number of active links to keep the entire LAG up. For example, for a LAG consisting of 4 ports and the minimum links set to 2, at least 2 links must be up for the LAG to be up. When the LAG falls below 2 active links, the entire LAG is brought down, and all applications using this LAG will be informed that the LAG is down. Currently, the implicit minimum link value is 1, which means if there is at least 1 link up the entire LAG will stay up.

To configure this ability, use the `configure sharing` _`port`_ **`minimum-active`** _`min_links_active`_ command.

Both static and LACP LAGs are supported. In the case of static LAG, we check if the number of active physical member port links is greater than or equal to the user-configured minimum link value. If so, the LAG remains up. If the number of active physical member port links falls below the configured minimum link value, the static LAG is brought DOWN and all applications receive a Link-Down message for this LAG. As soon as the number of Active physical member ports equals or exceed the configured minimum link value, the static LAG is brought UP and all applications receive a Link-Up message for this LAG.

In the case of LACP, we keep track of the how many member ports LACP has requested to be added to the LAG. After successfully negotiating with its peer, LACP will send a request to add a member port to the LAG. When the number of member ports LACP has requested to be added to the LAG drops below the configured minimum link value, the LACP LAG will be brought down and all applications will receive a Link-Down message for this LAG. As soon LACP has added enough member ports such that the total member ports equals or exceed the configured minimum link value, the LAG is brought up and all applications receive a Link-Up message for this LAG.

Both static and LACP LAGs can be used with _MLAG_ on either the ISC or the MLAG ports. We will verify that the minimum links feature behaves properly for static and LACP LAGs used by MLAG.

> **Note**
> For static LAGs, ensure that both ends of the LAG use the same value for minimum links. If the minimum links value differs, one side may see the LAG as down, where the other side may see the LAG as up.

Health Check Link Aggregation

The Health Check _LAG_ application allows you to create a link aggregation group where individual member links can monitor a particular TCP/IP address and TCP port.

When connectivity to the TCP/IP address and TCP port fails, the member link is removed from the link aggregation group.

Establishing the status of a TCP connectivity is based on standard TCP socket connections. As long as the switch can establish a TCP connection to the target switch

and TCP port, the connection is considered up. The TCP connection will retry based on the configured frequency and miss settings.

A typical use case for this application is when a user wishes to connect each member link to a Security Server to validate traffic. Each member link of the Health Check LAG is connected to an individual Security Server. The LAG is added to a _VLAN_ on the same subnet as the Security Server IP addresses they wish to monitor. Each member port is configured to monitor a particular IP address and TCP port. The Health Check LAG application attempts to do a TCP connect to each IP/TCP port through each member port. The Health Check LAG, by virtue of the sharing algorithm, will load balance traffic across the member links. If a TCP connection cannot be established through the member link, the port is removed from the aggregator and traffic through that particular link is redistributed to the other LAG member links.

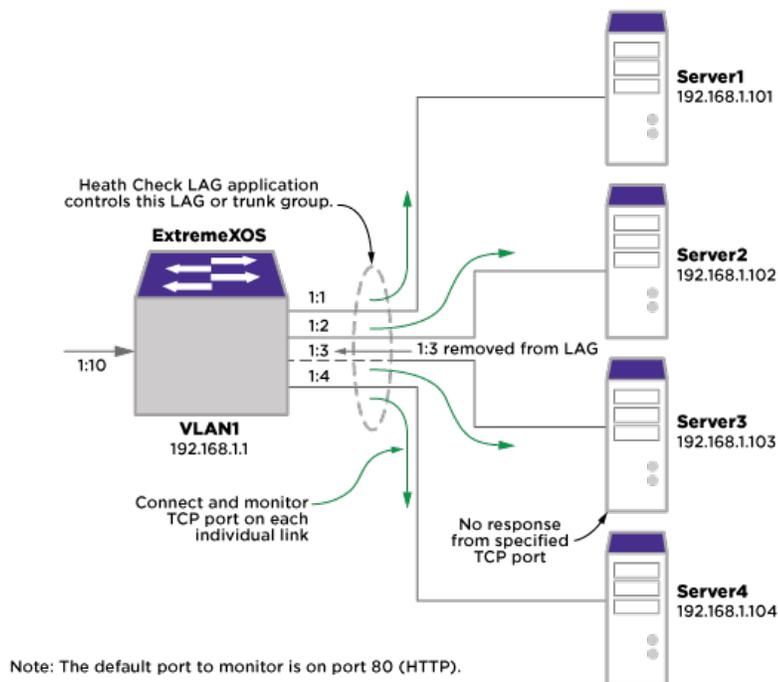
Figure 13 displays an example of a Health Check LAG.


Figure 13: Health Check LAG Example

Guidelines for Load Sharing

Load Sharing Guidelines

For ExtremeXOS standalone switches and SummitStacks the following rules apply to load sharing.

- A static _LAG_ can contain up to eight ports.
- An LACP LAG can contain twice the number of ports as a static LAG. The maximum number of selected links is the same as the limit for a static LAG. The remaining links are standby links.

- A Health Check LAG can contain the same number of ports as a static LAG.
- You can configure only the address-based load-sharing algorithm as described in the following sections:
  ◦ Address-Based Load Sharing on page 250
  ◦ Link Aggregation Standard and Custom Algorithms on page 250
- The maximum number of LAGs for ExtremeSwitching series switches is 128.

> **Note**
> See Configuring LACP on page 263 for the maximum number of links, selected and standby, per LACP.

Guidelines for the Switches

For the ExtremeSwitching X450-G2, X460-G2, X590, X465, X695 series switches, the following rules apply to load sharing.

- A static LAG can contain up to 32 ports when configured to use the L2,L3,L3_L4 or custom algorithm.
- For all the algorithms, LACP LAG can contain up to 64 ports per LAG, which includes up to 32 selected links and 32 standby links.
- A SummitStack consisting entirely of X450-G2, X460-G2, X590, and X465 switches can contain up to 64 ports for all algorithms. All platforms have the same stacking limits.

Load Sharing Rules and Restrictions for All Switches

Additionally, the following rules apply to load sharing on all switches:

- The ports in the *LAG* do not need to be contiguous. The ports in the LAG can span multiple stacked switches.
- A LAG that spans multiple nodes must use ports that have the same maximum bandwidth capability, with one exception—you can mix media type on 1 Gbps ports.
- On both ingress and egress direction, when you configure an *ACL* to a LAG group, you must configure each of the member ports exclusively.

Configuring Switch Load Sharing

To set up a switch for load sharing, or link aggregation, among ports, you must create a load-sharing group of ports, also known as a *LAG*.

> **Note**
> See Guidelines for Load Sharing on page 260 for specific information on load sharing for each specific device.

The first port in the load-sharing group is configured to be the master logical port. This is the reference port used in configuration commands and serves as the LAG group ID. It can be thought of as the logical port representing the entire port group.

All the ports in a load-sharing group must have the same exact configuration, including autonegotiation, duplex setting, _ESRP_ host attach or don't-count, and so on. All the ports in a load-sharing group must also be of the same bandwidth class.

Creating and Deleting Load Sharing Groups

To define a load-sharing group, or _LAG_, you assign a group of ports to a single, logical port number.

- To enable or disable a load-sharing group, use the following command

  ```
  enable sharing port grouping port_list {algorithm [address-based {L2 |
  L3 | L3_L4 | custom} | port-based }]} {lacp | health-check}
  disable sharing port
  ```

  > **Note**
  > All ports that are designated for the LAG must be removed from all VLANs prior to configuring the LAG.

Adding and Deleting Ports in a Load-Sharing Group

Ports can be added or deleted dynamically in a load-sharing group, or Load sharing group (_LAG_).

> **Note**
> When aggregator membership changes on a LAG, both redistribution of flows, as well as some traffic loss, may be expected.

- To add or delete ports from a load-sharing group, use the following commands:

  ```
  configure sharing port add ports port_list
  configure sharing port delete ports port_list
  ```

  > **Note**
  > See Configuring LACP on page 263 for the maximum number of links, selected and standby, per LACP.

Configuring the Load Sharing Algorithm

For some traffic on selected platforms, you can configure the load sharing algorithm. This is described in Load-Sharing Algorithms on page 249.

- The commands for configuring load sharing algorithms are:

  On SummitStack and all ExtremeSwitching series switches:

  ```
  enable sharing port grouping port_list {algorithm [address-based {L2 |
  L3 | L3_L4 | custom} | port-based }]} {lacp | health-check}
  ```

  On SummitStack:

  ```
  enable sharing port grouping port_list {algorithm [address-based {L2 |
  L3 | L3_L4 | custom} | port-based }]} {lacp | health-check}
  ```

  On all platforms:

```
configure sharing address-based custom [ipv4 [L3-and-L4 | source-only
| destination-only | source-and-destination] | hash-algorithm [xor |
crc-16]]
```

Configuring LACP

To configure LACP, you must, again, first create a *LAG*. The first port in the LAG serves as the logical port for the LAG. This is the reference port used in configuration commands. It can be thought of as the logical port representing the entire port group, and it serves as the LAG Group ID.

1. Create a LAG using:

```
enable sharing port grouping port_list {algorithm [address-based {L2 |
L3 | L3_L4 | custom} | port-based }]} {lacp | health-check}
```

The port you assign using the first parameter becomes the logical port for the link aggregation group and the LAG Group ID when using LACP. This logical port must also be included in the port list of the grouping itself.

2. If you want to override the default prioritization in LACP for a specified LAG, use:

```
configure sharing port lacp system-priority priority
```

This step is optional; LACP handles prioritization using system MAC addresses.

3. Add or delete ports to the LAG as desired using:

```
configure sharing port add ports port_list
```

4. Override the ports selection for joining the LAG by configuring a priority for a port within a LAG by using the command:

```
configure lacp member-port port priority port_priority
```

5. Change the expiry timer using:

```
configure sharing port lacp timeout [long | short]
```

The default value for the timeout is long, or 90 seconds.

6. Change the activity mode using:

```
configure sharing port lacp activity-mode [active | passive]
```

The default value for the activity mode is active.

7. Configure the action the switch takes for defaulted LAG ports.

```
configure sharing port lacp defaulted-state-action [add | delete]
```

The default value for defaulted LAG ports is delete the default ports.

> **Note**
> Always verify the LACP configuration by issuing the `show ports sharing` command; look for the ports listed as being in the aggregator.

Configuring Health Check Link Aggregation

To configure Health Check link aggregation you must first create a *LAG*. One port in the LAG serves as the logical port for the LAG and is the reference port used in configuration commands.

When you create the LAG, no monitoring is initially configured. The LAG is created in the same way that a static LAG is created and if no monitoring is ever created, this LAG behaves like a static LAG.

1. Create a LAG using:

   ```
   enable sharing port grouping port_list {algorithm [address-based {L2 |
   L3 | L3_L4 | custom} | port-based }]} {lacp | health-check}
   ```

   The port you assign using the *port* parameter becomes the logical port for the link aggregation group and the LAG Group ID when using Health Check link aggregation. This logical port must also be included in the port list of the grouping itself.

2. Configure monitoring for each member port using:

   ```
   configure sharing health-check member-port port add tcp-tracking IP
   Address {tcp-port TC Port frequency sec misses count}
   ```

   If the TCP-port, frequency, or misses are not specified, the defaults described in the *ExtremeXOS 32.4 Command Reference Guide* are used.

3. Add the LAG to a *VLAN* whose subnet is the same as the configured tracking IP addresses.

   ```
   configure vlan vlan add port lag port [tagged | untagged]
   ```

   All of the tracking IP addresses must be in the same subnet in which the LAG belongs.

   > **Note**
   > VLANs to which Health Check LAG ports are to be added must be configured in loopback mode. This is to prevent the VLAN interface from going down if all ports are removed from the Health Check LAG. In a normal LAG when all ports are removed from the aggregator, the trunk is considered DOWN. As a consequence, if this were the only port in the VLAN, the VLAN interface would be brought DOWN as well. In the Health Check LAG situation, this would cause the TCP monitoring to fail because the L3 vlan interface used by TCP monitoring would no longer send or receive TCP data.

Modifying Configured Health Check LAG

The following commands are used to modify the configured Health Check *LAG*.

1. Delete the monitoring configuration for a member port using the following command:

   ```
   configure sharing health-check member-port port delete tcp-tracking IP
   Address {tcp-port TC Port}
   ```

2. Enable or disable monitoring for a member port in the Health Check LAG using the following command:

   ```
   configure sharing health-check member-port port [disable | enable]
   tcp-tracking
   ```

Load-Sharing Examples

This section provides examples of how to define load sharing, or link aggregation, on stand-alone switches, as well has defining dynamic link aggregation.

Load Sharing on a Stand-alone Switch

The following example defines a static load-sharing group that contains ports 9 through 12, and uses the first port in the group as the master logical port 9:

```
enable sharing 9 grouping 9-12
```

In this example, logical port 9 represents physical ports 9 through 12.

When using load sharing, you should always reference the master logical port of the load-sharing group (port 9 in the previous example) when configuring or viewing *VLAN*s; the logical port serves as the *LAG* Group ID. VLANs configured to use other ports in the load-sharing group will have those ports deleted from the VLAN when load sharing becomes enabled.

Cross-Module Load Sharing on SummitStack

The following example defines a static load-sharing group that contains ports 9 through 12 on slot 3, ports 7 through 10 on slot 5, and uses port 7 in the slot 5 group as the primary logical port, or *LAG* Group ID:

```
enable sharing 5:7 grouping 3:9-3:12, 5:7-5:10
```

In this example, logical port 5:7 represents physical ports 3:9 through 3:12 and 5:7 through 5:10.

When using load sharing, you should always reference the LAG Group ID of the load-sharing group (port 5:7 in the previous example) when configuring or viewing *VLAN*s. VLANs configured to use other ports in the load-sharing group will have those ports deleted from the VLAN when load sharing becomes enabled.

Address-based load sharing can also span modules.

Single-Module Load Sharing on SummitStack

The following example defines a static load-sharing, or link aggregation, group that contains ports 9 through 12 on slot 3 and uses the first port as the master logical port 9, or *LAG* group ID:

```
enable sharing 3:9 grouping 3:9-3:12
```

In this example, logical port 3:9 represents physical ports 3:9 through 3:12.

LACP Example

The following configuration example:

- Creates a dynamic *LAG* with the logical port (LAG Group ID) of 10 that contains ports 10 through 12.
- Sets the system priority for that LAG to 3.

- Adds port 5 to the LAG.

```
enable sharing 10 grouping 10-12 lacp
configure sharing 10 lacp system-priority 3
configure sharing 10 add port 5
```

Health Check LAG Example

The following example creates a Health Check *LAG* of 4 ports:

```
create vlan v1
configure v1 ip 192.168.1.1/24
enable sharing 5 grouping 5-8 health-check
enable loopback-mode v1
configure v1 add port 5
configure sharing health-check member-port 5 add track-tcp 192.168.1.101 tcp-port 8080
configure sharing health-check member-port 6 add track-tcp 192.168.1.102 tcp-port 8080
configure sharing health-check member-port 7 add track-tcp 192.168.1.103 tcp-port 8080
configure sharing health-check member-port 8 add track-tcp 192.168.1.104 tcp-port 8080
```

Displaying Switch Load Sharing

You can display static and dynamic load sharing. In the link aggregation displays, the types are shown by the following aggregation controls:

- Static link aggregation—static
- Link Aggregation Control Protocol—LACP
- Health check link aggregation—hlth-chk

- To verify your configuration, use the following command:

  `show ports sharing`
- Verify LACP configuration, use the following command:

  `show lacp`
- To display information for the specified *LAG*, use the following command:

  `show lacp lag `*`group-id`*` {`**`detail`**`}`
- To display LACP information for a port that is a member of a LAG, use the following command:

  `show lacp member-port `*`port`*` {`**`detail`**`}`

  Refer to for information on displaying summary load-sharing information.
- To clear the counters, use the following command:

  `clear lacp counters`
- To display the LACP counters, use the following command:

  You can display the LACP counters for all member ports in the system by using:

  `show lacp counters`
- To display information for a health check LAG, use the following command:

  `show sharing health-check`

MLAG

MLAG Overview

The *MLAG* feature allows you to combine ports on two switches to form a single logical connection to another network device. The other network device can be either a server or a switch that is separately configured with a regular *LAG* (or appropriate server port teaming) to form the port aggregation.

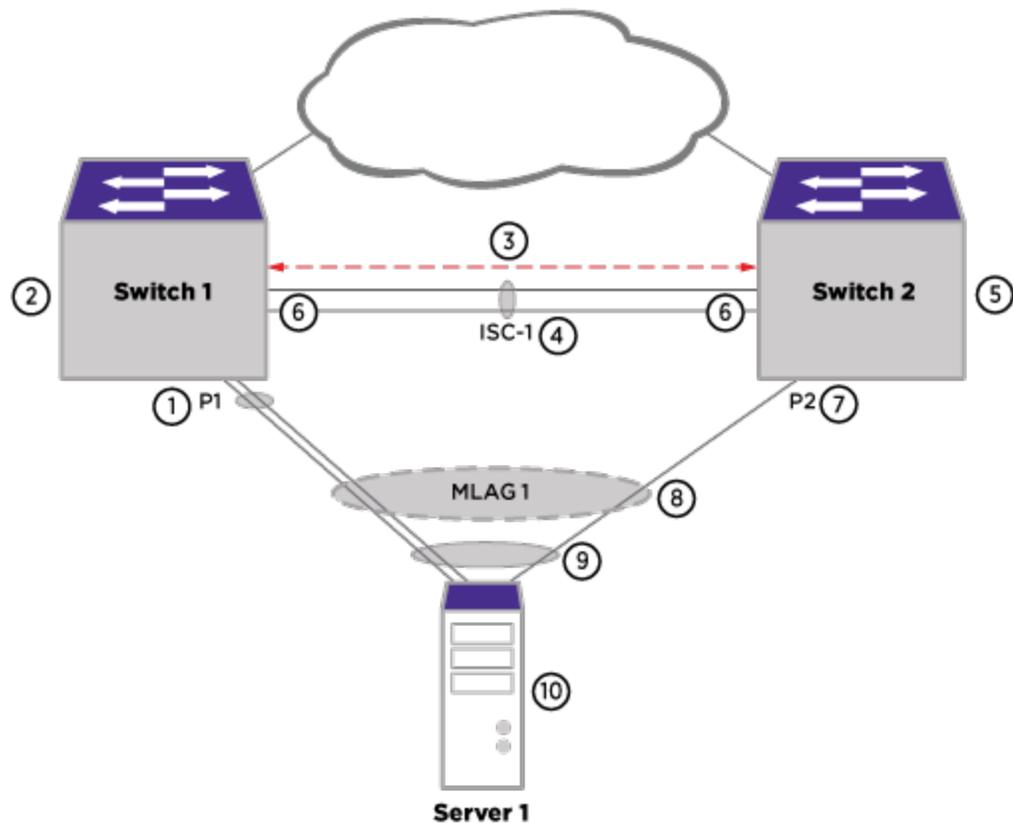
The following diagram displays the elements in a basic MLAG configuration:


Figure 14: MLAG Elements

1. MLAG port that is a load-shared link. This port is the peer MLAG port for <Switch2:Port P2>.
2. MLAG peer switch for Switch 2.
3. Inter-switch connection (ISC or ISC *VLAN*) has only the ISC port as a member port on both MLAG peers.
4. ISC link that connects MLAG peers.
5. MLAG peer switch for Switch 1.
6. ISC ports.
7. MLAG port that is a non-load-shared link. This port is the peer MLAG port for <Switch1:Port P1>.

8. MLAG group (MLAG-ID 1) that has two member ports (one load-shared and one non-load-shared member).
9. MLAG remote node sees the MLAG ports as regular load-shared link.
10. MLAG remote node - can be a server or a switch.

The operation of this feature requires two ExtremeXOS switches interconnected by an Inter-Switch connection (ISC). The ISC is a normal, directly connected, Ethernet connection and it is recommended that you engineer reliability, redundancy where applicable, and higher bandwidth for the ISC connection. Logically aggregate ports on each of the two switches by assigning MLAG identifiers (MLAG-ID). Ports with the same MLAG-ID are combined to form a single logical network connection. Each MLAG can be comprised of a single link or a LAG on each switch. When an MLAG port is a LAG, the MLAG port state remains up until all ports in the LAG go down.

As long as at least one port in the LAG remains active, the MLAG port state remains active. When an MLAG port (a single port or all ports in a LAG) fails, any associated MAC _FDB (forwarding database)_ entries are moved to the ISC, forcing traffic destined to the MLAG to be handled by the MLAG peer switch. Additionally, the MLAG peer switch is notified of the failure and changes its ISC blocking filter to allow transmission to the MLAG peer port. In order to reduce failure convergence time, you can configure MLAG to use ACLs for redirecting traffic via the "fast" convergence-control option.

Each of the two switches maintains the MLAG state for each of the MLAG ports and communicates with each other to learn the MLAG states, MAC FDB entries, and IP multicast entries of the peer MLAG switch.

ISC Blocking Filters

The ISC blocking filters are used to prevent looping and optimize bandwidth utilization.

When at least one _MLAG_ peer port is active, the upper layer software initiates a block of traffic that ingresses the ISC port and needs to be forwarded to the local MLAG ports. This is considered to be the steady state condition. In normal steady state operation most network traffic does not traverse the ISC. All unicast packets destined to MLAG ports are sent to the local MLAG port only. However, flood and multicast traffic will traverse the ISC but will be dropped from MLAG peer port transmission by the ISC blocking filter mechanism. The ISC blocking filter matches all Layer 2 traffic received on the ISC and blocks transmission to all MLAG ports that have MLAG peer ports in the active state.

When there are no active MLAG peer ports, the upper layer software initiates an unblocking of traffic that ingresses the ISC port and needs to be forwarded to the local MLAG ports thus providing redundancy. This is considered to be the failed state.

Linkup Isolation

Under certain circumstances, a temporary (less than a second) loop condition exists when an MLAG port becomes operational, but before the remote _MLAG_ peer installs the ISC blocking filter (see ISC Blocking Filters on page 268). MLAG linkup isolation addresses this condition by preventing any flood traffic (broadcast, unknown, unicast, etc.) received on a just operational MLAG port from being forwarded to ISC ports until the remote MLAG peer installs the ISC blocking filter.

Inter-Switch Communication

Keep-alive Protocol

MLAG peers monitor the health of the ISC using a keep-alive protocol that periodically sends health-check messages. The frequency of these health-check hellos is configurable. When the MLAG switch stops receiving health check messages from the peer, it could be because of the following reasons:

- Failure of the ISC link when the remote peer is still active.

- The remote peer went down.

If the ISC link alone goes down when the remote peer is alive, both the MLAG peers forward the south-bound traffic, resulting in duplication of traffic. However, this does not result in traffic loops. This is because the remote node load shares to both the MLAG peers and does not forward the traffic received on one of the load shared member ports to other member ports of the same load shared group.

Starting in ExtremeXOS 15.5, health check messages can also be exchanged on an alternate path by separate configuration – typically the "Mgmt" *VLAN*. If the peer is alive when the ISC link alone goes down, one of the MLAG peers disables its MLAG ports to prevent duplicate south-bound traffic to the remote node. To reduce the amount of traffic on the alternate path, health check messages are initiated on the alternate path only when the ISC link goes down. When the ISC link is up, no health check messages are exchanged on the alternate path.

When the MLAG switch misses 3 consecutive health check messages from the peer, it declares that the MLAG peer is not reachable on the ISC link. It then starts sending out health check messages on the alternate path to check if the peer is alive. When the first health check message is received from the MLAG peer on the alternate path, it means that the peer is alive. In this scenario, one of the MLAG peers disables its MLAG ports to prevent duplication of south-bound traffic to the remote node.

> **Note**
> The MLAG switch having the lower IP address for the alternate path VLAN disables its ports.

When the ISC link comes up and the switch starts receiving health check messages on the ISC control VLAN, the ports that were disabled earlier have to be re-enabled. This action is not performed immediately on the receipt of the first health check message on the ISC control VLAN. Instead the switch waits for 2 seconds before enabling the previously disabled ports. This is done to prevent frequent enabling and disabling of MLAG ports due to a faulty ISC link up event.

MLAG Status Checkpointing

Each switch sends its MLAG peer information about the configuration and status of MLAGs that are currently configured over the ISC link.

This information is checkpointed over a TCP connection that is established between the MLAG peers after the keep-alive protocol has been bootstrapped.

Authentication for Checkpoint Messages

The checkpoint messages exchanged between the MLAG peers over the TCP connection are sent in plain text and can be subjected to spoofing. Starting from ExtremeXOS 15.5 a provision is provided as part of this feature to secure the checkpoint connection against spoofing.

A key for authentication must be configured on both the MLAG peer switches. This key will be used in calculating the authentication digest for the TCP messages. TCP_MD5SIG socket option will be used for authentication and so only _MD5 (Message-Digest algorithm 5)_ authentication is supported. The configured key will be used in setting up TCP_MD5SIG option on the checkpoint socket. The same key must be configured on both the MLAG peers. The checkpoint connection will not be established if different keys are configured on the MLAG peer switches.

PIM MLAG Support

ExtremeXOS allows configuring PIM on both _MLAG_ peers. PIM adjacencies between each MLAG vlan are established across the ISC link.

> **Note**
> PIM MLAG is supported only on default VR and is not supported on user-created VRs.

- The checkpoint PIM state between MLAG peers. This should include all MLAG egresses.

- You can verify that PIM functionality for MLAG is present by issuing the following show command:

  ```
  show pim cache {{detail} | {state-refresh} {mlag-peer-info}
  {group_addr {source_addr}}}
  ```

- Additionally, the existing show pim cache command displays ingress _VLAN_ information for all MLAG peers.

  The output of the command is shown below:

  ```
  Index    Dest Group      Source              InVlan   Origin
      [0001]  226.1.1.1       112.2.2.202 (S)    fifthteen Sparse
     Expires after 203 secs UpstNbr: 51.15.15.2
     RP: 61.2.2.2 via 51.15.15.2 in fifthteen
     Peer Ingress VLAN (ISC 1): 51.15.15.4/24 (Same)
     EgressIfList =  eight(0)(FW)(SM)(I) , five(0)(FW)(SM)(I)
     PrunedIfList =  ten(0)(SM)(AL)
  ```

Multiple VLAN Registration Protocol (MVRP) over Multi-switch Link Aggregation (MLAG)

This feature adds support for Multiple _VLAN_ Registration Protocol (MVRP) on _MLAG_. The objective of running Multiple VLAN Registration Protocol (MVRP) over MLAG is to propagate the VLANs across the MLAG peers and to have the VLAN database synced, so that the remote switches/servers continue to see a single logical connection.

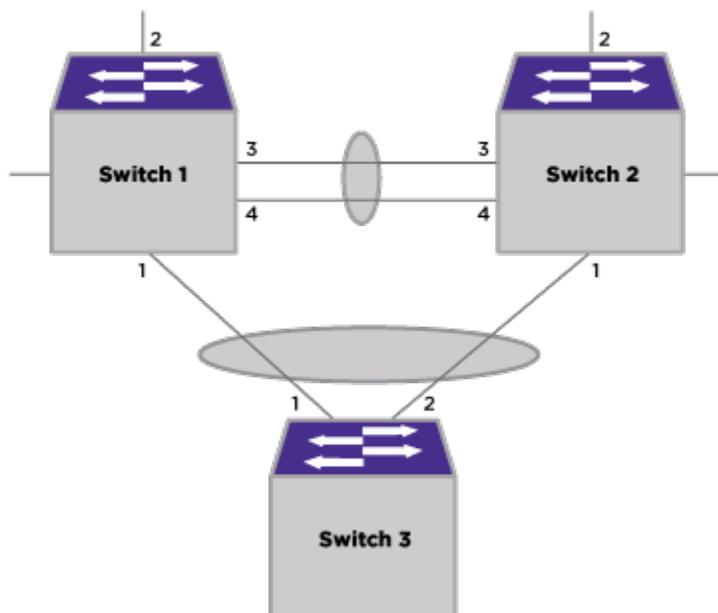
Checkpointing


Figure 15: Checkpointing

The primary reason for checkpointing is keeping the MLAG peers synchronized. The VLAN membership status of MLAG ports is maintained similarly through checkpointing.

There are two types of checkpointing that are done:
- PDU checkpointing
- Bulk checkpointing

PDU Checkpointing

Each incoming MRP PDU on a MLAG port is encapsulated and sent to the MLAG peer through the ISC connection. On the MLAG peer, the packet is de-capsulated and processed by the MRP process as if received by the local MLAG port. This ensures that the local MLAG port on the peer is also added to the VLAN. The MVRP propagation happens normally in addition to the PDU checkpointing. In Figure 15 on page 271, Switch 1 and 2 are MLAG peers connected through ISC port (*LAG* ports 3,4). Switch 3 can send the MVRP PDUs to either Switch 1 or Switch 2 based on which MLAG peer is up. Assuming the MVRP PDU is sent to Switch 1, port 1 of Switch 1 is added to the VLAN and the PDU is checkpointed to Switch 2. If checkpointing is not done, port 1 of Switch 2 does not get added to the dynamic VLAN, since the MVRP PDU is not received on that port.

Bulk Checkpointing

When the MLAG peer comes up for the first time, bulk checkpointing of VLAN membership of the MLAG ports occurs. The peer that comes up sends a "pull" message to the active peer. Upon receiving the pull message, MVRP PDU is constructed for each

of the MLAG ports and checkpointed through the ISC connection. Upon receiving the checkpointed PDU, it is decapsulated and processed as if it were received locally by the MRP process. This way the MLAG ports of the peer that came up gets added to VLANs. Bulk checkpointing is also done when MVRP is enabled on the MLAG port.

MVRP Packet Received on MLAG Port Process

The following is the sequence of operations when an MVRP packet is received on a MLAG port.

1. MVRP packet is parsed by MRP process.
2. Upon successful parsing, the MVRP packet is encapsulated by the VSM and sent to the corresponding MLAG peer.
3. The MLAG index is encapsulated along with the packet.
4. In the remote MLAG peer, the packet is de-capsulated.
5. From the MLAG index, the local MLAG port is determined.
6. The MVRP packet is processed as if the PDU has been received by the local MLAG port

Orchestration Mode for Checkpointing MLAG Port Configuration

With *MLAG*, the port configuration for the MLAG member links must be identical on the MLAG peer switches. To reduce the configuration complexity and to minimize the risk of inconsistency, you can use orchestration mode so that any configuration commands are now checkpointed to the MLAG peer switch.

After entering this orchestration mode, like the existing virtual-router mode, the configuration prompt changes indicating that commands issued are within this context:

```
(orchestration bottom) X670G2-48x-4q.4 #
```

> **Note**
> Enabling orchestration mode on both MLAG peers at same time is not recommended. If orchestration mode is enabled on both MLAG peers and you execute commands on both switches at same time, the switch may abort execution of the command.

For information about the orchestration commands, see

> **Note**
> If you need to have different settings on each MLAG peer (for example, IP addresses), you need to perform those configuration steps outside of orchestration mode.

Multi-switch Link Aggregation Group (MLAG) Port Reload Delay Timer

On certain platforms, it takes few seconds between the first port and last port to come up. When lower numbered ports are used as Multi-switch Link Aggregation Group (MLAG) ports and higher numbered ports are used as inter-switch connection (ISC) ports, MLAG ports come up first before the ISC ports. In such cases, traffic from the

servers MLAGed to the peers that traverse the ISC can be lost during the duration when the traffic hashes to the MLAG peer while the ISC is still not up.

The MLAG reload delay timer keeps MLAG ports disabled for the configured duration while the switch configuration is loading. This timer is also useful for cases where network-facing Layer 3 protocols, like OSPF, are yet to converge on the node that has just come up. This feature is disabled by default.

Support for More than One MLAG Peer

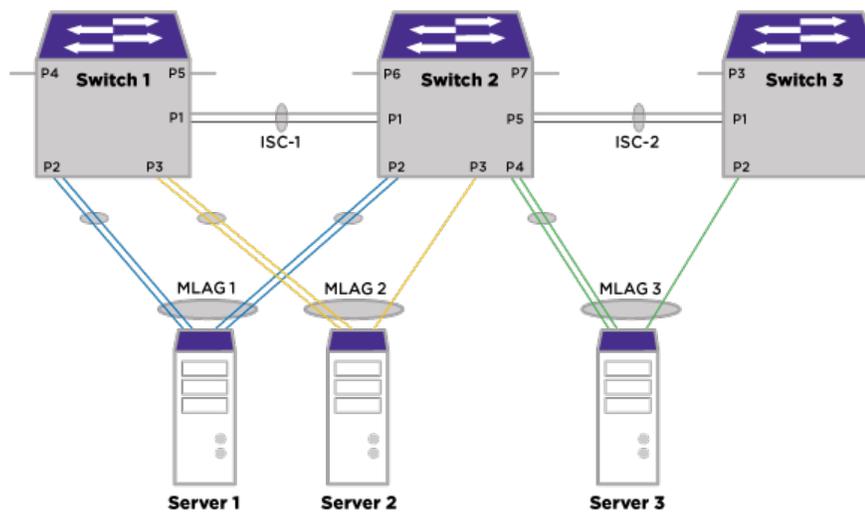
Beginning in ExtremeXOS 15.5, each _MLAG_ switch can support the creation of two MLAG peers. The following topology is now supported:


Figure 16: Two MLAG Peer Topology

All basic MLAG functionality and traffic forwarding rules that existed earlier apply with this topology.

> **Note**
> A port is an MLAG port only with respect to a particular MLAG peer switch. In the above example, the "green" port on switch-2 is an MLAG port with respect to switch-3 on ISC-2. It is not an MLAG port with respect to switch-1 on ISC-1. Similarly, on switch-2, "blue" and "orange" ports are MLAG ports with respect to switch-1 on ISC-1. They are not MLAG ports with respect to switch-3 on ISC-2.

Traffic Flows

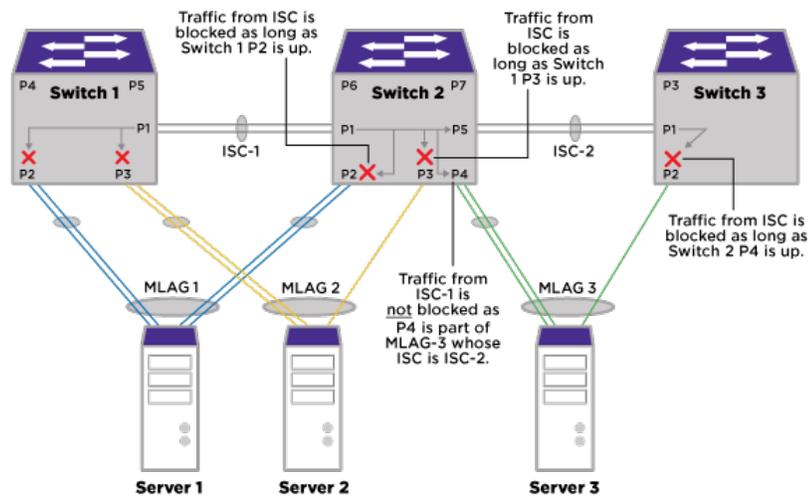
In the steady state when all the ports are enabled, the _MLAG_ blocking rule prevents traffic coming from the ISC port to be forwarded to its MLAG ports. So, in steady state, any unknown (unknown unicast/broadcast/multicast) traffic from Switch-1 to Switch-2 over ISC-1 will not be flooded to "blue" and "orange" MLAG ports on switch-2. However, since the "green" MLAG port on switch-2 does not correspond to ISC-1, the traffic from ISC-1 will be forwarded to "green" MLAG port as shown in the following illustration:


Figure 17: Traffic Flow

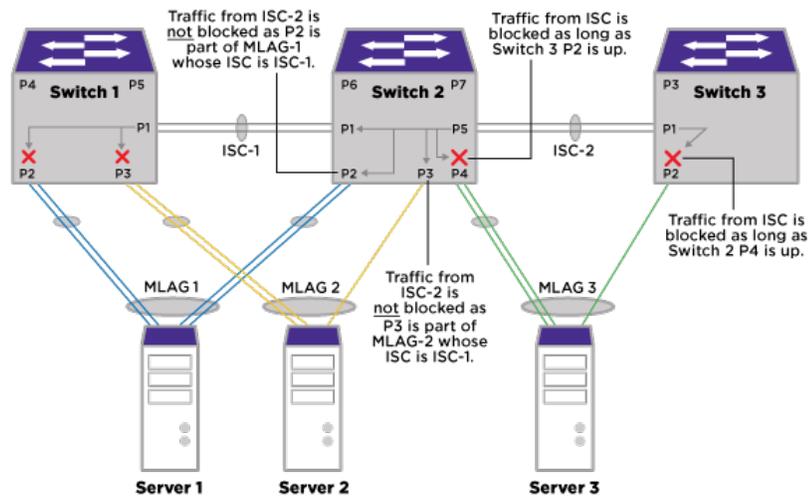
In steady state, the unknown traffic from Switch-3 to Switch-2 over ISC-2, will be blocked to "green" MLAG ports. However, this traffic will be sent to "blue" and "orange" MLAG ports.


Figure 18: Traffic Flow (Unknown Traffic Switch-3 to Switch-2)

MLAG Peer Port Failure

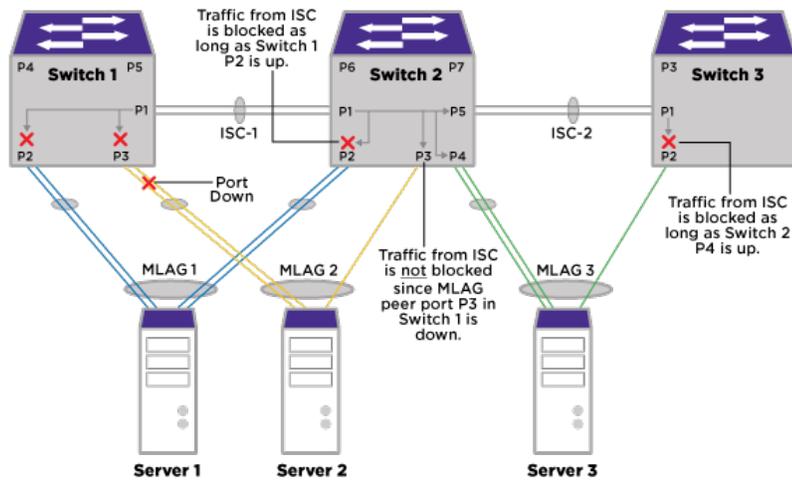
In the case of an *MLAG* port failure, the blocking rule on the peer MLAG switch will be removed and the traffic coming on the ISC will be forwarded to the corresponding MLAG port.


Figure 19: Peer Port Failure
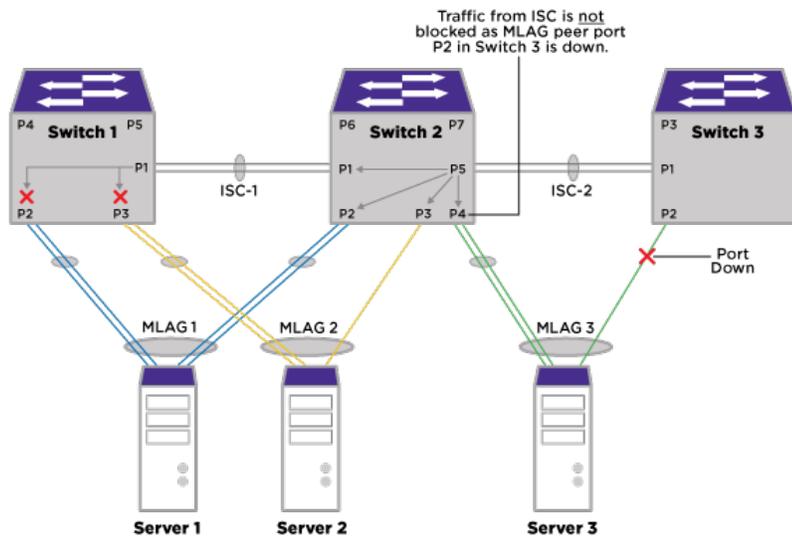

Figure 20: Peer Port Failure (cont.)

FDB Checkpointing

All *FDB* entries on VLANs having ISC port as a member will be checkpointed to the peer *MLAG* switch(es). FDB entries learned on an MLAG port will be checkpointed to the corresponding MLAG port on the peer switch. FDB entries on the non-MLAG, non-ISC port will be checkpointed to the corresponding ISC port on the peer switch.

Layer-2 IP Multicast

The receiver Rx1 sends an *IGMP (Internet Group Management Protocol)* report towards Server 1. Since server 1 is connected to both Switch 1 and Switch 2 through a *LAG*, let us assume that it selects a port towards Switch 2 to forward the report. This results in Switch 2 receiving a report on port P2. It adds the port to the group table. Switch 2

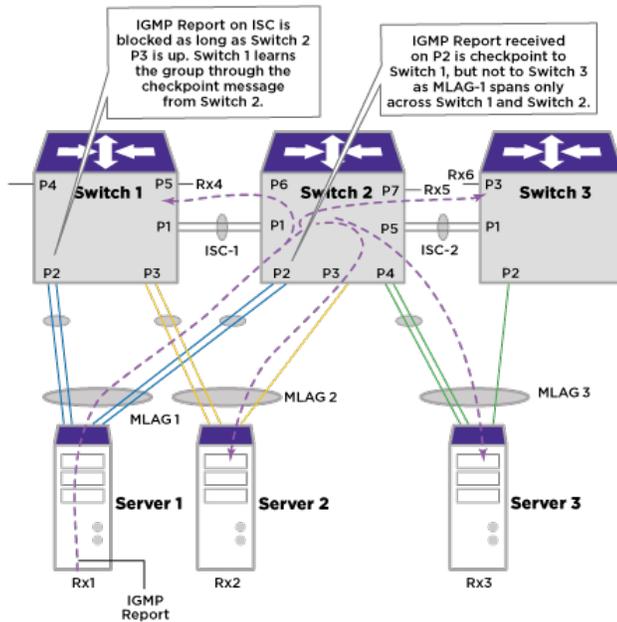
sends a checkpoint message to Switch 1 since Switch 1 is the _MLAG_ peer for MLAG-1. But Switch 2 doesn't checkpoint the report to Switch 3 since Switch 3 is not an MLAG peer for MLAG-1. However, Switch 2 forwards the report towards Switch 3 over ISC. Switch 3 would learn this on ISC port. The group information tables on each of the switches appears below.


Figure 21: Group Information Table per Switch

Table 25: Switch 1

Group	Port
G1	P2

Table 26: Switch 2

Group	Port
G1	P2

Table 27: Switch 3

Group	Port
G1	P1

Figure 22 depicts a scenario where a multicast stream STR1 ingressing Switch 1 will reach Rx1 and Rx2 directly via P2 and P3 respectively. Similarly traffic ingressing Switch 2 will reach Rx3 through P4 directly.

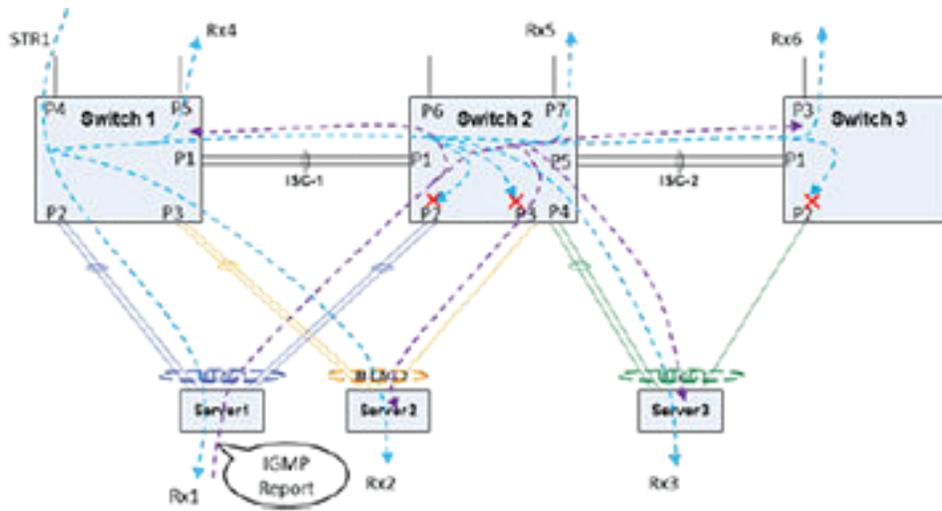
Figure 22: Multicast Stream Ingressing Example


Figure 23 figure depicts a traffic flow scenario when the local MLAG port is down. When the local MLAG port is down, IGMP group information received from the peer MLAG router will result in ISC being added as egress port. Now traffic stream STR1 ingressing Switch 1 will go over ISC-1 to Switch 2 where it gets forwarded towards Server 2 over P3.
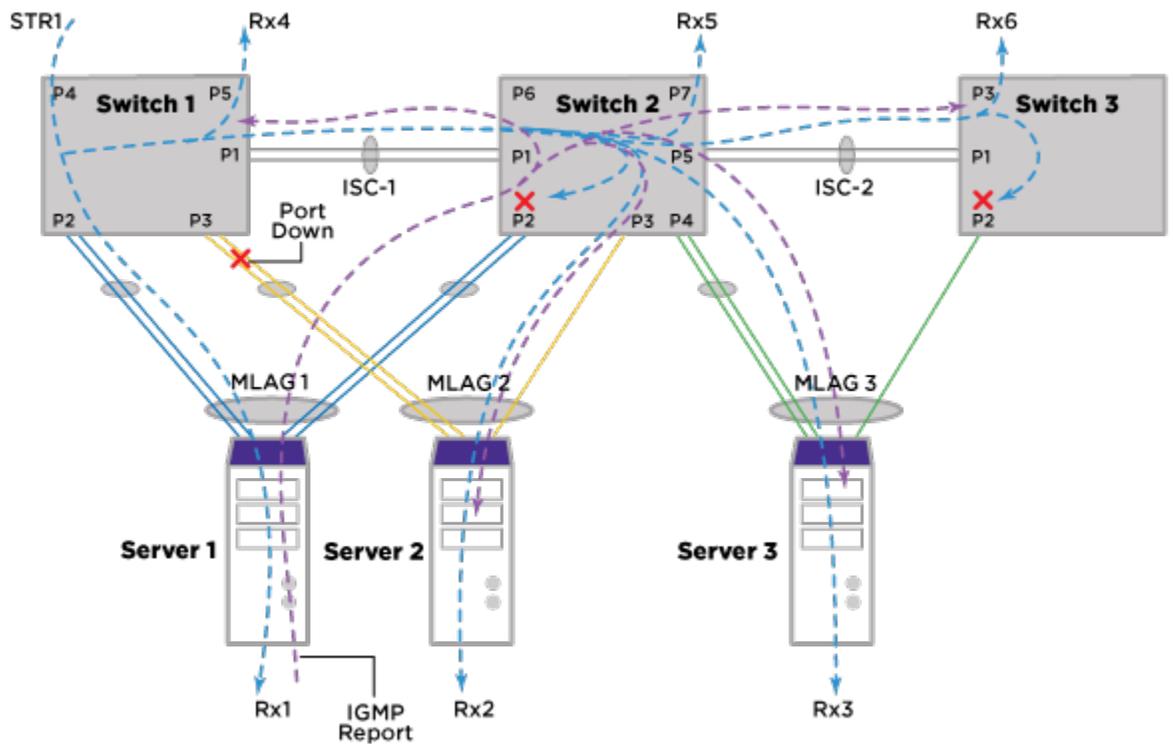

Figure 23: Traffic Flow with Local MLAG Port Down

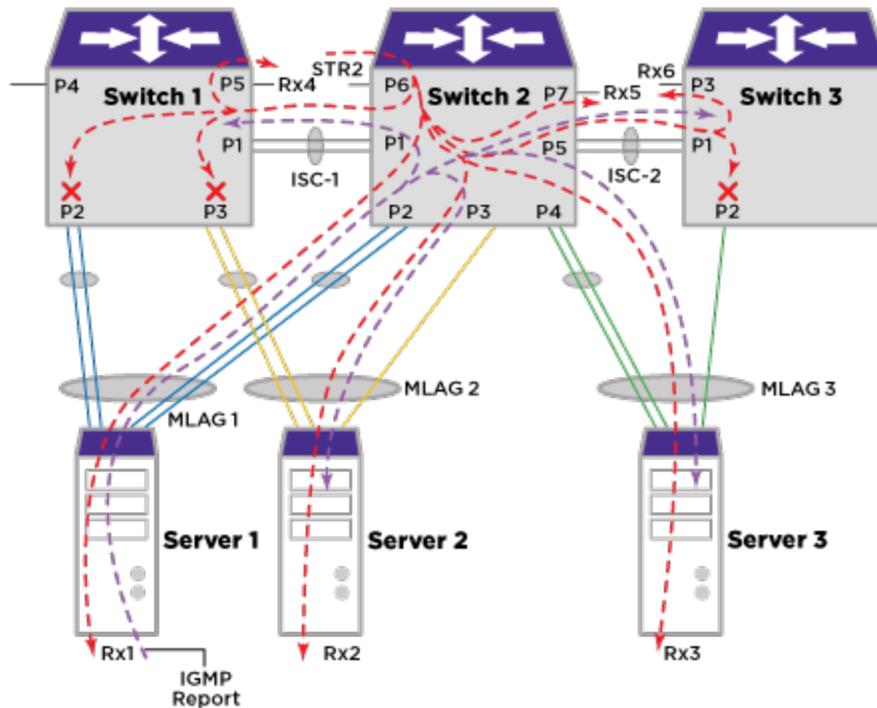
Figure 24 illustrates a scenario where a multicast stream STR2 ingressing Switch 2 will reach Rx1, Rx2 and Rx3 directly via P2, P3 and P4 respectively.


Figure 24: Multicast Stream Ingressing Switch 2 Example

Layer 3 IP Multicast using PIM-SM

Consider the following sample topology for MLAG:

```
DUT-1(core lic)======ISC vlan=======DUT-2(core lic)

| |

+---------------DUT-3(edge lic)---------------+
```

DUT-1 and DUT-2 are MLAG peers, DUT-3 is a L2 switch whose uplink is a LAG up to the pair of MLAG switches.

- RP and BSR can be configured on same device along with the MLAG configuration, but we recommend to keep RP node away from MLAG peers. One MLAG peer will be Designated Router (DR) and another one will be elected as NON-DR for MLAG VLAN. DR node will send *,G and try to pull the traffic from RP, and Non-DR will not pull the traffic until DR is alive. If you config RP on Non-DR node then both MLAG peers will pull the traffic which triggers the assert to avoid the traffic duplication. It is not recommended to setup RP on any VLAN on MLAG peers.
- It is recommended to avoid the assert operation since a small amount of traffic duplication happens during the assert operation. We can avoid assert in some scenario but not all the scenarios.
- DR priority configuration will help to make RP node as DR. The DR priority feature is available from 15.3.2 release onwards.

- It is recommended that for PIM-SM deployments, the RP is configured on loopback VLANs instead of regular VLANs. This ensures continuous connectivity to the RP without needing active ports present in that respective VLAN.
- It is recommended that for PIM-SM deployments, route-to-source must exist and receivers should get the traffic from the SPT tree in the MLAG configurations. *,G forwarding in MLAG is not a recommended configuration.

MLAG Limitations and Requirements

The _MLAG_ feature has the following limitations:

- MLAG peer switches must be of the same platform family. The following MLAG peers are allowed:
  - ExtremeSwitching switches with ExtremeSwitching switches
  - SummitStack with SummitStack

> **Note**
> In the case of ExtremeSwitching standalone switches, it is strongly recommended that MLAG peer switches be of the same type.
> In the case of SummitStack switches, we recommend that the MLAG ports be from slots of similar capability.

- Layer 2 protocols such as _EAPS_ or _STP (Spanning Tree Protocol)_ will be configured to not allow the blocking of the ISC.
- The number of MLAG ports for each pair of switches is limited to the number of physical ports in the system.
- MLAG peers should run the same version of ExtremeXOS for proper functioning.
- _ESRP_ cannot be configured in a MLAG environment with more than one peer.
- The MLAG peers in a multi peer setup cannot be looped however can be extended as a linear daisy chain.

> **Note**
> The behavior of ExtremeXOS 30.1 has changed if locally configured IP addresses are used to determine network reachability. For details, see the `ping` command.

MLAG Requirements

The following table shows additional MLAG requirements that are specific to other protocols and features.

Items	Impact
VLAN:Membership	You must add the respective port (or *LAG*) that is part of an MLAG to a VLAN on both MLAG peers. The set of configured VLANs on [Switch1:P1] must be identical to the set of VLANs configured on [Switch2:P2]. You must add the ISC to every VLAN that has an MLAG link as a member port.
VMAN:Membership	The restrictions are the same as those for VLAN Membership.
VLAN:ISC	You must create a Layer 3 VLAN for control communication between MLAG peers. You cannot enable IP forwarding on this VLAN. The ISC is exclusively used for inter-MLAG peer control traffic and should not be provisioned to carry any user data traffic. Customer data traffic however can traverse the ISC port using other user VLANs.
VMAN:ISC	Although not recommended, a VMAN may be configured to carry Inter-MLAG peer traffic,
LAG:Load-Sharing Algorithm	It is recommended but not required that LAGs that form an MLAG be configured to use the same algorithm.
Ports:Flooding	To disable flooding on an MLAG, you must disable flooding on both ports (or LAGs) that form the MLAG.
Ports:Learning	To disable learning on an MLAG, you must disable learning on both ports (or LAGs) that form the MLAG. Learning is disabled by default on ISC ports.
FDB:Static & Blackhole entries	Configuration must be identical on both MLAG peers for entries that point to an MLAG port.
FDB:Limit learning	Learning limits are applicable to member ports of each peer. The limit on the MLAG is the sum of the configured value on each peer.
FDB:MAC Lockdown	This is supported but needs configuration on both peers. A switch can still receive checkpointed MAC addresses from its peer in the window between executing the lockdown command on both switches.
EAPS	MLAG ports cannot be configured to be EAPS ring ports. Configuration of the ISC port as an EAPS blocked port is disallowed.
STP	You should ensure that the ISC port is never blocked by STP. You should configure in such a way that one of the MLAG peers become root bridge and also configure MLAG peers with backup root option. Loop protect feature should not be enabled on LAG ports on access switches. Enabling this feature on MLAG ports is acceptable. For more information about STP and MLAG, see STP and MLAG on page 1382.

Items	Impact
VRRP	VRRP must be enabled on Layer 3 VLANs that have MLAG member ports.
ESRP	MLAG and ISC ports must be added as ESRP host-attach ports.
EDP/LLDP (Link Layer Discovery Protocol)	There are no restrictions but the remote end of the MLAG will display different neighbors for different ports in the same LAG.
ELSM	ELSM is not to be configured on MLAG ports at either end of an MLAG.
Software-Redundant Ports	These are not to be configured on MLAG ports at either end of an MLAG.
Mirroring	Mirroring on local ports in an MLAG is supported. Mirroring of MLAG peer ports to a local port is not supported.
Routing Protocols	OSPFV2/OSPFV3 neighborship can be formed across an MLAG.
Multicast:*IGMP*	All timers related to IGMP must be identical on both the peers.
Multicast:PIM	PIM should be configured on both the MLAG peers, and the PIM timers must be identical. MLAG functionality must not be enabled on PIM Intermediate routers. It should be enabled only on Last Hop (LHR) and First Hop (FHR) routers. MLAG peer switches S1 and S2 perform Checkpoint PIM for S and G states. This should include all MLAG egresses. To avoid traffic drops due to asserts, do not include ISC port in MLAG egresses if the ingress VLAN includes ISC port, and both the peers have the same ingress for the S, G cache.
Multicast:MVR	MVR should be enabled on only one of the MLAG peer switches. MVR must not be enabled on MLAG VLANs.
Multicast:PIM Snooping	This is not supported.
Multicast:IPv6	There are no restrictions.
CFM	There are no restrictions.
MPLS:General	MPLS cannot be enabled on VLANs having MLAG member ports.
MPLS:VPLS	VPLS must be configured for redundancy using ESRP. The ESRP master VLAN must include the ISC ports and the VPLS service VLAN ports as members. Pseudowires cannot traverse an ISC link. You should not add the ISC port as a member to MPLS VLANs that can be used by LSPs that can carry Layer 2 VPN traffic terminating on MLAG peer switches.
ACLs	It is strongly recommended that configuration be identical across peers on MLAG ports.
QoS	It is strongly recommended that configuration be identical across peers on MLAG ports.
NetLogin	Supported. NetLogin should be enabled across the MLAG ports of both the peers.

Items	Impact
VLAN:PVLAN	If an MLAG port is a member of either a subscriber VLAN or a network VLAN, the ISC port needs to be added as a member of the network VLAN. Subscriber VLANs in a private VLAN cannot have overlapping MLAG ports as members. Configuring dedicated loopback ports for subscriber VLANs in a private VLAN that shares an MLAG port causes duplicate traffic to be sent to the remote node.
W-MLAG	Supported.

Configuring MLAGs

This section provides the commands used to configure MLAGs and display information about those configured.

- To create an *MLAG* peer switch association structure, use the following command:

  `create mlag peer peer_name`

- To delete a peer switch, use the following command:

  `delete mlag peer peer_name`

- To associate an MLAG peer structure with an MLAG peer switch IP address, use the following command:

  `configure mlag peer peer_name ipaddress peer_ip_address {vr VR}`

- To unconfigure the association, use the following command:

  `unconfigure mlag peer peer_name ipaddress`

- To configure the time interval between health check hello packets exchanged between MLAG peer switches, use the following command:

  `configure mlag peer peer_name interval msec`

- To unconfigure the time interval setting and reset the interval to the default of 1000 ms, use the following command:

  `unconfigure mlag peer peer_name interval`

- To bind a local port or *LAG* to an MLAG specified with an integer identifier, use the following command:

  `enable mlag port port peer peer_name id identifier`

- To disable a local port or LAG from an MLAG, use the following command:

  `disable mlag port port`

- To enable the current ports associated with the given MLAG ID, use the following command:

  `enable ports [mlag-id mlag_id]`

- To disable the current ports associated with the given MLAG ID, use the following command:

  `disable ports [mlag-id mlag_id]`

- To set a preference for having a fast convergence time or conserving access lists, use the following command:

  ```
  configure mlag ports convergence-control [conserve-access-lists |
  fast]
  ```

  > **Note**
  >
  > Executing the `refresh policy` command with MLAG configuration may result in health check hellos not reaching the CPU. To avoid MLAG peer connectivity disruption, you can either execute the `disable access-list refresh blackhole` command or temporarily increase the peer hello interval to a large value (for instance, 10000 ms) and reset it back once refresh policy is complete.

- To enable or disable MLAG linkup isolation, use the following command:

  ```
  configure mlag ports link-up-isolation [on | off]
  ```

- To start orchestration mode, use the following command:

  ```
  start orchestration mlag peer_name
  ```

- To stop orchestration mode, use the following command:

  ```
  stop {orchestration}
  ```

- To configure MLAG reload delay timer, use the following command:

  ```
  configure mlag ports reload-delay reload-delay
  ```

- To enable MLAG reload delay timer, use the following command:

  ```
  enable mlag port reload-delay
  ```

- To disable MLAG reload delay timer, use the following command:

  ```
  disable mlag port reload-delay
  ```

- To view the configured MLAG reload delay timer setting, use the following command:

  ```
  show mlag ports {port_list}
  ```

- To rename an existing MLAG peer, use the following command:

  ```
  configure { mlag peer } peer_name name new_peer_name
  ```

Displaying MLAG Information

- To display information about an *MLAG* peer, including MLAG peer switch state, MLAG group count, and health-check statistics, use the following commands:

  ```
  show mlag peer {peer_name}
  ```

- To display each MLAG group, including local port number, local port status, remote MLAG port state, MLAG peer name, MLAG peer status, local port failure count, remote MLAG port failure count, and MLAG peer failure count, use the following command:

  ```
  show mlag ports {port_list}
  ```

- To see if a port is part of an MLAG group, or an ISC port, use the following command:

  ```
  show ports {port_list } information {detail}
  ```

Example of MLAG Configuration

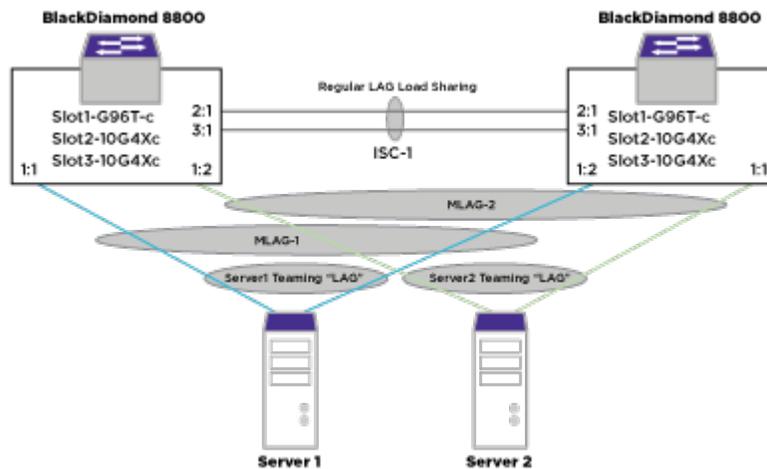
Below is an example of how to configure an *MLAG*. Figure 25 shows a finished MLAG network.


Figure 25: Simple MLAG Configuration

1. Create the Inter-Switch Connection (ISC).

   Description: The ISC provides an out-of-band IP communications path between the two MLAG peer switches to exchange keep-alive packets and to checkpoint various state information between switches.

   On the "Left" BlackDiamond 8800 switch:

   ```
   enable sharing 2:1 group 2:1,3:1
   create vlan isc
   config vlan isc tag 3000
   config vlan isc add port 2:1 tag
   config vlan isc ipaddress 1.1.1.1/24
   ```

   On the "Right" BlackDiamond 8800 switch:

   ```
   enable sharing 2:1 group 2:1,3:1
   create vlan isc
   config vlan isc tag 3000
   config vlan isc add port 2:1 tag
   config vlan isc ipaddress 1.1.1.2/24
   ```

2. Create the MLAG peer and associate the peer switch's IP address.

   Description: By creating an MLAG peer you associate a peer name that can be associated with the peer switch's IP address and other peer configuration properties. The peer is then bound to each individual MLAG port group.

   On the "left" BlackDiamond 8800 switch:

   ```
   create mlag peer "rightBD8K"
   config mlag peer "rightBD8K" ipaddress 1.1.1.2
   ```

   On the "right" BlackDiamond 8800 switch:

   ```
   create mlag peer "leftBD8K"
   config mlag peer "leftBD8K" ipaddress 1.1.1.1
   ```

3. Create the MLAG port groups.

> **Tip**
> At this point, you could use orchestration mode to allow you to checkpoint all commands issued on the one switch to its MLAG peer. For more information about, MLAG orchestration, see Orchestration Mode for Checkpointing MLAG Port Configuration on page 272.

Description: Creates an MLAG port group by specifying the local switch's port, the MLAG peer switch, and an "mlag-id" which is used to reference the corresponding port on the MLAG peer switch. The specified local switch's port can be either a single port or a load share master port.

On the "left" BlackDiamond 8800 switch:

```
enable mlag port 1:1 peer "rightBD8K" id 1
enable mlag port 1:2 peer "rightBD8K" id 2
```

On the "right" BlackDiamond 8800 switch:

```
enable mlag port 1:2 peer "leftBD8K" id 1
enable mlag port 1:1 peer "leftBD8K" id 2
```

4. Verify MLAG peers and ports are operational.

Description: After MLAG groups are configured, you can verify the connections via the show mlag peer and show mlag ports commands. Be sure to note the peer status, the Local Link State, and the Remote Link status.

On the "left" BlackDiamond 8800 switch:

```
BD-8810.5 # show mlag peer
Multi-switch Link Aggregation Peers:
MLAG Peer          : leftBD8k
VLAN               : isc              Virtual Router    : VR-Default
Local IP Address   : 1.1.1.2          Peer IP Address   : 1.1.1.1
MLAG ports         : 2                Tx-Interval       : 1000 ms
Checkpoint Status  : Up               Peer Tx-Interval  : 1000 ms
Rx-Hellos          : 184              Tx-Hellos         : 184

```

5. Add ISC port to *VLAN*.
   Description: The ISC port must be added as a member port for any VLAN that has MLAG member ports.

```
create vlan "xyz"
```

On the "left" BlackDiamond 8800 switch:

```
configure vlan "xyz" add port 1:1, 2:1 tagged
```

On the "right" BlackDiamond 8800 switch:

```
configure vlan "xyz" add port 1:2, 2:1 tagged
```

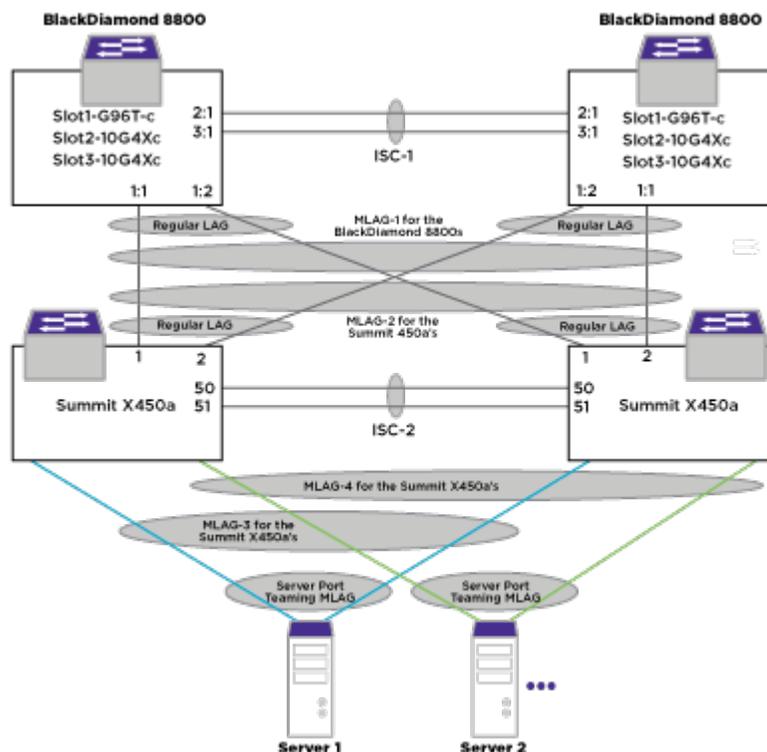
Figure 25 on page 284, shows a basic MLAG network. Figure 26 shows a network with back-to-back aggregation. There is one MLAG configured on the BlackDiamond switches and three configured on the ExtremeSwitching switches.


Figure 26: Two-tier MLAG Network

MLAG-LACP

Beginning in ExtremeXOS 15.3, the ExtremeXOS *MLAG* feature supports Link Aggregation Control Protocol (LACP) over MLAG ports. To do this, all MLAG peer switches use a common MAC in the System Identifier portion of the LACPDU transmitted over the MLAG ports. The following options and requirements are provided:

• The MLAG peer that has the highest IP address for the ISC control *VLAN* is considered the MLAG LACP master. The switch MAC of the MLAG LACP master is used as the System Identifier by all the MLAG peer switches in the LACPDUs transmitted over the MLAG ports. This is the default option.

- You can configure a common unicast MAC address for use on all the MLAG peer switches. This MAC address is used as the System Identifier by all the MLAG peer switches in the LACPDUs transmitted over the MLAG ports. This configuration is not checkpointed to the MLAG peers, and you must make sure that the same MAC address is configured on all the MLAG switches. Additionally, you must ensure that this address does not conflict with the switch MAC of the server node that teams with the MLAG peer switches.

> **Note**
> When LACP shared ports are configured as MLAG ports, a _LAG_ ID change after MLAG peer reboot may result in MLAG ports being removed and re-added to the aggregator. To avoid the MLAG port flap, it is recommended to configure a common LACP MAC in both the MLAG peers using the `configure mlag peer` `peer_name` `lacp-mac` `lacp_mac_address` command.

LACPDU Transmission on MLAG Ports

To prevent the server node from forming two separate aggregators to the _MLAG_ peers (which could result in a loop), it is necessary that both MLAG peers transmit LACP PDUs with the same System Identifier and Actor Key. The following points discuss how the System Identifier is determined:

- The MLAG peers must communicate at least once with each other to generate LACP PDUs on MLAG ports. If the MLAG peers do not communicate with each other, no LACP PDUs are sent out on the MLAG ports. The MLAG peers checkpoint their system MAC and checkpoint the configured MAC to the peer to determine the LACP Operational MAC.
- If no LACP MAC is configured on the MLAG peers, the LACP Operational MAC is the MAC address of the MLAG peer that has the highest IP address for ISC control _VLAN_.
- If a different LACP MAC address is configured on the MLAG peers, the configured MAC is not used. In this case, the LACP Operational MAC address is the MAC address of the MLAG peer that has the highest IP address for ISC control VLAN.
- The configured MAC address is only used when the same MAC is configured on both the MLAG peers.

Scalability Impact on Load Shared Groups

When static load sharing is used for the _MLAG_ ports, and if there is a single link connecting the server node and the MLAG peer switches, the port does not need to be configured as a load shared port on the MLAG peer switches. Configuring LACP on MLAG ports can reduce the number of load shared ports that can be configured in the system.

Configuration Guidelines

- LACP configuration for MLAG ports (system priority, LACP timeout, activity mode, etc.) should be the same on all the MLAG peer switches.
- We recommend that the server node has a lower System Aggregation Priority than the MLAG peers so that the server node chooses which of the ports can be aggregated. As an example, there are a maximum of 8 ports that can be aggregated together, and there are eight links from Peer1 to the Server, and another

eight links from Peer2 to the server node. When the server node has a lower System Aggregation Priority, it can choose which of the total available links can be aggregated together.

· If the Port Aggregation Priority is not configured for the load shared member ports, there is a chance that only the links from server node to one of the MLAG peer are aggregated together (based on the port numbers). In this instance, the links from the server node to the other MLAG peer are unused. To avoid this, you can configure the Port Aggregation Priority on the server node so that the number of active links to the MLAG peers is balanced.

· You must configure load sharing groups on all the MLAG ports even if they contain just one port.

· It is recommended to configure static LACP MAC on both MLAG peers to avoid traffic interruption during failure scenarios.

Below are sample configurations.

Configuration on Peer1

```
create vlan "isc"
configure vlan isc tag 4000
enable sharing 5 grouping 5,10 lacp
configure vlan "isc" add ports 5 tagged
configure vlan "isc" ipaddress 1.1.1.1/8

create mlag peer "peer2"
configure mlag peer "peer2" ipaddress 1.1.1.2
configure mlag peer "peer2" lacp-mac 00:11:22:33:44:55

enable sharing 6 grouping 6,12 lacp
enable sharing 18 grouping 18 lacp
enable mlag port 6 peer "peer2" id 1
enable mlag port 18 peer "peer2" id 2
```

Configuration on Peer2

```
create vlan "isc"
configure vlan isc tag 4000
enable sharing 5 grouping 5,10 lacp
configure vlan "isc" add ports 5 tagged
configure vlan "isc" ipaddress 1.1.1.2/8

create mlag peer "peer1"
configure mlag peer "peer1" ipaddress 1.1.1.1
configure mlag peer "peer1" lacp-mac 00:11:22:33:44:55
enable sharing 20 grouping 20 lacp
enable sharing 6 grouping 6,15 lacp
enable mlag port 20 peer "peer1" id 1
enable mlag port 6 peer "peer1" id 2
```

Configuration on Server Nodes (assumed to be Extreme Switches)

```
enable sharing 1 grouping 1,2,3 lacp
configure sharing 1 lacp system-priority 100
configure lacp member-port 1 priority 10
configure lacp member-port 2 priority 20
configure lacp member-port 3 priority 15
```

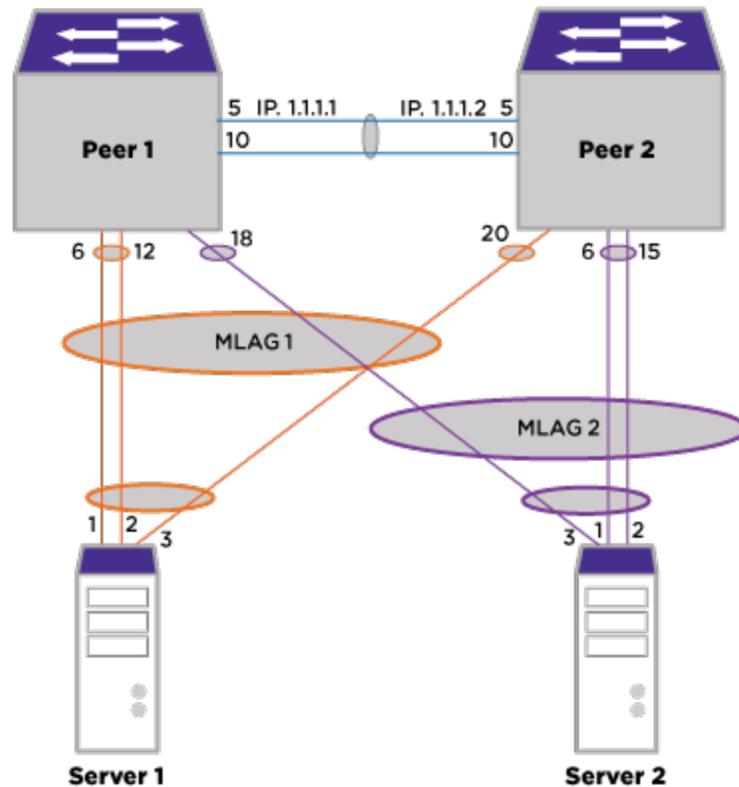
Here is an illustration of the configuration:


Figure 27: LACP Ports in MLAG Configuration

Mirroring

Mirroring is a function on existing Extreme Networks switches that allows copies of packets to be replicated to additional ports without affecting the normal switching functionality. The mirrored data actually occupies fabric bandwidth, so it is very likely that normal forwarding and mirroring cannot both be done at line rate. In the most general terms, traffic ingressing and/or egressing an interface is mirrored. For ports, traffic ingressing and/or egressing a port can be mirrored (refer to the `configure mirror add` command). For *VLAN*s and virtual ports, only traffic ingressing these interfaces are mirroring.

One of the common uses of the mirroring functionality is packet capture; for example sending copies of all packets that arrive on port P, vlan V, to a monitor port Q. Previous implementations of mirroring were limited to a single instance, where only one destination port (or port list) was allowed to be configured in the system. That implementation was also limited to 128 total sources of this traffic (also referred to as filters). Only VLAN and VLAN/port "filters" are currently implemented as filters.

ExtremeXOS supports Multi Instanced Mirroring that expands the number of destinations allowed to match the hardware capabilities. (Current hardware allows for up to 4 ingress mirroring instances and two egress mirroring instances.) A mirroring

instance consists of a unique destination port, or port list, and the source filters associated with it. Our current implementation allows for 128 per instance.

> **Note**
> You can have a maximum of 16 mirroring instances in the switch (including the default mirroring instance) but only 4 can be active at a time as explained below:
> - Four (4) ingress
> - Three (3) ingress and one (1) egress
> - Two (2) ingress and two (2) egress
>
> The maximum possible combinations for mirroring instances include:
> - 2 (ingress + egress)
> - 1 (ingress + egress) + 2 ingress
> - 1 (ingress + egress) + 1 egress + 1 ingress
>
> In general, there are four hardware resource slots. Each single instance uses one slot, while one (ingress + egress) instance uses two slots. So, you can use of total four slots, but there can be no more then two egress instances.

> **Note**
> You can accomplish port mirroring using ACLs, or CLEAR-Flow. See ACLs on page 781 and CLEAR-Flow on page 1235 for more information.

A virtual port is a combination of a VLAN and a port. The monitor port or ports can then be connected to a network analyzer or RMON probe for packet analysis. The system uses a traffic filter that copies a group of traffic to the monitor port(s). You can have only one monitor port or port list on the switch. This feature allows you to mirror multiple ports or VLANs to a monitor port, while preserving the ability of a single protocol analyzer to track and differentiate traffic within a broadcast domain (VLAN) and across broadcast domains (for example, across VLANs when routing).

> **Note**
> The mirroring filter limits discussed later do not apply when you are using ACLs or CLEAR-Flow.

Up to 128 mirroring filters can be configured across all active mirroring instances.

ExtremeXOS can also enables hardware mirroring of Ethernet frames to a specified remote IPv4 address, which can reside zero or more router hops away. This is useful for ExtremeAnalytics, Application Telementry, or other forms of remote network analysis or monitoring.

ExtremeXOS has enhanced mirroring to support IPFIX flows to be mirrored as well. This is done by using the mirroring capabilities in ExtremeXOS along with IPFIX to provide additional information about flows to our Application Analytics appliance (previously known as Purview). As mentioned earlier, ExtremeXOS can collect statistics about flows that are recognized based on configured flow keys. However ExtremeXOS cannot inspect packets deeper than the L4 (TCP) level. Mirroring this traffic to the Application Analytics appliance allows for deep packet inspection beyond L4 when provided a

copy of the packet payload. This enhancement provides the ability to mirror the first 15 packets of any flow to a port where Application Analytics can receive copies for deep packet inspection. As with mirroring, this allows you to configure multiple mirroring instances.

Tagging of Mirrored packets

The following conditions describe tagging of mirrored packets:

- Untagged ingress mirrored traffic egresses the monitor port(s) untagged. Tagged ingress mirrored traffic egresses the monitor port tagged.
- Egress mirrored traffic always egresses the monitor port tagged.
- On ExtremeSwitching series switches, all traffic ingressing the monitor port or ports is tagged only if the ingress packet is tagged. If the packet arrives at the ingress port as untagged, the packet egresses the monitor port or ports as untagged.

Guidelines for Mirroring

The traffic filter on ExtremeSwitching series switches can be defined based on one of the following criteria:

- **Physical port**—All data that traverses the port, regardless of *VLAN* configuration, is copied to the monitor port(s). You can specify which traffic the port mirrors:
  ◦ Ingress—Mirrors traffic received at the port.
  ◦ Egress—Mirrors traffic sent from the port.
  ◦ Ingress and egress—Mirrors traffic either received at the port or sent from the port.

    If you omit the optional parameters, all traffic is forwarded; the default for port-based mirroring is ingress and egress.

    > **Note**
    > You can create an instance where the source is ingress only. When you add a source, pay attention to the monitor port.

- VLAN—All packets ingressing any port on a particular VLAN, regardless of the physical port configuration, is copied to the monitor port(s).
- Virtual port—All traffic ingressing the switch on a specific VLAN and port combination is copied to the monitor port(s).
- IPFIX—mirror the first 15 packets of any IPFIX flow to a port where Purview can receive a copy of the packet for deep packet inspection.
- ExtremeSwitching series switches support a maximum of 128 mirroring filters per instance.
- ExtremeXOS supports up to 16 monitor ports for one-to-many mirroring.
- Only traffic ingressing a VLAN can be monitored; you cannot specify ingressing or egressing traffic when mirroring VLAN traffic and a virtual port filter.
- In normal mirroring, a monitor port cannot be added to a load share group. In one-to-many mirroring, a monitor port list can be added to a load share group, but a loopback port cannot be used in a load share group.

- Two packets are mirrored when a packet encounters both an ingress and egress mirroring filter.
- The configuration of **remote-tag** does not require the creation of a VLAN with the same tag; on these platforms the existence of a VLAN with the same tag as a configured **remote-tag** is prevented. This combination is allowed so that an intermediate remote mirroring switch can configure remote mirroring using the same remote mirroring tag as other source switches in the network. Make sure that VLANs meant to carry normal user traffic are not configured with a tag used for remote mirroring.

  When a VLAN is created with **remote-tag**, that tag is locked and a normal VLAN cannot have that tag. The tag is unique across the switch. Similarly if you try to create a **remote-tag** VLAN where **remote-tag** already exists in a normal VLAN as a VLAN tag, you cannot use that tag and the VLAN creation fails.

Mirroring Rules and Restrictions

This section summarizes the rules and restrictions for configuring mirroring:

- Each configured mirror instance that you configure is saved, regardless of its state.
- To change monitor ports you must first remove all the filters.
- You cannot mirror the monitor port.
- The mirroring configuration is removed only if the configuration matches the removed _VLAN_ or slot. If you have a match you can do the following:
  - Delete a VLAN (for all VLAN-based filters).
  - Delete a port from a VLAN (for all VLAN-, port-based filters).
  - Unconfigure a slot (for all port-based filters on that slot).
- Any mirrored port can also be enabled for load sharing (or link aggregation); however, each individual port of the load-sharing group must be explicitly configured for mirroring.
- When traffic is modified by hardware on egress, egress mirrored packets may not be transmitted out of the monitor port as they egressed the port containing the egress mirroring filter. For example, an egress mirrored packet that undergoes VLAN translation is mirrored with the untranslated VLAN ID. In addition, IP multicast packets which are egress mirrored contain the source MAC address and VLAN ID of the unmodified packet.
- The monitor port is automatically removed from all VLANs; you cannot add it to a VLAN.
- You cannot use the management port in mirroring configurations.
- You cannot run ELSM and mirroring on the same port. If you attempt to enable mirroring on a port that is already enabled for ELSM, the switch returns a message similar to the following: `Error: Port mirroring cannot be enabled on an ELSM enabled port.`
- With one-to-many mirroring, you need to enable jumbo frame support in the mirror-to port and loopback port, if you need to mirror tagged packets of length 1519 to 1522.

- The loopback port is dedicated for mirroring, and cannot be used for other configurations. This is indicated through the glowing LED.
- Egress mirrored packets are always tagged when egressing the monitor port. If an egress mirrored packet is untagged on the egress mirrored port, the mirrored copy contains a tag with an internal VLAN ID.
- As traffic approaches line rate, mirroring rate may decrease. Since mirroring makes copies of traffic, the bandwidth available will be devoted mostly to regular traffic instead of mirrored traffic when the load is high.
- A mirror port cannot be a *LAG*.

Configuring Mirroring

- To create a named mirror instance, use the following command:

  ```
  create mirror mirror_name {to [port port | port-list port_list
  loopback-port port] { remote-tag rtag } | remote-ip remote_ip_address
  {{ vr } {vr_name } {from [ source_ip_address | auto-source-ip]}{ping-
  check [on | off]} priority priority_value ]} {description mirror-desc}
  ```

- If you want to configure mirroring on multiple ports, and did not configure this with the above `create` command, use the following command using the **port-list** option:

  ```
  configure mirror mirror_name {to [port port | port-list port_list
  | loopback port port] | remote-ip {add} remote_ip_address {{vr}
  vr_name } {from [source_ip_address | auto-source-ip]} {ping-check [on
  | off]}]} {remote-tag rtag | port none} {priority priority_value}
  ```

  The port-list is a list of monitor ports that transmit identical copies of mirrored packets. The loopback-port is an unused port that is required when you mirror to a port-list. The loopback-port is not available for switching user data traffic. Certain L2 control protocol packets, such as *STP*, LACP, and *LLDP*, cannot be mirrored with one-to-many mirroring. The remote IP address option allows you enable hardware mirroring of Ethernet frames to a specified remote IPv4 address, which can reside zero or more router hops away.

  For high availability, you can add up to four redundant remote IP addresses. If you are adding another (redundant) remote IP address to an existing mirror that already has a remote IP address configured, you must use the **add** option.

- Mirroring is disabled by default. To enable mirroring, use one of the following commands:

  ◦ `enable mirror mirror_name`

  ◦ `enable mirror to [port port | port-list port_list loopback-port port] {remote-tag tag}`

  ◦ `enable mirror {mirror_name} to remote-ip remote_ip_address {{vr} vr_name} {priority priority_value} {from [source_ip_address | auto-source-ip]} {ping-check [on | off]}]}`

- To disable mirroring, use the following command:

  `disable mirror [`*`mirror_name`*` | `**`all`**`]`

- To remove one or all remote IP addresses, use the following command:

  `configure mirror {`*`mirror_name`*` **to remote-ip delete** [**all** |`
  `remote_ip_address`` {{`**`vr`**`} `*`vr_name`*`}] }`

  To delete all or the last remaining remote IP address, you must disable the mirror first.

To create policy-based mirrors, see Table 105 on page 1002.

Verifying the Mirroring Configuration

The `show mirroring` command lists the ports that are involved in mirroring and identifies the monitor port. The display differs slightly depending on the platform.

Remote Mirroring

Remote mirroring enables the user to mirror traffic to remotely connected switches. Remote mirroring allows a network administrator to mirror traffic from several different remote switches to a port at a centralized location. There are two kinds of remote mirroring: Layer-2 using a remote VLAN tag, and Layer-3 using GRE encapsulation through a routed network to a remote IP address. This section describes remote mirroring using Layer-2. Remote mirroring is accomplished by reserving a dedicated _VLAN_ throughout the network for carrying the mirrored traffic. You can enable remote mirroring on the ExtremeSwitching series switches.

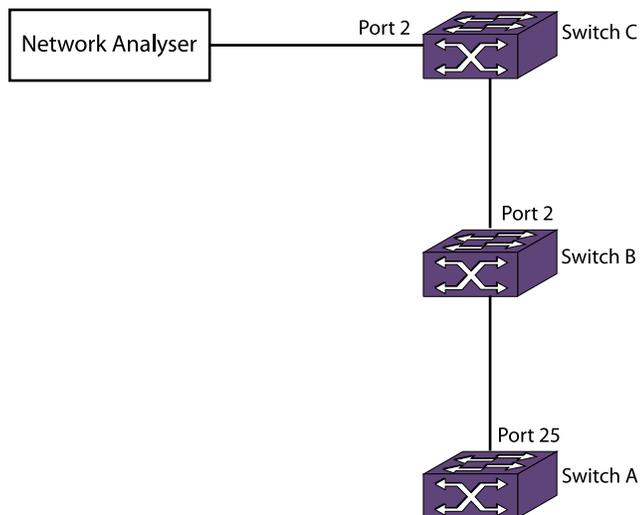
Figure 28 shows a typical remote mirroring topology. Switch A is the source switch that contains ports, VLANs, and/or virtual ports to be remotely mirrored. Port 25 is the local monitor port on Switch A. Switch B is the intermediate switch. Switch C is the destination switch, which is connected to the network analyzer.


Figure 28: Remote Mirroring Topology

All the mirrored packets are tagged with the **remote-tag** specified by the source switch, whether the packet is already tagged or not. The intermediate switches forward the remote-tagged mirrored packets to the adjacent intermediate/destination switch, as these ports are added as tagged. The port connected to the network analyzer is added as untagged in the destination switch. This causes the destination switch to remove the remote-tag, and the mirrored packet reaches the network analyzer as the source switch sent it.

Unlike basic mirroring, remote mirroring does not remove VLAN membership from the local monitor port(s). This allows remote mirroring to use the existing network topology to transport remote mirrored packets to a destination switch.

Configuration Details

This section describes in detail the configuration details for the topology shown in

Configuring the Source Switch

The **remote-tag** keyword followed by the tag is added in the command to enable mirroring. For example, you can establish ports 24 and 25 as monitor ports, from which any mirrored packets are transmitted with an additional *VLAN* tag containing a VLAN ID of 1000:

Remote mirroring can also be enabled to a single port, without the **port-list** and **loopback-port** keywords.

- To establish ports 24 and 25 as monitor ports, follow the example:

```
enable mirror to port-list 24,25 loopback-port 1 remote-tag 1000
```

The `show mirror` output displays the remote tag when remote mirroring is configured.
- To enable remote mirroring to port 25, follow the example:

```
enable mirror to port 25 remote-tag 1000
```

Configuring the Intermediate Switch

Reserve a *VLAN* with the remote-mirroring keyword in all the intermediate switches for remote mirroring. When you enable mirroring with **remote-tag 1000**, you need to reserve a VLAN with tag **1000** in all the intermediate switches for remote mirroring. The remote mirroring VLAN in the intermediate switches is used for carrying the mirroring traffic to the destination switch. The ports connecting the source and destination switches are added as tagged in the intermediate switches.

Another way to configure a remote mirroring VLAN is to create a normal VLAN and disable learning on the VLAN. _IGMP_ snooping must be disabled on that VLAN for you to remotely mirror multicast packets through the switch.

- You may add the **remote-mirroring** keyword when you configure the tag to differentiate a normal VLAN from the remote mirroring VLAN.

```
create vlan remote_vlan
configure vlan remote_vlan tag 1000 remote-mirroring
configure vlan remote_vlan add ports 1,2 tagged
```

Using the **remote-mirroring** keyword automatically disables learning and IGMP snooping on the VLAN.

- You may use the following configuration for creating the remote mirroring VLAN:

```
create vlan remote_vlan
configure vlan remote_vlan tag 1000
disable learning vlan remote_vlan
disable igmp snooping remote_vlan
```

Configuring the Destination Switch

Remote mirroring _VLAN_ on the destination switch. The configuration on the destination switch is same as that of the intermediate switches, except that the port connected to the network analyzer is added as untagged whereas all the other ports connected to the switches are added as tagged.

```
create vlan remote_vlan
configure vlan remote_vlan tag 1000 remote-mirroring
configure vlan remote_vlan add ports 1 tagged
configure vlan remote_vlan add ports 2 untagged
```

For a remote mirroring VLAN, the configured tag displayed by the show vlan output is remote tag instead of the normal tag.

Remote Mirroring Guidelines

The following are guidelines for remote mirroring:

- Configurations of remote mirroring, which might cause protocol packets to be remotely mirrored, are not recommended. Since all packet types are mirrored when you configure remote mirroring, remotely mirrored protocol packets may have undesirable affects on intermediate and destination switches. Blocking _EDP_ packets on a remote mirroring _VLAN_ is one example of a case where you must perform an extra action to accommodate the remote mirroring of protocol packets.

  For EDP configuration on the remote mirroring VLAN, in the intermediate and destination switches you need to install _ACL_ to block the EDP packets on the remote mirroring VLAN. Use the following commands for installation:
```
create access-list remote_edp " ethernet-destination-address 00:e0:2b:00:00:00 mask
ff:ff:ff:ff:ff:ff ;" "deny"
conf access-list add "remote_edp" first vlan "remote_vlan"
```

Using Remote Mirroring with Redundancy Protocols

You can use remote mirroring with one-to-many mirroring to provide a redundant path from the source switch to the destination switch. Using *EAPS* or Spanning Tree can provide remote mirroring packets a redundant loop-free path through the network. You should perform the configuration of EAPS or Spanning Tree before adding mirroring filters on the source switch to prevent looping.

Remote Mirroring with EAPS

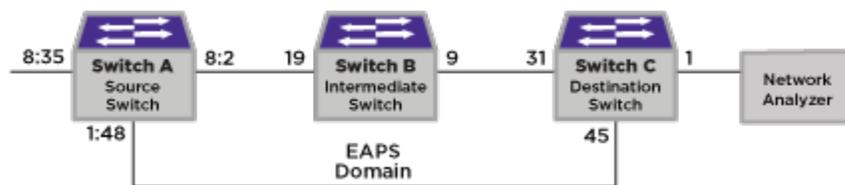
In Figure 29, the traffic from switch A is mirrored to the two ports 8:2 and 1:48 to connect to the destination switch. Using the configuration shown, remote mirrored packets have a loop-free redundant path through the network using *EAPS*.


Figure 29: Remote Mirroring with EAPS

The configuration for the topology in the above figure is given in the following sections.

Switch A Configuration

```
enable mirror to port-list 8:2,1:48 loopback-port 8:1 remote-tag 1000
configure mirror add port 8:35 create vlan eaps_control
configure vlan eaps_control tag 1001
configure vlan eaps_control add ports 8:2,1:48 tag
create eaps eaps1
configure eaps1 mode master
configure eaps1 primary port 8:2
configure eaps1 secondary port 1:48
configure eaps1 add control eaps_control
configure eaps1 add protected internalMirrorLoopback
enable eaps1
enable eaps
```

Switch B Configuration

```
create vlan remote_vlan
configure vlan remote_vlan tag 1000 remote-mirroring
configure vlan remote_vlan add ports 19,9 tag
create vlan eaps_control
configure vlan eaps_control tag 1001
configure vlan eaps_control add ports 19,9 tag
create eaps eaps1
configure eaps1 mode transit
configure eaps1 primary port 19
configure eaps1 secondary port 9
configure eaps1 add control eaps_control
configure eaps1 add protected remote_vlan
enable eaps1
enable eaps
```

Switch C configuration

```
create vlan remote_vlan
configure vlan remote_vlan tag 1000 remote-mirroring
configure vlan remote_vlan add ports 31,45 tag
configure vlan remote_vlan add ports 1
create vlan eaps_control
configure vlan eaps_control tag 1001
configure vlan eaps_control add ports 31,45 tag
create eaps eaps1
configure eaps1 mode transit
configure eaps1 primary port 31
configure eaps1 secondary port 45
configure eaps1 add control eaps_control
configure eaps1 add protected remote_vlan
enable eaps1
enable eaps
```

> **Note**
> The internalMirrorLoopback is an internal VMAN created when enabling
> mirroring to multiple ports. Depending on the platform, the internal *VLAN* or
> VMAN needs to be added as the protected VLAN in the source switch in order
> to block the ports for mirroring when EAPS is complete.

Remote Mirroring With STP

For the same topology shown in , you can use *STP* instead of
using *EAPS*. A sample configuration follows.

Switch A Configuration

```
enable mirror to port-list 8:2,1:48 loopback-port 8:1 remote-tag 1000
configure mirror add port 8:35
create vlan v1
configure vlan v1 tag 1001
configure vlan v1 add ports 8:2,1:48 tag
create stp stp1
configure stp1 mode dot1w
configure stp1 add v1 ports all
configure stp1 tag 1001
configure stp1 add vlan internalMirrorLoopback ports 8:2,1:48
enable stp1
enable stpd
```

Switch B Configuration

```
create vlan remote_vlan
configure vlan remote_vlan tag 1000 remote-mirroring
configure vlan remote_vlan add ports 19,9 tag
create vlan v1
configure vlan v1 tag 1001
configure vlan v1 add ports 19,9 tag
create stp stp1
configure stp1 mode dot1w
configure stp1 add v1 ports all
configure stp1 tag 1001
configure stp1 add vlan remote_vlan ports all
enable stp1
enable stpd
```

Switch C Configuration

```
create vlan remote_vlan
configure vlan remote_vlan tag 1000 remote-mirroring
configure vlan remote_vlan add ports 31,45 tag
configure vlan remote_vlan add ports 1
create vlan v1
configure vlan v1 tag 1001
configure vlan v1 add ports 31,45 tag
create stp stp1
configure stp1 mode dot1w
configure stp1 add v1 ports all
configure stp1 tag 1001
configure stp1 add vlan remote_vlan ports 31,45
enable stp1
enable stpd
```

Remote Mirroring Using Layer 3

To use remote mirroring using Layer 3, enable IPv4 forwarding along the routed path to the device collecting GRE-encapsulated mirrored packets, also known as ERSPAN. Then, configure the collector device's IP address as the remote IP address in the following command:

enable mirror {*mirror_name*} to **remote-ip** *remote_ip_address* {{**vr**} *vr_name*} {**priority** *priority_value*} {**from** [*source_ip_address* | **auto-source-ip**]} {**ping-check** [**on** | **off**]}}

To configure the GRE protocol type, use the command:

configure **mirror to remote-ip protocol-type** [**erspan-v1** | **trans-ether-bridging** | **user-defined** *protocol_value*]

Redundant Remote IP Address Mirroring

For high availability, each instance of a mirror to a remote IP address can have up to four remote IP addresses configured with a unique priority—from 1 (least preferred) to 100 (most preferred), with a default of 50. For each mirror instance, the remote IP address with the highest priority value that is deemed "up" is used as the destination IP address for GRE-tunneled mirrored traffic. All other remote IP addresses deemed "up" for that mirror instance are on standby, ready to be used in the event the preferred remote IP address goes down. Each remote IP address is monitored independently with ping health check, route tracking, and gateway ARP tracking.

To add more redundant remote IP addresses, use the following command using the **remote-ip** , **add**, and **priority** options:

configure mirror *mirror_name* {**to** [**port** *port* | **port-list** *port_list* | **loopback port** *port*] **|** **remote-ip** {**add**} *remote_ip_address* {{**vr**} *vr_name* } {**from** [*source_ip_address* | **auto-source-ip**]} {**ping-check** [**on** | **off**]}} {**remote-tag** *rtag* | **port none**} {**priority** *priority_value*}

Extreme Discovery Protocol

The *EDP* is used to gather information about neighbor Extreme Networks switches. EDP is used by the switches to exchange topology information. Information communicated using EDP includes:

- Switch MAC address (switch ID)
- Switch software version information
- Switch IP address
- Switch *VLAN* IP information
- Switch port number
- Switch configuration data: duplex and speed
- Local and neighbor VLAN IDs

EDP is enabled on all ports by default, including the management port. EDP enabled ports advertise information about the Extreme Networks switch to other switches on the interface and receives advertisements from other Extreme Networks switches. Information about other Extreme Networks switches is discarded after a timeout interval is reached without receiving another advertisement.

Starting with ExtremeXOS 30.3, EDP detects mismatches when untagged ports are used in configurations where the port endpoints are used in VLANs that have different VLAN IDs. While this is not technically invalid, it nearly always indicates a mis-configuration. If a mismatch ID is detected, a log event is generated. The event is only generated once per boot. There is also a command to display port/VLAN ID endpoints for easy comparison (`show edp {`**`ports`** `[`**`all`** `| ` *ports*`] {`**`detail`** `| ` **`vlan-id`** `{`**`mismatch`** `{`**`untagged`**`}} {`**`neighbor`** *nbr*`}}}`).

- To disable EDP on specified ports, use the following command:

  `disable edp ports [`*ports* `| ` **`all`**`]`

- To enable EDP on specified ports, use the following command:

  `enable edp ports [`*ports* `| ` **`all`**`]`

- To clear EDP counters on the switch, use the following command:

  `clear counters edp`

  This command clears the following counters for EDP protocol data units (PDUs) sent and received per EDP port:

  - Switch PDUs transmitted
  - VLAN PDUs transmitted
  - Transmit PDUs with errors
  - Switch PDUs received
  - VLAN PDUs received
  - Received PDUs with errors

- To view EDP port information on the switch, use the following command:

  ```
  show edp {ports [all | ports] {detail | vlan-id {mismatch {untagged}}
  {neighbor nbr}}}
  ```

- To configure the advertisement interval and the timeout interval, use the following command:

  ```
  configure edp advertisment-interval timer holddown-interval timeout
  ```

For information about displaying EDP status, see

ExtremeXOS Cisco Discovery Protocol

Network elements exchange various information with neighboring elements that ranges from the switch IP/Mac addresses, switch names, versions of software, etc. This information is maintained in an Information Base, and management applications use it to create a topology map and manage the entire network. Vendor-specific discovery protocols are used to learn about network neighbor elements and their capabilities, and to exchange this information. Cisco Discovery Protocol (CDP) is a Cisco® proprietary protocol that runs between direct connected network entities (routers, switches, remote access devices, IP telephones) to provide information sharing capabilities. ExtremeXOS supports CDP, and is called EXOS-CDP.

Limitations

The ExtremeXOS support for CDP has the following limitations:

- *SNMP* for this feature is not supported.
- You should use this feature mainly for the network-endpoint devices, but you can also use it in network-network devices that have CDP support.
- When port access is controlled by net login, the port must be authorized before it receives CDP packets.

Platform Support

This feature is supported on all ExtremeXOS platforms.

EXOS CDP Support

The ExtremeXOS-CDP implementation gathers information about network neighbors that support the Cisco Discovery protocol. This includes edge devices (VoIP phones) in the network-edge domain.

EXOS-CDP runs on top of the controlled port of an 802 MAC client. If port access is controlled by IEEE 802.1X, the port must be authorized before you enable CDP protocol receive functionality. CDP also runs over an aggregated MAC client, and the CDP protocol information must run over all the physical MAC clients of the aggregated ports. The spanning tree state of a port does not affect the transmission of CDP PDUs.

Each CDP message contains information identifying the source port as a connection endpoint identifier. It also contains at least one network address that can be used by an NMS to reach a management agent on the device (through the indicated source port). Each CDP message contains a time-to-live value, which tells the recipient when to discard each element of learned topology information.

By default EXOS-CDP feature is disabled.

Both CDP version 1 and version 2 are supported in EXOS-CDP implementation.

CDP Packet Format

The CDP control packets are encapsulated to the Sub-network Access Protocol (SNAP), and are sent as multicasts with Cisco®-defined multicast MAC address 01:00:0C:CC:CC:CC.

The following table lists and describes the CDP packet fields.

Field	Description
Version	Version of the CDP being used values 0x1 or 0x02
Time-to-Live (TTL)	TTL indicates the amount of time in seconds that a receiver should retain the information contained in this packet.
Check Sum	Standard IP checksum
Type	Indicates the type of the TLV
Length	Indicates the total length of the Type,Length,Value fields
Value	Indicates the value of the TLV

Different Types of TLVs

The following list identifies the different types of TLVs.

*   Device ID Information TLVs

    This TLV is used to identify Device name in form of Character string. In EXOS-CDP implementation it will be the configurable value. System Mac address will be the default Device ID. Both receive and transmit of this TLV is supported.

*   Address Information TLVs

    This TLV contains a number that indicates how many addresses are contained in the packet, followed by one entry for each address being advertised. The addresses advertised are the ones assigned to the interface on which the CDP message is sent. A device can advertise all addresses for a given protocol suite and, optionally, can advertise one or more loopback IP addresses. If the device can be managed by *SNMP,* the first entry in the address type/length/value is an address at which the device receives SNMP messages. Maximum of 32 IP address are supported. Both receive and transmit of this TLV is supported.

The following table identifies and describes the various fields in the Address Information TLV.

Field	Description
Protocol Type	Protocol type It can be one of the following values 1. NLPID 2. 802.2 format
Length	Length of the protocol field.
Protocol	One of the following values: ◦ 0x81—ISO CLNS (protocol type 3D 1) ◦ 0xCC—IP (protocol type 3D 1) ◦ 0xAAAA03 000000 0800—Pv6 (protocol type 3D 2) ◦ 0xAAAA03 000000 6003—DECNET Phase IV (protocol type 3D 2) ◦ 0xAAAA03 000000 809B—AppleTalk (protocol type 3D 2) ◦ 0xAAAA03 000000 8137—Novell IPX (protocol type 3D 2) ◦ 0xAAAA03 000000 80c4—Banyan VINES (protocol type 3D 2) ◦ 0xAAAA03 000000 0600— XNS (protocol type 3D 2) ◦ 0xAAAA03 000000 8019—Apollo Domain (protocol type 3D 2)
Address Length	Length of the address fields in bytes
Address	Address of the interface or the address of the system if addresses are not assigned to the interface.

- Port ID TLVs

  The port ID contains an ASCII character string that identifies the port on which the CDP message is sent. Both receive and transmit of this TLV is supported.

- Capabilities TLVs

  The capability TLV describes the device's functional capability. It can be set to one of the bits listed below. Both receive and transmit of this TLV is supported.

  The following table identifies and describes the various bits in the Capabilities TLV.

Bit Description	Bit Description
0x01	Performs level 3 routing for at least one network layer protocol.
0x02	Performs level 2 transparent bridging.
0x04	Performs level 2 source-route bridging. A source-route bridge would set both this bit and bit 0x02.
0x08	Performs level 2 switching. The difference between this bit and bit 0x02 is that a switch does not run the *STP*.
0x10	Sends and receives packets for at least one network layer protocol. If the device is routing the protocol, this Bit should not be set.

Bit Description	Bit Description
0x20	The bridge or switch does not forward *IGMP* Report packets on non-router ports.
0x40	Provides level 1 functionality.

- Version TLV

  The version TLV contains a character string that provides information about the software release version that the device is running. In EXOS-CDP version will be software version. Both receive and transmit of this TLV is supported.

- Platform TLV

  The platform TLV contains an ASCII character string that describes the hardware platform of the device. These platform TLV values are EXOS platform information that is the same seen when you issue the `show switch` command. Both receive and transmit of this TLV is supported.

- Native *VLAN* TLV

  The native VLAN TLV indicates, per interface, the assumed VLAN for untagged packets on the interface. CDP learns the native VLAN for an interface. Both receive and transmit of this TLV is supported.

- Duplex TLV

  The duplex TLV indicates the duplex configuration of the interface. Both receive and transmit of this TLV is supported.

- Voice VLAN Query TLV

  The voice VLAN query TLV indicates what VLAN ID is to be used for voice. This TLV is mostly used in IP Phones to configure the voice VLAN. IP Phone will query the Neighbor switch for voice VLAN. The switch will reply the VLAN ID value by transmitting in CDP PDU with type voice vlan reply TLV. Only receive functionality is supported.

- Voice VLAN Reply TLV

  The voice VLAN reply TLV indicates the voice VID for the VOIP VLAN Query. The switch will reply the VLAN ID value when it receives the voice vlan query TLV. Only transmit functionality is supported. When the VOIP VLAN Query is received immediately a CDP PDU is sent with reply TLV filled.

- Power TLV

  The power TLV indicates the amount of power consumed by remote devices. Only receive functionality is supported.

- Power Request TLV

  The power request TLV indicates the power requested by the powered device (PD). Only the receive functionality of this TLV is supported.

- Power Available TLV

The power available TLV indicates the power available in the powered source device. This information will be sent in the CDP PDU to the powered device (PD). Only the transmission of this TLV is supported.

- MTU TLV

The MTU TLV indicates the size of the largest datagram that can be sent/received by a remote device. Only receive functionality is supported.

- Trust Bit TLV

The trust bit TLV offers the ability to specify whether the PC port of the phone is trusted. Only transmit functionality is supported. This value is configured by CLI command to say whether the port is trusted/untrusted. Only the transmission of this TLV is supported.

- Untrust QOS TLV

The untrust QOS TLV offers the ability to specify whether the PC port of the phone is untrusted then what to mark the L2 packet cos bit. Only the transmission of this TLV is supported. This value is configured by user through CLI command.

- System Name TLV

The system name TLV indicates the value of the remote device's sysName MIB object. Both transmit and receive functionality is supported.

- System Object ID TLV

The system object ID TLV indicates the value of the remote device's sysObjectID MIB. Only receive functionality is supported.

- Management Address TLV

The management address indicates the IP address for which the device accepts the SNMP messages. Both transmit and receive functionality is supported. CDP advertises Management Address TLV with only one IP address.

To configure a specified VLAN's IP address as the management address to be advertised by CDP, use the following command:

```
configure cdp management-address [{vlan} vlan_name | vlan vlan_id]
{primary-ip | secondary-ip secondary_ip_address}]
```

- Location TLV

The location TLV indicates the physical location, which says either the postal pin address. Both transmit and receive functionality is supported. The location value will be configured by `configure snmp syslocation sysLocation`

EXOS CDP Protocol Operations

The ExtremeXOS CDP implementation performs the following tasks:

- Adds a filter for CDP Multicast MAC when the CDP protocol is enabled on port.
- Processes received CDP messages.

- Transmits CDP messages to peer when CDP is enabled.
- Maintains the current neighbor's information in the local database.

Protocol Operations

- **Multicast Address**

    This EXOS-CDP Implementation describes the operation of the protocol for reception of CDPPDUs on a single port, using a Multicast Mac address as the destination (01:00:0C:CC:CC:CC).

- **CDP Initialization**

    The following EXOS CDP related functions are created as part of the existing CDP process.

    ◦ Upon system initialization, the appropriate default values are assigned to CDP global, port, and neighbor data structure.
    ◦ Retrieval of non-volatile configuration values.

- **CDP Frame Reception**

    Frames that are recognized as CDP frames are validated to determine whether they are properly constructed and contain the correct CDP packet format. Frames that pass validation criteria are used to update the contents of the neighbor entries in the database.

    If the neighbor entry does not exist in the CDP neighbor database, a new entry is created. If the neighbor entry already exists in the database, new information contained in the CDP PDU is used to replace the changed information of the existing entry in the neighbor database.

    One of the parameters received in an incoming CDP PDU is the TTL value. This determines how long the information is stored in the neighbor database before it is aged out and deleted. Aging out old data ensures that neighbor entries are purged that were originated by systems that are no longer neighbors, either because of system failure or system inactivation.

- **CDP Port/Connection Failure**

    If the port, or the connection to the remote system fails, the neighbor entity from the database is not deleted. It will be deleted after the associated TTL timer expires.

- **Timers**

    The timers are started when at least one neighbor is created. Once the timer expires, it checks the neighbor database and deletes the neighbor entry when the hold time reaches 0.

- **CDP PDU Validation**

    The following attributes are validated in the received CDP PDU:

    ◦ The checksum must be re-calculated in order for the packet to be valid. Otherwise, the EXOS-cdp will reject the packet. Standard IP checksum mechanism is used for calculating the checksum
    ◦ The receiving CDP packet length must be greater than, or equal to 4.

- ◦ The packet version must be 1 or 2.
- **CDP Frame Transmission**

  Under normal circumstances, remote devices send CDP messages at a configured interval (default 1 minute). If you enable CDP between CDP Messages in Extreme Switches, the feature must wait for next CDP PDU to update in the neighbor database. To avoid this delay when CDP is enabled, a CDP PDUs is sent to peer.

  For every default configuration of message interval 60 seconds, CDP packets are transmitted on the CDP-enabled ports.This message interval is the configurable through CLI. The default value is 60 seconds, and the range for this message interval is 5 to 254 seconds

- **Storing CDP Neighbors**

  Advertisements received from the peer contain time-to-live information that indicates the length of time a receiving device holds CDP information before discarding it.

  A neighbor entry is discarded after three advertisements from the device are missed.

- **CDP Packet Statistics**

  CDP counters of total TX and RX CDP control packets are maintained on each port.

- **CDP and Link Aggregation**

  CDP will run on all member ports of the link aggregated ports. Transmit and receive of CDP control packets will be for each individual port. CDP will be enabled for each individual port of the link aggregated ports.

  For example, if ports 1,2,3 are part of link aggregation, then the administrator needs to enable CDP on Port 1, Port 2, and Port 3. Rx and Tx of CDP will be enabled for ports 1, 2, and 3.

Software-Controlled Redundant Port and Smart Redundancy

Using the software-controlled redundant port feature, you can back up a specified Ethernet port (primary) with a redundant, dedicated Ethernet port. Both ports must be on the same switch.

If the primary port fails, the switch will establish a link on the redundant port and the redundant port becomes active. Only one side of the link must be configured as redundant because the redundant port link is held in standby state on both sides of the link. This feature provides very fast path or network redundancy.

> **Note**
> You cannot have any Layer 2 protocols configured on any of the VLANs that are present on the ports.

The Smart Redundancy feature allows control over how the failover from a redundant port to the primary port is managed. If this feature is enabled, which is the default setting, the switch attempts to revert to the primary port as soon as it can be recovered.

If the feature is disabled, the switch attempts only to recover the primary port to active if the redundant port fails.

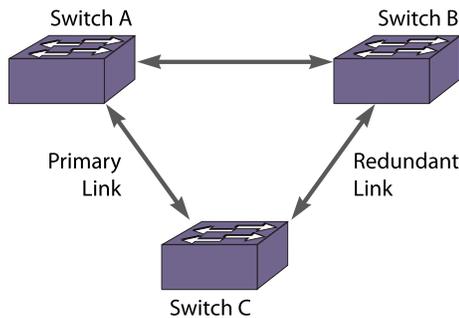
A typical configuration of software-controlled redundant ports is a dual-homed implementation (shown in Figure 30). This example maintains connectivity only if the link between switch A and switch B remains open; that link is outside the scope of the software-controlled port redundancy on switch C.


Figure 30: Dual-Homed Implementation for Switch C

In normal operation, the primary port is active and the software redundant switch (switch C) blocks the redundant port for all traffic, thereby avoiding a loop in the network. If the switch detects that the primary port is down, the switch unblocks the redundant port and allows traffic to flow through that redundant port.

> **Note**
> The primary and redundant ports must have identical *VLAN* membership.

You configure the software-controlled redundant port feature either to have the redundant link always physically up but logically blocked, or to have the link always physically down. The default value is to have the link physically down, or Off.

By default, Smart Redundancy is always enabled. If you enable Smart Redundancy, the switch automatically fails over to the redundant port and returns traffic to the primary port after connectivity is restored on that port. If you do not want the automatic restoration of the primary link when it becomes active, disable Smart Redundancy.

Guidelines for Software-Controlled Redundant Ports and Port Groups

Software-controlled redundant ports and port groups have the following guidelines and limitations:

- You cannot have any Layer 2 protocols configured on any of the *VLAN*s that are present on the ports. (You will see an error message if you attempt to configure software redundant ports on ports with VLANs running Layer 2 protocols.)
- The primary and redundant ports must have identical VLAN membership.
- The master port is the only port of a load-sharing group that can be configured as either a primary or redundant port. Also, all ports on the load-sharing group must fail before the software-controlled redundancy is triggered.
- You must disable the software redundancy on the master port before enabling or disabling load sharing.

- You can configure only one redundant port for each primary port.
- Recovery may be limited by _FDB_ aging on the neighboring switch for unidirectional traffic. For bi-directional traffic, the recovery is immediate.

Configuring Software-Controlled Redundant Ports

When provisioning software-controlled redundant ports, configure only one side of the link as redundant. To enable the software-controlled redundant port feature, the primary and redundant ports must have identical _VLAN_ membership.

In the following figure only the ports on switch C would be configured as redundant.

- To configure a software-controlled redundant port, use the following command:
  ```
  configure ports primaryPort redundant secondaryPort {link [on | off]}
  ```

  The first port specified is the primary port. The second port specified is the redundant port.
- Unconfigure a software-controlled redundant port, use the following command and enter the primary port(s):
  ```
  unconfigure ports port_list redundant
  ```
- To configure the switch for the Smart Redundancy feature, use the following command:
  ```
  enable smartredundancy port_list
  ```
- To disable the Smart Redundancy feature, use the following command:
  ```
  disable smartredundancy port_list
  ```

Verifying Software-Controlled Redundant Port Configurations

You can verify the software-controlled redundant port configuration by issuing a variety of commands.

- To display the redundant ports as well as which are active or members of load-sharing groups, use the following command:
  ```
  show ports redundant
  ```
- To display information on which ports are primary and redundant software-controlled redundancy ports, use the following command:
  ```
  show port {mgmt | port_list | tag tag} information {detail}
  ```

Refer to for more information on the `show port information` command.

Configuring Automatic Failover for Combination Ports

ExtremeSwitching Switches with Shared Copper/Fiber Gigabit Ports Only

On ExtremeSwitching switches with shared copper/fiber gigabit ports, you configure automatic failover using the combination ports. These ports are called combination ports because either the fiber port or the copper port is active, but they are never active

concurrently. These ports, also called redundant ports, are shared PHY copper and fiber ports.

If you plan to use the automatic failover feature, ensure that port settings are set correctly for autonegotiation.

> **Note**
> You may experience a brief episode of the link going down and recovering during the failover.

- To display the port type currently used as well as the preferred media setting, use the following command:

  ```
  show port {mgmt | port_list | tag tag} information {detail}
  ```

  Refer to Displaying Port Information on page 311 for more information on the `show port information` command.

  Hardware determines when a link is lost and swaps the primary and redundant ports to maintain stability.

  After a failover occurs, the switch keeps the current port assignment until there is another failure or until you change the assignment using the CLI.

- To change the uplink failover assignment, use the following command:

  ```
  configure ports port_list preferred-medium [copper | fiber] {force}
  ```

  The default preferred-medium is fiber. If using the **force** option, it disables automatic failover. If you force the preferred-medium to fiber and the fiber link goes away, the copper link is not used, even if available.

  > **Note**
  > When the Tx of active fiber link is disconnected while Rx is still connected, the fiber link goes down but the copper link does not come up.

  For more information about combination ports on ExtremeSwitching switches, see the *hardware installation guide* for your switch.

Displaying Port Information

You can display summary port configuration information. The following commands display summary port configuration information:

```
show ports {mgmt | port_list | tag tag} configuration {no-refresh}
```

```
show port {mgmt | port_list | tag tag} information {detail}
```

The `show ports configuration` command shows either summary configuration information on all the ports, or more detailed configuration information on specific ports. If you specify the **no-refresh** parameter, the system displays a snapshot of the data at the time you issue the command.

The `show ports information` command shows you either summary information on all the ports, or more detailed information on specific ports. The output from the command differs very slightly depending on the platform you are using.

To display real-time port utilization information, use the following command:

show ports {**mgmt** | *port_list* | **tag** *tag* | **stack-ports** *stacking-port_list*} **utilization** {**bandwidth** | **bytes** | **packet**}

To display the remote end of the link's advertised auto-negotiation ability, use the following command:

show **ports** {*port_list*} **advertised**

> **Note**
> This command is applicable only for port speed of up to 1Gbps This command is not applicable for Extended Edge Switching bridge port extenders (BPE) ports.

When you use a parameter (packets, bytes, or bandwidth) with the above command, the display for the specified type shows a snapshot per port when you issue the command.

Optic Port Compatibility Check

For QSFP/QSFP28 (non-stacking) ports on all supported platforms, the **show port information** and **show port information detail** commands identify whether a port is properly configured for the required partition or speed, or if there is not appropriate licensing support. For example, these commands will indicate:

- if a QSFP28 to 4xSFP28 breakout cable has the QSFP28 end inserted into a port that is misconfigured for 1x100G partition mode; or
- if a 1x100G QSFP28 optic is inserted into a port that is not licensed to run at the indicated higher speed

The "?" symbol is used to indicate an optic with a mismatched partition. If an optic is a third party unsupported optic, then the "!" unsupported indication will override the "?" mismatched partition indication.

If the switch does not have the proper license to operate at the optic's given speed, then the port cannot be partitioned for any corresponding port speeds. For example, if a 100G optic is inserted into an unlicensed port regardless of the operating mode, the CLI will display "?$" to indicate a mismatched partition and unlicensed port. In addition to these CLI display indications, a corresponding informational message will be logged to help determine the cause of the indications.

To show mismatched partitions, run the following commands:

show port {**mgmt** |*port_list* | **tag** *tag*} **information** {**detail**}

show ports {**mgmt** | *port_list* | **tag** *tag*} **configuration** {**no-refresh** | **refresh**}

ExtremeXOS Port Description String

ExtremeXOS provides a configurable per-port "display-string" parameter that is displayed on each of the `show port` CLI commands, exposed through the _SNMP_ ifAlias element, and accessible through the XML port.xsd API. Previously, the field was limited to 20 characters. This feature provides a new and separate per-port field call "description-string" that allows you to configure strings up to 255 characters.

Some characters are not permitted as they have special meanings. These characters include the following:

- "
- <
- >
- :
- <space>
- &.

The first character should by alphanumeric.

This new field is CLI accessible only through the `show port info detail` command, but you can also access it through the SNMP ifAlias object of IfXTable from IF-MIB (RFC 2233), and through the XML API.

Configure Port decription-string

To configure up to 255 characters associated with a port, issue the command:

```
configure port port_list description-string string
```

If you configure a string longer than 64 characters, the following warning will be displayed: `Note: Port description strings longer than 64 chars are only accessible via SNMP if the following command is issued: configure snmp ifmib ifalias size extended`

To control the accessible string size (default 64, per MIB) for the _SNMP_ ifAlias object, issue the command:

```
config snmp ifmib ifalias size [default | extended]
```

If you choose the extended size option, the following warning will be displayed: `Warning: Changing the size to [extended] requires the use of increased 255 chars long ifAlias object of ifXtable from IF-MIB(RFC 2233)`

You can always configure a 255-character-long string regardless of the configured value of ifAlias size. Its value only affects the SNMP behavior.

Port Isolation

The Port Isolation feature blocks accidental and intentional inter-communication between different customers residing on different physical ports. This feature provides

a much simpler blocking mechanism without the use of _ACL_ hardware. The fundamental requirements are as follows:

- Blocking Rules: All traffic types received on a isolation port is blocked from being forwarded through other 'isolation' ports.
- All traffic types received on an isolation port can be forwarded to any other port.
- All traffic types received on non-isolation ports are permitted to be forwarded to isolation ports.

There is no access-list hardware use. The blocking mechanism is a set of one or two table memories. These resources are not shared with other features, nor do they have any scaling limits that can be reached by configuring this feature. Port isolation can be configured in conjunction with other features, including VPLS, IDM, and _Extreme Network Virtualization (XNV)_. However, you cannot configure a mirror-to port to be an isolated port.

Configuring Port Isolation

To enable isolation mode on a per-port basis, perform the following tasks:

1. Issue the `configure ports` _port_list_ **isolation** [**on** | **off**] command.

   You can issue this command either on a single port or on a master port of a load share group. If you issue this command on a non-master port of a load share group, the command will fail. When a port load share group is formed, all of the member ports assume the same isolation setting as the master port.
2. Issue the `show port info detail` and `show port info` outputs to display the current isolation settings.

Energy Efficient Ethernet

As part of the 802.3az standard, Energy Efficient Ethernet (EEE) is targeted at saving energy in Ethernet networks for a select group of physical layer devices, or PHYs. The PHYs use EEE during idle periods to reduce power consumption. If you do not utilize EEE, the PHY is fully powered up even when there is no traffic being sent. Enabling EEE reduces significant power consumption on the switch. Within ExtremeXOS, a PHY/switch combination, or a PHY with autogrEEEN capability is provided to allow EEE to work. In a typical setup, the PHY and switch communicate when to enter or exit low power idle (LPI) mode.

AutoGrEEEn technology implements the EEE standard directly into PHYs, and enables the EEE mode when interfacing with non-EEE enabled MAC devices,. This allows you to make existing network equipment EEE-compliant by simply changing the PHY devices. EEE is currently only implemented for copper ports

Previously, most wireline communications protocols used continuous transmission, consuming power whether or not data was sent. EEE puts the PHY in an active mode only when real data is sent on the media. To save energy during gaps in the data stream, EEE uses a signaling protocol that allows a transmitter to indicate the data gap and to allow the link to go idle. This signaling protocol is also used to indicate that the link needs to resume after a pre-defined delay.

The EEE protocol uses an LPI signal that the transmitter sends to indicate that the link can go idle. After sending LPI for a period (Ts = time to sleep), the transmitter stops signaling altogether, and the link becomes quiescent. Periodically, the transmitter sends some signals so that the link does not remain quiescent for too long without a refresh. When the transmitter wishes to resume the fully functional link, it sends normal idle signals. After a pre-determined time (Tw = time to wake), the link is active and data transmission resumes.

The EEE protocol allows the link to be re-awakened at any time; there is no minimum or maximum sleep interval. This allows EEE to function effectively in the presence of unpredictable traffic. The default wake time is defined for each type of PHY, and is designed to be similar to the time taken to transmit a maximum length packet at the particular link speed.

The refresh signal serves the same purpose as the link pulse in traditional Ethernet. The heartbeat of the refresh signal ensures that both partners know that the link is present, and allows for immediate notification following a disconnection. The frequency of the refresh prevents any situation where one link partner is disconnected and another inserted without causing a link fail event. This maintains compatibility with security mechanisms that rely on continuous connectivity and require notification when a link is broken.

The maintenance of the link through refresh signals also allows higher layer applications to understand that the link is continuously present, preserving network stability. You can also use the refresh signal to test the channel, and create an opportunity for the receiver to adapt to changes in the channel characteristics. For high speed links, this is vital to support the rapid transition back to the full speed data transfer without sacrificing data integrity. The specific makeup of the refresh signal is designed for each PHY type to assist the adaptation for the medium supported.

Supported Platforms

EEE is supported on the following Extreme Networks platforms:
- ExtremeSwitching X435—all 1 GbE ports.
- ExtremeSwitching X440-G2—all copper ports
- ExtremeSwitching X450-G2—BASE-T ports only
- ExtremeSwitching X460-G2—all copper ports, except the 16 multi-rate ports on the X460-G2-16mp-32p-10GE4
- ExtremeSwitching X465—copper 10/100/1000 ports
- ExtremeSwitching X590—100Mb, 1Gb, and 10Gb on 10GBaseT ports of X590-24t-1q-2c

Configuring Energy Efficient Ethernet

- To enable or disable the EEE feature on EXOS, use the following command:

  ```
  configure ports port_list eee [on | off]
  ```

  The keyword **on** specifies that the port advertises to its link partner that it is EEE capable at certain speeds. If both sides, during auto-negotiation, determine that

they both have EEE on and are compatible speed wise, they will determine other parameters (how long it takes to come out of sleep time, how long it takes to wake up) and the link comes up. During periods of non-activity, the link will shut down parts of the port to save energy. This is called LPI for low power idle. When one side sees it must send something, it wakes up the remote and then transmits.

- To display the statistics of the EEE features, use the following command:
  show **ports** *port_list* **eee** {**no-refresh** | **refresh** } { **port-number**}

Node Alias

Node Alias Overview

Node Alias is a feature that you can use to discover information about end systems on a per-port basis. As the packets from the end systems transit through a Node Alias-enabled port, its key attributes are captured in a database that can be queried (see CTRON Alias MIB on page 2019). Enabling Node Alias on ports of interest provides a powerful troubleshooting tool for network administrators.

> **Note**
> By default, Node Alias is disabled on all ports.

Limitations

Currently, 100 packets per second per slot are admitted for snooping. Packets are dropped if the rate exceeds 100 pps.

Node Alias Database Information

Each entry in the Node Alias database consists of the following fields:
- Incoming port
- *VLAN* ID
- Source MAC address
- Protocol address—Depending on the protocol type, this could be the IPv4/IPv6 source IP address, or the UDP source port in cases where the destination IP is broadcast, etc., the *virtual router (VR)* ID and Priority for *VRRP*.
- Node Alias ID—A unique number that identifies an entry
- Entry creation time

The database is capable of holding 8,192 entries per-slot. To avoid starvation among ports, each port is allowed to create only its share of entries in the database. The default maximum per port is 8,192 divided by the number of ports on the slot. For example, on a 64-port slot, this translates to 128 entries per port. You can modify the per-port maximum (configure **nodealias ports** [*port_list* |**all**] **maxentries** *entries*) up to the limit of 8,192.

As a result of snooping one frame, Node Alias may create additional entries to facilitate the searching based on finer details, such as protocol type. For example, when a *BGP (Border Gateway Protocol)* frame is received, two entries are created: one entry with protocol type IP, and another entry with protocol type BGP.

Node Alias also supports VMAN. For VMANs, itt includes the VMAN ID, instead of VLAN ID in the database.

If the ports are combined to form a *LAG*, Node Alias must be enabled on individual ports; enabling Node Alias on the master port does not automatically enable Node Alias on member ports.

Supported Protocols

Node Alias is enabled by default to capture all of the following supported protocols: IPv4, IPv6, *OSPF*, BGP, VRRP, DHCPS, DHCPC, BOOTPS, BOOTPC, UDP, BPDU, LLMNR, SSDP, and mDNS. You can selectively disable any of these protocols.

> **Note**
> - ARP is categorized under IP.
> - UDP entry is created when destination IP address is broadcast.
> - BPDU means *STP* and GVRP frames.

Configuring Node Alias

Setting up Node Alias takes two steps:

1. Enabling (or disabling) Node Alias on port(s):

   > **Note**
   > By default, Node Alias is disabled on all ports.

   > **Note**
   > Node Alias should be separately enabled/disabled on a *LAG* ports.

   ```
   enable nodealias ports [port_list | all]

   disable nodealias ports [port_list | all]
   ```

2. Enabling (or disabling) certain protocols for Node Alias to snoop:

   > **Note**
   > By default, Node Alias is enabled to capture all of the following supported protocols: IPv4, IPv6, OSPF, *BGP*, *VRRP*, DHCPS, DHCPC, BOOTPS, BOOTPC, UDP, BPDU, LLMNR, SSDP, and mDNS.

   ```
   enable nodealias protocol [protocol_name | all]

   disable nodealias protocol [protocol_name | any]
   ```

To modify the per-port maximum number of alias entries in the Node Alias database, use the following command:

```
configure nodealias ports [port_list |all] maxentries entries
```

To show Node Alias information, use the following commands:

```
show nodealias
```

```
show nodealias ports {port_list| all}
```

```
show nodealias mac mac_address {protocol protocol_name | ports
[port_list | all]}
```

```
show nodealias ip ip_address
```

```
show nodealias protocol protocol_name
```

To clear node alias entries out of the Node Alias feature database by specified port(s) or alias ID, use the following command:

```
clear nodealias { ports [port_list | all] | alias-id alias_id }
```

Using Locally Administered MAC Addresses

ExtremeXOS switches do not use a unique per-port MAC address when transmitting bridge protocol data units (BPDUs). As a result, switch management can become inaccessible when switch MAC addresses are learned on the wrong L2 path (corresponding to a blocking port). Starting with ExtremeXOS 22.3, you can direct the switch to generate locally administered addresses (LAA). When this feature is enabled, for Spanning Tree Protocol (STP), the source MAC address is changed to LAA MAC while transmitting the STP/RSTP/MSTP BPDUs. When LAA is enabled, the source MAC address is assigned as 06xx:xx:xx:xx;xx. The "06" replaces the first byte of the system MAC address.

Limitations

Only STP uses LAA MAC.

To direct the switch to generate unique locally administered MAC addresses, use the following command:

```
enable switch locally-administered-address
```

To disable generating unique locally administered MAC addresses, use the following command:

```
disable switchlocally-administered-address
```

To see the status of this feature, use the command:

```
show switch {detail}
```

Enabling/Disabling the USB Port

For enhanced security, you can enable or disable a USB port on a switch. The USB port is enabled by default.

Supported Platforms

All ExtremeSwitching platforms.

Limitations

Stack support is not available. You need to enable this command individually on each node in a stack.

Using USB Port Commands

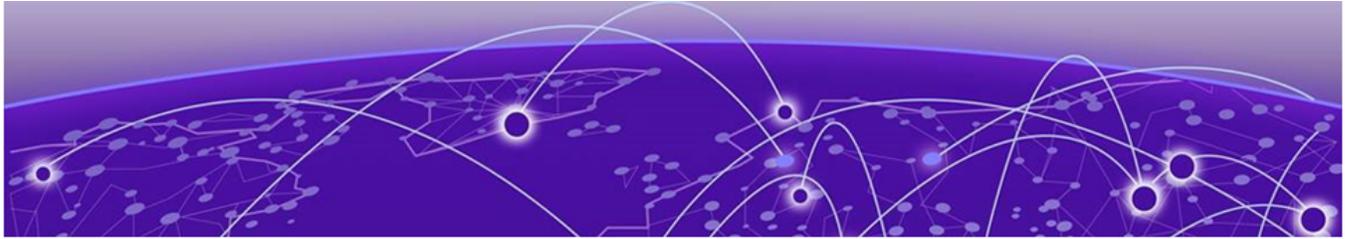
To enable the USB port, use the following command:

```
enable switch usb
```

To disable the USB port, use the following command:

```
disable switch usb
```

To show the status of the USB port, use the following command:

```
show switch usb
```


Extended Edge Switching

Extended Edge Switching Overview

What Is Extended Edge Switching?

Virtual Port Extenders (VPEX) Description

Figure 31 on page 321 shows the VPEX switching architecture, based on the *IEEE 802.1BR* specification, comprising one or two controlling bridges (CBs), and one or more bridge port extenders (BPEs) (see Bridge Port Extenders Description on page 321). In this document, BPEs are V400 and V300 Virtual Port Extenders, and CBs are ExtremeXOS switches.

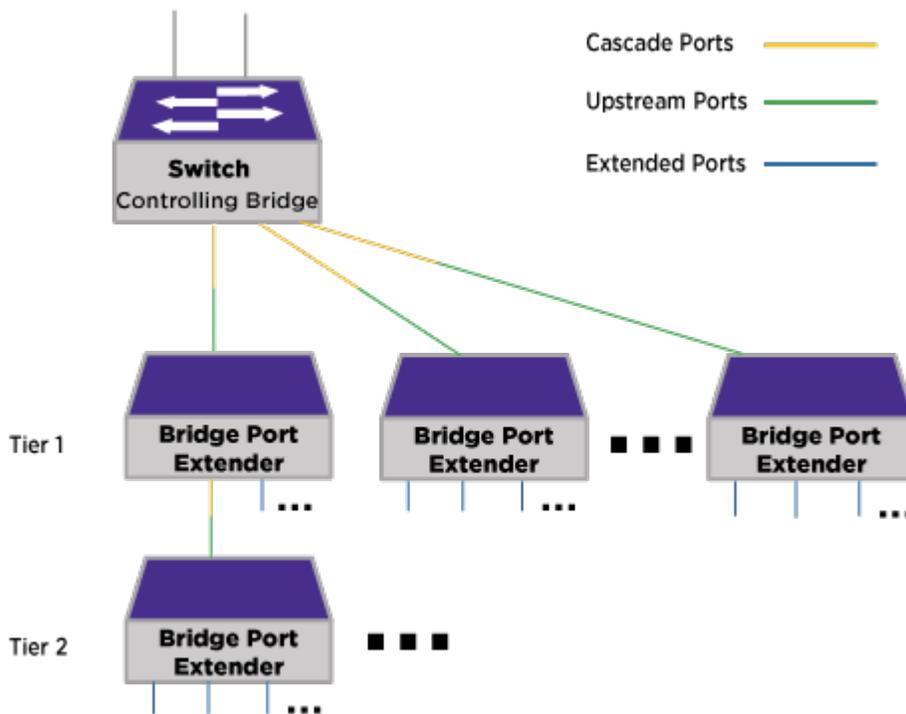
In this architecture, ports on the CB or BPEs connecting to BPEs are termed *cascade ports*, while corresponding ports on BPEs connecting them to the CB or upstream BPEs are termed *upstream ports*. Ports from the BPEs connected to the rest of the network are termed *extended ports*.


Figure 31: VPEX Architecture

Bridge Port Extenders Description

Bridge port extenders (BPEs) are devices that do not fully process packets, nor make forwarding or filtering decisions. Instead, BPEs simply receive packets from extended ports and forward packets towards the upstream controlling bridge for L2/L3/Policy processing.

> **Note**
> Due to the lack of extensive processing performed on BPEs, traffic entering on a BPE extended port that is destined to exit another extended port on the same BPE is forwarded to the controlling bridge (CB), and then forwarded back to the BPE, rather than processed exclusively within the BPE.

Important Terminology

The following terms are important for understanding virtual port extenders (VPEX):

- **Bridge Port Extenders (BPEs)**— Devices that do not fully process packets, nor make forwarding or filtering decisions. Instead, BPEs simply receive packets from extended ports and forward packets towards the upstream controlling bridge for L2/L3 processing.
- **Cascade port**—a port on a controlling bridge or BPE that connects to an upstream port.
- **Controlling Bridge (CB)**—In this context, a switch that provides full L2/L3 packet processing and filtering functionality for cascade ports and extended ports.

- **E-Channel-ID (E-CID)**—Identifies the BPE destination port (or port-list for multicast E-CID).
- **E-Tag**—A tag header immediately following the 802.1BR EtherType (0x893F) that contains the E-CID; this tag is only resident between bridge port extenders and controlling bridge devices.
- **Edge Control Protocol (ECP)**—Provides basic acknowledgement and re-transmission mechanism for reliable delivery; used for PE-CSP transmission.
- **Extended bridge**—A controlling bridge combined with one or more BPEs.
- **Extended ports**—Ports from BPEs connected to the rest of the network.
- **Port Extender Control and Status Protocol (PE-CSP)**—Simple command/response protocol that allows a controlling bridge to discover, program, and obtain status from a bridge port extender.
- **Upstream port**—Port on a BPE that connects to a cascade port.
- **Virtual Port Extender (VPEX)**—A switching architecture based on the *IEEE 802.1BR* specification, comprising a CB, and one or more BPEs.

Chassis Analogy

VPEX, with its controlling bridge (CB) and bridge port extenders (BPEs), is analogous to a chassis with slots.

When you enter VPEX mode (using), the CLI prompt changes to show that the CB is in VPEX mode and is slot 1 in this context:

```
Slot-1 VPEX X670G2-48x-4q.14 #
```

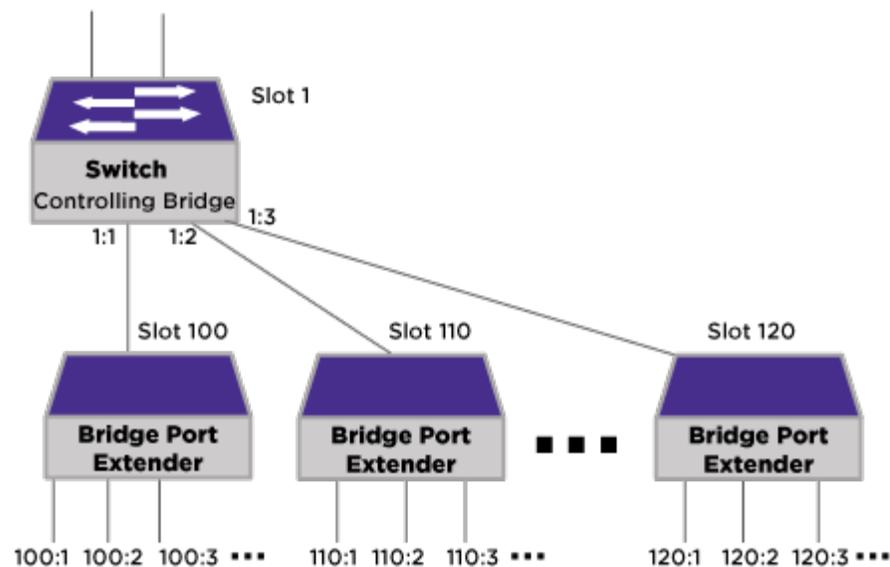
In VPEX mode, you refer to ports in the familiar slot:port notation in applicable commands, where the CB is always slot 1, and the BPEs are slots 100–162 (see Figure 32).


Figure 32: Extended Bridge—Chassis Analogy

The Value of Bridge Port Extenders

Since the bridge port extenders (BPEs) are managed like slots in a chassis under a single management domain, multiple layers of a traditional network can be reduced from a configuration and management perspective, greatly simplifying the network operation.

As opposed to expanding the network using additional switches, BPEs provide the following benefits:

- No console. BPEs are configured and managed through the controlling bridge (CB) user interface, so there is no need to connect a terminal console connection to each BPE.
- No out-of-band management.
- Single point of license management.
- Single point for configuring/debugging/diagnostics.
- Single node when managed by Extreme Management Center or other management software products.

How Do Bridge Port Extenders Interact with the Controlling Bridge?

Bridge port extenders (BPEs) are initially discovered using a type-length-value (TLV) extension to the Link Layer Discovery Protocol (LLDP) along with certain LLDP-MED TLVs that specify serial number, model name, hardware version, and firmware version.

After initial discovery, the controlling bridge (CB) uses the Port Extender Control and Status Protocol (PE-CSP) to control and manage the BPE. PE-CSP is a simple command/response protocol (see Port Extension Control and Status Protocol on page 325) that runs on top of the Edge Control Protocol (ECP), which provides reliable delivery (see Edge Control Protocol on page 324).

In the data-plane, the BPE receives Ethernet packets on its extended ports, inserts an E-TAG with an E-CID identifying the source port, and forwards it on its upstream ports towards the CB. When the CB receives a packet on a cascaded port, it uses the E-CID within the E-TAG to identify the source extended port and performs the L2/L3/policy forwarding decisions for the packet. Based on these forwarding decisions, the CB inserts an E-TAG to identify the destination and forwards the packet out the corresponding cascaded port. If the forwarding decision is to forward to another extended port, the CB inserts an E-Tag. The BPE receives the packet on its upstream port, processes the associated E-TAG, and forwards the packet out the corresponding egress extended port(s).

When the CB receives a packet with an unknown destination (unknown unicast, unknown multicast or broadcast), it inserts a special E-TAG assigned to the VLAN for flooding and sends out only one copy of the packet on the cascade port irrespective of the number of extended ports that need to transmit the packet. Each BPE performs the appropriate replication. If some of the recipients are members of extended port LAG, a BPE does not replicate a copy of the flood packet to them. Instead, the CB has to send an additional copy using the E-TAG assigned to one of the member ports of the extended port LAG. The CB selects one member of the extended port LAG to receive the packet based on hashing of packet fields.

Edge Control Protocol

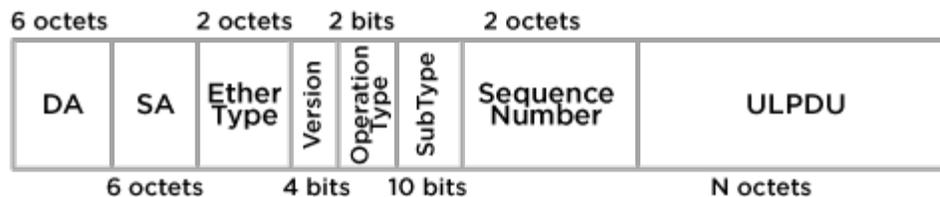
The Edge Control Protocol (ECP) provides reliable transport for the Port Extender Control and Status Protocol (PE-CSP) protocol. It includes a basic acknowledgement and retransmission facility. The Edge Control Protocol Data Unit (ECPDU) structure (Figure 33) is slightly modified from the IEEE 802.1Q-2014. Preceding the ECPDU structure is the Destination and Source Address.


Figure 33: ECPDU Structure

- **DA (Destination MAC address)**—The destination MAC address of the Ethernet frame that contains an ECPDU is specified by the Upper Layer Protocol (ULP). When ECP is carrying PE CSP, the destination address used is the Bridge Group Address, nearest non-TPMR Bridge group address (01-80-c2-00-00-03) as listed in Table-8-1 of the *802.1Q-2014*. The DA is 6 octets long.

Extended Edge Switching

How Do Bridge Port Extenders Interact with the
Controlling Bridge?

The BPE device accepts either the nearest non-TPMR bridge group address or the individual MAC address sent in its LLDP PE TLV.

- **SA (Source MAC address)**—The source MAC address of the bridge. The SA is six octets long.
- **EtherType**—ECP Ethertype (0x8940). The ECP EtherType is two octets long.
- **Version**—The ECP protocol version. The version is 4 bits long, and the value is 1.
- **Operation Type**—Defines the operation type. It is 2 bits long. The values are:
  - ◦ ECP Request (0x0)
  - ◦ ECP acknowledgment (0x1)
- **SubType**—Defines the ULP type included in the PDU. The value of Subtype is 0x2 when BPE CSP is the ULP. See table 43-1 of *IEEE-802.1Q-2014*. The SubType field is a 10 bits long.
- **Sequence Number**—The Sequence Number field identifies the sequential order of the PDU with respect to other ECPDUs. The first sequence number can start anywhere, but each subsequent sequence number is incremented by one. The Sequence Number is 2 octets long.
- **ULPDU**—The ULPDU contains the Upper Layer Protocol Data Unit if the operation type value is "ECP Request". The ULPDU field is absent if the operation type value is "ECP Acknowledgment". The length of this field is upper layer dependent. The ULPDU in this case is PE-CSP.

Port Extension Control and Status Protocol

The Port Extension Control and Status Protocol (PE-CSP) is a simple request/response protocol that runs over ECP and is initiated upon detection of a bridge port extender using the LLDP protocol. Each controlling bridge (CB) has a single PE-CSP protocol instance on each cascade port. In the case of a cascade port that is a LAG, the PE-CSP instance runs on the LAG and transmits on the current master port in the LAG. There is a separate PE-CSP session per LAG member port, but configuration commands are sent over a chosen single port in the LAG.

Each PE-CSP PDU is made of a command TLV and zero or more additional TLVs.

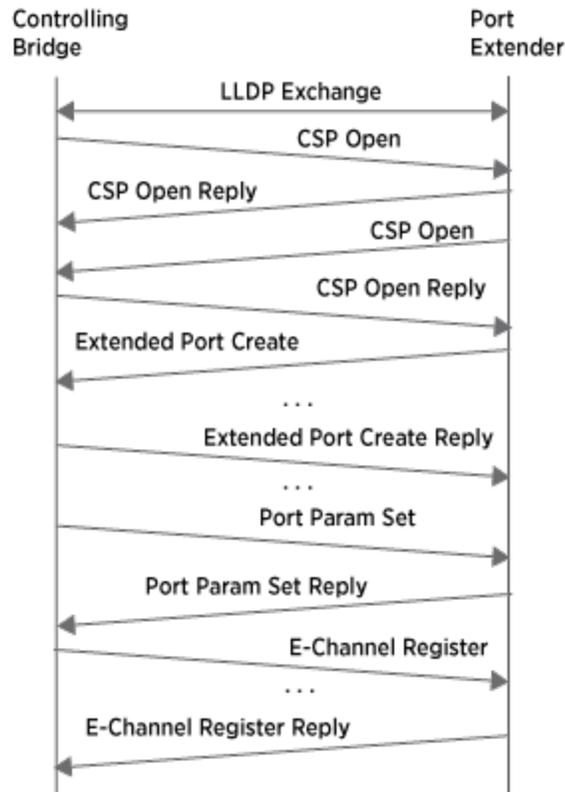
Figure 34 shows a typical PE-CSP exchange between a CB and a bridge port extender (BPE).


Figure 34: Example PE-CSP Protocol Exchange

Redundant Controlling Bridges

For added resiliency and redundancy, the VPEX architecture allows you to form an extended bridge using multiple controlling bridges (CBs).

You can use MLAGs to form an extended bridge with two CBs, also serving as MLAG peers, connected to dual-homed BPE devices using MLAG cascaded ports (see).

> **Note**
> When using MLAG, you must run LACP on the CB MLAG cascade ports.

> **Note**
> With an MLAG/Extended Edge Switching topology, enabling policy and using policy features does not work with the ONEPolicy default resource profile. Use the profile-modifier feature to free up ACL resources from any specific policy profile (see).

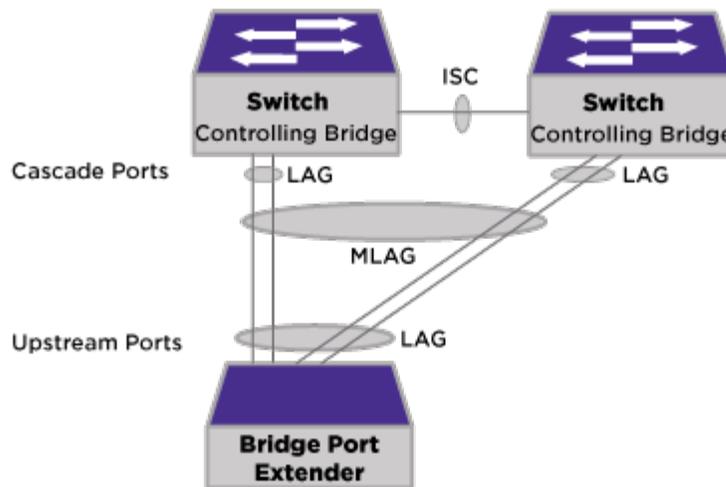
> **Note**
>
> Extended Edge Switching Auto-configuration (see Configuring Extended Edge Switching Topology with Partial Automation (Auto-configuration) on page 346) uses values within the range of 5100 to 5164 to configure an MLAG port ID. It is recommended that you do not use values within this range when configuring MLAG port IDs manually, since the MLAG port might be unconfigured by auto-configuration when auto-configuration finds the MLAG port ID has already been used.


Figure 35: Redundant Controlling Bridge Architecture with MLAG over Cascaded Ports

With redundant CBs attached to each BPE, the associated extended port configuration must be identical on each controlling bridge. To reduce the configuration complexity and to minimize the risk of inconsistency, you can use orchestration mode so that any configuration commands are now checkpointed to the MLAG peer switch. Before entering orchestration mode, ensure that any configuration parameters (connecting ports for the BPEs, VLAN names, numbers etc.) are the same for both CBs.

After entering this orchestration mode, like the existing virtual-router mode, the configuration prompt changes indicating that commands issued are within this context:

```
(orchestration bottom) X670G2-48x-4q.4 #
```

When using automation (see Configuring Extended Edge Switching Topology with Partial Automation (Auto-configuration) on page 346 and Configuring Extended Edge

[Switching Topology with Full Automation](#) on page 344) to set up redundant CB MLAGs, the following occurs:

- The same slot number is assigned to the same BPE on both CBs.
- MLAG port is configured for first tier BPEs. The MLAG port identifier is set to 5,000 plus the BPE's slot number.

To enter orchestration mode, use the following command:

```
start orchestration mlag peer_name
```

To exit orchestration mode, use the following command:

```
stop {orchestration}
```

Extended Edge Switching Rings

Extended Edge Switching rings allow two Extended Edge Switching (VPEX) cascades to be joined together to form a control plane ring. If a link breaks or a bridge port extender (BPE) otherwise leaves, the remaining BPEs reform two data plane cascades, thus keeping both control and data plane connectivity to the controlling bridge (CB) alive. This provides a redundant connection from any BPE in the ring to the CB. This is especially useful in a wiring closet application where the BPEs are located in the closet, and the CB is located more centrally, and there are only two links wired from the CB to the closet. Each cascade is formed from the control plane perspective only; the data plane acts as if there were two cascades consisting of BPEs that are each present in only one cascade. You can only achieve full redundancy with redundant CBs (see [Redundant Controlling Bridges](#) on page 326).

Rings are not explicitly configured, but rather are detected and created automatically. A ring contains the BPEs that were used in its formation. The life of a ring is ended by either a configuration command that changes one or both cascades, or a reboot of the CBs.

To support a wiring closet with only two links, each BPE that directly connects to the CB connects with only one link in its *MLAG (Multi-switch Link Aggregation Group)*. To support this capability without forcing you to reserve and not use a port on one of the CBs, ExtremeXOS supports "one-arm" MLAGs where one CB has a connection reserved, and the other does not (see [One-Arm MLAGs](#) on page 332). This allows MLAG operation as if one link were down, meaning that both CBs are able to switch to the MLAG. ExtremeXOS also supports regular cross-connected MLAG at the top of the ring.

Multiple rings are supported. However, each ring must be completely separate from all others. For example, a simple ring could be formed from a single CB ports 1:1 and 1:2, while a separate ring could be formed from ports 1:3 and 1:4. Multiple rings cannot otherwise intersect, except at the CB itself.

Limitations

- A maximum of 8 BPEs per ring is supported.
- A ring can be formed from exactly one or two cascades. A cascade (or any part thereof) can be a part of at most one ring.

- Three-way MLAG is not supported.

For information about setting up a ring, see Configuring Extended Edge Switching Ring Topology on page 349.

Forming a Ring

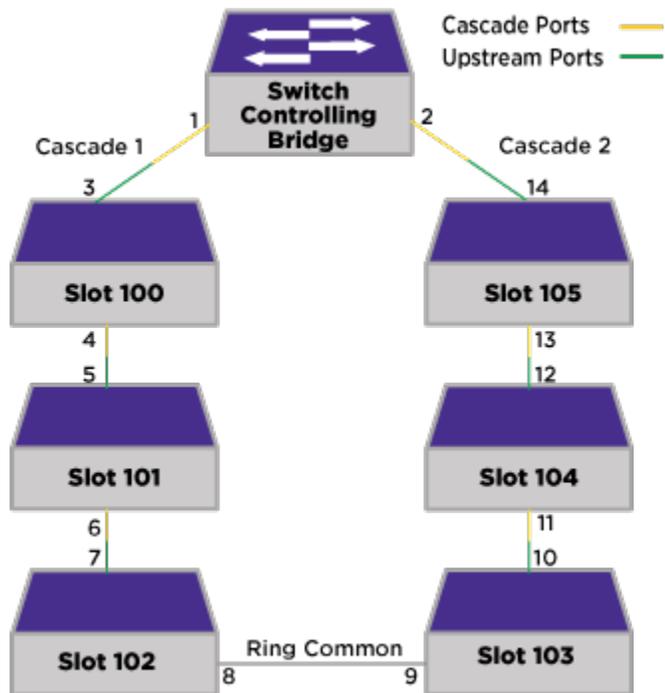
To form a ring, you configure one or two cascades and allow them to form. After that, you connect the end bridget port extenders (BPEs) of these cascades to each other, or the end of the single unconfigured cascade to a port on the controlling bridge (CB). After establishing the control plane, the formed cascades are as shown in Figure 36.


Figure 36: Simple Extended Edge Switching Ring

In Figure 36, the "ring common" link between slot 102 port 8 and slot 103 port 9 forms the ring between the two cascades. In a complete ring, the ring common link does not carry data plane traffic. When the cascades were formed, both BPEs have active upstream ports. Since slot 102 port 8 and slot 103 port 9 are up, both begin sending *LLDP (Link Layer Discovery Protocol)* packets. Using LLDP, the connection between cascade slot 100 to 102 and cascade slot 105 to 103 is discovered, which initiates the ring detection and configuration process.

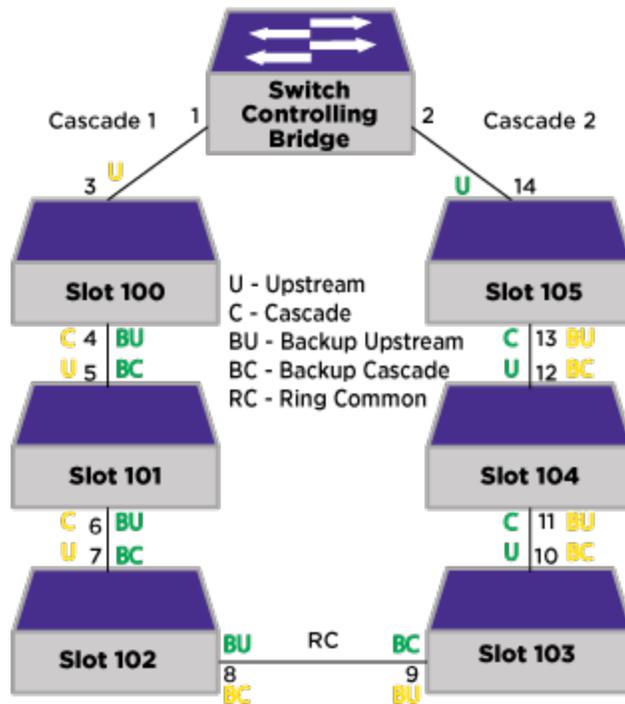
The completed control plane on a ring establishes two counter-directional cascades with backup cascade and upstream ports that are dynamically configured (Figure 37). While the CB retains knowledge of a ring even when the ring is severed, the BPEs do not. A BPE is only in ring mode when the ring is being brought up or is complete. When not in ring mode, a BPE does not have a backup upstream port or any forwarding information associated to any backup direction.


Figure 37: Counter-directional Cascades on Completed Ring

Data Plane Establishment and Operation

> The data plane is established initially as two separate and distinct cascades as shown in Figure 36 on page 329. After the ring control plane is established, the data plane remains the same, except that the cascades are extended in both directions around the ring to facilitate failover if a link break occurs.

Link Failure Handling

> When a link in the ring goes down, the ring splits into two separate cascades. This occurs in the following sequence of events:
>
> 1. Link Failure Detection and the Ring Link Fail Notification (RLFN) Message
> 2. Ring Disable Message
> 3. Traffic Re-routing and Cascade Information Clearing
> 4. Failed Link Restoration
>
> When the connection between two BPEs in a ring is severed, the BPE whose upstream port was at the point of disconnection sends a notification of the failure to its active cascade port. Simultaneously, that BPE will "fail over" to its backup upstream port, changing the upstream direction of the data plane. The notification is called a Ring Link Failure Notification (RLFN). When the downstream BPE receives it, it forwards the RLFN to its active cascade port. If the BPE received the RLFN over its active upstream port, it too fails over as above. The end result is one or two data plane cascades terminating at the broken connection with no remaining backup path, which is re-established after the next ring detection. The new backup upstream direction is established on all nodes. Some BPEs will have different upstream and backup

upstream ports than those that were originally established. The cascades that were established when the ring was severed remain in place.

Uneven Cascade Lengths and Ring Re-balancing

When a ring is formed from two unequal length cascades, or re-formed due to a ring link break and restoration, there is a desire to equalize the cascades from a data plane perspective. This reduces traffic flow over one cascade at the expense of the other. This becomes especially important when a ring has been severed resulting in two unequal length data planes, and then rejoins. Although not described in Forming a Ring on page 329, rebalancing always take place after control plane ring formation. By always re-balancing, regardless of how the two cascades are configured, the result is two approximately equal length data plane cascades. By default, ring re-balancing is disabled; however, you can globally enable all ring re-balancing.

Dual Controlling Bridges in Ring Topologies (MLAGs)

In an Extended Edge Switching ring topology with dual (redundant) controlling bridges (CBs), *MLAG*s are used to synchronize and coordinate the ring state between the two CBs. For more information about redundant CBs, see Dual Controlling Bridges in Ring Topologies (MLAGs) on page 331.

Two MLAG topology types are supported:

- **Cross-connect MLAG**—requires 48-port bridge port extenders (BPEs) with four trusted ports (for example, V400-48p-10GE4). See Cross-Connect MLAGs on page 331.
- **One-armed MLAG**—used for wiring closet with existing cabling limitations or smaller BPEs. See One-Arm MLAGs on page 332.

Cross-Connect MLAGs

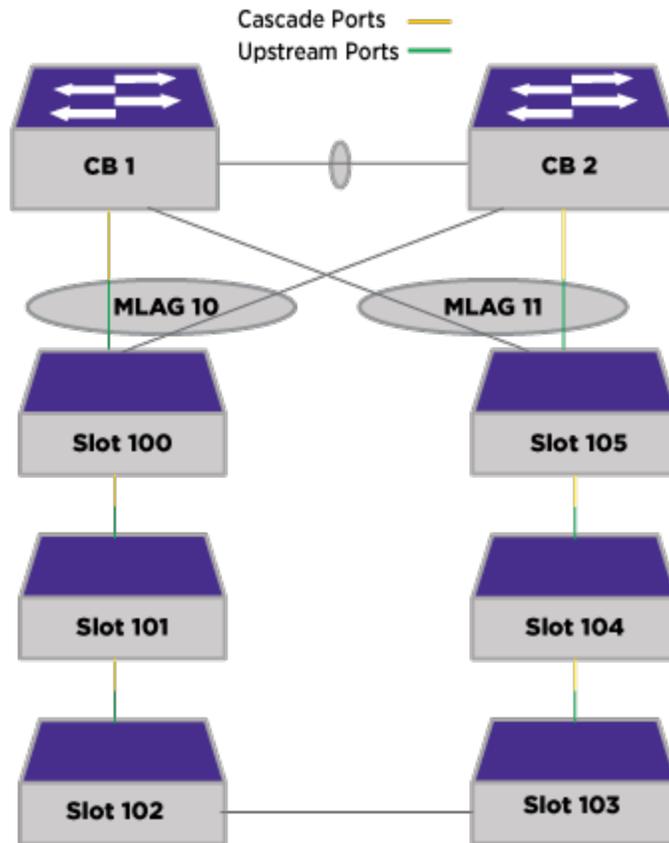
For dual (redundant) controlling bridges (CBs) on Extended Edge Switching rings, you can use cross-connect *MLAG*s. Cross-connect MLAGS require 48-port bridge port extenders (BPEs) with four trusted ports (for example, V400-48p-10GE4). Figure 38 shows a ring formed using CBs connected to a BPE ring using two cross-connect MLAGs.


Figure 38: Cross-Connect MLAG

One-Arm MLAGs

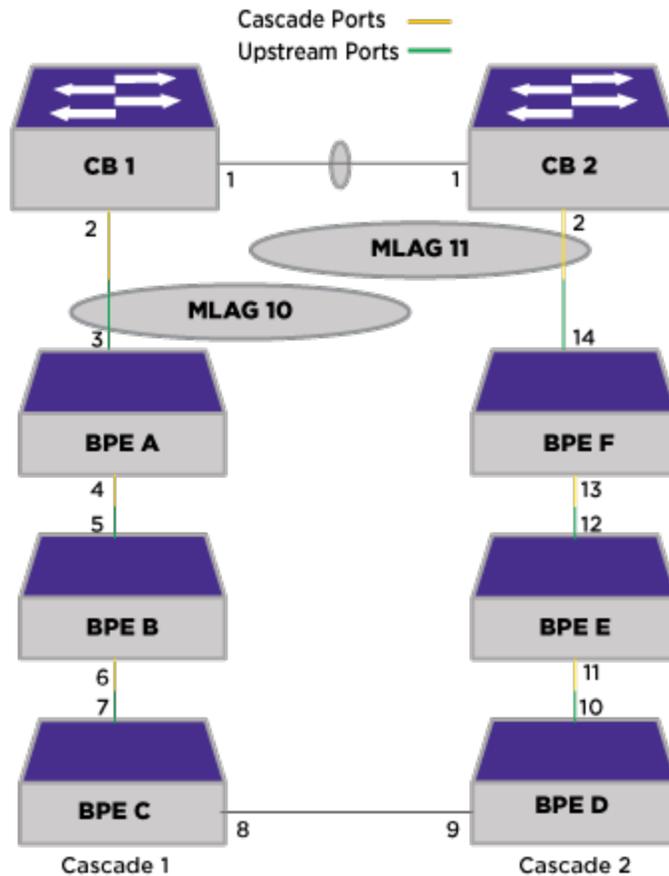
In some wiring closet applications, bridge port extenders (BPEs) are located in the closet, and the controlling bridge (CB) is located more centrally, and there are only two links wired from the CB to the closet. An important capability of Extended Edge Switching rings is to provide redundancy among BPEs that have only two trusted ports. In this configuration the CB neighbor has only one link to one of the cascades of the ring. To overcome this limitation, you can use a one-arm *MLAG* to achieve CB redundancy. Figure 39 shows a ring formed using CBs connected to a BPE ring using two one-armed MLAGs. One-armed MLAG uses virtual MLAG ports where a physical port connection is not present. The virtual port is always down, so MLAG blocking rules are not applied.


Figure 39: One-Arm MLAG

CB-1 and CB-2 are both aware of both MLAGs.

On CB-1, Cascade 1 is configured with port 2 as the native cascade port, and similarly, on CB-2, Cascade 2 is configured with port 2 as the native cascade port.

On CB-1, Cascade 2 is configured to use MLAG 11. On CB-2, Cascade 1 is configured to use MLAG 10. Such configurations are retained by the local CB even if the specified MLAG does not exist when the configuration is first processed.

When the first MLAG comes up, CB-1 and CB-2 elect a master that is the controller of all CSP sessions with BPEs that reside at any tier other than tier 1 (the BPEs directly connected to the CB). The same mastership applies to both MLAGs. Because the MLAGs are one-armed, the master sends messages to such BPEs through the CB that is directly connected to tier 1 of the related cascade. You can determine which CB is the master using the `show` `vpex ports` `{ports_list}` command.

Each CB establishes and controls the CSP session with the tier 1 BPE that is locally connected. The master CB establishes and controls all CSP sessions with BPE that are not at tier 1.

Optimized IP Multicast Replication

With optimized IP multicast replication, a controlling bridge (CB) only sends one copy of the IP multicast traffic per receiver VLAN for a particular IP multicast group. For example, if group 225.0.0.1 has five receivers in VLAN v1 and four receivers in VLAN v2, the CB sends one copy to VLAN v1 and one copy to VLAN v2 and the bridge port extender (BPE) does the replication.

If the receivers of VLAN v1 (or VLAN v2) are spread across different native cascade ports, separate copies might be sent for VLAN v1 on each native cascade port depending on the best path to reach a receiver. However, when the receiver is an extended port LAG, the CB has to do the replication. Because extended port LAG members could belong to different BPEs, and because BPE cannot do the pruning, the CB has to send copies to the individual LAG member. For instance, if VLAN v1 membership includes a LAG comprising ports 101:1, 103:1, and another LAG comprising ports 102:1, 102:2, two copies are sent, one for the 101:1 LAG member and another one for the 102:1 LAG member.

Because replication and VLAN flooding both use multicast ECIDs, using optimized IP multicast reduces the number of VLANs with extended ports to 3,000.

Supported Bridge Port Extender Models

The following V400 bridge port extender (BPE) models are available:

Table 28: V400 BPE Models

Model Numbers	Description
V400-24t-10GE2	V400 Series 24 10/100/1000BASE-T, 2 1000/10GBaseX unpopulated SFP+ ports, fixed power supply and fan.
V400-24p-10GE2	V400 Series 24 10/100/1000BASE-T PoE+, 2 1000/10GBaseX unpopulated SFP+ ports, fixed power supply and fans, and optional redundant power supply.
V400-48t-10GE4	V400 Series 48 10/100/1000BASE-T, 4 1000/10GBaseX unpopulated SFP+ ports, fixed power supply and fan.
V400-48p-10GE4	V400 Series 48 10/100/1000BASE-T PoE+, 4 1000/10GBaseX unpopulated SFP+ ports, fixed power supply, fans, and optional redundant power supply.

The following V300 BPE models are available:

Table 29: V300 BPE Models

Model Numbers	Description
V300-8P-2T-W	V300 Series 8 port 10/100/1000BASE-T POE+ ports half/full duplex, 2x1000 BASE-T ports, PoE powered 802.3bt Type 4, fanless. **Note:** The V300-8P-2T-W model can only be directly attached to a controlling bridge. It cannot be cascaded.
V300-8P-2X	V300 Series 8 port 10/100/1000BASE-T POE+ ports half/full duplex, 2 × SFP+ ports, fanless.
V300-8T-2X	V300 Series 8 port 10/100/1000BASE-T ports half/full duplex, 2 × SFP+ ports, fanless.
V300HT-8P-2X	V300 Series 8 port 10/100/1000BASE-T POE+ ports half/full duplex, 2 × SFP+ ports, fanless, high-temperature model.
V300HT-8T-2X	V300 Series 8 port 10/100/1000BASE-T ports half/full duplex, 2 × SFP+ ports, fanless, high-temperature model.

> **Important**
> On V400 BPEs, only SFP+ ports can be used for upstream/cascade ports.

> **Important**
> On V300 BPEs, only ports 9 and 10 can be used as upstream ports.

For information about which optics are supported with the V300 and V400 Virtual Port Extenders, see the *Extreme Hardware/Software Compatibility and Recommendation Matrices*.

Supported Platforms

The following switches are supported as controlling bridges (CBs):

ExtremeSwitching X465 and X590 series switches.

> **Note**
> The V300-8P-2T-W BPE requires PoE, and therefore can only use the ExtremeSwitching X465 series switches as CBs.

Extended Edge Switching on Stacking Overview

With Extended Edge Switching on Stacking, Extended Edge uses the stack, rather than MLAG, to provide redundancy to a BPE. This is done by having certain components of EXOS synchronize their primary and backup nodes with respect to the Extended Edge Switching state. The primary node performs all Extended Edge Switching controlling bridge functions while the backup is kept in sync with the primary. This simplifies

configuration, as all stack switches are managed with a single configuration file and control point that resides on the elected primary switch. The backup switch can become the primary switch upon failure of the primary switch if the failure is caused by a crash, a power-off, or a management action.

Use of MLAG in Extended Edge Switching on Stacking

When Stacking provides the controlling bridge, MLAGs will not service individual BPEs. All BPE LAGs that connect to a controlling bridge provided by a stack terminate in a single LAG at the controlling bridge. The LAG at the controlling bridge can consist of member ports provided by different nodes in the stack. Preventing Extended Edge Switching MLAG in Stacking is enforced by the CLI, and ZTPStack will not attempt to activate MLAG on the stack.

MLAG can be used to provide redundancy using two stacks. An MLAG is defined for a user device using stack node front panel ports that are not used to provide the cascade port function.

> **Note**
> BPE ports cannot be used to form MLAGs.

Extended Edge Switching and Stack Modes Combined

Either Extended Edge Switching mode or stacking mode can be used independently. A switch reboot is required to enter the combined mode and enable Extended Edge when already in stacking mode. A reboot is also required to enable stacking mode when in Extended Edge Switching mode (assuming that Extended Edge Switching MLAG is not in use). Both can be enabled simultaneously with a single reboot.

Extended Edge Switching Autoconfiguration and ZTPStack

ZTPStack enables both Extended Edge Switching and stacking when bringing up a stack that has attached BPEs. Once in stacking mode and Extended Edge Switching mode simultaneously, ZTPStack (on stacks that have a default EXOS configuration) enables Extended Edge autoconfiguration.

Supported Topologies

BPEs at the "first tier" (directly connected to the stack) can connect any or all of their intended upstream ports to any switch in the stack.

A cascaded BPE (tier 2 or higher) can connect its upstream ports only to the same BPE, meaning only point-to-point upstream topologies are supported below tier 1. Cascade ports that are configured on LAGs impose the restriction that all of the LAG members must be provided by the same BPE, or must all be provided by the stack directly.

Two BPE cascades can be connected together at their ends forming an Extended Edge Switching Ring.

Redudancy and Hitless Failover

Extended Edge Switching on Stacking uses the stack redundancy feature. All of the data and states associated with the Extended Edge Switching feature are continuously checkpointed to the backup node. The backup node is prepared to take over the controlling bridge function for the stack if there is a primary node failure.

Limitations

All nodes in a stack running Extended Edge Switching must be controlling bridge capable. Any attempt to add a non-capable slot to a stack running Extended Edge will fail. Enabling Extended Edge Switching on a stack that contains a non-capable node will fail.

You must use the same class of controlling bridge for both the primary and backup. For example, if an X465 series switch is the primary node, then the backup must also be an X465 series switch.

The primary-capable node in a stack that has the least maximum supported number of BPEs determines the maximum for the stack. When using Extended Edge with Stacking, BPEs cannot be attached to configured MLAG ports.

Supported Platforms

The following devices are supported as controlling bridges (CBs):

ExtremeSwitching X465 and X590 series switches.

The V300 and V400 BPEs can be attached to a stack that is configured as a controlling bridge.

> **Note**
> The V300-8P-2T-W BPE requires PoE, and therefore can only connect to the ExtremeSwitching X465 series switch.

Supported Commands

Existing Extended Edge display commands show the same result on the primary and backup nodes.

The **enable/disable vpex** and **enable/disable stacking** commands are aware of the capability of each node in the stack. The **enable vpex** command will fail if any node in the stack is not Extended Edge-capable.

The **show slot** command shows the Failed state for the attempted addition of a new stack node that does not support the controlling bridge function when the Extended Edge Switching feature is enabled. A message is logged at the time this failure occurs. The **show slot** command also shows the presence of any BPEs that have occupied slots.

Use the **`show vpex stacking`** command to show Extended Edge Switching information for all nodes in the stack topology.

ZTPStack Behavior

ZTPStack runs on all Extended Edge switches that have not yet been configured. ZTPStack is a function that either sets up SummitStack, or detects BPEs and sets up MLAG and enables Extended Edge Switching and Exteded Edge autoconfiguration.

With Extended Edge Switching on stacking, ZTPStack prefers stacking operation to MLAG. Controlling bridge capable switches that are normally deployed in stacking environments will default to stacking-support enabled mode.

When stacking-support is enabled (by default on certain switches), ZTPStack will enable Extended Edge Switching upon detection of an attached BPE, but will not reboot the switch. Stacking automation (push button or easy-setup) completes this task.

Software Upgrade

The package containing EXOS and the supported BPE image can be loaded on a stack (the `.lst` file). The installation of the images is performed on all stack nodes in the active stack topology.

Bridge Port Extender General Limitations

- In the Extended Edge Switching architecture, Layer-2, Layer-3, multicast, and filtering operations take place on the controlling bridge. The controlling bridge switch and attached BPEs constitute a single, extended switch system. Therefore, the Extended Edge Switching system assumes the scale and limits from the specific controlling bridge model in use. For applicable limits, see the Limits tables in the *ExtremeXOS Release Notes*.
- Certain ExtremeXOS features are not supported or have limitations. For information, see ExtremeXOS Feature Compatibility with V300 and V400 Virtual Port Extenders on page 339.
- A maximum of 48 attached BPEs is supported.
- A maximum of 4 levels (tiers) of cascaded BPEs is supported.

> **Note**
> The V300-8P-2T-W model must be directly attached to the controlling bridge (1 tier only).

- A maximum of 4 upstream ports (in a LAG) per BPE is supported (with V400-48).
- Trusted ports on BPEs cannot be used as user data ports. No protocols or features should be applied/configured on this port.

ExtremeXOS Feature Compatibility with V300 and V400 Virtual Port Extenders

Table 30 shows which ExtremeXOS features are supported, or are not supported, or that have limitations when used with V300 and V400 Virtual Port Extenders.

Table 30: ExtremeXOS Feature Compatibility with V300 and V400 Virtual Port Extenders

ExtremeXOS Feature	Status
ACLs	Ingress (first and second stage) and egress ACLs are supported with the following limitations: • Ingress ACLs applied to a list of extended ports results in one hardware rule per extended port. This is the same behavior as regular ports when counters and/or meters are used. • Egress ACLs applied to an egress port do NOT match L2 flood traffic, but egress ACLs applied to VLANs do. • Ingress ACLs with Replace-ethernet-destination-address action, replace-ethernet-source-address, and replace-vlan-id actions are not supported when packets are egressing extended ports. • L3/L4 match criteria are not available in the same egress ACL key as an extended port match. • ACL byte counters include an extra 8 bytes per packet (Ethertype + Etag) for the added encapsulation. • Egress ACLs applied to extended port LAGs are not supported. Use egress ACLs bound to VLANs/any instead. **Note:** When installing ACL rules bound to a set of ports, rules are replicated for each port if there are ACL counters and counter compression is not enabled or if the ports are extended ports. **Note:** You can consume an excessive number of ACLs if you bind them to each individual (extended) port in cases where you have many extended ports. To avoid this, consider policy (role-based assignments per user) for access-control (see Policy Roles on page 971), ACLs bound to VLANs, wildcarded applications (see Configuring the ACL Rule on the Interface on page 811), or two-stage ACLs (see Two-Stage ACL on page 782).
AVB	Not supported.
BFD	Supported, except on extended ports.
CFM	Supported, except on extended ports.
Diffserv examination	Supported.
Disable slot	Not supported. **Note:** You can take a BPE slot offline by disabling the corresponding cascade port(s).

Table 30: ExtremeXOS Feature Compatibility with V300 and V400 Virtual Port Extenders (continued)

ExtremeXOS Feature	Status
Dot1p examination	Disabled by default on extended ports; enabled by default on controlling bridge cascade ports. Use cascade port Dot1p examination for extended port traffic to conserve ACL hardware resources.
EAPS	Supported, except that EAPS ring ports cannot be extended ports.
EDP/LLDP/CDP	Supported. **Note:** BPEs will not appear as EDP neighbors.
EEE	Supported.
ELSM	Not supported.
ERPS	Supported, except that ERPS ring ports cannot be extended ports.
ESRP	Not supported.
Fabric Attach	ExtremeXOS Fabric Attach (FA) supports FA servers and FA Proxies to be Extended Edge Switching controlling bridge (CB) nodes connected with bridge port extenders (BPEs) in two different topologies: • Single-arm *MLAG* ring—see Single-ARM MLAG Ring Topology Configuration Examples on page 753. • Cross-connect MLAG—see Cross-Connect MLAG Topology Configuration Examples on page 765.
FDB	
FDB: Limit learning	Supported.
FDB: MAC lockdown	Supported.
FDB: Static and blackhole entries	Supported, except that multi-port unicast FDBs entries are not supported.
Flood rate-limit	Not supported on extended ports.
HcLAG	Not supported.
Identity Management	Identity Management should not be enabled on cascade ports.
L2 PBR	Not supported.
FDB: multi-port unicast entries	Not supported.
L3	
L3: PBR	Supported.
L3: Gateway routers	Gateway router connected to extended port LAGs is not supported.

Table 30: ExtremeXOS Feature Compatibility with V300 and V400 Virtual Port Extenders (continued)

ExtremeXOS Feature	Status
L3: IP unicast forwarding	Maximum gateways (using `configure iproute sharing max-gateways ` *`max_gateways`*) must be greater than or equal to the number of active extended LAG members.
L3: Routing protocols	Supported on CB; not supported on extended ports.
L3 Tunnels	Supported on CB ports. Not supported on extended ports.
LAG: LACP	Supported. The default and only supported algorithm on extended port LAGs is "custom."
V300 Virtual Port Extender LEDs	Supported. For information about the location of BPE LEDs, see the *V300 Virtual Port Extender Quick Reference Guide*.
V400 Virtual Port Extender LEDs	Supported. For information about the location of BPE LEDs, see the *V400 Virtual Port Extender Quick Reference Guide*.
Mirroring	Mirroring extended ports is supported. Mirroring to extended ports is supported, except for ExtremeSwitching the X695 series switch. Ingress mirroring of an extended port will include an 802.1BR E-tag. **Note: Workaround**: You can avoid this 802.1BR E-tag by doing the following: 1. Run the command: `enable mirroring to port-list 1:1 loopback 1:2`. Where in this example, port 1:2 is not connected to anything. 2. Run the command: `configure mirroring add port 104:1`. Where in this example, port 104:1 is the extended port. Mirroring to BPE cascade ports is not supported. Limitations: Only known traffic to extended ports can be egress mirrored.
MLAG	Supported on cascade ports; not supported on extended ports. Not supported on cascade ports when in stacking mode.
MPLS/VPLS	Not supported.
Multicast	
Multicast: IGMP	Supported.
Multicast: MVR	Supported.
Multicast: PIM	Supported.
Multicast: PIM Snooping	Supported.
MVRP	Supported.

Table 30: ExtremeXOS Feature Compatibility with V300 and V400 Virtual Port Extenders (continued)

ExtremeXOS Feature	Status
Netlogin	Dot1X and MAC Auth supported, and supported with MLAG. Not supported: • Multi-supplicant (MAC-based VLANs) without ONEPolicy. • Port restart option. • Trusted ports. WebAuth is not supported with MLAG.
Node Alias	Supported.
OnePolicy	Basic policy supported: • Policy scale (number of users, roles, rules) same as CB. • LAG rules not supported on extended ports with tci-overwrite. • Per-port, policy-driven, ingress rate limiting is not supported on extended ports. • ExtremeSwitching X695 series switches as CBs do not support tci-overwrite.
PoE	Supported on select BPE models. See Supported Bridge Port Extender Models on page 334. Operator limit configuration is not supported on cascade ports. **Note:** The V300-8P-2T-W model is both a powered device (PD) and power supplying equipment (PSE). For information about its power output, see the *ExtremeSwitching Hardware Installation Guide for Switches Using ExtremeXOS Version 30*
Ports	
Ports: Flooding	Disabling flooding is supported.
Ports: Jumbo frame	Enabling/disabling jumbo support on extended ports is supported; cascade-ports default to jumbo enabled. For V300, only 1522, 2048, 10240 sizes are supported. Configuring jumbo frame sizes other than those values results in the next larger frame size being used for ingress; an egress filter enforces the MTU based on the actual jumbo size for the egress port. The max-frame-size on V400 is enforced only on ingress, and not on egress. The V300 enforces on both ingress and egress.
Ports: Learning	Disabling/enabling learning supported.
Ports: Statistics	On V300 ports, `show port packet` displays all packets 1024+ as "1024-1518". The "Jumbo" column is always "0".
PVLAN	Not supported.

Table 30: ExtremeXOS Feature Compatibility with V300 and V400 Virtual Port Extenders (continued)

ExtremeXOS Feature	Status
QoS	Supported: • 8 queues per extended port. • Peak-rate supported per qosprofile per extended port. • CBS is 32 Kbytes. • Scheduling algorithms WDRR and strict priority. • Egress per-port rate limit per extended port. **Note:** For V300, all queue shapers are disabled on a port if either of the two highest priority queues are in weighted round robin (WRR) on that port. Not supported: • Committed-rate per qosprofile per extended port. • For V300, per-queue packet drop counters. **Note:** Neither `show ports` `port_list` **qosmonitor** {**congestion**} {**no-refresh** | **refresh**} {**port-number**} nor `show ports` `port_list` **congestion** {**no-refresh** | **refresh**}{**port-number**} increments when there is egress congestion on a V300 port. Instead, you can view egress congestion using `show ports` {`port_list` | **stack-ports** `stacking-port-list`} **rxerrors** {**no-refresh** | **refresh**} on the ingress port (upstream port in many cases). **Note:** Dot1p examination is enabled by default on cascade ports, but disabled by default on extended ports. **Note:** When using hyrbid QoS scheduling, strict-priority queues must be the highest number queues.
Restart port	Not supported on extended ports. Use `disable/enable port` commands.
sFlow	Supported: sFlow hardware sampling on Extended Edge Switching extended ports is provided by the underlying Extended Edge Switching cascade port hardware. As such, the configured sample rate is programmed on the cascade port and is provided in aggregate to all subtended sFlow-enabled Extended Edge Switching extended ports.
Software-redundant ports	Supported.
STP	Supported, primarily for edge loop detection (edge guard); supported with MLAG redundancy for RSTP and MSTP protocol modes.
VLAN	
VLAN:Membership	Supported; users specify VLAN membership using <slot>:<port> notation; protocol VLANs not supported.

Table 30: ExtremeXOS Feature Compatibility with V300 and V400 Virtual Port Extenders (continued)

ExtremeXOS Feature	Status
VLAN: statistics	Supported on extended ports. **Note:** VLAN flood traffic is not counted in the transmit counters; displayed counts include an additional 8 bytes for the Ethertype + E-tag encapsulation.
VMAN/CEP	Not supported.
VMT/XNV	Not supported.
VRRP	Supported.
VXLAN	Supported for tagged and untagged tenant VLANs on extended ports. Extended port LAG in VXLAN is not supported. Extended ports cannot be in VXLAN network VLANs. Extended ports cannot participate in RIOT configurations. Ring is not supported for VXLAN extended ports. Optimized IP Multicast Replication is not supported for VXLAN extended ports.

Using VPEX Bridge Port Extenders

Configuring Extended Edge Switching Topology with Full Automation

You can automatically configure an Extended Edge Switching topology fully or in part. This capability allows for the more rapid and accurate setup of an Extended Edge Switching architecture.

However, the disadvantage of full automation is that you must start with an unconfigured controlling bridge (CB) (out of the shipping box) or unconfigure the CB switch. To avoid unconfiguring the CB, but to still avoid manually configuring the entire Extended Edge Switching topology, consider using partial automation (see Configuring Extended Edge Switching Topology with Partial Automation (Auto-configuration) on).

> **Note**
> Do not attach bridge port extenders (BPEs) to a partitioned port. Unconfiguring the CB removes the port partition configuration, and this causes full automation to fail.

Full automation for Extended Edge Switching performs the following tasks:

1. Determines if the switch is capable of being a CB.
2. Detects if any BPEs are attached.
3. Enables VPEX mode on the CB.

4. If you are setting up redundant CBs (see Redundant Controlling Bridges on page 326):

   • Detects the other CB.
   • Creates a VLAN on only the port(s) between the CBs.
   • Adds link local IP address to the VLAN.
   • Creates a LAG for the port(s) between the MLAG peers.
   • When the CB detects the IP address of the other CB VLAN, creates the MLAG peer.

5. Enables Extended Edge Switching auto-configuration (see Configuring Extended Edge Switching Topology with Partial Automation (Auto-configuration) on page 346, which performs the following tasks:

   a. Assigns the next available slot number to each BPE.
   b. Creates LAGs/MLAGs on cascade ports.
   c. Adds ports to existing cascade port LAGs.

6. Defaults to stacking-support enabled mode with Extended Edge Switching on stacking.

   > **Note**
   > ZTPStack will enable Extended Edge Switching upon detection of an attached BPE, but will not reboot the switch. Stacking automation (push button or easy-setup) completes this task.

   > **Note**
   > For full automation, the entire process can take about 6–7 minutes to complete depending upon the configuration.

To start full automation for Extended Edge Switching:

1. (Optional) If you are setting up redundant CBs, connect the two CBs to each other.
2. Attach BPE(s).
3. Ensure that full automation is enabled. Full automation is enabled by default. Run `show vpex`:

```
# show vpex
Virtual Port Extender: Disabled
Auto-Configuration:    Enabled
Ring rebalancing:      Auto
Zero Touch Provisioning: Nothing Provisioned - Existing configuration present

Cascade
Port/MLAG Id    Slot
===================
```

You should see `Zero Touch Provisioning: Nothing Provisioned - Existing configuration present`. If you see `Nothing Provisioned - Disabled`, run `restart process ztpstack`.

4. Ensure that none of the following files are present on the CB(s):
   - `default.xsf`
   - `default.py`
   - `autoexec.xsf`
   - `autoexec.py`

   For information about locating and deleting files on the switch, see Using the ExtremeXOS File System on page 138.

5. Ensure that the CB(s) do not have a configuration. Run `unconfigure switch {`**`all`** `|` **`erase`** `[`**`all`** `|` **`nvram`**`]}`. Use either:
   - `unconfigure switch`—removes configuration, but leaves other settings intact.
   - `unconfigure switch all`—removes configuration and resets all settings to factory defaults (recommended).

6. Reboot the CB(s).

7. The configuration applied by automation is not automatically saved. Save the configuration:
   - Manually: `save configuration {`**`primary`** `|` **`secondary`** `|` *`existing-config`* `|` *`new-config`*`}`
   - Automatically: `save configuration` **`automatic`** `{`**`every`** *`minutes`* `{`**`primary`** `|` **`secondary`** `|` *`existing-config`* `|` *`new-config`*`} |` **`never`**`}`

For information about troubleshooting an Extended Edge Switching topology, see Troubleshooting an Extended Edge Switching Topology on page 351.

> **Note**
>
> To avoid having automation start if you do want it to, run `terminate` **`vpex ztp`** or perform some configuration prior to attaching BPEs or have a `default.xsf` (or other similar file) file in place.
>
> To view automation status, use the command `show vpex`.

Configuring Extended Edge Switching Topology with Partial Automation (Auto-configuration)

The Extended Edge Switching auto-configuration feature allows the controlling bridge switch in an Extended Edge Switching topology to detect new bridge port extenders (BPEs) connected to ports not configured as cascade ports, and automatically configure cascade ports, extended slots, and LAGs/MLAGs on cascade ports. This capability allows for the more rapid and accurate setup of an Extended Edge Switching architecture, but still requires some manual configuration, in particular MLAG. To further reduce manual configuring, consider using full automation (see Configuring Extended Edge Switching Topology with Full Automation on page 344)

> **Note**
>
> Auto-configuration is disabled by default. If auto-configuration is enabled, Extended Edge Switching ports cannot be manually configured.

Cascade port connections to a BPE are automatically grouped into a LAG with the first detected connection set as the master logical port. Automatic LAG grouping occurs even if there is only a single connection to the BPE. With auto-configuration enabled, additional connections added after the initial Extended Edge Switching configuration is established are automatically added to the LAG. If you remove connection(s) and want the port(s) removed from the LAG, you must do this manually (see Adding and Deleting Ports in a Load-Sharing Group on page 262).

To use auto-configuration:

1. Attach BPEs as desired.
2. (Optional) Create the MLAG peer relationship between redundant CBs and ensure that both CBs are up (see Redundant Controlling Bridges on page 326). The rest of the MLAG setup for redundant CBs is handled automatically.
3. Enable VPEX mode:

   ```
   enable vpex
   ```
4. Reboot the CB(s) to allow the VPEX mode command to take effect.
5. Enable auto-configuration:

   ```
   enable vpex auto-configuration
   ```
6. Check that the intended cascade/ring configuration has been properly established:

   ```
   show vpex topology { port port_num} {summary | detail}
   ```
7. The configuration applied by automation is not automatically saved. Save the configuration:
   - Manually: `save configuration {primary | secondary | existing-config | new-config}`
   - Automatically: `save configuration automatic {every minutes {primary | secondary | existing-config | new-config} | never}`

The partial automation process detects the new BPEs connected to ports not configured as cascade ports, and automatically configures cascade ports, extended slots, and LAGs on cascade ports.

To show auto-configuration status, use the following command:

```
show vpex
```

To disable auto-configuration, use the following command:

```
disable vpex auto-configuration
```

For information about troubleshooting an Extended Edge Switching topology, see Troubleshooting an Extended Edge Switching Topology on page 351.

Manually Configuring Bridge Port Extenders

> **Tip**
> For an easier way to configure a Extended Edge Switching setup, use full automation (see Configuring Extended Edge Switching Topology with Full Automation on page 344) or partial automation (see Configuring Extended Edge Switching Topology with Partial Automation (Auto-configuration) on page 346).

Use manual configuration when you want precise control over items such as slot number assignment.

To manually setup up Extended Edge Switching:

1. Physically set up the bridge port extender(s) (BPEs). See the applicable *Virtual Port Extender Quick Reference Guide*.

   > **Note**
   > If you are using unconfigured (`unconfigure switch all`) or "out-of-the box" controlling bridge switches (CBs), to ensure that full automation does not start to run, do <u>not</u> reboot the CBs after connecting the BPEs.

2. On the CB, enable VPEX mode. Use the command:

   enable **vpex**

   This command enables VPEX mode and allows you to refer to ports in the *slot*:*port* notation in applicable commands. A reboot is required for the command to take effect. After rebooting, the CLI prompt changes to show that the switch is now slot 1 (for example):
   ```
   Slot-1 VPEX X465.14 #
   ```

3. (Optional) Set up a LAG with LACP on the switch to operate as the cascade port. Use the command:

   enable sharing *port* **grouping** *port_list* {**algorithm** [**address-based** {**L2** | **L3** | **L3_L4** | **custom}** | **port-based** }]} {resilient-hashing [**on** | **off**]} {distribution-mode [**all** | **local-slot** | **port-lists**]} {lacp | **health-check**}

   > **Note**
   > You cannot convert a cascade port to a LAG after the cascade port is created without first unconfiguring the slot from the cascade port.

4. Assign a slot number identifier to the attached BPE on the specified cascade port.
   Use the command:

   configure **vpex ports** *port_list* **slot** *slot_num*

   > **Note**
   > If the cascade port is part of a LAG, then configure the LAG master port as
   > the VPEX port.

   The behavior of this command is similar to configuring slots within a chassis.
   After assigning a slot number to the BPE, you can make port-level configuration
   choices with the familiar *slot*:*port* notation in other commands involving the port
   extender's ports (for example, configure vlan v1 add port 100:1).

5. (Optional) Add a descriptive name to a BPE. Use the command:

   configure **slot** *slot* **description** [*slot_description* | **none**]

   For information about troubleshooting an Extended Edge Switching topology, see
   Troubleshooting an Extended Edge Switching Topology on page 351.

Configuring Extended Edge Switching Ring Topology

The following procedure explains how to set up an Extended Edge Switching ring
topology.

Extended Edge Switching rings allow two Extended Edge Switching (VPEX) cascades
to be joined together to form a ring, or a single cascade to be joined back to the
controlling bridge (CB). When a link breaks or a bridge port extender (BPE) otherwise
leaves, the remaining BPEs form one or two new cascades that end at the ring break,
thus keeping connectivity to the CB alive.

For more information about Extended Edge Switching ring topology, see Extended
Edge Switching Rings on page 328.

Ensure that all BPEs are running the minimum VPEX version software to support
Extended Edge Switching (see *ExtremeXOS Release Notes*). For information about
upgrading the BPEs, see Upgrading the Controlling Bridge and Bridge Ports Extenders
on page 369.

1. Connect the BPEs into one or two cascades.

2. Configure the cascades and allow them to form. You can use either:
   - Full automation (Configuring Extended Edge Switching Topology with Full Automation on page 344).
   - Partial automation (Configuring Extended Edge Switching Topology with Partial Automation (Auto-configuration) on page 346).
   - Manual configuration (Manually Configuring Bridge Port Extenders on page 348).

   > **Note**
   > Ring re-balancing establishes two cascades of approximately equal length without regard to bandwidth consumption of a BPE. In a mixed node cascade, you should place the most bandwidth consuming BPEs as close as possible to the CB in the cascade. For example, a 48t BPE may use two-port LAGs to communicate with the CB, but a 24t BPE switch can only have one port in its upstream direction. Thus the 24-port BPEs should be placed at the tiers that are farther from the CB.

   Use the `show slot {`*`slot`* `{`**`detail`**`} |` **`detail`** `}` and `show` **`vpex topology`** `{` **`port`** *`port_num`*`} {`**`summary`** `|` **`detail`**`}` commands to ensure that the cascades have finished forming correctly.

3. Connect the end BPEs of these cascades to each other, or the end of the single cascade to a port on the CB.

   A message similar to the following appears:

   ```
   <Noti:VPEX.Ring.Dtect> Slot-1: Ring detected between ports <port1> and <port2>
   ```

4. (Optional) Turn on automatic ring re-balancing. Ring re-balancing is disabled by default. For more information about ring re-balancing, see Uneven Cascade Lengths and Ring Re-balancing on page 331. If you want to enable ring re-balancing, use the following command:

   `configure vpex` **`ring rebalancing`** `[`**`auto`** `|` **`off`**`]`

   When a ring contains different types of BPEs that provide different amounts of bandwidth, automatic ring re-balancing may cause an undesirable balance point as seen when using the `show` **`vpex topology`** `{` **`port`** *`port_num`*`} {`**`summary`** `|` **`detail`**`}` command. If so, wait until the ring state is complete. You can then force the balance point by disabling a cascade port at the desired re-balance point, disabling automatic re-balancing, and then enabling the cascade port that was disabled previously.

5. If you are using redundant CBs with one-arm MLAGs (see One-Arm MLAGs on page 332), have each MLAG peer declare a slot on the other peer's one-arm MLAG. Use the command:

   `configure` **`vpex mlag-id`** *`mlag_id`* **`peer`** *`peer_name`* **`slot`** *`slot_num`*

6. You can also set a preference for when Auto-Configuration configures the virtual MLAG ID. The default (cascade) configures the virtual MLAG ID whenever a 2nd-tier BPE is detected remotely, but not locally. To set the preference, use the command:

   `configure` **`vpex auto-configuration mlag-id`** `[`**`cascade`** `|` **`ring`**`]`

For information about troubleshooting an Extended Edge Switching topology, see Troubleshooting an Extended Edge Switching Topology on page 351.

Troubleshooting an Extended Edge Switching Topology

The following information provides tips on how to verify and troubleshoot your Extended Edge Switching topology.

Commands for Verifying/Troubleshooting Extended Edge Switching Topology

Use the following commands to verify and troubleshoot the Extended Edge Switching topology:

* `show configuration {`*module-name*`}` {**detail**} with *vpex* as the *module-name*—shows cascade port configuration.
* `show configuration {`*module-name*`}` {**detail**} with *vlan* as the *module-name* or with `|` *grep sharing*—shows LAG configuration.
* `show configuration {`*module-name*`}` {**detail**} with *devmgr* as the *module-name* —shows slot module type configuration.
* `show vpex`—shows mapping between cascade port and slot number.
* `show slot {`*slot* {**detail**} `|` **detail** `}`—shows status of BPE slot.
* `show `**vpex ports** {*ports_list*}—shows the status of the CSP control plane connections for each cascade port.
* `show `**vpex topology** { **port** *port_num*} {**summary** `|` **detail**}—shows the detected topology type, status, ring status (if applicable), and bridge port extender (BPE) interconnections.

Commands for Verifying/Troubleshooting Redundant Controlling Bridges (CBs)/MLAGs

To verify and troubleshooting the MLAG setup, use the following commands:

`show mlag peer {`*peer_name*`}`—shows if MLAG peer is up.

`show configuration {`*module-name*`}` {**detail**} with *vsm* as the *module-name*—shows MLAG port configuration.

Limitations When Using Automation to Set up Redundant CBs/MLAGs

The following limitations apply when using automation to set up redundant CBs.

Limitation	Workaround
If the CB has MLAG peer configuration, but its MLAG peer is down, you cannot enable auto-configuration.	• Remove the MLAG peer configuration to make it a single CB setup. • Bring up the MLAG peer.
If a BPE is configured before MLAG peer is configured, auto-configuration does not configure the MLAG port for the previously configured BPE.	Manually configure MLAG port for the previously configured BPE by setting the MLAG port ID to 5000 plus the BPE's slot number.

Selecting How VLAN Membership is Implemented for Extended Ports

In Extended Edge Switching hardware, the extended ports are represented as virtual ports. The VLAN membership of extended ports can be implemented in two ways:

- Hash table with VLAN and virtual port as key. Hash tables can lead to hash collisions at higher scale. (Default)
- Virtual port group. Programming the same group number in the VLAN table and virtual port table indicates membership. The hardware has 64 virtual port groups. You should select this option if many VLANs share the same extended ports.

Note that changing this configuration at run time could result in temporary loss of traffic while the tables are reprogrammed. It is preferable to identify which option works best for the particular topology and leave the setting unchanged during run time or schedule the change during a maintenance window.

To set the way VLAN membership is implemented, use the following command:

```
configure forwarding vpex vlan-port-filter [hash-table | port-group]
```

To see the current selection for VLAN membership, use the command:

```
show forwarding configuration
```

Configuring IP Multicast Replication

IP multicast (IPMC) replication involves generating multiple copies of incoming IPMC traffic to subscribed receivers. For more information about IPMC replication, see Optimized IP Multicast Replication on page 334.

To set the IPMC replication mode, on the controlling bridge or bridge port extenders, use the following command:

```
configure forwarding vpex ipmc replication [ controlling-bridge | bpe ]
```

To view the current selection for IPMC replication, use the following command:

```
show forwarding configuration
```

Unconfiguring VPEX Bridge Port Extenders

Unconfiguring the entire VPEX Setup and Disabling VPEX Mode

To unconfigure the entire VPEX setup on the switch and disable VPEX mode:

Disable VPEX mode. Use the command:

```
disable vpex
```

Disabling VPEX mode removes all port extender slot number assignments made using `configure vpex`. A reboot is required for this command to take effect.

Removing Bridge Port Extenders from Slot Assignments

You should only perform this procedure if you want to permanently remove the slot and all of its configuration, or if you want to rearrange the same BPEs into different slots.

To disassociate a bridge port extender (BPE) from a slot number assignment:

1. If the slot module is configured, use the command `unconfigure slot` *slot* .
2. `unconfigure` **vpex ports** *port_list* **slot**.

   The behavior of this command is similar to removing slots within a chassis. After executing this command, the BPE no longer occupies the slot number assignment.

Unconfiguring MLAG Slot Assignment

To unconfigure a slot previously declared on an <u>MLAG</u>, use the following command:

`unconfigure` **vpex mlag-id** *mlag_id* **slot**

Adding and Removing Bridge Port Extenders

The following information shows you how to add, replace, and remove bridge port extenders (BPEs) from cascades Extended Edge Switching topologies.

Replacing Bridge Port Extenders

You can replace bridge port extenders (BPEs) in existing Extended Edge Switching topologies.

This procedure explains how to replace a BPE with another BPE of the same model. If you want to replace an existing BPE with a different model, you need to remove the existing BPE, and then add the new BPE (see Inserting Additional Bridge Port Extenders on Cascades on page 353).

> **Note**
> For cascade topologies, control plane/traffic is disrupted on the cascade below the BPE being replaced until the new BPE is connected and accepted into the cascade.

To replace a BPE:

1. Detach the cables and remove the existing BPE.
2. Attach the cables to the new BPE.

Inserting Additional Bridge Port Extenders on Cascades

You can add additional bridge port extenders (BPEs) to existing Extended Edge Switching cascade topologies. You can add additional BPEs anywhere in the cascade. You can use either partial automation or manual configuration to add the additional BPE.

To add a BPE using **manual** configuration:

1. Choose the location of the BPE in the cascade:
    *   *Not* at the bottom: Unconfigure all BPEs below the intended location for the new BPE in the cascade starting from the bottom, and then moving up, using the procedure in Removing Bridge Port Extenders from Slot Assignments on page 353.
    *   *Bottom*: Complete step 2, and then you are done.
2. Attach the BPE, and configure it using the procedure in Manually Configuring Bridge Port Extenders on page 348 starting with step 3 on page 348.
3. Re-configure all of the BPEs below the new BPE starting from the top, and then moving down, using the same procedure as in step 2.

To add a BPE using **partial automation**, connect the BPE in the desired location, and then reboot the controlling (CB).

Inserting Additional Bridge Port Extenders on Rings

You can add bridge port extenders (BPEs) to existing Extended Edge Switching ring topologies. You can add BPEs anywhere in the ring.

To add a BPE:

1. Disconnect the cable between the two BPEs in the ring at the desired insertion point, which allows the ring to enter the severed state, and then re-converge into two operational cascades.
2. Connect the new BPE to the same connection points disconnected previously.

    If you have auto-configuration enabled (`enable` **`vpex auto-configuration`**), you are finished. If you want to manually configure the rest of the setup (ensure that auto-configuration is disabled), continue with the following steps.
3. (If you are connecting at the point where the configured cascades were joined, do *not* perform this step) Unconfigure the cascade port of the BPE connecting the new BPE using the procedure in Removing Bridge Port Extenders from Slot Assignments on page 353.

    > **Note**
    > To find where the configured cascades were joined, use the `show` **`vpex topology`** `{` **`port`** *`port_num`*`}` `{`**`summary`** `|` **`detail`**`}` command, and see where the dynamically created cascade ports ("d" flag) start on the cascade(s).

4. Configure the new BPE using the procedure in Manually Configuring Bridge Port Extenders on page 348 starting with step 3 on page 348.

Configuring a new VPEX port/slot in a ring destroys the ring, and changes the configured cascades that formed it. For the new cascades, one ends where the new slot/BPE was added and the other ends at the next BPE that is connected to the cascade with the new slot/BPE.

Removing Bridge Port Extenders from Cascades

You can permanently remove bridge port extenders (BPEs) from existing Extended Edge Switching cascades.

To remove a BPE:

1. Unconfigure the BPE to be removed, and all BPEs below the location of that BPE in the cascade starting from the bottom, and then moving up, using the command:
   `unconfigure` **`vpex ports`** *`port_list`* **`slot`**
2. Disconnect the desired BPE, and then re-cable the remaining BPEs as needed.
3. Re-configure all of the previously unconfigured BPEs, except for the removed BPE, starting from the top, and then moving down, using the procedure in Manually Configuring Bridge Port Extenders on page 348 starting with step 3 on page 348.
4. Unconfigure the removed BPE's slot assignment using the following command:
   `unconfigure slot` *`slot`*

To see an example of removing a BPE from a cascade, see Removing Bridge Port Extender from a Cascade Example on page 364.

Removing Bridge Port Extenders from Rings

You can permanently remove bridge port extenders (BPEs) from existing Extended Edge Switching rings.

To remove a BPE:

1. Disconnect both connections for the BPE. The ring enters the severed state.
2. Connect the two disconnected ports together. The ring does not re-form at this time.
3. Unconfigure the removed BPEs from the topology using the procedure in Removing Bridge Port Extenders from Slot Assignments on page 353.
   Configuring a new VPEX port/slot in a ring destroys the ring, and changes the configured cascades that formed it. For the new cascades, one ends where the new slot/BPE was added and the other ends at the next BPE that is connected to the cascade with the new slot/BPE.

Showing Bridge Port Extender Information

Use the following show commands to display information about the VPEX setup.

- To show the status of VPEX mode, and if applicable, switch port to bridge port extender (BPE) slot assignments, use the following command:

  `show vpex`

- To show status information about the BPE attached to the specified cascade ports, use the following command:

  `show` **`vpex ports`** `{`*`ports_list`*`}`

- To show BPE statistics control plane information on an individual per-cascade-port basis, use the following command:

```
show vpex ports {port_list} {statistics} {detail}
```

- To show BPE Edge Control Protocol (ECP) counter information, use the following command:

```
show vpex ports {port_list} ecp statistics
```

- To show attached BPE's cascade port, slot assignment number, and MAC addresses, use the following command:

```
show vpex bpe
```

- To show power supply, temperature, and fan status for BPEs, use the following command:

```
show vpex bpe {slot slot_num} {environment}
```

- To show general BPE control plane statistics, use the following command:

```
show vpex bpe {slot slot_num} {statistics} {detail}
```

- To show CPU utilization information for BPEs, use the command:

```
show vpex bpe {slot slot_num} cpu-utilization
```

- To show detailed image version information for BPEs, use the command:

```
show vpex bpe { slot slot_num} version detail
```

- To show a BPE's name, use the following command:

```
show slot {slot {detail} | detail }
```

- To show information about the Port Extension TLV, use the command:

```
show lldp {port [all | port_list]} neighbors {detailed}
```

- To show status and interconnection details of attached BPEs, use the command:

```
show vpex topology { port port_num} {summary | detail}
```

Taking a Bridge Port Extender Offline

You can take a bridge port extender (BPE) offline if needed. Note that in a cascade, disabling a cascade port takes the directly attached BPE offline with any downstream attached BPEs. When a BPE is taken offline, its extended ports go into a link down state.

In a cascade, to take a BPE offline, use the following command specifying the cascade port that the BPE is attached to in *port_list* (do not use the **all** option):

```
disable port [port_list | all]
```

> **Note**
> If the cascade port is part of a LAG, you must disable all ports in the LAG.

With a ring, disabling only the cascade or upstream port on a BPE results in a ring failover, so the BPE is not taken offline if only one connection is disabled. You must

disable all ports that can connect the BPE back to the controlling bridge (CB). Also, if there are load sharing groups connecting the BPE to another BPE or CB, all ports in that group must be disabled just to sever one of the connections.

Rebooting VPEX

Under normal circumstances, it is not necessary to reboot the BPEs slots. After rebooting a controlling switch, BPE upstream port down events cause the BPE's software to bring down all extended ports. This makes the BPE slot appear as down to any adjacently attached devices, and traffic properly re-converges on any redundant paths. When the controlling bridge switch comes back up, the BPE comes back up without any intervention. Therefore, using the commands `reboot` or `unconfigure` `switch` {**all** | **erase** [**all** | **nvram**]} does not reboot the attached BPEs. To reboot attached BPEs, you must use the **all** option.

To reboot *all* attached BPEs, use the following command specifying the **all** option:

`reboot {[`**time** *mon day year hour min sec*`] |` **cancel**`} {`**slot** *slot-number*`}` `|` **node-address** *node-address* `|` **stack-topology** {**as-standby**`} |` **all**`} |` **rolling**`}`

To reboot a *single* BPE, use the preceding command, specifying the BPE's slot in *slot-number*.

Configuration Examples

Full Automation Configuration Example

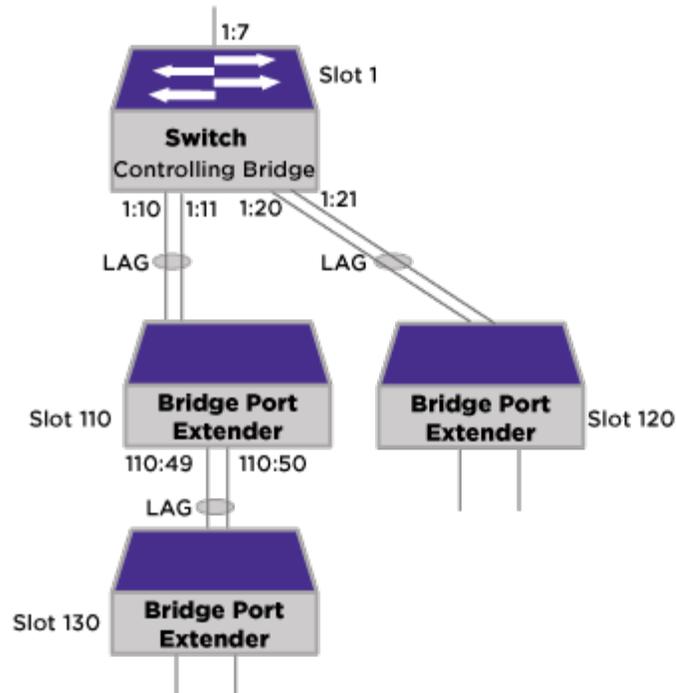
The following example shows how to use full automation (see Configuring Extended Edge Switching Topology with Full Automation on page 344) to set up a controlling bridge (CB) with three attached bridge port extenders (BPEs) in a two-tier structure (see Figure 42 on page 361).


Figure 40: CB with Two-Tier BPEs Topology

1. Attach BPEs.
2. Check for the presence `default.xsf`:

```
# ls /usr/local/cfg
drwxrwxrwx    2 root      root          1024 Apr 10 15:01 cc_logs
drw-r--r--    2 root      root          1024 Dec  4 17:43 lost+found
-rw-r--r--    1 admin     admin       442088 Apr 29 18:05 primary.cfg
-rw-r--r--    1 admin     admin       451011 Mar 14 13:27 primary_nonslotted.cfg
-rw-r--r--    1 admin     admin      1256747 Feb 26 05:24 primary_slotted.cfg
drw-r--r--    4 root      root          1024 Feb 26 05:23 ssl
drwxr-xr-x    2 root      root          1024 May 22 14:58 vmt
```

3. Remove CB configuration:

```
# unconfigure switch all
Restore all factory defaults and reboot? (y/N) Y
```

When the CB finishes rebooting, connected BPEs, extended slots, and LAGs on cascade ports are automatically configured.

4. Apply Layer 2 configuration:

> **Note**
>
> Due to unconfiguring the switch, a series of questions appear to apply the desired level of security configuration. Respond to the prompts as desired. For more information, see Using Safe Defaults Mode on page 50.

```
# configure vlan Default delete port all
# create vlan v100 tag 100
# configure vlan v100 add port 130:1-2, 120:1-2, 1:7 tagged
```

5. If required, you can use standard show commands to troubleshoot the network from the CB using the counters:

```
# show port 130:49-50, 120:49-50, 1:7 statistics no-refresh
Port   Link  Tx Pkt    Tx Byte    Rx Pkt    Rx Byte  Rx Pkt Rx Pkt  Tx Pkt Tx Pkt
       State Count       Count      Count      Count   Bcast  Mcast   Bcast  Mcast

```

Partial Automation Configuration Example

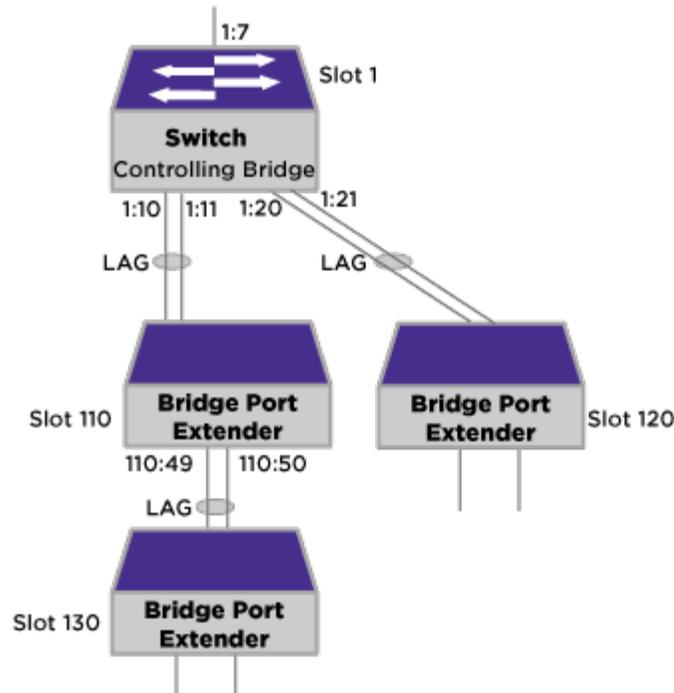
The following example shows how to use partial automation (see Configuring Extended Edge Switching Topology with Partial Automation (Auto-configuration) on page 346) to set up a controlling bridge (CB) with three attached bridge port extenders (BPEs) in a two-tier structure (see Figure 42 on page 361).


Figure 41: CB with Two-Tier BPEs Topology

1. Attach BPEs.
2. On the CB, enable VPEX mode:

```
465.1 # enable vpex
465.1 # reboot
Are you sure you want to reboot the switch? (y/N) Yes
Slot-1 VPEX 465.1 #
```

> 📋 **Note**
>
> After reboot, command prompt changes to show that you are in VPEX mode.

3. Enable auto-configuration:

```
Slot-1 VPEX 465.1 # enable vpex auto-configuration
VPEX Auto-Configuration is enabled for non-MLAG configuration.
```

4. Reboot the CB:

```
Slot-1 VPEX 465.1 # reboot
```

When the CB finishes rebooting, connected BPEs, extended slots, and LAGs on cascade ports are automatically configured.

5. Apply Layer 2 configuration:

```
Slot-1 VPEX 465.1 # configure vlan Default delete port all
Slot-1 VPEX 465.2 # create vlan v100 tag 100
Slot-1 VPEX 465.3 # configure vlan v100 add port 130:1-2, 120:1-2, 1:7 tagged
```

6. If required, you can use standard show commands to troubleshoot the network from the CB using the counters:

```
Slot-1 VPEX 465.3 # show port 130:49-50, 120:49-50, 1:7 statistics no-refresh
Port    Link   Tx Pkt     Tx Byte     Rx Pkt     Rx Byte   Rx Pkt Rx Pkt   Tx Pkt Tx Pkt
```

```
         State  Count        Count      Count       Count    Bcast  Mcast   Bcast   Mcast
======  =====  =======  ==========  =========  ==========  =======  ======  =======  ======

```

Manual Configuration Example

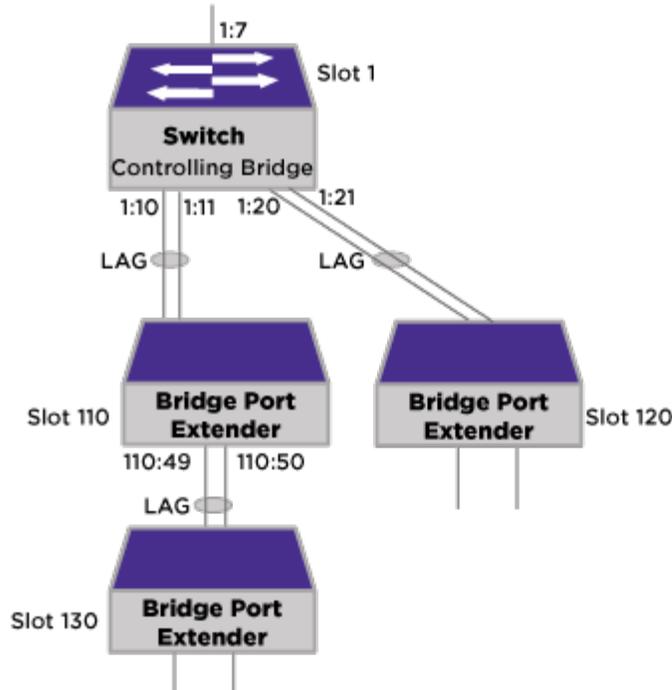
The following example shows how to manually set up a controlling bridge (CB) with three attached bridge port extenders (BPEs) in a two-tier structure (see Figure 42).


Figure 42: CB with Two-Tier BPEs Topology

1. Attach BPEs.

2. On the CB, enable VPEX mode:

```
X465.1 # enable vpex
X465.1 # reboot
Are you sure you want to reboot the switch? (y/N) Yes
Slot-1 VPEX X465.1 #
```

> **Note**
> After reboot, command prompt changes to show that you are in VPEX mode.

3. Create LAGs between CB and first-tier BPEs:

```
Slot-1 VPEX X465.1 # enable sharing 1:10 group 1:10-1:11 lacp
Slot-1 VPEX X465.2 # enable sharing 1:20 group 1:20-1:21 lacp
```

4. Configure slot identifiers associated with the first-tier BPEs:

```
Slot-1 VPEX X465.1 # configure vpex port 1:10 slot 110
WARNING: This command will remove VLAN membership from the
         port 1:10.
         Do you want to continue? (y/N)Yes

Slot-1 VPEX X465.2 # configure vpex port 1:20 slot 120
WARNING: This command will remove VLAN membership from the
         port 1:20.
         Do you want to continue? (y/N)Yes

Slot-1 VPEX X465.3 # show slot
Slots     Type                    Configured          State        Ports   Flags
--------------------------------------------------------------------------------
Slot-1    X465          X465         Operational    64    M
Slot-110 V400-48p-10GE4                                Operational   52
Slot-120 V400-48p-10GE4                                Operational   52
Flags : M - Backplane link to Master is Active
        B - Backplane link to Backup is also Active
        D - Slot Disabled
        I - Insufficient Power (refer to "show power budget")

Slot-1 VPEX X465.9 # show vpex
Virtual Port Extender: Enabled
Cascade
Port     Slot
=============
1:10     110
1:20     120
```

> **Note**
> Observe that the `show slot` command shows the CB as slot 1 with the two BPEs as slots 110 and 120.

> **Note**
> Observe that the `show vpex` command shows that ports 1:10 and 1:20 are the cascade ports connecting to the BPEs.

5. Create LAG between first-tier and second-tier BPEs:

```
Slot-1 VPEX X465.1 # enable sharing 110:49 group 110:49, 110:50 lacp
```

6. Configure slot identifier associated with the second-tier BPE:

```
Slot-1 VPEX X465.1 # configure vpex port 110:49 slot 130
WARNING: This command will remove VLAN membership from the
```

```
            port 110:49.
            Do you want to continue? (y/N)Yes

Slot-1 VPEX X465.3 # show slot
Slots     Type                Configured        State      Ports   Flags
-------------------------------------------------------------------------------
Slot-1    X465         X465        Operational   64    M
Slot-110 V400-48p-10GE4                          Operational   52
Slot-120 V400-48p-10GE4                          Operational   52
Slot-130 V400-48p-10GE4                          Operational   52
Flags : M - Backplane link to Master is Active
        B - Backplane link to Backup is also Active
        D - Slot Disabled
        I - Insufficient Power (refer to "show power budget")

Slot-1 VPEX X465.9 # show vpex
Virtual Port Extender: Enabled
Cascade
Port     Slot
=============
1:10     110
1:20     120
110:49   130
```

7. Apply Layer 2 configuration:

```
Slot-1 VPEX X465.1 # configure vlan Default delete port all
Slot-1 VPEX X465.2 # create vlan v100 tag 100
Slot-1 VPEX X465.3 # configure vlan v100 add port 130:1-2, 120:1-2, 1:7 tagged
```

8. If required, you can use standard show commands to troubleshoot the network from the CB using the counters:

```
Slot-1 VPEX X465.3 # show port 130:49-50, 120:49-50, 1:7 statistics no-refresh
Port   Link  Tx Pkt     Tx Byte     Rx Pkt     Rx Byte    Rx Pkt Rx Pkt Tx Pkt Tx Pkt
       State Count       Count       Count       Count     Bcast  Mcast  Bcast  Mcast
====== ===== ======= ========== ========= ========== ======= ====== ======= ======
130:1  A    97045942 6209457963         0          0       0      0       0      35
130:2  R           0          0         0          0       0      0       0       0
120:1  A          36       4715  97001731 6206623104       0      0       0      35
120:2  A    95802538 6897726741  95784987 7279063658       0    512       0     697
1:7    A    97045942       4715  97001731 6206623104       0      0       0       0

130:50          0        0          0          0          0          0          0          0
120:49          0        0          0          0          0          0          0         45
120:50  119803233        0          0          0          0          0          0        923
1:7     119803233        0          0          0          0          0          0        923
```

Removing Bridge Port Extender from a Cascade Example

The following example shows how to remove a bridge port extender (BPE) from a cascade.

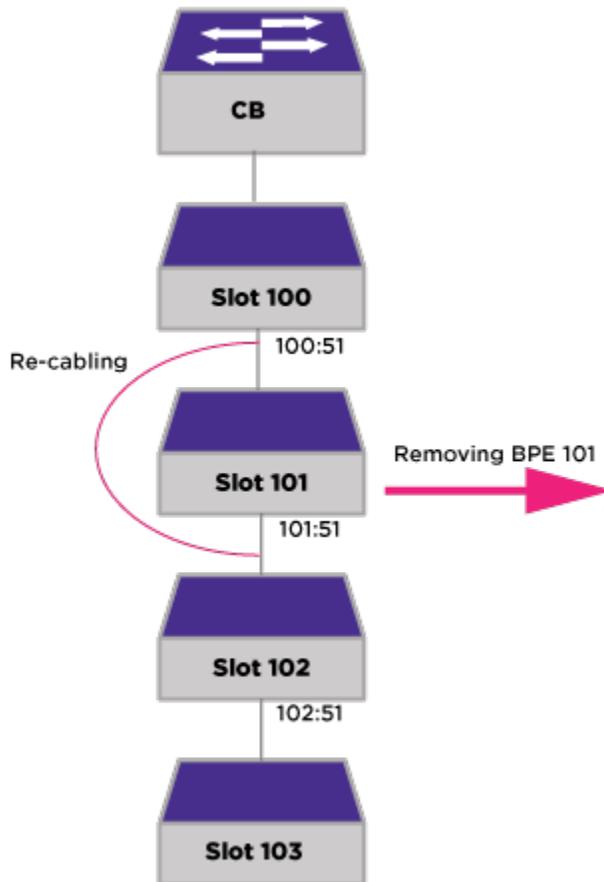
This example removes the BPE at slot 101 in a four-tier cascade and connects the BPE at slot 100 to the BPE at slot 102 (see Figure 43).


Figure 43: Removing BPE from Cascade

1. Unconfigure the bottom BPE:

   ```
   # unconfigure vpex port 102:51 slot
   ```

2. Unconfigure the next BPE from the bottom:

   ```
   # unconfigure vpex port 101:51 slot
   ```

3. Unconfigure the BPE being removed:

   ```
   # unconfigure vpex port 100:51 slot
   ```

4. Disconnect BPE 101, and connect BPE 100 to BPE 102.

5. Re-configure the BPE at slot 100:

   ```
   # configure vpex port 100:51 slot 102
   ```

6. Re-configure the BPE at slot 102:

   ```
   # configure vpex port 102:51 slot 103
   ```

7. Remove the slot assignment (101) from the removed BPE:

```
# unconfigure slot 101
```

Redundant Controlling Bridges Configuration Example

The following example shows how to use full automation, partial automation, or manual configuration to set up a redundant controlling bridge (CB) topology with three attached bridge port extenders (BPEs) in a two-tier structure (see Figure 44).

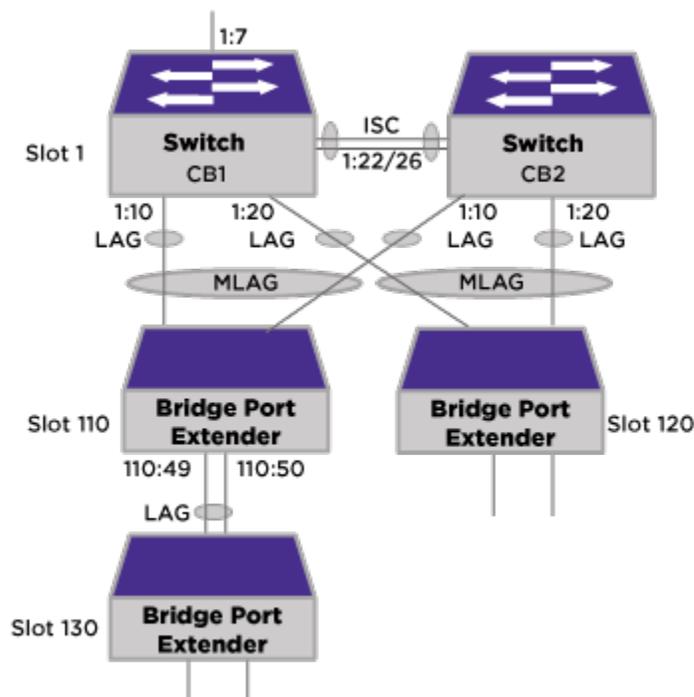
For more information about redundant CBs, see Redundant Controlling Bridges on page 326.


Figure 44: Redundant CBs with Two-Tier BPEs Topology

1. Connect the CBs.
2. Decide whether to use full or partial automation, or manual setup to configure the Extended Edge Switching topology:

   • For full automation, go to Full Automation Configuration Example on page 357.
   • For partial automation, go to Partial Automation Configuration Example on page 359.
   • For manual setup, continue with the rest of this procedure.

3. Create the peer relationship between the CBs on CB1:

```
enable sharing 1:22 group 1:22,1:26 lacp
create vlan isc tag 100
configure isc ipaddress 1.1.1.1/24
configure isc add port 1:22 tagged
```

```
create mlag peer vpex_peer
configure mlag peer vpex_peer ipaddress 1.1.1.2
```

4. Create the peer relationship between the CBs on CB2:

```
enable sharing 1:22 group 1:22,1:26 lacp
create vlan isc tag 100
configure isc ipaddress 1.1.1.2/24
configure isc add port 1:22 tagged
create mlag peer vpex_peer
configure mlag peer vpex_peer ipaddress 1.1.1.1
```

5. Start MLAG orchestration on CB1:

```
start orchestration mlag vpex_peer
```

📋 **Note**
The CLI prompt changes to inform you that you are in orchestration mode.

Using orchestration mode enforces that all configuration commands are now checkpointed to the MLAG peer switch.

6. Create LAGs between CB and first-tier BPEs by substituting the following commands in step 3:

```
Slot-1 VPEX X465.1 # enable sharing 1:10 group 1:10 lacp
Slot-1 VPEX X465.2 # enable sharing 1:20 group 1:20 lacp
```

7. Set up the rest of the MLAG by executing the commands in the Manual Configuration Example on page 361, inserting the following commands between step 2 and 3:

```
enable mlag port 1:10 peer vpex_peer id 101
enable mlag port 1:20 peer vpex_peer id 102
```

When LACP shared ports are configured as MLAG ports, a LAG ID change after MLAG peer reboot may result in MLAG ports being removed and re-added to the aggregator.

8. To avoid the MLAG port flap, configure a common LACP MAC in both MLAG peers:

```
configure mlag peer peer_name lacp-mac lacp_mac_address
```

If the ISC port belongs to a higher port number and the MLAG port comes up before the ISC port on reboot/failover, then it might create a short loop.

9. To avoid the short loop, configure the reload delay timer for the MLAG ports to bring up the MLAG port with some delay:

```
configure mlag ports reload-delay <time>
enable mlag port reload-delay
```

The ISC port now comes up before MLAG port:

10. Enable MLAG port isolation to prevent packet forwarding over the ISC before the blocking filters are installed:

```
configure mlag ports link-up-isolation on
```

For MLAG best practices with VPEX, see the following article: *MLAG best practices with VPEX*

Simple Ring Configuration Example

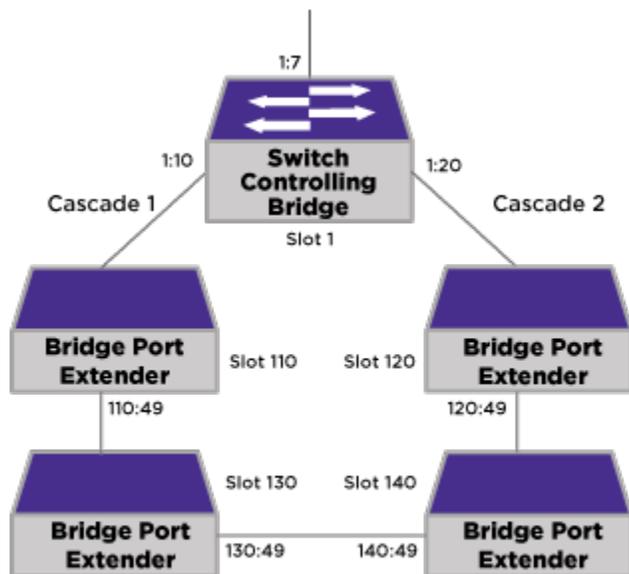
The following example shows how to set up a simple Extended Edge Switching ring configuration (see Figure 45).


Figure 45: CB with Simple Ring Topology

1. Attach BPEs.
2. On the CB, enable VPEX mode:

```
X465.1 # enable vpex
X465.1 # reboot
Are you sure you want to reboot the switch? (y/N) Yes
Slot-1 VPEX X465.1 #
```

> **Note**
> After reboot, command prompt changes to show that you are in VPEX mode.

3. Configure slot identifiers associated with the first-tier BPEs in cascades 1 and 2:

```
Slot-1 VPEX X465.1 # configure vpex port 1:10 slot 110
WARNING: This command will remove VLAN membership from the
         port 1:10.
         Do you want to continue? (y/N)Yes

Slot-1 VPEX X465.2 # configure vpex port 1:20 slot 120
WARNING: This command will remove VLAN membership from the
         port 1:20.
         Do you want to continue? (y/N)Yes

Slot-1 VPEX X465.3 # show slot
Slots    Type                 Configured          State      Ports  Flags
-----------------------------------------------------------------------------
```

```
Slot-1   X465          X465          Operational   64   M
Slot-110 V400-48p-10GE4                            Operational   52
Slot-120 V400-48p-10GE4                            Operational   52
Flags : M - Backplane link to Master is Active
        B - Backplane link to Backup is also Active
        D - Slot Disabled
        I - Insufficient Power (refer to "show power budget")

Slot-1 VPEX X465.9 # show vpex
Virtual Port Extender: Enabled
Cascade
Port     Slot
=============
1:10     110
1:20     120
```

> **Note**
>
> Observe that the `show slot` command shows the CB as slot 1 with the two BPEs as slots 110 and 120.

> **Note**
>
> Observe that the `show vpex` command shows that ports 1:10 and 1:20 are the cascade ports connecting to the BPEs.

4. Configure slot identifiers associated with the second-tier BPEs in cascades 1 and 2:

```
Slot-1 VPEX X465.1 # configure vpex port 110:49 slot 130
WARNING: This command will remove VLAN membership from the
        port 110:49.
         Do you want to continue? (y/N)Yes

Slot-1 VPEX X465.2 # configure vpex port 120:49 slot 140
WARNING: This command will remove VLAN membership from the
        port 120:49.
         Do you want to continue? (y/N)Yes

Slot-1 VPEX X465.3 # show slot
Slots    Type                  Configured        State       Ports   Flags
--------------------------------------------------------------------------------
Slot-1   X465          X465          Operational   64   M
Slot-110 V400-48p-10GE4                            Operational   52
Slot-120 V400-48p-10GE4                            Operational   52
Slot-130 V400-48p-10GE4                            Operational   52
Slot-140 V400-48p-10GE4                            Operational   52
Flags : M - Backplane link to Master is Active
        B - Backplane link to Backup is also Active
        D - Slot Disabled
        I - Insufficient Power (refer to "show power budget")

Slot-1 VPEX X465.9 # show vpex
Virtual Port Extender: Enabled
Cascade
Port     Slot
=============
1:10     110
1:20     120
```

```
110:49   130
120:49   140
```

> **Note**
> Observe that the `show slot` command shows the CB as slot 1 with the four BPEs as slots 110, 120, 130, and 140.

> **Note**
> Observe that the `show vpex` command shows that ports 1:10, 1:20, 110:49, and 120:49 are the cascade ports connecting to the BPEs.

5. Connect the end of cascade 1 to cascade 2 to form the ring:

```
<Noti:VPEX.Ring.Dtect> Slot-1: Ring detected between ports 140:49 and 130:49
```

Upgrading the Controlling Bridge and Bridge Ports Extenders

Periodically, there will be software upgrades for the controlling bridge (CB) and bridge ports extenders (BPEs).

The CBs run ExtremeXOS software, while the BPEs run VPEX software that is either packaged with the ExtremeXOS software or provided as a separate modification file. The different image files are distinguishable by their file extension:

- .xos—ExtremeXOS CB-only image file (example: SummitX-22.6.0.19.xos).
- .xmod—ExtremeXOS modification file with VPEX software for the BPEs (example: SummitX-22.6.0.19-vpex-bpe-1.1.0.41.xmod).

> **Note**
> Starting with ExtremeXOS 30.2, the diagnostic image is in a separate xmod file (example: onie-30.2.2.x-vpex_bpe_diag-1.0.0.1.xmod) that is not included in the regular BPE xmod or combined list files, but is installed on the BPE at the factory. We anticipate that you will not generally need to update this image.

- .lst—Combined ExtremeXOS CB software and VPEX BPE file (example: summitX-22.6.0.19-vpex_controlling_bridge.lst).

For complete information about how to perform a software upgrade, see the Software Upgrade and Boot Options on page 1958 chapter.

There are two methods for upgrading BPEs:

- **Automatic**—The advantage of automatically upgrading BPEs is that it is easier than manual upgrading, and does not require manual intervention.
- **Manual**—You can upgrade devices individually at a time of your choosing. The disadvantage is that you must initiate the upgrade manually on each CB and BPE.

Automatic Upgrading

Upgrading automatically uses .lst files, so that the CB and BPEs are upgraded together to ensure that all hardware is up-to-date.

When the upgrade is performed, the CB is upgraded (requires a reboot), and when the BPE boots up, it performs a version check. If the BPE image is up-to-date, the BPE progresses to the operational state. However, if the BPE image needs to be upgraded, the BPE retrieves the software image file from the CB, upgrades itself, and then reboots.

Starting with ExtremeXOS 30.5, an improved version of automatic upgrading is available for MLAG/redundant CB configurations. You can reboot each CB sequentially, rather than rebooting both simultaneously, avoiding the loss of network connectivity. To use automatic upgrading, ensure that:

- Both CBs are running the same ExtremeXOS and BPE xmod version.
- ISC connectivity is present (required for information exchange between CBs during upgrade).

1. Ensure that automatic upgrading is enabled (default behavior). Use the `show vpex` command to see if automatic upgrading is enabled. If not enabled, use the `enable` **`vpex auto-upgrade`** command to enable it.
2. On the first CB, install the .lst image. After installation, reboot the first CB.
3. After the first CB has finished rebooting and has synchronized all of the slot and ring information, on the second CB, install the.lst image, and then reboot it.

> **Note**
>
> If you do not have automatic upgrading enabled when using redundant CBs, and a BPE image upgrade is needed, you must reboot both CBs simultaneously. Simultaneous reboot is required because sequential rebooting (waiting for each to come fully operational before proceeding to reboot the other) maintains BPE connectivity. Because the BPE does not re-attach, it is not upgraded if needed.

After an upgrade occurs, the log shows messages similar to the following indicating that the BPE has been upgraded:

```
08/04/2017 17:57:25.69 <Info:HAL.Card.Info> Slot-1: VPEX BPE slot 100 Active image VER
1.1.0.41
08/04/2017 17:53:44.52 <Info:HAL.Card.Info> Slot-1: Upgrading VPEX BPE slot 110 image
from ver 1.1.0.40 to 1.1.0.41
08/04/2017 17:53:43.70 <Info:HAL.Card.Info> Slot-1: VPEX BPE slot 120 Active image VER
1.1.0.40
```

Manual Upgrading

For manual upgrading, you update each CB and BPE image individually in a "rolling" fashion.

To manually upgrade:

1. Upgrade ExtremeXOS on your first CB using .xos image file (install image, and then reboot); do not install xmod.
2. For redundant CB topologies, repeat 1 for each redundant CB.

3. Install the xmod on each CB, and then reboot each BPE one at a time, using `reboot slot` *BPE slot* on the master CB, allowing the upgrade and initialization to complete for each BPE before proceeding to the next.

> **Note**
> To determine which CB is the master, use the `show` **vpex ports** *{ports_list}* command. The switch with the M flag is the master CB.

> **Note**
> Rebooting a BPE tears down the connection to any additional BPEs that are cascaded from that BPE, so proper redundancy planning is required.

BGP Auto-peering

Auto-peering Introduction

Auto-peering is a network of cooperating interconnected devices that create an AutoBGP for any topology, providing fully redundant, multipath routing. The fabric grows dynamically and freely, not bound to any well-known topology such as Clos or Leaf/Spine.

Auto-peering nodes build a secure network by running the very scalable Border Gateway Protocol (BGP) to exchange topology and host information about IP networks. It uses IPv6 as the network layer to transport IPv4 and IPv6 traffic.

Any device connecting to an auto-peering device is an attachment point to the network. This network provides the underlay for services such as *VXLAN (Virtual Extensible LAN)*, policy, VRF, and Fabric Attach. The AutoBGP device applies policy rules as it discovers external devices. These devices can be any IP host, LAG-attached servers and bridges, or gateway routers. By default, auto-peering allows connectivity for all attached hosts, allowing for a controller-less operation. However, interconnection (trunk ports) between fabric nodes should not be LAG ports; you should not enable port sharing on trunk ports.

Auto-peering uses a combination of the Link Layer Discovery Protocol (LLDP) and external BGP over an IPv6 Transport Layer to create the network. Auto-peering uses LLDP to discover surrounding nodes and the node's capabilities. LLDP is extended to advertise networking capabilities.

ExtremeXOS 31.1 introduces explicit CLI commands to configure OneConfig, which allows for ExtremeCloud IQ support for BGP Auto-peering (see Configuring BGP Auto-peering on page 383).

BGP Auto-peering Feature Description

> **Note**
> BGP auto-peering relies on a default STPD instance "s0" to resolve loops on the default VLAN.

> **Note**
> Auto-peering automatically creates VLANs dynamically when using the `create auto-peering` **`bgp routerid`** `ipaddress` **`AS-number`** `asNumber` command.

> **Note**
> The command `create auto-peering` **`bgp routerid`** `ipaddress` **`AS-number`** `asNumber` uses eBGP adjacencies. The AS number should be different for all devices participating in the network.

After executing the command `create auto-peering` **`bgp routerid`** `ipaddress` **`AS-number`** `asNumber` , the following series of events occurs, setting up the auto-peering:

1. AutoBGP capability is advertised out all ports by LLDP automatically. AutoBGP gets its configuration using cloud connector through Zero Touch Provisioning. A Python script initiates default VLAN and BGP configuration that is needed for AutoBGP.
2. When an AutoBGP-capable neighbor is detected out a port, LLDP notifies the AutoBGP manager.
3. The AutoBGP manager assigns the LLDP-learned port to one of the VLANs within its configured range and notifies VLAN manager. DHCP Relay is enabled on this VLAN.
4. AutoBGP informs LLDP of the IPv6 link-local address configured on that VLAN along with the BGP router ID and AS number.
5. LLDP sends the AutoBGP information (IPv6 link-local, router ID, and AS number) to the remote neighbor and learns the remote neighbor information and then send this to the AutoBGP manager.
6. The AutoBGP manager creates an AutoBGP route to the learned remote router ID in route manager.
7. The AutoBGP manager creates and enables the BGP neighbor.
8. The AutoBGP is formed and host route updates occur allowing end-to-end connectivity.
9. MBGP capability to carry VXLAN information is automatically enabled on each BGP peer when AutoBGP is enabled. In addition BGP is registered as a client of the Overlay Tunnel Manager (OTM), which maintains VNI/LTEP information.
10. The MBGP IPv4-VXLAN capability is used to advertise the Assisted Replication role if it is configured as "Replicator" or "Leaf".

11. The MBGP L2VPN-EVPN capability is automatically enabled to allow auto-peers to advertise and accept EVPN routes.
12. VXLAN tunnels are automatically programmed into OTM when EVPN routes are received containing a VNI and RTEP that is the BGP next-hop.

IP Multicast Forwarding (PIM-DM)

IP Multicast traffic within the BGP auto-peering network is forwarded using PIM-Dense Mode (PIM-DM) configured on ExtremeXOS devices. BGP auto-peering automatically enables PIM-DM globally for IPv4 and IPv6, as well as on each VLAN interface. Access VLANS must be configured and IPMC forwarding should be enabled to enable PIM-DM.

IPv4 Multicast sources and receivers from the access side are switched in the cloud. AutoBGP VLANs have only v6 interfaces, so PIM-DM is enabled in v6 mode on the network side. IPv6 network interfaces are added to the egress list of IPv4 cache entries so that IPv4 traffic reaches auto-peering devices. PIM-DM works on flood and prune mechanism so interfaces that have v6 and v4 neighbors or IGMP group joins receive the multicast traffic. IPv6 PIM-enabled interfaces process the IPv4 Multicast traffic and replicate it to the Multicast-enabled outgoing interfaces.

All the PIM-DM functionalities are supported in the auto-peering cloud:

- IPv4 cache miss on IPv6 interfaces
- Switching IPv4 Multicast traffic to IPv6 auto-peering interfaces
- MLD snooping
- PIM-DM join/prune, assert, graft, graft ACK
- PIM-DM state refresh
- ECMP (load splitting)

Auto-peering Connection with PIM-Spare Mode (SM) Domain

PIM-DM is able to connect with PIM-SM domains present outside of the auto-peering network. ExtremeXOS creates (*,*,RP) cache entries to pull the traffic from the SM domain to the auto-peering domain. The auto-peering network then applies dense behavior to the incoming Multicast traffic. Traffic originating from Dense Mode is carried until it meets a Multicast border router (MBR) node where both auto-peering and PIM-SM interfaces are present. PIM-SM becomes the first-hop router (FHR) for the incoming stream and generates a register message to RP.

Auto-peering Connection with PIM-DM Domain

PIM-DM interfaces switch and receive Multicast streams with non-auto-peering DM interfaces.

Existing PIM-SM Domains within the Auto-peering Network

SM and DM domains cannot overlap within the auto-peering network. Since auto-peering interfaces are configured with DM, existing SM configuration may not function as expected.

Limitations

- Slow path forwarding of IP Multicast traffic within an BGP auto-peering network is not supported.
- Avoiding "loss of first packet" of IP Multicast is not supported.
- PIM should be enabled on all the auto-peering devices, so PIM snooping is not recommended.
- PIM-SM and SSM modes are not supported within the auto-peering network.

External Router Support

A leaf node may support *OSPF (Open Shortest Path First)*v2 and *BGP (Border Gateway Protocol)* to function as a border leaf gateway. This node must be configured using the CLI to ensure the correct router ID and AS number is applied so that it interoperates with neighboring BGP or OSPFv2 non-auto-peering nodes.

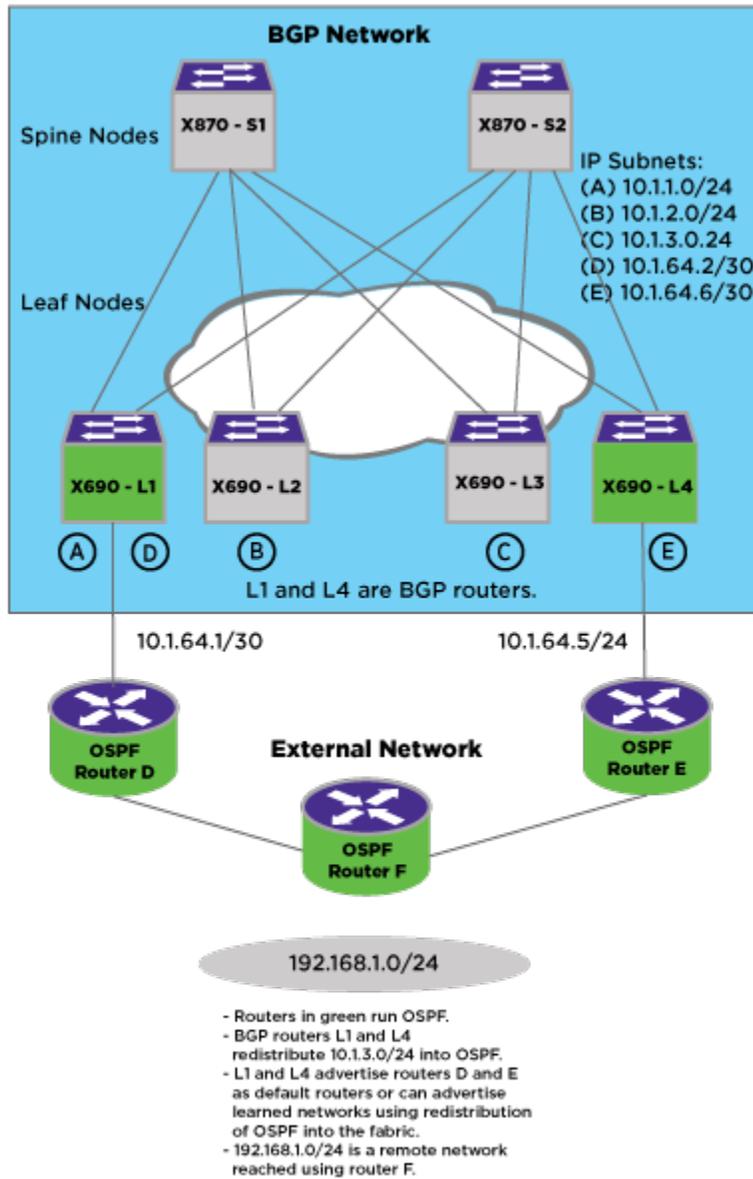
The protocols Intermediate System to Intermediate System (ISIS) and *RIP (Routing Information Protocol)* are not supported.


Figure 46: BGP Auto-peering with OSPF

BGP Auto-peering Plug-and-Play Redundancy

BGP auto-peering allows for devices to redundantly connect with network devices in any manner. EasyLAG, an active/standby service, is the default redundancy feature, which allows a LAG-connected device to attach to the network (see AutoBGP LAG Active/Standby Mode on page 377).

AutoBGP LAG Active/Standby Mode

For each Link Aggregation Control Protocol (LACP)-attached port, information on the port is distributed through the auto-peering network using a proprietary Border Gateway Protocol (BGP)-based mechanism. It uses the private AFI/SAFI to propagate the Ethernet segment ID and remote router ID as next hop.

This information is used, with a deterministic mechanism (lowest router ID), by a switch to place its port in standby mode. Standby mode means "Oper Status Down," and link down. If the active port goes down, the switch in the standby mode detects this using the same BGP mechanism, and makes its port active. Packets are reflected until BGP convergence of Ethernet segment ID to participating nodes.

For each attached client, only one attached port per switch is allowed. By default, after enabling auto-peering, each switch automatically supports creation of LAGs on all edge (client) ports, and prevents creation of LAGs on all auto-peering ports.

After BGP auto-peering is enabled on a switch (`create auto-peering` **`bgp routerid`** `ipaddress` **`AS-number`** `asNumber`), the equivalent of the following configuration is enacted for every Ethernet port (X) on the switch:

```
enable sharing X grouping X lacp
configure sharing X lacp fallback enable
configure sharing X lacp fallback timeout 1
```

This allows a LAG to come up on LAG-capable attached devices, and to have the port become a forwarding bridge port in one second if attached to a non-LAG capable (or LAG is disabled) device. If the attached device later becomes able to support LAG, LAG automatically comes up. In the same manner, as manually executing the commands, this produces a persistent state, and the commands appear in the configuration. This configuration persists after reboots.

If auto-peering is disabled on a switch, the equivalent of the following command is automatically executed:

```
disable sharing X
```

Routing through the Underlay (VXLAN and AutoBGP Networks)

It is valuable to provide a shortcut IPv4 routing service directly over the underlay and avoiding using an external router to perform the same function, and thereby reducing traffic "trombone" effect.

The following are possible scenarios:

- Attachment devices such as routers, firewalls, and servers that are connected on _VLAN (Virtual LAN)_s without a _VXLAN_ enabled.

  Currently, the ingress fabric router responds to all _ARP (Address Resolution Protocol)_s regardless of target IP address. This is sometimes called "local proxy ARP" and is disabled on VXLAN interfaces. Local proxy is a valid setting with non-VXLAN VLANs and fabric routing.

- IP hosts attached to a VLAN associated with a VXLAN and having a VNI. They are directly routed at the ingress switch with no VTEP encapsulation if the packet has a

DMAC equal to VMAC as explained below and the destination host is in the routing table.

Normally, a host uses ARP for its default gateway when it must reach a destination that does not match its own network/subnet. A receiving auto-peering router responds with its virtual MAC for any ARP request whose target IP address matches its configured IP address, and if the source IP address is of the same subnet for which it is connected. Subsequent host packets destined to a remote host have a destination MAC address matching the VMAC and are routed directly at the ingress switch without VTEP encapsulation. Packets may be routed locally if any destination host is attached to the same ingress switch, but have a different VNI or in the case where they are connected on VLANs without VXLAN enabled. It is presumed that forwarding routers in the path have reachability to the destination host as they are learned using the _VRRP (Virtual Router Redundancy Protocol)_ host mobility feature (see VRRP Host Mobility on page 1439) and propagated by _BGP_ throughout the network. Any ARP packets not requesting the VIP of the auto-peering node are consumed on the ingress switch by ARP/L2 _FDB (forwarding database)_ and the underlying VXLAN feature. Hence, subsequent packets with non-VMAC match FDB entries and those destinations are sent over VXLAN tunnels.

To allow the feature, configure an IP address and subnet mask and enable IP forwarding on a VLAN associated with a VNI. Enabling IPv6 forwarding should be not permitted, so IPv6 traffic must be tunneled. For ExtermeXOS 22.4 and later, along with the IPv6 restriction, this service is limited to the default VR. If VRF is required, do not use this feature. Additionally, VRRP and host mobility should also be enabled on the VLAN.

VXLAN to Non-VXLAN Routing in a Non-AutoBGP Network

ExtremeXOS 22.4 and later allow the IP Forwarding flag to be set for _VLAN_ interfaces with a _VXLAN_ association for IPv4 traffic. This qualifies any ExtremeSwitching switch that supports VXLAN but does not support routing in-and-out of tunnels (RIOT) (see Routing in and out of Tunnels (RIOT) on page 1026) or IP fabric.

For example, an ExtremeSwitching switch may use VXLAN over an _OSPF_-based underlay. It is possible a remote destination network is learned by OSPF on one of its underlay VLAN interfaces that has no VXLAN association. While the CLI allows this setup, this is not a validated design and is therefore not recommended.

VXLAN to Non-VXLAN Routing in an AutoBGP Network

Consider two pair of ExtremeSwitching switches as leaf nodes connected to two different pair of ExtremeSwitching switches as spine nodes with BGP auto-peering enabled. There is a mix of _VXLAN_ and non-VXLAN _VLAN_s. In this case, all routing is accomplished through VLANs associated with VXLAN having VNIs or through other valid normal routing means and distributed to all auto-peering nodes. This configuration is valid and supported. VRRP and host mobility should be enabled on both VXLAN tenant and non-VXLAN VLANs for this to work.

VXLAN to VXLAN Routing in an AutoBGP Network

Consider hosts A and B that reside within an *BGP* auto-peering domain. Hosts A and B are attached on two different *VXLAN*s: A on VNI 1000 and B on VNI 2000. A connects directly to ExtremeSwitching -leaf1 on VLAN 10 while B connects to ExtremeSwitching -leaf2 on VLAN 20. The switches are connected to two spine switches of a different model using FBRC VLANs 100 and 200, respectively. In this case, all routing is accomplished through VLANs associated with VXLANs having VNIs. This configuration is valid and supported. In ExtremeXOS 22.5 and later, support routing in-and-out of tunnels (RIOT) (see Routing in and out of Tunnels (RIOT) on page 1026) is supported, so underlay routing is not needed in this case.

EVPN and VRF Support

BGP with EVPN carries virtual network identifier (VNI) and source virtual tunnel end point (VTEP) as part of the MP-BGP standard messaging payload, thereby enabling control plane learning of L2 and L3 reachability information for greater scale of *VXLAN* networks. As MAC addresses are learned, they are inserted into the EVPN instance table to be propagated by MP-BGP to all other VTEPS in AutoBGP. Learned MACs addresses using BGP are inserted into the local *FDB* and *ARP* tables associated with the virtual network. This provides robustness to VXLAN networks with a reduced reliance on flooding when combined with ARP suppression. For a description of EVPN control plane protocol, see *RFC 7432*. For a description of VXLAN and network virtualization overlay solution using EVPN, see *RFC draft-ietf-bess-overlay-08*.

EVPN Route Distinguisher and Route Target

A default route distinguisher (RD) per MAC address VRF is auto-assigned per provider edge (PE) as described in Section 7.9 of *RFC 7432*; Type 1 RD format is the PE loopback address, plus 12-bit Ethernet tag—one MAC VRF per Ethernet tag. Auto-derived route target (RT) is type 0 RD formatted as 2 byte AS number, plus 24-bit network services identifier (NSI) as described in Section 5.2.1 of *RFC draft-ietf-bess-overlay-08*. The default 2-byte AS number is 64,716. The RD is of local significance only—every VLAN defined on the node has the same number of MAC VRFs associated with it. For example, two AutoBGP nodes 1.1.1.1 and 2.2.2.2 with each having two untagged VLANS 10 and 20. When AutoBGP node 1.1.1.1 advertises EVPN NLRIs from two MAC VRFs using RDs of 1.1.1.1...10 and 1.1.1.1..20, it is possible that VLAN 10 on 1.1.1.1 is associated with VNI 1000 and on 2.2.2.2 VNI, 1000 is associated with VLAN 20. It is the NSI/VNI that brings the VXLAN together on the overlay and ensures that it is properly represented by the RT.

IP VRF Limitations

The following limitations apply to IP VRF:

- IP VRF route leaking is not supported.
- Route reflection is not supported.
- VRF is not supported for underlay routing.
- Static routes are supported per VRF, but only for external routers that are attached on a tenant VLAN.

Asymmetric Routing

AutoBGP nodes perform asymmetric routing for EVPN type 2 IP/MAC routes that are associated with a local virtual network identifier (VNI). They are installed into the *FDB* and *ARP* tables. They are not installed in the VRF RTM. Locally learned IP hosts using *VRRP* host-mobility may be installed in the VRF RTM. Asymmetric routing requires all VNIs to be created and associated with a VRF on all participating nodes.

Consider an AutoBGP network that supports an "Engineering" VRF consisting of two subnetted VNIs for hosts A through H, and VRFs are created with VNI mappings, using policy or other means. A host is placed into a VLAN on an attachment port of a device which corresponds to a VNI. In order to support asymmetric routing, all virtual networks are created on all nodes even if are no local host IP/MACs are discovered. If there is no VLAN assigned to a VNI, one is chosen and assigned an internal tag. The VLAN is given a loopback designation. If a host is later discovered, that is associated with another VLAN with same the VNI, the new VLAN replaces it and will have no loopback designation. Here, A on L1 routes to H on L4 as A-H are on two different VNIs. There are no local hosts on VNI 20 on L1, in which case, the loopback designation for the internally chosen VLAN enables asymmetric routing to take place. L4 then bridges to H. Troubleshooting can be achieved by looking into the FDBs and ARP tables on each node.

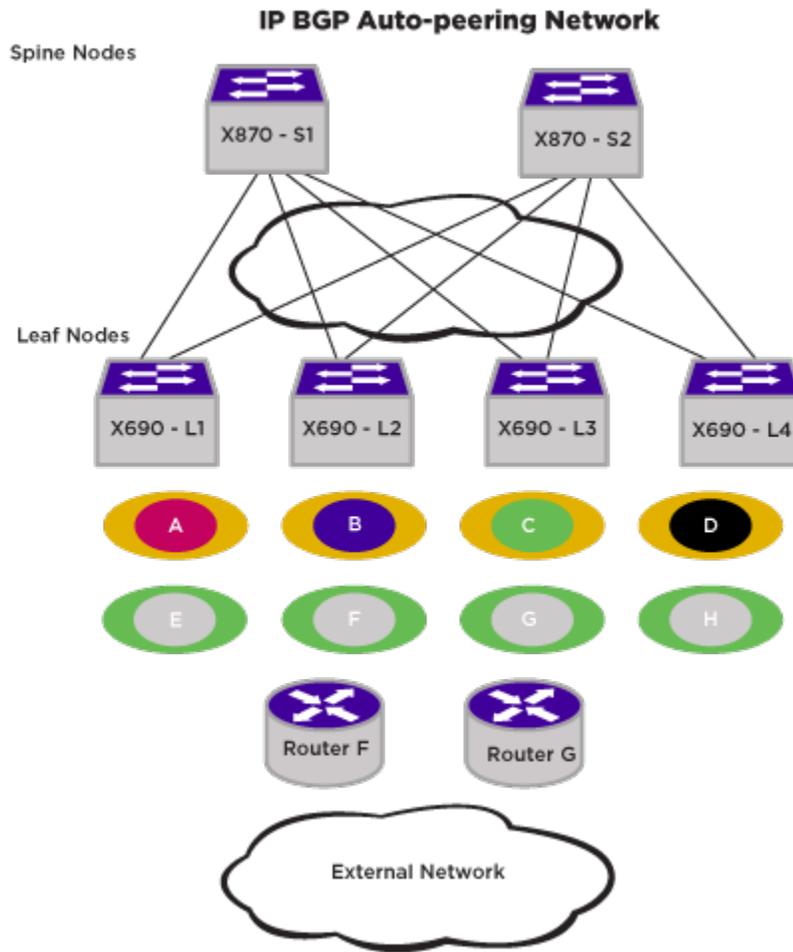

Figure 48: EVPN and Asymmetric VRF Routing in BGP Auto-peering with Routers

Supported Platforms

ExtremeSwitching X465, X590, X695 series switches.

This feature requires the Advanced Edge or Base license. For more information about licenses, see the *ExtremeXOS 32.4 Feature License Requirements*.

BGP Auto-peering Feature Limitations

> **Note**
> BGP and OSPFv2 Auto-peering are mutually exclusive. Only one form of Auto-peering can exist at a time.

The following features are not supported in BGP auto-peering:

- Stacking
- AutoBGP LAG with Extended Edge Switching
- Static LAG attachments to AutoBGP

- AutoBGP links on Extended Edge Switching ports
- MPLS, VPLS, L2VPN, L3VPN
- PIM Snooping, PIM-SM, SSM mode
- OSPF, OSPFv3, ISIS, RIP, RIPNG per VRF
- IPv6 within VRF
- VRF route leaking
- EVPN multi-homing Ethernet segments
- Explicit-remotes mode used for VNET flooding
- AutoBGP MLAG
- EVPN does not interoperate with third-party devices

The following limitations apply:
- Manual configuration of MLAG is supported. One MLAG peer per leaf node.
- Loss of first multicast packet in the flow is expected due to slow path forwarding.
- Static router must be an external router per VRF.
- VLANS spanning multiple bridges, where each bridge is AutoBGP LAG connected, must be VXLAN-based, or AutoBGP LAG replaced with MLAG.
- VLANs behind a bridge that is AutoBGP LAG connected *and* AutoBGP node has same VLAN ports must be VXLAN-based or AutoBGP LAG replaced with MLAG.

Configuring BGP Auto-peering

To create and enable BGP auto-peering, use the command:

```
create auto-peering bgp routerid ipaddress AS-number asNumber
```

To delete BGP auto-peering, use the command:

```
delete auto-peering
```

To show the status of BGP auto-peering and the learned auto-peering interfaces and corresponding remote peer information, use the command:

```
show auto-peering {bgp | ospf}
```

OneConfig Commands

To add dynamic BOOTP relay servers that the DHCP relay agent uses to forward DHCP traffic received from host attachments, use the following command:

```
configure auto-peering one-config bootprelay [add | delete] [ip_address
| ipv6_address] vr vrname
```

To configure a list of OneConfig dynamic Auto-peering static routes, use the following command:

```
configure auto-peering one-config iproute [add | delete] [host | hostv6]
[[ipaddress {netmask} | ipNetmask] gateway | ipNetmaskv6 gatewayv6] {vr
vrname }
```

To specify a list of OneConfig dynamic auto-peering services, use the following command:

```
configure auto-peering one-config nsi-id id type [nsi | vrf] [add |
delete] [[ipaddress {netmask} | ipNetmask ] | ipNetmaskv6] {vr vrname }
```

To configure a list of unique values that identify the remote Auto-peering devices to which this device can also automatically form an adjacency, use the following command:

```
configure auto-peering one-config remote id [add | delete] id {password
[none | {encrypted} tcpPassword]}
```

To configure the auto-peering TCP MD5 password devices will configure in the TCP MD5, use the following command:

```
configure auto-peering one-config password [none | {encrypted}
tcpPassword]
```

To configure the ID used by each device when automatically forming an adjacency with an BGP Auto-peering neighbor, use the following command:

```
configure auto-peering one-config id [none | id]
```

To show auto-peered OneConfig information configured on the device, use the command:

```
show auto-peering one-config {remote | service | route | database |
bootprelay}
```

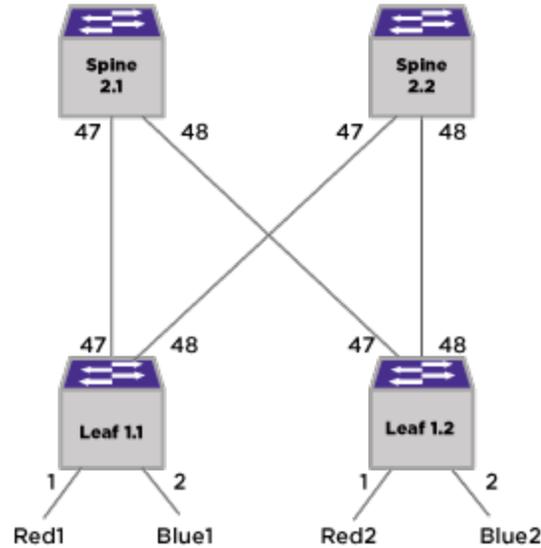
BGP Auto-peering Examples

The following are some examples of BGP auto-peering configurations.

BGP Auto-peering Simple Leaf/Spine Example

The following example shows a simple leaf/spine topology with users on _VLAN_s, red and blue, noted as 1 and 2.

> **Note**
> An Advanced Edge or Base license must be installed on all devices.

Devices labeled with router IDs 10.255.x.y:


Leaf 1

```
configure vlan default delete ports 1-2
create vlan "red" tag 100
configure vlan red add ports 1 untagged
configure vlan "red" ipaddress 10.1.1.1/24
enable ipforwarding vlan "red"

create vrrp vlan "red" vrid 1
configure vrrp vlan "red" vrid 1 priority 255
configure vrrp vlan "red" vrid 1 host-mobility on
configure vrrp vlan "red" vrid 1 add 10.1.1.254
enable vrrp vlan "red" vrid 1

create vlan "blue" tag 200
configure vlan "blue" ipaddress 10.1.2.1/24
configure vlan blue add ports 2 untagged
enable ipforwarding vlan "blue"

create vrrp vlan "blue" vrid 1
configure vrrp vlan "blue" vrid 1 priority 255
configure vrrp vlan "blue" vrid 1 host-mobility on
configure vrrp vlan "blue" vrid 1 add 10.1.2.254
enable vrrp vlan "blue" vrid 1

create auto-peering bgp vlans routerid 10.255.1.1 AS-number 4278124801
```

Leaf 2

```
configure vlan default delete ports 1-2
create vlan "red" tag 100
configure vlan red add ports 1 untagged
configure vlan "red" ipaddress 10.1.1.1/24
enable ipforwarding vlan "red"

create vrrp vlan "red" vrid 1
```

```
configure vrrp vlan "red" vrid 1 priority 255
configure vrrp vlan "red" vrid 1 host-mobility on
configure vrrp vlan "red" vrid 1 add 10.1.1.1
enable vrrp vlan "red" vrid 1

create vlan "blue" tag 200
configure vlan "blue" ipaddress 10.1.2.1/24
configure vlan blue add ports 2 untagged

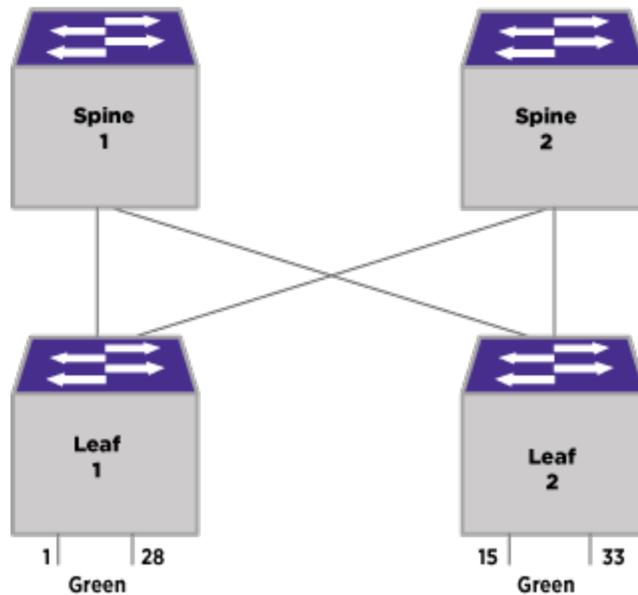
BGP Auto-peering Leaf/Spine with VXLAN Example

The following example shows a leaf/spine topology of ExtremeSwitching switches with *VXLAN* with users on *VLAN* green.

Note
An Advanced Edge or Base license must be installed on all switches.

The following commands reserve 10 VLANs.


Leaf 1

```
create auto-peering bgp routerid 1.1.1.120 AS-number 345200

create vlan "tenant"
configure vlan tenant tag 901
configure vlan tenant add ports 1,28 tagged
configure vlan tenant suppress arp-only (recommended but not necessary)

configure vlan tenant ipaddress 10.1.1.1 255.255.255.0
disable igmp snooping vlan "tenant"
enable ipforwarding vlan tenant

create vrrp vlan tenant vrid 151
configure vrrp vlan tenant vrid 151 host-mobility on
configure vrrp vlan tenant vrid 151 add 10.1.1.254

OSPFv2 Auto-peering

OSPFv2 Auto-peering Introduction

ExtremeXOS *OSPF (Open Shortest Path First)*v2 auto-peering is a network of cooperating interconnected devices that automatically create an OSPFv2 network for any topology, providing fully redundant, multipath routing. Node participation grows dynamically and is not bound to any well-known topology such as Clos or Leaf/Spine. OSPF is a link-state routing protocol that provides fast convergence and scalability. It is an interior gateway protocol (IGP) commonly used in large enterprise networks.

Auto-peering nodes build a secure network by running the OSPFv2 protocol over unnumbered point-to-point links to exchange database information that describes the topology of the autonomous system.

Any device connecting to an auto-peering device is an attachment point to the network. This network provides the underlay for services such as *VXLAN (Virtual Extensible LAN)*, policy, VRF, and Fabric Attach.

OSPFv2 Auto-peering Feature Description

After running the command `create` **`auto-peering ospf routerid`** *`ipaddress`*, the default OSPF configuration that is needed for auto-peering is created, and the AutoOSPFv2 capability is advertised out all ports using *LLDP (Link Layer Discovery Protocol)*. The default configuration includes the routerid, and vxlan-extensions and export of host-mobility routes. The following series of events occurs, setting up auto-peering:

1. When an OSPFv2 Auto-peering–capable neighbor is detected out a port, LLDP messages are sent.
2. LLDP-learned port is assigned to a new dynamically created VLAN, as an unnumbered interface.
3. LLDP learns of the OSPFv2 router ID.

4. LLDP sends the AutoOSPFv2 information to the remote neighbor and learns the remote neighbor's information.
5. An Auto-peering route is created to the learned remote router ID.
6. When OSPF learns of the auto-peering dynamic VLAN, it automatically enables a point-to-point link on that VLAN and places it in the backbone area.
7. The OSPF Auto-peering network is formed. OSPFv2 routes are propagated. The nexthop of the routes is the neighbor's router ID. The routes have the loose next hop flag set so the gateway can be resolved by the auto-peering route.
8. When OSPF Auto-peering is enabled, the OSPFv2 capability to carry VXLAN information is automatically enabled on each OSPFv2 peer.
9. VNI/LTEP pairs are passed to the OSPFv2 client which generates OSPFv2-opaque advertisements to any peers.
10. When an OSPFv2-opaque LSA is received containing a VNI/LTEP pair, the OSPFv2 client passes this to the client interface.

OSPFv2 Auto-peering Limitations

> **Note**
> BGP and OSPFv2 Auto-peering are mutually exclusive. Only one form of Auto-peering can exist at a time.

The following capabilities are not supported on OSPFv2 Auto-peering:
- Stacking
- Automatic LAG configuration with MLAG
- Automatic LAG configuration with Extended Edge Switching
- Static Lag attachments to AutoOSPF
- AutoOSPF links on Extended Edge Switching ports
- MPLS, VPLS, L2VPN, L3VPN
- PIM snooping, PIM-SM, PIM-DM, SSM mode
- OSPFv2, OSPFv3, ISIS, RIP, RIPNG per VRF
- Automatic MLAG configuration
- Multiple links between two OSPFv2 auto-peering enabled switches (instead LAG can be configured to avoid connectivity problem due to link failure).

Other limitations:
- One MLAG peer per node.
- Static router must be an external router per VRF.
- VLANs spanning multiple bridges, where each bridge has automatically configured LAG connections, must be VXLAN-based or replaced with MLAG.

OSPFv2 Auto-peering Supported Platforms

ExtremeSwitching X465, X590, and X695 series switches.

This feature requires the Advanced Edge license. For more information about licenses, see the *ExtremeXOS 32.4 Feature License Requirements*.

Configuring OSFPv2 Auto-peering

To create and enable OSPFv2 Auto-peering, use the following command:

```
create auto-peering ospf routerid ipaddress
```

To delete OSPFv2 Auto-peering, use the following command:

```
delete auto-peering
```

To view OSPFv2 and BGP auto-peering status, use the following command:

```
show auto-peering {bgp | ospf}.
```

Universal Port

Universal Port is a flexible framework that enables automatic switch configuration in response to special events such as:

- User login and logoff
- Device connection to or disconnection from a port
- Time of day
- EMS event messages

> **Note**
> The Universal Port feature is supported only on the platforms listed for this feature in the license tables in the *ExtremeXOS 32.4 Feature License Requirements* document.

The primary component of the Universal Port feature is the profile, which is a special form of command script that runs when triggered by the events mentioned above.

Profiles execute commands and use variables as do the scripts described in Using CLI Scripting on page 439. The primary difference is that a profile can be executed manually or automatically in response to switch events.

> **Note**
> The term *profile* is distinct from the term *policy* because a policy is only one particular application of a profile.

Universal Port works with the following ExtremeXOS components and third-party products:

- ExtremeXOS Network Login
- ExtremeXOS LLDP
- ExtremeXOS CLI Scripting
- Status Monitoring and Statistics
- RADIUS Servers
- Active directory services such as LDAP and Microsoft Active Directory

The following are some examples of how you can use Universal Port on a network:

- Automatically provision a VoIP phone and the attached switch port with appropriate *PoE (Power over Ethernet)* budget and *QoS (Quality of Service)* settings when the phone connects.
- Create security policies that can follow a user as the user roams around a campus. For example, an engineer can walk from Building 1 to Building 5, plug his PC into the network and be authenticated with the appropriate access rights and ACLs.
- Support separate authentication for VoIP phones and workstations on the same port.
- Create profile templates with variables so that you can re-use templates with different address ranges and parameters.
- Apply different security policies for different locations (for example, a restricted area).
- Disable wireless access after business hours.

> **Note**
> Special scripts can be run when the switch boots. For more information, see Using Autoconfigure and Autoexecute Files on page 1979.

Profile Types

The ExtremeXOS software supports two types of profiles: static and dynamic.

Static Profiles

Static profiles are so named because they are not triggered by dynamic system events. To trigger a static profile, you must enter a command at the switch prompt or run a script that contains the command to start a static profile. The following guidelines apply to static profiles:

- Static profiles are not limited to individual ports and can include system-wide configuration changes.
- Static profiles are not assigned to a port and are not specific to a device or a user.
- Changes made by static profiles are persistent. They are saved in the switch configuration and are preserved during system reboots.

Static profiles are typically used to establish default switch settings. Using scripts and variables, you can create static profiles that serve as templates for initializing switches

or reconfiguring switches to manually respond to network or business events. These templates can simplify complex configuration tasks such as Netlogin.

Dynamic Profiles

Dynamic profiles are so named because they are dynamically triggered by the following types of events:

- Device discovery and disconnect
- User- or standards-based authentication and logoff
- Time of day
- Switch events reported by the EMS

Dynamic profiles are event- or action-driven and do not require an administrator to start the profile.

Without dynamic profile support, IT personnel must be available when devices are added, moved, or changed so they can configure both the network port and the new device. These tasks typically take a long time, do not support mobility, and are often prone to human error.

When dynamic profiles are configured properly and a device connects to an edge port, a triggering event triggers a profile that runs a script to configure the port appropriately. The script can use system run-time variables and information gathered from tools such as Netlogin and *LLDP (Link Layer Discovery Protocol)* to customize the port configuration for the current network environment. For example, the profile can customize the port configuration based on the user ID or MAC address. Dynamic profiles allow you to automate the network response to a variety of network events.

Dynamic profiles create temporary states. For example, if a power outage causes the switch to restart, all ports return to the default configuration. When a triggering event such as a specific device connection occurs again, the profile is applied again. When the device is no longer connected, the disconnect event can trigger another profile to unconfigure the port.

The temporary state configured by a dynamic profile is configured by prepending the `configure cli mode non-persistent` command to the script. The temporary nature of profile configuration is critical for network security. Imagine a situation where a dynamic security profile is used. If the information granting access to specific network resources is saved in the configuration, the switch is restarted, and a user loses network connectivity on a secure port, the secure port still provides network access after the switch restarts. Anybody else can access network resources simply by connecting to that secure port.

Although the switch configuration returns to the default values after a restart, there is no automatic configuration rollback for dynamic profiles. For example, if a profile grants secure access to network resources at user login, the configuration is not automatically rolled back when the user logs off. To roll back the configuration at user log off, you must create another profile that responds to user log off events.

To support configuration rollback, the scripting feature allows you to save information used in dynamic profiles in variables. When a profile is activated and you want the option to roll back to the previous default setting, some information must be saved, such as the default _VLAN (Virtual LAN)_ setting or the default configuration of a port. Essentially anything modified from the previous setting can be preserved for future use by the profile that rolls back the configuration.

There can be multiple profiles on a switch, but only one profile runs at a time. Data from a trigger event is used to select the appropriate profile, and that data can also be used to make decision points within a profile. A typical example is the use of a _RADIUS (Remote Authentication Dial In User Service)_ server to specify a particular profile and then apply port-based policies to the user based on the user's location.

There is no profile hierarchy and no software validation to detect if a new profile conflicts with older profile. If two profiles conflict, the same profile might produce different results, depending on the events leading up to the profile trigger. When you create profiles, you must be familiar with all profiles on the switch and avoid creating profiles that conflict with each other.

Dynamic Profile Trigger Types

The following sections describe the types of dynamic profile trigger types: device, user authentication, time, and event-management system.

Device Triggers

Device triggers launch a profile when a device connects to or disconnects from a port.

The two types of device triggers are labeled device-detect and device-undetect in the software. Profiles that respond to these triggers are called device-detect profiles or device-undetect profiles.

Typically, a device-detect profile is used to configure a port for the device that has just connected.

Likewise, a device-undetect profile is used to return the port to a default configuration after a device disconnects. A variety of different devices can be connected to a port. When devices connect to the network, Universal Port helps provide the right configuration at the port.

Device triggers respond to the discovery protocols IEEE 802.1ab _LLDP_ and ANSI/TIA-1057 LLDP-MED for Voice-over-IP (VoIP) phone extensions. A device-detect trigger occurs when an LLDP packet reaches a port that is assigned to a device-detect profile. A device-undetect trigger occurs when periodically transmitted LLDP packets are not received anymore. LLDP age-out occurs when a device has disconnected or an age-out time has been reached. LLDP must be enabled on ports that are configured for device-detect or device-undetect profiles. LLD P is described in LLDP.

The combination of device triggers and LLDP enables the custom configuration of devices that connect to switch ports. For example, VoIP phones can send and receive information in addition to normal device identification information. The information

sent through LLDP can be used to identify the maximum power draw of the device. The switch can then set the maximum allocated power for that port.

If the switch does not have enough *PoE* left, the switch can take action to lower the PoE loading and try again. The switch can also transmit additional VoIP files and call server configuration information to the phone so the phone can register itself and receive necessary software and configuration information.

There can only be one device-detect profile and one device-undetect profile per port. To distinguish between different connecting devices, you can use if-then-else statements in a profile along with detailed information provided through LLDP.

User Authentication Triggers

User authentication triggers launch a profile when a user or an identified device logs in or out of the network using Network Login on page 897.

The network login feature does not permit any access beyond the port until the user or device is authenticated.

The two types of user authentication triggers are labeled user-authenticate and user-unauthenticated in the software. Profiles that respond to these triggers are called user-authenticate profiles or user-unauthenticated profiles. Typically, a user-authenticate profile is used to configure a port for a user and device that has just connected. Likewise, a user-unauthenticated profile is used to return the port to a default configuration after a user or device disconnects. Successful network login triggers the user-authenticate profile, and either an explicit logout, a session time out, or a disconnect triggers the user-unauthenticated profile.

> **Note**
> VoIP phones are also capable of being authenticated before being allowed on the network. The phone begins 802.1X authentication based on a personal username and password. This authentication step is available and supported by the latest firmware from vendors such as Avaya and Mitel.

Network login requires a *RADIUS* server for user or device authentication.

The RADIUS server provides the following features:
- Centralized database for network authentication
- Further centralization when connected to an LDAP or Active Directory database
- Dynamic switch configuration through Vendor Specific Attributes (VSAs)

VSAs are values that are passed from the RADIUS server to the switch after successful authentication. VSAs can be used by the switch to configure connection attributes such as security policy, *VLAN*, and location. For more information on RADIUS and VSAs, see Security on page 1085.

The following sections introduce each of the network login event types that can trigger profiles:
- 802.1X Network Login

- MAC-Based Network Login
- Web-Based Network Login

802.1X Network Login

Network login 802.1X requires 802.1X client software on the device to be authenticated.

At login, the user supplies a user name and password, which the switch passes to the RADIUS server for authentication. When the user passes authentication, the RADIUS server notifies the switch, and the user-authenticate profile is triggered.

One advantage of 802.1X network login is that it can uniquely identify a user. A disadvantage is that not all devices support 802.1X authentication. For more information, see Network Login on page 897.

MAC-Based Network Login

MAC-based network login requires no additional software, and it does not require any interaction with the user.

When network login detects a device with a MAC address that is configured on the switch, the switch passes the MAC address and an optional password to the RADIUS server for authentication. When the device passes authentication, the RADIUS server notifies the switch, and the user-authenticate profile is triggered.

One advantage of MAC-based network login is that it requires no special software. A disadvantage is that security is based on the MAC address of the client, so the network is more vulnerable to spoofing attacks. For more information, see Network Login on page 897.

> **Note**
> MAC-based authentication can also be used to identify devices. For example, an entire MAC address or some bits of the MAC address can identify a device and trigger switch port auto-configuration similar to the *LLDP*-based device detect event. The difference between MAC-based authentication and LLDP authentication is that MAC-based authentication does not provide information on the connected device. The advantage of MAC-based authentication is that it enables non-LLDP devices to trigger profiles.

> **Note**
> UPM VSA is supported in ONEPolicy in *NetLogin* mode.

Web-Based Network Login

Web-based network login requires a *DHCP (Dynamic Host Configuration Protocol)* server and may require a DNS server.

At login, the user supplies a user name and password through a web browser client, which the switch passes to the RADIUS server for authentication. When the user passes authentication, the RADIUS server notifies the switch, and the user-authenticate profile is triggered.

Some advantages of web-based network login are that it can uniquely identify a user and it uses commonly available web client software. Some disadvantages are a lower level of security and the IP configuration requirement. For more information, see Network Login on page 897.

Time Triggers

Time triggers launch a profile at a specific time of day or after a specified period of time.

For example, you can use time triggers to launch profiles at the following times:

- 6:00 p.m. every day
- One-time after 15 minutes
- One hour intervals

A profile that uses a time trigger is called a time-of-day profile. You might use a time trigger to launch a profile to disable guest _VLAN_ access, shut down a wireless service, or power down a port after business hours. Time triggers enable profiles to perform timed backups for configurations, policies, statistics, and so forth. Anything that needs to happen on a regular basis or at a specific time can be incorporated into a time-of-day profile. Time-of-day profiles are not limited to non-persistent-capable CLI commands and can use any command in the ExtremeXOS CLI.

Unlike the device-detect and user-authenticate triggers, time triggers do not have an equivalent function to the device-undetect or user-unauthenticated triggers. If you need the ability to unconfigure changes made in a time-of-day profile, just create another time-of-day profile to make those changes.

Event Management System Triggers

EMS-event triggers launch a profile when the EMS produces a message that conforms to a predefined definition that is configured on the switch. The ExtremeXOS EMS feature is described in CLEAR-Flow on page 1235.

Profiles that respond to EMS-event triggers are called EMS-event profiles. Typically, an EMS-event profile is used to change the switch configuration in response to a switch or network event.

The EMS events that trigger Universal Port profiles are defined in EMS filters and can be specified in more detail with additional CLI commands.

You can create EMS filters that specify events as follows:

- Component.subcomponent
- Component.condition
- Component.subcomponent.condition

You can use the `show log components` command to display all the components and subcomponents for which you can filter events. If you specify a filter to take action on a component or subcomponent, any event related to that component triggers the profile. You can use the show log events all command to display all the conditions or

events for which you can filter events. If you decide that you want to configure a profile to take action on an _ACL (Access Control List)_ policy change, you can add a filter for the ACL.Policy.Change event.

You can further define an event that triggers a Universal Port profile by specifying an event severity level and text that must be present in an event message.

When a specified event occurs, event information is passed to the Universal Port profile in the form of variables, which can be used to modify the switch configuration.

EMS-triggered profiles allow you to configure responses for any EMS event listed in the `show log components` and `show log events all` commands. However, you must be careful to select the correct event and corresponding response for each profile. For example, if you attempt to create a Universal Port log target for a specific event (component.subcomponent.condition) and you accidentally specify a component (component), the profile is applied to all events related to that component. Using EMS-triggered profiles is similar to switch programming. They provide more control and therefore more opportunity for misconfiguration.

Unlike the device-detect and user-authenticate triggers, EMS-event triggers do not have an equivalent function to the device-undetect or user-unauthenticated triggers.

If you need the ability to unconfigure changes made in an EMS-event profile, just create another static or dynamic profile to make those changes.

How Device-detect Profiles Work

Device-detect profiles enable dynamic port configuration without the use of a _RADIUS_ server. Device-detect profiles and device-undetect profiles are triggered as described earlier in Device Triggers on page 395.

When a device connects to a port that has a device-detect profile configured, the switch runs the specified profile and stops. Only one device detect profile can be configured for a port, so the same profile runs each time a device is detected on the port. Only one device-undetect profile can be configured for a port, so the same profile is run each time the switch detects that all previously-connected devices are no longer connected.

How User Authentication Profiles Work

User-authentication profiles can be assigned to user groups or individual users. Typically, a company creates profiles for groups such as software engineering, hardware engineering, marketing, sales, technical support, operations, and executive. These kinds of categories make profile management more streamlined and simple.

The authentication process starts when a switch receives an authentication request through Network Login. The authentication request can be for a specific user or a MAC address. A user name and password might be entered directly or by means of other security instruments, such as a smart card. A MAC address would be provided by _LLDP_, which would need to be operating on the ingress port. Netogin enforces authentication before granting access to the network. All packets sent by a client on the port do not

go beyond the port into the network until the user is authenticated through a *RADIUS* server.

Starting with ExtremeXOS 30.4, the authentication VLAN information from ONEPolicy is passed to Netlogin, so that UPM scripts can make use of this information. Note that dynamic VLANS are not fully supported, because a dynamic VLAN can be created prior to the client being authenticated. In such cases, the VLAN appears as "<not found> xxx" where "xxx" is the VLAN number, rather than the VLAN name, which usually appears. UPM VLAN processing also does not function, because the VLAN has not yet been created.

The switch authenticates the user through a RADIUS server, which acts as a centralized authorization point for all network devices. The RADIUS server can contain the authentication database, or it can serve as a proxy for a directory service database, such as LDAP or Active Directory. The switch also supports optional backup authentication through the local switch database when a RADIUS server is unavailable.

The RADIUS server responds to the switch and either accepts or denies user authentication. When user authentication is accepted, the RADIUS server can also send Vendor Specific Attributes (VSAs) in the response. The VSAs can specify configuration data for the user such as the Universal Port profile to run for logon, a *VLAN* name, a user location, and a Universal Port profile to run for logout. Extreme Networks has defined vendor specific attributes that specify configuration settings and can include variables to be processed by the Universal Port profile. If profile information is not provided by the RADIUS server, the user-authenticate profile is used.

Profiles are stored and processed on the switch. When a user name or MAC address is authenticated, the switch places the appropriate port in forwarding mode and runs either a profile specified by the RADIUS server, or the profile defined for the authentication event. The profile configures the switch resources for the user and stops running until it is activated again.

When a user or MAC address is no longer active on the network, due to logoff, disconnect, or inactivity, user unauthentication begins.

To complete unauthentication, the switch stops forwarding on the appropriate port and does one of the following:

1. Runs an unauthenticate profile specified by the RADIUS server during authentication.
2. Runs an unauthenticate profile configured on the switch and assigned to the affected port.
3. Runs the authenticate profile initially used to authenticate the user .

The preferred unauthenticate profile is one specified by the RADIUS server during authentication. If no unauthenticate profiles are specified, the switch runs the authenticate profile used to authenticate the user or device.

Profile Configuration Guidelines

You can configure both static and dynamic profiles using the CLI, Extreme Management Center, or the Ridgeline Universal Port Manager.

Obtaining Profiles

You can write your own profiles.

You can obtain profiles from the Extreme Networks website, another Extreme Networks user or partner, or Extreme Networks professional services.

Sample profiles are listed in Sample Universal Port Configurations on page 416. The Universal Port Handset Provisioning Module is a collection of profiles and documentation that is available with other samples on the Extreme Networks website.

Profile Rules

All profiles have the following restrictions:

- Maximum 5000 characters in a profile.
- Maximum 128 profiles on a switch.
- Profiles are stored as part of the switch configuration file.
- Copy and paste is the only method to transfer profile data using the CLI.
- Unless explicitly preceded with the command `configure cli mode persistent`, all non-persistent-capable commands operate in non-persistent mode when operating in dynamic profiles.
- Unless explicitly preceded with the command `configure cli mode non-persistent`, all non-persistent-capable commands operate in persistent mode when operating in static profiles.

> **Note**
>
> There is no profile hierarchy, which means users must verify there are no conflicting rules in static and dynamic profiles. This is a normal requirement for ACLs, and is standard when using policy files or dynamic ACLs.
>
> When the switch is configured to allow non-persistent-capable commands to operate in non-persistent mode, the switch configuration related to the non-persistent commands is not saved to the configuration file. This behavior enables the ports to return to their initial state when a reboot or power cycle occurs. You can view the configuration changes made by non-persistent commands through the application's show commands, but the changes do not appear in `show configuration {`*module-name*`} {`**detail**`}` .

Multiple Profiles on the Same Port

Multiple Universal Port profiles can be created on a switch, but only one profile per event can be applied per port. Different profiles on the same port apply to different events—different authentication events for different devices or users.

You can configure multiple user profiles on a port or a group of ports. For instance, you might create user-authentication profiles for different groups of users, such as Engineering, Marketing, and Sales.

You can also configure a device-triggered profile on a port that supports one or more user profiles. However, you can configure only one device-triggered profile on a port.

Supported Configuration Commands and Functions

Static and dynamic profiles support the full ExtremeXOS command set. They also support the built-in functions described in Using CLI Scripting on page 439.

Commands that are executed in persistent mode become part of the saved switch configuration that persists when the switch is rebooted. Commands that are executed in non-persistent mode configure temporary changes that are not saved in the switch configuration and do not persist when the switch is rebooted.

However, a subset of these commands operates by default in non-persistent mode when executed in a dynamic profile.

Most commands operate only in persistent mode. The subset of commands that operate in non-persistent mode are called non-persistent-capable commands. The Universal Port feature uses the non-persistent-capable commands to configure temporary changes that could create security issues if the switch were rebooted or reset. The use of non-persistent-capable commands in scripts and Universal Port profiles allows you to make temporary configuration changes without affecting the default configuration the next time the switch is started.

The following table shows the non-persistent capable CLI commands.

Non-Persistent-Capable Configuration Commands

ACL Commands

```
configure access-list add dynamic_rule [ [[first | last] {priority
p_number} {zone zone} ] | [[before | after] rule] | [ priority p_number
{zone zone} ]] [ any | vlan vlanname | ports portlist ] {ingress |
egress}
```

```
configure access-list delete ruleName [ any | vlan vlanname | ports
portlist | all] {ingress | egress}
```

LLDP Commands

```
configure lldp ports portlist [advertise | dont advertise | no-advertise
| dcbx] {all-tlvs | management-address | port-description | system-
capabilities | system-description | system-name | vendor-specific}
```

Port Commands

```
disable port [port_list | all]
```

```
disable jumbo-frame ports [all | port_list]
```

```
enable port [port_list | all]
```

```
enable jumbo-frame ports [all | port_list]
```

Power over Ethernet Commands

```
configure inline-power label string ports port_list
```

```
configure inline-power operator-limit milliwatts ports [all |port_list]
```

```
configure inline-power priority [critical | high | low] ports port_list
```

```
disable inline-power
```

```
disable inline-power ports [all | port_list]
```

```
disable inline-power slot slot
```

```
enable inline-power
```

```
enable inline-power ports [all | port_list]
```

```
enable inline-power slot slot
```

```
unconfigure inline-power priority ports [all | port_list]
```

VLAN Commands

```
configure {vlan} vlan_name add ports [port_list | all] {tagged |
untagged} {{stpd} stpd_name} {dot1d | emistp | pvst-plus}}
```

```
configure ip-mtu mtu vlan vlan_name
```

QOS/Rate-limiting Commands

```
configure ports port_list {qosprofile} qosprofile
```

Show Commands

All show commands can be executed in non-persistent mode.

By default, all commands operate in persistent mode with the following exceptions:

- In Universal Port dynamic profiles, the non-persistent-capable commands operate in non-persistent mode unless preceded by the `configure cli mode persistent` command in the profile.
- In the CLI, CLI scripts, and static profiles, the non-persistent-capable commands operate in non-persistent mode only when preceded by the `configure cli mode non-persistent` command.

You can use the `configure cli mode persistent` command and the `configure cli mode non-persistent` command to change the mode of operation for non-persistent-capable commands multiple times within a script, profile, or configuration session.

Universal Port Variables

Universal Port uses CLI Scripting variables to make system and trigger event information available to profiles. For more information, see Using CLI Scripting on page 439.

Variables allow you to create profiles and scripts that respond to the state of the switch as defined in the variables. When a profile is triggered, the system passes variables to the profile. You can also create and use variables of your own. User-defined variables are limited to the current context unless explicitly saved.

> **Note**
> You must enable CLI scripting before using variables or executing a script.

If you save variables (as described in Saving, Retrieving, and Deleting Session Variables on page 450), certain data from one profile can be reused in another profile for another event. For example, between login and logout events, the data necessary for the rollback of a port configuration can be shared.

The following sections describe the variables that are available to profiles:

- Common Variables
- User Profile Variables
- Device Detect Profile Variables
- Event Profile Variables

Common Variables

Table 31 shows the variables that are always available for use by any script. These variables are set up for use before a script or profile is executed.

Table 31: Common Variables

Variable Syntax	Definition
$STATUS	Status of last command execution.
$CLI.USER	Username for the user who is executing this CLI.
$CLI.SESSION_ID	An identifier for a session. This identifier is available for the rollback event when a device or user times out.
$CLI.SESSION_TYPE	Type of session of the user.
$EVENT.NAME	This is the event that triggered this profile.
$EVENT.TIME	Time this event occurred. The time is in seconds since epoch.
$EVENT.TIMER_TYPE	Type of timer, which is periodic or non_periodic.
$EVENT.TIMER_NAME	Name of the timer that the Universal Port is invoking.

Table 31: Common Variables (continued)

Variable Syntax	Definition
$EVENT.TIMER_LATE_SECS	Time difference between when the timer fired and when the actual shell was run in seconds.
$EVENT.PROFILE	Name of the profile that is being run currently.

User Profile Variables

Table 32 shows the variables available to user profiles.

Table 32: User Profile Variables

Variable Syntax	Definition
$EVENT.USERNAME	Name of user authenticated. This is a string with the MAC address for MAC-based user-login.
$EVENT.NUMUSERS	Number of authenticated supplicants on this port after this event occurred. **Note:** For user-authenticated events, the initial value of this variable is 0. For user unauthenticated events, the initial value is 1.
$EVENT.USER_MAC	MAC address of the user.
$EVENT.USER_PORT	Port associated with this event.
$EVENT.USER_VLAN	*VLAN* associated with this event or user. **Note:** If the VLAN is assigned dynamically, and the name is not available at the time of authentication, "$EVENT.USER_VLAN" is returned as "<Not Found> xxx" where xxx is the VLAN number. This is not translated by UPM VLAN processing and appears for diagnostic purposes only.
$EVENT.USER_ALL_VLANS	When a user is authenticated to multiple VLANs, this variable includes all VLANs for which the user is authenticated.
$EVENT.USER_IP	IP address of the user if applicable. Otherwise, this variable is blank.

Device Detect Profile Variables

Table 33 shows the variables available to device detect profiles.

Table 33: Device Profile Variables

Variable Syntax	Definition
$EVENT.DEVICE	Device identification string. Possible values for EVENT.DEVICE are: AVAYA_PHONE, GEN_TEL_PHONE, ROUTER, BRIDGE, REPEATER, WLAN_ACCESS_PT, DOCSIS_CABLE_SER, STATION_ONLY and OTHER. These strings correspond to the devices that the *LLDP* application recognizes and reports to the Universal Port management application.
$EVENT.DEVICE_IP	The IP address of the device (if available). Blank if not available.
$EVENT.DEVICE_MAC	The MAC address of the device (if available). Blank if not available.
$EVENT.DEVICE_POWER	The power of the device in milliwatts (if available). Blank if not available.
$EVENT.DEVICE_MANUFACTURER_NAME	The manufacturer of the device.
$EVENT.DEVICE_MODEL_NAME	Model name of the device.
$EVENT.USER_PORT	Port associated with the event.

Event Profile Variables

Table 34 shows the variables available to event profiles.

Table 34: Event Profile Variables

Variable Syntax	Definition
$EVENT.NAME	The event message.
$EVENT.LOG_DATE	The event date.
$EVENT.LOG_TIME	The event time.
$EVENT.LOG_COMPONENT_SUBCOMPONENT	The component and subcomponent affected by the event as it appears in the show log components command display.
$EVENT.LOG_EVENT	The event condition as it appears in the show log events command display.
$EVENT.LOG_FILTER_NAME	The EMS filter that triggered the profile.
$EVENT.LOG_SEVERITY	The event severity level defined in EMS.

Table 34: Event Profile Variables (continued)

Variable Syntax	Definition
$EVENT.LOG_MESSAGE	The event message with arguments listed in the format %1%.
$EVENT.LOG_PARAM_0 to $EVENT.LOG_PARAM_9	Event arguments 0 to 9.

Collecting Information from Supplicants

A supplicant is a device such as a VoIP phone or workstation that connects to the switch port and requests network services.

As described in LLDP, LLDP is a protocol that can be used to collect information about device capabilities from attached devices or supplicants.

To use Universal Port with LLDP, you must enable LLDP on the port.

Note

Avaya and Extreme Networks have developed a series of extensions for submission to the standards consortium for inclusion in a later version of the LLDP-MED standard:

- Avaya Power conservation mode
- Avaya file server
- Avaya call server

The following is an example of information provided through LLDP about an IP phone:

```
LLDP Port 1 detected 1 neighbor
Neighbor: (5.1)192.168.10.168/00:04:0D:E9:AF:6B, age 7 seconds
- Chassis ID type: Network address (5); Address type: IPv4 (1)
Chassis ID      : 192.168.10.168
- Port ID type: MAC address (3)
Port ID     : 00:04:0D:E9:AF:6B
- Time To Live: 120 seconds
- System Name: "AVAE9AF6B"
- System Capabilities : "Bridge, Telephone"
Enabled Capabilities: "Bridge, Telephone"
- Management Address Subtype: IPv4 (1)
Management Address        : 192.168.10.168
Interface Number Subtype  : System Port Number (3)
Interface Number          : 1
Object ID String          : "1.3.6.1.4.1.6889.1.69.1.13"
- IEEE802.3 MAC/PHY Configuration/Status
Auto-negotiation        : Supported, Enabled (0x03)
Operational MAU Type    : 100BaseTXFD (16)
- MED Capabilities: "MED Capabilities, Network Policy, Inventory"
MED Device Type : Endpoint Class III (3)
- MED Network Policy
Application Type  : Voice (1)
Policy Flags      : Known Policy, Tagged (0x1)
VLAN ID           : 0
L2 Priority       : 6
DSCP Value        : 46
```

```
- MED Hardware Revision: "4625D01A"

- MED Software Revision: "a25d01a2_7.bin"
- MED Serial Number: "061622014487"
- MED Manufacturer Name: "Avaya"
- MED Model Name: "4625"
- Avaya/Extreme Conservation Level Support
Current Conservation Level: 0
Typical Power Value        : 7.4 Watts
Maximum Power Value        : 9.8 Watts
Conservation Power Level   : 1=7.4W
- Avaya/Extreme Call Server(s): 192.168.10.204
- Avaya/Extreme IP Phone Address: 192.168.10.168 255.255.255.0
Default Gateway Address        : 192.168.10.254
- Avaya/Extreme CNA Server: 0.0.0.0
- Avaya/Extreme File Server(s): 192.168.10.194
- Avaya/Extreme IEEE 802.1q Framing: Tagged
```

> **Note**
> LLDP is tightly integrated with IEEE 802.1X authentication at edge ports. When used together, LLDP information from authenticated end point devices is trustable for automated configuration purposes. This tight integration between 802.1X and LLDP protects the network from automation attacks.

Supplicant Configuration Parameters

As described in LLDP, LLDP is a protocol that can be used to configure attached devices or supplicants. The following LLDP parameters are configurable on the switch ports when device-detect profiles execute are:

- *VLAN* Name
- Port VLAN ID
- Power Conservation Mode
- Avaya File Server
- Avaya Call server
- 802.1Q Framing

Universal Port Configuration Overview

Because Universal Port operates with multiple ExtremeXOS software features and can operate with multiple third-party products, Universal Port configuration can require more than just the creation of profiles and triggers.

No single overview procedure can cover all the possible Universal Port configurations. The following sections provide overviews of the common types of Universal Port configurations.

Device-Detect Configurations

A Universal Port device-detect configuration requires only a switch and supplicants. If *PoE* devices will connect to the switch, the switch should support PoE. Supplicants should support *LLDP* in the applicable software or firmware.

> **Note**
>
> To support supplicant configuration, you might consider adding a *DHCP* server to your network.

Use the following procedure to configure Universal Port for device detection:

1. Create a device-detect profile as described in Creating and Configuring New Profiles on page 411.
2. Create a device-undetect profile as described in Creating and Configuring New Profiles on page 411.
3. Assign the device-detect profile to the edge ports as described in Configuring a Device Event Trigger on page 412.
4. Assign the device-undetect profile to the edge ports as described in Configuring a Device Event Trigger on page 412.
5. Verify that correct profiles are assigned to correct ports using the following command:

```
show upm event event-type
```

6. Enable LLDP message advertisements on the ports that are configured for device-detect profiles as described in LLDP.
7. Test profile operation as described in Verifying a Universal Port Profile on page 415.

User-Authentication Configurations

A Universal Port user-authenticate configuration requires specific components:

- An Extreme Networks switch, which might need to include *PoE* support.
- *RADIUS* server for user authentication and VSA transmission.
- Supplicants that support the authentication method you select. *LLDP* support is recommended, but is optional when MAC address authentication is used.

> **Note**
>
> To support supplicant configuration, you might consider adding a *DHCP* server to your network. For VoIP applications, you can use a TFTP server and a call server to provide for additional supplicant configuration.

Use the following procedure to configure Universal Port for user login:

1. Configure the RADIUS server as described in Security on page 1085. The configuration should include the following:
   - User ID and password for RADIUS clients.
   - Extreme Networks custom VSAs.
   - Addition of the edge switch as a RADIUS client.

2. Create a user-authenticate profile as described in Creating and Configuring New Profiles on page 411.

3. Create a user-unauthenticate profile as described in Creating and Configuring New Profiles on page 411.

4. Assign the user-authenticate profile to the edge ports as described in Configuring a User Login or Logout Event Trigger on page 412.

5. Assign the user-unauthenticate profile to the edge ports as described in Configuring a User Login or Logout Event Trigger on page 412.

6. Configure network login on the edge switch as described in Network Login.

7. Configure the edge switch as a RADIUS client as described in Security.

8. Verify that correct profiles are assigned to correct ports by entering the following command:

   ```
   show upm event event-type
   ```

9. Enable LLDP message advertisements on the ports that are configured for device-detect profiles as described in LLDP Overview on page 455.

10. Test profile operation as described in Verifying a Universal Port Profile on page 415.

Time-of-Day Configurations

To configure Universal Port to use a time-of-day profile, use the following procedure:

1. Create a profile as described in Creating and Configuring New Profiles on page 411.

2. Create and configure a timer as described in Configuring a Universal Port Timer on page 412.

3. Create the timer trigger and attach it to the profile as described in Configuring a Timer Trigger on page 412.

EMS-Event Configurations

To configure Universal Port to use an EMS-event profile, use the following procedure:

1. Create the EMS-Event profile as described in Creating and Configuring New Profiles on page 411.

2. Create and configure an event filter to identify the trigger event as described in Creating an EMS Event Filter on page 413.

3. Create the event trigger and attach it to the profile and filter as described in Configuring an EMS Event Trigger on page 413.

4. Enable the event trigger as described in Enabling and Disabling an EMS Event Trigger on page 413.

Using Universal Port in an LDAP or Active Directory Environment

The RADIUS server can operate in proxy mode with information stored in a central directory service such as LDAP or Active Directory.

This proxy mode is configured between the RADIUS server and the central directory service. Once configured, supplicants can be authenticated from the central directory service.

For more information, see the following:

- Setting Up Open LDAP on page 1188.
- RADIUS server product documentation
- Product documentation for your central directory service

Configuring Universal Port Profiles and Triggers

You can configure both static and dynamic profiles using the CLI, Extreme Management Center, or the Ridgeline Universal Port Manager.

> **Note**
> In the CLI, "upm" is used as an abbreviation for the Universal Port feature.

Creating and Configuring New Profiles

When you create and configure a new profile, you are basically writing a script within a profile that can be triggered by system events. For more information on the rules, commands, and variables that apply to profiles, see Profile Configuration Guidelines on page 401.

1. Create and configure a new profile using the following command:

   `configure upm profile profile-name maximum execution-time seconds`

2. After you enter the command, the switch prompts you to add command statements to the profile as shown in the following example:

```
switch # create upm profile detect-voip
Start typing the profile and end with a . as the first and the only character on a
line.
Use - edit upm profile <name> - for block mode capability
create log message Starting_Script_DETECT-voip
set var callServer 192.168.10.204
set var fileServer 192.168.10.194
set var voiceVlan voice
set var CleanupProfile CleanPort
set var sendTraps false
#
.
switch #
```

The example above creates a log entry and sets some variables, but it is not complete. This example shows that after you enter the `create upm profile` command, you can enter system commands. When you have finished entering commands, you can exit the profile creation mode by typing the period character (`.`) at the start of a line and pressing **[Enter]**.

Editing an Existing Profile

- Edit an existing profile.

   `edit upm profile profile-name`

Configuring a Device Event Trigger

There are two types of device event triggers, which are named as follows in the CLI: device-detect and device-undetect. When you configure a device event trigger, you assign one of the two device event trigger types to a profile and specify the ports to which the triggered profile applies.

To configure a device event trigger, use the following command:

```
configure upm event upm-event profile profile-name ports port_list
```

Replace `upm-event` with one of the device event trigger types: device-detect or device-undetect.

Configuring a User Login or Logout Event Trigger

There are two types of user event triggers, which are named as follows in the CLI: user-authenticate and user-unauthenticated. When you configure a user event trigger, you assign one of the two user event trigger types to a profile and specify the ports to which the triggered profile applies.

To configure a user event trigger, use the following command:

```
configure upm event upm-event profile profile-name ports port_list
```

Replace `upm-event` with one of the device event trigger types: user-authenticate or user-unauthenticated.

Configuring a Universal Port Timer

To configure a Universal Port timer, you must complete two steps:

1. Create the timer by using the following command:
   ```
   create upm timer timer-name
   ```
2. Configure the timer by using the following commands:
   ```
   configure upm timer timer-name after time-in-secs {every seconds}
   ```
   ```
   configure upm timer timer-name at month day year hour min secs {every seconds}
   ```

Configuring a Timer Trigger

When you configure a timer trigger, you assign a configured timer to a profile. When the configured time arrives, the switch executes the profile.

To configure a timer trigger, use the following command:

```
configure upm timer timerName profile profileName
```

Replace `timerName` with the timer name and `profileName` with the profile name.

Creating an EMS Event Filter

An EMS event filter identifies an event that can be used to trigger a profile. To create an EMS event filter, use the following procedure:

1. Create a log filter to identify the event by using the following command:

   `create log filter` *name* `{copy` *filter name*`}`

2. Configure the log filter using the following commands:

   `configure log filter` *name* `[add | delete] {exclude} events [`*event-condition* `| [all |` *event-component*`] {severity` *severity* `{only}}]`

   `configure log filter` *name* `[add | delete] {exclude} events [`*event-condition* `| [all |` *event-component*`] {severity` *severity* `{only}}] [match | strict-match]` *type value*

Configuring an EMS Event Trigger

When you configure an EMS event trigger, you identify an EMS filter that defines the event and a profile that runs when the event occurs. To configure an EMS event-triggered profile, use the following procedure:

1. Create a log target to receive the event notification by using the following command:

   `create log target upm {`*upm_profile_name*`}`

2. Configure the log target to specify a filter and any additional parameters that define the event by using the following commands:

   `configure log target upm {`*upm_profile_name*`} filter` *filter-name* `{severity [[`*severity*`] {only}]}`

   `configure log target upm {`*upm_profile_name*`} match {any |` *regex*`}`

Enabling and Disabling an EMS Event Trigger

When you configure an EMS event trigger, it is disabled.

To enable an EMS event trigger or disable a previously enabled trigger, use the following commands:

`enable log target upm {`*upm_profile_name*`}`

`disable log target upm {`*upm_profile_name*`}`

Unconfiguring a Timer

To unconfigure a timer, use the following command:

`unconfigure upm timer` *timerName* `profile` *profileName*

Managing Profiles and Triggers

Use the following actions to manage profiles and triggers.

Manually Executing a Static or Dynamic Profile

Profiles can be run from the CLI by configuring the system to run as it would when the trigger events happen. This facility is provided to allow you to test how the system behaves when the actual events happen. The actual configuration is applied to the switch when the profile is run.

> **Note**
> Variables are not validated for correct syntax.

To manually execute a profile, use the following command:

```
run upm profile profile-name {event event-name} {variables variable-string}
```

Example:

```
run upm profile afterhours
```

If the **variables** keyword is not present, but an event variable is specified, you are prompted for various environment variables appropriate for the event, including the VSA string for user authentication.

Displaying a Profile

To display a profile, use the following command:

```
show upm profile name
```

Displaying Timers

Display a list of timers and associated timer information.

```
show upm timers
```

Displaying Universal Port Events

Display events for trigger types. You can display a list of events that relate to one of the following trigger types:

- device-detect
- device-undetect
- user-authenticate
- user-unauthenticated

To display a list of Universal Port events for one of the above triggers, use the following command:

```
show upm event event-type
```

Replace `event-type` with one of the trigger types listed above.

Displaying Profile History

To display a list of triggered events and associate event data, enter one of the following commands:

```
show upm history {profile profile-name | event upm-event | status [pass
| fail] | timer timer-name | detail}
```

```
show upm history exec-id number
```

Verifying a Universal Port Profile

To verify a Universal Port profile configuration, trigger the profile and verify that it works properly. Trigger the profile based on the trigger type as follows:

- Device triggers–plug in the device
- Authentication triggers–authenticate a device or user
- Timer triggers–temporarily configure the timer for an approaching time
- EMS event triggers–reproduce the event to which the trigger responds

You can use the commands described earlier in this section to view information about the profile and how it behaves.

Because Universal Port works with multiple switch features, you might want to enter commands to examine the configuration of those features.

The following commands are an example of some of the commands that can provide additional information about profile operation.

Run:

```
show lldp
show lldp neighbors
show log
show netlogin
```

Handling Profile Execution Errors

To conserve resources, the switch stores only the last execution log for the profile that resulted in an error.

The status column displays the status of the last command executed in a profile. If the last command was successful, the status shows "pass"; otherwise, the status shows "failed". If you wish to terminate the execution of a profile on encountering the first error, you must include the line "`configure cli scripting mode abort-on-error`" in the beginning of the profile. Otherwise, the profile executes all the commands even if an error was encountered and displays the status of the last command executed.

- To see a tabular display showing the complete history of the last 100 profiles, use the following command:

```
show upm history {profile profile-name | event upm-event | status
[pass | fail] | timer timer-name | detail}
```

Use the `detail` keyword to display the actual executions that happened when the profile was run.

- To display a specific execution that was run, use the following command:

  `show upm history exec-id` *`number`*

Select the exec-id number from the list in the tabular display.

Disabling and Enabling a Profile

Universal Port profiles are automatically enabled when they are created.

To disable a profile or enable a previously disabled profile, use the following commands:

`disable upm profile` *`profile-name`*

`enable upm profile` *`profile-name`*

Deleting a Profile

To delete a profile, use the following command:

`delete upm profile` *`profile-name`*

Deleting a Timer

To delete a timer, use the following command:

`delete upm timer` *`timer-name`*

Deleting an EMS Event Trigger

To delete an EMS event trigger, use the following command:

`delete log target upm {`*`upm_profile_name`*`}`

Sample Universal Port Configurations

The following sections provide example configurations for a switch, profile, and policy file.

Sample MAC Tracking Profile

The example in this section shows how to create a profile that takes action based on the MAC tracking feature. When the MAC tracking feature detects a MAC move in a _VLAN_, the MAC tracking feature generates an EMS log, which then triggers a profile.

> **Note**
> You can also use the Identity Management feature to configure ports in response to MAC device detection events. For more information, see Identity Management.

Switch Configuration

The general switch configuration is as follows:

```
#Vlan  config
create vlan v1
configure v1 add ports 1:17-1:18
configure vlan v1 ipadd 192.168.10.1/24
#mac tracking config
create fdb mac-tracking entry 00:01:02:03:04:01
create fdb mac-tracking entry 00:01:02:03:04:02
create fdb mac-tracking entry 00:01:02:03:04:03
create fdb mac-tracking entry 00:01:02:03:04:04
create fdb mac-tracking entry 00:01:02:03:04:05
#Log filter configuration
create log filter macMoveFilter
configure log filter "macMoveFilter" add events "FDB.MACTracking.MACMove"
#Meter configuration for ingress /egress rate limit
create meter m1
configure meter m1 peak-rate 250 mbps
create meter m2
configure meter m2 peak-rate 500 mbps
```

MAC Tracking EMS Log Message

The MAC tracking feature produces the following EMS log message and message parameters:

```
The MAC address %0% on VLAN '%1%' has moved from port %2% to port %3%"
EVENT.LOG_PARAM_1 "vlan name"
EVENT.LOG_PARAM_2 "source port"
EVENT.LOG_PARAM_3 "moved port"
```

Profile Configuration

The profile is configured as follows:

```
create upm profile macMove    ;# editor
enable cli scripting
create access-list dacl1 "source-address  192.168.10.0/24 " "permit ;count dacl1"
create access-list dacl2 "source-address  192.168.11.0/24 " "permit ;count dacl2"
create access-list dacl3 "source-address  192.168.15.0/24 " "deny ;count dacl3"
create access-list dacl4 "source-address  192.168.16.0/24 " "deny ;count dacl4"
create access-list dacl5 "source-address  192.168.17.0/24 " "deny ;count dacl5"
configure access-list add dacl1 first ports $(EVENT.LOG_PARAM_3)
configure access-list add dacl2 first ports $(EVENT.LOG_PARAM_3)
```

```
configure access-list add dacl3 first ports $(EVENT.LOG_PARAM_3)
configure access-list add dacl4 first ports $(EVENT.LOG_PARAM_3)
configure access-list add dacl5 first ports $(EVENT.LOG_PARAM_3)
conf access-list ingress_limit vlan v1
conf access-list ingress_limit ports $(EVENT.LOG_PARAM_3)
conf access-list egress_limit any   ;# enter . for SAVE/EXIT
log target configuration
create log target upm "macMove"
configure log target upm "macMove" filter "macMoveFilter"
enable log target upm "macMove"
```

Policy File Configuration

This example uses the following two policy files:

```
Ingress rate limit (ingress_limit.pol)
================================
entry ingress {
if {
ethernet-source-address 00:AA:00:00:00:01;
ethernet-destination-address 00:BB:00:00:00:01;
} then {
Meter m1;
count c1;
}
}
Egress QoS (egress_limit.pol)
================================
entry egress {
if {
ethernet-source-address 00:BB:00:00:00:01;
ethernet-destination-address 00:AA:00:00:00:01;
} then {
qosprofile qp2;
count c2;
}
}
```

Console Logs

The following show commands display the switch configuration:

```
* (debug) BD-12804.7 # show log con fil

Universal Port Handset Provisioning Module Profiles

The Universal Port Handset Provisioning Module provides the following profiles:

Device-Triggered Generic Profile

This is a template for configuring network parameters for VoIP phone support without 802.1X authentication. The profile is triggered after an *LLDP* packet is detected on the port.

> **Note**
>
> The MetaData information is used by the Ridgeline to create a user-friendly interface to modify the variables. You can ignore the MetaData while using the CLI.

```
#********************************
# Last Updated: April 11, 2007
# Tested Phones: Avaya 4610, 4620, 4625
# Requirements: LLDP capable devices
#********************************
# @MetaDataStart
# @ScriptDescription "This is a template for configuring network parameters for VoIP
phones support LLDP but without authentication.  The module is triggered through the
detection of an LLDP packet on the port.   The following network side configuration is
done: enable SNMP traps, QOS assignment, adjust POE reservation values based on device
requirements, add the voiceVlan to the port as tagged. "
# @VariableFieldLabel "Voice VLAN name"

```

Sample Static Profiles

The following configuration creates a profile and runs it statically:

```
* BD-10808.4 # Create upm profile p1
Enable port 1:1
.
* BD-10808.4 #run upm profile p1
* BD-10808.4 # show upm history exec 8006
UPM Profile: p1
Event:  User Request    , Time run: 2006-10-18 11:56:15
Execution Identifier: 8006      Execution Status: Pass
Execution Information:
1 # enable cli scripting
2 # set var EVENT.NAME USER-REQUEST
3 # set var EVENT.TIME 1161172575
4 # set var EVENT.PROFILE p1
5 # enable port 1:1
```

This profile creates and configures *EAPS (Extreme Automatic Protection Switching)* on the edge switch for connecting to the aggregation switch, creates specific *VLAN*s and

assigns tags, configures network login, and configures the _RADIUS_ client component
on the switch.

```
#*************************************************
# Last Updated: May 11, 2007

Sample Configuration with Device-Triggered Profiles

The following example demonstrates how to configure Universal Port for device detection:

```
# Create and configure the VLAN for the VoIP network.
#
switch 1 # create vlan voice
switch 2 # configure voice ipaddress 192.168.0.1/24
# Create the universal port profile for device-detect on the switch.
#
switch 3 # create upm profile detect-voip
Start typing the profile and end with a . as the first and the only character on a line.
Use - edit upm profile <name> - for block mode capability
create log message Starting_Script_DETECT-voip
set var callServer 192.168.10.204
set var fileServer 192.168.10.194
set var voiceVlan voice
set var CleanupProfile CleanPort
set var sendTraps false
#
create log message Starting_DETECT-VOIP_Port_$EVENT.USER_PORT
#*************************************************************
# adds the detected port to the device "unauthenticated" profile port list
#*************************************************************
create log message Updating_UnDetect_Port_List_Port_$EVENT.USER_PORT
configure upm event Device-UnDetect profile CleanupProfile ports $EVENT.USER_PORT
#*************************************************************
# adds the detected port to the proper VoIP vlan
#*************************************************************

Sample Configuration with User-Triggered Profiles

This example demonstrates how to configure a _RADIUS_ server and Universal Port for user login. The first part of the example shows the RADIUS server configuration. For more information on RADIUS server configuration, see Security on page 1085.

```
# Configure the RADIUS server for the userID and password pair.
# For FreeRADIUS, edit the users file located at /etc/raddb/users as shown in the
# following lines.
#
#Sample entry of using an individual MAC addresses
00040D50CCC3    Auth-Type := EAP, User-Password == "00040D50CCC3"
Extreme-Security-Profile = "phone LOGOFF-PROFILE=clearport;",
Extreme-Netlogin-VLAN = voice
#Sample entry of using wildcard MAC addresses (OUI Method)
00040D000000    Auth-Type := EAP, User-Password == "1234"
Extreme-Security-Profile = "phone LOGOFF-PROFILE=clearport;",
Extreme-Netlogin-VLAN = voice
#Sample entry of using numeric UserID and password
10284    Auth-Type := EAP, User-Password == "1234"
Extreme-Security-Profile = "voip LOGOFF-PROFILE=voip",
Extreme-Netlogin-Vlan = voice
#Sample entry of using a text UserID and password
Sales    Auth-Type := EAP, User-Password == "Money"
Extreme-Security-Profile = "Sales-qos LOGOFF-PROFILE=Sales-qos",
Extreme-Netlogin-Vlan = v-sales
```

```
# Define the Extreme custom VSAs on RADIUS.
# For FreeRADIUS, edit the dictionary file located at //etc/raddb/dictionary to
# include the following details:
VENDOR          Extreme        1916
ATTRIBUTE       Extreme-CLI-Authorization       201     integer Extreme
ATTRIBUTE       Extreme-Shell-Command           202     string  Extreme
ATTRIBUTE       Extreme-Netlogin-Vlan           203     string  Extreme
ATTRIBUTE       Extreme-Netlogin-Url            204     string  Extreme
ATTRIBUTE       Extreme-Netlogin-Url-Desc       205     string  Extreme
ATTRIBUTE       Extreme-Netlogin-Only           206     integer Extreme
ATTRIBUTE       Extreme-User-Location           208     string  Extreme
ATTRIBUTE       Extreme-Netlogin-Vlan-Tag       209     integer Extreme
ATTRIBUTE       Extreme-Netlogin-Extended-Vlan  211     string  Extreme
ATTRIBUTE       Extreme-Security-Profile        212     string  Extreme
ATTRIBUTE       Extreme-CLI-Profile             213     string  Extreme

VALUE   Extreme-CLI-Authorization       Disabled        0
VALUE   Extreme-CLI-Authorization       Enabled         1
VALUE   Extreme-Netlogin-Only           Disabled        0
VALUE   Extreme-Netlogin-Only           Enabled         1
# End of Dictionary
# Add the switch as an authorized client of the RADIUS server.
# For FreeRADIUS, edit the file located at //etc/raddb/clients.conf to include the
# switches as details:
#
client  192.168.10.4 {
secret = purple
shortname = SummitX
# End of clients.conf
```

The rest of this example demonstrates the configuration that takes place at the ExtremeXOS switch:

```
# Create the universal port profile for user-authenticate:
* switch 1 # create upm profile phone
Start typing the profile and end with a . as the first and the only character on a line.
Use - edit upm profile <name> - for block mode capability
create log message Starting_Script_Phone
set var callServer 192.168.10.204
set var fileServer 192.168.10.194
set var voiceVlan voice
set var CleanupProfile CleanPort
set var sendTraps false
#
create log message Starting_AUTH-VOIP_Port_$EVENT.USER_PORT

# Enable LLDP message advertisements on the ports.
#
* switch 17 # enable lldp ports 11-20
```

Sample Timer-Triggered Profile

The following profile and timer configuration disables *PoE* on ports 1 to 20 everyday at 6:00 p.m.:

```
* switch 1 # create upm profile eveningpoe
Start typing the profile and end with a . as the first and the only character on a line.
Use - edit upm profile <name> - for block mode capability
create log message Starting_Evening
disable inline-power ports 1-20
.
*switch 2
*switch 3 # create upm timer night
*switch 4 # config upm timer night profile eveningpoe
*switch 5 # config upm timer night at 7 7 2007 19 00 00 every 86400
```

Sample Profile with QoS Support

The example below can be used with an ExtremeSwitching series switch that supports *QoS* profiles qp1 and qp8.

When the user or phone logs in with a particular MAC address, the script configures the QoS profile configured by the user in the *RADIUS* server for the USER-AUTHENTICATED event. In this example, the user sets the QoS profile to be qp8.

You must configure network login, the RADIUS server, and Universal Port on the switch as part of the user log-in authentication process. For more information on configuring the RADIUS users file, see Security on page 1085.

The following example is an entry in the RADIUS users file for the MAC address of the phone:

```
00040D9D12A9 Auth-Type := local, User-Password == "test"
Extreme-security-profile = "p1 QOS=\"QP8\";LOGOFF-PROFILE=p2;VLAN=\"voice-        test\";"
```

Below is the Universal Port profile configuration for this example:

```
Create upm profile p1
set var z1 $uppercase($EVENT.USER_MAC)
set var z2 $uppercase(00:04:0d:9d:12:a9)
#show var z1
#show var z2
if ($match($EVENT.NAME, USER-AUTHENTICATED) == 0) then
    if ($match($z1, $z2) == 0) then
         configure port $EVENT.USER_PORT qosprofile $QOS
    endif
endif
.
```

Sample Event Profile

If not configured properly, the *STP (Spanning Tree Protocol)* can create loops in a network.

Should these loops develop, they can cause network degradation and eventually crash the network by duplicating too many Ethernet frames. By leveraging Universal Port and the Extreme Loop Recovery Protocol (ELRP) as shown in example below, it is not only possible to detect and isolate the egress port, but it is also possible to disable the egress port to break loops.

Note

This example illustrates how to create an event profile that reconfigures the switch after an event. After this example was created, ELRP was updated with the capability to disable a port without the help of an event profile. For more information, see Using ELRP to Perform Loop Tests on page 1998.

When a loop is detected on ports where ELRP is enabled and configured, ELRP logs a message using the following format:

```
01/17/2008 08:08:04.46 <Warn:ELRP.Report.Message> [CLI:ksu:1] LOOP DETECTED : 436309
transmited, 64 received, ingress slot:port (1) egress slot:port (24)
```

To view more information on format of this command, enter the show log events command as shown in the following example:

```
* BD8810-Rack2.6 # show log events "ELRP.Report.Message" details
Comp    SubComp      Condition                Severity      Parameters
------- -----------  ----------------------  -------------  ----------
ELRP    Report       Message                  Warning       8 total
0 - string
1 - string
2 - number (32-bit
unsigned int)
3 - string
4 - number (32-bit
unsigned int)
5 - number (unsigned int)
6 - string
7 - string
"[%0%:%1%:%2%] %3% : %4% transmited, %5% received, ingress slot:port (%6%) egress
slot:port (%7%)"
```

In the example log statement, the *VLAN* ksu, the ports is all, and the interval is "1."

If a loop is detected, we want to disable the egress port on which the ELRP control packets went out. In this example, we enable ELRP on all ports of a VLAN as follows:

```
configure elrp-client periodic vlan ports all interval 1 seconds
```

We want the profile to disable egress ports 1 and 24 (which have been configured for loop). If we enable ELRP on only one port, then the port alone would be disabled.

We observe that parameter 7 is the one we have to disable from the above log message and the details for that event.

Configuring Universal Port Example

The following procedure configures Universal Port to disable the egress port identified by parameter 7:

1. Create the profile and add the command to disable the egress port as follows:

```
create upm profile disable_port_elrp
disable port $EVENT.LOG_PARAM_7
```

2. Verify that the profile is created and enabled by entering the following command:

```
show upm profile
```

3. Create the EMS configuration by entering the following commands:

```
create log target upm disable_port_elrp
create log filter f1
configure log filter f1 add event ELRP.Report.Message match string "LOOP"
enable log target upm "disable_port_elrp"
configure log target upm "disable_port_elrp" filter f1
```

4. At this point, connect the ports 1 and 24 to form a loop.

   Two log messages will be logged when the loop is detected on ports 1 and 24 and ELRP is enabled both. This triggers the disable_port_elrp profile twice, and ports 1 and 24 should be disabled.

5. View the log.

```
> show log
01/17/2008 08:08:05.49 <Info:vlan.dbg.info> Port 24 link down
01/17/2008 08:08:05.22 <Noti:UPM.Msg.upmMsgExshLaunch> Launched profile
disable_port_elrp for the event log-message
01/17/2008 08:08:04.69 <Info:vlan.dbg.info> Port 1 link down
01/17/2008 08:08:04.46 <Noti:UPM.Msg.upmMsgExshLaunch> Launched profile
disable_port_elrp for the event log-message
01/17/2008 08:08:04.46 <Warn:ELRP.Report.Message> [CLI:ksu:1] LOOP DETECTED : 436309
transmited, 64 received, ingress slot:port (1) egress slot:port (24)
01/17/2008 08:08:04.46 <Warn:ELRP.Report.Message> [CLI:ksu:1] LOOP DETECTED : 436309
transmited, 63 received, ingress slot:port (24) egress slot:port (1)
01/17/2008 08:08:03.50 <Info:vlan.dbg.info> Port 24 link up at 1 Gbps speed and full-
duplex
```

6. To view the profile execution history, enter the show upm history command.

   f you want to see the more details, enter the show upm history details command to see all the profiles or display information on a specific event by entering the exec-id.

7. To view the configuration, use the show config upm and show config ems commands.

Sample Configuration for Generic VoIP LLDP

Sample Configuration for a Video Camera

This template adds an _ACL_ to an edge port when a video camera connects.

The profile configures and applies an ACL onto a switch port when a user authenticates. This ACL blocks a particular IP address from accessing the video camera and assigns the user to _QoS_ profile 7.

```

```
Using CLI Scripting

CLI-based scripting allows you to create a list of commands that you can execute manually with a single command or automatically when a special event occurs.

CLI-based scripting supports variables and functions, so that you can write scripts that operate unmodified on multiple switches and in different environments. It allows you to significantly automate switch management.

> **Note**
> Special scripts can be used to configure the switch when it boots. For more information, see Using Autoconfigure and Autoexecute Files on page 1979.

Setting Up Scripts

Enabling and Disabling CLI Scripting

The **permanent** option enables CLI scripting for new sessions only and makes the configuration change part of the permanent switch configuration so that the scripting configuration remains the same when the switch reboots. When the command is used without the permanent option, it enables CLI scripting for the current session only. If you do not include the permanent option, CLI scripting is disabled the next time the switch boots.

- To support scripting, including the testing of script-related commands, enable scripting using the following command. CLI scripting is disabled by default.

  ```
  enable cli scripting {permanent}
  ```

  > **Note**
  > CLI scripting cannot be enabled when CLI space auto completion is enabled with the `enable cli space-completion` command.

- To disable scripting, use the following command:

  ```
  disable cli scripting {permanent}
  ```

Creating Scripts

There are two ways to create scripts.The method you choose depends on how you want to execute the script.

If you want to create a script file to configure a switch or a switch feature, and you plan to execute that script manually, you can create a script file.

If you want to create a script that is activated automatically when a device or user connects to or disconnects from a switch port, you should create the script with the Universal Port feature. The following sections provide more information on these options.

Creating a Script File

A script file is an ASCII text file that you can create with any ASCII text editor program. The text file can contain CLI commands and can use the scripting options described in the following sections:

- Using Script Variables on page 444
- Using Special Characters in Scripts on page 446
- Using Operators on page 447
- Using Control Structures in Scripts on page 448
- Using Built-In Functions on page 449

You can move an ASCII script file to the switch using the same techniques described for managing ASCII configuration files in Software Upgrade and Boot Options on page 1958.

Creating Scripts for Use with the Universal Port Feature

The Universal Port feature allows you to create dynamic profiles that are activated by a trigger event, such as a user or device connection to a switch port.

These dynamic profiles contain script commands and cause dynamic changes to the switch configuration to enforce a policy. The universal port profiles support all the scripting options listed in Creating Scripts for Use with the Universal Port Feature on page 440 for creating script files. For more information on entering script commands in a universal port profile, see Universal Port on page 392.

ExtremeXOS Shell RC Script

The ExtremeXOS Shell (EXSH) will run an RC script after a successful login. This script must be named `exshrc.xsf` and placed in the default configuration directory (`/usr/local/cfg`). This script is not user-account-specific and runs when any user logs in.

This RC script follows the ExtremeXOS scripting rules and is primarily meant for shell-specific configuration, but is capable of running any ExtremeXOS commands.

The following are some examples of commands that could be placed in this file:

```
alias ps "show process"
disable clipaging
configure cli columns 256 lines 200
```

Python Scripting

Introduced in ExtremeXOS 15.6, Python scripting provides the ability to customize your switch and add functionality quickly by downloading and running scripts without the need for engineering expertise. Python scripting is extended using the synonymous `load script` and `run script` commands.

> **Note**
> To use Python scripting, FIPS mode must be off (`configure security fips-mode [`**on** | **off**`]` and you need to ensure that Python support is enabled (`configure security python [`**on** | **off**`]`).

Expect Functionality

It may be necessary to interact with ExtremeXOS using Expect scripting functionality. The Python community offers a pexpect.py module that can provide this capability. ExtremeXOS uses pexpect.py version 3.2. For documentation, see https://pypi.python.org/pypi/pexpect/

The pexpect.py provides interfaces to run interactive shell commands and to process the results through expect like functions. The challenge with exsh.clicmd() is that it is a synchronous call and not a separate process. The exshexpect.py module was developed to provide a wrapper for pexpect.py that interfaces to exsh.clicmd().

Below is an example of using pexect together with the exshexpect module.

```
import pexpect
```

```
import exshexpect
```

Create a prompt for expect that will not match any command output.

```
exosPrompt = '::--:--::'
```

Create an expect object. Pass in the prompt and the back end function to call:

```
p = exshexpect.exshspawn(exosPrompt, exsh.clicmd)
```

Use sendline to send commands to the backend function (in this case exsh.clicmd) :

```
p.sendline('show fan') <-
```

```
idx = p.expect([exosPrompt, pexpect.EOF, pexpect.TIMEOUT])
```

```
print 'idx=',idx
```

```
print 'before->',p.before
```

```
print 'after->',p.after
```

Special case for passing in a command with an additional argument described in exsh.clicmd():

```
p.send('enable debug-mode\nC211-6BB4-E6F5-B579\n')
```

In the line above, use send() and include 'newline' terminations for the command and the additional parameter.

This is the same as calling:

```
exsh.clicmd('enable debug-mode', True, args='C211-6BB4-E6F5-B579')
```

but using expect to process any response.

```
idx = p.expect([exosPrompt, pexpect.EOF, pexpect.TIMEOUT])
```

Creating Sockets Using Python Scripts

Creating a socket in a Python script defaults to the management interface. You can change the VR when the socket is create by using the following example:

Example: Binding the socket to VR-Default (258) for an UDP socket:
```
import IN
from socket import *
udp_sock = socket(AF_INET, SOCK_DGRAM)
udp_sock.setsockopt(SOL_SOCKET,IN.SO_BINDTODEVICE,"vrf_258")

.
.
.
# your program here
.
.
.

udp_sock.close()
```

> **Note**
> Do not use os.system('echo 2 > /proc/self/ns_id') to do this because os.system() spawns a subprocess. The subprocess will switch to vr-default, and then exit. The calling process will still be using the same VR as before.

Using VRF_258 maps the socket to VR-Default.

In cases where the socket needs to be mapped to a user VR, include the followiung API in the script to get the VR name in kernel.

Example: API to find the VRF_name for a given user VR.
```
import exsh
def vrfNameFromvrName(vrName):
  lst = exsh.clicmd("debug cli show namespace vrId | begin namespaceEntry", True)
  lines = lst.split('\n')
  # ignore first two lines
  lines.pop(0)
  lines.pop(0)
  vrfName = None
  for line in lines:
    if line == "":
    break
  name, id, peer = line.split()
  if name == vrName:
    vrfName = "vrf_" + str(256 + (int(id)))
```

```
     break
return vrfName
```

Python Scripting Examples

Example 1

This is a single line script that illustrates the `exsh.clicmd ()` called from a Python script.

```
print exsh.clicmd('show switch', True)
```

In this example, the second parameter passed to `exsh.clicmd ()` is True. This returns the CLI display output that would have normally been sent to the user. In this case, the line prints the output anyway, which is shown below.

```
SysName:          X670V-48x

```

Example 2

In this example, we create a number of *VLAN (Virtual LAN)*s in the form of `prefix tag` and add tagged port lists to each VLAN. There are a number of methods for collecting user input and validating the data type. This example uses a simple `while True:` loop until the input is the correct type. A more robust example would also apply range checking etc... to the vlan tag(s). E.g. Create vlans with tags from 1000 to 1099 The prefix is 'dave', so each vlan name will have a name like 'dave1000', 'dave1001' etc... The user provided port list will be added to each vlan name as tagged ports.

```
import sys
while True:
    prefix = raw_input('enter vlan name prefix:')
    if len(prefix):
        break

while True:
```

```
        reply = raw_input('beginning vlan tag:')
        if reply.isdigit():
            minTag = int(reply)
            break

while True:
    reply = raw_input('ending vlan tag:')
    if reply.isdigit():
        maxTag = int(reply)
        break

if minTag > maxTag:
    print 'Beginning vlan id cannot be greater than ending vlan id'
    sys.exit(-1)

while True:
    portlist = raw_input('port list:')
    if len(portlist):
        break

print 'Creating vlans from ',prefix+str(minTag),'to',prefix+str(maxTag)

for vlanId in range(minTag,maxTag + 1):
    vlanName = prefix + '{0:>04d}'.format(vlanId)
    cmd = 'create vlan '+vlanName + ' tag ' + str(vlanId)
    print exsh.clicmd(cmd, True)
    cmd = 'config vlan ' + vlanName + ' add port ' + portlist + ' tag'
    print exsh.clicmd(cmd, True)
```

> **Note**
> UPM variables can be used with Python scripting. They must be passed as arguments of the script.

Using Script Variables

Variable names must be followed by white space or otherwise enclosed in parentheses.

For example: create vlan v($X)e where X is the variable. The variable created will persist through the session and will not get reset after disable/enable cli scripting.

Table 35 shows the predefined system variables that are always available for use by any script. Predefined variables are automatically set up for use before a script or profile is executed.

> **Note**
> You must enable CLI scripting before using these variables or executing a script.

Table 35: Predefined System Variables

Variable Syntax	Definition
$STATUS	Status of last command execution. Values -100 to 100 are reserved and automatically set by the software, but you can override the value with the command `return statusCode`. Common values are: 0—Successful command completion-53—Variable not found-57—WHILE depth exceeded 78—Script timeout
$CLI.USER	User who is executing this CLI.
$CLI.SESSION_TYPE	User session type.
$CLI.SCRIPT_TIME_REMAINING	When a script timeout value is configured with the `configure cli script timeout timeout` command, the system creates this variable, which returns the following values (in seconds): If no script is running, this variable returns the configured timeout value. If a script is aborted due to timeout, this variable returns the value 0. If a script finishes execution (before the timeout value is reached), this variable returns the remaining time.
$CLI.SCRIPT_TIMEOUT	When a script timeout value is configured with the `configure cli script timeout timeout` command, the system creates this variable, which returns the current timeout value. If no script is running, this variable returns the configured timeout value.

Table 36 shows the system variables that you must define before use.

Table 36: System Variables that Must Be Created

Variable Syntax	Definition

$CLI.OUT	Output of last show command. The maximum size of this variable is 1 MB. This output can be used for operations such as match and regexp. For more information on these operations, see Using Built-In Functions on page 449.
	You must define this variable before it is used. To define this variable, enter either of the following statements:
	`set var CLI.OUT " "`
	`set var CLI.OUT 0`
	We recommend that you delete this variable after each use.

Creating Variables

You can create your own variables and change their values. When using variables, the following guidelines apply:

- Variable names are case insensitive and are limited to 32 characters.
- The variable name must be unique.
- A variable can be referenced as $X or $(X).
- If a variable already exists, it is overwritten. No error message is displayed.
- The variable expression can be a constant value, another variable, or a combination of the above with operators and functions. Operators are described in , and functions are described in .
- Only the `set var` command supports expression evaluation.
- If the variable name X contains special characters such as +-/*, then the variable needs to be enclosed in parentheses. For example: set var z ($(x) + 100).
- When you use a variable with a TCL special character in the $TCL function, the variable must be enclosed in braces. For example: set var x $TCL(string length ${CLI.USER}.
- For more information on TCL functions, see Using Built-In Functions on page 449.

> **Note**
> ExtremeXOS does not consider the dot/period character as a de-limiter. This is different from standard TCL behavior, where dot/period is considered as a de-limiter.

- To create a variable and set a value for it, or to change a variable value, use the following command:

```
set var varname _expression
```

The following examples show various ways to define or change variables:

```
set var x 100

set var x ($x + 2)

set var y ($x - 100)
```

- To display all variables or a specified variables, use the following command:

```
show var {varname}
```

Using Special Characters in Scripts

The dollar sign ($) character and quote (") characters have special purposes in scripts.

The ($) indicates a variable, and the (") surrounds text strings. To use these characters as regular characters, precede the special character with a backslash character (\). For example:

```
set var variablename \$<varname>
set var CLI.USER "Robert \"Bob\" Smith"
```

Scripts also support quote characters within quotes.

Using Operators

Operators allow you to manipulate variables and evaluate strings.

Some operators can be used in all numeric expressions, while others are restricted to integer or string expressions. Table 37 lists the operators supported and provides comments on when they can be used. The valid operators are listed in decreasing order of precedence.

Table 37: Operators

Operator	Action	Comments
-	Unary minus	None of these operands can be applied to string operands, and the bit-wise NOT operand can be applied only to integers.
+	Unary plus	
~	Bit-wise NOT	
!	Logical NOT	
*	Multiply	None of these operands can be applied to string operands, and the remainder operand can be applied only to integers. The remainder always has the same sign as the divisor and an absolute value smaller than the divisor.
/	Divide	
%	Remainder	
+	Add	These operands are valid for any numeric operations.
-	Subtract	
<<	Left shift	These operands are valid for integer operands only. A right shift always propagates the sign bit.
>>	Right shift	
<	Boolean less	Each operator produces 1 if the condition is true, 0 otherwise. These operators can be applied to strings as well as numeric operands, in which case string comparison is used.
>	Boolean greater	
<=	Boolean less than or equal	
>=	Boolean greater than or equal	
==	Boolean equal	Each operator produces a zero or one result. These operators are valid for all operand types.
!=	Boolean not equal	
&	Bit-wise AND	This operator is valid for integer operands only.
^	Bit-wise exclusive OR	This operator is valid for integer operands only.
|	Bit-wise OR	This operator is valid for integer operands only.
&&	Logical AND	This operator produces a result of 1 if both operands are non-zero. Otherwise, it produces a result of 0. This operator is valid for numeric operands only (integers or floating-point).

Table 37: Operators (continued)

Operator	Action	Comments
||	Logical OR	This operator produces a result of 0 if both operands are zero. Otherwise, it produces a result of 1.This operator is valid for numeric operands only (integers or floating-point).
x?y:z	If-then-else (as in the C programming language)	If x evaluates to non-zero, then the result is the value of y. Otherwise the result is the value of z. The x operand must have a numeric value.

Using Control Structures in Scripts

The CLI supports the control structures described in the following sections.

Conditional Execution

```
IF (<expression>) THEN
<statements>
ELSE
<statements>
ENDIF
```

The expression must be enclosed in parentheses.

Loop While Condition is TRUE

```
WHILE (<expression>) DO
    <statements>
ENDWHILE
```

The expression must be enclosed in parentheses.

Nesting is supported up to five levels. The Ctrl-C key combination can be used to break out of any While loop(s).

The operators mentioned in Using Operators on page 447 can be used in an expression in the set var command or in an IF or WHILE condition.

If there is incorrect nesting of an IF condition or WHILE loop, an error message appears. If a user tries to type more than five WHILE loops or five IF conditions, an error message appears. Breaking out of any number of WHILE loops always clears the WHILE condition.

Comments can be inserted by using the number sign (#).

Using Built-In Functions

Built in functions allow you to manipulate and evaluate the variables inside your script and the script output. Table 38 shows the built-in functions. Table 39 on page 449 shows the built-in Tool Command Language (TCL) functions.

> **Note**
> ExtremeXOS uses TCL version 8.5.14.

Table 38: Built-In Functions

Syntax	Function
$MATCH(string 1, string 2)	Compares the two strings string 1 and string 2. Returns 0 if string1 matches string2. It returns -1,0, or 1, depending on whether string1 is less than, equal to, or greater than string2.
$READ(prompt)	Displays a prompt for user input and accepts input until the user presses **[Enter]** or the session times out. Replace prompt with the prompt to display to the user.
$TCL(function args)	Calls a TCL built-in function (see Table 39 on page 449). Note that the software does not support the simultaneous operation of multiple TCL functions. For more information on TCL functions, go to http://www.tcl.tk/man/tcl8.3/TclCmd/contents.htm.
$UPPERCASE(string)	Returns the string uppercased.
$VAREXISTS(varname)	Returns zero if the specified variable does not exist. Returns non-zero if the specified variable does exist.

Table 39: Supported TCL Functions

Function	Function Type	Description
after	System related	Execute a command after a time delay.
binary	String handling	Insert and extract fields from binary strings.
clock	System related	Obtain and manipulate time.
concat	List handling	Join lists together.
expr	Math	Evaluate an expression.
join	List handling	Create a string by joining list elements together.
lindex	List handling	Retrieve an element from a list.
linsert	List handling	Insert elements into a list.
list	List handling	Create a list.
llength	List handling	Count the number of elements in a list.
lrange	List handling	Return one or more adjacent elements from a list.

Table 39: Supported TCL Functions (continued)

Function	Function Type	Description
lreplace	List handling	Replace elements in a list with new elements.
lsearch	List handling	See if a list contains a particular element.
lsort	List handling	Sort the elements of a list.
regexp	String handling	Match a regular expression against a string.
regsub	String handling	Perform substitutions based on regular expression pattern matching.
re_syntax	String handling	Syntax of TCL regular expressions.
split	List handling	Split a string into a proper TCL list.
string	String handling	Manipulate strings.

For examples of scripts that use TCL functions, see CLI Scripting Examples on page 454.

Control Script Configuration Persistence

When a script runs, the commands within the script can make persistent changes to the switch configuration, which are saved across reboots, or it can make non-persistent changes. Non-persistent configuration changes remain part of the switch configuration only until the switch reboots.

The default setting for scripts is non-persistent. To change the script configuration persistence setting, use the following command:

```
configure cli mode [persistent | non-persistent]
```

Saving, Retrieving, and Deleting Session Variables

Session variables are the set of variables that are active for a particular session. For example, if a device is detected on a universal port and this triggers a profile (and the script commands within it), the variable values that were active when the profile started are replaced with the variable values defined in the profile. The first session is the device-undetected session, and the second session is the device-detected session. Each session has its own set of variables and values.

The software allows you to save session variables before replacing them. In the example above, this allows you to retrieve the earlier values when the port returns to the device-undetected state. Up to five variables can be saved or retrieved at a time. These variables are saved to system memory using a key, which is an ID for the saved variables. You are responsible for generating unique keys. When you want to retrieve the variables, you use the key to identify the variables to be retrieved.

- To save up to five session variables, use the following command:
  ```
  save var key key [var1 var2 ...]
  ```

- To retrieve saved session variables, use the following command:

  `load var key` *key* [*var1 var2 …*]

- To delete saved session variables, use the following command:

  `s`delete var key *key*

The variables saved by the save var command are saved using the specified key and are retrievable and restored in the context that this profile was applied. They are available to rollback events like user-unauthenticate and device-undetect.

> **Note**
> For SummitStack, session variables are saved on the master ExtremeSwitching switch. To repopulate session variables after a failover event, manually execute the appropriate script.

Nesting Scripts

The ExtremeXOS software supports three levels of nested scripts. An error appears if you attempt to start a fourth-level script. The following example demonstrates nested scripts:

```
Load script x1
# Script x1 contents:
Cmd 1
Cmd 2
Load script x2
Cmd 3
Cmd 4
# Script x2 contents:
Cmd 1
Cmd 2
Load script x3
```

In the above example, Cmd x is a generic representation for any script command. Script x1 is the first level script and launches the second level script Script x2. Script x2 launches the third level script Script x3. If Script x3 contained a command to launch another script, the script would not launch the software would generate an error.

Executing Scripts

You can execute scripts by loading a script file or through the Universal Port feature.

Execute a Script File

Transfer the script file to the switch and use the `load script` *filename* {**arg1**} {**arg2**} `...` {**arg9**} command.

Executing a Universal Port Script

Universal port scripts are called profiles and are executed based on several types of trigger events, including device detection and undetection and user authentication and unauthentication.

For information on how to create profiles and configure the triggers, see Universal Port on page 392.

Configuring Error Handling

The default error handling behavior is to ignore errors. You can change options within the scripts.

To control script error handling, use the following command:

```
configure cli mode scripting [abort-on-error | ignore-error]
```

Aborting a Script

There are three ways to abort a script:

- Press **[Ctrl]** + **C** while the script is executing.
- Configure the switch to abort a script when an error occurs by using the following command:
  ```
  configure cli mode scripting [abort-on-error | ignore-error]
  ```
- Abort a script and store a status code in the $STATUS variable by using the following command:
  ```
  return statusCode
  ```

Displaying CLI Scripting Information

You can use the information in the following sections to display CLI scripting information.

Viewing CLI Scripting Status

The `show switch management` command displays whether or not CLI scripting is enabled, whether or not the configuration is persistent, and the CLI scripting error mode as shown in the following example:

```
# show switch management
CLI idle timeout                  : Enabled (20 minutes)
CLI max number of login attempts : 3
CLI max number of sessions        : 8
CLI paging                        : Enabled
CLI space-completion              : Disabled (this session only)
CLI configuration logging         : Disabled (without expansion)
CLI journal size                  : 100
CLI password prompting only       : Disabled
CLI display moved-keywords        : Hidden
CLI moved-keywords hidden release : 31.5
CLI RADIUS cmd authorize tokens   : 2
CLI scripting                     : Disabled (this session only)
CLI scripting error mode          : Ignore-Error (this session only)
CLI script search path            : ".:/usr/local/cfg" (this session only)
CLI persistent mode               : Persistent (this session only)
CLI prompting                     : Enabled (this session only)
CLI screen size                   : 24 Lines 80 Columns (this session only)
CLI refresh                       : Enabled
CLI history expansion             : Disabled
```

```
Image integrity checking          : Off
Current system port notation      : slot:port
Configured system port notation   : slot:port
Telnet access                     : Enabled (tcp port 23 vr all)
                                  : Access Profile : not set
SSH access                        : Disabled (Key invalid, tcp port 22 vr all)
                                  : Secure-Mode    : Off
                                  : Access Profile : not set
SSH2 idle time                    : 60 minutes
SSH2 rekey interval               : 4096 MB and no time limit
Web access                        : Enabled (tcp port 80)
                                  : Access Profile : not set
Total Read Only Communities       : 0
Total Read Write Communities      : 0
RMON                              : Disabled
SNMP access                       : Disabled
                                  : Access Profile : not set
SNMP Notifications                : Enabled
SNMP Notification Receivers   : None
SNMP stats:      InPkts 0        OutPkts   0        Errors 0        AuthErrors 0
                 Gets   0        GetNexts  0        Sets   0        Drops      0
SNMP traps:      Sent   0        AuthTraps Enabled
SNMP inform:     Sent   0        Retries   0        Failed 0
(pacman debug) Slot-1 switch_model-EXOS.2 #
```

Viewing CLI Scripting Variables

The `show var` command displays the currently defined variables and their values as shown in the following example:

```
Switch.4 # show var
---------------------------------------
Count : 3
---------------------------------------
----------------------------------------------------------------------
variableName                     variableValue
-------------------------------  --------------------------------
CLI.SESSION_TYPE                 serial
CLI.USER                         admin
STATUS                           0
----------------------------------------------------------------------
```

Controlling CLI Script Output

When the `load script` command is entered, the software disables CLI scripting output until the script is complete, and then CLI scripting output is enabled.

When the CLI scripting output is disabled, the only script output displayed is the `show var {`*varname*`}` command and its output. When the CLI scripting output is enabled, all script commands and responses are displayed.

Use the `enable cli scripting` **output** and `disable cli scripting output` commands to control what a script displays when you are troubleshooting.

CLI Scripting Examples

The following script creates 100 VLANS with IP Addresses from 10.1.1.1/16 to 10.100.1.1/16:

```
enable cli scripting
Set var count 1
while ($count < 101) do
Create vlan v$count
configure vlan v$count ipaddress 10.$(count).1.1/16
set var count ($count + 1)
endwhile
show vlan
```

The following script introduces a 60-second delay when executed:

```
set var temp $TCL(after [expr 60 *1000])
```

The following script displays the date and time:

```
set var CLI.OUT " "
show switch
set var date $TCL(lrange ${CLI.OUT} 27 29)
set var year $TCL(lrange ${CLI.OUT} 31 31)
set var date $TCL(linsert $date 3 $year)
set var time $TCL(lrange ${CLI.OUT} 30 30)
show var date
show var time
```

The following script sorts the _FDB (forwarding database)_ table in descending order:

```
set var CLI.OUT " "
show fdb
set var x1 $TCL(split ${CLI.OUT} "\n")
set var x2 $TCL(lsort -decreasing $x1)
set var output $TCL(join $x2 "\n")
show var output
```

The following script extracts the MAC address given the age of an FDB entry:

```
set var CLI.OUT " "
show fdb
set var input $TCL(split ${CLI.OUT} "\n")
set var y1 $TCL(lsearch -glob $input *age*)
set var y2 $TCL(lindex $input $y1)
set var y3 $TCL(split $y2 " ")
set var y4 $TCL(lindex $y3 0)
show var y4
```

LLDP Overview

The Link Layer Discovery Protocol (LLDP) is defined by IEEE standard 802.1ab and provides a standard method for discovering physical network devices and their capabilities within a given network management domain.

LLDP-enabled network devices include repeaters, bridges, access points, routers, and wireless stations, and LLDP enables these devices to do the following:

- Advertise device information and capabilities to other devices in the management domain.
- Receive and store device information received from other network devices in the management domain.

LLDP-discovered information can be used to do the following:

- Discover information from all LLDP compatible devices in a multivendor environment.
- Trigger universal port profiles that can configure a switch port for a remote device (see Universal Port on page 392).
- Supply identity information that can be used for authentication and identity management (see LLDP).
- Provide device information to *SNMP (Simple Network Management Protocol)* compatible Network Management Systems such as Extreme Management Center or Ridgeline, which can present the information in inventory reports and topology maps.

The following sections provide additional information on LLDP support in the ExtremeXOS software.

Supported Advertisements (TLVs)

LLDP (Link Layer Discovery Protocol) defines a set of common advertisement messages. These are distributed in Type Length Value (TLV) format in an LLDP packet (see LLDP Packets on page 461).

The individual advertisements within the packet are called TLVs, and each TLV advertises device information or a device capability. Certain TLVs are mandatory and are always advertised after LLDP is enabled; optional TLVs are advertised only when so enabled by default or during configuration.

The following sections provide more information on TLVs.

Mandatory TLVs

Mandatory TLVs are those TLVs that must be advertised (as defined in IEEE standard 802.1ab) when *LLDP* is enabled.

If you enable LLDP on a port, the mandatory TLVs are advertised and there is no command to disable this advertising.

Table 40: Mandatory TLVs

Name	Comments
Chassis ID	The ExtremeXOS software advertises the system's MAC address in this TLV to uniquely identify the device. **Note:** *EDP (Extreme Discovery Protocol)* also uses the MAC address to identify the device.
Port ID	The ExtremeXOS software advertises the port ID in this TLV to uniquely identify the port that sends the TLVs. This port ID is the ifName object in the MIB.
Time to live (TTL)	This TLV indicates how long the record should be maintained in the LLDP database. The default value is 120 seconds (or 2 minutes). When a port is shutting down or LLDP is disabled on a port, this TLV is set to value 0, which indicates that the record for this port should be deleted from the database on other devices. Although you cannot directly configure the TTL TLV, you can configure the transmit hold value, which is used to calculate the TTL TLV. (See Configuring LLDP Timers on page 464 for more information.)
End-of-LLDP PDU	The end-of-LLDPDU (LLDP protocol data unit) TLV marks the end of the data in each LLDP packet.

Optional TLVs

IEEE standard 802.1ab defines a set of optional TLVs, which are listed in the following table.

The system description TLV is advertised by default. All other optional TLVs must be configured to enable advertising. You can use the CLI to configure the optional TLVs, or you can use an _SNMP_-compatible network management system (NMS) such as Extreme Management Center or Ridgeline. For more information on the optional TLVs, see Configuring Optional TLV Advertisements on page 466.

Table 41: Optional TLVs

Name	Comments
Port description	Advertises the display-string that is configured for the port.
System name	Advertises the device's configured system name, which is configured with the configure snmp sysname command.

System description	Advertises show version command information similar to the following:
	`ExtremeXOS version 11.2.0.12 v1120b12 by release-manager`
	`on Fri Mar 18 16:01:08 PST 2005`
	The default configuration advertises this optional TLV when _LLDP_ is enabled.

System capabilities	Advertises bridge capabilities. If IP forwarding is enabled on at least one _VLAN (Virtual LAN)_ in the switch, the software also advertises router capabilities.
Management address	Advertises the IP address of the management VLAN in the management address TLV. If the management VLAN does not have an assigned IP address, the management address TLV advertises the system's MAC address, unless another VLAN's IP address is specified (see Management Address TLV on page 467).
VLAN name	Advertises the name of a tagged VLAN for the port. You can configure this TLV multiple times to support multiple VLANs.
Port VLAN ID	Advertises the untagged VLAN on the port.
Port and protocol VLAN ID	Advertises a VLAN and whether the port supports protocol-based VLANs or not. You can configure this TLV multiple times to support multiple VLANs.
MAC/PHY configuration/status	Advertises the autonegotiation and physical layer capabilities of the port.
Power via MDI	For Ethernet (_PoE (Power over Ethernet)_) or PoE+ ports, this TLV advertises the device type, power status, power class, and pin pairs used to supply power.
Link aggregation	Advertises information on the port's load-sharing (link aggregation) capabilities and status.
Maximum frame size	Advertises the maximum supported frame size for a port to its neighbors. When jumbo frames are not enabled on the specified port, the TLV advertises a value of 1518. If jumbo frames are enabled, the TLV advertises the configured value for the jumbo frames.

Avaya–Extreme Networks Optional TLVs

The software supports a set of TLVs that are proprietary to Avaya and Extreme Networks.

These TLVs advertise and receive information for Avaya voice over IP (VoIP) telephones, which include powered device (PD) information. Some TLVs are advertised by the switch, and some are advertised by the telephone. The switch starts advertising these proprietary TLVs when you enable *LLDP* and configure the specified TLVs to be advertised. The switch receives the proprietary TLVs when LLDP is enabled; you do not have to configure the switch to receive individual TLVs.

Table 42: Avaya–Extreme Networks TLVs

Name	Comments
PoE conservation level request	When the switch software needs to reduce power on a PoE-enabled port, this TLV advertises that request to the connected Avaya device.
Call server	The switch uses this TLV to advertise the IP addresses of up to eight call servers to an Avaya phone.
File server	The switch uses this TLV to advertise the IP addresses of up to four file servers to an Avaya phone.
802.1Q framing	The switch uses this TLV to advertise information about Layer 2 priority tagging to an Avaya phone.
PoE Conservation level support	An Avaya phone uses this TLV to communicate the current power consumption level and current conservation level for the phone, including typical power value, maximum power value, and available conservation power levels.
IP phone address	An Avaya phone uses this TLV to communicate the IP address and mask configured in the phone, as well as a default gateway address.
CNA server	An Avaya phone uses this TLV to communicate the IP address of a Converged Network Analyzer (CNA).
Fabric Attach (FA) Element	Used by FA elements to advertise their FA capabilities.
Fabric Attach (FA) Assignment	Used by FA clients to advertise service requests and by FA proxy and FA server elements to return the status of FA client service requests.

LLDP MED Optional TLVs

LLDP Media Endpoint Discovery (MED) is an extension to LLDP that is published as standard ANSI/TIA-1057. LLDP MED TLVs advertise and receive information for endpoint

devices, which can include powered device (PD) information. Some TLVs are advertised by the switch, and some are advertised by the endpoint device.

Table 43: LLDP MED TLVs

Name	Comments
LLDP MED capabilities	The switch uses this TLV to advertise the switch LLDP MED capabilities to endpoint devices. This TLV must be configured for advertisement before any other LLDP MED TLVs can be configured for advertisement, and advertisement for all other MED TLVs, must be disabled before advertisement for this TLV can be disabled.
Network policy	The switch uses this TLV to advertise network policy information for specific applications to endpoint devices. **Note:** Network policies cannot be configured by *SNMP*-based management programs.
Location ID	The switch uses this TLV to advertise a location ID to an endpoint device.
Extended power via MDI	The switch uses this TLV to advertise a power information and settings to an endpoint device on a *PoE*-capable port.
Hardware revision	An endpoint device uses this TLV to advertise the configured hardware revision to the switch.
Firmware revision	An endpoint device uses this TLV to advertise the configured firmware revision to the switch.
Software revision	An endpoint device uses this TLV to advertise the configured software revision to the switch.
Serial number	An endpoint device uses this TLV to advertise the configured serial number to the switch.
Manufacturer name	An endpoint device uses this TLV to advertise the configured manufacturer name to the switch.
Model name	An endpoint device uses this TLV to advertise the configured model name to the switch.
Asset ID	An endpoint device uses this TLV to advertise the configured asset ID to the switch.

You must enable the LLDP-MED capabilities TLV for advertising before you configure any other LLDP MED TLVs for advertising. Likewise, when disabling LLDP MED TLV advertisement, you can disable the LLDP-MED capabilities TLV only after you have disabled advertisement for all other LLDP MED TLVs.

After the LLDP-MED capabilities TLV is configured for advertising, the switch can receive LLDP MED TLVs from endpoints; you do not have to configure the switch to receive individual TLVs.

The switch advertises LLDP MED TLVs only after the switch receives an LLDP MED TLV from an endpoint, and the switch only advertises on ports from which an LLDP MED TLV has been received. This approach prevents the switch from advertising LLDP

MED TLVs to another switch, and it prevents the wasted bandwidth and processing resources that would otherwise occur.

The LLDP MED protocol extension introduces a new feature called MED fast start, which is automatically enabled when the LLDP MED capabilities TLV is configured for advertisement.

When a new LLDP MED-capable endpoint is detected, the switch advertises the configured LLDP MED TLVs every one second for the configured number of times (called the repeat count). This speeds up the initial exchange of LLDP MED capabilities. After the repeat count is reached, the LLDP MED TLVs are advertised at the configured interval.

> **Note**
> The fast-start feature is automatically enabled, at the default level of 3, when you enable the LLDP MED capabilities TLV on the port.

BGP Config Discovery Optional TLV

LLDP BGP (Border Gateway Protocol) Peer Discovery is an extension to LLDP from the IETF BGP LLDP Peer Discovery draft. The TLVs advertise BGP information that is used to discover BGP peers. The TLV is advertised when Auto-peering is created. LLDP BGP Config consists of a single TLV with multiple sub-TLVs within the TLV.

Table 44: BGP Config Discovery Optional TLV

Name	Comments
Peering address	Advertises the local IP addresses used for BGP sessions. When Auto-peering is created, this advertises the IPv6 link-local IP address of the system.
BGP local AS	Advertises the BGP local Autonomous System (AS) numbers. When Auto-peering is created, this advertises Auto-peering's AS-number.
BGP identifier	Advertises the local BGP identifier. When Auto-peering is created, this advertises Auto-peering's router ID.
Session group-ID	Advertises a value to identify a BGP session class or category.
BGP session capabilities	Advertises the capabilities of the BGP session.
Key chain	Advertises the key chain name used for BGP session authentication.

LLDP Redundancy Support on Stacking

ExtremeXOS 31.6 introduces active redundancy support for LLDP on stacking.

LLDP information (for example, LLDP neighbors, Fabric Attach Elements and Assignments) is continuously synchronized from the Primary to the Backup nodes. In case of Failover, the Backup becomes the Primary node, with all existing LLDP information retained. Existing LLDP and Fabric Attach neighbors are not re-learned.

Because Fabric Attach Assignments are retained, there is no impact on the traffic during Failover.

> **Note**
> Statistics information is not synchronized to the Backup. LLDP and Fabric Attach statistics start from empty on Failover.

LLDP Packets

LLDP packets transport TLVs to other network devices (see Figure 49).

The LLDP packet contains the destination multicast address, the source MAC address, the LLDP EtherType, the LLDPDU data (which contains the TLVs), and a frame check sequence (FCS). The LLDP multicast address is defined as 01:80:C2:00:00:0E, and the EtherType is defined as 0x88CC.

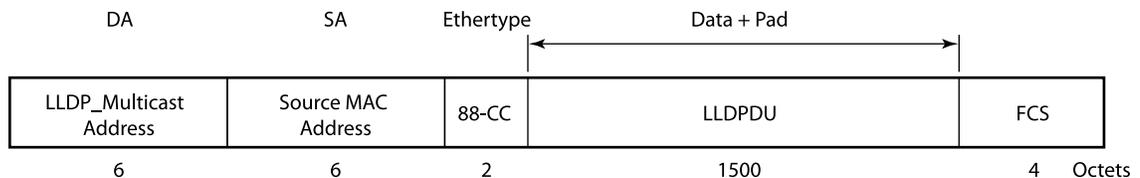
DA	SA	Ethertype	Data + Pad	
LLDP_Multicast Address	Source MAC Address	88-CC	LLDPDU	FCS
6	6	2	1500	4 Octets


Figure 49: LLDP Packet Format

The following characteristics apply to LLDP packets:

- They are IEEE 802.3 Ethernet frames.
- The frames are sent as untagged frames.
- The frames are sent with a link-local-assigned multicast address as the destination address.
- The *STP (Spanning Tree Protocol)* state of the port does not affect the transmission of LLDP frames.

The length of the packet cannot exceed 1500 bytes. As you add TLVs, you increase the length of the LLDP frame. When you reach 1500 bytes, the remaining TLVs are dropped. We recommend that you advertise information regarding only one or two VLANs on the LLDP port, to avoid dropped TLVs.

If the system drops TLVs because of exceeded length, the system logs a message to the EMS and the `show lldp statistics` command shows this information under the Tx Length Exceeded field.

> **Note**
> The LLDPDU maximum size is 1500 bytes, even with jumbo frames enabled. TLVs that exceed this limit are dropped.

Transmitting LLDP Messages

You can configure each port to transmit *LLDP* messages, receive LLDP messages, or both.

When configured to transmit LLDP messages, the LLDP agent running on the switch passes serially through the list of ports that are enabled for LLDP. For each LLDP-enabled port, the switch periodically sends out an untagged LLDP packet that contains the mandatory LLDP TLVs as well as the optional TLVs that are configured for advertisement. These TLVs are advertised to all neighbors attached to the same network. LLDP agents cannot solicit information from other agents by way of this protocol.

> **Note**
>
> When both IEEE 802.1X and LLDP are enabled on the same port, LLDP packets are not sent until one or more clients authenticate a port.
>
> Also, LLDP MED TLVs are advertised only after an LLDP MED TLV is received on a port that is configured for LLDP MED. (See LLDP MED Optional TLVs on page 458.)

The source information for TLVs is obtained from memory objects such as standard MIBs or from system management information. If the TLV source information changes at any time, the LLDP agent is notified. The agent then sends an update with the new values, which is referred to as a triggered update. If the information for multiple elements changes in a short period, the changes are bundled together and sent as a single update to reduce network load.

Receiving LLDP Messages

You can configure each port to transmit *LLDP* messages, receive LLDP messages, or both.

After you configure a port to receive TLVs, all LLDP TLVs are received (even if the LLDP MED capabilities TLV is not enabled). Each port can store LLDP information for a maximum of four neighbors.

> **Note**
>
> When both IEEE 802.1X and LLDP are enabled on the same port, incoming LLDP packets are accepted only when one or more clients are authenticated.

When configured to receive LLDP messages, the TLVs received at a port are stored in a standard Management Information Base (MIB), which makes it possible for the information to be accessed by an *SNMP*-compatible NMS such as Extreme Management Center or Ridgeline. Unrecognized TLVs are also stored on the switch, in order of TLV type. TLV information is purged after the configured timeout interval,

unless it is refreshed by the remote LLDP agent. You can also manually clear the LLDP information for one or all ports with the `clear lldp neighbors` command.

- To display TLV information received from LLDP neighbors, use the following command:

  `show lldp neighbors detailed`

  You must use the detailed variable to display all TLV information.

LLDP Management

You can manage *LLDP* using the CLI and/or an *SNMP*-compatible NMS such as Extreme Management Center or Ridgeline. LLDP works concurrently with the *EDP*. It also works independently; you do not have to run EDP to use LLDP.

You can use the `save configuration` command to save LLDP configurations across reboots.

The switch logs EMS messages regarding LLDP, including when optional TLVs exceed the 1500-byte limit and when more than four neighbors are detected on a port.

After you enable LLDP, you can enable LLDP-specific SNMP traps; the traps are disabled by default. After you enable LLDP-specific traps, the switch sends all LLDP traps to the configured trap receivers. You can configure the period between SNMP notifications; the default interval is five seconds.

You can configure an optional TLV to advertise or not advertise the switch management address information to the neighbors on a port. When enabled, this TLV sends out the IPv4 address configured on the management *VLAN*. If you have not configured an IPv4 address on the management VLAN, the software advertises the system's MAC address. LLDP does not send IPv6 addresses in this field.

Configuring and Managing LLDP

The following sections describe how to configure *LLDP* on the switch.

Configuration Overview

You configure *LLDP* per port, and each port can store received information for a maximum of four neighbors.

> **Note**
> LLDP runs with link aggregation.

You can configure LLDP per port.

1. Enable LLDP on the desired port(s) as described in Enabling and Disabling LLDP on page 464.
2. If you want to change any default timer values, see Configuring LLDP Timers on page 464.

3. Enable the *SNMP* traps and configure the notification interval as described in Configuring SNMP for LLDP on page 465.
4. Configure any optional TLV advertisements as described in Configuring Optional TLV Advertisements on page 466.

> **Note**
> By default, an LLDP-enabled port advertises the optional system description TLV. By default, all other optional TLVs are not advertised.

Enabling and Disabling LLDP

LLDP is enabled on all ports by default. When you enable LLDP on one or more ports, you select whether the ports will only transmit LLDP messages, only receive the messages, or both transmit and receive LLDP messages.

After you enable LLDP, the following TLVs are automatically added to the LLDPDU:

- Chassis ID
- Port ID
- TTL
- System description
- End of LLDPDU

All of these, except the system description, are mandated by the 802.1ab standard and cannot be configured. For information on changing the system description TLV advertisement, see System Description TLV on page 467.

- Enable LLDP.

  ```
  enable lldp ports [all | port_list] {receive-only | transmit-only}
  ```
- Disable LLDP.

  ```
  disable lldp ports [all | port_list] {receive-only | transmit-only}
  ```

Configuring LLDP Timers

The *LLDP* timers apply to the entire switch and are not configurable by port. After you enable LLDP, LLDP timers control the time periods for the transmission and storage of LLDP TLVs as follows:

- Reinitialization period (default is two seconds).
- Delay between LLDP transmissions (default is two seconds)—applies to triggered updates, or updates that are initiated by a change in the topology.

- Transmit interval (default is 30 seconds)—applies to messages sent periodically as part of protocol.
- Time-to-live (TTL) value (default is two minutes)—time that the information remains in the recipient's LLDP database.

> **Note**
> Once the LLDP MED TLVs begin transmitting (after detecting LLDP MED TLVs from a connected endpoint), those TLVs are also controlled by these timers.

When LLDP is disabled or if the link goes down, LLDP is reinitialized. The reinitialize delay is the number of seconds the port waits to restart the LLDP state machine; the default is two seconds.

The time between triggered update LLDP messages is referred to as the transmit delay, and the default value is two seconds. You can change the default transmit delay value to a specified number of seconds or to be automatically calculated by multiplying the transmit interval by 0.25.

Each LLDP message contains a TTL value. The receiving LLDP agent discards all LLDP messages that surpass the TTL value; the default value is 120 seconds. The TTL is calculated by multiplying the transmit interval value and the transmit hold value; the default transmit hold value is four.

- To change the default reinitialize delay period, use the following command:

  ```
  configure lldp reinitialize-delay seconds
  ```

  LLDP messages are transmitted at a set interval; this interval has a default value of every 30 seconds.
- To change this default value, use the following command:

  ```
  configure lldp transmit-interval seconds
  ```
- To change the value for the transmit delay, use the following command:

  ```
  configure lldp transmit-delay [ auto | seconds]
  ```
- To change the default transmit hold value, use the following command:

  ```
  configure lldp transmit-hold hold
  ```

Configuring SNMP for LLDP

By default, *SNMP LLDP* traps are disabled on all ports. The default value for the interval between SNMP LLDP trap notifications is 5 seconds.

- To enable LLDP SNMP traps on one or more ports, use the following command:

  ```
  enable snmp traps lldp {ports [all | port_list]}
  ```

  The traps are only sent for those ports that are both enabled for LLDP and have LLDP traps enabled.
- To disable the LLDP SNMP traps on one or more ports, use the following command:

  ```
  disable snmp traps lldp {ports [all | port_list]}
  ```

- To change the default value for the interval for the entire switch, use the following command:

  ```
  configure lldp snmp-notification-interval seconds
  ```

  > **Note**
  > If you want to send traps for LLDP MED, you must configure it separately. Use the `enable snmp traps lldp-med {ports [all | port_list]}` command to enable these traps.

Configuring Optional TLV Advertisements

By default, the ExtremeXOS software advertises the mandatory _LLDP_ TLVs (which are not configurable) and the optional system description TLV. For details, see Supported Advertisements (TLVs) on page 456). All other optional TLVs are not advertised.

You can choose to advertise or not advertise any optional TLV, but be aware that the total LLDPDU length, which includes the mandatory TLVs, cannot exceed 1500 bytes. Optional TLVs that cause the LLDPDU length to exceed the 1500-byte limit are dropped. You can see if the switch has dropped TLVs by referring to the EMS log or by issuing the `show lldp statistics` command.

The following sections describe configuration for the following types of optional TLVs.

Configuring Standards-Based TLVs

This section describes the following optional standards-based TLVs.

Port description TLV

The port description TLV advertises the ifDescr MIB object, which is the ASCII string you configure.

The string can be configured using the `configure ports display-string` command.

If you have not configured this parameter, the TLV carries an empty string.

To control advertisement of the port description TLV, use the following command:

```
configure lldp ports [all | port_list] [advertise | no-advertise] port-description
```

System name TLV

The system name TLV advertises the configured system name for the switch. This is the sysName as defined in RFC 3418, which you can define using the `configure snmp sysname` command.

To control advertisement of the system name TLV, use the following command:

```
configure lldp ports [all | port_list] [advertise | no-advertise] system-name
```

System Description TLV

By default, the ExtremeXOS software advertises this TLV whenever you enable _LLDP_ on a port, but you can disable advertisement. This TLV advertises show version command information similar to the following in the system description TLV:

```
ExtremeXOS version 11.2.0.12 v1120b12 by release-manager
on Fri Mar 18 16:01:08 PST 2005
```

To control advertisement of the system description TLV, use the following command:

`configure lldp ports [all | port_list] [advertise | no-advertise] system-description`

System Capabilities TLV

The system capabilities TLV advertises the capabilities of the switch and which of these capabilities are enabled. When so configured, the ExtremeXOS software advertises bridge capabilities. If IP forwarding is enabled on at least one _VLAN_ in the switch, the software also advertises router capabilities.

To control advertisement of the system capabilities TLV, use the following command:

`configure lldp ports [all | port_list] [advertise | no-advertise] system-capabilities`

Management Address TLV

The management address TLV advertises the IP address of the management _VLAN_. If the management VLAN does not have an assigned IP address, the management address TLV advertises the system's MAC address, unless another VLAN's IP address is specified. _LLDP_ does not recognize IPv6 addresses in this field.

To specify a VLAN IP address, other than the Management VLAN, for advertisement as the management address, use the following command:

`configure lldp **management-address** [[[{**vlan**} vlan_name | **vlan** vlan_id] {**primary-ip** | **secondary-ip** secondary_ip_address}] | **mac-address**]`

To turn on or off advertisement of the management address TLV, use the following command:

`configure lldp ports [all | port_list] [advertise | no-advertise] management-address`

> **Note**
> The ExtremeXOS software sends only one management address.

VLAN Name TLV

The _VLAN_ name TLV advertises a VLAN name for one or more VLANs on the port. You can advertise this TLV for tagged and untagged VLANs. When you enable this TLV for tagged VLANs, the TLV advertises the IEEE 802.1Q tag for that VLAN. For untagged VLANs, the internal tag is advertised.

If you do not specify a VLAN when you configure this TLV, the switch advertises all VLAN names on the specified ports. You can choose to advertise one or more VLANs for the specified ports by specifying the name of a VLAN in the configuration command. You can repeat the command to specify multiple VLANs.

To control advertisement of the port VLAN Name TLV, use the following command:

```
configure lldp ports [all | port_list] [advertise | no-advertise]
vendor-specific dot1 vlan-name {vlan [all | vlan_name]}
```

> **Note**
> Because each VLAN name requires 32 bits and the LLDPDU cannot exceed 1500 bytes, we recommend that you configure each port to advertise no more than one or two specific VLANs. Optional TLVs that cause the LLDPDU length to exceed the 1500-byte limit are dropped.

Port VLAN ID TLV

The port _VLAN_ ID advertises the untagged VLAN on that port. Thus, only one port VLAN ID TLV can exist in the LLDPDU. If you configure this TLV and there is no untagged VLAN on the specified port, this TLV is not included in the LLDPDU.

- To control advertisement of the port VLAN ID TLV, use the following command:
  ```
  configure lldp ports [all | port_list] [advertise | no-advertise]
  vendor-specific dot1 port-vlan-ID
  ```

Port and Protocol VLAN ID TLV

When configured for advertisement, this TLV advertises whether the specified _VLAN_s on the specified ports support protocol-based VLANs or not.

If you do not specify a VLAN when you configure this TLV, the switch advertises protocol-based VLAN support for all VLAN names on the specified ports. You can choose to advertise support for one or more VLANs for the specified ports by specifying the name of a VLAN in the configuration command. You can repeat the configuration command to specify multiple VLANs.

Because all VLANs on Extreme Networks switches support protocol-based VLANs, the switch always advertises support for protocol-based VLANs for all VLANs for which this TLV is advertised. If no protocol-based VLANs are configured on the port, the switch sets the VLAN ID value to 0.

- To control advertisement of the port and protocol VLAN ID TLV, use the following command:
  ```
  configure lldp ports [all | port_list] [advertise | no-advertise]
  vendor-specific dot1 port-protocol-vlan-ID {vlan [all | vlan_name]}
  ```

> **Note**
> Because a TLV is advertised for every VLAN that is advertised, and because the LLDPDU cannot exceed 1500 bytes, we recommend that you advertise this VLAN capability only for those VLANs that require it. Optional TLVs that cause the LLDPDU length to exceed the 1500-byte limit are dropped.

MAC/PHY Configuration/Status TLV

When configured for advertisement, this TLV advertises the autonegotiation and physical layer capabilities of the port. The switch adds information about the port speed, duplex setting, bit rate, physical interface, and autonegotiation support and status.

- To control advertisement of the port and protocol MAC/PHY configuration/status TLV, use the following command:

```
configure lldp ports [all | port_list] [advertise | no-advertise]
vendor-specific dot3 mac-phy
```

Power Via MDI TLV

When configured for advertisement on Ethernet (*PoE*) or PoE+ ports, this TLV advertises the device type, power status, power class, and pin pairs used to supply power.

The device type field contains a binary value that represents whether the *LLDP-*compatible device transmitting the LLDPDU is a power sourcing entity (PSE) or powered device (PD), as listed in Table 45.

Table 45: Power Management TLV Device Information

Value	Power source
0	PSE device
1	PD device
2-3	Reserved

Control advertisement of the power via MIDI TLV.

```
configure lldp ports [all | port_list] [advertise | no-advertise]
vendor-specific dot3 power-via-mdi {with-classification}
```

Refer to for Configuring Avaya-Extreme TLVs on page 470 and Configuring LLDP MED TLVs on page 471 more information on power-related TLVs.

Link Aggregation TLV

When configured for advertisement, this TLV advertises information on the port's load-sharing (link aggregation) capabilities and status.

To control advertisement of the link aggregation TLV, use the following command:

```
configure lldp ports [all | port_list] [advertise | no-advertise]
vendor-specific dot3 link-aggregation
```

Maximum frame size TLV

When configured for advertisement, this TLV advertises the maximum supported frame size for a port to its neighbors. When jumbo frames are not enabled on the specified port, the TLV advertises a value of 1518. If jumbo frames are enabled, the TLV advertises the configured value for the jumbo frames.

To control advertisement of the maximum frame size TLV, use the following command:

```
configure lldp ports [all | port_list] [advertise | no-advertise]
vendor-specific dot3 max-frame-size
```

Configuring Avaya-Extreme TLVs

This section describes the following optional proprietary Avaya-Extreme Networks TLVs that you can configure the switch to transmit.

> **Note**
> You can display the values for these TLVs using the `show lldp neighbors detailed` command.

PoE Conservation Level Request TLV

When configured for advertisement, this TLV advertises a request to the connected PD to go into a certain power conservation level or go to the maximum conservation level. This *LLDP* TLV is sent out only on *PoE*-capable Ethernet ports.

By default, the requested conservation value on this proprietary LLDP TLV is 0, which is no power conservation. You can change this level temporarily using a network station or *SNMP* with the MIB; this change is not saved across a reboot.

- To control advertisement of the PoE conservation level request TLV, use the following command:

  ```
  configure lldp ports [all | port_list] [advertise | no-advertise]
  vendor-specific avaya-extreme poe-conservation-request
  ```

Call Server TLV

When configured for advertisement, this TLV advertises the IP addresses of up to eight call servers. Avaya phones use this addressing information to access call servers.

- To control advertisement of the call server TLV and define call server addresses, use the following command:

  ```
  configure lldp ports [all | port_list] [advertise | no-advertise]
  vendor-specific avaya-extreme call-server ip_address_1 {ip_address_2
  {ip_address_3 {ip_address_4 {ip_address_5 {ip_address_6 {ip_address_7
  {ip_address_8}}}}}}
  ```

File Server TLV

When configured for advertisement, this TLV advertises the IP addresses of up to 4 file servers. Avaya phones use this address information to access file servers.

- To control advertisement of the file server TLV and define file server addresses, use the following command:

  ```
  configure lldp ports [all | port_list] [advertise | no-advertise]
  vendor-specific avaya-extreme file-server ip_address_1 {ip_address_2
  {ip_address_3 {ip_address_4}}}
  ```

802.1Q Framing TLV

When configured for advertisement, this TLV advertises information about Layer 2 priority tagging for Avaya phones.

- To control advertisement of the 802.1Q framing TLV, use the following command:

  `configure lldp ports [all | ` *`port_list`* `] [advertise | no-advertise] vendor-specific avaya-extreme dot1q-framing [tagged | untagged | auto]`

  > **Note**
  >
  > For this command to work, you must have previously enabled both the `configure lldp ports vendor-specific med capabilities` and the `configure lldp ports vendor-specific med policy application` commands. (See Configuring LLDP MED TLVs on page 471 for complete information.)

Configuring LLDP MED TLVs

> **Note**
>
> After you enable an *LLDP* MED TLV, the switch waits until it detects a MED-capable device before it begins transmitting the configured LLDP MED TLVs.
>
> You must configure the LLDP MED capabilities TLV to advertise before any of the other LLDP MED TLVs can be configured. Also, this TLV must be set to no-advertise after all other MED TLVs are set to no-advertise.

This approach assures that network connectivity devices advertise LLDP MED TLVs only to end-devices and not to other network connectivity devices.

The following sections describe LLDP MED TLVs and features.

> **Note**
>
> You can display the values for these TLVs using the `show lldp neighbors detailed` command.

LLDP MED capabilities TLV

This TLV advertises the *LLDP* MED capabilities of the switch and must be enabled before any of the other LLDP MED TLVs can be enabled.

To enable configuration and transmission of any other LLDP MED TLV and to determine the LLDP MED capabilities of endpoint devices, use the following command:

`configure lldp ports [all | ` *`port_list`* `] [advertise | no-advertise] vendor-specific med capabilities`

LLDP MED Fast-Start Feature

The *LLDP* MED fast-start feature allows you to increase the learning speed of the switch for LLDP MED TLVs. The fast-start feature is automatically enabled once you enable the LLDP MED capabilities TLV.

By default, the switch sends out the LLDPDU every second for up to the default repeat count, which is 3. Once the repeat count is reached, the configured transmit interval value is used between LLDPDUs. You can configure the repeat count to any number in the range of 1 to 10.

To configure the LLDP fast-start feature, use the following command:

```
configure lldp med fast-start repeat-count count
```

Network policy TLV

This TLV advertises which *VLAN* an endpoint should use for the specified application. You can configure only one instance of an application on each port, and you can configure a maximum of eight applications, each with its own DSCP value and/or priority tag.

To control advertisement and configure one or more network policy TLVs for a port, use the following command:

```
configure lldp ports [all | port_list] [advertise | no-advertise]
vendor-specific med policy application [voice | voice-signaling |guest-
voice | guest-voice-signaling | softphone-voice | video-conferencing
| streaming-video | video-signaling] vlan vlan_name dscp dscp_value
{priority-tagged}
```

Location identification TLV

This TLV advertises one of three different location identifiers for a port, each with a different format.

- Coordinate-based, using a 16-byte hexadecimal string.
- Civic-based, using a hexadecimal string with a minimum of six bytes.
- ECS ELIN, using a numerical string with a range of 10-25 characters.

To control advertisement and configure location information, use the following command:

```
configure lldp ports [all | port_list] [advertise | no-advertise]
vendor-specific med location-identification [coordinate-based hex_value
| civic-based hex_value | ecs-elin elin]
```

Extended power-via-MDI TLV

This TLV advertises fine-grained power requirement details, including the *PoE* settings and support. You can enable this TLV only on PoE-capable ports; the switch returns an error message if you attempt to transmit this *LLDP* TLV over a non-PoE-capable port.

To control advertisement for this TLV, use the following command:

```
configure lldp ports [all | port_list] [advertise | no-advertise]
vendor-specific med power-via-mdi
```

SNMP Traps for LLDP MED

To receive *SNMP* traps on the *LLDP* MED, you must enable these separately from the other LLDP traps. (See Configuring SNMP for LLDP on page 465.)

* Enable the LLDP MED SNMP traps.

  `enable snmp traps lldp-med {ports [all | port_list]}`

* Disable the LLDP MED SNMP traps.

  `disable snmp traps lldp-med {ports [all | port_list]}`

Clearing LLDP Neighbor Entries

* To remove the *LLDP* entries received on one or more ports from the switch database, use the following command:

  `clear lldp neighbors [all | port port_list]`

Unconfiguring LLDP

* To unconfigure the *LLDP* timers, use the following command:

  `unconfigure lldp`

  This command returns the LLDP timers to default values; LLDP remains enabled, and all the configured TLVs are still advertised.

* To leave LLDP enabled, but reset the advertised TLVs to the five default TLVs, use the following command, and specify the affected ports:

  `unconfigure lldp port [all | port_list]`

Displaying LLDP Information

The following sections describe how to display *LLDP* information for the switch. The system displays information on the LLDP status and statistical counters of the ports, as well as about the LLDP advertisements received and stored by the system.

You can display information on the LLDP port configuration and on the LLDP neighbors detected on the port.

Displaying LLDP Port Configuration Information and Statistics

* To display *LLDP* port configuration information, use the following command:

  `show lldp {port [all | port_list]} {detailed}`

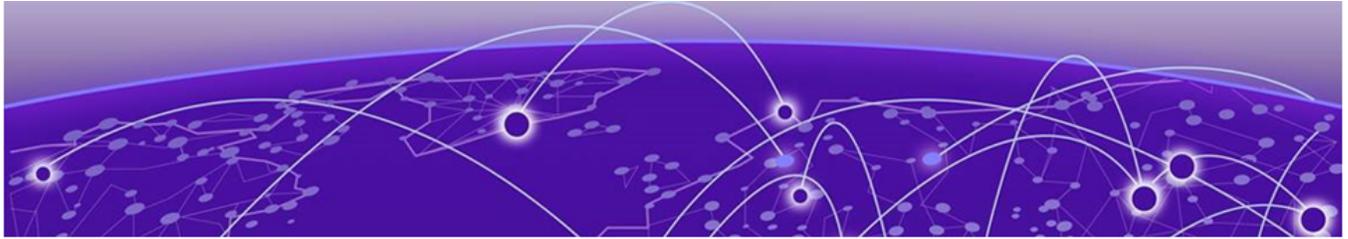
* To display the statistical counters related to the LLDP port, use the following command:

  `show lldp {port [all | port_list]} statistics`

Display LLDP Information Collected from Neighbors

- Display information collected from *LLDP* neighbors.

  ```
  show lldp neighbors
  ```

  > **Note**
  > You must use the detailed option to display information on the proprietary
  > Avaya-Extreme Networks TLVs and the LLDP MED TLVs.


OAM

Operation, Administration, and Maintenance (OAM) includes functions used to detect network faults, measure network performance and distribute fault-related information, including CFM, Y.1731, EFM, and BFD.

CFM

Connectivity Fault Management (CFM), discussed in the IEEE 802.1Q-2011 standard and originally specified in the IEEE 802.1ag-2007 standard, allows you to detect, verify, and isolate connectivity failures in virtual bridged LANs.

Part of this specification is a toolset to manually check connectivity, which is sometimes referred to as Layer 2 ping.

> **Note**
> The ExtremeXOS implementation of CFM is based on the IEEE 802.1Q-2011 and Y.1731 standards.

There is no direct interaction between CFM and other Layer 2 protocols; however, blocked *STP (Spanning Tree Protocol)* ports are taken into consideration when forwarding CFM messages.

CFM Overview

You can create hierarchical networks, or domains, and test connectivity within a domain by sending Layer 2 messages, known as *CCM (Connectivity Check Message)*.

> **Note**
> Extreme Networks uses values defined in IEEE 802.1Q-2011 for the MAC addresses and Ethernet type for CFM.

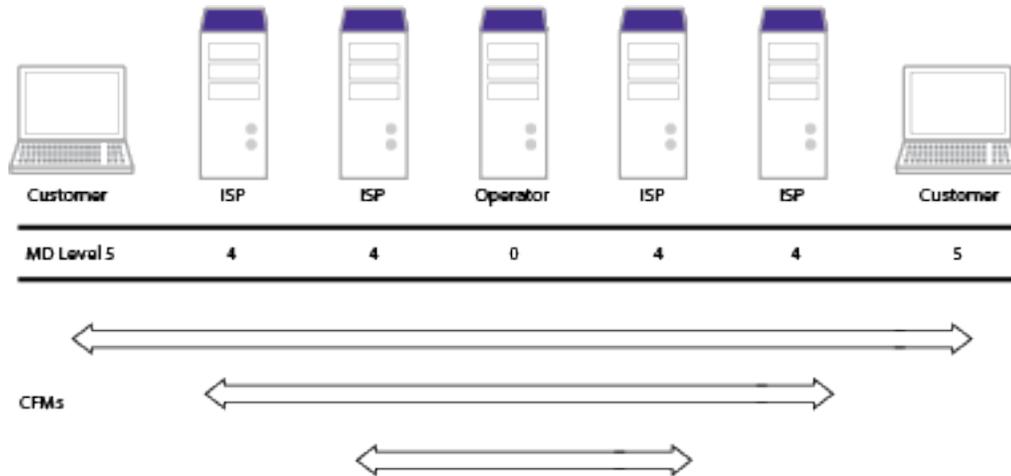
Figure 50 shows an example of hierarchical CFM domains.


Figure 50: CFM Hierarchical Domains Example

> **Note**
> The arrows in the above figure indicate the span that CCM messages take, not the direction. (See Figure 51 on page 477 for more information on spans for CCM messages.) This has been removed until the missing xref can be fixed.

To achieve this hierarchical connectivity testing, create and configure the following entities:

- Maintenance domains, or domains
- Maintenance domain (MD) level; a unique hierarchical numeric value for each domain
- Maintenance associations (MAs)
- Maintenance points (MPs) and *MEP (Maintenance End Point)*, which are one of the following types:
  ◦ UP MEPs
  ◦ DOWN MEPs
- Maintenance intermediate points (MIPs)

> **Note**
> The CFM filter function (CFF) is no longer supported from ExtremeXOS 12.1. The functionality of CFF is implicitly performed by MEPs.

An UP MEP sends CFM frames toward the frame filtering entity, which forwards the frames to all other ports of a service instance other than the port on which the UP MEP is configured. This is similar to how the frame filtering entity forwards a normal data frame, taking into account the port's *STP* state. For an UP MEP, a CFM frame exits from a port if only if the STP state of the port is in the forwarding state.

A DOWN MEP sends CFM frames directly to the physical medium without considering the port STP state. For a DOWN MEP, a CFM frame exits from a port even if the port STP state is in blocking state.

Figure 51 shows the concept of UP and DOWN MEP at logical level:

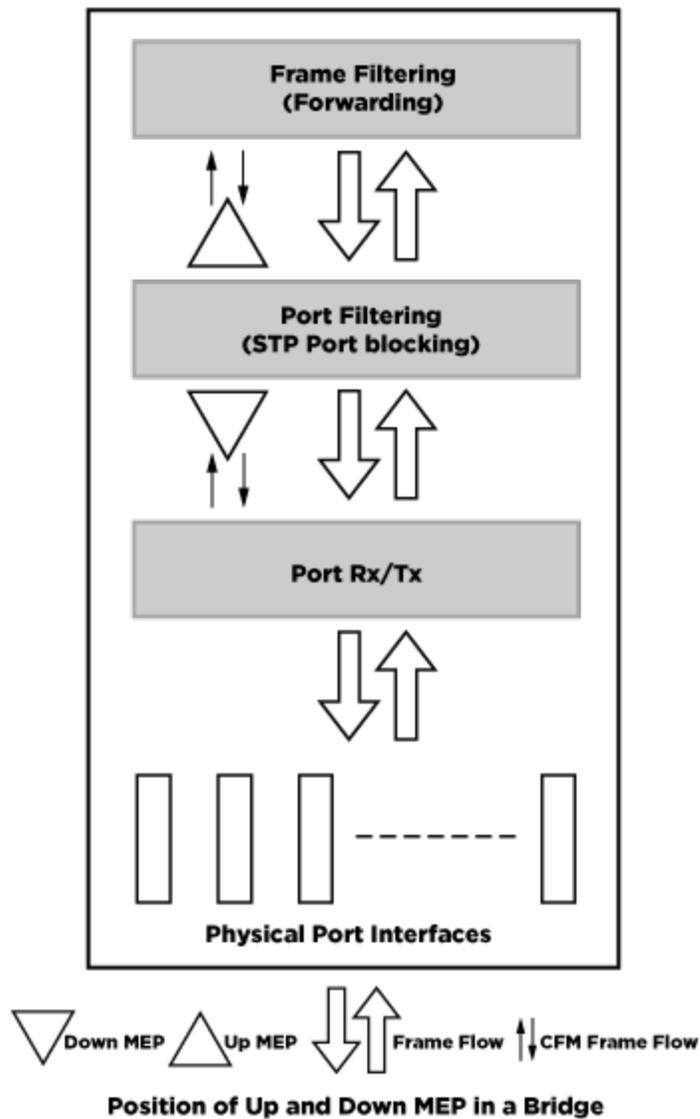
Position of Up and Down MEP in a Bridge


Figure 51: CFM UP and DOWN MEP at the Logical Level

You must have at least one MP on an intermediate switch in your domain. Ensure that you map and configure all ports in your domain carefully, especially the UP MEPs and the DOWN MEPs. If these are incorrectly configured, the CCMs are sent in the wrong direction in your network, and you will not be able to test the connectivity within the domain.

You can have up to eight domains on an Extreme Networks switch. A domain is the network or part of the network for which faults are to be managed; it is that

section where you are monitoring Layer 2 connectivity. A domain is intended to be fully connected internally.

> **Note**
> Domains may cross VR boundaries; domains are not *virtual router (VR)*-aware.

You assign each domain an MD level, which functions in a hierarchy for forwarding CFM messages. The MD levels are from 0 to 7. The highest number is superior in the CFM hierarchy.

The IEEE standard 802.1Q-2011 recommends assigning different MD levels to different domains for different network users, as follows:

- 5 to 7 for end users
- 3 and 4 for Internet service providers (ISPs)
- 0 to 3 for operators (entities carrying the information for the ISPs)

All CFM messages with a superior MD level (numerically higher) pass throughout domains with an inferior MD level (numerically lower). CFM messages with an inferior MD level are not forwarded to domains with a superior MD level. Refer to the following table for an illustration of domains with hierarchical MD levels.

Table 46: MD Levels and Recommended Use

MD level	0	1	2	3	4	5	6	7
Use	Operator			Service provider	Customer			
Superiority	Most inferior	< ----- Inferior / Superior ----- >						Most superior

Within a given domain, you create maintenance associations (MAs). Extreme Networks' implementation of CFM associates MAs with service instances (a service instance can be a *VLAN (Virtual LAN)*, VMAN, BVLAN, or SVLAN). All of the ports in that VLAN service instance are now in that MA and its associated domain. In general, you should configure one MIP on each intermediate switch in the domain and a MEP on every edge switch.

Each MA associates with one service instance, and a service instance can be associated with more than one MA. The MA is unique within the domain. One switch can have 8 domains, 128 ports, and 256 associations (see Supported Instances for CFM on page 480).

> **Note**
> You cannot associate the Management VLAN with an MA or a domain.

You assign the MPs to ports: UP MEPs, DOWN MEPs, and MIPs. These various MPs filter or forward the CFM messages to test the connectivity of your network.

Each configured MEP periodically sends out a Layer 2 multicast or unicast CCM message.

The destination MAC address in the CCM frame is from a multicast MAC address range that is reserved for CFM messages. Each MEP must have a MEP ID that is unique within the MA. The MEPs send the CCM messages differently, depending on the configuration, as follows:

- The DOWN MEPs sends out a single CCM message.
- The UP MEPs potentially sends the CCM message to all ports on the service instance (MA)—except the sending port—depending on the MPs configured on the outgoing ports.

> **Note**
> Ensure that you configured the UP and DOWN MEPs correctly, or the CCMs will flow in the wrong direction through the domain and not allow connectivity testing.

MIPs define intermediate points within a domain. MIPs relay the CCM messages to the next MIP or MEP in the domain.

You configure the time interval for each MEP to send a CCM. We recommend setting this interval for at least one second. Each MEP also makes a note of what port and what time it received a CCM. This information is stored in the CCM database.

Each CCM has a time-to-live (TTL) value also noted for that message. This TTL interval is 3.5 times the CCM transmission interval you configured on the switch that is originating the CCM. After the TTL expires, the connectivity is considered broken, and the system sends a message to the log. One important result of the continual transmission of CCM frames is that the MAC address of the originating MEP is known to all MPs in the association.

> **Note**
> All MEPs in an MA must be configured with the same CCM transmission interval.

The MD values are from 0 to 7; in the hierarchy, the MD level of 0 is lowest and 7 is highest.

Not all combinations of MPs are allowed on the same port within an MA; only the following combinations can be on the same port within an MA:

- UP MEP and MIP
- DOWN MEP with neither UP MEP nor MIP

CFM protocol imposes the following MP restrictions within an MA on a switch:

- MA can have either up MEP or down MEP and not both.
- MA can have multiple Down MEPs.
- Only one Up MEP per MA.
- MA can have both up MEP and MIP.
- MA cannot have MIP if down MEP is present.
- Down MEPs on regular ports are created in hardware for all CCM intervals for platforms that support CFM in hardware (ExtremeSwitching X460-G2).

- Up MEPs and MEPs on *LAG (Link Aggregation Group)* ports are created in software with CCM intervals 100 msec–600000 sec on all platforms.
- Dynamic Remote MEP learning is not supported for the MEPs created in hardware. You must explicitly create static Remote MEPs.
- Sender-Id-IP Address cannot be configured for the MEPs created in hardware.
- Unicast CCM transmission is not supported by the MEPs created in hardware.
- Domain name format should be of string type to create any MEPs in hardware in that domain.
- The CCM transmission state is disabled by default for the MEPs created in hardware by the CFM user interface.
- The CCM transmission state is enabled by default for the MEPs created in hardware by CFM clients like *ERPS (Ethernet Ring Protection Switching)*.
- The hardware Remote MEP status appears in `show cfm detail`. It is also forwarded to the client if created by a client like ERPS.
- CFM objects like domain, association, MEP, Remote MEP created by a client are not saved by dot1ag.

> **Note**
> An MA can have an UP MEP in one switch and a DOWN MEP on another switch for the same MA.

Ping and Traceroute

When operators see a connectivity fault message from CCM in the system log, they can send a loopback message (LBM) or a link trace message (LTM).

These are also referred to as a Layer 2 ping or a traceroute message. You can send with an LBM or an LTM only from an MEP (either UP or DOWN).

You can only send a ping from a MEP, and you ping to the unique system MAC address on the switch you are testing connectivity to. The operator sends out a unicast LBM, and the first MIP or MEP on the switch with the destination MAC address matching the embedded MAC address replies with an LBR (loopback reply).

You can only send a traceroute (LTM) from a MEP. You send the traceroute to the unique system MAC address on the switch to which you are testing connectivity. The system sends out an LTM to the special multicast address. If the destination address is not present in the *FDB (forwarding database)*, the LTM is flooded on all the ports in the MIP node. Each MIP in the path passes the frame only in the direction of the path and sends a link trace reply (LTR) message back to the originating with information that the LTM passed. The traceroute command displays every MIP along the path (see `traceroute mac port`).

Supported Instances for CFM

Table 47 displays the CFM support in ExtremeXOS.

Table 47: ExtremeXOS CFM Support

Item	Limit	Notes
Domains	8	Per switch; one for each MD level
Associations (MAs)	256	Per switch
UP MEPs	32	Per switch
DOWN MEPs	256 hardware-placed MEPs 32	Per switch
MIPs	32	Per switch
Total CFM ports	128	Per switch; total number of all ports for all service instances assigned to an MA (see command for ports configured for CFM)
Entries in the CCM database	2000	Number of remote end points stored in a CCM database on each MEP; 64 end points per MEP (additional CCMs discarded after this limit is reached)
CFM Segments	1000	Maximum number of CFM segments for Y.1731.
CFM Groups	1000	Maximum number of CFM groups.

> **Note**
> The total number of CFM ports is a guideline, not a limit enforced by the system.

CFM Groups

Loop detection protocols like *EAPS (Extreme Automatic Protection Switching)*/*ERPS* want to depend upon CFM to detect link status for faster failover recovery.

They register with LMEP and RMEP objects created by CFM in order to receive the link status event notifications to take the necessary action.

Currently LMEP is identified with domain, association, port, MEPId quadruples. And RMEP is identified with domain, association, LMEP, RMEPId quadruples. Each LMEP can be tied up to multiple RMEPs. So applications need to configure domain, association, LMEP and RMEPs through a client/server interface.

To simplify this, CFM provides a simple API to client applications to register/deregister CFM with a specified string name. The string name can be identified as a CFM group that binds an LMEP to multiple RMEPs. The group name is unique across the switch. Each application can create its own group for a required LMEP/RMEP combination.

You can associate a group to each LMEP created on a port. There exists a one-to-one relationship between LMEP-port-group. Whenever CFM stops receiving CCMs on this port, it informs a group DOWN event to registered clients like ERPS/EAPS. Whenever CFM starts receiving the CCMs again on this port, a group UP event is sent to registered clients.

Configuring CFM

To configure CFM, create a maintenance domain and assign it a unique MD level. Next, associate MAs with the specified domain and assign MPs within that MA. Optionally, you can configure the transmission interval for the CCMs, destination MAC type for an MA and remote MEPs statically in an MA.

If a MEP fails to receive a CCM before the last advertised TTL value expires, the system logs a message. After the network administrator sees the system log message, he can send a Layer 2 ping and/or a traceroute message to isolate the fault.

> **Note**
>
> Except for ExtremeSwitching X460-G2 series switches, which support hardware-based CFM, CFM does not use *ACL (Access Control List)*; there are no additional ACL entries present for CFM in the `show access-list dynamic` command output. ExtremeSwitching X460-G2 series switches consume two lookup-stage ACLs in one system slice.

ExtremeXOS 15.5 provides support for transmitting and receiving ITU-T Y.1731 CCMs. The main difference between IEEE 802.1ag and ITU-T Y.1731 CCMs is between the MAID and MEG ID formats in CCMs:

- MAID ---- MA (format + length + name) with/without MD (format + length +name) details.
- MEG ID ---- MEG (format + length + name) without MD details.
- MA is referred to as MEG in Y.1731 and both are same.
- MA assumes four formats (string/integer/vpn-id/vlan-id) for its name.
- MEG assumes ICC format which is a combination of ICC (6 bytes) + organization specific UMC (6 bytes).
- To support Y.1731 CCMs, an additional name format for MEG name is added for association.

Creating Maintenance Domains

You can create maintenance domains (MDs), or domains, and assign a unique MD level at that time. Available MD levels are numbered from 0 to 7. Higher numerical values are superior MD levels in the CFM hierarchy. Each switch can have a total of eight domains, each with a unique MD level.

You can name domains using any one of the following three formats:
- Simple string—Use an alphanumeric character string with a maximum of 43 characters.

- Domain name server (DNS) name—Use an alphanumeric character string with a maximum of 43 characters.
- MAC address plus 2-octet integer—Use a MAC address and a 2-octet integer. The display format is XX.XX.XX.XX.XX.XX.YYY, where X is the MAC address, and Y is the 2-octet integer. For example, a domain name in this format using 123 as the 16-bit unsigned integer appears as follows: 00:11:22:33:44:55.123.

> **Note**
> Whatever convention you choose, you must use that same format throughout the entire domain.

The CFM messages carry the domain name, so the name and naming format must be identical to be understood throughout the domain. You can, however, use different naming conventions on different domains on one switch (up to eight domains allowed on one switch). User-created CFM names are not case sensitive.

- To create a domain and assign an MD level using the DNS convention, use the following command:.

  ```
  create cfm domain dns name md-level level
  ```

- To create a domain and assign an MD level using the MAC address convention, use the following command:.

  ```
  create cfm domain mac mac-addr int md-level level
  ```

- To create a domain and assign an MD level using the string convention, use the following command :

  ```
  create cfm domain string str_name md-level level
  ```

- Although you assign an MD level to the domain when you create that domain, you can change the MD level on an existing domain by running:

  ```
  configure cfm domain domain_name md-level level
  ```

- To delete a domain, use the following command:

  ```
  delete cfm domain domain
  ```

Creating and Associating MAs

Within a given domain, you can associate maintenance associations (MAs). Extreme Networks' implementation of CFM associates MAs with service instances. All of the ports in that service instance are now in that MA and its associated domain.

Each MA associates with one service instance, and each service instance may associate with more than one MA; you can configure more than one MAs in any one domain.

Like the domains, ExtremeXOS supports multiple formats for naming the MA. The following formats are supported for naming the MAs:

- Character string
- 2-octet integer
- RFC 2685 VPN

- VLAN ID
- Y.1731 MEG name

- To add an MA to a domain using the character string format, use the following command:

  `configure cfm domain domain_name add association string name [vlan vlan_name|vman vman_name]`

- To add an MA to a domain using the 2-octet integer format, use the following command:

  `configure cfm domain domain_name add association integer int [vlan vlan_name|vman vman_name]`

- To add an MA to a domain using the RFC 2685 VPN ID format, use the following command:

  `configure cfm domain domain_name add association vpn-id oui oui index index [vlan vlan_name|vman vman_name]`

- To add an MA to a domain using the VLAN ID format, use the following command:

  `configure cfm domain domain_name add association vlan-id vlanid [vlan vlan_name|vman vman_name]`

- To add an MA using Y.1731 compliant MEG, use the following command: `configure cfm domain domain_name add association meg [meg name] [vlan vlan_name| vman vman_name]`

- To delete an MA from a domain, use the following command:

  `configure cfm domain domain_name delete association association_name`

  In addition to supporting multicast destination MAC address for CCM and LTM frames specified by the 802.1ag standard, ExtremeXOS CFM supports the use of a unicast destination address for CCM and LTM frames.

  This allows the support of a CFM operation in a network where use of multicast address is prohibited.

- To configure the destination MAC address type for an MA, use the following command:

  `configure cfm domain domain-name association association_name destination-mac-type [unicast | multicast]`

- Use the following command to add a remote MEP to an MA statically:

  `configure cfm domain domain-name association association_name add remote-mep mepid { mac-address mac_address }`

  ExtremeXOS CFM supports configuring remote MEPs statically for CFM operation where dynamic discovery of MEPs in an MA using multicast address is prohibited.

- To delete a remote MEP from an MA, use the following command:

  `configure cfm domain domain-name association association_name delete remote-mep mepid`

- To configure a remote MEP MAC address, use the following command:

  `configure cfm domain domain-name association association_name remote-mep mepid mac-address mac_address`

Creating MPs and the CCM Transmission Interval

Within an MA, you configure the following MPs:

- Maintenance end points (MEPs), which are one of the following types:
  - ◦ UP MEPs—transmit CCMs, and maintain CCM database.
  - ◦ DOWN MEPs—transmit CCMs, and maintain CCM database.
- Maintenance intermediate points (MIPs)—pass CCMs through.

Each MEP must have an ID that is unique for that MEP throughout the MA.

- To configure UP and DOWN MEPs and its unique MEP ID, use the following command:

  configure cfm domain *domain_name* **association** *association_name* **ports** *port_list* add [**end-point** [**up** | **down**] **mepid group** { *group_name* }] | [**intermediate-point**]]

- To change the MEP ID on an existing MEP, use the following command:

  configure cfm domain *domain_name* **association** *association_name* **ports** *port_list* **end-point** [**up** | **down**] **mepid** { *mepid* }

- To delete UP and DOWN MEPs, use the following command:

  configure cfm domain *domain_name* **association association_name ports** *port_list* delete [[**end-point** [**up** | **down**]] | **intermediate-point**]

- To configure a MIP, use the following command:

  configure cfm domain *domain_name* **association** *association_name* **ports** *port_list* add [**end-point** [**up** | **down**] **mepid group** { *group_name* }] | [**intermediate-point**]

- To delete a MIP, use the following command:

  configure cfm domain *domain_name* **association** *association_name* **ports** *port_list* delete [[**end-point** [**up** | **down**]] | **intermediate-point**]

- To configure the transmission interval for the MEP to send CCMs, use the following command:

  configure cfm domain *domain_name* **association** *association_name* **ports** *port_list* **end-point** [**up** | **down**] **transmit-interval** [**3**| **10** | **100** | **1000** | **10000** | **60000** | **600000**]

- To unconfigure the transmission interval for the MEP to send CCMs and return it to the default, use the following command:

  unconfigure cfm domain *domain_name* **association** *association_name* **ports** *port_list* **end-point** [**up** | **down**] **transmit-interval**

- To enable or disable a MEP, use the following command:

  configure cfm domain *domain_name* **association** *association_name* **ports** *port_list* **end-point** [**up** | **down**] [**enable** | **disable**]

Configuring EAPS for CFM Support

Assigning MEP Group Names to New MEP

To assign MEP Group name when creating a MEP, use the following command:

```
configure cfm domain domain_name association association_name ports
port_list add [[ end-point [ up | down ] mepid group { group_name }] |
[ intermediate-point ]]
```

Assign MEP Group Name to Existing MEP

To assign a MEP Group name to an existing MEP, use the following command:

```
configure cfm domain domain_name association association_name ports
port_list end-point [up|down] [add|delete] group group_name
```

Add a RMEP to MEP Group

To add specific RMEPs for a MEP Group to monitor, use the following command:

```
configure cfm group group_name [add|delete] rmep mepid
```

Monitoring CFM in EAPS

Displaying MEP Groups

To display MEP groups, use the following command:

```
show cfm groups {group_name}
```

```
# sh cfm groups
Group : eapsCfmGrp1     Status : UP
Local MEP     : 11      port  : 41
Remote MEPs   : 10
Client(s)     : eaps
Domain        : MD1
Association   : MD1v2
Group : eapsCfmGrp2     Status : UP
Local MEP     : 12      port  : 31
Remote MEPs   : 13
Client(s)     : eaps
Domain        : MD1
Association   : MD1v2
```

Executing Layer 2 Ping and Traceroute Messages

If the system logs a missed CCM message, the operator can use Layer 2 ping and traceroute messages to isolate the fault. (See Ping and Traceroute for information on how each MP handles these messages.)

> **Note**
> You must have all the CFM parameters configured on your network before issuing the ping and traceroute messages.

- To send a Layer 2 ping, use the following command:
  ```
  ping mac mac port port {domain} domain_name {association}
  association_name
  ```
- To send a Link Trace Message (LTM) and receive information on the path, use the following command:
  ```
  traceroute mac mac {up-end-point} port port {domain} domain_name
  {association} association_name {ttl ttl}
  ```

Displaying CFM

To verify your CFM configuration, you can display the current CFM configuration using the `show cfm` command.

The information this command displays includes the total ports configured for CFM, the domain names and MD levels, the MAs and associated service instances, and the UP and DOWN MEPs.

To display the CCM database for each MEP, use the `show cfm detail` command.

Counters are added for missed-hellos, which mainly help to constantly monitor the health of CFM session path and hence tweaking the configured interval times to get the best reliability with the shortest fail over times for radio and wireless networks that rely on CFM to detect any failures. These counters can be displayed using `show cfm session counters missed-hellos` command. The counters can be cleared using "clear counters cfm session missed-hellos" command.

CFM Example

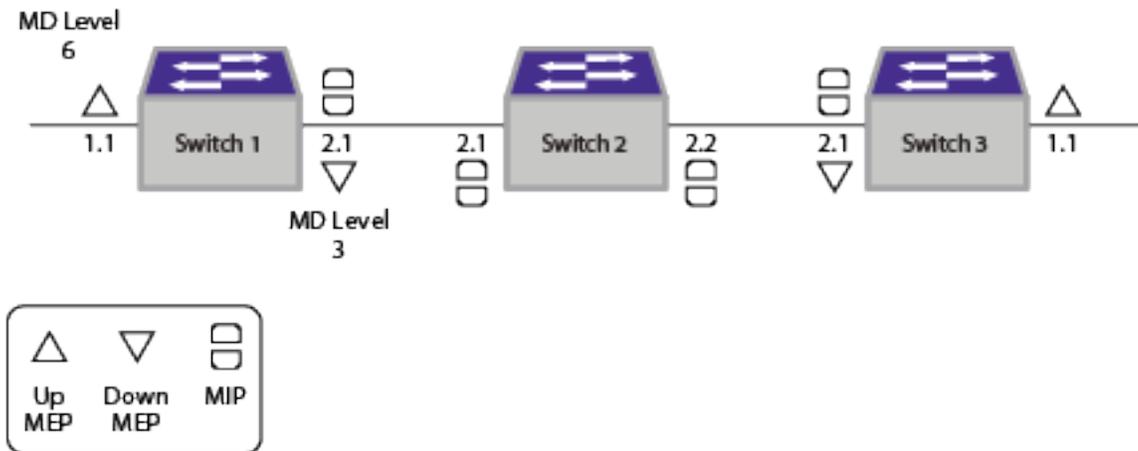
As shown in Figure 52 on page 487, this example assumes a simple network and assumes that CFM is configured on the access switches, as well as the necessary VMANs configured with the ports added. This example shows a VMAN associated with two maintenance domains and two different MAs. UP MEPs are configured for an MA with MD level 6 and DOWN MEPs are configured for an MA with MD level 3.


Figure 52: CFM Configuration Example

- Configure switch 1 for this example.

```
create cfm domain string cust-xyz-d6 md-level 6
configure cfm domain cust-xyz-d6 add association string cust-xyz-d6-m100 vman m100
configure cfm domain cust-xyz-d6 association cust-xyz-d6-m100 port 1:1 add end-point
up 10
configure cfm domain cust-xyz-d6 association cust-xyz-d6-m100 port 2:1 add
intermediate-point
create cfm domain string core-d3 md-level 3
```

```
configure cfm domain core-d3 add association string core-d3-m100 vman m100
configure cfm domain core-d3 association core-d3-m100 port 2:1 add end-point down 10
```

• Configure switch 2 for this example.

```
create cfm domain string core-d3 md-level 3
configure cfm domain core-d3 add association string core-d3-m100 vman m100
configure cfm domain core-d3 association core-d3-m100 port 2:1 add intermediate-point
configure cfm domain core-d3 association core-d3-m100 port 2:2 add intermediate-point
```

• Configure switch 3 for this example.

```
create cfm domain string cust-xyz-d6 md-level 6
configure cfm domain cust-xyz-d6 add association string cust-xyz-d6-m100 vman m100
configure cfm domain cust-xyz-d6 association cust-xyz-d6-m100 port 1:1 add end-point
up 20
configure cfm domain cust-xyz-d6 association cust-xyz-d6-m100 port 2:1 add
intermediate-point
create cfm domain string core-d3 md-level 3
configure cfm domain core-d3 add association string core-d3-m100 vman m100
configure cfm domain core-d3 association core-d3-m100 port 2:1 add end-point down 20
```

• To display the group database, use the following command:

```
show cfm groups
```

Y.1731—Compliant Performance Monitoring

Compliant performance monitoring is based on the ITU-T Y.1731 standard and deals with the Ethernet Delay Measurement (ETH-DM) function and Ethernet Frame-Loss Measurement (ETH-LM).

Frame-Delay Measurement

ExtremeXOS software supports:

• Two-way delay measurement—Delay Measurement Message (DMM) and Delay Measurement Reply (DMR).
• Continuous (proactive) measurement of frame delay and frame delay variation.
• On-demand measurement of frame delay and frame delay variation.

By default, DMM is not enabled. You must explicitly enable the DMM transmission for a CFM segment, either as continuous or on-demand mode.

A network interface is considered attached to a subnetwork. The term *segment* is used to refer to such a subnetwork, whether it be an Ethernet LAN, a ring, a WAN link, or even an SDH virtual circuit.

Frame-Delay measurement is done between two specific end points within an administrative domain. Frame delay and frame delay variation measurements are performed in a maintenance association end point (MEP) by sending and receiving periodic frames with ETH-DM information to and from the peer end point during the diagnostic interval.

When a CFM segment is enabled to generate frames with ETH-DM information, it periodically sends frames with ETH-DM information to its peer in the same maintenance association (MA) and expects to receive frames with ETH-DM information from its peer in the same MA.

The following list offers specific configuration information that is required by a peer to support ETH-DM:

- Maintenance domain (MD) level—The MD level at which the peer exists.
- Priority—The priority of the frames with ETH-DM information.
- Drop eligibility—Frames with ETH-DM information that are always marked as drop ineligible.
- Transmission rate.
- Total transmit interval.

A node transmits frames with ETH-DM information with the following information element:

- TxTimeStampf: Timestamp at the transmission time of the ETH-DM frame.
- RxTimeStampb: Timestamp at which the switch receives the DMR back.

  Whenever a valid DMM frame is received by the peer, a DMR frame is generated and transmitted to the requesting node.

- A DMM frame with a valid MD level and a destination MAC address equal to the receiving node's MAC address is considered to be a valid DMM frame. Every field in the DMM frame is copied to the DMR frame with the following exceptions:
  - The source and destination MAC addressed are swapped.
  - The OpCode field is changed from DMM to DMR.

The switch makes two-way frame delay variation measurements based on its ability to calculate the difference between two subsequent two-way frame delay measurements.

To allow a more precise two-way frame delay measurement, the peer replying to the frame with ETH-DM request information may include two additional timestamps in the ETH-DM reply information:

- RxTimeStampf—Timestamp at the time of receiving a frame with ETH-DM request information
- TxTimeStampb—Timestamp at the time of transmitting a frame with ETH-DM reply information

Here the frame delay is calculated by the peer that receives the DMR as follows:

- Frame Delay = (RxTimeStampb - TxTimeStampf) - (TxTimeStampb - RxTimeStampf)

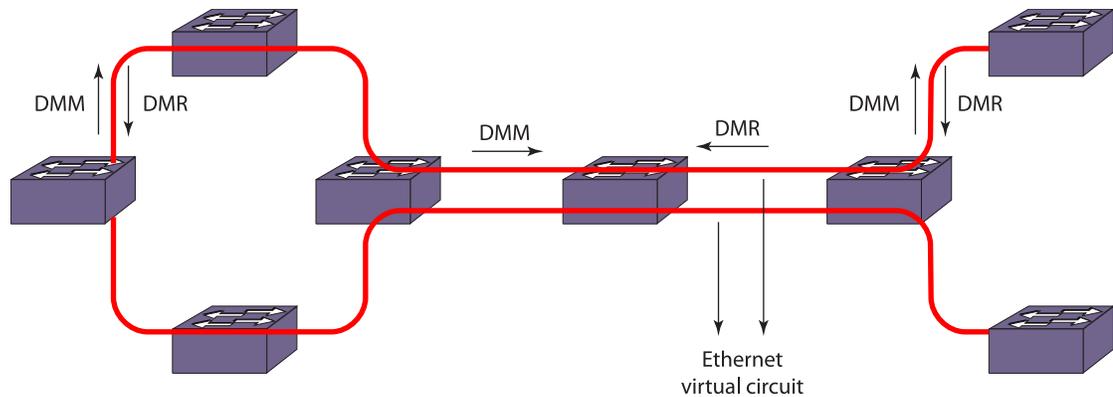
Figure 53 describes the DMM and DMR message flows between two end points.


Figure 53: Two-Way Frame Delay and Frame Delay Variance Measurement

The PDUs used to measure frame delay and frame delay variation are the DMM and the DMR PDUs where DMM is initiated from a node as a request to its peer and DMR is the reply from the peer.

If you try to enable the transmission for a CFM segment whose configuration is not complete, the trigger is rejected and an error message similar to the following is given:

```
ERROR: CFM Configuration is not complete for segment "s1" to start transmission
```

> **Note**
> A CFM segment without a domain and an association is considered to be an incomplete segment.

Upon enabling the transmission from a CFM segment, the segment transmits DMM frames, one at each transmit-interval which is configured through the CLI. If the user enables on-demand transmission, the segment transmits "X" number of DMMs and moves back to the disabled state, where "X" is the number of frames specified by the user through the CLI.

For continuous transmission, the segment continues to transmit DMM frames until stopped by the user. This transmission continues even after reboot for both continuous and on-demand mode. For on-demand transmission, the segment, which was enabled to transmit "X" number of frames, and is still transmitting, starts transmitting again "X" number of frames after reboot, or failover, or process restart. The old statistics are not preserved for both continuous and on-demand mode for all the above three scenarios.

Upon transmitting a DMM, the segment is expected to get a reply from the destination within the specified time. If a reply is received after that time, that reply will be considered as a delayed one.

If a reply is not received within the transmit-interval, that is, between two subsequent DMM transmissions, then that frame is considered as lost. Once the percentage of the sum of lost and delayed frames reaches the alarm threshold, an alarm is generated and the segment is moved to the alarming state. This state is maintained until the percentage of valid replies reaches the clear threshold. These alarm and clear states are maintained for a specified window, which holds a set of recent frames and their corresponding delays.

Various times are recorded at the segment level during the transmission of DMM frames.

- Start time—Time at which the segment started the current transmission.
- Min delay time—Time at which the minimum delay occurred in the current transmission window.
- Max delay time—Time at which the maximum delay occurred in the current transmission window.
- Alarm time—The recent alarm time, if any, during the current transmission.

The mean delay and delay variance for the current window is also measured whenever the user polls the segment statistics.

Frame-Loss Measurement

Frame-loss is measured by sending and receiving frames with frame-loss information between peer maintenance end points (MEPs).

Frame-loss ratio is defined as a percentage of the number of service frames not delivered divided by the total number of service frames during a defined time interval, where the number of service frames not delivered is the difference between the number of service frames arriving at the ingress Ethernet flow point and the number of service frames delivered at the egress Ethernet flow point in a point-to-point Ethernet connection (see Figure 54).

$$\text{Frame Loss Ratio} = \left(\frac{\text{Svc Frames at Ingress} - \text{Svc Frames at Engress}}{\text{Total \# Svc Frames for Time Interval}} \right) \times 100$$

■ = Service Frames Not Delivered

Figure 54: Frame-Loss Ratio Formula

To support frame-loss measurement, a MEP requires the following configuration information:

- Maintenance domain (MD) level—MD level at which the MEP exists.
- Frame-loss measurement transmission period—time interval when frame-loss measurement frames are sent.
- Priority—identifies the priority of the frames with frame-loss measurement information (configurable per operation).
- Drop eligibility—frames with frame-loss measurement information are always marked as drop ineligible (not necessarily configured).

A maintenance intermediate point (MIP) is transparent to frames with frame-loss measurement information. Therefore MIPs do not require any information to support frame-loss measurement functionality.

There are two frame-loss measurement methods:

- Dual-Ended Frame-Loss Measurement
- Single-Ended Frame-Loss Measurements

Dual-Ended Frame-Loss Measurement

Dual-ended frame-loss measurement is a form of proactive OAM for performance monitoring and is useful for fault management.

> **Note**
> ExtremeXOS does not support dual-ended frame-loss measurement.

MEPs send periodic dual-ended frames with frame-loss measurement information to peer MEPs in a point-to-point MD. Each MEP terminates the dual-ended frames with frame-loss measurement information and makes the near-end and far-end loss measurements. Near-end frame loss refers to frame loss associated with ingress data frames, while far-end frame loss refers to frame loss associated with egress data frames. This function is used for performance monitoring at the same priority level as used for CCM.

The protocol data unit (PDU) for dual-ended frame-loss measurement information is Continuity Check Message (CCM).

Single-Ended Frame-Loss Measurements

Single-ended frame-loss measurement facilitates on-demand OAM. MEPs carry out frame-loss measurments by sending frames to peer MEPs with frame-loss measurement request information and receiving frames with frame-loss measurement reply information. This Y_1731 frame-loss measurement depends on VLAN statistics.

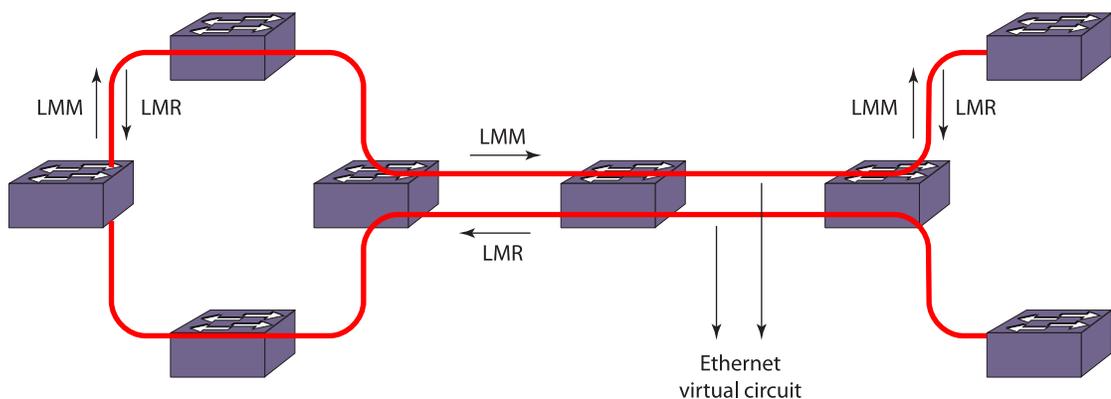
The PDU for single-ended frame-loss measurement requests is Loss Measurement Message (LMM). The PDU for single-ended frame-loss measurement reply is Loss Measurement Reply (LMR). Figure 55 shows the transmission of LMM and LMR for frame-loss measurement.


Figure 55: Two-Way Frame-Loss Measurement

A MEP maintains two local counters for each peer MEP it is monitoring for frame-loss:

- TxFCl—in-profile data frames transmitted to the peer MEP.
- RxFCl—in-profile data frames received from the peer MEP.

For an on-demand loss measurement, a MEP periodically transmits LMM frames with TxFCf (value of the local TxFCl counter at the time of LMM frame transmission). Upon receiving a valid LMM frame, a MEP sends an LMR frame to the requesting MEP.

(Valid LMM frames have a valid MD level and a destination MAC address equal to the receiving MEP's MAC address.)

An LMR frame contains the following values:
- TxFCf—TxFCf value copied from the LMM frame.
- RxFCf—RxFCl value when the LMM frame was received.
- TxFCb—TxFCl value when the LMR frame was transmitted.

Upon receiving an LMR frame, a MEP uses the following values to make near-end and far-end loss measurements:
- Received LMR frame's TxFCf, RxFCf, and TxFCb values, and local counter RxFCl value at the time this LMR frame was received. These values are represented as TxFCf[tc], RxFCf[tc], TxFCb[tc], and RxFCl[tc]; where tc is the time the current reply frame was received.
- Previous LMR frame's TxFCf, RxFCf, and TxFCb values, and local counter RxFCl value at the time the previous LMR frame was received. These values are represented as TxFCf[tp], RxFCf[tp], TxFCb[tp], and RxFCl[tp],where tp is the time the previous reply frame was received.

Far-End Frame Loss = (TxFCf[tc] – TxFCf[tp]) – (RxFCf[tc] – RxFCf[tp])

Near-End Frame Loss = (TxFCb[tc] – TxFCb[tp]) – (RxFCl[tc] – RxFCl[tp])

Availability Time and Severly Errored Seconds (SES)

Frame loss is measured by sending and receiving frames with frame-loss information between peer MEPs.

Each MEP performs frame-loss measurements which contribute to unavailable time. Since a bidirectional service is defined as unavailable if either of the two directions is declared unavailable, frame-loss measurement must facilitate each MEP to perform near-end and far-end frame loss measurements.

Near-end frame loss refers to frame loss associated with ingress data frames, while far-end frame loss refers to frame loss associated with egress data frames. Both near-end and far-end frame loss measurements contribute to near-end severely errored seconds (near-end SES) and far-end severely errored seconds (far-end SES) respectively, which together contribute to unavailable time.

A period of unavailable time begins at the onset of x consecutive Severely Errored Seconds (SES) events. These x seconds are part of unavailable time. A new period of available time begins at the onset of x consecutive non-SES events. These x seconds are part of available time.

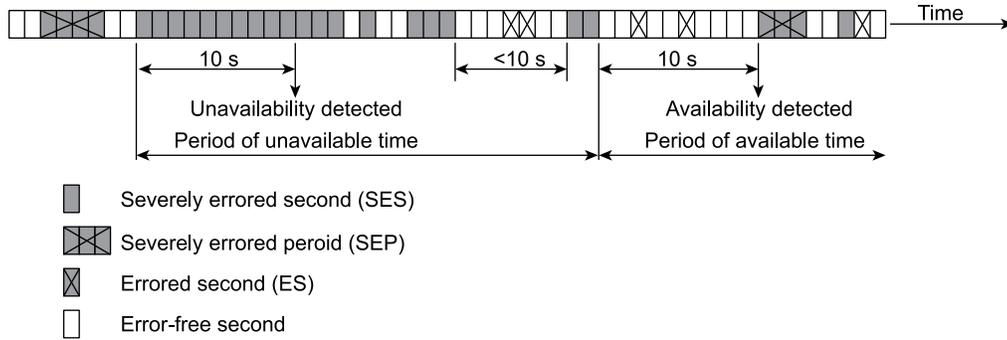
A SES is declared when, during one measurement period, the number of frames lost exceeds a threshold. ExtremeXOS logs the start and end time of the unavailable periods (see Figure 56 from ITU-T G.7710).


Figure 56: SES

Configuring a CFM Segment

Use the following commands to configure a CFM segment.

Some of these commands are optional and, if not configured, the default values are used. Table 48 lists the default values for delay measurement for a CFM segment.

Table 48: Default Values for Delay Measurement for a CFM Segment

Configuration	Default Values
Transmit interval	10 seconds
Window	60 frames
Timeout	50 milliseconds
Alarm threshold	10%
Clear threshold	95%
Dot1p priority	6

Table 49 lists the default values for loss measurement for a CFM segment.

Table 49: Default Values for Loss Measurement for a CFM Segment

Configuration	Default Values
LMM Transmit interval	90 seconds
Dot1p priority	6
Window	1200 frames
SES threshold	0.01
Consecutive available count	4

> **Note**
> The statistics for a particular transmission are preserved until the user triggers the transmission once again or if `clear counters cfm segment` is triggered from the CLI.

Managing a CFM Segment

You can create, delete, add CFM segments.

- To create a CFM segment, use the following command:

  ```
  create cfm segment segment_name destination mac_addr {copy
  segment_name_to_copy}
  ```

- To delete a CFM segment, use the following command:

  ```
  delete cfm segment [segment_name | all]
  ```

- To add a CFM domain to a CFM segment, use the following command:

  ```
  configure cfm segment segment_name add domain domain_name association
  association_name
  ```

- To delete a CFM domain from a CFM segment, use the following command:

  ```
  configure cfm segment segment_name delete domain association
  ```

- To configure the transmission interval between two consecutive DMM or two consecutive LMM frames, use the following command:

  ```
  configure cfm segment segment_name {frame-delay | frame-loss}
  transmit-interval interval
  ```

  The same transmit-interval is used for both delay and loss measurements.

- To get separate values for delay and loss measurements, use the following command:

  ```
  configure cfm segment frame-delay/frame-loss transmit interval
  interval
  ```

- To configure the dot1p priority of a DMM frame, use the following command:

  ```
  configure cfm segment segment_name frame-delay dot1p dot1p_priority
  ```

- To configure the dot1p priority of a LMM frame, use the following command:

  ```
  configure cfm segment segment_name frame-loss dot1p dot1p_priority
  ```

- To configure the dot1p priority of the CFM segment, use the following command:

  ```
  configure cfm segment segment_name dot1p dot1p_priority
  ```

  The same priority is used for both delay and loss measurements.

- To get separate values of priority for delay and loss measurements, use the following command:

  ```
  configure cfm segment segment_name frame-delay dot1p dot1p_priority
  ```

  ```
  configure cfm segment segment_name frame-loss dot1p dot1p_priority
  ```

- To configure the alarm and clear threshold value for CFM segment, use the following command:

  ```
  configure cfm segment segment_name [alarm-threshold | clear-threshold]
  value
  ```

- To configure the window size to be used for calculating the threshold values, use the following command:

  ```
  configure cfm segment segment_name window size
  ```

  The same window size is used for both delay and loss measurements.

- To get separate values of window size for delay and loss measurements, use the following:

  ```
  configure cfm segment segment_name frame-loss window window_size

  configure cfm segment segment_name frame-delay window window_size
  ```

- To configure the window size of a DMM frame to be used for calculating the threshold values, use the following command:

  ```
  configure cfm segment segment_name frame-delay window window_size
  ```

- To configure the window size of a LMM frame to be used for calculating the threshold values, use the following command:

  ```
  configure cfm segment segment_name frame-loss window window_size
  ```

- To trigger DMM frames at the specified transmit interval, use the following command:

  ```
  enable cfm segment frame-delay measurement segment_name mep mep_id
  [continuous | count ] value
  ```

- To disable the transmission of the DMM frames for a particular CFM segment, use the following command:

  ```
  disable cfm segment frame-delay measurement segment_name mep mep_id
  ```

- To show the configuration and status of a specific CFM segment, use the following command:

  ```
  show cfm segment {segment_name}
  ```

- To show the configuration and status of a specific CFM segment doing delay measurement, use the following command:

  ```
  show cfm segment frame-delay {segment_name]}
  ```

- To show the configuration and status of a specific CFM segment doing loss measurement, use the following command:

  ```
  show cfm segment frame-loss {segment_name]}
  ```

- To display the frame delay statistics for the CFM segment, use the following command:

  ```
  show cfm segment frame-delay statistics {segment-name}
  ```

- To configure the timeout value for a CFM segment, use the following command:

  ```
  configure cfm segment segment_name timeout msec
  ```

- To add or delete the local MEP for a given CFM segment, use the following command:

  ```
  configure cfm segment segment_name frame-loss [add|delete] mep mep_id
  ```

- To set the percentage of frames lost in a measurement period so that it will be marked as SES (severely errored second), use the following command:

  ```
  configure cfm segment segment_name frame-loss ses-threshold percent
  ```

- To set the number of consecutive measurements used to determine the availability status of a CFM segment, use the following command:

  ```
  configure cfm segment segment_name frame-loss consecutive frames
  ```

- To start the transmission of LMM frames for the set transmit interval, use the following command:

```
enable cfm segment frame-loss measurement segment_name mep mep_id
[continuous | count frames]
```

> **Note**
>
> For the above command, If the the segment is not completely configured, frames are not transmitted and an error occurs.

- To stop the transmission of the LMM frames for a particular CFM segment, use the following command:

```
disable cfm segment frame-loss measurement segment_name mep mep_id
```

- To display the frame loss or frame delay statistics for the CFM segment, use the following command:

```
show cfm segment {{segment_name} | {frame-delay {segment_name}} |
{frame-loss {segment_name {mep mep_id}}}}
```

> **Note**
>
> Frame-loss measurements are not supported on platforms where the _VLAN_ packet statistics are not retrieved, and on up-meps.

Clearing CFM Information

- To clear cfm segment counters, use the following commands:

```
clear counters cfm segment segment_name
```

```
clear counters cfm segment all
```

- To clear cfm segment counters specific to DMM, use the following command:

```
clear counters cfm segment segment_name frame-delay
```

- To clear cfm segment counters specific to LMM, use the following commands:

```
clear counters cfm segment segment_name frame-loss
```

```
clear counters cfm segment segment_name frame-loss mep mep_id
```

Y.1731 MIB Support

ExtremeXOS 15.5 supports Y.1731 performance measurement MIB defined by MEF - 36. The performance monitoring process is made up of a number of performance monitoring instances, known as performance monitoring (PM) sessions. A PM session can be initiated between two MEPs in a MEG and be defined as either a loss measurement (LM) session or delay measurement (DM) session. The LM session can be used to determine the performance metrics frame loss ratio, availability, and resiliency. The DM session can be used to determine the performance metrics Frame Delay.

The MIB is divided into a number of different object groupings: the PM MIB MEP objects, PM MIB loss measurement objects, PM MIB delay measurement objects, and SOAM PM notifications. The initial implementation of MIB supports GET operations for Frame Loss& Frame Delay.

MIB Specific Data

- A measurement interval of 15 min to be supported
- Default message period/transmit-interval of LMMs is 1 sec (Min = 1sec in current CLI) * Default message period/transmit-interval of DMMs is 100msec (Min = 1 sec in current CLI)
- Repetition Time can be set to 0 which means that there is no gap between measurement intervals
- Number of History measurement intervals can be 2-1000, though it expects at least 32 measurement intervals to be stored and 96 are recommended.
- Both DM and LM sessions are MEP to MEP sessions. The index of all the DM/LM tables includes MD, MA, MEP table indices as well as the particular DM/LM session.
- Currently DM sessions are not MEP-to MEP based but only segment based sessions. To support DM tables in the MIB, changes are required in the current CLI & backend delay implementation.

Limitations

- Currently we are storing a maximum of 1800 frames data for each LMM/DMM session. But to support at least 2 history and 1 current measurement intervals, we need to store 2700 frames (if message period is 1 sec, Repetition time is 0, measurement interval is 15 min) for each delay/loss session.
- Each frame's data is about 60 bytes for LMM and which takes about 44 MB of memory for 288 sessions

EFM OAM—Unidirectional Link Fault Management

Unidirectional Link Fault Management

With EFM OAM, certain physical layers can support a limited unidirectional capability.

The ability to operate a link in a unidirectional mode for diagnostic purposes supports the maintenance objective of failure detection and notification. Unidirectional OAM operation is not supported on some legacy links but is supported on newer links such as 100BASE-X PCS, 1000BASE-X PCS, and 10GbE RS. On technologies that support the feature, OAM PDUs can be transmitted across unidirectional links to indicate fault information. To the higher layers, the link is still failed in both directions, but to the OAM layer, some communication capabilities exist. The distinction between a unidirectional link and a normal link is shown in Figure 57.

Normal link operation

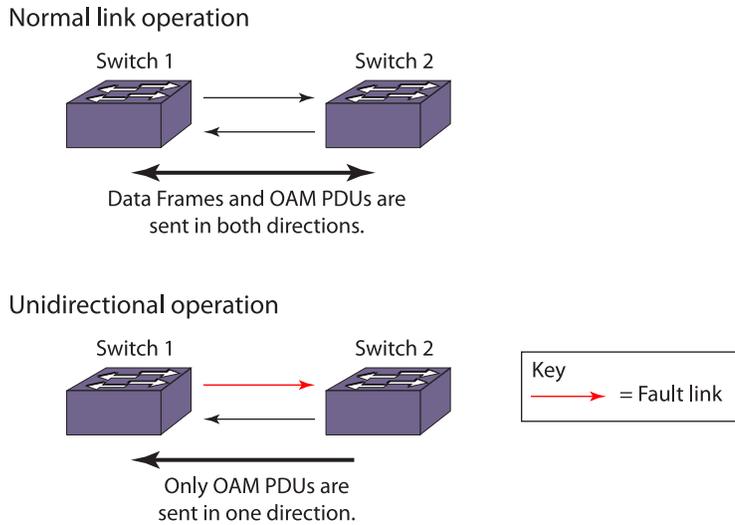
Unidirectional operation


Figure 57: Normal Link and Unidirectional Operation

You can enable unidirectional link fault detection and notification on individual ports with CLI commands. This allows appropriate register settings to transmit OAM PDUs even on a link that has a slowly deteriorating quality receive path or no receive path at all. Then, when a link is not receiving a signal from its peer at the physical layer (for example, if the peer's laser is malfunctioning), the local entity can set a flag in an OAM PDU to let the peer know that its transmit path is inoperable.

The operation of OAM on an Ethernet interface does not adversely affect data traffic because OAM is a slow protocol with very limited bandwidth potential, and it is not required for normal link operation. By utilizing the slow protocol MAC address, OAM frames are intercepted by the MAC sub layer and cannot propagate across multiple hops in an Ethernet network. This implementation assures that OAM PDUs affect only the operation of the OAM protocol itself and not user data traffic.

The IEEE 802.3ah standard defines fault notifications based on one-second timers. But by sending triggered OAM PDUs on detecting link down/local fault rather that waiting to send on periodic PDUs, failure detection is less than one second can be achieved, thereby accelerating fault recovery and network restoration.

EFM OAM uses standard length Ethernet frames within the normal frame length of 64 to 1518 bytes as PDUs for their operation. Table 50 describes the fields of OAM PDUs.

Table 50: OAM PDU Fields

Field	Octets	Description	Value
Destination Address	6	Slow protocol multicast address	01:80:C2:00:00:02
Source Address	6	Port's individual MAC address	Switch MAC
Length/Type	2	Slow protocol type	0x8809
Subtype	1	Identifies specific slow protocol	0x03

Table 50: OAM PDU Fields (continued)

Field	Octets	Description	Value
Flags	2	Contains status bits	see the following figure
Code	1	Identifies OAM PDU type	0x00 (Information TLV)
Data/Pad	42-1496	OAM PDU data	0x00 (END of TLV)
FCS	4	Frame check sequence	

Configuring Unidirectional Link Fault Management

To configure unidirectional link fault management on a port or ports, use the following command:

```
enable ethernet oam ports [port_list | all] link-fault-management
```

To clear the counters on a configured port, use the following command:

```
clear ethernet oam {ports [port_list} counters
```

To unconfigure unidirectional link fault management, use the following command:

```
disable ethernet oam ports [port_list | all] link-fault-management
```

To display the Ethernet OAM settings, use the following command:

```
show ethernet oam {ports [port_list} {detail}
```

When configured, the following behavior on the port is observed:

- A log indicates that traffic on the port is blocked.
- All received traffic on that port is blocked except for Ethernet OAM PDUs.
- To higher layers, a failure is reported as a link down but OAM can use the link to send OAM traffic.

Two-Way Active Measurement Protocol

The Two-Way Active Measurement Protocol, defined in RFC 5357, specifies an industry standard for measuring round-trip performance between two devices that support the TWAMP protocols. TWAMP defines two protocols; the TWAMP-Control protocol and the TWAMP-Test protocol. The TWAMP-Control protocol is used to setup test sessions. The test sessions use the TWAMP-Test protocol to transmit and reflect performance measurement packets. The TWAMP-Control protocol utilizes TCP for communication, while the TWAMP-Test protocol utilizes UDP.

> **Note**
> Only the TWAMP-Test protocol is supported.

The test sessions are setup via the 'Request-Session' command message, sent from the Control-Client to the Server. The Server replies with an 'Accept Session' message, which indicates if the Server is capable of accommodating the request or not. The Control-Client may send several 'Request-Session' command messages to setup multiple test sessions. To begin the tests, the Control-Client transmits a 'Start-Session' command message. The Server replies with a 'Start-Ack' message. The Control-Client does not begin its test until it receives the 'Start-Ack' message. This allows the Server ample time to configure the test sessions. The Control-Client will stop the test sessions with a 'Stop-Sessions' message. The Server does not respond to this message.

The ExtremeXOS 16.1 implementation of TWAMP consists of the development of the TWAMP logical role of the Session-Reflector. The user is required to configure endpoints, which define the destination of TWAMP-Test packets generated by the client. An endpoint receiving a new TWAMP-test packet creates a test session consisting of the following four-part tuple; client IP address, client UDP port, endpoint IP address, and endpoint UDP port. The tuple does not include the VR because it requires the default VR for the first phase. A session timeout value, configured globally, determines the amount of time test sessions exist after the last reception of a TWAMP-Test packet. Test sessions are used to keep track of the session data, such as the sequence number. The Session-Reflector will still respond to TWAMP-Test packets that do not match an existing test session or if a new test session cannot be created due to lack of resources.

TWAMP-Test Protocol

The TWAMP logical roles of the Session-Sender and Session-Reflector use the TWAMP-Test protocol. The Session-Sender, controlled by the Client, transmits TWAMP-Test packets to the Session-Reflector. The Session-Reflector processes the packet, copies the fields from that packet into the reply, and then transmits a reply packet back to the Session-Sender. The reply packet is larger than the request packet unless the Clients adds padding.

The implementation of the Session-Reflector relies on the user to create endpoints, which open up available ports for reflecting TWAMP-Test packets. The endpoint configuration acts as a control list to limit the number of locally opened sockets. The user may choose to use authentication or encryption to protect the transmitted data from nefarious entities. The shared keys used for the TWAMP-Test derive from the TWAMP 3-way handshake that establishes the control session. Both devices must configure matching shared keys.

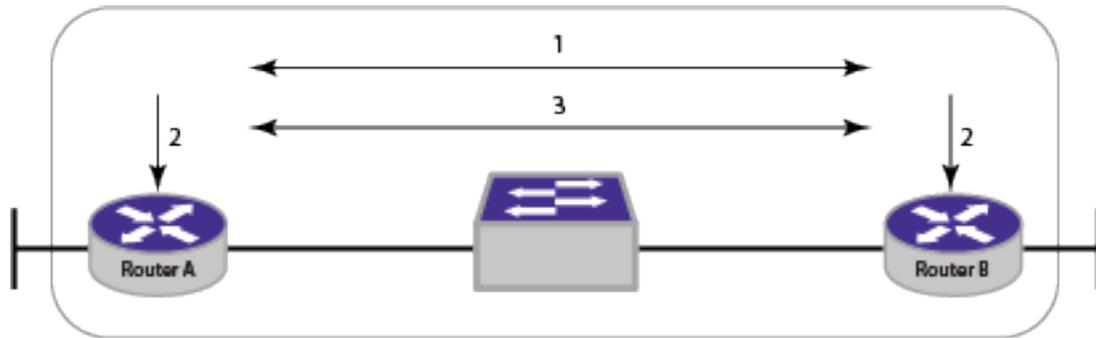
Bidirectional Forwarding Detection (BFD)

BFD Overview

Bidirectional Forwarding Detection (BFD) is a hello protocol that provides the rapid detection of failures in the path and informs the clients (routing protocols) to initiate the route convergence.

It is independent of media, routing protocols, and data protocols. BFD helps in the separation of forwarding plane connectivity and control plane connectivity.

Different routing protocol hello mechanisms operate in variable rates of detection, but BFD detects the forwarding path failures at a uniform rate, thus allowing for easier network profiling and planning, and consistent and predictable re-convergence time.

Figure 58 shows a BFD topology.


1. Routing protocol (BFD client) discovers neighbor.
2. Routing protocol informs BFD to create session with neighbor.
3. BFD establishes session with neighbor.

Figure 58: BFD Topology

The routing protocols first learn the neighbor and make entries in the forwarding table. Then protocols can register the neighbor address with BFD and ask to monitor the status of the path. BFD establishes the session with a remote BFD and monitors the path status.

You can configure detection multipliers and TX and RX intervals on a directly connected interface (*VLAN*).
- The detection multiplier signifies the number of BFD packets the BFD server waits for after which a timeout is declared.
- The receive interval is the interval at which the BFD server is ready to receive packets.
- The transmit interval is the interval at which the BFD server is ready to transmit packets.

For example, when two nodes, A and B, initiate a BFD session between them, a negotiation about the receive and transmit intervals occurs.

The receive interval of node A is calculated as the maximum of the configured receive interval of node A and the configured transmit interval of node B. The same applies to node B.

If multiple clients ask for the same neighbor on the same interface, then a single BFD session is established between the peers.

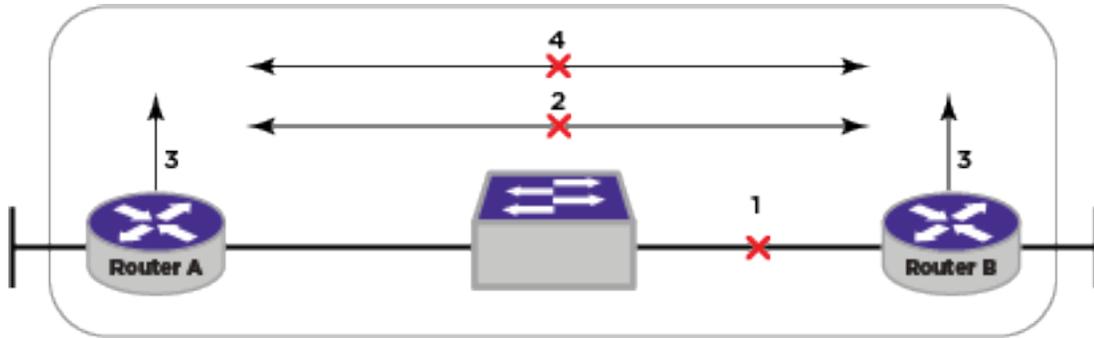
Figure 59 shows the behavior when a failure occurs.


Figure 59: BFD Failure Detection

BFD detects the failure first, and then informs the registered clients about the neighbors.

BFD operates in an asynchronous mode in which systems periodically send BFD control packets to one another. If a number of those packets in a row are not received by the other system, the session is declared to be down.

Simple password authentication can be included in the control packet to avoid spoofing.

BFD for OTM, BGP, and hitless failover are supported.

This feature is available on all platforms.

> **Note**
> BFD can be used to protect IPv4 & IPv6 static routes, OSPFv2 & *OSPFv3 (Open Shortest Path First version 3)* interfaces and *BGP (Border Gateway Protocol)* and *MPLS (Multiprotocol Label Switching)* interfaces. For more information, see Configuring Static Routes on page 1581, BFD for OSPF on page 1663, or refer to Managing the MPLS BFD Client on page 1524.

Limitations

The following limitations apply to BFD in this release:

- *BGP*, *OSPF (Open Shortest Path First)*, *MPLS*, OTM, and static routes act as BFD clients.
- The echo function is not supported.
- Hardware assist BFD is supported only on standalone X460-G2, X465, X590, and X695 series switches.
- The number of sessions handled by BFD at minimal timers (less than 100ms) varies depending on the platform type, the implementation type (H/w or S/w), and the processing load (which is influenced by other protocols being enabled or other system conditions such as software forwarding).
- The following scaling limits apply to BFD hardware assist:
  ◦ Maximum 900 sessions if PTP feature not enabled.
  ◦ Maximum 425 sessions with PTP enabled.

◦ Maximum of 256 sessions with 3 ms transmit interval.

Configuring BFD

You can enable, disable, configure, and unconfigure BFD.

- To enable or disable BFD, use the following command:

  `[enable | disable] bfd vlan vlan_name`

- To configure the detection multipliers and TX and RX intervals, use the following command:

  `configure bfd vlan vlan_name [{detection-multiplier multiplier} {receive-interval rx_interval} {transmit-interval tx_interval}]`

- To specify either authentication using a simple password or no authentication, use the following command:

  `configure bfd vlan vlan_name authentication [none | simple-password {encrypted} password]]`

- To unconfigure BFD, use the following command:

  `unconfigure bfd vlan vlan_name`

Configuring BFD Intervals

In case of BFD implemented in software, the ability to run low-range sub-second intervals depends on the CPU load, which in turn depends on other protocol configurations and system conditions, such as software forwarding. It also depends on switch model.

To find a suitable low-range interval for the chosen configuration and network load, statistics of missed hello packets can help. These hello packets are exchanged between BFD peers, and if n number of packets are missed in a row, path failure will be declared, where n is detection-multiplier. However, missed hellos less than n number will not declare failure, but if statistics are steadily increasing, it can indicate that the currently chosen BFD interval is not appropriate.

In that case, a next longer interval/ higher detection multiplier can be chosen for the BFD session, and statistics can be monitored again. In addition, when statistics are observed periodically, missed hellos can give an indication of whether health of the path is deteriorating. These statistics are collected continuously for each BFD session. The commands to display the statistics of missed hellos are provided in Displaying BFD Information on page 505.

Setting Strict BFD Session Protection

If the BFD session is down, but BFD protected static route is still in the routing table after reboot, the BFD session is never established, because during reboot, the BFD session is in the INIT state, and the static route is brought up without considering BFD session state. This situation can cause traffic loss because the link to the gateway actually is down. This command turns down the static route during reboot if BFD session is in the INIT state. This behavior is different from other BFD clients (such as *OSPF*) in the same INIT situation.

To enable strict BFD session protection, use the following command:

```
enable iproute {protection} bfd strict
```

> **Note**
> Enabling strict BFD generates a warning message to reboot the switch so as
> to update the route table: `WARNING: Please reboot the switch for the`
> `strict BFD to take effect.`

To disable strict BFD session protection, use the following command:

```
disable iproute {protection} bfd strict
```

To show strict BFD session protection status, use the following command:

```
show iproute bfd
```

Displaying BFD Information

The following commands display information regarding BFD configuration and
process.

- To display information on BFD sessions, use the following command:
  ```
  show bfd
  ```
- To display information on BFD global counters, use the following command:
  ```
  show bfd counters
  ```
- To display information on BFD session counters, use the following command:
  ```
  show bfd session {ipv4 | ipv6} {ipaddress} counters {vr [vrname |
  all]}
  ```
- To display the configuration of a specific interface or those specific counters, use the
  following command:
  ```
  show bfd vlan {vlan_name}
  ```
- To display the counters of a specific interface, use the following command:
  ```
  show bfd vlan {vlan_name} counters
  ```
- To display the session status of a particular client, use the following command:
  ```
  show bfd session client [ bgp {ipv4 | ipv6} | mpls | ospf {ipv4 |
  ipv6} | static {ipv4 | ipv6}] {vr [vrname | all]}
  ```
- To display the session status information for all VRs, use the following command:
  ```
  show bfd session {ipv4 | ipv6} {ipaddress } { vr [vrname |all ] }
  ```
- To display session status information in detail for all VRs, use the following
  command:
  ```
  show bfd session {ipv4 | ipv6} {ipaddress } detail {vr [vrname | all]}
  ```
- To display counters of missed hello packets for all available sessions, use the
  following command:
  ```
  show bfd session counters missed-hellos {session-id first {- last} |
  neighbor ipaddress {vr [vrname | all]} | vr [vrname| all]} {detail |
  no-refresh | refresh}
  ```

- To display counters of missed hello packets for a session using neighbor IP address, use the following command:

  ```
  show bfd session counters missed-hellos neighbor ipaddress {vr [vrname
  | all]}
  ```

- To display counters of missed hello packets for a particular range of session ID, use the following command:

  ```
  show bfd session counters missed-hellos session-id first {- last}
  ```

- To show strict BFD session protection status, use the following command:

  ```
  show iproute bfd
  ```

Clearing BFD Information

To clear global, session, or interface counters, use the following command:

```
clear counters bfd {session | interface | missed-hellos}
```

To clear missed hellos counters for a session using neighbor IP address:

```
clear counters bfd missed-hellos neighbor ipaddress {vr [vrname | all]}
```

To clear missed hellos counters for a particular range of session ID:

```
clear counters bfd missed-hellos {session-id first {- last}
```

BFD Hardware Assist

Bidirectional Forwarding Detection (BFD) hardware assist support provides the functionality to run a BFD session in hardware. Effective failure detection requires BFD to run at high frequencies (using aggressive timers as low as 3 ms), which was not possible in the Software Mode because of CPU and ExtremeXOS restrictions.

Starting with ExtremeXOS 30.5, BFD hardware assist supports multi-hop.

To make BFD sessions run in the hardware, the following configuration is required:

- Hardware BFD is enabled by configuring one of the unused front panel port as a loopback port, which should not be available for switching user data traffic. This port is used internally by the BFD hardware to send control packets.
- Ensure IP forwarding is enabled on the BFD interfaces.
- The next hop MAC address of the neighbor should be known for the session creation. The BFD process triggers ARP to resolve the next hop MAC address, if this is not configured statically.

L2 topology convergence time might affect the BFD sessions running at the shortest interval.

Unconfiguring loopback for BFD disables the hardware assist support. The supported shortest interval is 3 ms in hardware mode.

Sample configuration:

Configure the port 1 as loopback port dedicated for BFD:

```
#configure bfd hardware-assist primary loopback-port 1
```

To check the number of BFD sessions supported in the hardware and configured loopback port:

```
#show bfd
..
..
Hardware Assist Operational State        : Enabled(Loopback
port not configured)
Hardware Assist Primary Loopback Port    : 1
Hardware Assist Secondary Loopback Port  : None
Maximum # of Hardware Assist Sessions    : 900
```

To find the session running the hardware:

```
#show bfd session detail
Neighbor       : 10.10.10.2          Local       : 10.10.10.1
VR-Name        : VR-Default          Interface   : v1
Session Type   : Single Hop          State       : Down
..
Hardware Assist                : Yes
```

To see the hardware counters:

```
#show bfd counters
#show bfd session 10.10.10.2 counters
```

BFD MIB Table Support

ExtremeXOS 15.5 supports read-only for all BFD MIB tables, global objects, and supports BFD notifications as well. BFD-MIB implementation is based on draft-ietf-bfd-mib-14, and draft-ietf-bfd-tc-mib-02. Currently, the BFD MIB is kept under the enterprise MIB in ExtremeXOS implementation.

The SET operation is supported only for MIB object 'bfdSessNotificationsEnable' (to control up/down traps). The default value for this object is disabled state. No notification is sent in disabled state. Thus, the SET operation is also supported for this MIB object in order to control the emission of traps.

BFD Session Up/Down Traps

BFD has two traps, one for notifying that the session moved to the UP state, and the other trap for notifying that the session moved to DOWN state. To reduce the number of traps sent to NMS, a single trap is generated to combine the status changes of multiple sessions if the sessions have contiguous session IDs and multiple sessions move to either the UP or DOWN state in the same window of time. However, status changes of different types (UP & DOWN), will not be mixed in single trap. The window of time to combine the traps can be configured using the CLI command `configure snmp traps batch-delay bfd`.

For example, if sessions with session IDs 1, 2, 3, 4, and 5 are moving to the UP state in the same window of time, then a single trap is sent with low range index 1 and high

range index 5. As a second example, after all sessions moved to the UP state, session ID 2 goes DOWN and comes back UP before generating the first trap. In this case also, the first trap which is the UP trap, is set to include all sessions. Then, the second trap would be the DOWN trap for session ID 2, and finally the third trap would be the UP trap again for session ID 2. Thus, events are not missed or reordered.

NMS relates traps to sessions using only the session index which is provided in traps. It is necessary that the session index does not change until NMS retrieves session details via GET requests. To achieve this, the session will be retained for fifteen minutes after deletion is initiated by the BFD client (control protocol). During this period transmission and reception of BFD control packets will be stopped. If BFD protection is requested for the same destination again within this period, the same session index is reused. With this change, NMS can also have good history of the session to a particular destination.

Configuring SNMP Traps for BFD

To enable snmp traps for bfd:

```
enable snmp traps bfd {session-down | session-up}
```

To disable snmp traps for bfd:

```
disable snmp traps bfd {session-down | session-up}
```

To configure batch delay for sending the traps:

```
configure snmp traps batch-delay bfd {none | delay}
```

To display the configuration:

```
show snmp traps bfd
```

> **Note**
> *SNMP (Simple Network Management Protocol)* traps for BFD are disabled by default for both session-down and session-up.

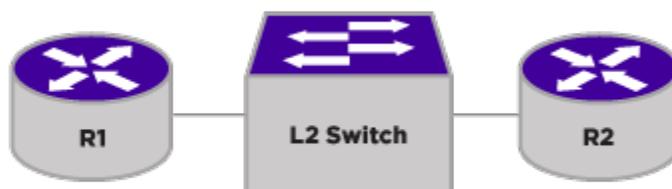
Configuration Example


Figure 60: BFD Configuration Example

Consider the network segment like above, wherein two routers R1 and R2 are connected via an L2 switch. Following is the list of commands to configure BFD protection for static routes.

Router R1:

1. Create vlan and configure IP address.

   ```
   create vlan v1 tag 100
   ```

   ```
   configure vlan v1 add port 2 tagged
   ```

   ```
   configure vlan v1 ipaddress 10.0.0.1/24 2
   ```

2. Create BFD session to the next-hop which is being monitored.

   ```
   enable iproute bfd 10.0.0.2 vr VR-Default
   ```

3. Configure `iproute add <destination network> <gateway> bfd`

PoE

Power over Ethernet (PoE) is an effective method of supplying 48 VDC power to certain types of powered devices (PDs) through Category 5 and above twisted pair Ethernet cables.

PDs include wireless access points, IP telephones, laptop computers, web cameras, and other devices. With PoE, a single Ethernet cable supplies power and the data connection, reducing costs associated with separate power cabling and supply.

In a SummitStack, power is maintained across a failover on all PoE ports of non-primary nodes but is lost on all PoE ports of the failed primary node. Each ExtremeSwitching switch has its own PSU and the power budget for each ExtremeSwitching switch is determined by the internal/external PSUs connected to that ExtremeSwitching switch.

PoE+ supports higher power levels as defined by the IEEE 802.3at standard.

PoE++ supports higher power levels as defined by the IEEE 802.3bt standard.

Extreme Networks PoE Devices

Following is a list of the Extreme Networks devices that support PoE+ and PoE++ and the minimum required software:

PoE+

- ExtremeSwitching X450-G2-24p-GE4—ExtremeXOS 16.1 and later.
- ExtremeSwitching X450-G2-48p-GE4—ExtremeXOS 16.1 and later.
- ExtremeSwitching X450-G2-24p-10GE4—ExtremeXOS 16.1 and later.
- ExtremeSwitching X450-G2-48p-10GE4—ExtremeXOS 16.1 and later.
- ExtremeSwitching X460-G2-24p-10GE4—ExtremeXOS 15.6 and later.
- ExtremeSwitching X460-G2-48p-10GE4—ExtremeXOS 15.6 and later.
- ExtremeSwitching X460-G2-24p-GE4—ExtremeXOS 15.6 and later.
- ExtremeSwitching X460-G2-48p-GE4—ExtremeXOS 15.6 and later.

- ExtremeSwitching X460-G2-16mp-32p-10GE4—ExtremeXOS 15.6 and later.
- ExtremeSwitching X460-G2-24p-24hp-10GE4—ExtremeXOS 22.2 and later.
- ExtremeSwitching X440-G2-48p-10GE4—ExtremeXOS 21.1 and later.
- ExtremeSwitching X440-G2-24p-10GE4—ExtremeXOS 21.1 and later.
- ExtremeSwitching X440-G2-12p-10GE4—ExtremeXOS 21.1 and later.
- ExtremeSwitching X465-48P—ExtremeXOS 30.2 and later.
- ExtremeSwitching X435-8P-4S—ExtremeXOS 30.5 and later.
- ExtremeSwitching X435-24P-4S—ExtremeXOS 30.5 and later.
- ExtremeSwitching X435-8P-2T-W—ExtremeXOS 30.5 and later.

PoE++

- ExtremeSwitching X465-24MU-24W—ExtremeXOS 30.2 and later.
- ExtremeSwitching X465-48W—ExtremeXOS 30.2 and later.
- ExtremeSwitching X465-24MU—ExtremeXOS 30.2 and later.
- ExtremeSwitching X465-24W—ExtremeXOS 30.2 and later.
- ExtremeSwitching X465i-48W—ExtremeXOS 30.5 and later.

Summary of PoE Features

The ExtremeXOS implementation of *PoE (Power over Ethernet)* supports the following features:

- Configuration and control of the power distribution for PoE at the system, slot, and port levels
- Real-time discovery and classification of IEEE 802.3af-compliant PDs and many legacy devices
- Support for IEEE 802.3at-compliant PDs on PoE+ devices
- Support for IEEE 802.3bt compliant PDs on PoE++ devices
- Monitor and control of port PoE fault conditions including exceeding configured class limits and power limits and short-circuit detection
- Support for configuring and monitoring PoE status at the system, slot, and port levels
- Management of an over-subscribed power budget
- Port LED control for indicating the link state
- Support for hitless failover in a SummitStack with a master and backup node.
- (Fast PoE) Ability to provide PoE power when the switch is powered on without waiting for boot up based on last saved PoE state (ExtremeSwitching X435; and X465 (per port) series switches only).
- (Perpetual PoE) Preserve PoE power delivery to devices during reboot (ExtremeSwitching X465 and X435 series switches only).

Power Delivery

This section describes how the system provides power to the PDs. ExtremeXOS always configures the PoE controller to use Dynamic Power Management mode.

Enabling PoE to the Switch

PoE is enabled by default. For details about changing the configuration, see Configuring PoE on page 517.

Power Reserve Budget

Power supply equipment (PSEs) can be categorized as either Type 1, Type 2, Type 3, or Type 4 PSEs . Type 3 PSEs support powered devices (PDs) up to class 6. Type 4 PSEs support PDs up to class 8.

ExtremeSwitching X435 Switches Only

The power budget for:

- X435-24P-4S switches is 370W
- X435-8P-4S switches is 124W

The power budget for the X435-8P-2T-W switch is based on the two PoE uplink ports.

Source Wattage	Output
P9 + P10	Watts
0 + 0	0
30 + 0	0
60 + 0	25
90 + 0	45
0 + 30	0
30 + 30	25
60 + 30	45
90 + 30	65
0 + 60	25
30 + 60	45
60 + 60	65
90 + 60	85
0 + 90	45
30 + 90	65
60 + 90	85
90 + 90	100

ExtremeSwitching X440-G2 Switches Only

ExtremeSwitching X440-G2 has an internal PSU. The power budgets for the X440-G2-48p, X440-G2-24p, and X440-G2-12p are 740W, 380W, and 200W respectively.

ExtremeSwitching X450-G2 Switches Only

The ExtremeSwitching X450-G2 non-PoE+ models support a fixed internal 156W AC/DC PSU, whereas X450-G2 PoE+ models support dual, hot-swappable 1100W/715W/PSUs. 315W is not yet supported in X450-G2.

ExtremeSwitching X460-G2 Switches Only

The ExtremeSwitching X460-G2 supports two PSUs : 1100W and 715W. When 1100W is used, the switch is capable of delivering 850W of power. When 715W is used, the switch is capable of delivering 500W of power.

ExtremeSwitching X465 Switches Only

ExtremeSwitching X465 48P model supports 30W PoE+. ExtremeSwitching X465 24MU-24W, 48W, 24MU, and 24W models support PoE++ Type 3 (60W) and uPoE Type 4 (90W). The following power budgets will be possible on these models:

Table 51: X465 PoE Power Budget

Guard Band

To reduce the chances of ports fluctuating between powered and non-powered states, newly inserted PDs are not powered when the actual delivered power for the switch is within a preset value below the configured inline power budget for that slot or switch.

This band is called the guard band and the value used is 20 W for all ExtremeSwitching series switches. However, actual aggregate power can be delivered up to the configured inline power budget for the slot or switch (for example, when delivered power from ports increases or when the configured inline power budget for the slot is reduced).

If total consumed power is within the guard band, new ports are not powered up.

PD Disconnect Precedence

After a PD is discovered and powered on an ExtremeSwitching switch, the actual power drain is continuously measured.

If the usage for power by PDs is within the guard band, the system begins denying power to PDs.

You can configure the switch to handle a request for power that exceeds the power budget situation in one of two ways, called the disconnect precedence:

- Disconnect PDs according to the configured *PoE* port priority for each PD.
- Deny power to the next PD requesting power, regardless of that port's PoE priority. The default value is deny-port.

Port Priority Enabled

- When a PD is detected on a specific port, the PoE controller allows power on the port if available power form the power source is greater than the maximum power threshold configured on the port and the total allocated power is below the guard band.
- When available power is less than the maximum power threshold configured on the port and port priority is less than the port priority set on all powered ports, the PoE controller does not allow power on the port.
- When available power is less than the maximum power threshold configured on the port and the port priority is greater than the priority of currently powered ports, the PoE controller disconnects the two priority ports(s) and allows the port to power up.
- When the total consumed power exceeds the configured power limit of the power source, the PoE controller disconnects the low priority ports(s) and allows the port to power up.

Port Priority Disabled

- When a PD is detected on a specific port, the PoE controller allows power on the port if available power from the power source is greater than the maximum power threshold configured on the port and the total allocated power is below the guard band. Note that "maximum power threshold" is the same as "operator-limit".

- When available power is less than the maximum power threshold configured on the port, the PoE controller does not allow power on this port.
- When the total consumed power exceeds the configured power limit of the power source, the PoE controller starts powering down ports beginning with the highest port number.

Port Disconnect or Fault

On all _PoE_ devices, when a port enters a fault state if you set the operator limit lower than the amount requested by the PD, the system removes power from that port. The power removed is, again, available only to other ports on the same slot or stand-alone switch. The port stays in the fault state until you disable that port, disconnect the attached PD, or reconfigure the operator limit to be high enough to satisfy the PD requirements.

When a port is disconnected or otherwise moves into a fault state, _SNMP (Simple Network Management Protocol)_ generates an event (after you configure SNMP and a log message is created).

Port Power Cycling

You can set ports to experience a power-down, discover, or power-up cycle.

On the ExtremeSwitching X460-G2 series switches, this power-cycling occurs without returning the power to the slot's reserved power budget. This function allows you to reset PDs without losing their claim to the reserved power budget.

PoE Usage Threshold

The system generates an _SNMP_ event when any slot or stand-alone switch has consumed a specified percentage of that slot's reserved power budget or of the entire power for the stand-alone switch.

The default value is 70%; you can configure this threshold to generate events from 1% to 99% consumption of the reserved power budget. You can also configure the system to log an EMS message when the usage threshold is crossed (for more information on EMS, see Using the Event Management System/Logging on page 549).

Legacy Devices

ExtremeXOS software allows the use of non-standard PDs with the switch. These are PDs that do not comply with the IEEE 802.3af standard.

The system detects non-standard PDs using a capacitance measurement. You must enable the switch to detect legacy devices; the default value is disabled.

Detecting a PD through capacitance is used only if the following two conditions are both met:
- Legacy PD detection is enabled.

- The system unsuccessfully attempted to discover the PD using the standard resistance measurement method.

PoE Operator Limits

You can set the power limit that a PD can draw on the specified ports. For *PoE*, the range is 3,000 to 16800mW and the default value is 15,400 mW. For PoE+, the range is 3,000 to 32,000 mW and the default value is 30,000 mW. For PoE++ Type 3, the range is 3,000 mW to 64,000 mW and the default value is 60,000 mW. For PoE++ Type 4, the range is 3,000 mW to 98,000 mW and the default value is 90,000 mW.

If the measured power for a specified port exceeds the port's operator limit, the power is withdrawn from that port and the port moves into a fault state.

If you attempt to set an operator limit outside the accepted range, the system returns an error message.

With a **class-based** operator-limit type, if a class4 PD is attached, then the operator-limit set will be ignored and the switch will not deliver more than 30W to the PD.

When **class-based** operator-limit is configured on a port, "Max Allowed Power" will show the maximum power for the class of the attached PD. Without the **class-based** option, "Max Allowed Power" will show the configured or default value of operator-limit.

Configuring PoE

PoE supports a full set of configuration and monitoring commands that allows you to configure, manage, and display PoE settings at the system, slot, and port level. To enable inline power, or PoE, you must have a powered switch.

To configure inline power, or PoE, you must accomplish the following tasks:

1. Enable inline power to the system, slot, and/or port.
2. On ExtremeSwitching X450-G2, X440-G2, X460-G2, X620, X435, X465, series switches, configure the disconnect precedence for the PDs in the case of excessive power demands.
3. Configure the threshold for initiating system alarms on power usage.

Additionally, you can configure the switch to use legacy PDs, apply specified PoE limits to ports, apply labels to PoE ports, and configure the switch to allow you to reset a PD without losing its power allocation.

For complete information on using the CLI commands, see the *ExtremeXOS 32.4 Command Reference Guide*.

Enable Inline Power

- To enable inline power to the switch, slot, or port, and to enable fast and perpetual PoE, use the following commands:

```
enable inline-power [{fast {ports [port_list | all]}} | perpetual]
```

```
enable inline-power [fast | perpetual] slot slot
```

```
enable inline-power ports [all | port_list]
```

- To disable inline power to the switch, slot, or port, and to disable fast and perpetual PoE, use the following commands:

```
disable inline-power [{fast {ports [port_list | all]}} | perpetual]
```

```
disable inline-power [fast | perpetual] slot slot
```

```
disable inline-power ports [all | port_list]
```

Disabling the inline power to a PD immediately removes power from the PD. Inline power is enabled by default.

- To display the configuration for inline power, use the following command:

```
show inline-power
```

- To display fast and perpetual PoE status, use the following commands:

```
show inline-power [fast | perpetual]
```
```
show inline-power [fast | perpetual] slot slot
```
```
show inline-power fast ports {port_list}
```

Setting the Disconnect Precedence

ExtremeSwitching X435, X450-G2, and X460-G2 _PoE_ series switches only.

> **Note**
> The switch generates an _SNMP_ event if a PD goes offline, and the port's state moves from Power to Searching. You must configure SNMP to generate this event.

When the actual power used by the PDs on a switch or slot exceeds the power budgeted for that switch or slot, the switch refuses power to PDs. There are two methods used by the switch to refuse power to PDs, and whichever method is in place applies to all PoE slots in the switch. This is called the disconnect precedence method, and you configure one method for the entire switch.

The available disconnect precedence methods are:

- Deny port
- Lowest priority

The default value is deny port. Using this method, the switch simply denies power to the next PD requesting power from the slot, regardless of that port's PoE priority or port number.

> **Note**
> Starting with ExtremeXOS 30.2, on ExtremeSwitching X465 and X620 series switches, priority of the port is given preference even though the disconnect precedence is deny port.

Using the lowest priority method of disconnect precedence, the switch disconnects the PDs connected to ports configured with lower PoE priorities (for information about port priorities, see Configuring the PoE Port Priority on page 519).

When several ports have the same PoE priority, the lower port numbers have higher PoE priorities. That is, the switch withdraws power (or disconnects) those ports with the highest port number(s).

The system keeps dropping ports, using the algorithm you selected with the disconnect ports command, until the measured inline power for the slot is lower than the reserved inline power.

- To Configure the disconnect precedence for the switch, use the following command:

  ```
  configure inline-power disconnect-precedence [deny-port | lowest-
  priority]
  ```

- To return the disconnect precedence to the default value of deny port, use the following command:

  ```
  unconfigure inline-power disconnect-precedence
  ```

- To display the currently configured disconnect precedence, use the following command:

  ```
  show inline-power
  ```

Configuring the PoE Port Priority

Supported for ExtremeSwitching X460-G2 *PoE* series switches only.

You can configure the PoE port priority to be low, high, or critical. The default value is low.

If you configure the disconnect precedence as lowest priority and the PDs request power in excess of the switch's or slot's reserved power budget, the system allocates power to those ports with the highest priorities first.

If several ports have the same PoE priority, the lower port numbers have higher PoE priorities. That is, the switch withdraws power (or disconnects) those ports with the highest port number(s).

- To configure PoE port priority, use the following command:

  ```
  configure inline-power priority [critical | high | low] ports
  port_list
  ```

- To reset the port priority to the default value of low, use the following command:

  ```
  unconfigure inline-power priority ports [all | port_list]
  ```

- To display the PoE port priorities, use the following command:

  ```
  show inline-power configuration ports {port_list}
  ```

Configuring the Usage Threshold

The system generates an *SNMP* event after a preset percentage of the reserved power for any slot or total power for a stand-alone switch is actually used by a connected PD. This preset percentage is called the usage threshold and is the percentage of the

measured power to the budgeted power for each slot or total power for a stand-alone switch.

The default value for this usage threshold is 70%. You can configure the usage threshold to be any integer between 1% and 99%.

- To configure the threshold percentage of budgeted power used on a slot or the total power on a stand-alone switch that causes the system to generate an SNMP event and EMS message, use the following command:

  `configure inline-power usage-threshold threshold`

- To reset the threshold that causes the system to generate an SNMP event and EMS message per slot to 70% for measured power compared to budgeted power, use the following command:

  `unconfigure inline-power usage-threshold`

- To display the currently configured usage threshold, use the following command:

  `show inline-power`

Configuring the Switch to Detect Legacy PDs

The *PoE* device can detect non-standard, legacy PDs, which do not conform to the IEEE 802.3af standard, using a capacitance measurement. However, you must specifically enable the switch to detect these non-standard PDs; the default value for this detection method is disabled.

This configuration applies to the entire switch; you cannot configure the detection method per slot.

The switch detects PDs through capacitance only if both of the following conditions are met:

- The legacy detection method is enabled.
- The switch unsuccessfully attempted to discover the PD using the standard resistance measurement method.

- To configure a switch to detect legacy, non-standard PDs for a specified slot, use the following command:

  `configure inline-power detection [`**`802.3af-only`** `|` **`legacy-and-802.3af`** `[`**`4-point`** `|` **`2-point`**`] |` **`bypass`**`] ports port_list`

- To configure the switch to detect legacy PDs on a switch, use the following command:

  `configure inline-power detection [`**`802.3af-only`** `|` **`legacy-and-802.3af`** `[`**`4-point`** `|` **`2-point`**`] |` **`bypass`**`] ports port_list`

Configuring the Operator Limit

You can configure the maximum amount of power that the specified port can deliver to the connected PD, in milliwatts (mW). For *PoE*, the default value is 15400 mW, and the range is 3000 to 16800 mW. For PoE+, the range is 3,000 to 32,000 mW and the default value is 30,000 mW. For PoE++ Type 3, the range is 3,000 mW to 64,000 mW

and the default value is 60,000 mW. For PoE++ Type 4, the range is 3,000 mW to 98,000 mW and the default value is 90,000 mW.

If the operator limit for a specified port is less than the power drawn by the legacy PD, the legacy PD is denied power.

- To set the operator limit on specified ports, which limits how much power a PD can draw from that port, use the following command:

  `configure inline-power operator-limit` *milliwatts* `ports` [**all** | *port_list*]

- To reset the operator limit to the default value of 15.4 W for PoE, 30 W for PoE+, or 60 W for PoE++, use the following command:

  `unconfigure inline-power operator-limit ports [all |`*port_list*`]`

- To display the current operator limit on each port, use the following command:

  `show inline-power configuration ports {`*port_list*`}`

  > **Note**
  > With a **class-based** operator-limit type, if a class4 PD is attached, then the operator-limit set will be ignored and the switch will not deliver more than 30W to the PD.
  > When **class-based** operator-limit is configured on a port, "Max Allowed Power" will show the maximum power for the class of the attached PD. Without the **class-based** option, "Max Allowed Power" will show the configured or default value of operator-limit.

Configuring the Inline-Power Budget

You can configure *PoE* power budget values based on PSU capability on ExtremeSwitching X450-G2 series switches only.

1. To configure the inline-power budget, use the following command:

   `configure inline-power` **budget** [**redundant** | **maximum**]`.`

   Specify the **maximum** option to configure the default maximum inline-power drawn.

2. To display power budget information, use the following command:

   `show inline-power`

Configuring PoE Port Labels

You can assign labels to a single or group of *PoE* ports using a string of up to 15 characters.

- To assign a label to PoE ports, use the following command:

  `configure inline-power label` *string* `ports` *port_list*

  To rename a port or to return it to a blank label, reissue the command.

- To display the PoE port labels, use the following command:

  `show inline-power configuration ports {`*port_list*`}`

Power Cycling Connected Powered Devices

You can power cycle a connected PD without losing the power allocated to its port using the following command:

```
reset inline-power ports port_list
```

Displaying PoE Settings and Statistics

You can display the *PoE* status, configuration, and statistics for the system, slot, and port levels.

Clearing Statistics

You can clear the *PoE* statistics for specified ports or for all ports.

To clear the statistics and reset the counters to 0, enter the following command:

```
clear inline-power stats ports [all | port_list]
```

Displaying System Power Information

You can display the status of the inline power for the system and, for additional information, display the power budget of the switch.

Display System PoE Status

- Display the *PoE* status for the switch.
  ```
  show inline-power [fast | perpetual]
  ```

  The command provides status for the following areas:
  - Configured inline power status—The status of the inline power for the switch: enabled or disabled.
  - System power surplus—The surplus amount of power on the system, in watts, available for budgeting.
  - Redundant power surplus—The amount of power on the system, in watts, available for budgeting if one power supply is lost.
  - System power usage threshold—The configured power usage threshold for each slot, shown as a percentage of budgeted power. After this threshold has been passed on any slot, the system sends an *SNMP* event and logs a message.
  - Disconnect precedence—The method of denying power to PDs if the budgeted power on any slot is exceeded.
  - Legacy mode—The status of the legacy mode, which allows detection of non-standard PDs.

  The output indicates the following inline power status information for each slot:
  - Inline power status—The status of inline power. The status conditions are:
  - Enabled

- Disabled
- Firmware status—The operational status of the slot. The status conditions are:
- Operational
- Not operational
- Disabled
- Subsystem failure
- Card not present
- Slot disabled

- Budgeted power—The amount of inline power, in watts, that is reserved and available to the slot.
- Measured power—The amount of power, in watts, that is currently being used by the slot.

PoE optimization options:
- **Fast**—Specifies showing fast PoE power status, which is the ability to provide power to devices at the time of switch power on without waiting for boot up based on last saved PoE state.
- **Perpetual**—Specifies showing perpetual PoE power status, which is the ability to preserve PoE power delivery to devices during reboot. Perpetual PoE is a switch-wide setting.

Displaying PoE Status and Statistics on Stand-alone Switches

To display the *PoE* statistics for the switch, run the `show inline-power stats` command.

The command provides the following information:
- Firmware status—Displays the firmware state:
  - Operational
  - Not operational
  - Disabled
  - Subsystem failure

- Firmware revision—Displays the revision number of the PoE firmware.
- Total ports powered—Displays the number of ports powered on specified slot.
- Total ports awaiting power—Displays the number of remaining ports in the slot that are not powered.
- Total ports faulted—Displays the number of ports in a fault state.
- Total ports disabled—Displays the number of ports in a disabled state.

Displaying Port PoE Information

You can display the *PoE* configuration, status, and statistics per port.

Displaying Port PoE Configuration

To display *PoE* configuration for each port, use the following command:

```
show inline-power configuration ports {port_list}
```

This command provides the following information:

- Config—Indicates whether the port is enabled to provide inline power:
  - Enabled: The port can provide inline power.
  - Disabled: The port cannot provide inline power.
- Operator Limit—Displays the configured limit, in milliwatts, for inline power on the port.
- Label—Displays a text string, if any, associated with the port (15 characters maximum).
- Priority – Displays the configured PoE priority of the port.
- Detection – Displays the configured detection of the PoE Port
- Classification – Displays the configured classification of the PoE Port
- Fast – Displays the configured status of fast PoE of the PoE Port

Display Port PoE Status

To display the *PoE* status per port, run the `show inline-power info {`**detail**`}` **ports** `{port_list}` command. This command provides the following information:

- State—Displays the port power state:
  - Disabled
  - Searching
  - Delivering
  - Faulted
  - Disconnected
  - Other
  - Denied
- PD's power class—Displays the class type of the connected PD:
  - "-----": disabled or searching
  - "class0": class 0 device
  - "class1": class 1 device
  - "class2": class 2 device
  - "class3": class 3 device
  - "class4": class 4 device
  - "class5": class 5 device
  - "class6": class 6 device
  - "class7": class 7 device
  - "class8": class 8 device
- Volts—Displays the measured voltage. A value from 0 to 2 is valid for ports that are in a searching or discovered state.

- Curr—Displays the measured current, in milliamperes, drawn by the PD.
- Power—Displays the measured power, in watts, supplied to the PD.
- Fault—Displays the fault value:
  - None
  - UV/OV fault
  - UV/OV spike
  - Over current
  - Overload
  - Undefined
  - Underload
  - HW fault
  - Discovery resistance fail
  - Operator limit violation
  - Disconnect
  - Discovery resistance, A2D failure
  - Classify, A2D failure
  - Sample, A2D failure
  - Device fault, A2D failure
  - Force on error

The **detail** command option lists all inline power information for the selected ports. Detail output displays the following information:

- Configured admin state
- Inline power state
- MIB detect status
- Label
- Operator limit
- PD class
- Max allowed power
- Measured power
- Line voltage
- Current
- Fault status
- Detailed status
- Priority

To display PoE fast information by port, run the `show inline-power` **fast ports** *{port_list}* command. This command displays the following information:

- Port status (enabled/disabled)
- Operator limits
- Priority
- Detection method

Displaying Port PoE Statistics

To display the *PoE* statistics for each port, run the `show inline-power stats ports {port_list}` command. The command provides the following information:

- State—Displays the port power state:
    - Disabled
    - Searching
    - Delivering
    - Faulted
    - Disconnected
    - Other
    - Denied
- PD's power class—Displays the class type of the connected PD:
    - "-----": disabled or searching
    - "class0": class 0 device
    - "class1": class 1 device
    - "class2": class 2 device
    - "class3": class 3 device
    - "class4": class 4 device
    - "class5": class 5 device
    - "class6": class 6 device
    - "class7": class 7 device
    - "class8": class 8 device
- Absent—Displays the number of times the port was disconnected.
- InvSig—Displays the number of times the port had an invalid signature.
- Denied—Displays the number of times the port was denied.
- Over-current—Displays the number of times the port entered an overcurrent state.
- Short—Displays the number of times the port entered undercurrent state.

Status Monitoring and Statistics

Viewing statistics on a regular basis allows you to see how well your network is performing. If you keep simple daily records, you can see trends emerging and notice problems arising before they cause major network faults. In this way, statistics can help you get the best out of your network.

The status monitoring facility provides information about the switch.

This information may be useful for your technical support representative if you have a problem. ExtremeXOS software includes many command line interface (CLI) show commands that display information about different switch functions and facilities.

> **Note**
> For more information about show commands for a specific ExtremeXOS feature, see the appropriate chapter in this guide.

Viewing Port Statistics

ExtremeXOS software provides a facility for viewing port statistical information. The summary information lists values for the current counter for each port in the system. The switch automatically refreshes the display (this is the default behavior).

You can also display a snapshot of the real-time port statistics at the time you issue the command and view the output in a page-by-page mode. This setting is not saved; therefore, you must specify the **no-refresh** parameter each time you want a snapshot of the port statistics.

Values are displayed to nine digits of accuracy.

- View port statistics with the following command:

  `show ports {`*port_list* `|` **stack-ports** *stacking-port-list*`}` **statistics** `{`**no-refresh**`}`

  The switch collects the following port statistical information:
  - Link State—The current state of the link. Options are:
    - Active (A)—The link is present at this port.
    - Ready (R)—The port is ready to accept a link.
    - Loopback (L)—The port is configured for WANPHY loopback.
  - Transmitted Packet Count (TX Pkt Count)—The number of packets that have been successfully transmitted by the port.
  - Transmitted Byte Count (TX Byte Count)—The total number of data bytes successfully transmitted by the port.
  - Received Packet Count (RX Pkt Count)—The total number of good packets that have been received by the port.
  - Received Byte Count (RX Byte Count)—The total number of bytes that were received by the port, including bad or lost frames. This number includes bytes contained in the Frame Check Sequence (FCS), but excludes bytes in the preamble.
  - Received Broadcast (RX Bcast)—The total number of frames received by the port that are addressed to a broadcast address.
  - Received Multicast (RX Mcast)—The total number of frames received by the port that are addressed to a multicast address.
- View port statistics for SummitStack stacking ports with the following command:

  `show ports stack-ports {`*stacking-port-list*`}` **statistics** `{`**no-refresh**`}`

Viewing Port Errors

The switch keeps track of errors for each port and automatically refreshes the display (this is the default behavior). You can also display a snapshot of the port errors at the time you issue the command and view the output in a page-by-page mode. This setting is not saved; therefore, you must specify the *no-refresh* parameter each time you want a snapshot of the port errors.

- View port transmit errors with the following command:

  `show ports {`*port_list* `|` **stack-ports** *stacking-port-list*`}` **txerrors** `{`**no-refresh**`}`

  The switch collects the following port transmit error information:
  - Port Number—The number of the port.

- Link State—The current state of the link. Options are:
  - Active (A)—The link is present at this port.
  - Ready (R)—The port is ready to accept a link.
  - Loopback (L)—The port is configured for WANPHY loopback.
- Transmit Collisions (TX Coll)—The total number of collisions seen by the port, regardless of whether a device connected to the port participated in any of the collisions.
- Transmit Late Collisions (TX Late Coll)—The total number of collisions that have occurred after the port's transmit window has expired.
- Transmit Deferred Frames (TX Deferred)—The total number of frames that were transmitted by the port after the first transmission attempt was deferred by other network traffic.
- Transmit Errored Frames (TX Errors)—The total number of frames that were not completely transmitted by the port because of network errors (such as late collisions or excessive collisions).
- Transmit Lost Frames (TX Lost)—The total number of transmit frames that do not get completely transmitted because of buffer problems (FIFO underflow).
- Transmit Parity Frames (TX Parity)—The bit summation has a parity mismatch.
- View port receive errors with the command:

  ```
  show ports {port_list | stack-ports stacking-port-list} rxerrors {no-refresh}
  ```

  The switch collects the following port receive error information:

  - Port Number
  - Link State—The current state of the link. Options are:
    - Active (A)—The link is present at this port.
    - Ready (R)—The port is ready to accept a link.
    - Loopback (L)—The port is in Loopback mode.

  - Receive Bad CRC Frames (RX CRC)—The total number of frames received by the port that were of the correct length but contained a bad FCS value.
  - Receive Oversize Frames (RX Over)—The total number of good frames received by the port greater than the supported maximum length of 1,522 bytes.
  - Receive Undersize Frames (RX Under)—The total number of frames received by the port that were less than 64 bytes long.
  - Receive Fragmented Frames (RX Frag)—The total number of frames received by the port that were of incorrect length and contained a bad FCS value.
  - Receive Jabber Frames (RX Jabber)—The total number of frames received by the port that were greater than the support maximum length and had a Cyclic Redundancy Check (CRC) error.
  - Receive Alignment Errors (RX Align)—The total number of frames received by the port with a CRC error and not containing an integral number of octets.
  - Receive Frames Lost (RX Lost)—The total number of frames received by the port that were lost because of buffer overflow in the switch.

- For SummitStack stacking ports, you can also view transmit and receive errors with the following commands:

  `show ports stack-ports` *stacking-port-list*`}`**txerrors** `{`**no-refresh**`}`

  `show ports stack-ports {`*stacking-port-list*`}`**rxerrors** `{`**no-refresh**`}`

  Information displayed is identical to the details displayed for non-stacking ports.

Port Link-Flap Detection

This feature detects excessive link flapping (link going up and down rapidly) on a physical port and can take the following actions:

- **Disables port**—After the port is disabled due to excessive link flapping, the port either stays down for the configured disable time value or can be re-enabled manually.
- **Reports issue to Syslog**—Adds an entry in the log for a link down event (see Link-Flap Detection Syslog Messages on page 531).
- **Generates SNMP trap**—SNMP trap generated for a link down event (see SNMP Traps on page 531).

You can configure the interval, threshold (maximum number of link down events), and disable time, and which of the preceding actions to take on a per port basis.

Link-Flap Detection Threshold Value Dependencies

Dependency on Hardware Link Scan Interval

The maximum value configurable for threshold depends on the link-flap interval value and the link scan interval. For example, if the link scan interval is 50 ms (default link-scan interval on most platforms), maximum link down/up events detectable by the hardware is 20 per second. Thus the maximum number of link-flaps detectable per second is 10. If the link-flap interval is 20 seconds, the maximum configurable threshold value is 20 * 10 = 200.

Thus, the maximum configurable value for threshold = link-flap interval (seconds) * maximum link-flaps detectable/second.

Dependency on Debounce Timer

The debounce timer is implemented at the chip level. Since the link-flap algorithm is implemented at a higher level in the *VLAN (Virtual LAN)* manager application, any link-flaps within the debounce timer are not reported to HAL nor the VLAN manager. For example, if the debounce timer is configured to be 400 ms, then any link-flaps within that interval are not reported to HAL and hence they are not counted.

Link-Flap Detection Syslog Messages

If you've configured link-flap detection to send log messages, the following messages are sent after excessive flapping:

- If the threshold is exceeded, and the log action is set, and the disable port action is not set, then a log message similar to the following appears:

```
03/31/2016 15:56:36.52 <Noti:vlan.msgs.PortLinkFlapActLogEvent> Port 1 link-flap
detection operational status is UP. Link has flapped more than 3 times in 60 seconds.
```

- If the log action and disable port action are set, and the threshold is exceeded, then a log message similar to the following appears:

```
03/31/2016 15:51:13.61 <Noti:vlan.msgs.PortLinkFlapActLogEvent> Port 2 link-flap
detection operational status is DOWN. Link has flapped more than 3 times in 60
seconds.
```

- This log message appears when all of the following conditions are met:
  - Disable port action is set on a port.
  - The number of link-flaps on the port exceeds the threshold.
  - You issue the command `enable log debug-mode`.
  - You add the event to the log filter (for example: "conf log filter "DefaultFilter" add events vlan.msgs.PortLinkFlapActDsblPort")

```
03/31/2016 15:51:13.61 <Summ:vlan.msgs.PortLinkFlapActDsblPort> Port 2 is disabled for
excessive link flapping. Link has flapped more than 3 times in 60 seconds.
```

SNMP Traps

If configured, after excessive link flapping an *SNMP (Simple Network Management Protocol)* trap notification is generated for link up or down events. The trap notification "etsysLinkFlapViolation" includes the following information regarding the port in violation of threshold:

- Interface index
- Interface name
- Operation status (up or down)

Port Link-Flap Statistics

Statistics	Description
Current Lin- Flaps	Number of link-flaps in the current interval before the threshold is exceeded.
Total Link-Flaps	Total number of link-flaps accumulated for this port since the feature was turned on.
Time Elapsed	Time in seconds that has passed in the current interval.
Threshold Exceeded	Number of times a given port has exceeded the threshold value for the maximum number of tolerated link-flaps per interval.

Configuring Port Link-Flap Detection

To turn on or off port link-flap detection, use the following command:

configure **ports** [*port_list* | **all**] **link-flap-detection** [**on** | **off**]

To set interval, threshold (maximum number of link down events), and disable time values for link-flap detection, use the following command:

configure **ports** [*port_list* | **all**] **link-flap-detection** [{**interval** [*interval* | **indefinitely**]} {**threshold** *threshold*} {**disable-time** [*disable_time* | **until-cleared**]}]

To reset interval, threshold (maximum number of link down events), and disable time to defaults for link-flap detection, use the following command.

unconfigure **ports** [*port_list* | **all**] **link-flap-detection** {**interval**} {**threshold**} {**disable-time**}

To add or delete actions (disabling ports, logging events, generating *SNMP* traps) to be taken when excessive link-flapping is detected, use the following command:

configure **ports** [*port_list* | **all**] **link-flap-detection action** [**add** | **delete**] [{{**disable-port**} {**log**} {**trap**}} | **all-actions**]

To manually enable ports that have been disabled due to excessive link flapping, use the following command:

clear **ports** [*port_list* | **all**] **link-flap-detection status**

To clears the counters related to port link flapping, use the following command.

clear **ports** [*port_list* | **all**] **link-flap-detection counters**

To display the link-flap detection status for ports, use the following command:

show ports [*port_list* | **all**] **link-flap-detection** [**disabled-ports** | **configuration** | **counters** {**refresh** | **no-refresh**}]

Using the Port Monitoring Display Keys

Table 52 on page 532 describes the keys used to control the displays that appear if you use any of the show ports commands without specifying the **no-refresh** parameter (this is the default behavior).

Table 52: Port Monitoring Display Keys with Auto-Refresh Enabled

Key(s)	Description
[U]	Displays the previous page of ports.
[D]	Displays the next page of ports.
[Esc]	Exits from the screen.

Table 52: Port Monitoring Display Keys with Auto-Refresh Enabled (continued)

Key(s)	Description
[0]	Clears all counters.
[Space]	Cycles through the following screens: • Packets per second • Bytes per second • Percentage of bandwidth **Note:** Available only using the `show ports utilization` command.

Table 53 describes the keys used to control the displays that appear if you use any of the show ports commands and specify the **no-refresh** parameter.

Table 53: Port Monitoring Display Keys with Auto-Refresh Disabled

Key	Description
[Q]	Exits from the screen.
[Space]	Displays the next page of ports.

Viewing VLAN Statistics

ExtremeXOS software provides the facility for configurable *VLAN* statistics gathering and display of packet and byte counters on the port level and on the VLAN level.

> **Note**
> The ExtremeSwitching X435 series switches do not support VLAN statistics.

Configuring VLAN Statistics

- Configure the switch to start counting *VLAN* statistics with the commands:

  ```
  clear counters
  ```

  ```
  configure ports [port_list|all] monitor vlan vlan_name {rx-only | tx-only}
  ```

- View VLAN statistics at the port level with the command:

  ```
  show ports {port_list} vlan statistics {no-refresh}
  ```

  The switch collects and displays the following statistics:

  ○ Port—The designated port.
  ○ VLAN—The associated VLANs.
  ○ Rx Frames Count—The total number of frames successfully received by the port on the designated VLAN.
  ○ Rx Byte Count—The total number of bytes that were received by the port on the designated VLAN.

- ◦ Tx Frame Count—The total number of frames that were transmitted by the port on the designated VLAN.
- ◦ Tx Byte Count—The total number of bytes that were transmitted by the port on the designated VLAN.

Frame and byte counters are also displayed through _SNMP_.

- • View VLAN statistics at the VLAN level with the command:

`show ports {`_`port_list`_`}` **`vlan statistics`** `{`**`no-refresh`**`}`

The switch collects and displays the following statistics:

- ◦ VLAN—The designated VLAN.
- ◦ Rx Total Frames —The total number of frames successfully received by the port.
- ◦ Rx Byte Count—The total number of bytes that were received by the port.
- ◦ Tx Total Frames—The total number of frames that were transmitted by the port.
- ◦ Tx Byte Count—The total number of bytes that were transmitted by the port.

- • Stop counting VLAN statistics.

`unconfigure ports [`_`port_list`_` |`**`all`**`]` **`monitor vlan`** _`vlan_name`_

> **Note**
> While using VLAN statistics, traffic also matching egress _ACL (Access Control List)_ counters will cause the VLAN statistics Tx counter to not increment.

Guidelines and Limitations

The following describes guidelines for this feature.

- • Support for VMAN statistics are provided in the same manner as _VLAN_ statistics. CLI commands use the same syntax as used with monitoring VLANs including the use of the **vlan** keyword in CLI commands. _SNMP_ access uses the same MIB objects as used for VLAN statistics.

Statistics for VLANs encapsulated within VMANs are not supported.

- • ExtremeSwitching series switches provide support only for byte counters.
- • All of the counters supported are 64 bit counters. No indication of counter rollover is supported.
- • Packets originating from the switch's CPU or forwarded by the CPU may not be reflected in transmit statistics.

Performing Switch Diagnostics

The switch provides a facility for running normal or extended diagnostics.

In simple terms, a normal routine performs a simple ASIC and packet loopback test on all ports, and an extended routine performs extensive ASIC, ASIC-memory, and packet loopback tests. By running and viewing the results from diagnostic tests, you can detect and troubleshoot any hardware issues.

On ExtremeSwitching series switches, you run the diagnostic routine on the switch or on the stacking ports. Running the switch or stacking port diagnostic routine affects system operation; the switch is unavailable during the diagnostic test.

> **Note**
> Before running diagnostics, you must power on the External Power Supply (EPS) when it is connected to the switch.

When you run diagnostics, the switch verifies that the:

- Registers can be written to and read from correctly.
- Memory addresses are accessed correctly.
- Application-Specific Integrated Circuit (ASICs) and Central Processing Unit (CPUs) operate as required.
- External ports can send and receive packets.
- Sensors, hardware controllers, and LEDs are working correctly.

When you run diagnostics on the SummitStack stacking ports, the switch completes a hardware test to ensure that the stacking ports are operational.

> **Note**
> The ExtremeSwitching X465, X590, and X695 series switches do not include the diagnostic image in the main ExtremeXOS core software image (.xos). Instead, they have a separate diagnostic image that is upgraded using an XMOD file. For information about how to install an XMOD file, see Installing a Modular Software Package on page 1971.

> **Note**
> Version 32.3 removes operational diagnostics and XMOD support for X435 series switches.

Running Diagnostics

If you run the diagnostic routine, the switch reboots and then performs the diagnostic test.

During the test, traffic to and from the ports on the switch is temporarily unavailable. When the diagnostic test is complete, the switch reboots and becomes operational again.

To run the diagnostic routine on the stack ports, you need a dedicated stacking cable that connects stack port 1 to stack port 2, which are located at the rear of the switch. The stacking cable is available from Extreme Networks. The switch performs a hardware test to confirm that the stack ports are operational; traffic to and from the ports on the switch is temporarily unavailable. This Bit Error Rate Test (BERT) provides an analysis of the number of bits transmitted in error.

After the switch runs the diagnostic routine, test results saved to the switch's EEPROM and messages are logged to the syslog.

- Run diagnostics with the following command:

  `run diagnostics [`**`extended`**` | `**`normal`**` | `**`stack-port`**`] {`**`slot`**` [`*`slot`*` | `**`A`**` | `**`B`**`]}`

  Where the following is true:

  `extended`—Reboots the switch and performs extensive ASIC, ASIC-memory, and packet loopback tests. Extended diagnostic tests take a maximum of five minutes. The CPU is not tested.

  - **`normal`**—Reboots the switch and performs a simple ASIC and packet loopback test on all ports.
  - **`stack-port`**—Performs a BERT on the stacking ports and reboots the switch.

LED Behavior During Diagnostic Testing

Table 54 describes the LED behavior during a diagnostic test.

Table 54: ExtremeSwitching Switch LED Behavior

LED	Color	Indicates
MGMT	Green blinking	Normal operation is occurring.
	Amber blinking	Diagnostic test in progress.

While diagnostic tests are running, the MGMT LED blinks amber. If a diagnostic test fails, the MGMT LED continues to blink amber. During normal operation, the MGMT LED blinks green.

Displaying Diagnostic Test Results

- Display the status of the last diagnostic test run on the switch.

  `show diagnostics {[`*`cr`*`] | `**`slot`**` [`*`slot_number`*`]}`

Using the System Health Checker

The system health checker is a useful tool to monitor the overall health of your system.

The software performs a proactive, preventive search for problems by polling and reporting the health of system components, including power supplies, power supply controllers, and fans. By isolating faults to a specific module, backplane connection, control plane, or component, the system health checker notifies you of a possible hardware fault.

The system health checker polls and reads the switch fabric and CPU registers.

Polling is always enabled on the system and occurs in the background every 10 seconds; the polling value is not a user-configured parameter.

System health check errors are reported to the Syslog. If you see an error, contact Extreme Networks Technical Support (see Help and Support on page 9). There are no health checking tests related to the stacking links in a SummitStack.

To display the system health check setting, including polling and how ExtremeXOS software handles faults on the switch, use the command: `show switch`

The system health check setting, displayed as SysHealth check, shows the polling setting and how ExtremeXOS handles faults. The polling setting appears as Enabled, and the fault handling setting appears in parenthesis next to the polling setting.

Using ELSM

Extreme Link Status Monitoring (ELSM) is an Extreme Networks proprietary protocol that monitors network health by detecting CPU and remote link failures.

ELSM is available only on Extreme Networks devices and operates on a point-to-point basis. You can configure ELSM on the ports that connect to other network devices and on both sides of the peer connection.

About ELSM

ELSM monitors network health by exchanging various hello messages between two ELSM peers.

ELSM uses an open-ended protocol, which means that an ELSM-enabled port expects to send and receive hello messages from its peer. The Layer 2 connection between ports determines the peer connection. Peers can be either directly connected or separated by one or more hubs. If there is a direct connection between peers, they are considered neighbors.

If ELSM detects a failure, the ELSM-enabled port responds by blocking traffic on that port. For example, if a peer stops receiving messages from its peer, ELSM brings down that connection by blocking all incoming and outgoing data traffic on the port and notifying applications that the link is down.

In some situations, a software or hardware fault may prevent the CPU from transmitting or receiving packets, thereby leading to the sudden failure of the CPU. If the CPU is unable to process or send packets, ELSM isolates the connections to the faulty switch from the rest of the network. If the switch fabric sends packets during a CPU failure, the switch may appear healthy when it is not. For example, if hardware forwarding is active and software forwarding experiences a failure, traffic forwarding may continue. Such failures can trigger control protocols such as *ESRP (Extreme Standby Router Protocol)* or *EAPS (Extreme Automatic Protection Switching)* to select different devices to resume forwarding. This recovery action, combined with the CPU failure, can lead to loops in a Layer 2 network.

ELSM Hello Messages

ELSM uses two types of hello messages to communicate the health of the network to other ELSM ports. The following describes the hello messages:

- Hello+ — The ELSM-enabled port receives a hello message from its peer and no problem is detected.
- Hello- — The ELSM-enabled port has not received a hello message from its peer.

In addition to the ELSM port states described in the next section, ELSM has hello transmit states. The hello transmit states display the current state of transmitted ELSM hello messages and can be one of the following:

- HelloRx(+)—The ELSM-enabled port is up and receives Hello+ messages from its peer. The port remains in the HelloRx+ state and restarts the HelloRx timer each time it receives a Hello+ message. If the HelloRx timer expires, the hello transmit state enters HelloRx(-). The HelloRx timer is 6 * hello timer, which by default is 6 seconds.
- HelloRx(-)—The ELSM-enabled port either transitions from the initial ELSM state or is up but has not received hello messages because there is a problem with the link or the peer is missing.

For information about displaying ELSM hello messages and hello transmit states, see

ELSM Port States

Each ELSM-enabled port exists in one of the following states:

- Up—Indicates a healthy remote system and this port is receiving Hello+ messages from its peer.

  If an ELSM-enabled port enters the Up state, the up timer begins. Each time the port receives a Hello+ message from its peer, the up timer restarts and the port remains in the Up state. The up timer is 6 * hello timer, which by default is 6 seconds.
- Down—Indicates that the port is down, blocked, or has not received Hello+ messages from its peer.

  If an ELSM-enabled port does not receive a hello message from its peer before the up timer expires, the port transitions to the Down state. When ELSM is down, data packets are neither forwarded nor transmitted out of that port.
- Down-Wait—Indicates a transitional state.

  If the port enters the Down state and later receives a Hello+ message from its peer, the port enters the Down-Wait state. If the number of Hello+ messages received is greater than or equal to the hold threshold (by default, two messages), the port transitions to the Up state. If the number of Hello+ messages received is less than the hold threshold, the port enters the Down state.
- Down-Stuck—Indicates that the port is down and requires user intervention.

If the port repeatedly flaps between the Up and Down states, the port enters the Down-Stuck state. Depending on your configuration, there are two ways for a port to transition out of this state:

By default, automatic restart is enabled, and the port automatically transitions out of this state. For more information, see the `enable elsm ports` *`port_list`* **`auto-restart`** command.

If you disabled automatic restart, and the port enters the Down-Stuck state, you can clear the stuck state and enter the Down state by using one of the following commands:
◦ `clear elsm ports` *`port_list`* **`auto-restart`**
◦ `enable elsm ports` *`port_list`* **`auto-restart`**

> **Note**
> If you reboot the peer switch, its ELSM-enabled peer port may enter the Down-Stuck state. If this occurs, clear the stuck state using one of the following commands:
> • `clear elsm ports` *`port_list`* **`auto-restart`**
> • `enable elsm ports` *`port_list`* **`auto-restart`**

For information about displaying ELSM port states, see Displaying ELSM Information on page 544.

Link States

The state of the link between ELSM-enabled (peer) ports is known as the *link state*. The link state can be one of the following:
• Ready—Indicates that the port is enabled but there is no physical link
• Active—Indicates that the port is enabled and the physical link is up

• View the state of the link between the peer ports using the commands:
  `show elsm ports` **`all`** `|` *`port_list`*
  `show ports {`*`port_list`*`}` **`information`** `{`**`detail`**`}`

If you use the `show elsm ports` **`all`** `|` *`port_list`* command, the Link State row displays link state information.

If you use the `show ports {`*`port_list`*`}` information command, the Link State column displays link state information.

If you use the `show ports {`*`port_list`*`}` information command and specify the **`detail`** option, the ELSM Link State row displays ELSM link state information. For more information, see ELSM Link States on page 540.

For more information about these show commands, see Displaying ELSM Information on page 544.

ELSM Link States

The state of the ELSM logical link is known as the ELSM link state. The ELSM link state can be one of the following:

- ELSM is enabled and the ELSM peer ports are up and communicating
- ELSM is enabled but the ELSM peer ports are not up or communicating
- ELSM is disabled

- View the current state of ELSM on the switch using the commands:
  - `show elsm`

  `show elsm ports` **`all`** `|` *`port_list`*

  `show ports {`*`port_list`*`}` **`information`** `{`**`detail`**`}`

  If you use the `show elsm` commands, the following terms display the ELSM link state:
  - Up—Indicates that ELSM is enabled and the ELSM peer ports are up and communicating; the ELSM link state is up. In the up state, the ELSM-enabled port sends and receives hello messages from its peer.
  - Down—Indicates that ELSM is enabled, but the ELSM peers are not communicating; the ELSM link state is down. In the down state, ELSM transitions the peer port on this device to the down state. ELSM blocks all incoming and outgoing switching traffic and all control traffic except ELSM PDUs.

  If ELSM is disabled, the switch does not display any information.

  If you use the `show ports {`*`port_list`*`}` **`information`** `{`**`detail`**`}` command, the following columns display the current state of ELSM on the switch:
  - Flags
    - L—Indicates that ELSM is enabled on the switch
    - - —Indicates that ELSM is disabled on the switch

  - ELSM
    - up—Indicates that ELSM is enabled and the ELSM peer ports are up and communicating; the ELSM link state is up. In the up state, the ELSM-enabled port sends and receives hello messages from its peer.
    - dn—Indicates that ELSM is enabled, but the ELSM peers are not communicating; the ELSM link state is down. In the down state, ELSM transitions the peer port on this device to the down state. ELSM blocks all incoming and outgoing switching traffic and all control traffic except ELSM PDUs.
    - - —Indicates that ELSM is disabled on the switch.

  If you specify the optional **`detail`** parameter, the following ELSM output is called out in written explanations versus displayed in a tabular format:
  - ELSM Link State (displayed only if ELSM is enabled on the switch)
    - Up—Indicates that ELSM is enabled and the ELSM peer ports are up and communicating; the ELSM link state is up. In the up state, the ELSM-enabled port sends and receives hello messages from its peer.

- ▪ Down—Indicates that ELSM is enabled, but the ELSM peers are not communicating; the ELSM link state is down. In the down state, ELSM transitions the peer port on this device to the down state. ELSM blocks all incoming and outgoing switching traffic and all control traffic except ELSM PDUs.

- ◦ ELSM
  - ▪ Enabled—Indicates that ELSM is enabled on the switch
  - ▪ Disabled—Indicates that ELSM is disabled on the switch

For more information about these show commands, see Displaying ELSM Information on page 544.

ELSM Timers

To determine whether there is a CPU or link failure, ELSM requires timer expiration between the ELSM peers. Depending on the health of the network, the port enters different states when the timers expire. For more information about the ELSM port states, see ELSM Port States on page 538.

Table 55 describes the ELSM timers. Only the hello timer is user-configurable; all other timers are derived from the hello timer. This means that when you modify the hello timer, you also modify the values for down, up, and HelloRx timers.

Table 55: ELSM Timers

Timer	Description
Hello	The ELSM hello timer is the only user-configurable timer and specifies the time in seconds between consecutive hello messages. The default value is 1 second, and the range is 100 milliseconds to 255 seconds.
Down	The ELSM down timer specifies the time it takes the ELSM port to cycle through the following states: • Down—Indicates that the port is down, blocked, or has not received Hello+ messages from its peer. • Down-Wait—Indicates a transitional state.Up—Indicates a healthy remote system and this port is receiving Hello+ messages from its peer. By default, the down timer is (2 + hold threshold) * hello timer, which is 4 seconds. If the hold threshold is set to 2 and the hello timer is set to 1 second, it takes 4 seconds for the ELSM port receiving messages to cycle through the states. After the down timer expires, the port checks the number of Hello+ messages against the hold threshold. If the number of Hello+ messages received is greater than or equal to the configured hold threshold, the ELSM receive port moves from the Down-Wait state to the Up state. If the number of Hello+ messages received is less than the configured hold threshold, the ELSM receive port moves from the Down-Wait state back to the Down state and begins the process again.

Table 55: ELSM Timers (continued)

Timer	Description
Up	The ELSM up timer begins when the ELSM-enabled port enters the UP state. Each time the port receives a Hello+ message, the timer restarts. Up timer is the UpTimer threshold * hello timer. It is configurable and the range is 3 to 60 seconds. By default, the UpTimer threshold is 6. Therefore, the default up timer is 6 seconds (6*1).
HelloRx	The ELSM HelloRx timer specifies the time in which a hello message is expected. If the port does not receive a hello message from its peer, there is the possibility of a CPU or link failure. By default the HelloRx timer 6 * hello timer, which is 6 seconds.

Configuring ELSM on a Switch

This section describes the commands used to configure ELSM on the switch.

> **Note**
> ELSM and mirroring are mutually exclusive. You can enable either ELSM, or mirroring, but not both.

> **Note**
> ELSM is not to be configured on *MLAG (Multi-switch Link Aggregation Group)* ports at either end of an MLAG.

Enabling ELSM

ELSM works between two connected ports (peers), and each ELSM instance is based on a single port. The Layer 2 connection between the ports determines the peer. You can have a direct connection between the peers or hubs that separate peer ports. In the first instance, the peers are also considered neighbors. In the second instance, the peer is not considered a neighbor.

• Enable ELSM on one or more ports with the command:

```
enable elsm ports port_list
```

When you enable ELSM on a port, ELSM immediately blocks the port and it enters the Down state. When the port detects an ELSM-enabled peer, the peer ports exchange ELSM hello messages. At this point, the ports enter the transitional Down-Wait state. If the port receives Hello+ messages from its peer and does not detect a problem, the peers enter the Up state. If a peer detects a problem or there is no peer port configured, the port enters the Down state.

For more information about the types of ELSM hello messages, see ELSM Hello Messages on page 538. For information about configuring the ELSM hello timer, see the next section.

Configuring the ELSM Hello Timer

The ELSM hello timer is the only user-configurable timer and specifies the time in seconds between consecutive hello messages. The default value is 1 second, and the

range is 1 to 128 seconds. Although other timers rely on the hold timer for their values, you do not explicitly configure the down, up, or HelloRx timers. If you modify the hello timer on one port, we recommend that you use the same hello timer value on its peer port.

A high hello timer value can increase the time it takes for the ELSM-enabled port to enter the Up state. The down timer is (2 + hold threshold) * hello timer. Assuming the default value of 2 for the hold threshold, configuring a hello timer of 128 seconds creates a down timer of (2 + 2) 128, or 512 seconds. In this scenario it would take 512 seconds for the port to transition from the Down to the Up state.

- Configure the ELSM hello timer with the command:

  ```
  configure elsm ports port_list hellotime hello_time
  ```

Configuring the ELSM Hold Threshold

The ELSM hold threshold determines the number of Hello+ messages the ELSM peer port must receive to transition from the Down-Wait state to the Up state. For example, a threshold of 1 means the ELSM port must receive at least one Hello+ message to transition from the Down-Wait state to the Up state. The default is two messages, and the range is one to three messages.

After the down timer expires, the port checks the number of Hello+ messages against the hold threshold. If the number of Hello+ messages received is greater than or equal to the configured hold threshold, the ELSM receive port moves from the Down-Wait state to the Up state.

If the number of Hello+ messages received is less than the configured hold threshold, the ELSM receive port moves from the Down-Wait state back to the Down state and begins the process again.

If you modify the hold threshold on one port, we recommend that you use the same hold threshold value on its peer port.

You must configure the hold threshold on a per-port basis, not on a per-switch basis.

- Configure the ELSM hold threshold with the command:

  ```
  configure elsm ports port_list hold-threshold hold_threshold
  ```

Configure Automatic Restart

You must explicitly configure automatic restart on each ELSM-enabled port; this is not a global configuration. By default, ELSM automatic restart is enabled. If an ELSM-enabled port goes down, ELSM bypasses the Down-Stuck state and automatically transitions the down port to the Down state, regardless of the number of times the port goes up and down. For information about the port states, see ELSM Port States on page 538.

If you disable ELSM automatic restart, the ELSM-enabled port can transition between the following states multiple times: Up, Down, and Down-Wait. When the number of state transitions is greater than or equal to the sticky threshold, the port enters the Down-Stuck state. The ELSM sticky threshold specifies the number of times a port can transition between the Up and Down states. The sticky threshold is not user-

configurable and has a default value of 1. That means a port can transition only one time from the Up state to the Down state. If the port attempts a subsequent transition from the Up state to the Down state, the port enters the Down-Stuck state.

The following user events clear or re-set the sticky threshold:
- Enabling automatic restart on the port using the following command:

  `enable elsm ports port_list **auto-restart**`
- Clearing the port that is in the Down-Stuck state using the following command:

  `clear elsm ports port_list **auto-restart**`
- Disabling and re-enabling the port using the following commands:
  - `disable ports [port_list|**all**]`
  - `enable ports [port_list|**all**]`
- Disabling ELSM on the port using the following command:

  `disable elsm ports port_list`

We recommend that you use the same automatic restart configuration on each peer port.
- If the port enters the Down-Stuck state, you can clear the stuck state and enter the Down state by using one of the following commands:

  `clear elsm ports port_list **auto-restart**`

  `enable elsm ports port_list **auto-restart**`

  If you use the `enable elsm ports port_list **auto-restart**` command, automatic restart is always enabled; you do not have to use the `clear elsm ports port_list **auto-restart**` command to clear the stuck state.
- Disable automatic restart with the command:

  `disable elsm ports port_list **auto-restart**`
- Re-enable automatic restart with the command:

  `enable elsm ports port_list **auto-restart**`

  We recommend that you use the same automatic restart configuration on each peer port.

Disabling ELSM

- Disable ELSM on one or more ports with the command:

  `disable elsm ports port_list`

When you disable ELSM on the specified ports, the ports no longer send ELSM hello messages to their peers and no longer maintain ELSM states.

Displaying ELSM Information

- Display summary information for all of the ELSM-enabled ports on the switch with the command:

  `show elsm`

This command displays in a tabular format the operational state of ELSM on the configured ports.

If ports are configured for ELSM (ELSM is enabled), the switch displays the following information:

◦ Port—The port number of the ELSM-enabled port.

◦ ELSM State—The current state of ELSM on the port. For information about the port states, see ELSM Port States on page 538.

◦ Hello time—The current value of the hello timer, which by default is 1 second. For information about configuring the hello timer, see Configuring the ELSM Hello Timer on page 542.

If no ports are configured for ELSM (ELSM is disabled), the switch does not display any information.

• Display detailed information for one or more ELSM-enabled ports on the switch.

```
show elsm ports all | port_list
```

In addition to the port, ELSM state, and hello timer information, this command displays in a tabular format the following:

◦ Link State—The state of the link between ELSM-enabled ports. For information about the link states, see Link States on page 539.

◦ ELSM Link State—The current state of the ELSM logical link on the switch. For more information, see ELSM Link States on page 540.

◦ Hello Transmit State—The current state of ELSM hello messages being transmitted.

◦ Hold Threshold—The number of Hello+ messages required by the ELSM-enabled port to transition from the Down-Wait state to the Up state within the hold threshold.

◦ UpTimer Threshold—The number of hello times that span without receiving Hello+ packets before a port changes its ELSM state from Up to Down.

◦ Auto Restart—The current state of ELSM automatic restart on the port.

◦ Sticky Threshold—The number of times a port can transition between the Up and Down states. The sticky threshold is not user-configurable and has a default value of 1.

◦ Sticky Threshold Counter—The number of times the port transitions from the Up state to the Down state.

◦ Down Timeout—The actual waiting time (msecs or secs) before a port changes its ELSM state from Down to Up after receiving the first Hello+ packet. It is equal to [Hello Time * (Hold Threshold+2)].

◦ Up Timeout—The actual waiting time (msecs or secs) before a port changes its ELSM state from Up to Down after receiving the last Hello+ packets. It is equal to [Hello Time * UpTimer Threshold].

The remaining output displays counter information.

- Use the counter information to determine the health of the ELSM peers and how often ELSM has gone up or down.

  The counters are cumulative.

  ◦ Rx Hello+—The number of Hello+ messages received by the port.
  ◦ Rx Hello- —The number of Hello- messages received by the port.
  ◦ Tx Hello+—The number of Hello+ messages sent by the port.
  ◦ Tx Hello- —The number of Hello- messages sent by the port.
  ◦ ELSM Up/Down Count—The number of times ELSM has been up or down.
- Display summary port information in a tabular format for one or more ELSM-enabled ports with the command:

  ```
  show ports {port_list} information {detail}
  ```

  This command displays the following ELSM information:

  ◦ Flags
    ▪ L—ELSM is enabled on the switch
    ▪ - —ELSM is disabled on the switch

  ◦ ELSM (For more information, see ELSM Link States on page 540.)
    ▪ up—ELSM is enabled and the ELSM link state is up.
    ▪ dn—ELSM is enabled and the ELSM link state is down.
    ▪ - —ELSM is disabled on the switch.
- Display summary port information called out in written explanations versus displayed in a tabular format, use the **detail** parameter.

  ```
  show ports {port_list} information {detail}
  ```

  This command displays the following ELSM information:

  ◦ ELSM Link State (displayed only if ELSM is enabled on the switch). For more information, see ELSM Link States on page 540.
    ▪ Up—ELSM is enabled and the ELSM link state is up.
    ▪ Down—ELSM is enabled and the ELSM link state is down.

  ◦ Link State—The state of the link between ELSM-enabled ports. For information about the link states, see Link States on page 539.
  ◦ ELSM
    ▪ Enabled—ELSM is enabled on the switch.
    ▪ Disabled—ELSM is disabled on the switch.

Clearing ELSM Counters

Before clearing the ELSM counters, you should use the `show elsm` and `show elsm ports` commands to view the ELSM information.

- Clear only the ELSM-related counters gathered by the switch using the command:

  ```
  clear elsm {ports port_list} counters
  ```

  You can also use the `clear counters` command, which clears all of the counters on the device, including those associated with ELSM.

Using ELSM with Layer 2 Control Protocols

You can use ELSM with Layer 2 control protocols such as *STP (Spanning Tree Protocol)*, *ESRP*, *EAPS*, and so on to improve the recovery of Layer 2 loops in the network.

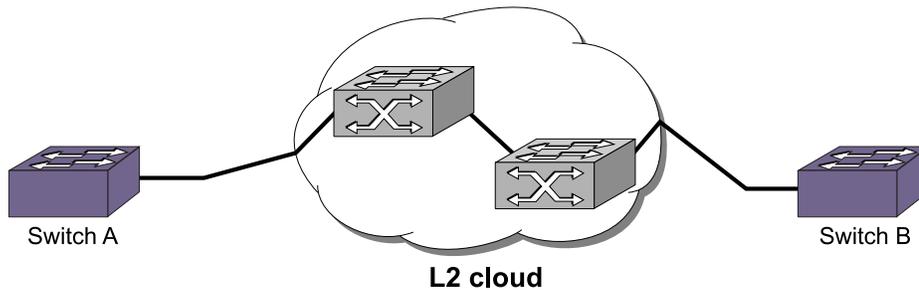
ELSM detects remote link failures if the established link is through a Layer 2 transport cloud and the ELSM endpoints traverse the Layer 2 cloud in a point-to-point fashion, as shown in Figure 61 on page 547.


Figure 61: ELSM Through a Layer 2 Cloud

A sudden failure of the switch CPU may cause the hardware to continue forwarding traffic. For example, ESRP may select a second device for forwarding traffic thereby creating a Layer 2 loop in the network. If you configure ELSM and the CPU fails, ELSM closes the connection to the faulty device to prevent a loop.

ELSM Configuration Example

The following example configures ELSM on two ports connected directly to each other and assumes the following:

> **Note**
> In the following sample configurations, any lines marked (Default) represent default settings and do not need to be explicitly configured.

Switch A Configuration

- ELSM-enabled port—Port 1
- Hello timer—2 seconds
- Hello threshold—2 hello messages

```
enable elsm ports 1
configure elsm ports 1 hellotime 2
configure elsm ports 1 hold-threshold 2 (Default)
```

Switch B Configuration

- ELSM-enabled port—Slot 2, port 1
- Hello timer—2 seconds
- Hello threshold—2 hello messages

```
enable elsm ports 2:1
configure elsm ports 2:1 hellotime 2
configure elsm ports 2:1 hold-threshold 2 (Default)
```

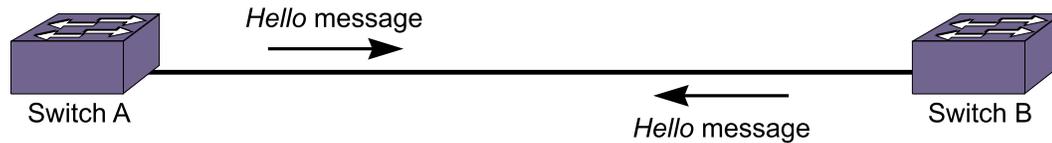
After you enable ELSM on the ports, the peers exchange hello messages with each other as displayed in Figure 62.


Figure 62: Extreme Networks Switches with ELSM-Enabled Ports Exchanging Hello Messages

To configure ELSM with _LAG (Link Aggregation Group)_, enable ELSM on each port member of the LAG, as shown in the following example:

```
enable sharing 7 grouping 7-9, 41 algorith address-based L2
enable elsm port 7
enable elsm port 8
enable elsm port 9
enable elsm port 41

# sh elsm
Port ELSM State Hello Time
==== ========== ==========
7    Up         1 (secs)
8    Down       1 (secs)
9    Down       1 (secs)
41   Up         1 (secs)
```

Viewing Fan Information

You can view detailed information about the fans installed in your switch. Depending on your switch model, different information may be displayed.

For ExtremeSwitching X435 series switches, only the X435-24P-4S switches have a fan (internal).

- View detailed information about the health of the fans with the command: `show fans`

   The switch collects and displays the following fan information:

   ◦ State—The current state of the fan. Options are:
      ▪ Empty: There is no fan installed.
      ▪ Failed: The fan failed.
      ▪ Operational: The fan is installed and working normally.
   ◦ NumFan—The number of fans in the fan tray.
   ◦ Fan Name, displayed as Fan-1, Fan-2, and so on—Specifies the individual state for each fan in a fan tray and its current speed in revolutions per minute (rpm).

   > **Note**
   > For the ExtremeSwitching X435-24P-4S switches, you cannot view the fan speed.

Viewing the System Temperature

Depending on your switch model, you can view the temperature in Celsius for the power controllers, power supplies, and fan trays installed in your switch. In addition, depending on the software version running on your switch, additional or different temperature information might be displayed.

You can view the system temperature with the command: `show temperature`

System Temperature Output

SummitStack

The following output shows a sample display from a SummitStack.

```
Slot-3 Stack.1 # show temperature
Field Replaceable Units              Temp (C)    Status   Min   Normal   Max
-------------------------------------------------------------------------------
Slot-1          :
Slot-2          : SummitX                34.50    Normal   -10    0-54   59
Slot-3          : SummitX                36.50    Normal   -10    0-66   67
Slot-4          :
Slot-5          :
Slot-6          :
Slot-7          :
Slot-8          :
Slot-3 Stack.2 #
```

ExtremeSwitching Switches Only

On ExtremeSwitching series switches, the output includes the current temperature and operating status of the switch. The following shows a sample display from an ExtremeSwitching switch:

```
# show temperature
Field Replaceable Units              Temp (C)    Status   Min   Normal   Max
-------------------------------------------------------------------------------
Switch          : SummitX                30.00    Normal   -10    0-52   57
```

The switch monitors its temperature and generates a warning if the temperature exceeds the normal operating range. If the temperature exceeds the maximum limit, the `show switch` output indicates the switch in an OPERATIONAL (Overheat) mode, and the `show temperature` output indicates an error state due to overheat.

Using the Event Management System/Logging

We use the general term *event* for any type of occurrence on a switch that could generate a log message or require an action.

For example, a link going down, a user logging in, a command entered on the command line, or the software executing a debugging statement, are all events that might generate a log message. The system for saving, displaying, and filtering events is called the EMS. With EMS, you have many options about which events generate log messages, where the messages are sent, and how they are displayed.

Using EMS you can:

- Send event messages to a number of logging targets (for example, syslog host and NVRAM).
- Filter events per target, by:
  ◦ Component, subcomponent, or specific condition (for example, _BGP (Border Gateway Protocol)_ messages, _IGMP (Internet Group Management Protocol)._ Snooping messages, or the IP.Forwarding.SlowPathDrop condition).
  ◦ Match expression (for example, any messages containing the string "user 5").
  ◦ Matching parameters (for example, only messages with source IP addresses in the 10.1.2.0/24 subnet).
  ◦ Severity level (for example, only messages of severity critical, error, or warning).
- Change the format of event messages (for example, display the date as "12-May-2005" or "2005-05-12").
- Display log messages in real time and filter the messages that are displayed, both on the console and from Telnet sessions.
- Display stored log messages from the memory buffer or NVRAM.
- Upload event logs stored in memory buffer or NVRAM to a TFTP server.
- Display counts of event occurrences, even those not included in filter.
- Display debug information using a consistent configuration method.

EMS supports IPv6 as a parameter for filtering events.

Sending Event Messages to Log Targets

You can specify seven types of targets to receive log messages:

- Console display
- Current session (Telnet or console display)
- Memory buffer (can contain 200 to 20,000 messages)
- NVRAM (messages remain after reboot)
- Primary node (for SummitStack)
- Backup node (for SummitStack)
- Syslog server, supports IPv6 address family as of ExtremeXOS 21.1

The first six targets exist by default; but before enabling any syslog host, you must add the host's information to the switch using the `configure syslog` command. Extreme Management Center or Ridgeline can be a syslog target.

By default, the memory buffer and NVRAM targets are already enabled and receive messages.

- To start sending messages to the targets, use the following command:
  ```
  enable log target [console | memory-buffer | nvram | primary-
  node|backup-node| session | syslog [all | ipaddress udp-port
  {udp_port} | ipPort | ipaddress tls_port {tls_port}] {vr vr_name}
  {local0...local7}]]
  ```

After you enable this feature, the target receives the messages for which it is configured. See Target Configuration on page 551 for information on viewing the current configuration of a target. The memory buffer can contain only the configured number of messages, so the oldest message is lost when a new message arrives, when the buffer is full.

· To stop sending messages to the target, use the following command:

```
disable log target [console | memory-buffer | nvram |primary-node |
backup-node | session | syslog [all | ipaddress udp-port {udp_port}
| ipPort | ipaddress tls_port {tls_port}] {vr vr_name} {local0 ...
local7}]]
```

Refer to your UNIX documentation for more information about the syslog host facility.

Primary and Backup Systems—SummitStack Only

A system with primary and backup nodes (SummitStack) keeps the two systems synchronized by executing the same commands on both.

However, the full data between the EMS servers is not synchronized. The reason for this design decision is to make sure that the control channel is not overloaded when a high number of log messages are generated.

To capture events generated by the primary node onto the backup node, two additional targets are shown in the target commands—one called primary-node and one called backup-node. The first target is active only on the non-primary (backup) EMS server and is used to send matching events to the primary EMS server. The other target is active only on the primary EMS server and is used to send matching events to all other EMS servers.

If the condition for the backup target is met by a message generated on the primary node, the event is sent to the backup node. When the backup node receives the event, it detects if any of the local targets (NVRAM, memory, or console) are matched. If so that event gets processed. The session and Syslog targets are disabled on the backup node, as they are handled on the primary. If the condition for the primary target is met by a message generated on the backup, the event is sent to the primary node.

Note that the backup target is active only on the primary node, and the primary target is active only on the backup node.

Filtering Events Sent to Targets

Not all event messages are sent to every enabled target. Each target receives only the messages for which it is configured.

Target Configuration

To specify the messages to send to an enabled target, you can set a message severity level, a filter name, and a match expression. These items determine which messages are sent to the target. You can also configure the format of the messages in the targets. For example, the console display target is configured to get messages of severity info and greater, the NVRAM target gets messages of severity warning and greater, and the memory buffer target gets messages of severity debug-data and greater. All the

targets are associated by default with a filter named DefaultFilter that passes all events at or above the default severity threshold. All the targets are also associated with a default match expression that matches any messages (the expression that matches any message is displayed as Match : (none) from the command line). And finally, each target has a format associated with it.

- To display the current log configuration of the targets, use the following command:

  ```
  show log configuration target {console | memory-buffer | nvram |
  primary-node | backup-node | session | syslog {ipaddress {udp-port
  {udp_port }}| ipPort |ipaddress tls-port {tls_port}} {vr vr_name}
  {[local0...local7]}}
  ```

- To configure a target, you use specific commands for severity, filters, and formats, use the following command:

  ```
  configure log target [console | memory-buffer | nvram |primary-
  node |backup-node | session | syslog [all | ipaddress {udp-port
  {udp_port}} | ipPort | ipaddress tls-port {tls_port} ] {vr vr_name}
  {local0...local7 }] {severity severity {only}}
  ```

  In addition, you can configure the source IP address for a syslog target. Configuring the source IP address allows the management station or syslog server to identify from which switch it received the log messages.

- To configure the source IP address for a syslog target, use the following command.

  ```
  configure log target syslog [all | ipaddress {udp-port {udp_port}} |
  ipPort | ipaddress tls-port {tls_port}] {vr vr_name} {local0...local7}
  from source-ip-address
  ```

  > **Note**
  > The address family (i.e IPv4 or IPv6) of the specified source IP address must be the same as the address family of the syslog server.

Severity

Messages are issued with one of the following severity levels: Critical, Error, Warning, Notice, Info, Debug-Summary, Debug-Verbose, or Debug-Data, which are described in Table 56.

When a message is sent to a syslog target, the severity is mapped to a corresponding syslog priority value (see RFC 3164).

The three severity levels for extended debugging—Debug-Summary, Debug-Verbose, and Debug-Data—require that log debug mode be enabled (which may cause a performance degradation).

See Displaying Debug Information on page 564 for more information about debugging.

Table 56: Severity Levels Assigned by the Switch

Level	Description
Critical	A serious problem has been detected that is compromising the operation of the system; the system cannot function as expected unless the situation is remedied. The switch may need to be reset.
Error	A problem has been detected that is interfering with the normal operation of the system; the system is not functioning as expected.
Warning	An abnormal condition, not interfering with the normal operation of the system, has been detected that indicate that the system or the network in general may not be functioning as expected.
Notice	A normal but significant condition has been detected, which signals that the system is functioning as expected.
Info (Informational)	A normal but potentially interesting condition has been detected, which signals that the system is functioning as expected; this level simply provides potentially detailed information or confirmation.
Debug-Summary	A condition has been detected that may interest a developer seeking the reason underlying some system behavior.
Debug-Verbose	A condition has been detected that may interest a developer analyzing some system behavior at a more verbose level than provided by the debug summary information.
Debug-Data	A condition has been detected that may interest a developer inspecting the data underlying some system behavior.

Configuring Severity Level

You can use more than one command to configure the severity level of the messages sent to a target.

- The most direct way to set the severity level of all the sent messages is to use the following command:

  ```
  configure log target [console | memory-buffer | nvram |primary-
  node |backup-node | session | syslog [all | ipaddress {udp-port
  {udp_port}} | ipPort | ipaddress tls-port {tls_port} ] {vr vr_name}
  {local0...local7 }] {severity severity {only}}
  ```

  When you specify a severity level, messages of that severity level and greater are sent to the target. If you want only those messages of the specified severity to be sent to the target, use the keyword **only**. For example, specifying **severity warning** will send warning, error, and critical messages to the target, but specifying **severity warning only** sends only warning messages.

- You can also use the following command to configure severity levels, which associate a filter with a target:

  ```
  configure log target [console | memory-buffer | | primary-node | |
  backup-node | nvram | session | syslog [all | ipaddress {udp-port
  ```

```
{udp_port}} | ipPort | ipaddress tls-port {tls_port} ]{vr vr_name}
{local0...local7}] filter filter-name {severity severity {only}}
```

When you specify a severity level as you associate a filter with a target, you further restrict the messages reaching that target. The filter may allow only certain categories of messages to pass. Only the messages that pass the filter and then pass the specified severity level reach the target.

Finally, you can specify the severity levels of messages that reach the target by associating a filter with a target. The filter can specify exactly which message it will pass. Constructing a filter is described in Filtering By Components and Conditions on page 555.

Components and Conditions

The event conditions detected by ExtremeXOS are organized into components and subcomponents.

- To get a listing of the components and subcomponents in your release of ExtremeXOS, use the following command:

  show log components {event component } {version}

  For example, to get a list of the components and subcomponents in your system, use the following command: show log components

  The following is partial output from this command:

  ```
  Severity
  Component          Title                                         Threshold
  ------------------ --------------------------------------------- -------------
  ...
  ...
  STP                Spanning-Tree Protocol (STP)                  Error
  InBPDU             STP In BPDU subcomponent                      Warning
  OutBPDU            STP Out BPDU subcomponent                     Warning
  System             STP System subcomponent                       Error
  ...
  ...
  ```

  The display above lists the components, subcomponents, and the severity threshold assigned to each. In EMS, you use a period (.) to separate component, subcomponent, and condition names. For example, you can refer to the InBPDU subcomponent of the *STP* component as STP.InBPDU. On the CLI, you can abbreviate or **[Tab]** complete any of these.

  A component or subcomponent typically has several conditions associated with it.

- To see the conditions associated with a component, use the following command:

  show log events [event condition | [all | event component] {severity severity {only}}] {details}

  For example, to see the conditions associated with the STP.InBPDU subcomponent, use the following command: show log events stp.inbpdu

  The following is sample output from this command:

```
Comp     SubComp      Condition                 Severity        Parameters
-------  -----------  ----------------------    -------------   ----------
STP      InBPDU       Drop                      Error           2 total
STP      InBPDU       Dump                      Debug-Data      3 total
STP      InBPDU       Trace                     Debug-Verbose   2 total
STP      InBPDU       Ign                       Debug-Summary   2 total
STP      InBPDU       Mismatch                  Warning         2 total
```

The display above lists the five conditions contained in the STP.InBPDU component, the severity of the condition, and the number of parameters in the event message. In this example, the severities of the events in the STP.InBPDU subcomponent range from error to debug-summary.

When you use the **details** keyword, you see the message text associated with the conditions.

- For example, if you want to see the message text and the parameters for the event condition STP.InBPDU.Trace, use the following command: `show log events stp.inbpdu.trace details`

  The following is sample output from this command:

```
Comp     SubComp      Condition                 Severity        Parameters
-------  -----------  ----------------------    -------------   ----------
STP      InBPDU       Trace                     Debug-Verbose   2 total
0 - string
1 - string (printf)
Port=%0%: %1%
```

The Comp heading shows the component name, the SubComp heading shows the subcomponent (if any), the Condition heading shows the event condition, the Severity heading shows the severity assigned to this condition, the Parameters heading shows the parameters for the condition, and the text string shows the message that the condition will generate. The parameters in the text string (for example, %0% and %1% above) will be replaced by the values of these parameters when the condition is encountered and displayed as the event message.

Filtering By Components and Conditions

You may want to send the messages that come from a specific component that makes up ExtremeXOS or to send the message generated by a specific condition. For example, you might want to send only those messages that come from the _STP_ component, or send the message that occurs when the IP.Forwarding.SlowPathDrop condition occurs. Or you may want to exclude messages from a particular component or event. To do this, you construct a filter that passes only the items of interest, and you associate that filter with a target.

1. The first step is to create the filter using the `create log filter` command.

   You can create a filter from scratch, or copy another filter to use as a starting point. (It may be easiest to copy an existing filter and modify it.)

2. To create a filter, use the following command:

```
create log filter name {copy filter_name}
```

   If you create a filter from scratch, that filter initially blocks all events until you add
   events (either the events from a component or a specific event condition) to pass.
   You might create a filter from scratch if you want to pass a small set of events and
   to block most events. If you want to exclude a small set of events, use the default
   filter that passes events at or above the default severity threshold (unless the filter
   has been modified), named DefaultFilter, that you can copy to use as a starting point
   for your filter.

3. After you create your filter, you configure filter items that include or exclude events
   from the filter.

   Included events are passed; excluded events are blocked.

4. To configure your filter, use the following command:

```
configure log filter name [add | delete] {exclude} events [event-
condition | [all | event-component] {severity severity {only}}]
```

   For example, if you create the filter myFilter from scratch, use the following
   command to include events:

```
configure log filter myFilter add events stp
```

   All STP component events of at least the default threshold severity passes myFilter
   (for the STP component, the default severity threshold is error). You can further
   modify this filter by specifying additional conditions.

   For example, assume that myFilter is configured as before, and assume that you
   want to exclude the STP.CreatPortMsgFail event.

5. To add that condition, use the following command:

```
configure log filter myFilter add exclude events stp.creatportmsgfail
```

6. You can also add events and subcomponents to the filter.

   For example, assume that myFilter is configured as before, and you want to include
   the STP.InBPDU subcomponent. To add that condition, use the following command:

```
configure log filter myFilter add events stp.inbpdu
```

7. You can continue to modify this filter by adding more filter items.

   The filters process events by comparing the event with the most recently configured
   filter item first. If the event matches this filter item, the incident is either included
   or excluded, depending on whether the **exclude** keyword was used. If necessary,
   subsequent filter items on the list are compared. If the list of filter items is exhausted
   with no match, the event is excluded and is blocked by the filter.

8. To view the configuration of a filter, use the following command:

```
show log configuration filter {filter_name}
```

   The following is sample output from this command (for the earlier filter):

```
Log Filter Name: myFilter
 I/                                             Severity
 E   Comp.    Sub-comp.    Condition            CEWNISVD
 -   -------  -----------  --------------------  --------
```

```
I  STP     InBPDU                              --------
E  STP                  CreatPortMsgFail       -E------
I  STP                                         --------
Include/Exclude: I - Include,  E - Exclude
Component Unreg: * - Component/Subcomponent is not currently registered
Severity Values: C - Critical,  E - Error,  W - Warning,  N - Notice,  I - Info
Debug Severity : S - Debug-Summary,  V - Debug-Verbose,  D - Debug-Data
+ - Debug Severities, but log debug-mode not enabled
If Match parameters present:
Parameter Flags: S - Source,  D - Destination, (as applicable)
I - Ingress,  E - Egress,  B - BGP
Parameter Types: Port - Physical Port list,  Slot - Physical Slot #
MAC  - MAC address,  IP - IP Address/netmask,  Mask - Netmask
VID  - Virtual LAN ID (tag),  VLAN - Virtual LAN name
L4   - Layer-4 Port #,  Num  - Number,  Str  - String
Nbr  - Neighbor, Rtr  - Routerid, EAPS - EAPS Domain
Proc - Process Name
Strict Match   : Y - every match parameter entered must be present in the event
N - match parameters need not be present in the event
```

The `show log configuration filter` command shows each filter item, in the order that it will be applied and whether it will be included or excluded. The above output shows the three filter items, one including events from the STP.InBPDU component, one excluding the event STP.CreatPortMsgFail, and the next including the remaining events from the STP component. The severity value is shown as "*", indicating that the component's default severity threshold controls which messages are passed. The Parameter(s) heading is empty for this filter because no match is configured for this filter. Matches are described in Matching Expressions on page 557.

Each time a filter item is added to or deleted from a given filter, the specified events are compared against the current configuration of the filter to try to logically simplify the configuration. Existing items will be replaced by logically simpler items if the new item enables rewriting the filter. If the new item is already included or excluded from the currently configured filter, the new item is not added to the filter.

Matching Expressions

You can configure the switch so messages reaching the target match a specified match expression.

The message text is compared with the configured match expression to determine whether to pass the message on. To require that messages match a match expression, use the following command:

configure log target [**console** | **memory-buffer** | **nvram** | **primary-node**| **backp-node** | **session** | **syslog** [**all** | *ipaddress* {**udp-port** {*udp_port*}} | *ipPort* | *ipaddress* **tls-port** {*tls_port*}] {**vr** *vr_name*} {**local0 ... local7**}] **match** [**any** |*match-expression*]

The messages reaching the target will match the match-expression, a simple regular expression. The formatted text string that makes up the message is compared with the match expression and is passed to the target if it matches. This command does not affect the filter in place for the target, so the match expression is compared only with the messages that have already passed the target's filter. For more information on controlling the format of the messages, see Formatting Event Messages on page 560.

Simple Regular Expressions

A simple regular expression is a string of single characters including the dot character (.), which are optionally combined with quantifiers and constraints. A dot matches any single character, while other characters match only themselves (case is significant). Quantifiers include the star character (*) that matches zero or more occurrences of the immediately preceding token. Constraints include the caret character (^) that matches at the beginning of a message and the currency character ($) that matches at the end of a message. Bracket expressions are not supported. There are a number of sources available on the Internet and in various language references describing the operation of regular expressions. The following table shows some examples of regular expressions.

Table 57: Simple Regular Expressions

Regular Expression	Matches	Does Not Match
port	port 2:3 import cars portable structure	poor por pot
..ar	baar bazaar rebar	bar
port.*vlan	port 2:3 in vlan test add ports to vlan port/vlan	
myvlan$	delete myvlan error in myvlan	myvlan port 2:3 ports 2:4,3:4 myvlan link down

Matching Parameters

Rather than using a text match, EMS allows you to filter more efficiently based on the parameter values of the message.

In addition to event components and conditions and severity levels, each filter item can also use parameter values to further limit which messages are passed or blocked. The process of creating, configuring, and using filters has already been described in Filtering By Components and Conditions on page 555, so this section describes matching parameters with a filter item.

To configure a parameter match filter item, use the following command:

```
configure log filter name [add | delete] {exclude} events [event-
condition | [all | event-component] {severity severity {only}}] [match
| strict-match] type value
```

Each event in ExtremeXOS is defined with a message format and zero or more parameter types.

The `show log events` all command can be used to display event definitions (the event text and parameter types). Only those parameter types that are applicable given the

events and severity specified are exposed on the CLI. The syntax for the parameter types (represented by *type* in the command syntax above) is:

```
[address-family [ipv4-multicast | ipv4-unicast | ipv6-multicast | ipv6-
unicast] | bgp-neighbor ip address | bgp-routerid ip address | eaps eaps
domain name | {destination | source} [ipaddress ip address | L4-port
L4-port| mac-address mac-address] | esrp esrp domain name | {egress |
ingress} [slot slot number | ports portlist] | ipaddress ip address |
L4-port L4-port | mac-address mac_address | netmask netmask | number
number | port portlist | process process name | slot slotid | string
exact string to be matched | vlan vlan name | vlan tag vlan tag]
```

You can specify the ipaddress type as IPv4 or IPv6, depending on the IP version.

The following examples show how to configure IPv4 addresses and IPv6 addresses:

IPv4 address

- To configure an IP address, with a mask of 32 assumed, use the following command:
  ```
  configure log filter myFilter add events all match ipaddress 12.0.0.1
  ```
- To configure a range of IP addresses with a mask of 8, use the following command:
  ```
  configure log filter myFilter add events all match ipaddress 12.0.0.0/8
  ```

IPv6 address

- To configure an IPv6 address, with a mask of 128 assumed, use the following command:
  ```
  configure log filter myFilter add events all match ipaddress 3ffe::1
  ```
- To configure a range of IPv6 addresses with a mask of 16, use the following command:
  ```
  configure log filter myFilter add events all match ipaddress 3ffe::/16
  ```

IPv6 scoped address

- IPv6 scoped addresses consist of an IPv6 address and a *VLAN*. The following examples identify a link local IPv6 address.

To configure a scoped IPv6 address, with a mask of 128 assumed, use the following command:

```
configure log filter myFilter add events all match ipaddress fe80::1%Default
```

To configure a range of scoped IPv6 addresses with a mask of 16, use the following command:

```
configure log filter myFilter add events all match ipaddress fe80::/16%Default
```

To configure a scoped IPv6 address with any VLAN, use the following command:

```
configure log filter myFilter add events all match ipaddress fe80::/16%*
```

To configure any scoped IPv6 address with a specific VLAN, use the following command:

```
configure log filter myFilter add events all match ipaddress fe80::/0%Default
```

> **Note**
> In the previous example, if you specify the VLAN name, it must be a full match; wild cards are not allowed.

The `value` depends on the parameter type specified.

As an example, an event may contain a physical port number, a source MAC address, and a destination MAC address. To allow only those _RADIUS (Remote Authentication Dial In User Service)_ incidents, of severity notice and above, with a specific source MAC address, use the following command:

```
configure log filter myFilter add events aaa.radius.requestInit severity notice match
source mac-address 00:01:30:23:C1:00
```

The string type is used to match a specific string value of an event parameter, such as a user name. The exact string is matched with the given parameter and no regular expression is supported.

Match Versus Strict-Match

The **match** and **strict-match** keywords control the filter behavior for those incidents with event definition that does not contain all the parameters specified in a `configure log filter events match` command.

This is best explained with an example. Suppose an event in the XYZ component, named XYZ.event5, contains a physical port number, a source MAC address, but no destination MAC address. If you configure a filter to match a source MAC address and a destination MAC address, XYZ.event5 will match the filter when the source MAC address matches regardless of the destination MAC address because the event contains no destination MAC address. If you specify the **strict-match** keyword, then the filter will never match event XYZ.event5 because this event does not contain the destination MAC address.

In other words, if the **match** keyword is specified, an incident will pass a filter so long as all parameter values in the incident match those in the match criteria, but all parameter types in the match criteria need not be present in the event definition.

Formatting Event Messages

Event messages are made up of a number of items. The individual items can be formatted; however, EMS does not allow you to vary the order of the items.

- Format the messages for a particular target.

  `configure log target format`

  Using the default format for the session target, an example log message might appear as:

  ```
  06/25/2004 22:49:10.63 <Info:dm.Info> MSM-A: PowerSupply:4 Powered On
  ```

If you set the current session format using the following command:

```
configure log target session format timestamp seconds date mm-dd-yyyy event-name
component
```

The same example would appear as:

```
06/25/2004 22:49:10 <dm> PowerSupply:4 Powered On
```

• Provide some detailed information to technical support, set the current session format.

```
configure log target session format timestamp hundredths date mmm-dd event-name
condition process-name source-line
```

The same example then appears as:

```
Jun 25 22:49:10.63 <dm.info> devmgr: (dm.c:134) PowerSupply:4 Powered On
```

Displaying Real-Time Log Messages

You can configure the system to maintain a running real-time display of log messages on the console display or on a (Telnet) session.

• Turn on the log display on the console with the command:

```
enable log target console
```

This setting may be saved to the FLASH configuration and is restored on boot-up (to the console display session).

• Turn on log display for the current session with the command:

```
enable log target session
```

This setting only affects the current session and is lost when you log off the session.

The messages that are displayed depend on the configuration and format of the target. For information on message filtering, see Filtering Events Sent to Targets on page 551. For information on message formatting, see Formatting Event Messages on page 560.

Displaying Event Logs

The log stored in the memory buffer and the NVRAM can be displayed on the current session (either the console display or Telnet).

• Display the log using the command:

```
show log {messages [memory-buffer | nvram]} {events {event-condition |
event-component]} {severity severity {only}} {starting [date date time
time | date date | time time]} {ending [date date time time | date
date | time time]} {match regex} {chronological}
```

You can use many options to select those log entries of interest. You can select to display only those messages that conform to the specified:

◦ Severity

◦ Starting and ending date and time

◦   Match expression

The displayed messages can be formatted differently from the format configured for the targets, and you can choose to display the messages in order of newest to oldest or in chronological order (oldest to newest).

Log Buffer Threshold Alert

ExtremeXOS 16.1 now supports the ability to generate syslog message or trigger a *SNMP* trap when the log memory buffer is filled up to 90% of configured log lines. SNMP/SNMP trap is not supported by ExtremeXOS EMS module at this point. The feature provides that an alert in the form of log message will be generated when the log memory buffer is filled up to a certain percentage threshold. A new command has been added to allow you to configure the memory buffer alert. The alert will be based on the percentage used of the memory buffer. By default, the alert is disabled.

The new command can be used to enable the alert and to specify the percentage threshold that triggers alerts. When the percentage threshold is set to a value in the allowed range, the memory buffer alert is enabled. When the percentage threshold is set to none, the memory buffer alert is disabled. The alert triggered will be a log message with Notice severity.

If the alert is enabled, a log message will be generated in the following three scenarios:

1. When the actual use of the memory buffer first exceeds the configured percentage threshold.
2. When the configured memory buffer size is changed and the actual use of the buffer exceeds the configured percentage threshold.
3. When the configured percentage threshold is changed and the actual use of the buffer exceeds the re-configured percentage threshold.

When you execute the command `clear log`, the memory buffer will be emptied. When the new logs re-fill up to the configured percentage threshold, the log message will be re-generated. Output of `show log configuration` will be modified as well to include the information of memory buffer alert configuration and current memory buffer usage.

Uploading Event Logs

The log stored in the memory buffer and the NVRAM can be uploaded to a TFTP server.

*   Use the following command to upload the log:

    ```
    upload log [ ipaddress | hostname] {vr vr_name} {block-size
    block_size} filename {messages [memory-buffer | nvram] } {severity
    severity {only}} {match regex} {chronological}
    ```

    You must specify the TFTP host and the filename to use in uploading the log.

    There are many options you can use to select the log entries of interest. You can select to upload only those messages that conform to the specified:

    ◦   Severity

◦ Match expression

The uploaded messages can be formatted differently from the format configured for the targets, and you can choose to upload the messages in order of newest to oldest or in chronological order (oldest to newest).

Displaying Counts of Event Occurrences

EMS adds the ability to count the number of occurrences of events. Even when an event is filtered from all log targets, the event is counted.

- Display the event counters.

```
show log counters {event condition | [all | event component]} {include
| notified | occurred} {severity severity {only}}}
```

The system displays two counters. One counter displays the number of times an event has occurred, and the other displays the number of times that notification for the event was made to the system for further processing. Both counters reflect totals accumulated since reboot or since the counters were cleared using the `clear log counters` or `clear counters` command.

The `show log counters` command also displays an included flag (the column titled In in the output). The included flag is set to Y(es) if one or more targets are receiving notifications of this event without regard to matching parameters.

The keywords **include**, **notified**, and **occurred** display events only with non-zero counter values for the corresponding counter.

The output of the command:

```
show log counters stp.inbpdu severity debug-summary
```

is similar to the following:

```
Comp    SubComp     Condition               Severity      Occurred  In Notified
-------  -----------  ----------------------  ------------- --------  -- --------
STP     InBPDU      Drop                    Error                0  Y         0
STP     InBPDU      Ign                     Debug-Summary        0  N         0
STP     InBPDU      Mismatch                Warning              0  Y         0
Occurred  : # of times this event has occurred since last clear or reboot
Flags     : (*) Not all applications responded in time with there count values
In(cluded): Set to Y(es) if one or more targets filter includes this event
Notified  : # of times this event has occurred when 'Included' was Y(es)
```

The output of the command:

```
show log counters stp.inbpdu.drop
```

is similar to the following:

```
Comp    SubComp     Condition               Severity      Occurred  In Notified
-------  -----------  ----------------------  ------------- --------  -- --------
STP     InBPDU      Drop                    Error                0  Y         0
Occurred  : # of times this event has occurred since last clear or reboot
```

```
Flags     : (*) Not all applications responded in time with there count values
In(cluded): Set to Y(es) if one or more targets filter includes this event
Notified  : # of times this event has occurred when 'Included' was Y(es)
```

Displaying Debug Information

By default, a switch does not generate events of severity Debug-Summary, Debug-Verbose, and Debug-Data unless the switch is in debug mode. Debug mode causes a performance penalty, so it should only be enabled for specific cases where it is needed.

• Place the switch in debug mode using the command:

```
enable log debug-mode
```

When the switch is in debug-mode, any filters configured for your targets still affect which messages are passed on or blocked.

Logging Configuration Changes

ExtremeXOS allows you to record all configuration changes and their sources that are made using the CLI by way of Telnet or the local console. These configuration changes are noted in the log as event entries. Each log entry includes the user account name that performed the change and the source IP address of the client (if Telnet was used). Configuration logging applies only to commands that result in a configuration change. CLI configuration logging is disabled by default.

• To enable configuration logging, use the following command:

```
enable cli config-logging
```

• To d configuration logging, use the following command:

```
disable cli config-logging
```

You can specify that logged commands appear in fully expanded form, rather than the abbreviations you may have used when entering them in the command line.

For example, with command expansion enabled, a command entered in abbreviated format, such as

```
config por 33 auto of spee 10000 duplex ful
```

appears in the log as:

```
configure ports 33 auto off speed 10000 duplex full
```

• To enable command expansion, use the following command:

```
enable cli-config-logging expansion
```

• To disable command expansion, use the following command:

```
disable cli-config-logging expansion
```

Securing Syslog Transport Layer Security Sessions

By default, the following ciphers are enabled for Syslog Transport Layer Security (TLS) sessions:

aes128-sha, aes128-sha256; aes256-sha256; dhe-rsa-aes128-sha256; dhe-rsa-aes256-sha256

You can selectively enable and disable ciphers using the following command:

```
configure syslog tls cipher [[cipher | all] on | cipher off]
```

To see which ciphers are enabled or disabled for Syslog TLS sessions, use the following command:

```
show log configuration
```

Avoiding Potential Loss of TLS Syslog Logging

For Linux, by default, it takes about 15 minutes for kernel to end a TCP connection when transmitted data remains unacknowledged. This results in a potential loss of logs to TLS Syslog server during the 15 minutes window due to link down.

To reduce this time window, use the following command:

```
configure syslog tls tcp-user-timeout [seconds | default]
```

To view the value set for Syslog TLS TCP user timeout, use the following comamnd:

```
show log configuration
```

Disabling OCSP for TLS Connections to Remote Syslog Servers

For compliance with *RFC 6960* (X.509 Internet Public Key Infrastructure Online Certificate Status Protocol – OCSP), you can disable the OCSP check for Transport Layer Security (TLS) connections to remote Syslog servers by using the following command:

```
configure syslog tls ocsp [on | off]
```

To see the status of OCSP checking, use the following command:

```
show log configuration
```

> **Note**
> Be sure you understand the ramifications of turning off OCSP if you chose to do so.

Syslog TLS OCSP Attribute Configuration

Beginning with version 32.2, you can configure Syslog TLS OCSP attributes (nonce, override, and ocsp-nocheck, respectively) using the following commands:

- `configure syslog` **`tls ocsp nonce`** [**`on`** | **`off`**]
- `configure syslog` **`tls tls override`** [*`url`* | **`none`**]
- `configure syslog` **`tls ocsp signer ocsp-nocheck`** [**`on`** | **`off`**]

OCSP nonce cryptographically binds an OCSP request and an OCSP response with an `id-pkix-ocsp-nonce` extension to prevent replay attacks.

OCSP override configures one HTTP Online Certificate Status Protocol (OCSP) override URL for TLS connections to a remote Syslog server.

OCSP-nocheck

If this configuration is turned on, then the operating system assumes the OCSP signer certificate contains the ocsp-nocheck extension, whether it has the extension or not. This results in the system accepting the OCSP responses from this OCSP signer. By default, this configuration is off to maintain backward compatibility, but can be turned on or off per application. This is also applicable for both the override server and AIA servers.

Using the XML Notification Client

Introduction

This feature allows an event such as a configuration change, a fault, a change in status, the crossing of a threshold, or an external input to the system, to be sent as an asynchronous message or event notification to external web servers.

The only ExtremeXOS modules that support XML notification as targets are Identity Management and EMS.

XML notification does not provide any event filtering capability. However, in the case of EMS, the target Web server can be configured with log filters and conditions. The XML notification feature establishes and checks the connectivity with the web server only when an event is ready to be pushed. State transitions take place if required. Statistics are updated accordingly and can be monitored.

The Web servers must be configured and enabled using ExtremeXOS CLI with an IP address, port, protocol type, user authentication, session information, if any, and other web server configuration.

A maximum of four web servers can be configured at a time.

The XML schemas are defined using Web Services Description Language (WSDL) in the XML SDK.

HTTP Client Interface

The event notifications are sent in XML format, using SOAP transport protocol and HTTP/HTTPS.

The XML notification client can communicate with the external HTTP/HTTPS server. HTTP/HTTPS client interfaces maintain persistent connections with external Web servers as long as the target is activated on the switch.

The HTTP URL format for the server is `http://<ip-address>:<port>/<service>`. The default HTTP port number 80 is used if a port number is not configured.

HTTP basic access authentication method (Base64 algorithm) is used to encrypt the user name and password when making a request. HTTP cookies are not supported in this release.

Create a server certificate that can be used by the HTTPS server. To generate the secure certificate on a ExtremeXOS switch, see the configuration guidelines of the HTTP server, (see Secure Socket Layer on page 1225 for more information).

Configuring XML Notification

- Create a web server target on an XML client using the command:

  `create xml-notification target` *new-target* **url** *url* {**vr** *vr_name*} {**user** [**none** | *user*]} {**encrypted-auth** *encrypted-auth*} {**queue-size** *queue-size*}

- Configure a web server target on an XML client using the command:

  `configure xml-notification target` *target* [**url** *url* {**vr** *vr_name*} | **user** [**none** | *user*] | [**encrypted-auth** *encrypted-auth*] | [**queue-size** *queue-size*]]

- Add or delete an ExtremeXOS application to a web server target (EMS or Identity Management) using the command:

  `configure xml-notification target` *target* [**add** | **delete**] *module*

- Enable or disable web server target(s) using the command:

  [**enable**|**disable**] **xml-notification** [**all** | *target*]

- Delete a web server target on an XML client process using the command:

  `delete xml-notification target` *target*

- Unconfigure an XML client process using the command:

  `unconfigure xml-notification`

- Unconfigure and reset all statistics counters using the command:

  `clear counters xml-notification` {**all** | *target*}

Displaying XML Notification

- Display the configuration of a web server target using the command:

  `show xml-notification configuration` {*target*}

- Display the connection status, enable status, and event statistics of the target web server using the command:

  ```
  show xml-notification statistics {target}
  ```
- Display information on the stored certificate using the command:

  ```
  show ssl {detail}
  ```

Configuring Log Target in EMS

The following commands support the EMS XML target.

- Create a web server XML target using hte command:

  ```
  create log target xml-notification [ target_name | xml_target_name ]
  ```
- Configure the web server target with an EMS filter using the command:

  ```
  configure log target xml-notification xml_target_name filter filter-name {severity [[severity] {only}]}
  ```
- Enable the web server target using the command:

  ```
  enable log target xml-notification xml_target_name
  ```
- Disable the web server target using the command:

  ```
  disable log target xml-notification xml_target_name
  ```
- Delete the web server target XML target using the command:

  ```
  delete log target xml-notification xml_target_name
  ```
- Display XML target information using the command:

  ```
  show log configuration target xml-notification {xml_target_name}
  ```

Examples

Below are examples of configuring web server targets in a XML Notification module.

Scenario 1: Push filtered EMS events to external web server in a well-defined XML format.

Create a Web Server Target test1, create a log target and a filter in EMS, and attach the filter to the web target. Enable the target in both EMS and XML-Notification module.

```
create XML-notification target test1 url http://10.255.129.22:8080/xos/webservice user
admin
create log target xml-notification "test1"
create log filter xmlc_filter_1
configure log filter "xmlc_filter_1" add events idmgr
configure log target xml-notification "test1" filter "xmlc_filter-1"
enable log target xml-notification "test1"
enable XML-notification test1
```

Scenario 2: Push user identity events to the external web server without EMS module in a well defined (XML Schema) XML format.

Create a web server target and attach an idmgr module. Idmgr modules use an XML-notification backend library to trigger events. In this case, no special filters are supported.

```
create xml-notification target test2 url http://10.255.129.22:8080/xos/webservice user
admin
```

```
configure xml-notification target test2 add module idmgr
enable xml-notification test2
```

Scenario - 3: XMLC notifications using HTTPS

Install the SSH module. If not installed, refer to Understanding System Redundancy on page 89 for details on SSH and Secure Socket Layer on page 1225 for details on SSL.

```
configure ssl certificate privkeylen 1024 country us organization extreme common-name
name1
create xml-notification target test3 url https://10.120.91.64:8443/xos/webservice
configure xml-notification target "test3" user admin
configure xml-notification target "test3" add "ems"
enable xml-notification "test3"
```

Using sFlow

sFlow is a technology for monitoring traffic in data networks containing switches and routers. It relies on statistical sampling of packets from high-speed networks, plus periodic gathering of the statistics. A *UDP (User Datagram Protocol)* datagram format is defined to send the information to an external entity for analysis. sFlow consists of a *MIB (Management Information Base)*, and a specification of the packet format for forwarding information to a remote agent. For details on sFlow specifications, see RFC 3176; and for more general information, go to www.sflow.org.

The ExtremeXOS implementation is based on sFlow version 5, which is an improvement from the revision specified in RFC 3176.

Additionally, the switch software also allows you to set the individual port sampling rates, so that you can fine-tune sFlow statistics.

sFlow and mirroring are not mutually exclusive on ExtremeSwitching series switches, whether or not they are included in a SummitStack. You can enable them simultaneously.

However, be aware that the following limitations are present in the ExtremeXOS implementation:
- Generic port statistics are reported to the sFlow collector
- Non-extended data
- Only port-based sampling
- No MIB support

Sampling Mechanisms

ExtremeSwitching series switches support hardware-based sampling at a programmed interval.

With hardware-based sampling, the data path for a packet that traverses the switch does not require processing by the CPU. Fast path packets are handled entirely by ASICs and are forwarded at wire speed rate.

Both ingress and egress sFlow sampling can be enabled simultaneously on a port. The `enable sflow port` command provides an option to enable sFlow on ingress, or egress, or both directions. The default value is ingress. The sample rate is maintained on a per-port basis, so a given port has the same sample rate for ingress and egress traffic. Ingress and egress sFlows sample both unicast and multicast egress flows. The global enable/disable control of sFlow is common to both ingress and egress. When the global option is enabled, the port level sFlow parameter is applied to hardware.

When sFlow sampling is enabled on a port, the sFlow agent samples the traffic on that port, processed in slow path and passed on to the collector. You can configure the rate at which the packets are sampled.

ExtremeXOS 22.5 expands upon sFlow's capability by providing support for additional data structures that an sFlow agent can use to report table utilization statistics in sFlow counter samples (see Displaying sFlow Information on page 576).

Limitations of Egress sFlow

The following limitations apply to the egress sFlow feature:

- Due to the hardware limitation, destination port information is not supported for multicast traffic. The output interface index is populated as 0.
- Egress sFlow sampling does not support de-duplication of packets.
- For multicast traffic, the sampling rate, sample pool of the egress sFlow sampled datagram is populated as 0, because the source ID of the egress sampled multicast packet is unknown.
- For L3 unicast traffic, an unmodified packet is sampled and the destination port is supplied if the L3 traffic is a flow within single chip. When the egress port and ingress port are in different chips, then a modified packet is sampled and the destination ports are supplied. For L3 multicast traffic, unmodified packet is sampled and destination port is populated as zero.
- Packets dropped due to egress _ACL_ are sampled.
- In cases of unicast and multicast flooding, the packets are sampled before packet replication. If the ingress and member ports are in the same chip, then a single copy of the packet is sampled even though the egress sFlow is enabled on more than one member's ports. If the member ports are spread across different chip, then packets are sampled on a per-chip basis.
- In flooding cases, the least configured sampling rate among the member ports on a port group is considered as a sample rate. Even if you configure different sample rates on a member ports, egress sampling is based on the least configured sample rate among the member ports on a chip.

sFlow Destination Port

Currently, when a packet is sampled from the ingress traffic, the output interface index is populated as 0. This is applicable for both unicast and multicast traffic. As part of the egress sFlow, the output interface index is populated with the destination port information for unicast packets sampled in both ingress and egress directions. Multicast packet samples still have an output interface index as 0.

Table 58 illustrates the expected output of the ifIndex when based on traffic type, and sampling direction.

Table 58: IfIndex Traffic Type Sampling Direction

Case #	Ingress/Engress Unicast/ Multicast	Scenario
1	Ingress/unicast	sFlow sample includes both ingress and egress port (ifindex).
2	Egress/unicast	sFlow sample includes both ingress and egress port information.
3	Ingress/multicast	Egress port information cannot be provided because of hardware limitation. Egress ifindex is 0 and ingress ifindex is supplied.
4	Egress/multicast	Egress port information cannot be provided because of hardware limitation. Egress ifindex is 0 and ingress ifindex is supplied.

Configuring sFlow

ExtremeXOS allows you to collect sFlow statistics on a per port basis.

An agent residing locally on the switch sends data to a collector that resides on another machine. You configure the local agent, the address of the remote collector, and the ports of interest for sFlow statistics gathering. You can also modify default values for how frequently on an average a sample is taken and the maximum number of samples allowed before throttling the sample gathering.

To configure sFlow on a switch:

- Configure the local agent
- Configure the addresses of the remote collectors
- Enable sFlow globally on the switch
- Enable sFlow on the desired ports

Optionally, you may also change the default values of the following items:

- How often the statistics are collected
- How frequently a sample is taken, globally or per port
- How many samples per second can be sent to the CPU

Configuration Tasks

Use the following commands to configure the sFlow feature:

- `enable sflow ports` **all** | *port_list* {**ingress** | **egress** | **both**}

The keyword options enable you to configure sFlow types on a given set of ports. If you do not configure an sFlow type, then ingress sFlow sampling is enabled as the default configuration.

Use the following commands to display the type of sFlow configured on the physical interface, and various statistics about sFlow sampling:

- `show sflow configuration`
- `show sflow statistics`

    The following fields are displayed:

    - Received frames—Number of frames received on sFlow enabled ports.
    - Sampled Frames—Number of packets that have been sampled by sFlow.
    - Transmitted Frames—Number of UDP packets sent to remote collector(s).
    - Broadcast Frames—Number of broadcast frames received on sFlow enabled ports.
    - Multicast Frames—Number of multicast frames received on sFlow enabled ports.
    - Packet Drops—Number of samples dropped.

Configuring the Local Agent

The local agent is responsible for collecting the data from the samplers and sending that data to the remote collector as a series of UDP datagrams. The agent address is stored in the payload of the sFlow data, and is used by the sFlow collector to identify each agent uniquely. By default, the agent uses the management port IP address as its IP address.

- Change the agent IP address using the command:

    `configure sflow agent {`**`ipaddress`**`}` *`ipaddress`*

- Unconfigure the agent using the command:

    `unconfigure sflow agent`

Configuring the Remote Collector Address

You can specify up to four remote collectors to send the sFlow data to. Typically, you would configure the IP address of each collector. You may also specify a UDP port number different from the default value of 6343, and/or a *virtual router (VR)* different from the default of *VR-Mgmt*. When you configure a collector, the system creates a database entry for that collector that remains until the collector is unconfigured. All the configured collectors are displayed in the command: `show sflow {`**`configuration`**`}`.

- Configure the remote collector using the command:

    `configure sflow collector {`**`ipaddress`**`}` *`ipaddress`* `{`**`port`** *`udp-port-number`*`}` `{`**`vr`** *`vr_name`*`}`

- Unconfigure the remote collector and remove it from the database using the command:

    `unconfigure sflow collector {`**`ipaddress`**`}` *`ipaddress`* `{`**`port`** *`udp-port-number`*`}` `{`**`vr`** *`vr_name`*`}`

Enabling sFlow Globally on the Switch

Before the switch starts sampling packets for sFlow, you must enable sFlow globally on the switch.

• Enable sFlow globally using the command:

```
enable sflow
```

• Disable sFlow globally using the command:

```
disable sflow
```

When you disable sFlow globally, the individual ports are also put into the disabled state. If you later enable the global sFlow state, individual ports return to their previous state.

Enabling sFlow on the Desired Ports

• Enable sFlow on specific ports using the command:

```
enable sflow ports port_list {ingress | egress | both}
```

The **ingress** option allows you to configure the sFlow type on a given set of ports. This option is configured on the port by default.

You may enable and disable sFlow on ports irrespective of the global state of sFlow, but samples are not taken until both the port state and the global state are enabled.

• Disable sFlow on ports using the command:

```
disable sflow ports port_list
```

Additional sFlow Configuration Options

You can configure three global options to different values from the defaults. These options affect how frequently the sFlow data is sent to the remote collector, how frequently packets are sampled, and the maximum number of sFlow samples that could be processed in the CPU per second.

You can also configure how frequently packets are sampled per port.

Polling Interval

Each port counter is periodically polled to gather the statistics to send to the collector. If there is more than one counter to be polled, the polling is distributed in such a way that each counter is visited once during each polling interval, and the data flows are spaced in time. For example, assume that the polling interval is 20 seconds and there are 40 counters to poll. Two ports will be polled each second, until all 40 are polled.

• Configure the polling interval using the command:

```
configure sflow poll-interval seconds
```

Global Sampling Rate

The global sampling rate is the rate set on newly enabled sFlow ports. Changing this rate does not affect currently enabled sFlow ports. The default sample rate is 8192, so sFlow samples one packet out of every 8192 received.

- Use the following command to configure the switch to use a different sampling rate.

```
configure sflow sample-rate number
```

For example, if you set the sample rate number to 16384, the switch samples one out of every 16384 packets received. Higher numbers mean fewer samples and longer times between samples. If you set the number too low, the number of samples can be very large, which increases the load on the switch. Do not configure the sample rate to a number lower than the default unless you are sure that the traffic rate on the source is low.

The Global Sampling Rate applies to all ExtremeSwitching platforms.

> **Note**
> The minimum rate that these platforms sample is 1 out of every 256 packets. If you configure a rate to be less than 256, the switch automatically rounds up the sample rate to 256.

Per Port Sampling Rate

The per port sampling rate overrides the system-wide value.

The rate is rounded off to the next power of two, so if 400 is specified, the sample rate is configured as 512. The valid range is [256-536870912].

- Set the sampling rate on individual ports.

```
configure sflow ports port_list sample-rate number
```

Maximum CPU Sample Limit

A high number of samples can cause a heavy load on the switch CPU. To limit the load, there is a CPU throttling mechanism to protect the switch.

> **Note**
> Sflow sampling is limited to 2000 packets per second in the CPU. Any packets sent at a rate greater than 2000 pps are dropped.

On a stand-alone switch, whenever the limit is reached, the sample rate value is doubled on the ports from which the maximum number of samples are received. For ports that are sampled less frequently, the sampling rate is not changed; the sub-sampling factor is adjusted downward.

- Configure the maximum CPU sample limit.

```
configure sflow max-cpu-sample-limit rate
```

Unconfiguring sFlow

- Reset the configured values for sFlow to their default values and remove from sFlow any configured collectors and ports using the following ocmmand:

  ```
  unconfigure sflow
  ```

sFlow Configuration Example

In a service provider environment, you can configure sFlow to sample packets at the edge of the network to determine the hourly usage for each IP address in the data center.

You can capture web traffic, FTP traffic, mail traffic, and all bits of data that travel across service providers' edge routers to their customers' (end users') servers.

The example in this section assumes that you already have an sFlow data collector installed somewhere in your network. In many environments, the sFlow data collector is on a network PC.

The following sFlow configuration example performs the following tasks in a service provider environment:

- Configures the IP address of the sFlow data collector.

  > **Note**
  > In many environments, the sFlow data collector is not directly connected to the switch. Make sure to specify the VR used to forward traffic between the sFlow collector and the switch. In most cases the VR is *VR-Mgmt*.

- Configures the sampling rate on an edge port.
- Enables sFlow on the edge port.
- Enables sFlow globally on the switch.

```
configure sflow collector 10.127.11.88 vr vr-mgmt
configure sflow ports 5:21 sample-rate 8192
enable sflow ports 5:21 egress
enable sflow
```

Here is sample output for the configuration:

```
SFLOW Global Configuration
Global Status: enabled
Polling interval: 20
Sampling rate: 8192
Maximum cpu sample limit: 2000
SFLOW Configured Agent IP: 0.0.0.0
Operational Agent IP: 10.127.11.88
Collectors
SFLOW Port  Configuration Port Status  Sample-rate Subsampling Sflow-type
Config / Actual factor Ingress/Egress
5:21    enabled         8192 / 8192  1          Disabled / Enabled
```

Displaying sFlow Information

- To display the current configuration of sFlow, use the following command:

  `show sflow {`**`configuration`**`}`

- To display the sFlow statistics, use the following command:

  `show sflow statistics`

- To display the sFlow hardware table utilization statistics, use the following command:

  `show sflow `**`hardware-utilization`**` {`**`slot`**` [`*`slot_num`*` | `**`all`**`]}`

Using RMON

Using the Remote Monitoring (RMON) capabilities of the switch allows network administrators to improve system efficiency and reduce the load on the network.

> **Note**
> You can use the RMON features of the system only if you have an RMON management application and have enabled RMON on the switch.

About RMON

RMON is the common abbreviation for the Remote Monitoring Management Information Base (MIB) system defined by the Internet Engineering Task Force (IETF) documents RFC 1757 and RFC 2021, which allows you to monitor LANs remotely.

A typical RMON setup consists of the following two components:

- RMON agent
- Management workstation

RMON Agent

An RMON agent is an intelligent software agent that continually monitors port statistics and system variables.

The agent transfers the information to a management workstation on request, or when a predefined threshold is crossed.

Information collected by RMON includes Ethernet port statistics and history and the software version and hardware revision of the device. RMON generates alarms when threshold levels are met and then logs those events to the log. RMON can also send traps to the destination address configured by the management workstation. You can also use RMON to trigger a system reboot.

Management Workstation

A management workstation communicates with the RMON agent and collects the statistics from it.

The workstation does not have to be on the same network as the RMON agent and can manage the agent by in-band or out-of-band connections.

If you enable RMON on the switch, you can use a management workstation to review port statistics and port history, no configuration of the management workstation is necessary. However, you must use a management workstation to configure the alarm and event entries.

Supported RMON Groups of the Switch

The IETF defines nine groups of Ethernet RMON statistics. The switch supports the following four of these groups, as defined in RFC 1757:

- Statistics
- History
- Alarms
- Events

The switch also supports the following parameters for configuring the RMON agent and the trap destination table, as defined in RFC 2021:

- probeCapabilities
- probeSoftwareRev
- probeHardwareRev
- probeDateTime
- probeResetControl
- trapDestTable

The following sections describe the supported groups, the RMON probe configuration parameters, and the trap destination parameter in greater detail.

Statistics

The RMON Ethernet Statistics group provides traffic and error statistics showing packets, bytes, broadcasts, multicasts, and errors on an Ethernet port.

Information from the Statistics group is used to detect changes in traffic and error patterns in critical areas of the network.

History

The History group provides historical views of network performance by taking periodic samples of the counters supplied by the Statistics group.

The group features user-defined sample intervals and bucket counters for complete customization of trend analysis.

The group is useful for analysis of traffic patterns and trends on an Ethernet port, and for establishing baseline information indicating normal operating parameters.

Alarms

The Alarms group provides a versatile, general mechanism for setting threshold and sampling intervals to generate events on any RMON variable.

Both rising and falling thresholds are supported, and thresholds can be on the absolute value of a variable or its delta value.

> **Note**
> Creating an entry in the alarmTable does not validate the alarmVariable and does not generate a badValue error message.

Alarms inform you of a network performance problem and can trigger automated action responses through the Events group.

Events

The Events group creates entries in an event log and/or sends *SNMP* traps to the management workstation.

An event is triggered by an RMON alarm. The action taken can be configured to ignore it, to log the event, to send an SNMP trap to the receivers listed in the trap receiver table, or to both log and send a trap. The RMON traps are defined in RFC 1757 for rising and falling thresholds.

Effective use of the Events group saves you time. Rather than having to watch real-time graphs for important occurrences, you can depend on the Events group for notification. Through the SNMP traps, events can trigger other actions, which provides a mechanism for an automated response to certain occurrences.

RMON Probe Configuration Parameters

The RMON probe configuration parameters supported in ExtremeXOS are a subset of the probe configuration group as defined in RFC 2021. The probe configuration group controls and defines the operation of the RMON agent.

You can configure the following objects:

- probeCapabilities—View the RMON MIB groups supported on at least one interface by the probe.
- probeSoftwareRev—View the current software version of the monitored device.
- probeHardwareRev—View the current hardware version of the monitored device.
- probeDateTime—View the current date and time of the probe. For example, Friday December 31, 2004 at 1:30:15 PM EST is displayed as: 2004-12-31,13:30:15.0

  If the probe is aware of time zones, the display also includes the Greenwich Mean Time (GMT) offset. For example, Friday, December 31, 2004, 1:30:15 PM EST with the offset known is displayed as: 2004-12-31,13:30:15.0, -4.0

  If time information is unavailable or unknown, the time is not displayed.
- probeResetControl—Restart a managed device that is not running normally. Depending on your configuration, you can do one of the following:
  ◦ Warm boot—A warm boot restarts the device using the current configuration saved in non-volatile memory.

◦ Cold boot—A cold boot causes the device to reset the configuration parameters stored in non-volatile memory to the factory defaults and then restarts the device using the restored factory default configuration.

trapDestTable

The trapDestTable contains information about the configured trap receivers on the switch and stores this information in non-volatile memory.

To configure one or more trap receivers, see Using the Simple Network Management Protocol on page 110.

Extreme-RtStats-MIB

The extremeRtStatsTable provides the user with all the common measurement/monitoring attributes in a single table.

It includes measurements like utilization, error, and collision levels.

The extreme RtStatsUtilization variable gives an accurate measurement of segment utilization. ExtremeRtStatsCollisions is included in the segment utilization calculation for more accuracy. Collision statistics are collected periodically, and the segment utilization is calculated with a sampling interval of 5 minutes (300 seconds).

The extremeRtStatsTotalErrors variable is calculated by adding the following counters:
- extremeRtStatsCRCAlignErrors (receive errors)
- extremeRtStatsFragments (receive errors)
- extremeRtStatsJabbers (receive errors)
- extremeRtStatsCollisions (transmit errors)

Configuring RMON

RMON requires one probe per LAN segment, and stand-alone RMON probes traditionally have been expensive. Therefore, the approach taken by Extreme Networks has been to build an inexpensive RMON probe into the agent of each system. This allows RMON to be widely deployed around the network without costing more than traditional network management. The switch accurately maintains RMON statistics at the maximum line rate of all of its ports.

By default, RMON is disabled. However, even in the disabled state, the switch collects etherStats and you can configure alarms and events.

RMON saves the history, alarm, and event configurations to the configuration file. Runtime data is not stored in the configuration file and is subsequently lost after a system restart.

- Enable or disable the collection of RMON statistics on the switch using the commands:
  ```
  enable rmon
  disable rmon
  ```

By enabling RMON, the switch begins the processes necessary for collecting switch statistics.

Event Actions

The actions that you can define for each alarm are shown in Table 59.

Table 59: Event Actions

Action	High Threshold
no action	
log	Sends a log message.
log-and-trap	Sends both a log message and a trap to all trap receivers.
snmp-trap	Sends a trap to all trap receivers.

To be notified of events using *SNMP* traps, you must configure one or more trap receivers, as described in Using the Simple Network Management Protocol on page 110.

Display RMON Information

- View the status of RMON polling on the switch (the enable/disable state for RMON polling) using the command:

  ```
  show switch management
  ```

- View the RMON memory usage statistics for a specific RMON feature (for example, statistics, events, logs, history, or alarms) or for all features using the command:

  ```
  show rmon memory {detail | memoryType}
  ```

SMON

SMON is the common abbreviation for the Switch Network Monitoring Management Information Base (MIB) system defined by the Internet Engineering Task Force (IETF) document RFC 2613.

SMON is a set of MIB extensions for RMON that allows monitoring of switching equipment from a *SNMP* Manager in greater detail. The supported MIB tables are described in Supported Standards, Protocols, and MIBs on page 2017; smonPrioStatsControlTable and smonPrioStatsTable cannot be supported due to hardware limitations.

> **Note**
>
> When you delete all the mirroring filters through the portCopyConfigTable, the mirroring is disabled automatically.

Monitoring CPU Utilization

You can monitor the CPU utilization and history for all of the processes running on the switch.

By viewing this history on a regular basis, you can see trends emerging and identify processes with peak utilization. Monitoring the workload of the CPU allows you to troubleshoot and identify suspect processes before they become a problem. By default, the switch monitors CPU utilization every five seconds. In addition, when CPU utilization of a process exceeds 90% of the regular operating basis, the switch logs an error message specifying the process name and the current CPU utilization for the process.

Disabling CPU Monitoring

- Disable CPU monitoring using the command:

  ```
  disable cpu-monitoring
  ```

This command disables CPU monitoring on the switch; it does not clear the monitoring interval. Therefore, if you altered the monitoring interval, this command does not return the monitoring interval to five seconds. The next time you enable CPU monitoring, the switch uses the existing configured interval.

Enable CPU Monitoring

By default, CPU monitoring is enabled and occurs every five seconds. The default CPU threshold value is 90%.

- Enable CPU monitoring using the command:

  ```
  enable cpu-monitoring {interval seconds} {threshold percent}
  ```

  Where the following is true:

  ○ *seconds*—Specifies the monitoring interval. The default interval is 5 seconds, and the range is 5 to 60 seconds. We recommend the default setting for most network environments.
  ○ **threshold**—Specifies the CPU threshold value. CPU usage is measured in percentages. The default is 90%, and the range is 0% to 100%.

Displaying CPU Utilization History

- Display the CPU utilization history of one or more processes using the command:

  ```
  show cpu-monitoring {process name} {slot slotid}
  ```

  Where the following is true:

  ○ **name**—Specifies the name of the process.
  ○ **slot**—On a SummitStack, specifies the slot number of the target node. The number is a value from one (1) to eight (8).

Output from this command includes the following information:

- ◦ Process—The name of the process.
- ◦ Range of time (five seconds, ten seconds, and so forth)—The CPU utilization history of the process or the system. The CPU utilization history goes back only 1 hour.
- ◦ Total User/System CPU Usage—The amount of time recorded in seconds that the process spends occupying CPU resources. The values are cumulative meaning that the values are displayed as long as the system is running. You can use this information for debugging purposes to see where the process spends the most amount of time: user context or system context.
- • Clear the utilization history stored in the switch and reset the statistics to zero using the command:

  ```
  clear cpu-monitoring {process name} {slot slotid}
  ```

The following is sample truncated output from a switch:

```
X460G2-48p-G4.1 # show cpu-monitoring

        CPU Utilization Statistics - Monitored every 5 seconds
    ------------------------------------------------------------------------

    Process        5   10   30   1    5    30   1    Max           Total
                  secs secs secs min  mins mins hour              User/System
                  util util util util util util util util        CPU Usage

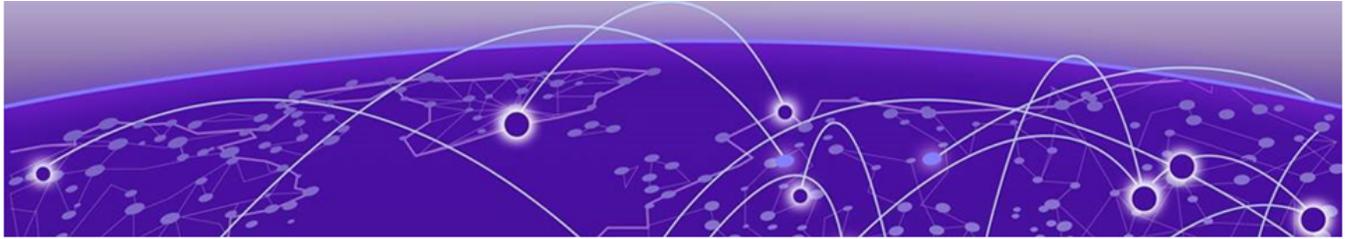
```


VLANs

This chapter contains information about configuring _VLAN (Virtual LAN)_s, displaying VLAN information, private VLANs, and VLAN translation. In addition, you can learn about the benefits and types of VLANs, along with valuable information about virtual routers.

VLANs Overview

Setting up _VLAN_s on the switch eases many time-consuming tasks of network administration while increasing efficiency in network operations.

> **Note**
> The software supports using IPv6 addresses, in addition to IPv4 addresses. You can configure the VLAN with an IPv4 address, IPv6 address, or both. See IPv6 Unicast Routing on page 1615 for complete information on using IPv6 addresses.

The term _VLAN_ is used to refer to a collection of devices that communicate as if they were on the same physical LAN.

> **Note**
> ExtremeXOS supports only 4,092 user-configurable VLANs. (VLAN 1 is the default VLAN, and 4,095 is the management VLAN, and you may not configure them.

Any set of ports (including all ports on the switch) is considered a VLAN. LAN segments are not restricted by the hardware that physically connects them. The segments are defined by flexible user groups that you create with the command line interface (CLI).

> **Note**
> The system switches traffic within each VLAN using the Ethernet MAC address. The system routes traffic between two VLANs using the IP addresses.

Benefits

Implementing *VLAN*s on your networks has the following advantages:

- **VLANs help to control traffic**—With traditional networks, broadcast traffic that is directed to all network devices, regardless of whether they require it, causes congestion. VLANs increase the efficiency of your network because each VLAN can be set up to contain only those devices that must communicate with each other.
- **VLANs provide extra security**—Devices within each VLAN can communicate only with member devices in the same VLAN. If a device in VLAN Marketing must communicate with devices in VLAN Sales, the traffic must cross a routing device.
- **VLANs ease the change and movement of devices**—With traditional networks, network administrators spend much of their time dealing with moves and changes. If users move to a different subnetwork, the addresses of each endstation must be updated manually.

Virtual Routers and VLANs

The ExtremeXOS software supports virtual routers. Each port can belong to multiple *virtual router (VR)*s. Ports can belong to different *VLAN*s that are in different virtual routers.

If you do not specify a virtual router when you create a VLAN, the system creates that VLAN in the default virtual router (*VR-Default*). The management VLAN is always in the management virtual router (*VR-Mgmt*).

After you create virtual routers, the ExtremeXOS software allows you to designate one of these virtual routers as the domain in which all your subsequent configuration commands, including VLAN commands, are applied. After you create virtual routers, ensure that you are creating each VLAN in the desired virtual router domain. Also, ensure that you are in the correct virtual router domain before you begin modifying each VLAN.

For information on configuring and using virtual routers, see Virtual Routers on page 723.

Types of VLANs

This section introduces the following types of VLANs:

- Port-Based VLANs
- Tagged VLANs
- Protocol-Based VLANs
- XNV Dynamic VLAN on page 684

> **Note**
> You can have netlogin dynamic VLANs and netlogin MAC-based VLANs. See Network Login on page 897 for complete information on netlogin.

VLANs can be created according to the following criteria:

- Physical port
- IEEE 802.1Q tag
- Ethernet, LLC SAP, or LLC/SNAP Ethernet protocol type
- A combination of these criteria

Port-Based VLANs

In a port-based *VLAN*, a VLAN name is given to a group of one or more ports on the switch.

At boot-up, all ports are members of the port-based VLAN default. Before you can add any port to another port-based VLAN, you must remove it from the default VLAN, unless the new VLAN uses a protocol other than the default protocol any. An untagged port can be a member of only one port-based VLAN.

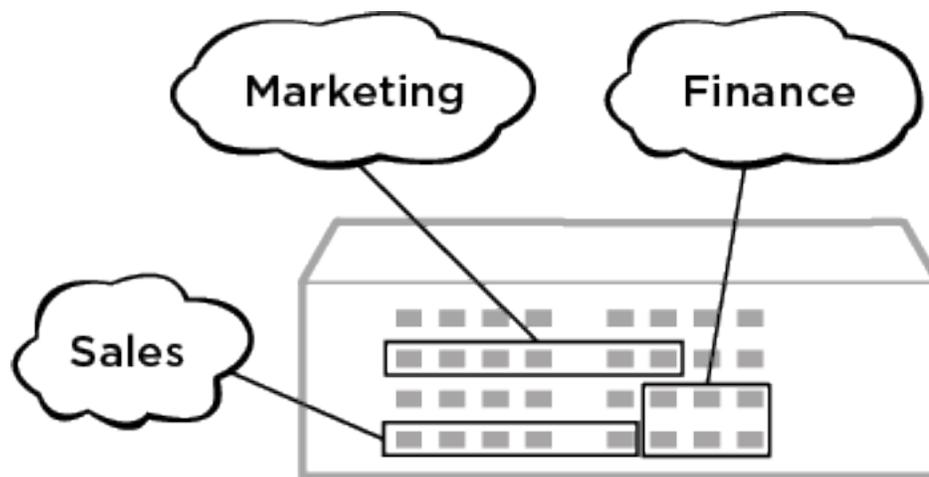
On the Extreme Networks switch in Figure 63, ports 9 through 14 are part of VLAN Marketing; ports 25 through 29 are part of VLAN Sales; and ports 21 through 24 and 30 through 32 are in VLAN Finance.


Figure 63: Example of a Port-Based VLAN on an Extreme Networks Switch

For the members of different IP VLANs to communicate, the traffic must be routed by the switch, even if the VLANs are physically part of the same switch. This means that each VLAN must be configured as a router interface with a unique IP address.

Spanning Switches with Port-Based VLANs

To create a port-based *VLAN* that spans two switches, you must do two things:

1. Assign the port on each switch to the VLAN.

2. Cable the two switches together using one port on each switch per VLAN.

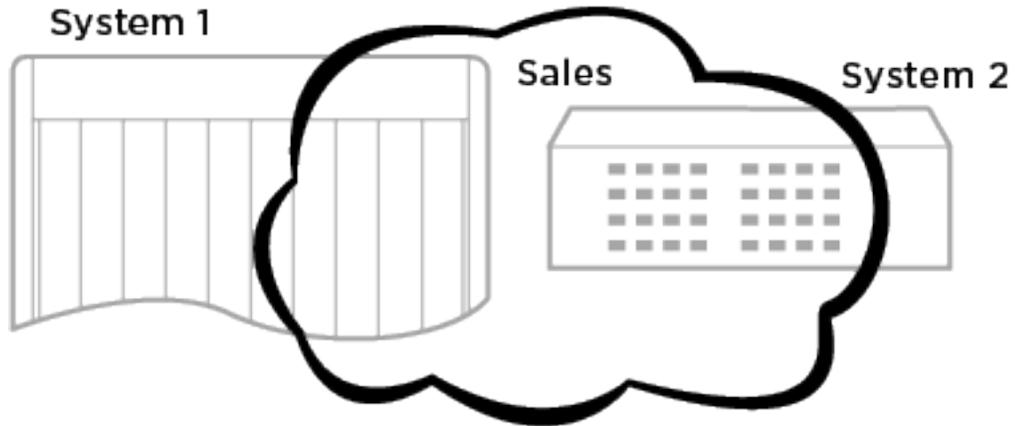
   Figure 64 illustrates a single VLAN that spans a BlackDiamond switch and another Extreme Networks switch. All ports on the System 1 switch belong to VLAN Sales. Ports 1 through 29 on the system 2 switch also belong to VLAN Sales. The two switches are connected using slot 8, port 4 on System 1 (the BlackDiamond switch), and port 29 on system 2 (the other switch).


Figure 64: Single Port-based VLAN Spanning Two Switches

3. To create multiple VLANs that span two switches in a port-based VLAN, a port on System 1 must be cabled to a port on System 2 for each VLAN you want to have span across the switches.
   At least one port on each switch must be a member of the corresponding VLANs as well.

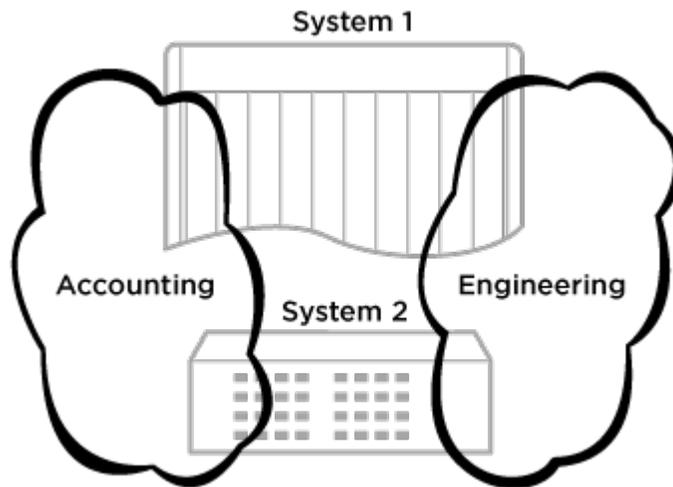
   Figure 65 illustrates two VLANs spanning two switches. On System 2, ports 25 through 29 are part of VLAN Accounting; ports 21 through 24 and ports 30 through 32 are part of VLAN Engineering. On System 1, all ports on slot 1 are part of VLAN Accounting; all ports on slot 8 are part of VLAN Engineering.


Figure 65: Two Port-Based VLANs Spanning Two Switches

VLAN Accounting spans System 1 and System 2 by way of a connection between System 2, port 29 and System 1, slot 1, port 6. VLAN Engineering spans System 1 and System 2 by way of a connection between System 2, port 32, and System 1, slot 8, port 6.

4. Using this configuration, you can create multiple port-based VLANs that span multiple switches, in a daisy-chained fashion.

Tagged VLANs

Tagging is a process that inserts a marker (called a tag) into the Ethernet frame. The tag contains the identification number of a specific *VLAN*, called the VLANid (valid numbers are 1 to 4094).

> **Note**
> The use of 802.1Q tagged packets may lead to the appearance of packets slightly bigger than the current IEEE 802.3/Ethernet maximum of 1,518 bytes. This may affect packet error counters in other devices and may also lead to connectivity problems if non-802.1Q bridges or routers are placed in the path.

Uses of Tagged VLANs

Tagging is most commonly used to create VLANs that span switches.

The switch-to-switch connections are typically called *trunks*. Using tags, multiple VLANs can span multiple switches using one or more trunks. In a port-based VLAN,

each VLAN requires its own pair of trunk ports, as shown in Figure 66 on page 589. Using tags, multiple VLANs can span two switches with a single trunk.

Another benefit of tagged VLANs is the ability to have a port be a member of multiple VLANs. This is particularly useful if you have a device (such as a server) that must belong to multiple VLANs. The device must have a Network Interface Card (NIC) that supports IEEE 802.1Q tagging.

A single port can be a member of only one port-based VLAN. All additional VLAN membership for the port must be accompanied by tags.

Assigning a VLAN Tag

Each VLAN may be assigned an 802.1Q VLAN tag. As ports are added to a VLAN with an 802.1Q tag defined, you decide whether each port uses tagging for that VLAN. The default mode of the switch is to have all ports assigned to the VLAN named default with an 802.1Q VLAN tag (VLANid) of 1 assigned.

Not all ports in the VLAN must be tagged. As traffic from a port is forwarded out of the switch, the switch determines (in real time) if each destination port should use tagged or untagged packet formats for that VLAN. The switch adds and strips tags, as required, by the port configuration for that VLAN.

> **Note**
> Packets arriving tagged with a VLANid that is not configured on a port are discarded.

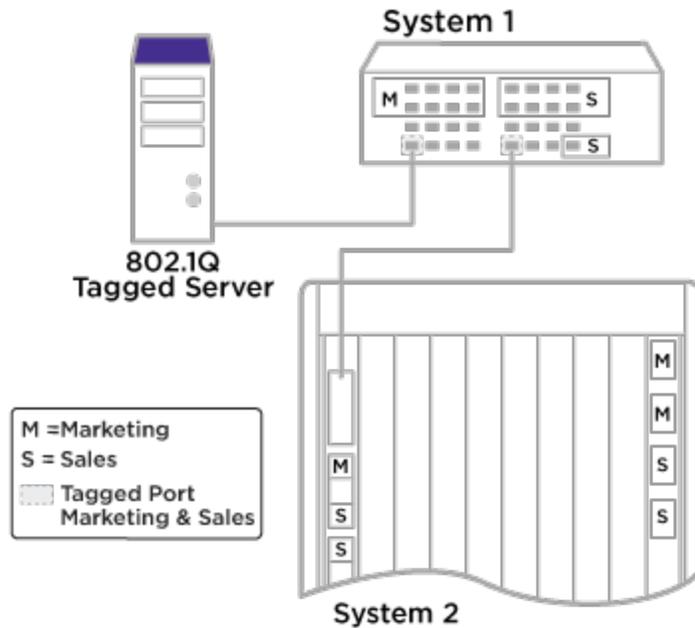
Figure 66 illustrates the physical view of a network that uses tagged and untagged traffic.


Figure 66: Physical Diagram of Tagged and Untagged Traffic

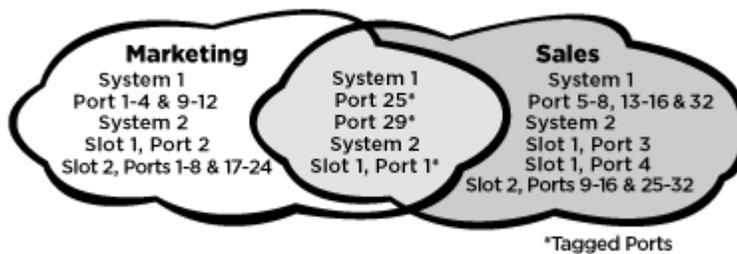
Figure 67 is a logical diagram of the same network.


Figure 67: Logical Diagram of Tagged and Untagged Traffic

In the figures above:

- The trunk port on each switch carries traffic for both VLAN Marketing and VLAN Sales.
- The trunk port on each switch is tagged.
- The server connected to port 25 on System 1 has a NIC that supports 802.1Q tagging.
- The server connected to port 25 on System 1 is a member of both VLAN Marketing and VLAN Sales.
- All other stations use untagged traffic.

As data passes out of the switch, the switch determines if the destination port requires the frames to be tagged or untagged. All traffic coming from and going to the server is tagged. Traffic coming from and going to the trunk ports is tagged. The traffic that comes from and goes to the other stations on this network is not tagged.

Mixing Port-Based and Tagged VLANs

You can configure the switch using a combination of port-based and tagged VLANs. A given port can be a member of multiple VLANs, with the stipulation that only one of its VLANs uses untagged traffic. In other words, a port can simultaneously be a member of one port-based VLAN and multiple tag-based VLANs.

> **Note**
> For the purposes of VLAN classification, packets arriving on a port with an 802.1Q tag containing a VLANid of 0 are treated as untagged.

Protocol-Based VLANs

Protocol-based _VLANs_ enable you to define a packet filter that the switch uses as the matching criteria to determine if a particular packet belongs to a particular VLAN.

Protocol-based VLANs are most often used in situations where network segments contain hosts running multiple protocols. For example, in Figure 68, the hosts are running both the IP and NetBIOS protocols.

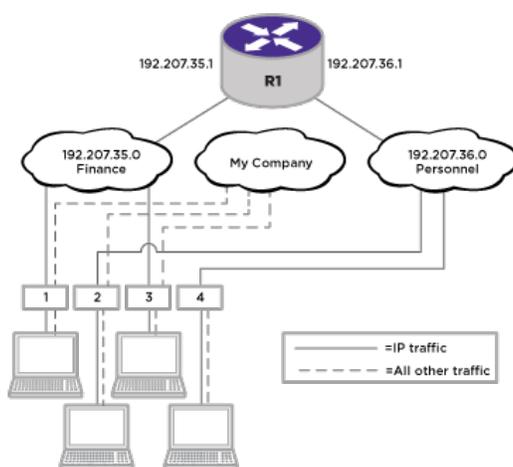
The IP traffic has been divided into two IP subnets, 192.207.35.0 and 192.207.36.0. The subnets are internally routed by the switch. The subnets are assigned different VLAN names, Finance and Personnel, respectively. The remainder of the traffic belongs to the VLAN named MyCompany. All ports are members of the VLAN MyCompany.


Figure 68: Protocol-Based VLANs

The following sections provide information on using protocol-based VLANs:

- Predefined Protocol Filters on page 591
- Defining Protocol Filters on page 591
- Configuring a VLAN to Use a Protocol Filter on page 592
- Deleting a Protocol Filter on page 592

Predefined Protocol Filters

The following protocol filters are predefined on the switch:

- IP (IPv4)
- IPv6 (11.2 IPv6)
- MPLS
- IPX
- NetBIOS
- DECNet
- IPX_8022
- IPX_SNAP
- AppleTalk

Defining Protocol Filters

If necessary, you can define a customized protocol filter by specifying EtherType, Logical Link Control (LLC), or Subnetwork Access Protocol (SNAP). Up to six protocols can be part of a protocol filter. To define a protocol filter:

1. Create a protocol using the following command:

   ```
   create protocol_name
   ```

   For example: `create protocol fred`

   The protocol name can have a maximum of 32 characters.

2. Configure the protocol using the following command:

   ```
   configure protocol_name add [etype | llc | snap] hex {[etype | llc |
   snap] hex}
   ```

   Supported protocol types include:

   etype—EtherType

   The values for **etype** are four-digit hexadecimal numbers taken from a list maintained by the IEEE. This list can be found at the following URL: http://standards.ieee.org/regauth/ethertype/index.html.

   > **Note**
   > Protocol-based *VLAN* for Etype from 0x0000 to 0x05ff are not classifying as per filter. When traffic arrive with these Etypes, it is classifed to native VLAN rather protocol based vlan.

   llc—LLC Service Advertising Protocol (SAP)

   The values for **llc** are four-digit hexadecimal numbers that are created by concatenating a two-digit LLC Destination SAP (DSAP) and a two-digit LLC Source SAP (SSAP).

   snap—EtherType inside an IEEE SNAP packet encapsulation

The values for **snap** are the same as the values for **etype**, described previously. For example:

```
configure protocol fred add llc feff
configure protocol fred add snap 9999
```

A maximum of 16 customized protocol filters can be active at a time.

> **Note**
> For more information about SNAP for Ethernet protocol types, see TR 11802-5:1997 (ISO/IEC) [ANSI/IEEE std. 802.1H, 1997 Edition].

Configuring a VLAN to Use a Protocol Filter

To configure a *VLAN* to use a protocol filter, use the following command:.

```
configure {vlan} [vlan_name |vlan_list] protocol {filter}filter_name
```

Deleting a Protocol Filter

If a protocol filter is deleted from a *VLAN*, the VLAN is assigned a protocol filter of 'any'. You can continue to configure the VLAN. However, no traffic is forwarded to the VLAN until a protocol is assigned to it.

Precedence of Tagged Packets Over Protocol Filters

If a *VLAN* is configured to accept tagged packets on a particular port, incoming packets that match the tag configuration take precedence over any protocol filters associated with the VLAN.

Default VLAN

The default switch configuration includes one default *VLAN* that has the following properties:

- The VLAN name is default.
- It contains all the ports on a new or initialized switch.
- The default VLAN is untagged on all ports. It has an internal VLANid of 1; this value is user-configurable.

VLAN Names

VLAN names must conform to the guidelines listed in Object Names on page 37.

VLAN names can be specified using the **[Tab]** key for command completion. VLAN names are locally significant. That is, VLAN names used on one switch are only meaningful to that switch. If another switch is connected to it, the VLAN names have no significance to the other switch.

> **Note**
> We recommend that you use VLAN names consistently across your entire network.

You must use mutually exclusive names for the following:

- VLANs
- VMANs
- IPv6 tunnels
- SVLANs
- CVLANs
- BVLANs

Configuring VLANs on the Switch

Refer to the following sections for instruction on configuring VLANs on a switch:

VLAN Configuration Overview

The following procedure provides an overview of _VLAN_ creation and configuration:

1. Create and name the VLAN.

   `create [ {`**`vlan`**`}` _`vlan_name`_ `|` **`vlan`** _`vlan_list`_`]` `{`**`tag`** _`tag`_ `}` `{`**`description`** _`vlan-description`_ `}` `{`**`vr`** _`name`_ `}`

2. If needed, assign an IP address and mask (if applicable) to the VLAN as described in
3. If any ports in this VLAN will use a tag, assign a VLAN tag.

   `configure {`**`vlan`**`}` _`vlan_name`_ **`tag`** _`tag`_ `{`**`remote-mirroring`**`}`

4. Assign one or more ports to the VLAN.

   `configure {`**`vlan`**`} [`_`vlan_name`_ `|` _`vlan_list`_`] add ports [`_`port_list`_ `|` **`all`**`]` `{`**`tagged`** _`tag`_ `|` **`untagged`**`} {{`**`stpd`**`}` _`stpd_name`_`} {`**`dot1d`** `|` **`emistp`** `|` **`pvst-plus`**`}}`

   As you add each port to the VLAN, decide if the port will use an 802.1Q tag.

5. For the management VLAN on the switch, configure the default IP route for _VR VR-Mgmt_.

   > **Note**
   > See IPv4 Unicast Routing on page 1557 for information on configuring default IP routes or adding secondary IP addresses to VLANs.

VLAN ID and VLAN ID List Specification

As of ExtremeXOS 16.1, you can now refer to a *VLAN* by VID as an alternative. Specifying lists of VIDs is a is a useful shortcut to all users that can reduce the number of commands required to configure the switch.

For example consider a case where two ports should be added to four tagged VLANs. Normally this would require four commands:

```
configure vlan red add ports 2,10 tagged

configure vlan blue add ports 2,10 tagged

configure vlan green add ports 2,10 tagged

configure vlan orange add ports 2,10 tagged
```

Assuming the tags for the VLANs are 100, 200, 300, 400 respectively this configuration can be accomplished with a single command:

```
configure vlan 100,200,300,400 add ports 2, 10 tagged
```

> **Note**
> Commands enhanced with VID list support operate in a "best effort" fashion. If one of the VIDs in a VID list do not exist the command is still executed for all of the VIDs in the list that do exist. No error or warning is displayed for the invalid VIDs unless all of the specified VIDs are in valid.

Creating and Deleting VLANs

- To create a *VLAN*, use the following command:
  ```
  create [ {vlan} vlan_name | vlan vlan_list] {tag tag } {description
  vlan-description } {vr name }
  ```
- To delete a VLAN, use the following command:
  ```
  delete vlan vlan_name | vlan_list
  ```

Managing a VLAN IP Address

> **Note**
> If you plan to use this *VLAN* as a control VLAN for an *EAPS (Extreme Automatic Protection Switching)* domain, do not assign an IP address to the VLAN.

- Configure an IP address and mask for a VLAN.

> **Note**
> IPv4 addresses with 31-bit prefixes can be configured on network VLANs and the management VLAN. Applications and protocols can use these IPv4 addresses.

```
configure [ {vlan} vlan_name | vlan vlan_id] ipaddress [ipaddress
{netmask} | {ipNetmask} | ipv6-link-local | {eui64} ipv6_address_mask]
```

> **Note**
>
> Each IP address and mask assigned to a VLAN must represent a unique IP subnet. You cannot configure the same IP subnet on different VLANs on the same _VR_.
>
> The software supports using IPv6 addresses, in addition to IPv4 addresses. You can configure the VLAN with an IPv4 address, IPv6 address, or both. See IPv6 Unicast Routing on page 1615 for complete information on using IPv6 addresses.

- Remove an IP address and mask for a VLAN.

```
unconfigure [ {vlan} vlan_name | vlan vlan_id]ipaddress
{ipv6_address_mask}
```

Configuring a VLAN Tag

To configure a _VLAN_, use the following command:

```
configure {vlan} vlan_name tag tag {remote-mirroring}
```

Adding and Removing Ports from a VLAN

- To add ports to a _VLAN_, use the following command:

```
configure {vlan} [vlan_name | vlan_list] add ports [port_list | all]
{tagged tag | untagged} {{stpd} stpd_name} {dot1d | emistp | pvst-
plus}}
```

The system returns the following message if the ports you are adding are already _EAPS_ primary or EAPS secondary ports:

```
WARNING: Make sure Vlan1 is protected by EAPS, Adding EAPS ring ports to a VLAN could
cause a loop in the network.
Do you really want to add these ports? (y/n)
```

The system returns the following message if the ports that you are adding are untagged ports already associated with an untagged VLAN, and you are adding them to a different untagged VLAN or tagged VLAN

```
Port 1 untagged has been auto-moved from VLAN "Default" to "v2".
```

You can enable direct movement of untagged ports by enabling auto-move globally with the `configure vlan untagged-ports auto-move [on | off |inform]` command.

- To remove ports from a VLAN, use the following command:

```
configure {vlan} [vlan_name | vlan_list] delete ports [all | port_list
{tagged tag}]
```

Adding and Removing VLAN Descriptions

A _VLAN_ description is a string of up to 64 characters that you can configure to describe the VLAN. It is displayed by several show vlan commands and can be read by using _SNMP (Simple Network Management Protocol)_ to access the VLAN's ifAlias MIB object.

- To add a description to a VLAN, use the following command:

  `configure {`**`vlan`**`}` _`vlan_name`_ **`description`** [_`vlan-description`_ | **`none`**]

- To remove a description from a VLAN, use the following command

  `unconfigure {`**`vlan`**`}` _`vlan_name`_ **`description`**

Renaming a VLAN

To rename an existing _VLAN_, use the following command:

`configure {`**`vlan`**`}` _`vlan_name`_ | _`vlan_id`_ **`name`** _`name`_

The following rules apply to renaming VLANs:

- You cannot change the name of the default VLAN.
- You cannot create a new VLAN named default.

Enabling and Disabling VLANs

You can enable or disable individual _VLAN_s. The default setting is that all VLANs are enabled.

Consider the following guidelines before you disable a VLAN:

- Disabling a VLAN stops all traffic on all ports associated with the specified VLAN.
- You cannot disable any VLAN that is running any Layer 2 protocol traffic.

  When you attempt to disable a VLAN running Layer 2 protocol traffic (for example, the VLAN Accounting), the system returns a message similar to the following:

  `VLAN accounting cannot be disabled because it is actively used by an L2 Protocol`

- You can disable the default VLAN; ensure that this is necessary before disabling the default VLAN.
- You cannot disable the management VLAN.
- You cannot bind Layer 2 protocols to a disabled VLAN.
- You can add ports to and delete ports from a disabled VLAN.

1. Disable a VLAN by running:

   `disable vlan` _`vlan_name`_ | _`vlan_list`_

2. After you have disabled a VLAN, re-enable that VLAN.

   `enable vlan` _`vlan_name`_ | _`vlan_list`_

VLAN Configuration Examples

> **Note**
> To add an untagged port to a _VLAN_ you create, you must first delete that port from the default VLAN. If you attempt to add an untagged port to a VLAN before deleting it from the default VLAN, you see the following error message:
> ```
> Error: Protocol conflict when adding untagged port 1:2. Either add this port as
> tagged or assign another protocol to this VLAN.
> ```

The following example creates a port-based VLAN named accounting:

```
create vlan accounting
configure accounting ipaddress 132.15.121.1
configure default delete port 2:1-2:3,2:6,4:1,4:2
configure accounting add port 2:1-2:3,2:6,4:1,4:2
```

> **Note**
> Because VLAN names are unique, you do not need to enter the keyword **vlan** after you have created the unique VLAN name. You can use the VLAN name alone (unless you are also using this name for another category such as _STPD (Spanning Tree Domain)_ or _EAPS_, in which case we recommend including the keyword **vlan**).

The following stand-alone switch example creates a port-based VLAN named development with an IPv6 address:

```
create vlan development
configure development ipaddress 2001:0DB8::8:800:200C:417A/64
configure default delete port 1-3
configure development add port 1-3
```

The following example creates a protocol-based VLAN named ipsales.

Slot 5, ports 6 through 8, and slot 6, ports 1, 3, and 4-6 are assigned to the VLAN. In this example, you can add untagged ports to a new VLAN without first deleting them from the default VLAN, because the new VLAN uses a protocol other than the default protocol.

```
create vlan ipsales
configure ipsales protocol ip
configure ipsales add port 5:6-5:8,6:1,6:3-6:6
```

The following example defines a protocol filter, myprotocol and applies it to the VLAN named myvlan. This is an example only, and has no real-world application.

```
create protocol myprotocol
configure protocol myprotocol add etype 0xf0f0
configure protocol myprotocol add etype 0xffff
create vlan myvlan
configure myvlan protocol myprotocol
```

To disable the protocol-based VLAN (or any VLAN) in the above example, use the following command:

```
disable vlan myprotocol
```

To re-enable the VLAN, use the following command:

```
enable vlan myprotocol
```

IP and MAC Anycast

The IP and MAC anycast feature enables you to configure the anycast gateway MAC to be used by VLANs that enable IP anycast. Using this feature, you can set the same IP address and MAC address on all edge technology devices. This allows seamless IP mobility in the network for edge devices.

> **Note**
> IP and MAC anycast should be used only with VXLAN tenant VLANs. IP and MAC anycast should not be used with any protocols other than MLAG, since it might cause MAC flaps.

> **Note**
> Switching through a VXLAN tunnel to a remote L3 Anycast gateway is not supported.

To configure IP/MAC anycast:

1. Enable IP anycast on the desired VLANs by using the following command:

   ```
   enable ip anycast {vlan} vlan_name
   ```

2. Specify the anycast gateway MAC address that is used by VLANs that enable IP anycast by using the following command:

   ```
   configure ip anycast mac [none | mac]
   ```

3. To specify that configured secondary IP addresses respond to ARP requests with the anycast MAC address, use the following command and specify the **anycast** option:

   ```
   configure [ {vlan} vlan_name | vlan vlan_id]add secondary-ipaddress
   anycast [ip_address {netmask} | ipNetmask]
   ```

4. To configure a source VLAN to use as the source IP address in the BOOTPrelay packet, use the following command:

   ```
   configure bootprelay dhcp-agent source-vlan {vlan_name} {vr vrid}
   ```

5. To enable or disable a reply to multicast or anycast echo requests, use the following commands:

   ```
   enable icmp ipv6 [ignore-multicasts | ignore-anycasts]
   ```

   ```
   disable icmp ipv6 [ignore-multicasts | ignore-anycasts]
   ```

To view IP and MAC anycast information:

- For IP anycast status (enabled or disabled), use the following command:

```
show vlan {virtual-router vr-name}
```
• For IP anycast MAC information, use the following command:

```
show ipconfig {ipv4} {vlan vlan_name | tunnel tunnel_name}
```
• For IPv6 anycast MAC information, use the following command:

```
show ipconfig ipv6 {vlan vlan_name | tunnel tunnel_name}
```
• To view configured secondary IP addresses on a VLAN, use the following command:

```
show vlan {virtual-router vr-name}
```
• To view the selected source VLAN for BOOTPrelay, use the command `show bootprelay configuration {ipv4 | ipv6} {{vlan vlan_name } | {vr vr_name}}` .

• To view configuration information for ICMP multicast and anycast echo requests, use the following command:

```
show ipconfig ipv6
```

Displaying VLAN Information

To display general *VLAN* settings and information, use the following commands:
• `show vlan {virtual-router vr-name}`
• `show vlan vlan_name {ipv4 | ipv6}`
• `show vlan [tag tag | detail] {ipv4 | ipv6}`
• `show vlan description`
• `show vlan {vlan_name | vlan_list} statistics {no-refresh | refresh }`

> **Note**
> To display IPv6 information, you must use either the show vlan detail command or show vlan command with the name of the specified VLAN.

To display the VLAN information for other ExtremeXOS software features, use the following commands:
• `show {vlan} vlan_name dhcp-address-allocation`
• `show {vlan} vlan_name dhcp-config`
• `show {vlan} vlan_name eaps`
• `show {vlan} vlan_name security`
• `show {vlan} {vlan_name | vlan_list} stpd`

You can display additional useful information on VLANs configured with IPv6 addresses by issuing the command:

```
show ipconfig ipv6 vlan vlan_name
```

To isplay protocol information, issue the command:

```
show protocol {name}
```

Private VLANs

The following sections provide detailed information on private VLANs:

- PVLAN Overview on page 600
- Configuring PVLANs on page 609
- Displaying PVLAN Information on page 612
- PVLAN Configuration Example 1 on page 613
- PVLAN Configuration Example 2 on page 615

PVLAN Overview

PVLANs offer the following features:

- VLAN translation
- VLAN isolation

> **Note**
> PVLAN features are supported only on the platforms listed for this feature in the *ExtremeXOS 32.4 Feature License Requirements* document.

VLAN Translation in a PVLAN

VLAN translation provides the ability to translate the 802.1Q tags for several VLANs into a single VLAN tag. VLAN translation is an optional component in a PVLAN.

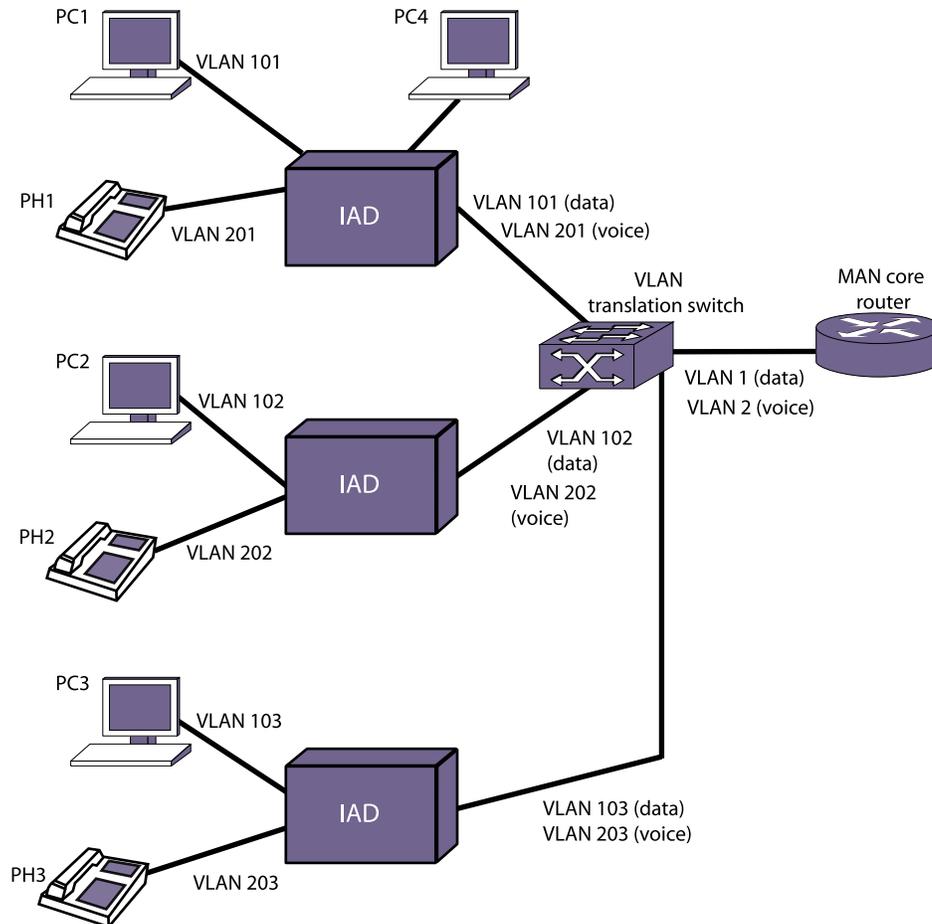
VLAN translation allows you to aggregate Layer 2 VLAN traffic from multiple clients into a single uplink VLAN, improving VLAN scaling. Figure 69 shows an application of VLAN translation.


Figure 69: VLAN Translation Application

In the figure, VLANs 101, 102, and 103 are subscriber VLANS that carry data traffic while VLANs 201, 202, and 203 are subscriber VLANs that carry voice traffic. The voice and data traffic are combined on integrated access devices (IADs) that connect to the VLAN translation switch. Each of the three clusters of phones and PCs uses two VLANs to separate the voice and data traffic. As the traffic is combined, the six VLANs are translated into two network VLANs, VLAN1 and VLAN2. This simplifies administration, and scales much better for large installations.

Conceptually, this is very similar to Layer 3 VLAN aggregation (superVLANS and subVLANs).

The primary differences between these two features are:

- VLAN translation is strictly a Layer 2 feature.
- VLAN translation does not allow communication between the subscriber VLANs.

VLAN Isolation

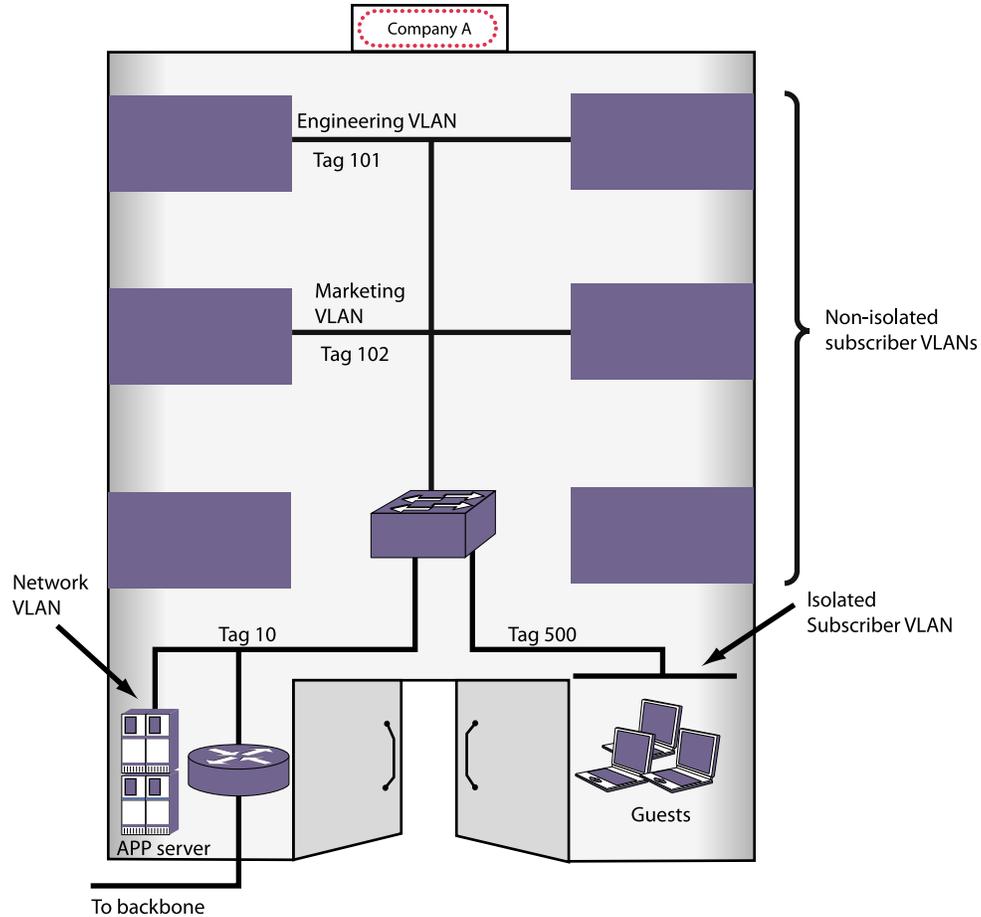
VLAN isolation provides Layer 2 isolation between the ports in a VLAN. shows an application of VLAN isolation.


Figure 70: VLAN Isolation Application

In this figure, ports in the Guest VLAN have access to services on the network VLAN, but Guest VLAN ports cannot access other Guest VLAN ports over Layer 2 (or the Marketing or Engineering VLANs). This provides port-to-port security at Layer 2.

PVLAN Components

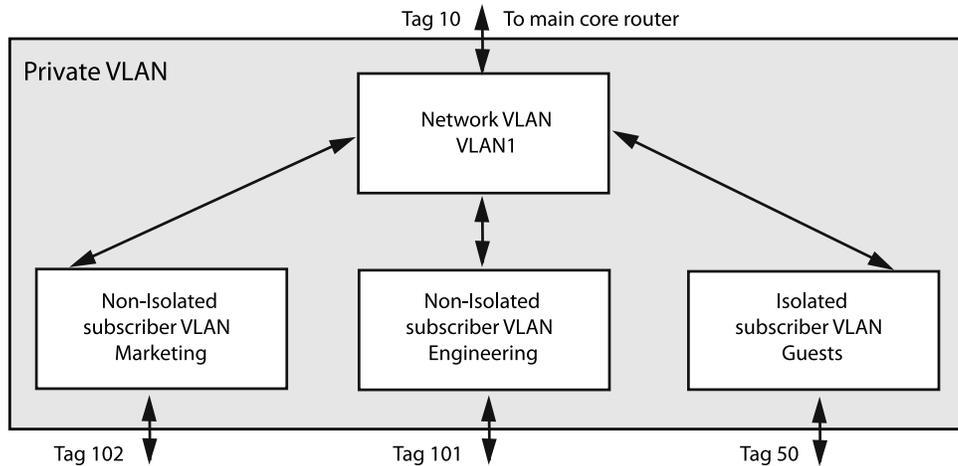
Figure 71 shows the logical components that support PVLAN configuration in a switch.


Figure 71: Private VLAN Switch Components

There is one network _VLAN_ in each PVLAN. Ports within a network VLAN, called network ports, can communicate with all VLAN ports in the PVLAN. Network devices that connect to the network VLAN ports are considered to be on the network side of the switch.

The network VLAN aggregates the uplink traffic from the other VLANS, called subscriber VLANs, for egress communications on a network VLAN port. A network port can serve only one PVLAN, but it can serve one or more subscriber VLANs. Ingress communications on the network VLAN port are distributed to the appropriate subscriber VLANs for distribution to the appropriate ports. Devices that connect to subscriber VLAN ports are considered to be on the subscriber side of the switch.

> **Note**
> PVLAN network-tagged packets are allowed to ingress on subscriber VLAN ports.

Tag translation within the PVLAN is managed at the egress ports. To enable tag translation for uplink traffic from the subscriber VLANs, you must enable tag translation on the appropriate network VLAN port. Tag translation is automatically enabled on subscriber VLAN egress ports when the subscriber VLAN is created and the port is added to the VLAN as tagged. Egress traffic from a subscriber VLAN is always tagged with the subscriber VLAN tag when the port is configured as tagged.

A non-isolated subscriber VLAN is basically a standard VLAN that can participate in tag translation through the network VLAN when VLAN translation is enabled on the network VLAN port.

You can choose to not translate tags on a network VLAN port, but this is generally used only for extending a PVLAN to another switch. A non-isolated subscriber VLAN that does not use tag translation is functionally equivalent to a regular VLAN, so it is better to create non-isolated VLANs only when you plan to use tag translation.

Ports in a non-isolated VLAN can communicate with other ports in the same VLAN, ports in the network VLAN, and destinations on the network side of the switch. As with

standard VLANs, non-isolated ports cannot communicate through Layer 2 with ports in other subscriber VLANs.

In Figure 71 on page 603, the Engineering and Marketing VLANs are configured as non-isolated subscriber VLANs, which means that they act just like traditional VLANs, and they can participate in tag translation when VLAN translation is enabled on a network VLAN port that leads to network side location.

VLAN isolation within the PVLAN is established by configuring a VLAN to be an isolated subscriber VLAN and adding ports to the isolated VLAN. Unlike normal VLANs, ports in an isolated VLAN cannot communicate with other ports in the same VLAN over Layer 2 or Layer 3. The ports in an isolated VLAN can, however, communicate with Layer 2 devices on the network side of the PVLAN through the network VLAN. When the network VLAN egress port is configured for tag translation, isolated VLAN ports also participate in uplink tag translation. When isolated subscriber VLAN ports are configured as tagged, egress packets are tagged with the isolated VLAN tag. As with standard VLANs and non-isolated VLANs, isolated ports cannot communicate through Layer 2 with ports in other subscriber VLANs.

PVLAN Support over Multiple Switches

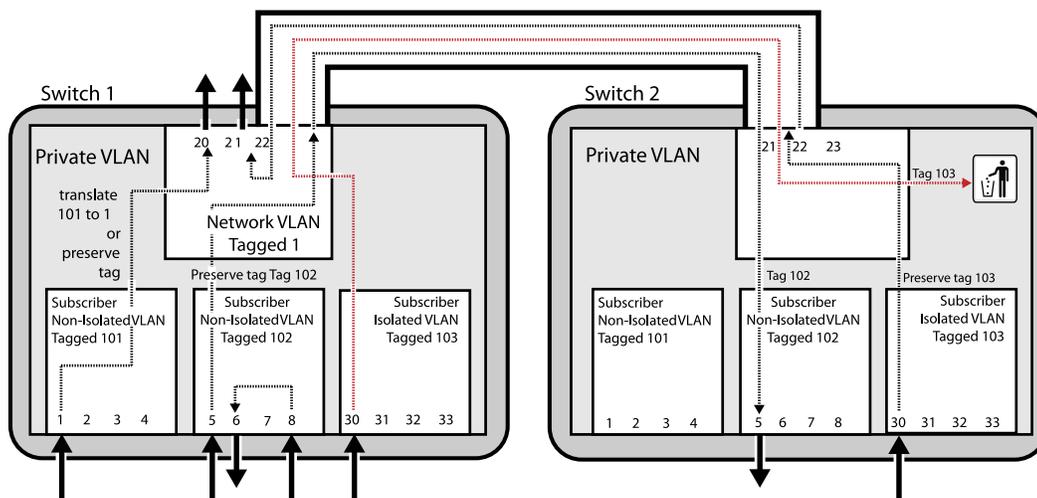
A PVLAN can span multiple switches. Figure 71 on page 603 shows a PVLAN that is configured to operate on two switches.


Figure 72: Private VLAN Support on Multiple Switches

A PVLAN can span many switches. For simplicity, this example shows only two switches, but you can extend the PVLAN to additional switches by adding connections between the network VLANs in each switch. The ports that connect two PVLAN switches must be configured as regular tagged ports. The network and subscriber VLANs on each switch must be configured with the same tags.

> **Note**
> Although using the same VLAN names on all PVLAN switches might make switch management easier, there is no software requirement to match the VLAN names. Only the tags must match.

When a PVLAN is configured on multiple switches, the PVLAN switches function as one PVLAN switch. Subscriber VLAN ports can access the network VLAN ports on any of the PVLAN switches, and non-isolated VLAN ports can communicate with ports in the same VLAN that are located on a different physical switch. An isolated VLAN can span multiple switches and maintain isolation between the VLAN ports.

The network and subscriber VLANs can be extended to other switches that are not configured for the PVLAN (as described in Extending Network and Subscriber VLANs to Other Switches on page 605). The advantage to extending the PVLAN is that tag translation and VLAN isolation is supported on the additional switch or switches.

Extending Network and Subscriber VLANs to Other Switches

A network or subscriber *VLAN* can be extended to additional switches without a PVLAN configuration on the additional switches.

You might want to do this to connect to existing servers, switches, or other network devices. You probably do not want to use this approach to support clients, as tag translation and VLAN isolation are not supported unless the PVLAN is configured on all PVLAN switches as described in PVLAN Support over Multiple Switches on page 604.

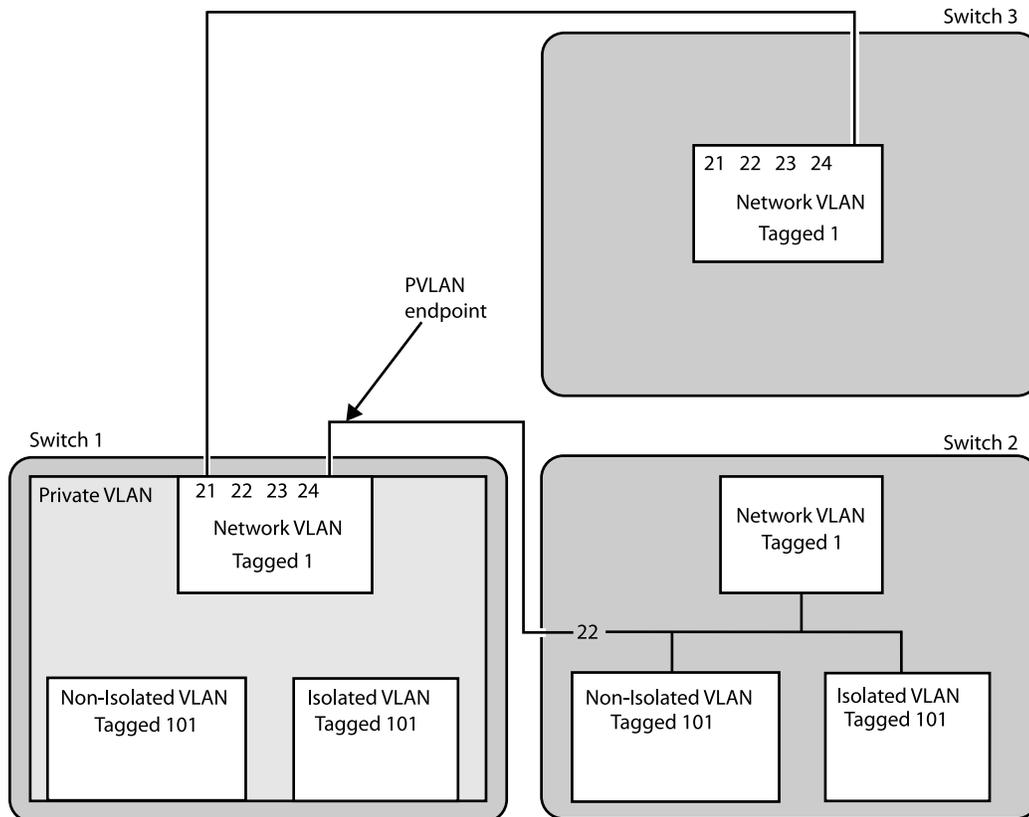
Figure 73 illustrates PVLAN connections to switches outside the PVLAN.


Figure 73: Private VLAN Connections to Switches Outside the PVLAN

In this configuration, Switch 1, Network VLAN Port 21 connects to a Switch 3 port that only supports the Network VLAN. The Network VLAN Port 21 on Switch 1 is configured as "translated," which translates subscriber VLAN tags to the network VLAN tag for

access to the Network VLAN extension on Switch 3. Switch 3, Port 24 is configured as tagged and only accepts traffic with the Network VLAN Tag. Switch 3 serves as an extension of the Network VLAN and can be used to connect to network devices such as servers or an internet gateway.

Switch 2, port 22 supports the Network, NonIsolated, and Isolated VLANs, but no PVLAN is configured.

Because port 22 supports multiple VLANs that are part of the PVLAN, and because these Switch 2 VLANs are not part of the PVLAN, Switch 1, port 24, must be configured as a PVLAN endpoint, which establishes the PVLAN boundary. Switch 2, port 22, is configured as a regular tagged VLAN port.

For most applications, it would be better to extend the PVLAN to Switch 2 so that the PVLAN features are available to the Switch 2 VLANs.

The configuration of Switch 2 behaves as follows:

- The Switch 2 NonIsolated VLAN ports can communicate with the NonIsolated VLAN ports on Switch 1, but they cannot participate in VLAN translation.
- The Switch 2 Isolated VLAN ports can communicate with other Switch 2 Isolated VLAN ports.
- The Switch 2 Isolated VLAN ports cannot participate in VLAN translation.
- The Switch 2 Isolated VLAN ports can receive broadcast and multicast info for the Isolated VLAN.
- Traffic is allowed from the Switch 1 Isolated VLAN ports to the Switch 2 Isolated VLAN ports.

MAC Address Management in a PVLAN

Each device that connects to a PVLAN must have a unique MAC address within the PVLAN. Each MAC address learned in a PVLAN requires multiple *FDB (forwarding database)* entries. For example, each MAC address learned in a non-isolated subscriber *VLAN* requires two FDB entries, one for the subscriber VLAN and one for the network VLAN. The additional FDB entries for a PVLAN are marked with the P flag in the `show fdb` command display.

The following sections describe the FDB entries created for the PVLAN components and how to estimate the impact of a PVLAN on the FDB table:

- Non-Isolated Subscriber VLAN
- Isolated Subscriber VLAN
- Network VLAN
- Calculating the Total FDB Entries for a PVLAN

Non-Isolated Subscriber VLAN

When a MAC address is learned on a non-isolated subscriber VLAN port, two entries are added to the FDB table:

- MAC address, non-isolated subscriber VLAN tag, and the port number
- MAC address, network VLAN tag, port number, and a special flag for tag translation

The network VLAN entry is used when traffic comes in from the network ports destined for an non-isolated port.

Isolated Subscriber VLAN

When a new MAC address is learned on an isolated subscriber VLAN port, two entries are added to the FDB table:

- MAC address, isolated subscriber VLAN tag, port number, and a flag that indicates that the packet should be dropped
- MAC address, network VLAN tag, port number, and a special flag for tag translation

Ports in the isolated VLAN do not communicate with one another.

If a port in the isolated VLAN sends a packet to another port in the same VLAN that already has an entry in the FDB, that packet is dropped. You can verify the drop packet status of an FDB entry by using the `show fdb` command. The D flag indicates that packets destined for the listed address are dropped.

The network VLAN entry is used when traffic comes in from the network ports destined for an isolated port.

Network VLAN

When a new MAC address is learned on a network VLAN port, the following entry is added to the FDB table: MAC address, network VLAN tag, and port number.

For every subscriber VLAN belonging to this PVLAN, the following entry is added to the FDB table: MAC address, subscriber VLAN tag, and port number

Calculating the Total FDB Entries for a PVLAN

The following formula can be used to estimate the maximum number of FDB entries for a PVLAN:

$FDBtotal = [(MACnon\text{-}iso + MACiso) * 2 + (MACnetwork * (VLANnon\text{-}iso + VLANiso + 1))]$

The formula components are as follows:

- MACnon-iso = number of MAC addresses learned on all the non-isolated subscriber VLANs
- MACiso = number of MAC addresses learned on all the isolated subscriber VLANs
- MACnetwork = number of MAC addresses learned on the network VLAN
- VLANnon-iso = number of non-isolated subscriber VLANs
- VLANiso = number of isolated subscriber VLANs

> **Note**
> The formula above estimates the worst-case scenario for the maximum number of FDB entries for a single PVLAN. If the switch supports additional PVLANs, apply the formula to each PVLAN and add the totals for all PVLANs. If the switch also support standard VLANs, there will also be FDB entries for the standard VLANs.

Layer 3 Communications

For PVLANs, the default switch configuration controls Layer 3 communications exactly as communications are controlled in Layer 2.

For example, Layer 3 communications is enabled between ports in a non-isolated subscriber *VLAN*, and disabled between ports in an isolated subscriber VLAN. Ports in a non-isolated subscriber VLAN cannot communicate with ports in other non-isolated subscriber VLANs.

You can enable Layer 3 communications between all ports in a PVLAN. For more information, see Managing Layer 3 Communications in a PVLAN on page 612.

PVLAN Limitations

The Private *VLAN* feature has the following limitations:

- Requires more *FDB* entries than a standard VLAN.
- VLAN tag duplication is not allowed.
- VLAN name duplication is not allowed.
- Each MAC address learned in a PVLAN must be unique. A MAC address cannot exist in two or more VLANs that belong to the same PVLAN.
- MVR cannot be configured on PVLANs.
- A VMAN cannot be added to a PVLAN.
- A PBB network (BVLAN) cannot be added to a PVLAN.
- *EAPS* control VLANs cannot be either subscriber or network VLANs.
- For PVLAN with *STP (Spanning Tree Protocol)* implementation, irrespective of port translation configuration in the Network VLAN, it is recommended to add both the Network VLAN and all subscriber VLANs to the STP.
- For PVLAN with EAPS implementation, irrespective of port translation configuration in the Network VLAN, it is recommended to add both the Network VLAN and all subscriber VLANs to the EAPS ring.
- *ESRP (Extreme Standby Router Protocol)* can only be configured on network VLAN ports (and not on subscriber VLAN ports). To support ESRP on the network VLAN, you must add all of the VLANs in the PVLAN to ESRP.
- There is no *NetLogin* support to add ports as translate to the network VLAN, but the rest of NetLogin and the PVLAN features do not conflict.
- *IGMP (Internet Group Management Protocol)* snooping is performed across the entire PVLAN, spanning all the subscriber VLANs, following the PVLAN rules. For VLANs that are not part of a PVLAN, IGMP snooping operates as normal.
- PVLAN and VPLS are not supported on the same VLAN.
- When two switches are part of the same PVLAN, unicast and multicast traffic require a tagged trunk between them that preserves tags (no tag translation).
- Subscriber VLANs in a PVLAN cannot exchange multicast data with VLANs outside the PVLAN and with other PVLANs. However, the network VLAN can exchange

multicast data with VLANs outside the PVLAN and with network VLANs in other PVLANs.

- PVLAN does not support IPv6.

> **Note**
> A maximum of 80% of 4K VLANs can be added to a PVLAN. Adding more VLANS will display the following log error:
> ```
> <Erro:HAL.VLAN.Error>Slot-<slot>: Failed to add egress vlan translation entry on port <port> due to "Table full".
> ```

If two or more member VLANs have overlapping ports (where the same ports are assigned to both VLANs), each additional VLAN member with overlapping ports must have a dedicated loopback port. To state it another way, one of the VLAN members with overlapping ports does not require a dedicated loopback port, and the rest of the VLAN members do require a single, dedicated loopback port within each member VLAN.

> **Note**
> There is a limit to the number of unique source MAC addresses on the network VLAN of a PVLAN that the switch can manage. It is advised not to exceed the value shown in the item "FDB (maximum L2 entries)" in the Supported Limits table of the *ExtremeXOS Release Notes*.

Configuring PVLANs

The following section describes how to configure a private *VLAN*.

Creating PVLANs

To create a *VLAN*, you need to do the following:

1. Create the PVLAN.
2. Add one VLAN to the PVLAN as a network VLAN.
3. Add VLANs to the PVLAN as subscriber VLANs.

- To create a PVLAN, use the following command:

  `create private-vlan` *name* {**vr** *vr_name*}

- To add a network VLAN to the PVLAN, create and configure a tagged VLAN, and then use the following command to add that network VLAN:

  `configure private-vlan` *name* **add network** *vlan_name*

- To add a subscriber VLAN to the PVLAN, create and configure a tagged VLAN, and then use the following command to add that subscriber VLAN:

  `configure private-vlan` *name* **add subscriber** *vlan_name* {**non-isolated**} {**loopback-port** *port*}

  By default, this command adds an isolated subscriber VLAN. To create a non-isolated subscriber VLAN, you must include the **non-isolated** option.

Configuring Network VLAN Ports for VLAN Translation

When subscriber _VLAN_ traffic exits a network VLAN port, it can be untagged, tagged (with the subscriber VLAN tag), or translated (to the network VLAN tag).

> **Note**
> All traffic that exits a subscriber VLAN port uses the subscriber VLAN tag, unless the port is configured as untagged. There is no need to configure VLAN translation (from network to subscriber VLAN tag) on subscriber VLAN ports.

1. To configure network VLAN ports for VLAN translation, use the following command and specify the network VLAN and port numbers:

   `configure {`**`vlan`**`} ` *`vlan_name`* ` | ` *`vlan_list`* ` ` **`add ports`** ` ` *`port_list`* ` ` **`private-vlan translated`**

2. If you want to later reconfigure a port that is configured for VLAN translation so that it does not translate tags, use the following command and specify either the **`tagged`** or the **`untagged`** option:

   `configure {`**`vlan`**`} ` *`vlan_name`* ` | ` *`vlan_list`* ` ` **`add ports`** ` [`*`port_list`* ` | ` **`all`**`]` `{`**`tagged`** ` | ` **`untagged`**`} {{`**`stpd`**`} ` *`stpd_name`*`} {`**`dot1d`** ` | ` **`emistp`** ` | ` **`pvst-plus`**`}}`

Configuring Non-Isolated Subscriber VLAN Ports

The process for configuring non-isolated _VLAN_ ports requires two tasks:

- Add a VLAN to the PVLAN as a non-isolated subscriber VLAN.
- Assign ports to the non-isolated subscriber VLAN.

These tasks can be completed in any order, but they must both be completed before a port can participate in a PVLAN. When configuration is complete, all egress traffic from the port is translated to the VLAN tag for that non-isolated VLAN (unless the port is configured as untagged).

> **Note**
> To configure VLAN translation for network VLAN ports, see Configuring Network VLAN Ports for VLAN Translation on page 610.

- To add a non-isolated subscriber VLAN to the PVLAN, use the following command:

  `configure private-vlan ` *`name`* ` ` **`add subscriber`** ` ` *`vlan_name`* ` ` **`non-isolated`**

- To add ports to a non-isolated VLAN (before or after it is added to the PVLAN), use the following command:

  `configure {`**`vlan`**`} ` *`vlan_name`* ` | ` *`vlan_list`* ` ` **`add ports`** ` [`*`port_list`* ` | ` **`all`**`]` `{`**`tagged`** ` | ` **`untagged`**`} {{`**`stpd`**`} ` *`stpd_name`*`} {`**`dot1d`** ` | ` **`emistp`** ` | ` **`pvst-plus`**`}}`

If you specify the tagged option, egress traffic uses the non-isolated VLAN tag, regardless of the network translation configuration on any network port with which these ports communicate. Egress traffic from a non-isolated VLAN port never carries the network VLAN tag.

Configuring Isolated Subscriber VLAN Ports

When a port is successfully added to an isolated *VLAN*, the port is isolated from other ports in the same VLAN, and all egress traffic from the port is translated to the VLAN tag for that VLAN (unless the port is configured as untagged).

> **Note**
> To configure VLAN translation for network VLAN ports, see Configuring Network VLAN Ports for VLAN Translation on page 610.

The process for configuring ports for VLAN isolation requires two tasks:

- Add a VLAN to the PVLAN as an isolated subscriber VLAN.
- Assign ports to the isolated subscriber VLAN.

These tasks can be completed in any order, but they must both be completed before a port can participate in an isolated VLAN.

- To add an isolated subscriber VLAN to the PVLAN, use the following command:
  ```
  configure private-vlan name add subscriber vlan_name
  ```
- To add ports to an isolated VLAN (before or after it is added to the PVLAN), use the following command:
  ```
  configure {vlan} vlan_name | vlan_list add ports [port_list | all]
  {tagged | untagged} {{stpd} stpd_name} {dot1d | emistp | pvst-plus}}
  ```

If you specify the tagged option, egress traffic uses the isolated VLAN tag, regardless of the network translation configuration on any network port with which these ports communicate. Egress traffic from an isolated VLAN port never carries the network VLAN tag.

Configuring a PVLAN on Multiple Switches

To create a PVLAN that runs on multiple switches, you must configure the PVLAN on each switch and set up a connection between the network VLANs on each switch. The ports at each end of the connection must be configured as tagged ports that do not perform tag translation.

To configure these types of ports, use the following command:

```
configure {vlan} vlan_name add ports port_list tagged
```

Configuring a Network or Subscriber VLAN Extension to Another Switch

You can extend a network or subscriber *VLAN* to another switch without configuring a PVLAN on that switch. This configuration is introduced in Extending Network and Subscriber VLANs to Other Switches on page 605.

- To configure the port on the switch that is outside of the PVLAN, use the following command:
  ```
  configure {vlan} vlan_name add ports port_list tagged
  ```

Adding a Loopback Port to a Subscriber VLAN

ExtremeSwitching series switches, whether or not included in a SummitStack, require a loopback port for certain configurations. If two or more subscriber *VLAN*s have

overlapping ports (where the same ports are assigned to both VLANs), each of the subscriber VLANs with overlapping ports must have a dedicated loopback port.

The loopback port can be added when the subscriber VLAN is added to the PVLAN.

If you need to add a loopback port to an existing subscriber VLAN, use the following command:

```
configure {vlan} vlan_name vlan-translation add loopback-port port
```

Managing Layer 3 Communications in a PVLAN

The default configuration for Layer 3 PVLAN communications is described in Layer 3 Communications.

To enable Layer 3 communications between all ports in a PVLAN, use the following command:

```
configure iparp add proxy [ipNetmask | ip_addr {mask}] {vr vr_name} {mac
| vrrp} {always}
```

Specify the IP address or subnet specified for the network _VLAN_ in the PVLAN. Use the **always** option to ensure that the switch will reply to ARP requests, regardless of the VLAN from which it originated.

Delete PVLANs

To delete an existing PVLAN, use the command:

```
delete private-vlan name
```

Remove a VLAN from a PVLAN

When you remove a _VLAN_ from a PVLAN, you remove the association between a VLAN and the PVLAN. Both the VLAN and PVLAN exist after the removal.

To remove a network or subscriber VLAN from a PVLAN, use the following command:

```
configure private-vlan name delete [network | subscriber] vlan_name
```

Deleting a Loopback Port from a Subscriber VLAN

To delete a loopback port from a subscriber _VLAN_, use the command:

```
configure {vlan} vlan_name vlan-translation delete loopback-port
```

Displaying PVLAN Information

This section describes how to display private _VLAN_ information.

Displaying Information for all PVLANs

To display information on all the PVLANs configured on a switch, use the command:

```
show private-vlan
```

Displaying Information for a Specific PVLAN

To display information about a single PVLANs, use the command:

```
show {private-vlan} name
```

Displaying Information for a Network or Subscriber VLAN

To display information about a network or subscriber VLAN, use the command:

```
show vlan {virtual-router vr-name}
```

The following flags provide PVLAN specific information:

s flat

Identifies a network VLAN port that the system added to a subscriber VLAN. All subscriber VLANs contain network VLAN ports that are marked with the s flag.

L flag

Identifies a subscriber VLAN port that is configured as a loopback port.

t flag

Identifies a tagged network VLAN port on which tag translation is enabled. The t flag only appears in the show vlan display for network VLANs.

e flag

Identifies a network VLAN port that is configured as an endpoint. The e flag only appears in the show vlan display for network VLANs.

Displaying PVLAN FDB Entries

To view all FDB entries including those created for a PVLAN, use the command:

```
show fdb {blackhole {netlogin [all | mac-based-vlans]} | netlogin [all
| mac-based-vlans] | permanent {netlogin [all | mac-based-vlans]} |
mac_addr {netlogin [all | mac-based-vlans]} | ports port_list {netlogin
[all | mac-based-vlans]} | vlan vlan_name | vlan_list {netlogin [all |
mac-based-vlans]} | {{vpls} {vpls_name}}}
```

The P flag marks additional FDB entries for PVLANs.

PVLAN Configuration Example 1

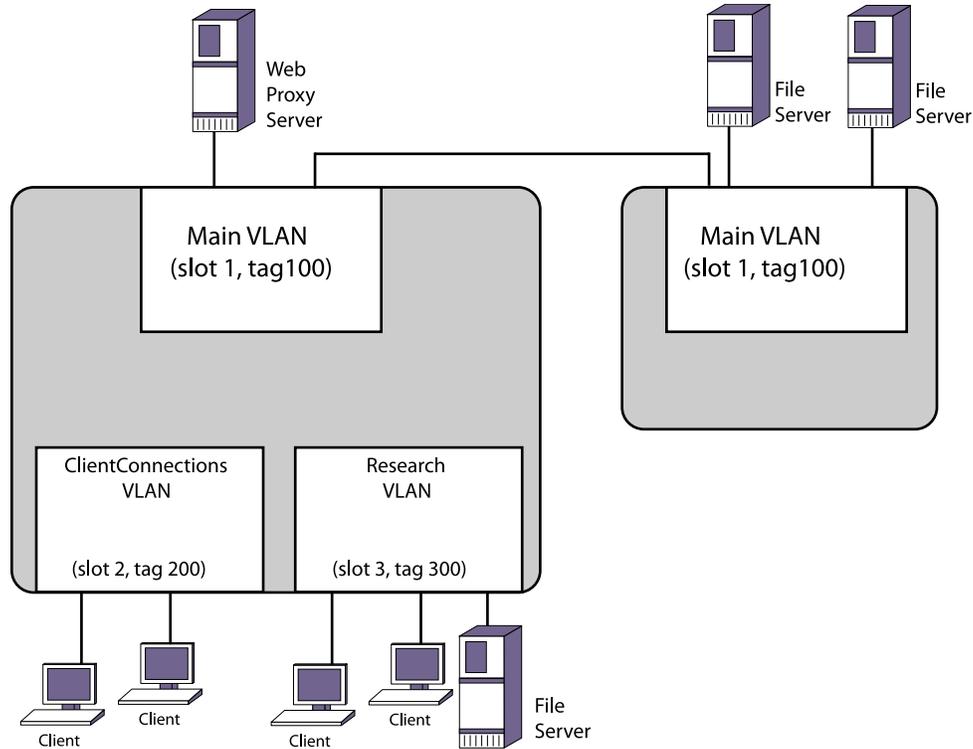
shows a PVLAN configuration example for a medical research lab.


Figure 74: PVLAN Configuration Example 1

The medical research lab hosts lots of visiting clients. Each client has their own room, and the lab wants to grant them access to the internet through a local web proxy server but prevent them from accessing other visiting clients. There is a lab in the building where many research workstations are located. Workstations within the lab require access to other lab workstations, the internet, and file servers that are connected to a switch in another building. Visiting clients should not have access to the Research _VLAN_ devices or the file servers on the remote switch.

The PVLAN in Figure 74 contains the following PVLAN components:

• Network VLAN named Main, which provides internet access through the proxy web server and access to file servers on the remote switch.

• Isolated subscriber VLAN named ClientConnections, which provides internet access for visiting clients and isolation from other visiting clients, the Research VLAN devices, and the remote file servers.

• Non-isolated subscriber VLAN named Research, which provides internet access and enables communications between Research VLAN devices and the remote file servers.

1. The first configuration step is to create and configure the VLANs on the local switch:

```
create vlan Main
configure vlan Main add port 1:*
configure vlan Main tag 100
create vlan ClientConnections
configure vlan ClientConnections add port 2:*
configure vlan ClientConnections tag 200
create vlan Research
```

```
configure vlan Research add port 3:*
configure vlan Research tag 300
```

2. The remote switch VLAN is configured as follows:

```
create vlan Main
configure vlan Main add port 1:*
configure vlan Main tag 100
```

3. The next step is to create the PVLAN on the local switch and configure each of the component VLANs for the proper role:

```
create private-vlan MedPrivate
configure private-vlan "MedPrivate" add network "Main"
configure private-vlan "MedPrivate" add subscriber "ClientConnections"
configure private-vlan "MedPrivate" add subscriber "Research" non-isolated
```

4. The final step is to configure VLAN translation on the local switch so that Research VLAN workstations can connect to the file servers on the remote switch:

```
configure Main add ports 1:1 private-vlan translated
```

5. To view the completed configuration, enter the `show private-vlan` command as follows:

```
show private-vlan
-----------------------------------------------------------------------------------
Name            VID  Protocol Addr        Flags              Proto  Ports  Virtual
Active router
/Total
-----------------------------------------------------------------------------------
MedPrivate                                                                VR-Default
Network VLAN:
-main         100  ------------------------------------   ANY    2 /48  VR-Default
Non-Isolated Subscriber VLAN:
-Research      300  ------------------------------------   ANY    2 /96  VR-Default
Isolated Subscriber VLAN:
-ClientConnections 200  --------------------------------   ANY    2 /52  VR-Default
```

PVLAN Configuration Example 2

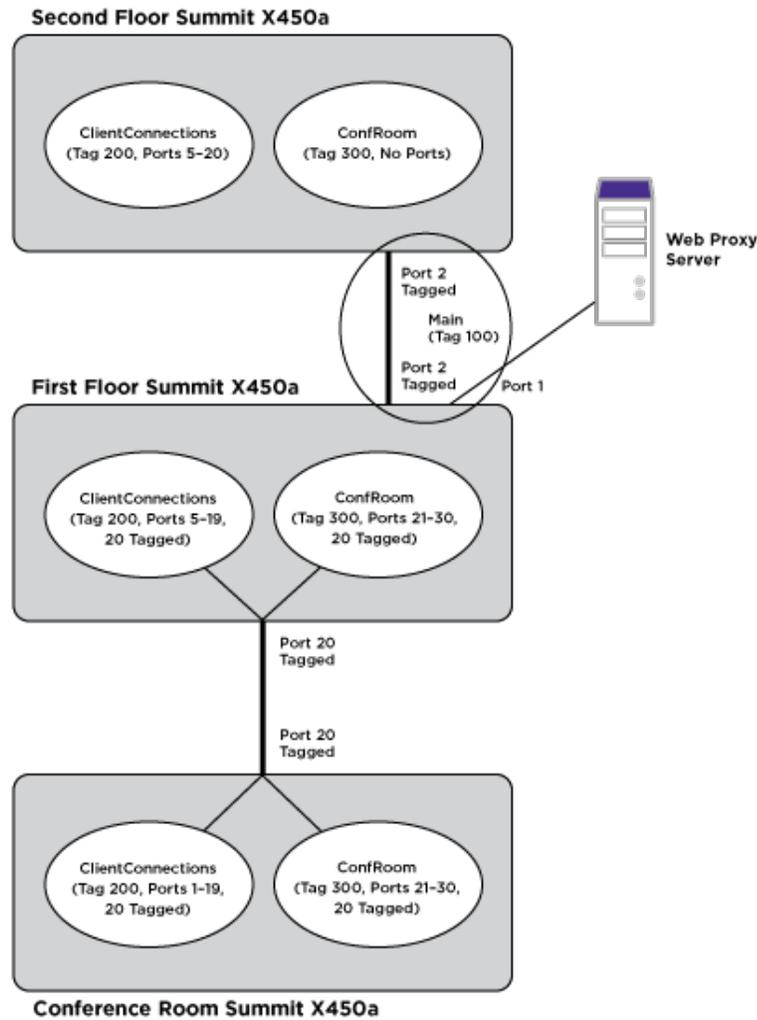
Figure 75 shows a PVLAN configuration example for a motel.


Figure 75: PVLAN Configuration Example 2

This motel has guest rooms, a conference room, and their web proxy server on the first floor, and guest rooms on the second floor. The motel has three ExtremeSwitching switches. There is one on the first floor in a closet, one on the first floor in the conference room, and one on the second floor.

The PVLAN in Figure 75 contains the following PVLAN components:

- A *VLAN* called Main that contains the web proxy server.
- A VLAN called ConfRoom that contains the ports for the conference room connections.
- A VLAN called ClientConnections that contains client PC connections for the guest rooms.

The goals for the motel network are as follows:

- Provide internet access for the ConfRoom and ClientConnections VLANs through the web proxy server.
- Prevent communications between the ConfRoom and ClientConnections VLANs.
- Enable communications between clients on the ClientConnections VLAN only within the conference room.
- Enable communications between devices on the ConfRoom VLAN.
- Prevent communications between the PCs in the ClientConnections VLAN that are not in the conference room.

Notice the following in this example:

- The ExtremeSwitching switches in the first floor closet and on the second floor contain the Main VLAN with a tag of 100. This VLAN is connected via a tagged port between the first and second floor switches.
- The switch in the conference room does not contain the Main VLAN and cannot be a PVLAN member.
- All of the switches have the ClientConnections VLAN, and it uses VLAN tag 200.
- All of the switches have the ConfRoom VLAN, and it uses VLAN tag 300.
- The Conference Room switch connects to the rest of the network through a tagged connection to the switch in the first floor closet.
- Because the switch in the first floor closet is a PVLAN member and uses the same port to support two subscriber VLANs, a loopback port is required in all subscriber VLANs, except the first configured subscriber VLAN (this applies to all switches).

> **Note**
>
> The following examples contain comments that follow the CLI comment character (#). All text that follows this character is ignored by the switch and can be omitted from the switch configuration.

The following commands configure the switch in the first floor closet:

```
# Create and configure the VLANs.
create vlan Main
configure vlan Main add port 1
configure vlan Main tag 100
configure vlan Main add port 2 tagged
create vlan ClientConnections
configure vlan ClientConnections tag 200
configure vlan ClientConnections add port 5-19
configure vlan ClientConnections add port 20 tagged
create vlan ConfRoom
configure vlan ConfRoom tag 300
configure vlan ConfRoom add port 21-30
configure vlan ConfRoom add port 20 tagged

# Create and configure the PVLAN named Motel.
create private-vlan Motel
configure private-vlan Motel add network Main
configure private-vlan Motel add subscriber ClientConnections # isolated subscriber VLAN
configure private-vlan "Motel" add subscriber "ConfRoom" non-isolated loopback-port 30
configure private-vlan Motel add subscriber ConfRoom non-isolated
# If you omit the loopback-port command, the above command produces the following error
message:
```

```
# Cannot add subscriber because another subscriber vlan is already present on the same
port, assign a loopback port when adding the subscriber vlan to the private vlan
```

```
# show vlan "ConfRoom"
VLAN Interface with name ConfRoom created by user
Admin State:    Enabled         Tagging:        802.1Q Tag 300

(I) Dynamically added by IDM
(U) Dynamically added uplink port
(V) Dynamically added by VM Tracking

# Note that the loopback port is flagged with an "L" and listed as a tagged port, and the
network VLAN ports are flagged with an "s" and listed as tagged ports.
```

The following commands configure the switch on the second floor:

```
# create and configure the VLANs
create vlan Main
configure vlan Main tag 100
configure vlan Main add port 2 tagged
create vlan ClientConnections
configure vlan ClientConnections tag 200
configure vlan ClientConnections add port 5-20
create vlan ConfRoom
configure vlan ConfRoom tag 300
# Create and configure the PVLAN named Motel.
create private-vlan Motel
configure private-vlan Motel add network Main
configure private-vlan Motel add subscriber ClientConnections # isolated subscriber VLAN
configure private-vlan Motel add subscriber ConfRoom non-isolated
```

The following commands configure the switch in the conference room:

```
# create and configure the VLANs
create vlan ClientConnections
configure vlan ClientConnections tag 200
configure vlan ClientConnections add port 1-19
configure vlan ClientConnections add port 20 tag
create vlan ConfRoom
configure vlan ConfRoom tag 300
configure vlan ConfRoom add port 21-30
```

```
configure vlan ConfRoom add port 20 tag
# The VLANs operate as extensions of the VLANs on the Summit in the first floor closet.
There is no PVLAN configuration on this switch.
```

VLAN Translation

The *VLAN* translation feature described in this section provides the same VLAN translation functionality that is provided for PVLANs. This is described in VLAN Translation in a PVLAN on page 600.

> **Note**
>
> The VLAN translation feature is supported only on the platforms listed for this feature in the license tables in the *ExtremeXOS 32.4 Feature License Requirements* document.

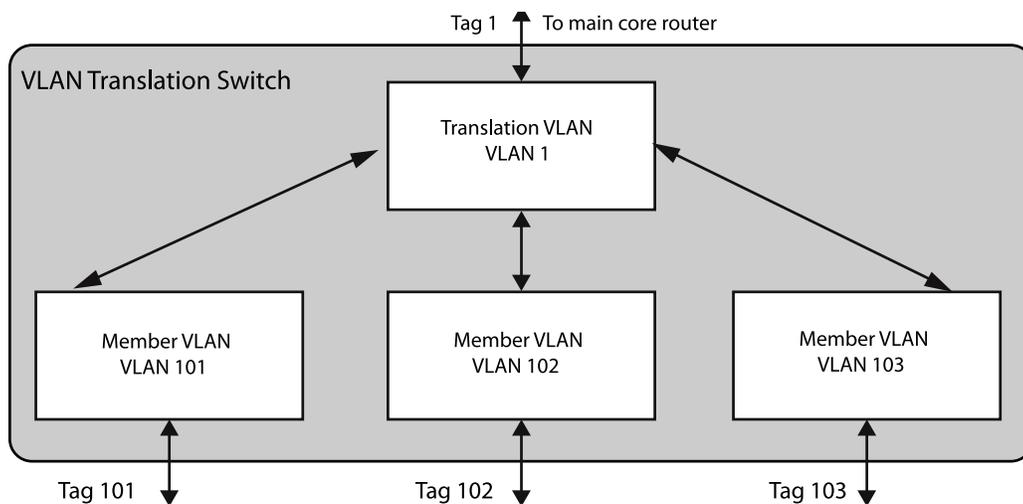
Figure 76 shows how VLAN translation is configured in the switch.


Figure 76: VLAN Translation Switch Configuration

VLAN1 is configured as a translation VLAN . The translation VLAN is equivalent to the network VLAN in the PVLAN implementation of VLAN translation.

VLANs 101, 102, and 103 are configured as member VLANs of translation VLAN1. The member VLANs are equivalent to the non-isolated subscriber VLANs in the PVLAN implementation of VLAN translation.

This configuration enables tag translation between the translation VLAN and the member VLANs. All member VLANs can communicate through the translation VLAN, but they cannot communicate through Layer 2 with each other.

VLAN Translation Behavior

You should be aware of the behavior of unicast, broadcast, and multicast traffic when using *VLAN* translation.

Unicast Traffic

Traffic on the member *VLAN*s can be either tagged or untagged.

Traffic is switched locally between client devices on the same member VLAN as normal. Traffic cannot be switched between clients on separate member VLANs. Traffic from any member VLAN destined for the translation VLAN is switched and the VLAN tag is translated appropriately. Traffic from the translation VLAN destined for any member VLAN is switched and the VLAN tag is translated.

Broadcast Behavior

Broadcast traffic generated on a member *VLAN* is replicated in every other active port of that VLAN as normal.

In addition, the member VLAN traffic is replicated to every active port in the translation VLAN and the VLAN tag is translated appropriately. Broadcast traffic generated on the translation VLAN is replicated to every other active port in this VLAN as usual. The caveat in this scenario is that this traffic is also replicated to every active port in every member VLAN, with VLAN tag translation. In effect, the broadcast traffic from the translation VLAN leaks onto all member VLANs.

Multicast Behavior

IGMP snooping can be enabled on member and translation *VLAN*s so that multicast traffic can be monitored within the network.

IGMP snooping software examines all IGMP control traffic that enters the switch. IGMP control traffic received on a VLAN translation port is forwarded by the CPU to all other ports in the translation group. Software VLAN translation is performed on the packets which cross the translation boundary between member and translation VLANs. The snooping software detects ports joining and leaving multicast streams. When a VLAN translation port joins a multicast group, an *FDB* entry is installed only on receiving a data miss for that group. The FDB entry is added for the requested multicast address and contains a multicast PTAG. When a VLAN translation port leaves a multicast group, the port is removed from the multicast list. The last VLAN translation port to leave a multicast group causes the multicast FDB entry to be removed.

VLAN Translation Limitations

The *VLAN* translation feature has the following limitations:
- Requires more *FDB* entries than a standard VLAN.
- VLAN tag duplication is not allowed.
- VLAN name duplication is not allowed.
- Each MAC address learned in the translation and member VLANs must be unique. A MAC address cannot exist in two or more VLANs that belong to the same VLAN translation domain.
- MVR cannot be configured on translation and member VLANs.
- A VMAN cannot be added to translation and member VLANs.
- A PBB network (BVLAN) cannot be added to translation and member VLANs.

- *EAPS* control VLANs cannot be either translation or member VLANs.
- EAPS can only be configured on translation VLAN ports (and not on member VLAN ports). To support EAPS on the network VLAN, you must add all of the translation and member VLANs to the EAPS ring.
- *STP* can only be configured on translation VLAN ports (and not on member VLAN ports). To support STP on the translation VLAN, you must add the translation VLAN and all of the member VLANs to STP.
- *ESRP* can only be configured on translation VLAN ports (and not on member VLAN ports). To support ESRP on the network VLAN, you must add the translation VLAN and all of the member VLANs to ESRP.
- There is no *NetLogin* support to add ports as translate to the translation VLAN, but the rest of NetLogin and the PVLAN feature do not conflict.
- *IGMP* snooping is performed across the entire VLAN translation domain, spanning all the member VLANs. For VLANs that are not part of a VLAN translation domain, IGMP snooping operates as normal.
- VLAN translation and VPLS are not supported on the same VLAN.
- Member VLANs in a VLAN translation domain cannot exchange multicast data with VLANs outside the VLAN translation domain. However, the translation VLAN can exchange multicast data with VLANs outside the VLAN translation domain and with translation VLANs in other VLAN translation domains.

Interfaces

Use the following information for selecting and configuring *VLAN* translation interfaces:

- A single physical port can be added to multiple member VLANs, using different VLAN tags.
- Member VLANs and translation VLANs can include both tagged and untagged ports.

Configuring Translation VLANs

To create a translation *VLAN*, do the following:

1. Create the VLAN that will become the translation VLAN.
2. Add a tag and ports to the prospective translation VLAN.
3. Add member VLANs to the prospective translation VLAN.

A prospective translation VLAN becomes a translation VLAN when the first member VLAN is added to it.

- To add a member VLAN to a translation VLAN, use the following command:

  ```
  configure {vlan} vlan_name vlan-translation add member-vlan
  member_vlan_name {loopback-port port}
  ```
- To delete a member VLAN from a translation VLAN, use the following command:

  ```
  configure {vlan} vlan_name vlan-translation delete member-vlan
  [member_vlan_name | all]
  ```

- To view the translation VLAN participation status of a VLAN, use the following command:

```
show vlan {virtual-router vr-name}
```

Displaying Translation VLAN Information

This section describes how to display translation _VLAN_ information.

Displaying Information for a Translation or Member VLAN

To display information about a translation or member _VLAN_, use the command:

```
show vlan {virtual-router vr-name}
```

Displaying Translation VLAN FDB Entries

To view all _FDB_ entries including those created for a translation _VLAN_, use the command:

```
show fdb {blackhole {netlogin [all | mac-based-vlans]} | netlogin [all
| mac-based-vlans] | permanent {netlogin [all | mac-based-vlans]} |
mac_addr {netlogin [all | mac-based-vlans]} | ports port_list {netlogin
[all | mac-based-vlans]} | vlan vlan_name | vlan_list {netlogin [all |
mac-based-vlans]} | {{vpls} {vpls_name}}}
```

The T flag marks additional FDB entries for translation VLANs.

VLAN Translation Configuration Examples

The following configuration examples show _VLAN_ translation used in three scenarios:

- Basic VLAN Translation on page 622
- VLAN Translation with ESRP Redundancy on page 623
- VLAN Translation with STP Redundancy on page 625

Basic VLAN Translation

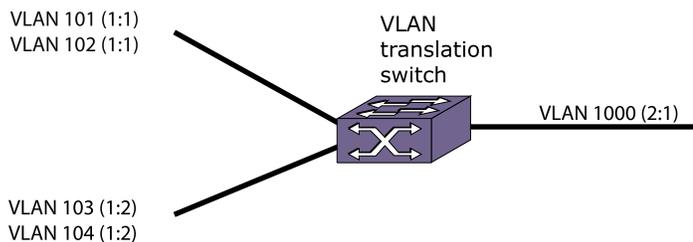
The example in Figure 77configures a basic _VLAN_ translation network. This network provides VLAN translation between four member VLANs and a single translation VLAN.


Figure 77: VLAN Translation Configuration Example

The following configuration commands create the member VLANs:

```
create vlan v101
configure v101 tag 101
```

```
configure v101 add ports 1:1 tagged
create vlan v102
configure v102 tag 102
configure v102 add ports 1:1 tagged
create vlan v103
configure v103 tag 103
configure v103 add ports 1:2 tagged
create vlan v104
configure v104 tag 104
configure v104 add ports 1:2 tagged
```

The following configuration commands create the translation VLAN and enable VLAN translation:

```
create vlan v1000
configure v1000 tag 1000
configure v1000 add ports 2:1 tagged
configure v1000 vlan-translation add member-vlan v101
configure v1000 vlan-translation add member-vlan v102 loopback-port 1:23
configure v1000 vlan-translation add member-vlan v103
configure v1000 vlan-translation add member-vlan v104 loopback-port 1:24
```

VLAN Translation with ESRP Redundancy

The example in Figure 78 configures a *VLAN* translation network with *ESRP* redundancy.

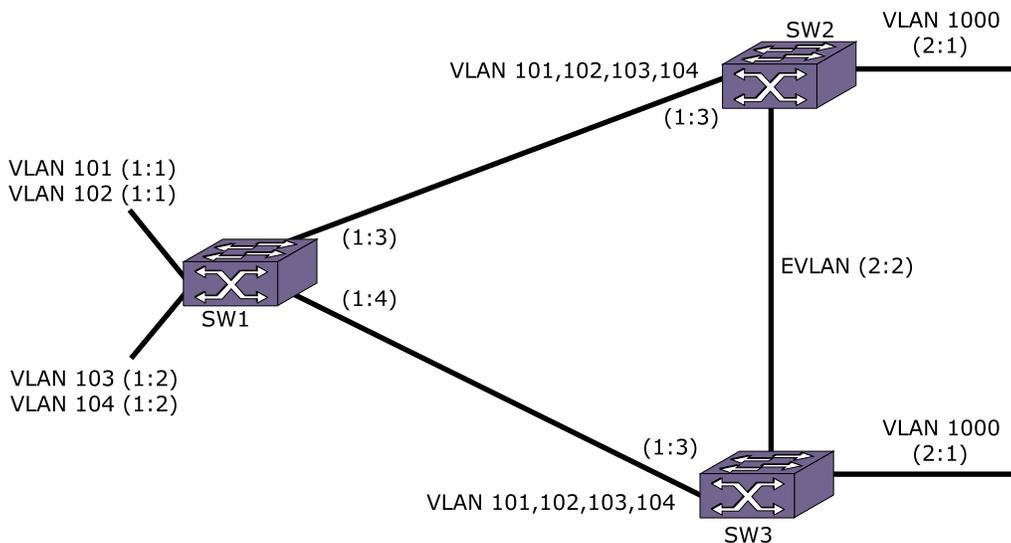
The SW2 and SW3 VLAN translation switches are protected by an ESRP control VLAN. The master ESRP switch performs the translation and provides the connectivity to the backbone. If a failure occurs, the slave ESRP switch takes over and begins performing the translation.


Figure 78: ESRP Redundancy Configuration Example

The following configuration commands create the member VLANs on SW1:

```
create vlan v101
configure v101 tag 101
```

```
configure v101 add ports 1:1 tagged
configure v101 add ports 1:3 tagged
configure v101 add ports 1:4 tagged
create vlan v102
configure v102 tag 102
configure v102 add ports 1:1 tagged
configure v102 add ports 1:3 tagged
configure v102 add ports 1:4 tagged
create vlan v103
configure v103 tag 103
configure v103 add ports 1:2 tagged
configure v103 add ports 1:3 tagged
configure v103 add ports 1:4 tagged
create vlan v104
configure v104 tag 104
configure v104 add ports 1:2 tagged
configure v104 add ports 1:3 tagged
configure v104 add ports 1:4 tagged
```

The configuration for SW2 and SW3 is identical for this example.

The following configuration commands create the member VLANs on SW2:

```
create vlan v101
configure v101 tag 101
configure v101 add ports 1:3 tagged
create vlan v102
configure v102 tag 102
configure v102 add ports 1:3 tagged
create vlan v103
configure v103 tag 103
configure v103 add ports 1:3 tagged
create vlan v104
configure v104 tag 104
configure v104 add ports 1:3 tagged
```

This set of configuration commands creates the translation VLANs and enables VLAN translation on SW2:

```
create vlan v1000
configure v1000 tag 1000
configure v1000 add ports 2:1 tagged
configure v1000 vlan-translation add member-vlan v101
configure v1000 vlan-translation add member-vlan v102
configure v1000 vlan-translation add member-vlan v103
configure v1000 vlan-translation add member-vlan v104
```

The final set of configuration commands creates the ESRP control VLAN and enables ESRP protection on the translation VLAN for SW2:

```
create vlan evlan
configure evlan add ports 2:2
enable esrp evlan
configure evlan add domain-member v1000
```

The following configuration commands create the translation VLAN and enable VLAN translation onVLANs that have overlapping ports:

```
configure v1000 vlan-translation add member-vlan v102 loopback-port 1:22
configure v1000 vlan-translation add member-vlan v103 loopback-port 1:23
configure v1000 vlan-translation add member-vlan v104 loopback-port 1:24
```

VLAN Translation with STP Redundancy

The example in Figure 79 configures a VLAN translation network with redundant paths protected by STP.

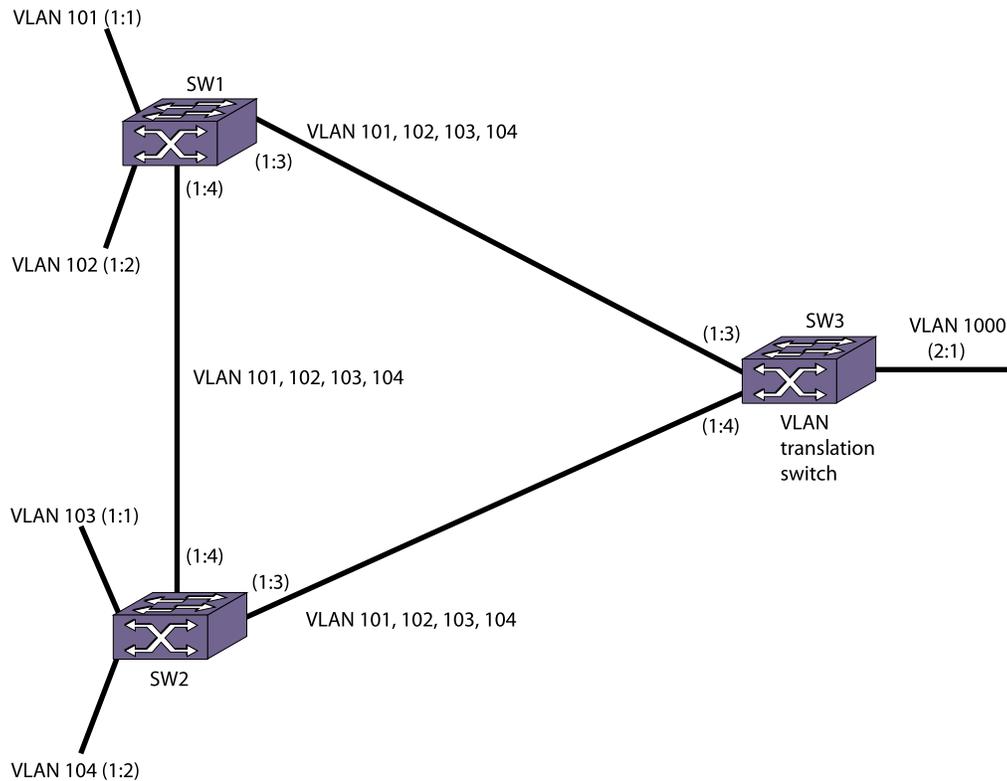
Parallel paths exist from the member VLAN portion of the network to the translation switch. STP ensures that the main path for this traffic is active and the secondary path is blocked. If a failure occurs in the main path, the secondary paths are enabled.


Figure 79: STP Redundancy Configuration Example

The following configuration commands create the member VLANs and enable STP on SW1:

```
create vlan v101
configure v101 tag 101
configure v101 add ports 1:1 tagged
configure v101 add ports 1:3 tagged
configure v101 add ports 1:4 tagged
create vlan v102
configure v102 tag 102
configure v102 add ports 1:2 tagged
configure v102 add ports 1:3 tagged
configure v102 add ports 1:4 tagged
create vlan v103
configure v103 tag 103
configure v103 add ports 1:3 tagged
configure v103 add ports 1:4 tagged
create vlan v104
configure v104 tag 104
configure v104 add ports 1:3 tagged
configure v104 add ports 1:4 tagged
create stpd stp1
configure stp1 tag 101
```

```
configure stp1 add vlan v101
configure stp1 add vlan v102
configure stp1 add vlan v103
configure stp1 add vlan v104
enable stpd stp1
```

These configuration commands create the member VLANs and enable STP on SW2:

```
create vlan v103
configure v103 tag 103
configure v103 add ports 1:1 tagged
configure v103 add ports 1:3 tagged
configure v103 add ports 1:4 tagged
create vlan v104
configure v104 tag 104
configure v104 add ports 1:2 tagged
configure v104 add ports 1:3 tagged
configure v104 add ports 1:4 tagged
create vlan v101
configure v101 tag 101
configure v101 add ports 1:3 tagged
configure v101 add ports 1:4 tagged
create vlan v102
configure v102 tag 102
configure v102 add ports 1:3 tagged
configure v102 add ports 1:4 tagged
create stpd stp1
configure stp1 tag 101
configure stp1 add vlan v101
configure stp1 add vlan v102
configure stp1 add vlan v103
configure stp1 add vlan v104
enable stpd stp1
```

This set of configuration commands creates the member VLANs and enables STP on
SW3:

```
create vlan v101
configure v101 tag 101
configure v101 add ports 1:3 tagged
configure v101 add ports 1:4 tagged
create vlan v102
configure v102 tag 102
configure v102 add ports 1:3 tagged
configure v102 add ports 1:4 tagged
create vlan v103
configure v103 tag 103
configure v103 add ports 1:3 tagged
configure v103 add ports 1:4 tagged
create vlan v104
configure v104 tag 104
configure v104 add ports 1:3 tagged
configure v104 add ports 1:4 tagged
create stpd stp1
configure stp1 tag 101
configure stp1 add vlan v101
configure stp1 add vlan v102
configure stp1 add vlan v103
configure stp1 add vlan v104
enable stpd stp1
```

The final set of configuration commands creates the translation VLAN and enables VLAN translation on SW3:

```
create vlan v1000
configure v1000 tag 1000
configure v1000 add ports 2:1 tagged
configure v1000 vlan-translation add member-vlan v101
configure v1000 vlan-translation add member-vlan v102
configure v1000 vlan-translation add member-vlan v103
configure v1000 vlan-translation add member-vlan v104
```

The following configuration commands create the translation VLAN and enable VLAN translation on VLANs that have overlapping ports:

```
configure v1000 vlan-translation add member-vlan v102 loopback-port 1:22
configure v1000 vlan-translation add member-vlan v103 loopback-port 1:23
configure v1000 vlan-translation add member-vlan v104 loopback-port 1:24
```

Port-Specific VLAN Tag

The Port-specific _VLAN_ feature adds a layer of specificity between the port tag and the VLAN/VMAN tag: a port-specific VLAN tag. This feature adds the following functionality to the existing VLAN:

- Ability to associate a tag to a VLAN port. This tag is used as a filter to accept frames with matching VID. It is also used as the tag of the outgoing frames.
- Ability to add multiple VLAN ports on the same physical port as long as those VLAN ports are associated with different tags.
- Allows the existing untagged and tagged VLAN ports to be part of the VLAN.
- Ability to learn MAC address on port, tag and VLAN instead of only on the port.As a consequence of the previous point, ability to add static MAC address to port, tag and VLAN.
- Ability to specify limit-learning and MAC lockdown on a port, tag and VLAN, instead of only on the port.
- Rate limiting and counting of frames with matching VIDs is supported with the existing _ACL (Access Control List)_.

The Port-specific VLAN tag allows tagged VLAN ports to be configured with tag values. When the tag is not configured, it is implicit that the tag of the tagged port is the tag of the VLAN. We call the tag of the port the "port tag", and the tag of the VLAN the "base tag". The port tag is used to determine the eligibility of the frames allowed to be part of the VLAN. Once the frame is admitted to the VLAN port, the base tag is used. From a functional standpoint, the frame tag is rewritten to the base tag.

The base tag then is translated to the port tag for the outgoing frame.

> **Note**
> The port tag is equal to the base tag when the port tag is not specified, so the current VLAN behavior is preserved.

Untagged VLAN ports also have port tag, which is always the same as the base tag. Outgoing frames are untagged. The untagged VLAN port always has an implicit port tag thats's always equal to the base tag. There can be only one untagged VLAN port

on a physical port. It receives untagged frames, and tagged frames, and transmits only untagged frames.

A tagged VLAN port can have a port tag configured, or not. When not configured, the port tag is equal to the base tag. There can be more than one tagged VLAN port on a physical port. It receives tagged frames with tag equals to the port tag, and transmits tagged frames with port tag.

When the VLAN is assigned to L2VPN, the base tag is the tag that is carried by the pseudo-wire when the dot1q include is enabled. It can be viewed that VPLS PW port tag is equal to the base tag. To assign a VLAN with a port-specific tag to an L2VPN, use the existing `configure vpls` *vpls_name* `add service` **vlan** *vlan_name* command.

Since every tagged VLAN port has different VIDs, forwarding between them on the same physical port (hairpin switching) is possible. From the external traffic point of view, the frame tags are rewritten from the receive port tag to the transmit port tag. Since each port tag is a different VLAN port, a frame that has to be broadcasted to multiple VLAN ports is sent out multiple times with different tags when the VLAN ports are on the same physical port. Each port + port tag is an individual VLAN port.

MAC addresses are learned on the VLAN port. This means that the port in the _FDB_ entry is the port + port tag. A unicast frame destined to a MAC address that is in the FDB is sent out of the associated VLAN port. As mentioned earlier, there is only one MAC addressed learned on the VLAN. If the MAC address is learned on a different port or a different tag, it is a MAC move. It is transmitted out of the physical port only on the associated VLAN port tagged with the port tag when the VLAN port is tagged.

When there are multiple tagged VLAN ports on the transmit port, only one frame with the right tag is transmitted. It is transmitted untagged on an untagged VLAN port. Accordingly, the static MAC address is configured on a VLAN port. This means that the port tag is specified when the tag is not equal to the base tag. The command to flush FDB does not need to change. But, a VLAN port-specific flush needs to be implemented to handle the case when a VLAN port is deleted. This flush is internal and not available through the CLI.

Per VLAN port (port + tag) rate limiting and accounting is achieved by the existing ACL. Use match condition `vlan-id` to match the port VID. You can use action `count` and `byte-count` for accounting. And you can use `show access-list counter` to view the counters. Action meter can be used for rate limiting. To create a meter, use the `create meter` command, and configure the committed rate and maximum burst size.

Supported Platforms

Port-Specific VLAN Tag is supported on the following platforms:
- ExtremeSwitching X460-G2 (supported from ExtremeXOS 15.6)
- ExtremeSwitching X465
- ExtremeSwitching X590
- ExtremeSwitching X695 (supported from ExtremeXOS 31.2)

Port-Specific Tags in L2VPN

You can assign a *VLAN* with port specific tag to VPLS/VPWS using the `configure vpls` *vsi* `add service vlan` *vl* command. Because this is a single VLAN, the base VID is used when dot1q include is enable. For example, when VLAN 100 that has ports on Ethernet port 1 with port tag 10 and 11 is assigned to L2VPN, the tag that is carried by the pseudo wire is 100. The configuration for this example is as follows:

```
create vlan exchange tag 100
config vlan exchange add ports 1 tagged 10
config vlan exchange add ports 1 tagged 11
config vpls vsi1 add service vlan exchange
```

Similarly, the following is an example for VPWS. There can only be a single VLAN port in the VLAN for assignment to VPWS to be successful:

```
create vlan exchange tag 100
config vlan exchange add ports 1 tagged 10
config l2vpn vpws pw1 add service vlan exchange
```

VLAN Port State

VLAN port state is the same as the state of the Ethernet port.

ACLs

You can use the existing match vlan-id *ACL* to accomplish counting and metering. You can assign the ACL to both ingress and egress port. The followings are the examples of such configuration. The port 3 tag is 4 and the port 4 tag is 5. These ACLs will match the frame vlan-ID, and the vlan-ID specified in the match criteria is independent of the port tag.

```
Content of acl.pol
entry tag_1 {
   if {
     vlan-id 4;
     } then {
       packet-count tag_1_num_frames;
       meter tag_1_meter;
     }
}
entry tag_2 {
   if {
     vlan-id 5;
     } then {
       byte-count tag_2_num_bytes;
       meter tag_2_meter;
     }
}
Content of acl_egress.pol
entry tag_1_egr {
   if {
     vlan-id 4;
     } then {
       packet-count tag_1_egr_num_frames;
       meter tag_1_egr_meter;
     }
}
entry tag_2_egr {
   if {
     vlan-id 5;
     } then {
```

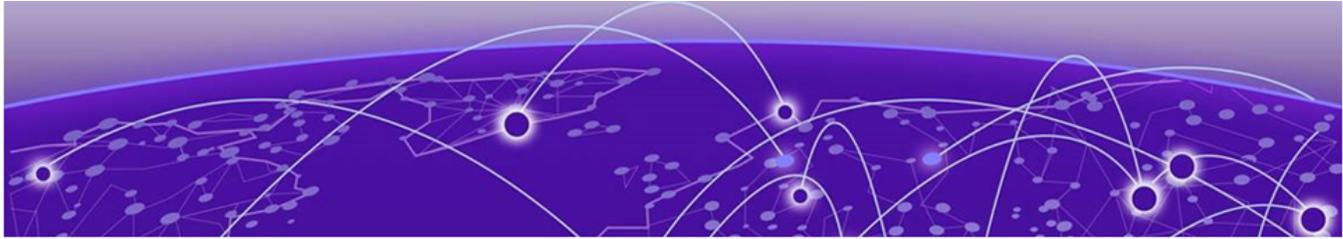
```
        byte-count tag_2_egr_num_bytes;
        meter tag_2_egr_meter;
      }
}
```

Configuring Port-Specific VLAN Tags

The following specific commands are modified by the port-specific *VLAN* tag:

- `clear fdb`: Only clears on physical port or VLAN, not on a vlan port.
- `delete fdb`: All or specific MAC address, or specific MAC address on a VLAN.
- `enable/disable flooding ports`: Only on physical port (applies to all VLAN ports).
- `enable/disable learning`: Only on physical port (applies to all VLAN ports on the same physical port), or on a VLAN (applies to all VLAN ports of the VLAN).
- `show fdb stats`: Only on physical port or VLAN, not on a VLAN port.

Use the following commands to configure Port-specific VLAN tags:

- To configure the port-specific tag, use the `configure ports` *port_list* {**tagged** *tag*} **vlan** *vlan_name* [**limit-learning** *number* {**action** [**blackhole** | **stop-learning**]} |**lock-learning** | **unlimited-learning** | **unlocklearning**] command.
- To specify the port tag when you need to put multiple vlans into a broadcast domain, use the `configure` {**vlan**} *vlan_name* addports [**port_list** | **all**] {**tagged**{*tag*} | **untagged**} {{**stpd**} *stpd_name*} {**dot1d** | **emistp** | **pvst-plus**}} command.
- To specify a port tag to delete a VLAN port that has a different tag from the VLAN tag, use the `configure` {**vlan**} *vlan_name* deleteports [**all** | **port_list** {**tagged** *tag*}] command.
- To display output of a vlan that has a port-specific tag, use the `show vlan` command.
- To display port info that has port-specific tag statistics, use the `show port` info detail command.
- To adds a permanent, static entry to the *FDB*, use the `create fdb` **mac_addr vlan** *vlan_name* [**ports** *port_list* {**tagged** *tag*} | **blackhole**] command.
- To show output where the port tag is displayed, use the `show fdb` command.


VMAN (PBN)

The virtual metropolitan area network (VMAN) feature allows you to scale a Layer 2 network and avoid some of the management and bandwidth overhead required by Layer 3 networks.

> **Note**
> If a failover occurs, VMAN operation is not interrupted. The system has hitless failover—network traffic is not interrupted during a failover.

VMAN Overview

The VMAN feature is defined by the IEEE 802.1ad standard, which is an amendment to the IEEE 802.1Q *VLAN (Virtual LAN)* standard.

A VMAN is a virtual Metropolitan Area Network (MAN) that operates over a physical MAN or Provider Bridged Network (PBN). This feature allows a service provider to create VMAN instances within a MAN or PBN to support individual customers. Each VMAN supports tagged and untagged VLAN traffic for a customer, and this traffic is kept private from other customers that use VMANs on the same PBN.

The PBN uses Provider Bridges (PBs) to create a Layer 2 network that supports VMAN traffic. The VMAN technology is sometimes referred to as VLAN stacking or Q-in-Q.

> **Note**
> *Virtual MAN (VMAN)* is an Extreme Networks term that became familiar to Extreme Networks customers before the 802.1ad standard was complete. The term VMAN is used in the ExtremeXOS software and also in this document to support customers who are familiar with the term. The term PBN is also used in this guide to establish the relationship between this industry standard technology and the Extreme Networks VMAN feature.

Figure 80 shows a VMAN, which spans the switches in a PBN.

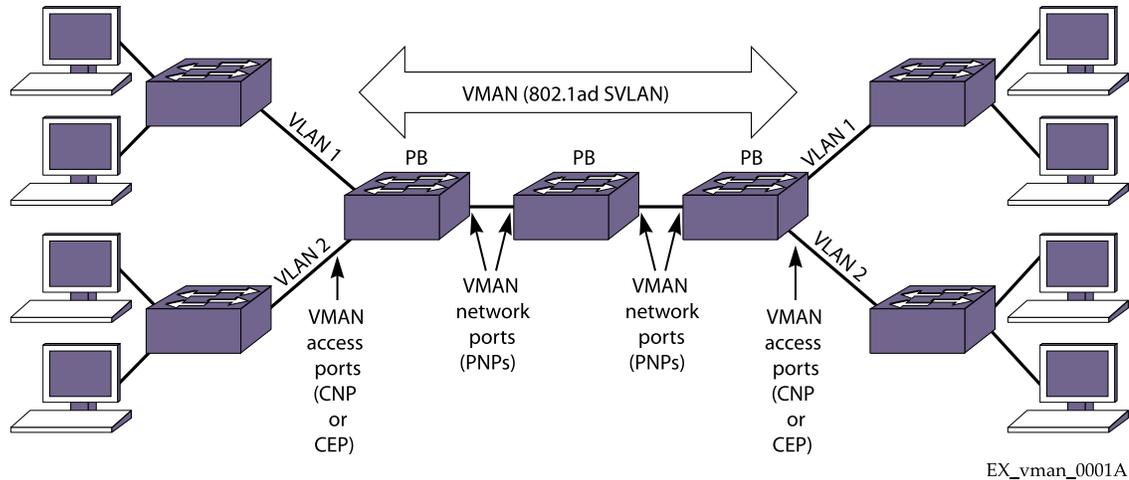
EX_vman_0001A


Figure 80: VMAN in PBN

The entry points to the VMAN are the access ports on the VMAN edge switches. Customer VLAN (CVLAN) traffic that is addressed to locations at other VMAN access ports enters the ingress access port, is switched through the VMAN, and exits the egress access port. If you do not configure any frame manipulation options, the CVLAN frames that exit the VMAN are identical to the frames that entered the VMAN.

VMAN access ports operate in the following roles:

- Customer Network Port (CNP)
- Customer Edge Port (CEP, which is also known as Selective Q-in-Q)

The CEP role, which is configured in software as a cep vman port, connects a VMAN to specific CVLANs based on the CVLAN CVID. The CNP role, which is configured as an untagged vman port, connects a VMAN to all other port traffic that is not already mapped to the port CEP role. These roles are described later.

All other VMAN ports (except the access ports) operate as VMAN network ports, which are also known as Provider Network Ports (PNPs) in the 802.1ad standard. The VMAN network ports connect the PBs that form the core of the VMAN. During configuration, the VMAN network ports are configured as tagged VMAN ports.

Figure 81 on page 633 shows one VMAN, but a PBN can support multiple VMAN instances, which are sometimes called VMANs or Service VLANs (SVLANs). VMANs allow you to partition the PBN for customers in the same way that VLANs allow you to partition a Layer 2 network. For example, you can use different VMANs to support different customers on the PBN, and the PBN delivers customer traffic only to the PBN ports that are configured for appropriate VMAN.

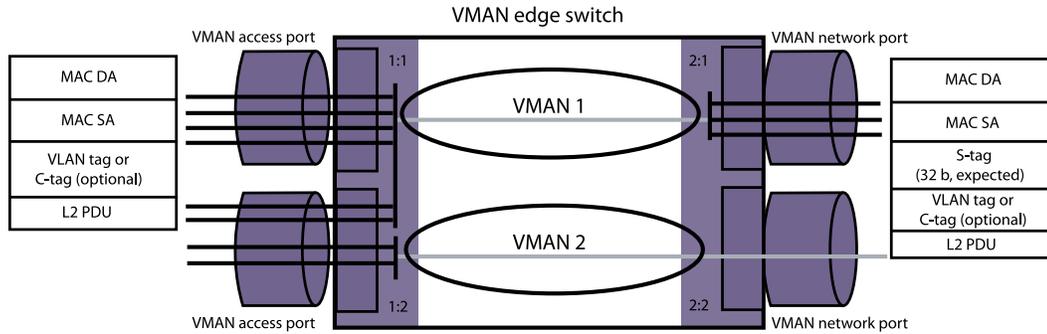
A VMAN supports two tags in each Ethernet frame, instead of the single tag supported by a VLAN Ethernet frame. The inner tag is referred to as the customer tag (C-tag), and this optional tag is based on the CVLAN tag if the source VLAN is a tagged VLAN. The outer tag is referred to as the service tag (S-tag) or VMAN tag or SVLAN tag, and it is the tag that defines to which SVLAN a frame belongs. Figure 81 on page 633 shows the frame manipulation that occurs at the VMAN edge switch.


Figure 81: Tag Usage at the VMAN Access Switch

In this example, the switch accepts CVLAN frames on VMAN access ports 1:1 and 1:2. The switch then adds the S-tag to the frames and switches the frames to network ports 2:1 and 2:2. When the 802.1ad frames reach the PB egress port, the egress switch removes the S-tag, and the CVLAN traffic exits the egress access port in its original form.

When the switch in the figure above acts as the egress switch for a VMAN, VMAN frames arrive on network ports 2:1 and 2:2. The switch accepts only those frames with the correct S-tag, removes the S-tags, and switches those frames to access ports 1:1 and 1:2. Unless special configuration options are applied, the egress frames are identical to ingress CVLAN frames. (Configuration options are described in VMAN Configuration Options and Features on page 637.)

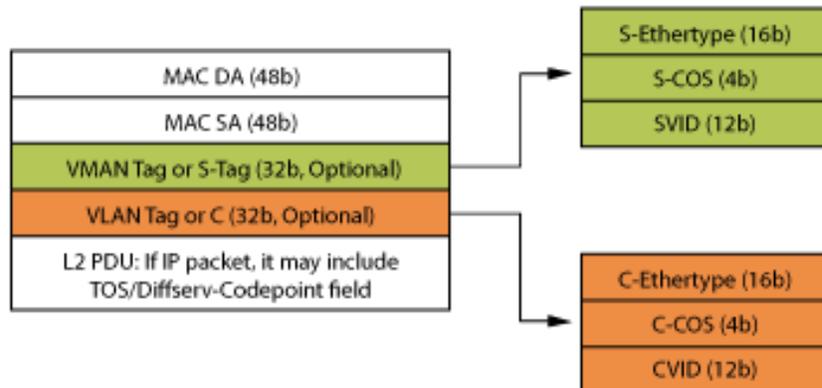
Figure 82 shows that the S-tags and C-tags used in VMAN frames contain more than just customer and service VLAN IDs.


Figure 82: S-tag and C-tag Components

Each S-tag and C-tag contains an ethertype, a Class of Service (CoS), and a SVLAN ID (SVID) or CVLAN ID (CVID). The ethertype is described in Secondary Ethertype Support on page 638, and the CoS is described in QoS Support on page 639.

The SVID is the VLAN tag you assign to a VMAN when you create it (see the `configure vman` *`vman_name`* **`tag`** *`tag`* command. The CVID represents the CVLAN tag for tagged VLAN traffic.

Switch ports support VMAN roles and features, which are described in the following sections:

- Customer Network Ports
- Customer Edge Ports
- CVID Translation
- CVID Egress Filtering

Customer Network Ports

Customer Network Ports (CNPs) are edge switch ports that accept all tagged and untagged CVLAN traffic and route it over a single VMAN. A CNP is simpler to configure than a CEP, because it supports one VMAN on a physical port and requires no configuration of CVIDs. The VMAN service provider does not need to know anything about the CVLAN traffic in the VMAN. The service provider simply manages the VMAN, and the ingress CVLAN traffic is managed by the customer or another service provider. This separation of CVLAN and VMAN management reduces the dependence of the separate management teams on each other, and allows both management teams to make changes independent of the other.

> **Note**
> The CNP term is defined in the IEEE 802.1ad standard and is also called a port-based service interface. The CNP operation is similar to a MEF 13 UNI Type 1.2, and in releases before ExtremeXOS 12.6, CNPs were known as VMAN access ports or untagged vman ports. With the addition of CEPs, the term VMAN access port is now a generic term that refers to CNPs and CEPs.

A PBN can support up to 4094 VMANs, and each VMAN can support up to 4094 CVLANs. Because each CNP connects to only one VMAN, the maximum number of customer VMANs on an edge switch is equal to the total number of switch ports minus one, because at least one port is required to serve as the PNP (Provider Network Port).

Customer Edge Ports

Each _CEP (Customer Edge Port)_ supports the configuration of connections or mappings between individual CVLANs and multiple VMANs.

This provides the following benefits:

- Each physical port supports multiple customers (each connecting to a separate VMAN).
- Each switch supports many more customer VMANs using CEPs instead of CNPs.

To define the connections between CVLANs and SVLANs, each CEP uses a dedicated CVID map, which defines the supported CVIDs on the CEP and the destination VMAN for each CVID. For example, you can configure a CEP to forward traffic from five specific

CVLANs to VMAN A and from ten other specific CVLANs to VMAN B. During VMAN configuration, certain ports are added to the VMAN as CEPs, and certain CVIDs on those ports are mapped to the VMAN. To enable customer use of a VMAN, service providers must communicate the enabled CVIDs to their customers. The customers must use those CVIDs to access the VMAN.

> **Note**
> The *CEP* term is defined in the IEEE 802.1ad standard and is also called a *C-tagged service interface*. The CEP operation is similar to a MEF 13 UNI Type 1.1.

Assigning Port CVID on Port-based or CEP VMAN Service

As of ExtremeXOS 21.1, an optional port CVID parameter has been added to the existing untagged and CEP VMAN port configuration options. When present, any untagged packet received on the port is double tagged with the configured port CVID and the SVID associated with the VMAN. If the port is untagged, packets received with a single CID still have the SVID added. If the port is CEP, only untagged and any specifically configured CVIDs are allowed. As double tagged ports are received from tagged VMAN ports and forwarded to untagged VMAN ports, the SVID associated with the VMAN is stripped. Additionally, the CVID associated with the configured port CVID is also stripped in the same operation. If the port is CEP and CEP egress filtering in enabled, only the specified port CVID and CVIDs are allowed to egress.

Much like the CVIDs configured as part of the CEP feature, the configured port CVID is not represented by a *VLAN* within ExtremeXOS. The implication is that protocols and individual services cannot be applied to the Port CVID alone. Protocols and services are instead applied to the VMAN and/or port as the VMAN represents the true layer-2 broadcast domain. Much like regular untagged and CEP VMAN ports, MAC *FDB (forwarding database)* learned occurs on the VMAN so duplicate MAC addresses received on multiple CVIDs which are mapped to the same VMAN can be problematic.

Even when the additional Port CVID is configured, the port still has all of the attributes of a regular untagged VMAN port. This means that any single c-tagged packets received on the same port will have just the SVID associated with the VMAN added to the packet. Likewise, any egress packet with a CVID other than the configured Port CVID will have just the SVID stripped. This is not true when the Port CVID specification is part of the CEP configuration, added in ExtremeXOS 16.2.1.

Coexistence with Tagged VLANs Interfaces, CEP VMAN Interfaces, and Tagged VMAN Interfaces

Since the port-cvid configuration still has the attributes of a regular untagged VMAN, all of the *VLAN* and VMAN exclusion and compatibility rules of a regular untagged VMAN port also apply. A list of these rules is contained in "EXOS Selective Q-in-Q". In ExtremeXOS 21.1, when port-cvid is specified as part of CEP, there can only be one such port-cvid on the port. Any adjacent CEP CVIDs will not be included in the same CVID range.

Protocol and Feature Interactions

This feature leverages existing untagged and CEP VMAN port infrastructure, therefore any protocol that works with a regular untagged and CEP VMAN port will also work when the optional Port CVID is additionally configured.

Protocols that locally originate control packets, such as *STP (Spanning Tree Protocol)* and ELRP which are used for loop prevention, will transmit packets as natively untagged on the wire when the port is an untagged VMAN member. These untagged packets will also be able to be received and processed by ExtremeXOS. This makes STP edge safeguard + BPDU guard or ELRP effective ways to detect and react to network loops on the device. However, since control packets are transmitted as untagged upstream devices may need additional configuration support to properly detect remote loops not directly attached to the device.

Other effective loop prevention mechanisms work without any interaction with untagged VMAN ports. For example, turning physical port auto-polarity off will prevent an accidental looped cable from becoming active. Likewise, storm-control rate limiting of broadcast and flood traffic can be applied in this environment to minimize the effects of a network loop. In addition to detecting, preventing, and minimizing the effects of a network loop, user *ACL (Access Control List)*s can be applied to gain visibility and control of L2, L3, and L4 match criteria even with double tagged packets. All applicable ACL action modifiers are available in this environment. IP multicast pruning within a VMAN can be accomplished via normal *IGMP (Internet Group Management Protocol)* snooping. ExtremeXOS supports full IGMP snooping and IP multicast pruning of single tagged and double tagged packets. However, when an IP address is configured on the VMAN, the IGMP protocol engine will transmit single tagged packets on tagged VMAN ports or untagged packets on untagged VMAN ports so upstream switch configuration and support may be necessary to properly propagate group memberships across the network.

CVID Translation

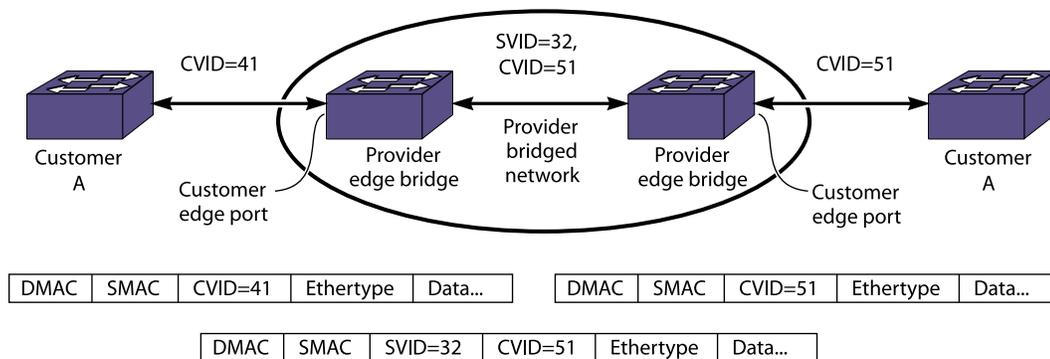
To support CVLANs that are identified by different CVIDs on different CEPs, some switches support a feature called CVID translation, which translates the CVID received at the VMAN ingress to a different CVID for egress from the VMAN (see Figure 83).


Figure 83: CVID Translation

You can use a CLI command to configure CVID translation for a single CVID or for a range of CVIDs, and you can enter multiple commands to define multiple CVIDs and

ranges for translation. The commands can be applied to a single port or a list of ports, and after configuration, the configuration applied to a port is retained by that port.

Note
CVID translation is available only on the platforms listed for this feature in the *ExtremeXOS 32.4 Feature License Requirements* document.

CVID translation can reduce the number of CVIDs that can be mapped to VMANs.

CVID Egress Filtering

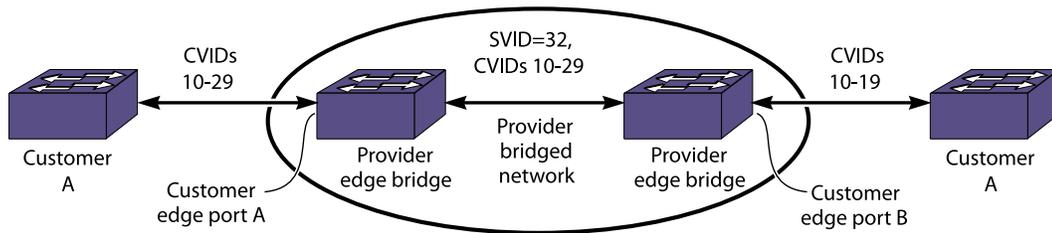
CVID egress filtering permits the egress from VMAN to CEP of only those frames that contain a CVID that has been mapped to the source VMAN; all other frames are blocked. For example, Customer Edge Port A in Figure 84 is configured to support CVIDs 10-29, and Customer Edge Port B is configured to support CVIDs 10-19. If CVID egress filtering is enabled on Customer Edge Port B, frames with CVIDs 20-29 will not be forwarded at the egress of Customer Edge Port B.


Figure 84: CVID Egress Filtering

You can enable CVID egress filtering for a single CEP or for all CEPs with a CLI command. You can also repeat the command to enable this feature on multiple CEPs.

Note
CVID egress filtering is available only on the platforms listed for this feature in the *ExtremeXOS 32.4 Feature License Requirements* document.

When this feature is enabled, it reduces the maximum number of CVIDs that can be mapped to VMANs. The control of CVID egress filtering applies to fast-path forwarding. When frames are forwarded through software, CVID egress filtering is always enabled.

VMAN Configuration Options and Features

As of ExtremeXOS 16.1, you can now referr to a VMAN by VID as an alternative. Specifying lists of VIDs is a is a useful shortcut to all users that can reduce the number of commands required to configure the switch.

Note
Commands enhanced with VID list support operate in a "best effort" fashion. If one of the VIDs in a VID list do not exist the command is still executed for all of the VIDs in the list that do exist. No error or warning is displayed for the invalid VIDs unless all of the specified VIDs are in valid.

ACL Support

The ExtremeXOS software includes VMAN (PBN) _ACL_ support for controlling VMAN frames.

VMAN ACLs define a set of match conditions and modifiers that can be applied to VMAN frames. These conditions allow specific traffic flows to be identified, and the modifiers allow a translation to be performed on the frames.

Secondary Ethertype Support

The C-tag and S-tag components that are added to all VMAN (PBN) frames include C-ethertype and S-ethertype components that specify an ethertype value for the customer _VLAN_ and VMAN, respectively.

> **Note**
> This feature is supported only on the platforms listed for this feature in the license tables in the _ExtremeXOS 32.4 Feature License Requirements_ document.

The C-tag and S-tag components that are added to all VMAN (PBN) frames include C-ethertype and S-ethertype components that specify an ethertype value for the customer VLAN and VMAN, respectively. The I-tag used in PBBN frames also includes an ethertype value. When a VLAN or VMAN frame passes between two switches, the ethertype is checked for a match. If the ethertype does not match that of the receiving switch, the frame is discarded.

The default ethertype values are:
- VLAN port (802.1q frames): 0x8100
- Primary VMAN port (802.1ad frames): 0x88A8
- Secondary VMAN port (802.1ad frames): Not configured

The secondary ethertype support feature applies only to VMANs. The ethertype value for VLAN frames is standard and cannot be changed.

If your VMAN transits a third-party device (in other words, a device other than an Extreme Networks device), you must configure the ethertype value on the Extreme Networks device port to match the ethertype value on the third-party device to which it connects.

The secondary ethertype support feature allows you to define two ethertype values for VMAN frames and select either of the two values for each port.

For example, you can configure ports that connect to other Extreme Networks devices to use the default primary ethertype value, and you can configure ports that connect to other equipment to use the secondary ethertype value, which you can configure to match the requirements of that equipment.

When you create a VMAN, each VMAN port is automatically assigned the primary ethertype value. After you define a secondary ethertype value, you can configure a port to use the secondary ethertype value. If two switch ports in the same VMAN use

different ethertype values, the switch substitutes the correct value at each port. For example, for VMAN edge switches and transit switches, the switch translates an ingress ethertype value to the network port ethertype value before forwarding. For egress traffic at VMAN edge switches, no translation is required because the switch removes the S-tag before switching packets to the egress port.

You can set the primary and secondary ethertypes to any value, provided that the two values are different.

QoS Support

The VMAN (PBN) feature interoperates with many of the *QoS (Quality of Service)* and HQoS features supported in the ExtremeXOS software.

One of those features is egress queue selection, which is described in the next section. For more information on other QoS and HQoS features that work with VMANs, see Quality of Service on page 862.

Egress Queue Selection

This feature examines the 802.1p value or Diffserv code point in a VMAN (PBN) S-tag and uses that value to direct the packet to the appropriate queue on the egress port.

> **Note**
> This feature is supported only on the platforms listed for this feature in the *ExtremeXOS 32.4 Feature License Requirements* document.

On some systems you can configure this feature to examine the values in the C-tag or the S-tag. For more information, see the list in the *ExtremeXOS 32.4 Feature License Requirements* document.. For instructions on configuring this feature, see Selecting the Tag used for Egress Queue Selection on page 643.

VMAN Double Tag Support

The VMAN double tag feature adds an optional port CVID parameter to the existing untagged VMAN port configuration. When present, any untagged packet received on the port will be double tagged with the configured port CVID and SVID associated with the VMAN. Packets received with a single CVID on the same port will still have the SVID added. As double tagged packets are received from tagged VMAN ports and forwarded to untagged VMAN ports, the SVID associated with the VMAN is stripped. Additionally, the CVID associated with the configured Port CVID is also stripped in the same operation.

Much like the CVIDs configured as part of the CEP feature, the configured Port CVID is not represented by a *VLAN* within ExtremeXOS. The implication is that protocols and individual services cannot be applied to the Port CVID alone. Protocols and services are instead applied to the VMAN and/or port as the VMAN represents the true layer-2 broadcast domain. Much like regular untagged VMAN ports, MAC *FDB* learning occurs on the VMAN, so duplicate MAC addresses received on multiple CVIDs that are

mapped to the same VMAN can be problematic. Even when the additional Port CVID is configured, the port still has all of the attributes of a regular untagged VMAN port. This means that any single c-tagged packets received on the same port will have just the SVID associated with the VMAN added to the packet. Likewise, any egress packet with a CVID other than the configured Port CVID will have the SVID stripped.

See Coexistence with Tagged VLANs Interfaces, CEP VMAN Interfaces, and Tagged VMAN Interfaces on page 635.

See Protocol and Feature Interactions on page 635.

Configuration

Configuring VMANs (PBNs)

Guidelines for Configuring VMANs

The following are VMAN configuration guidelines for all platforms:

- Duplicate customer MAC addresses that ingress from multiple VMAN access ports on the same VMAN can disrupt the port learning association process in the switch.
- VMAN names must conform to the guidelines described in Object Names on page 37.
- You must use mutually exclusive names for:
  - *VLAN*s
  - VMANs
  - IPv6 tunnels
- VMAN ports can belong to load-sharing groups.
- You can enable or disable jumbo frames before configuring VMANs. You can enable or disable jumbo frames on individual ports. See Configuring Ports on a Switch on page 224 for more information on configuring jumbo frames.
- *STP* operation on CVLAN components in a PEB as described in IEEE 802.1ad is not supported.
- The initial version of this feature does not implement an XML API.
- Multiple VMAN roles can be combined on one port with certain VLAN types as shown in Table 60.

Table 60: Port Support for Combined VMAN Roles and VLANs

Platform	Combined CNP, CEP, and Tagged VLAN [a,b]	Combined PNP, CNP, and CEP [a,b,c]	Combined PNP and Tagged VLAN	Combined PNP and Untagged VLAN
All ExtremeSwitching Universal platforms	X	X	X [d]	X

> **Note**
> If you already configured VLANs and VMANs on the same stand-alone switch
> using ExtremeXOS 11.4 or later, you cannot change the VMAN ethertype from
> 0X8100 without first removing either the VLAN or VMAN configuration.

Procedure for Configuring VMANs

This section describes the procedure for configuring VMANs. Before configuring
VMANs, review Guidelines for Configuring VMANs on page 640. To configure a VMAN,
complete the following procedure at each switch that needs to support the VMAN:

1. If you are configuring a SummitStack, or an ExtremeSwitching series switch, enable
    jumbo frames on the switch.

    > **Note**
    > You must enable jumbo frames before configuring VMANs on these
    > systems.

2. Create a VMAN using the command:

    `create vman vman_name | vman_list vr vr_name`

3. Assign a tag value to the VMAN using the command:.

    `configure vman vman_name | vman_list` **tag** `tag_id`

4. To configure PNP ports on a PEB or PB, use the following command with the **tagged**
    option:

    `configure vman vman_name | vman_id` **add ports** `[` **all** `|` `port_list` `]`
    `{`**untagged** `{` **port-cvid** `port_cvid}` `|` **tagged**`}`

5. To configure CNP ports on a PEB, use the following command with the **untagged**
    option:

    `configure vman vman_name` **add ports** `[` **all** `|` `port_list` `]` `{`**untagged**
    `{` **port-cvid** `port_cvid}` `|` **tagged**`}`

    > **Note**
    > You must configure CNP ports as **untagged**, so that the S-tag is stripped
    > from the frame on egress. If the **port-cvid** is configured, any untagged
    > packet received on the port will be double tagged with the configured
    > port CVID and the SVID associated with the VMAN. Packets received with
    > a single CVID on the same port will still have the SVID added as usual.
    > As double tagged packets are received from tagged VMAN ports and
    > forwarded to untagged VMAN ports,the SVID associated with the VMAN is
    > stripped. Additionally, the CVID associated with the configured port CVID is
    > also stripped in the same operation.

---

[a] Subsets of this group are also supported. That is, any two of these items are supported.
[b] When a CNP is combined with a CEP or tagged VLAN, any CVIDs not explicitly configured for a CEP or
     tagged VLAN are associated with the CNP.
[c] A PNP (tagged VMAN) and a CNP (untagged VMAN) or CEP cannot be combined on a port for which the
     selected VMAN ethertype is 0x8100.
[d] If the secondary VMAN ethertype is selected for the port, it must be set to 0x8100.

6. To configure CEP ports on a PEB, do the following:

   a. Use the following command to establish a physical port as a CEP and configure CVID mapping and translation:

   ```
   configure vman vman_name | vman_id add ports port_list cep [ cvid
   <cvid or cvid_range> { translate <cvid or cvid_range> } } | port-
   cvid <port_cvid> ] }
   ```

   b. Use the following commands to add or delete CVIDs for a CEP and manage CVID mapping and translation:

   ```
   configure vman vman_name | vman_id ports port_list add cvid {cvid |
   cvid_range} {translate cvid | cvid_range }

   configure vman vman_name ports port_list delete cvid {cvid |
   cvid_range }
   ```

   c. Use the following commands to manage CVID egress filtering for a CEP:

   ```
   enable vman cep egress filtering ports {port_list | all}

   disable vman cep egress filtering ports {port_list | all}
   ```

7. Configure additional VMAN options as described in Configuring VMAN Options on page 642.

8. To configure a _VLAN_ to use a VMAN, configure the VLAN on the switch port at the other end of the line leading to the VMAN access port.

Configuring VMAN Options

Configuring the Ethertype for VMAN Ports

The ethertype is a component of _VLAN_ and VMAN frames. It is introduced in Secondary Ethertype Support on page 638.

> **Note**
> This feature is supported only on the platforms listed for this feature in the license tables in the _ExtremeXOS 32.4 Feature License Requirements_ document.

To configure the ethertype for VMAN (PBN) ports, do the following:

1. Configure the primary and secondary (if needed) VMAN ethertype values for the switch using the following command:

   ```
   configure vman ethertype hex_value [primary | secondary]
   ```

   By default, all VMAN ports use the primary ethertype value.

2. If you plan to use a secondary ethertype, select the secondary ethertype for the appropriate VMAN ports using the following command:

   ```
   configure port port_list ethertype {primary | secondary}
   ```

Selecting the Tag used for Egress Queue Selection

By default, switches that support the enabling and disabling of this feature use the 802.1p value in the S-tag to direct the packet to the queue on the egress port.

> **Note**
>
> This feature is supported and configurable only on the platforms listed for this feature in the license tables in the *ExtremeXOS 32.4 Feature License Requirements* document.

- Configure egress queue dot1p examination of the C-tag using:
  ```
  enable dot1p examination inner-tag port [all | port_list]
  ```
- Return to the default selection of using the 802.1p value in the S-tag using:
  ```
  disable dot1p examination inner-tag ports [all | port_list]
  ```

> **Note**
>
> See Quality of Service on page 862 for information on configuring and displaying the current 802.1p and DiffServ configuration for the S-tag 802.1p value. To enable dot1p examination for inner-tag, dot1p examination for outer-tag must be disabled using the command `disable dot1p examination ports [all | port_list]`

Displaying VMAN Information

Use the following commands to display information on one or all VMANs.

```
show {vman} vman_name {ipv4 | ipv6}
```

```
show vman [tag tag_id | detail] {ipv4 | ipv6}
```

```
show {vman} vman_name eaps
```

> **Note**
>
> The display for the `show vman` command is different depending on the platform and configuration you are using. See the *ExtremeXOS 32.4 Command Reference Guide* for complete information on this command.

You can also display VMAN information, as well as all the VLANs, by issuing the `show ports information detail` command. And you can display the VMAN ethernet type and secondary etherType port_list by using the `show vman etherType` command

Configuration Examples

VMAN CEP Example

The following configuration configures a VMAN CEP to support up to 10 customer VLANs for each of three VMANs.

```
create vman cust1
```

```
create vman cust2
create vman cust3
config vman cust1 tag 1000
config vman cust2 tag 1001
config vman cust3 tag 1002
config vman cust1 add port 22 tag
config vman cust2 add port 22 tag
config vman cust3 add port 23 tag
config vman cust1 add port 1 cep cvid 100 - 109
config vman cust2 add port 1 cep cvid 110 - 119
config vman cust3 add port 1 cep cvid 120 - 129
enable vman cep egress filtering ports 1
```

Port 1 serves as the CEP, and egress filtering is enabled on the port. Ports 22 and 23 serve as CNPs, providing the connection between the CEP port and the rest of each VMAN.

Multiple VMAN Ethertype Example

Figure 85 shows a switch that is configured to support the primary ethertype on three ports and the secondary ethertype on a fourth port.

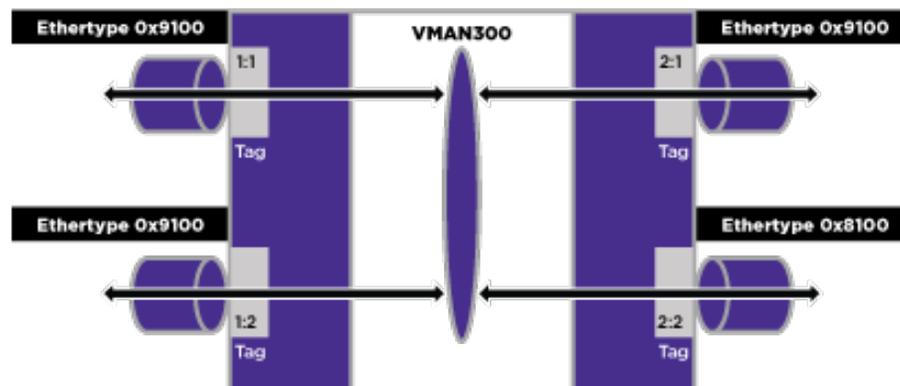
The primary VMAN (PBN) ethertype is changed from the default value, but that is not required.


Figure 85: Multiple VMAN Ethertype Example

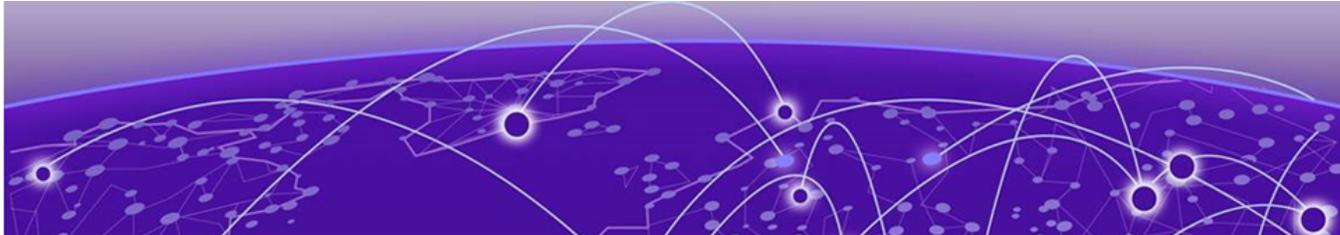
The following configuration commands accomplish what is shown above:

```
# configure vman ethertype 0x9100 primary
# configure vman ethertype 0x8100 secondary
#
# configure port 2:2 ethertype secondary
#
# create vman vman300
# configure vman vman300 tag 300
```

```
#
# configure vman vman300 add port 1:1, 2:1, 2:2 tagged
# configure vman vman300 add port 1:2 untagged
```


FDB

The *FDB (forwarding database)* chapter is intended to help you learn about forwarding databases, adding and displaying entries and entry types, managing the FDB, and MAC-based security. This chapter also provides information about MAC Address tracking.

The switch maintains a forwarding database (FDB) of all MAC addresses received on all of its ports. It uses the information in this database to decide whether a frame should be forwarded or filtered.

> **Note**
> See the *ExtremeXOS 32.4 Command Reference Guide* for details of the commands related to the FDB.

FDB Contents

Each *FDB* entry consists of:

- The MAC address of the device
- An identifier for the port and *VLAN (Virtual LAN)* on which it was received
- The age of the entry
- Flags

Frames destined for MAC addresses that are not in the FDB are flooded to all members of the VLAN.

How FDB Entries Get Added

The MAC entries that are added to the *FDB* are learned in the following ways:

- Source MAC entries are learned from ingress packets on all platforms. This is Layer 2 learning.
- On all switches, MAC entries can be learned at the hardware level.
- Virtual MAC addresses embedded in the payload of IP ARP packets can be learned when this feature is enabled.
- Static entries can be entered using the command line interface (CLI).
- Dynamic entries can be modified using the CLI.
- Static entries for switch interfaces are added by the system upon switch boot-up.

The ability to learn MAC addresses can be enabled or disabled on a port-by-port basis. You can also limit the number of addresses that can be learned, or you can lock down the current entries and prevent additional MAC address learning.

On SummitStacks with different ExtremeSwitching switch models, the FDB tables on some switches can be filled before the tables on other switches. In this situation, when a lower-capacity FDB table cannot accept FDB entries, a message appears that is similar to the following:

```
HAL.FDB.Warning> MSM-A: FDB for vlanID1 mac 00:00:03:05:15:04 was not added to slot 3 -
table full.
```

How FDB Entries Age Out

Software Aging Platforms

When a MAC is learned on a *VLAN*, an *FDB* entry is created for this MAC VLAN combination.Once an FDB entry is created, the aging counter in the `show fdb` output increases from 0 to "polling inteval".

The hardware is checked every "polling interval" seconds to see if there is traffic flow from the given FDB entry.If there is a traffic flow from this MAC, the entry is refreshed and aging counter is reset to 0.

If there is no traffic from that FDB entry during this polling interval, the age gets incremented till the configured age time (configured by `configure fdb agingtime seconds`). The entry gets removed when there is no traffic flow from this FDB entry when the age count reaches the configured age time.

Polling interval = FDB aging time/4 (subject to the minimum and maximum values being 10 and 60 seconds respectively).

FDB Entry Types

Dynamic Entries

A dynamic entry is learned by the switch by examining packets to determine the source MAC address, _VLAN_, and port information.

The switch then creates or updates an _FDB_ entry for that MAC address. Initially, all entries in the database are dynamic, except for certain entries created by the switch at boot-up.

Entries in the database are removed (aged-out) if, after a period of time (aging time), the device has not transmitted. This prevents the database from becoming full with obsolete entries by ensuring that when a device is removed from the network, its entry is deleted from the database.

The aging time is configurable, and the aging process operates on the supported platforms as follows:

- On all platforms, you can configure the aging time to 0, which prevents the automatic removal of all dynamic entries.
- On all platforms, the aging process takes place in software and the aging time is configurable.

For more information about setting the aging time, see Configuring the FDB Aging Time on page 651.

> **Note**
>
> If the FDB entry aging time is set to 0, all dynamically learned entries in the database are considered static, non-aging entries. This means that the entries do not age, but they are still deleted if the switch is reset.

Dynamic entries are flushed and relearned (updated) when any of the following take place:

- A VLAN is deleted.
- A VLAN identifier (VLANid) is changed.
- A port mode is changed (tagged/untagged).
- A port is deleted from a VLAN.
- A port is disabled.
- A port enters blocking state.
- A port goes down (link down).

A non-permanent dynamic entry is initially created when the switch identifies a new source MAC address that does not yet have an entry in the FDB. The entry can then be updated as the switch continues to encounter the address in the packets it examines. These entries are identified by the "d" flag in the `show fdb` command output.

Static Entries

A static entry does not age and does not get updated through the learning process.

A static entry is considered permanent because it is retained in the database if the switch is reset or a power off/on cycle occurs. A static entry is maintained exactly as it was created. Conditions that cause dynamic entries to be updated, such as *VLAN* or port configuration changes, do not affect static entries.

To create a permanent static *FDB* entry, see Adding a Permanent Unicast Static Entry on page 650.

If a duplicate MAC address is learned on a port other than the port where the static entry is defined, all traffic from that MAC address is dropped. By default, the switch does not report duplicate addresses. However, you can configure the switch to report these duplicate addresses as described in Managing Reports of Duplicate MAC Addresses for Static Entries on page 652.

A locked static entry is an entry that was originally learned dynamically, but has been made static (locked) using the MAC address lock-down feature. It is identified by the "s," "p," and "l" flags in show fdb command output and can be deleted using the `delete fdb` command. See MAC Address Lockdown on page 1105 for more information about this feature.

> **Note**
> Static FDB entries created on *EAPS (Extreme Automatic Protection Switching)-* or *STP (Spanning Tree Protocol)-*enabled ports forward traffic irrespective of the port state. Consequently, you should avoid such a configuration.

Blackhole Entries

A blackhole entry configures the switch to discard packets with a specified MAC destination address.

Blackhole entries are useful as a security measure or in special circumstances where a specific source or destination address must be discarded. Blackhole entries can be created through the CLI, or they can be created by the switch when a port's learning limit has been exceeded.

Blackhole entries are treated like permanent entries in the event of a switch reset or power off/on cycle. Blackhole entries are never aged out of the database.

Private VLAN Entries

A Private *VLAN* (PVLAN) creates special *FDB* entries. These are described in MAC Address Management in a PVLAN on page 606.

Managing the FDB

Increasing the FDB Table Size

Some platforms provide a Unified Forwarding Table that allows for flexible allocation of entries to L2, L3, or routes. You can configure this table with the `configure forwarding internal-tables [` **l2-and-l3** `|` **more** `[` **l2** `|` **l3-and-ipmc** `|` **routes** `{`**ipv6-mask-length** `[` **64** `|` **128**`]}]]` command.

Adding a Permanent Unicast Static Entry

To add a static entry use the following command:

`create fdb` *mac_addr* **vlan** *vlan_name* [**ports** *port_list* | **blackhole**]

The following example adds a permanent static entry to the _FDB_:

```
create fdb 00:E0:2B:12:34:56 vlan marketing port 3:4
```

The permanent entry has the following characteristics:

- MAC address is 00:E0:2B:12:34:56.
- _VLAN_ name is marketing.
- Slot number for this device is 3 (SummitStacks only).
- Port number for this device is 4.

You can specify multiple ports when you create a unicast static entry. However, all ports in the list must be on the same SummitStack switch. When the port list contains ports on different slots, the following error is generated:

```
Error: Multiple ports must be on the same slot for unicast MAC FDB entries.
```

Once the multiport static FDB entry is created, any ingress traffic with a destination MAC address matching the FDB entry is multicasted to each port in the specified list. If the FDB entry is the next hop for an IP adjacency, unicast routing sends the packet to the first port in the list.

> **Note**
>
> When a multiport list is assigned to a unicast MAC address, load sharing is not supported on the ports in the multiport list.

ExtremeSwitching series switches do not support this multiport feature natively using the FDB table. Instead, for each FDB entry of this type, a series of system _ACL (Access Control List)_s have been installed which match the specified MAC address and VLAN ID, and override the egress port forwarding list with the supplied list of ports. Multiple ACLs per FDB are required to handle Layer 2 echo kill by installing a unique ACL per individual port in the list to send matching traffic to all other ports in the list.

User-configured ACLs take precedence over these FDB-generated ACL rules, and the total number of rules is determined by the platform.

The hardware ACL limitations for each platform are described in ACLs on page 781.

Adding a Permanent Multicast Static Entry

On SummitStack and ExtremeSwitching series switches, you can create *FDB* entries to multicast MAC addresses (that is, 01:00:00:00:00:01) and list one or more ports.

Use the `create fdb` *mac_addr* **vlan** *vlan_name* [**ports** *port_list* | **blackhole**] command to enter the multicast FDB address. After traffic with a multicast MAC destination address enters the switch, that traffic is multicast to all ports on the list.

However, if the MAC address is in the IP multicast range (for example, 01:00:5e:XX:XX:XX), *IGMP (Internet Group Management Protocol)* snooping rules take precedence over the multicast static FDB entry. Of course, if you disable IGMP snooping on all VLANs, the static FDB entry forwards traffic.

Configuring the FDB Aging Time

- To configure the aging time for dynamic *FDB* entries, use the following command:.

  `configure fdb agingtime` *seconds*

  If the aging time is set to 0, all aging entries in the database are defined as static, nonaging entries. This means the entries will not age out, but non-permanent static entries can be deleted if the switch is reset.
- To display the aging time, use the following command:.

  `show fdb`

Adding Virtual MAC Entries from IP ARP Packets

Generally, the *FDB* is programmed with the source MAC address of frames that contain an IP ARP payload. MAC entries present in the ARP payload as Sender-MAC are not learned. When IP ARP Sender-MAC learning is enabled, the switch learns both the source MAC address and the Sender-MAC from the ARP payload, and the switch programs these MAC addresses in the FDB.

This feature is useful when you want the switch to learn the Sender-MAC address for a redundant protocol, such as *VRRP (Virtual Router Redundancy Protocol)*. For example, if your network has a gateway with a virtual MAC address, the switch learns the system MAC address for the gateway. If you enable the IP ARP Sender-MAC learning feature, the switch also learns the virtual MAC address embedded in IP ARP packets for the gateway IP address.

- To enable the IP ARP sender-MAC learning feature, use the command:

  `enable learning iparp` **sender-mac**
- To view the configuration of this feature, use the command:

  `show iparp`
- To disable this feature, use the command:

  `disable learning iparp` **sender-mac**

Managing Reports of Duplicate MAC Addresses for Static Entries

By default, if a MAC address that is a duplicate of a static MAC address entry is learned on another port (other than the port where the static MAC address is configured), traffic from the duplicate address is silently dropped.

- To enable or disable EMS and *SNMP (Simple Network Management Protocol)* reporting of duplicate addresses for static entries, use the commands:

  ```
  enable fdb static-mac-move

  disable fdb static-mac-move
  ```

- To control the number of EMS and SNMP reports per second issued, use the commands:

  ```
  configure fdb static-mac-move packets count
  ```

- To display the configuration of this feature, use the commands:

  ```
  show fdb static-mac-move configuration
  ```

Clearing FDB Entries

You can clear dynamic and permanent entries using different CLI commands. Clear dynamic *FDB* entries by targeting:

- Specified MAC addresses
- Specified ports
- Specified VLANs
- All blackhole entries

- To clear dynamic entries from the FDB, use the command:

  ```
  clear fdb {mac_addr | ports port_list | vlan vlan_name | blackhole}
  ```

- To clear permanent entries from the FDB, use the command:

  ```
  delete fdb [all | mac_address [vlan vlan_name ]
  ```

Supporting Remote Mirroring

The remote mirroring feature copies select traffic from select ports and VLANs and sends the copied traffic to a remote switch for analysis.

The mirrored traffic is sent using a *VLAN* that is configured for this purpose. For more information, see MLAG Limitations and Requirements on page 279.

Transit switches are the switches between the source switch where ports are mirrored and the destination switch where the mirrored traffic exits the network to a network analyzer or network storage device.

Because the mirrored traffic is an exact copy of the real traffic, a transit switch can learn the MAC addresses and make incorrect forwarding decisions.

Displaying FDB Entries and Statistics

Display FDB Entries

- Display *FDB* entries using the following command:

  ```
  show fdb {blackhole {netlogin [all | mac-based-vlans]} | netlogin
  [all | mac-based-vlans] | permanent {netlogin [all | mac-based-vlans]}
  | mac_addr {netlogin [all | mac-based-vlans]} | ports port_list
  {netlogin [all | mac-based-vlans]} | vlan vlan_name | vlan_list
  {netlogin [all | mac-based-vlans]} | {{vpls} {vpls_name}}}
  ```

  With no options, this command displays all FDB entries.

Display FDB Statistics

To display *FDB* statistics, use the command:

```
show fdb stats {{ports {all | port_list} | vlan {all} | {vlan} vlan_name
| vlan_list } {no-refresh}}
```

With no options, this command displays summary FDB statistics.

MAC-Based Security

MAC-based security allows you to control the way the *FDB* is learned and populated. By managing entries in the FDB, you can block and control packet flows on a per-address basis.

MAC-based security allows you to limit the number of dynamically-learned MAC addresses allowed per virtual port. You can also "lock" the FDB entries for a virtual port, so that the current entries will not change, and no additional addresses can be learned on the port.

You can also prioritize or stop packet flows based on the source MAC address of the ingress *VLAN* or the destination MAC address of the egress VLAN.

> 📝 **Note**
>
> For detailed information about MAC-based security, see Security on page 1085.

Managing MAC Address Learning

By default, MAC address learning is enabled on all ports. MAC addresses are added to the *FDB* as described in How FDB Entries Get Added on page 647.

When MAC address learning is disabled on a port, the switch no longer stores the source address information in the FDB. However, the switch can still examine the source MAC address for incoming packets and either forward or drop the packets based on this address. The source address examination serves as a preprocessor for packets. Forwarded packets are forwarded to other processes, not to other ports. For

example, if the switch forwards a packet based on the source address, the packet can still be dropped based on the destination address or the egress flooding configuration.

When MAC address learning is disabled, the two supported behaviors are labeled as follows in the software:

- forward-packets
- drop-packets

The drop-packets behavior is supported on SummitStack and ExtremeSwitching series switches. When the drop-packets option is chosen, EDP packets are forwarded, and all unicast, multicast, and broadcast packets from a source address not in the FDB are dropped. No further processing occurs for dropped packets.

The disable learning forward-packets option saves switch resources (FDB space), however, it can consume network resources when egress flooding is enabled. When egress flooding is disabled or the drop-packet option is specified, disabling learning adds security by limiting access to only those devices listed in the FDB.

> **Note**
> When the forward-packet option is chosen,
>
> - If unicast, multicast, and broadcast packet from a source address is not present in the FDB , the packets is flooded.
> - If the destination MAC is present in the forwarding database, the packet is forwarded.

- To disable learning on specified ports, use the command:

  disable learning {**drop-packets** | **forward-packets**} **port** [*port_list* | **all**]

- To enable learning on specified ports, use the command:

  enable learning {**drop-packets**} **ports** [**all** | *port_list*]

Managing Egress Flooding

Egress flooding takes action on a packet based on the packet destination MAC address. By default, egress flooding is enabled, and any packet for which the destination address is not in the *FDB* is flooded to all ports except the ingress port.

You can enhance security and privacy as well as improve network performance by disabling Layer 2 egress flooding on a port, *VLAN*, or VMAN. This is particularly useful when you are working on an edge device in the network. Limiting flooded egress packets to selected interfaces is also known as upstream forwarding.

> **Note**
> Disabling egress flooding can affect many protocols, such as IP and ARP.

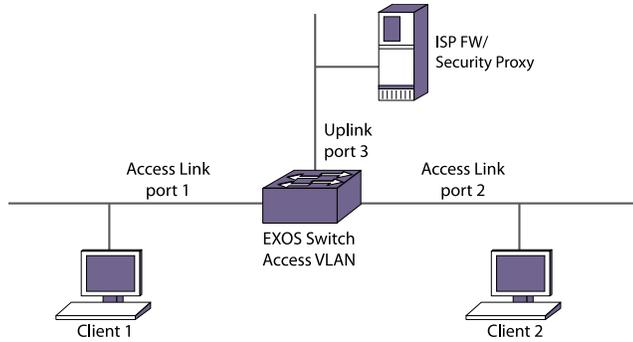
Figure 86 illustrates a case where you want to disable Layer 2 egress flooding on specified ports to enhance security and network performance.


Figure 86: Upstream Forwarding or Disabling Egress Flooding Example
In this example, the three ports are in an ISP-access VLAN. Ports 1 and 2 are connected to clients 1 and 2, respectively, and port 3 is an uplink to the ISP network. Because clients 1 and 2 are in the same VLAN, client 1 could possibly learn about the other client's traffic by sniffing client 2's broadcast traffic; client 1 could then possibly launch an attack on client 2.

However, when you disable all egress flooding on ports 1 and 2, this sort of attack is impossible, for the following reasons:
- Broadcast and multicast traffic from the clients is forwarded only to the uplink port.
- Any packet with unlearned destination MAC addresses is forwarded only to the uplink port.
- One client cannot learn any information from the other client. Because egress flooding is disabled on the access ports, the only packets forwarded to each access port are those packets that are specifically targeted for one of the ports. There is no traffic leakage.

In this way, the communication between client 1 and client 2 is controlled. If client 1 needs to communicate with client 2 and has that IP address, client 1 sends out an ARP request to resolve the IP address for client 2.

Guidelines for Enabling or Disabling Egress Flooding

The following guidelines apply to enabling and disabling egress flooding:
- Egress flooding can be disabled on ports that are in a load-sharing group. In a load-sharing group, the ports in the group take on the egress flooding state of the master port; each member port of the load-sharing group has the same state as the master port.
- *FDB* learning takes place on ingress ports and is independent of egress flooding; either can be enabled or disabled independently.
- Disabling unicast (or all) egress flooding to a port also prevents the flooding of packets with unknown MAC addresses to that port.
- Disabling broadcast (or all) egress flooding to a port also prevents the flooding of broadcast packets to that port.
- For SummitStack and ExtremeSwitching series switches, the following guidelines apply:
  - You can enable or disable egress flooding for unicast, multicast, or broadcast MAC addresses, as well as for all packets on one or more ports.

- Disabling multicasting egress flooding does not affect those packets within an *IGMP* membership group at all; those packets are still forwarded out.
- If IGMP snooping is disabled, multicast packets with static FDB entries are forwarded according to the FDB entry.

Configuring Egress Flooding

To enable or disable egress flooding on SummitStack and the ExtremeSwitching series switches, use the following commands:

```
enable flooding [all_cast | broadcast | multicast | unicast] ports
[port_list | all]
```

```
disable flooding [all_cast | broadcast | multicast | unicast] ports
[port_list | all]
```

Displaying Learning and Flooding Settings

To display the status of MAC learning and egress flooding, use the following commands:

```
show ports {mgmt | port_list | tag tag} information {detail}
```

```
show vlan {virtual-router vr-name}
```

```
show vman vman_list
```

The flags in the command display indicate the status.

Creating Blackhole FDB Entries

A blackhole *FDB* entry discards all packets addressed to or received from the specified MAC address. A significant difference between the above *ACL* policy and the `create fdb` command **blackhole** option is the hardware used to implement the feature. Platforms with limited hardware ACL table sizes are able to implement this feature using the FDB table instead of an ACL table.

- To create a blackhole FDB entry, use the command:
  ```
  create fdb mac_addr vlan vlan_name [ports port_list | blackhole]
  ```

  There is no software indication or notification when packets are discarded because they match blackhole entries.

  The **blackhole** option is also supported through access lists.

  > **Note**
  > Blackhole is not supported on port-specific *VLAN* tags.

  For example, the following ACL policy would also blackhole traffic destined to or sourced from a specific MAC address:

  ```
  entry blackhole_dest {
  if {
  ```

```
ethernet-destination-address 00:00:00:00:00:01;
} then {
deny;
}
}
entry blackhole_source {
if {
ethernet-source-address 00:00:00:00:00:01;
} then {
deny;
}
}
```

Managing MAC Address Tracking

The MAC address tracking feature tracks *FDB* add, move, and delete events for specified MAC addresses and for specified ports.

When MAC address tracking is enabled for a port, this feature applies to all MAC addresses on the port.

When an event occurs for a specified address or port, the software generates an EMS message and can optionally send an *SNMP* trap. When MAC address tracking is enabled for a specific MAC address, this feature updates internal event counters for the address. You can use this feature with the Universal Port feature to configure the switch in response to MAC address change events (for an example, see Universal Port on page 392).

> **Note**
>
> When a MAC address is configured in the tracking table, but detected on a MAC tracking enabled port, the per MAC address statistical counters are not updated.

The MAC address tracking feature is always enabled; however, you must configure MAC addresses or ports before tracking begins. The default configuration contains no MAC addresses in the MAC address tracking table and disables this feature on all ports.

Adding and Deleting MAC Addresses for Tracking

Use the following commands to add or delete MAC addresses in the MAC address tracking table:

create fdb mac-tracking entry *mac_addr*

delete fdb mac-tracking entry [*mac_addr* | **all**]

Enabling and Disabling MAC Address Tracking on Ports

Use the following command to enable or disable MAC addresses tracking on specific ports:

configure fdb mac-tracking {[**add**|**delete**]} **ports** [*port_list*|**all**]

Enabling and Disabling SNMP Traps for MAC Address Changes

The default switch configuration disables *SNMP* traps for MAC address changes.

Use the following commands to enable or disable SNMP traps for MAC address tracking events:

```
enable snmp traps fdb mac-tracking
```

```
disable snmp traps fdb mac-tracking
```

Configuring Automatic Responses to MAC Tracking Events

The EMS messages produced by the MAC address tracking feature can be used to trigger Universal Port profiles. These are described in Event Management System Triggers on page 398.

The subcomponent name for MAC address tracking events is FDB.MACTracking.

Displaying the Tracked MAC Addresses and Tracking Statistics

- To display the MAC address tracking feature configuration, including the list of tracked MAC addresses, use the command:

  ```
  show fdb mac-tracking configuration
  ```
- To display the counters for MAC address add, move, and delete events, use the command:

  ```
  show fdb mac-tracking statistics {mac_addr} {no-refresh}
  ```

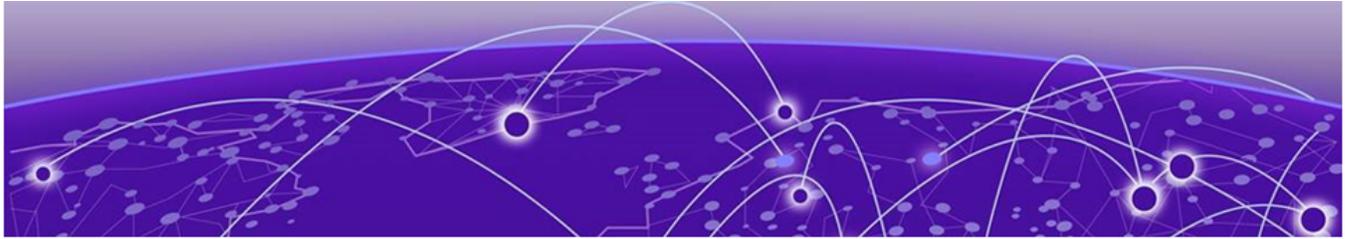
Clearing the Tracking Statistics Counters

There are several ways to clear the MAC tracking counters:

- Use the `clear counters` command.
- Use the **0** key while displaying the counters with the `show fdb mac-tracking statistics {mac_addr}` command.
- Enter the `clear counters fdb mac-tracking [mac_addr | all]` command.

Integrated Application Hosting

This chapter explains the Integrated Application Hosting (IAH) feature.

This chapter provides information on configuring, managing, and displaying IAN virtual machine (VM) information.


Integrated Application Hosting Overview

The Integrated Application Hosting (IAH) feature provides the ability to host guest VMs on ExtremeXOS-based switches.

The IAH infrastructure includes:

- ExtremeXOS Virtualization Manager component—responsible for guest VM management and control, management of networking connectivity, management of compute resources, and complete isolation of activity from ExtremeXOS.
- KVM (Kernel Virtual Machine)—Linux kernel feature enabling hardware-accelerated virtualization.
- QEMU (Quick EMUlator)—an open-source emulator and hypervisor.

VMs can be packaged as either OVAs (Open Virtual Appliance) or qcow2 or any QEMU-compatible (including VMDK) disk images.

Requirements

IAH requires the following:

- Core or Premier license (for more information about licenses, see the *ExtremeXOS 32.4 Feature License Requirements*)
- Solid State Storage Device SSD-120 (see SSD-120 Device on page 660).

SSD-120 Device

The SSD-120 device is a dedicated storage device, required for the Integrated Application Hosting (IAH) feature, and provides support for virtual machines (VMs) on ExtremeXOS-based switches, including:

- Storage of VM installation images (OVA and downloaded qcow2 or any QEMU-compatible (including VMDK) disk images)
- VM configuration files (libvirt XML format)
- Disk images for installed VMs
- Libvirt configuration files

Third-Party Virtual Machine (TPVM)

SSD-120 contains Third-Party Virtual Machine (TPVM), which is an Ubuntu-based VM appliance supporting a number of network-centric applications. TPVM allows you to run applications such as Docker Container, Syslog server, SNMP server, and RESTful applications, among others. TPVM runs as a separate, independent VM, sharing the host CPU, RAM, hard disk drive, and management resources with ExtremeXOS.

Folder Structure

The folder structure of SSD-120 is available at `/usr/local/vm`. The `/usr/local/vm/packages` folder is for storing downloaded OVA, qcow2, and QEMU-compatible VM installation files.

Virtual Machine (VM) Network Connectivity

Running virtual machines (VMs) can access the Management VLAN when an associated VM port is assigned an IP address on the Management VLAN. This access is intended for management/maintenance purposes, and shares the bandwidth of the management port with switch management.

The normal connectivity between a guest VM and the network is by dedicated ports. Any management operations (CLI commands, SNMP gets/sets, API calls, etc.) that can be applied to a front-panel port can also be applied to a dedicated port. Only one guest VM can be configured per dedicated port.

To configure Integrated Application Hosting (IAH) VMs, including adding dedicated ports, see Configuring Integrated Application Hosting (IAH) Virtual Machines on page 662 .

Integrated Application Hosting (IAH) GUI Support

The video output device of a guest OS is accessible using any VNC client.

For information about configuring VNC, see Configuring Integrated Application Hosting (IAH) Virtual Machines on page 662 and Integrated Application Hosting (IAH) Commands on page 664. For information about VNC limitations, see Integrated Application Hosting (IAH) Limitations on page 661.

Integrated Application Hosting (IAH) Supported Platforms

Integrated Application Hosting (IAH) is supported on the ExtremeSwitching X465-24MU, X465-24MU-24W, X465i-48W, and X465-24XE; and X695 series switches running a Core or Premier license. For more information about licenses, see the *ExtremeXOS 32.4 Feature License Requirements*.

Integrated Application Hosting (IAH) Limitations

Integrated Application Hosting (IAH) has the following limitations:

- A maximum of two CPU cores can be dedicated to VMs.
- Multiple guest VMs per dedicated port is not supported.
- On stacks, the VMs do not migrate to backup with a failover. You will need to restore the original master as master to access your VMs again.
- Only OVA, qcow2, and any QEMU-compatible files are supported. Compatibility issues might occur when using third-party OVA files. The image formats VMDK and qcow2 are generally more reliable than third-party OVA files.
- You cannot rename a VM after creating it.
- VNC servers are only accessible using SSH tunnel for security reasons.
- VNC support is not available on non-primary stack nodes.

Creating an Ubuntu Virtual Machine

To create an Ubuntu virtual machine (VM) qcow2 disk image:

1. Download Ubuntu server 16.04 LTS or 18.04 LTS:

   - http://releases.ubuntu.com/18.04.2/ubuntu-18.04.2-live-server-amd64.iso
   - http://releases.ubuntu.com/16.04.6/ubuntu-16.04.6-server-amd64.iso

2. Use virt-manager on a Linux system to create a VM with 2 CPUs, 4 GB RAM and 32 GB hard disk of qcow2 format. Select the option `customize configuration before install`.

3. Customize the configuration to change the hard disk bus type to `VirtIO`.

4. Start the VM.

5. Follow the prompts to complete the Ubuntu installation.

6. Enable the serial console:

   a. Edit the file `/etc/default/grub` to have the following settings:

   ```
   GRUB_CMDLINE_LINUX="console=tty1 console=ttyS0,115200"
   GRUB_TERMINAL="console serial"
   GRUB_SERIAL_COMMAND="serial --speed=115200 --unit=0 --word=8 --parity=no --stop=1"
   ```

   b. Update `/boot/grub/grub.cfg`: update-grub.

7. (Optional) Update the system and install additional software:

    a. Enable all repositories for apt:

        - apt-add-repository restricted
        - apt-add-repository universe
        - apt-add-repository multiverse
        - apt update

    b. Upgrade Ubuntu and software: `apt upgrade`.

    c. Reboot if required.

    d. Install additional software:

        - apt install build-essential
        - apt install checkinstall
        - apt install iperf apt install mtools
        - apt install netperf
        - apt install qemu-guest-agent
        - apt install tshark
        - apt install valgrind
        - apt install vim-gnome
        - apt install wireshark
        - apt install xterm

8. Fill the unused disk space with zeros so that the image interacts well with compression: `dd if=/dev/zero of=/mytempfile` (will eventually error out with 'out of space', but may take a while):

```
rm -f /mytempfile
```

9. Shutdown the VM.

10. Copy the qcow2 disk image onto an ExtremeXOSswitch and install it as a VM. The image is located at `/var/lib/libvirt/images/`.

    > **Note**
    > If you do not have root access, you the following command to create a copy of the disk image: `virsh vol-download --pool default disk_name.qcow2 my_copy.qcow2`.

    > **Note**
    > The image size can be reduced substantially because of all the adjacent zeroes: `qemu-img convert -O qcow2 my_copy.qcow2 my_reduced_copy.qcow2`.

Configuring Integrated Application Hosting (IAH) Virtual Machines

Ensure that you have a Core or Premier license installed on the switch (for more information about licenses, see the *ExtremeXOS 32.4 Feature License Requirements*), and that you have purchased a Solid State Storage Device (SSD) SSD-120.

To set up an Integrated Application Hosting (IAH) guest virtual machine (VM):

1. Install the Solid State Storage Device (SSD) SSD-120:

   a. Power down the switch.
   b. On the rear panel of the switch, remove the cover from the SSD slot.
   c. Insert SSD-120 into the SSD slot.
   d. Power up the switch.

2. Download a VM installation file (OVA, qcow2, or any QEMU-compatible file) to SSD-120 to `/usr/local/vm/packages` using the command `scp2 {`**`cipher`**` `*`cipher`*`}` `{`**`mac`**` `*`mac`*`}` `{`**`compression`**` [`**`on`**` | `**`off`**`]}` `{`**`port`**` `*`portnum`*`}` `{`**`vr`**` `*`vr_name`*`}` *`user`* `[`*`hostname`*` | `*`ipaddress`*`]:`*`remote_file`*` `*`local_file`*` . Alternatively, you can use the Third-Party Virtual Machine (TPVM), which is included on SSD-120.

3. Install the VM using one of the following commands:

   - Disk image: `create` **`vm`** *`vm_name`* **`image`** *`image_file`* `{`**`memory`** *`memory_size`*`}` `{`**`cpus`** *`num_cpus`*`}` `{`**`slot`** *`slot_ID`*`}{`**`vnc`** `[`**`none`** | *`vnc_display`*`]}`
   - OVA file: `create` **`vm`** *`vm_name`* **`ova`** *`ova_file`* `{`**`memory`** *`memory_size`*`}` `{`**`cpus`** *`num_cpus`*`}` `{`**`slot`** *`slot_ID`*`}` `{`**`vnc`** `[`**`none`** | *`vnc_display`*`]}`

   > **Note**
   > Compatibility issues might occur when using third-party OVA files. The image format qcow2 is generally more reliable.

   The default for number of CPUs allocated is 1. The default amount of RAM allocated to a VM is 4,096 MB. You can change this with the `create vm` command as needed.

   The VNC server only listens to the switch's loopback IP address (127.0.0.1). You need to forward TCP traffic from the server's port on the switch to a port that the client software is running on using an _SSH (Secure Shell)_ tunnel. On the switch, VNC port numbers range from 5,900 to 5,915.

   To create this setup, use the following command:

   `ssh admin@`*`mgmt_ip`*` -L `*`port_on_client_system`*`:127.0.0.1:`*`port_on_switch`*

4. Add IAH dedicated ports to the VM.

   `configure` **`vm`** *`vm_name`* `{`**`add`** | **`delete`**`}` **`ports`** *`portlist`*

5. Choose whether or not the VM should start up automatically when ExtremeXOS starts. Automatic start-up is disabled by default. To enable automatic start-up, use the following command:

   `enable` **`vm`** *`vm_name`* **`autostart`**

6. To open a session to the VM's serial console, use the following command:

   open **vm** *vm_name* {**console**}

   | **Note**
   | TPVM is configured to use a serial console.

   | **Note**
   | You cannot access the serial console before starting a VM. You must start the VM, and then reboot it to gain serial console access.

7. Optionally, add virtual interfaces to the VM using the following command (maximum 16 virtual interfaces):

   configure **vm** *vm_name* **add virtual-interface port** *port* {**vlan** *vlan_id*} {**name** *vf_name*}

8. Optionally, change the vm's disk bus or controller, using the following command:

   configure **vm** *vm_name* **disk bus-type** *bus_type*

   The default bus type is VirtIO, but some operating systems are do not support this, and as a consequence, the VM will fail to boot. You can configure the bus type to IDE or SCSI.

9. Start the VM.

   start **vm** *vm_name*

To check the status of the VM, use the following commands:

- For operational status information: show **vm** {*vm_name* | **detail**}

- For interfaces information: show **vm** *vm_name* **guest interfaces**

If needed to save disk space, after successful creation of the VM, you can delete the VM package file at /usr/local/vm/packages.

For additional IAH commands, see Integrated Application Hosting (IAH) Commands on page 664.

Integrated Application Hosting (IAH) Commands

The following topics shows all Integrated Application Hosting (IAH) for guest virtual machines (VMs) commands.

Creating VMs

    create **vm** *vm_name* **ova** *ova_file* {**memory** *memory_size*} {**cpus** *num_cpus*}
    {**slot** *slot_ID*} {**vnc** [**none** | *vnc_display*]}

    create **vm** *vm_name* **image** *image_file* {**memory** *memory_size*} {**cpus** *num_cpus*}
    {**slot** *slot_ID*}{**vnc** [**none** | *vnc_display*]}

Configuring VMs

```
configure vm vm_name {add | delete} ports portlist

open vm vm_name {console}

configure vm vm_name cpus num_cpus

configure vm vm_name memory memory_size

configure vm vm_name add virtual-interface port port {vlan vlan_id}
{name vf_name}

configure vm vm_name delete virtual-interface [name vf_name | mac
mac_addr]

configure vm vm_name vnc [none | vnc_display]

configure vm vm_name disk bus-type bus_type
```

Starting/Stopping/Suspending/Resuming VMs

```
start vm vm_name

stop vm vm_name [forceful | graceful]

restart vm vm_name {forceful | graceful}

suspend vm vm_name

resume vm vm_name
```

Enabling/Disabling Automatic Start-up for VMs

```
enable vm vm_name autostart

disable vm vm_name autostart
```

Deleting VMs

```
delete vm vm_name
```

Showing VM Information

```
show vm {vm_name | detail}

show vm vm_name guest interfaces

show vm vm_name virtual-interface {vf_name}
```

Clearing VM Storage

```
clear vm storage
```

Saving VMs

```
save vm vm_name state
```

Removing VMs

To remove all installed VMs, use the following command with the **all** option:

```
unconfigure switch {all | erase [all | nvram]}
```

> **Note**
> VM installation files (OVA, qcow2, QEMU-compatible) are not removed with this command.

Be aware that using this command generally resets the switch back to factory defaults, which includes removing the configuration file, management IP address, failsafe account, and SummitStack-specific parameters, and the rebooting the switch.

Exporting VM Disk Images

```
save vm vm_name image image_file
```

Integrated Application Hosting Use Cases

The following section provides use cases for the Integrated Application Hosting (IAH) feature.

Palo Alto Firewall Virtual Machine (VM) Use Case

Palo Alto Networks offers a virtualized version of its firewall that is compatible with the X86_64-based compute complex provided by the Extreme Networks Integrated Application Hosting (IAH) system. The following sections detail the procedure for integrating this VM into IAH.

Solution Requirements and Design

The virtual machine will load, start, and function. The first port configured to the VM is assigned to the Palo Alto management interface. Subsequent ports attach sequentially from Ethernet 1/1. Sub-interfaces do work with this VM, so it is easily possible to deploy the firewall with a single Integrated Application Hosting (IAH) forwarding plane

port, and break out ports using VLANs on the switch. The serial terminal function of ExtremeXOS works with no extra configuration required.

Table 61: Services Offered by the IAH Compute Environment on ExtremeXOS

Switch Models	Number of CPUs	Available RAM	Available Storage	Dedicated Management Port	Management Port BW	Number of Sideband Ports	Sideband BW Supported
X465i-48W	2	6GB	120GB	Yes	1G	2	10G
X465-24MU	2	6GB	120GB	Yes	1G	2	10G
X465-24MU-24W	2	6GB	120GB	Yes	1G	2	10G
X465-24XE	2	6GB	120GB	Yes	1G	2	10G
X695-48Y-8C	6	14GB	128GB	Yes	1G	1	10G

Table 62: Extreme Integration Elements

Minimum ExtremeXOS Version	Switch Model	Resources Required from IAH to Support Solution	License Requirement
30.7	X465-24MU-24W	2 CPU cores 5,730 KB of RAM	Core license
30.7	X695-48Y-8C	2 CPU cores 8,192 KB of RAM	Core license

Table 63: Palo Alto Integration Elements

AP OS	Application	Resources Required from IAH to Support Solution	License Requirement
9.1.2	PAN VM-100 (PA-KVM-9.1.2.qcow2)	2 CPU cores 5,730 KB of RAM	Standard Subscription
9.1.2	PAN VM-100 (PA-KVM-9.1.2.qcow2)	2 CPU cores 8,192 KB of RAM	Standard Subscription

> **Note**
> Virtual Interface mapping is not visible to the Palo Alto Firewall virtual machine. If all mapped interfaces are virtual, the VM will panic and go into maintenance mode.

Installation and Configuration Procedure

For this procedure port 57 is assigned to the "inside" VLAN on the switch. This VLAN requires an internal DHCP server on the 192.168.1.x/24 subnet. To create this, use the following command:

```
# configure Default add ports 57
```

To verify the Default VLAN configuration:

```
# show inside
X465-24MU-24W.5 # sh inside
VLAN Interface with name inside created by user
    Admin State:        Enabled     Tagging:   802.1Q Tag 10
    Description:        None
    Virtual router:     VR-Default
    IP Anycast:         Disabled
    IPv4 Forwarding:    Disabled
    IPv4 MC Forwarding: Disabled
    Primary IP:         192.168.1.254/24
    IPv6 Forwarding:    Disabled
    IPv6 MC Forwarding: Disabled
    IPv6:               None
    STPD:               None
    Protocol:           Match all unfiltered protocols
    Loopback:           Disabled
    NetLogin:           Disabled
    QosProfile:         None configured
    Egress Rate Limit Designated Port: None configured
    Flood Rate Limit QosProfile:      None configured
    Suppress ARP:       Disabled
    Suppress ND:        Disabled
    Proxy ARP:          Entry required
    Ports:   2.            (Number of active ports=1)
       Untag:       1,*57(Insight)
```

1. Transfer the firewall image to the switch by entering the directory of the images:

   ```
   # cd /usr/local/vm/packages/
   ```

   > **Note**
   > If you are unable to change to this directory, you are likely missing a Core license on your switch.

2. Transfer the image to the server/host with SFTP/SCP services:

   ```
   # scp2 vr VR-Default <username>@<IP Address of SCP Host>:PA-KVM-9.1.2.qcow2 PA-
   KVM-9.1.2.qcow2
   ```

3. Create the VM:

   ```
   # create vm PAN image PA-VM-KVM-9.1.2.qcow2 cpu 2 memory 5730
   Creating
   VM.....................................................................................
   ....................
   VM PAN created successfully.
   ```

4. Configure the VM with interfaces.

   Assign two interfaces to the firewall: port 57 and 58. The VM picks up the first interface that comes up. The management port is shared with the front panel management port of the switch and should be addressed for that management interface. Port 57 on the ExtremeSwitching X465 is directly connected to the forwarding plane of the switch

   ```
   # configure vm PAN add ports mgmt
   # configure vm PAN add ports 57
   # configure vm PAN add ports 58
   ```

   Adding these ports in sequence maps them in sequence as the VM boots. Palo Alto takes the first port for management, then the second port as Ethernet 1/1, and the third as Ethernet 1/2. The ports are configured on the switch to VLAN Mgmt (10.10.10.x), VLAN inside (192.168.1.x), and VLAN outside (10.10.100.x). Each VLAN has a DHCP server available for their respective subnets. If you want the VM to start automatically every time the switch is booted, add this command:

   ```
   # enable vm pan autostart
   ```

5. Verify the configuration of the VM:

   ```
   # shOW vm pan
       VM Name:          pan
       State:        Stopped
       Memory size: 5370 MB
       CPUs:         2
       Auto-start:  Disabled
       VNC:          127.0.0.1:1 (Port 5901)
       Disk:         vda
           Source:                   /mnt/vmdisk/.vm/pan_PA-VM-KVM-9.1.2.qcow2
           Disk bus type:        virtio
           Allocated size in bytes: 64424509440 (60.00 GB)
           Physical size in bytes:  5583732736 (5.20 GB)
           Read requests:        0
           Bytes read:           0
           Write requests:       0
           Bytes written:        0
       Network interfaces:
           Attached switch ports:   mgmt,57-58
   ```

6. Start the VM:

   ```
   # start vm pan
   ```

7. Open a console connection into the VM:

   ```
   # open vm PAN
   Connected to domain PAN
   Escape character is ^Y
   ```

   > **Note**
   > The Palo Alto firewall VM takes a moment to boot-up. It may be a few minutes before the prompt appears on the CLI.

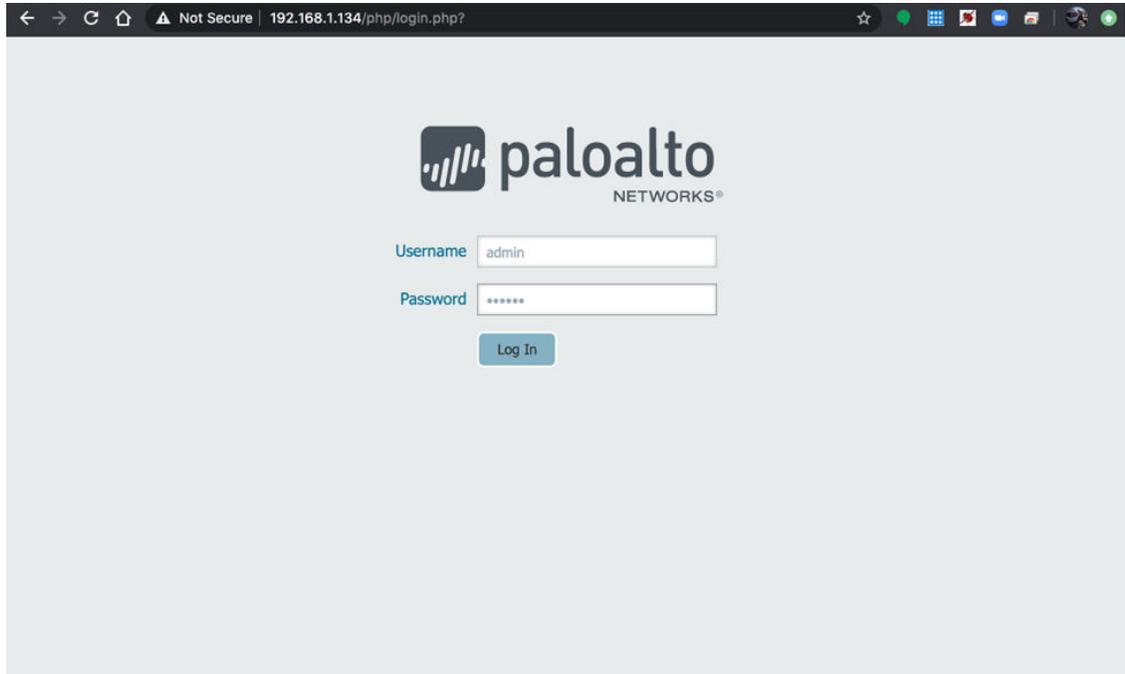
   The firewall will report the IP address it retrieved in the CLI before logon: DHCP: new IP 10.10.10.149 : mask 255.255.255.0


Figure 87: Palo Alto Firewall Logon Window

8. Open the serial connection to the firewall VM on the ExtremeXOS CLI:

```
Connected to the domain pan
Escape character is ^Y

PA-VIM Login:
```

9. Log on with the credentials: admin/admin.

10. Connect using VNC:

The IAH complex on ExtremeXOS also offers a proxy to a switch with a VNC connection to the VM. You can map up to 16 connections. In this case, VNC connection 1 is mapped. Opening this VNC session provides direct access to the VM "screen". No special configuration of the virtual machine is required.

You can see this configuration using the command `show vm pan`. The mapped port is 5901, but it is not directly accessible. To reach this port, it is necessary to map an SSH tunnel on the client accessing the switch. On MacOS and Linux environments, us the following command:

```
# ssh admin@<ip address of the switch> -L 5901:127.0.0.1:5901
```

You are prompted for your password, and a successful logon to the switch also creates an SSH tunnel to the VNC server. Use your favorite VNC client to open: 127.0.0.1:1.

11. Activate the firewall interface and assign VLANs for zones:

Configure according to Palo Alto instructions. The firewall interface is Eth1/1 and Eth1/2. This example is configured with each in Layer 3 mode for the X465. The interfaces are directed to request IP addressing from the switch DHCP server.

12. Confirm the DHCP server setup:

```
# show dhcp-server
    VLAN "inside":
    DHCP Address Range    : 192.168.1.100->192.168.1.110
    Netlogin Lease Timer : Not configured (Default = 10 seconds)
    DHCP Lease Timer      : Not configured (Default = 7200 seconds)
    Default Gateway       : 192.168.1.1
    Primary DNS Server    : 8.8.8.8
    Ports DHCP Enabled    : 1,57

    ============================================================================
    IP                 MAC                    State      Lease Time Left
    ============================================================================
       192.168.1.100   48:9b:d5:eb:1e:42   Assigned   0001:22:17

VLAN "outside":
    DHCP Address Range    : 10.10.100.100->10.10.100.110
    Netlogin Lease Timer : Not configured (Default = 10 seconds)
    DHCP Lease Timer      : Not configured (Default = 7200 seconds)
    Ports DHCP Enabled    : 58

    ============================================================================
    IP                 MAC                    State      Lease Time Left
    ============================================================================
       10.10.100.100   48:9b:d5:eb:1e:43   Assigned   0001:22:17
```

13. Continue configuring the firewall. For more information, see the Palo Alto Networks documentation.

The X465 is configured for two firewall interfaces mapped to non-trunked ports on the switch in Layer 3 mode for a total of two zones: inside and outside. DHCP was used to assign IP addresses. You can chose instead to use tagged VLANs on the switch ports 57 and 58 to present more switch VLANs to the firewall by sub-interfaces or VLANs. Using two sideband ports give the X465 a theoretical bandwidth of 20Gb/s in and 20Gb/s out for firewall inspection.

14. Configure the interfaces to allow PING and other services, so that bi-directional communication can be verified.

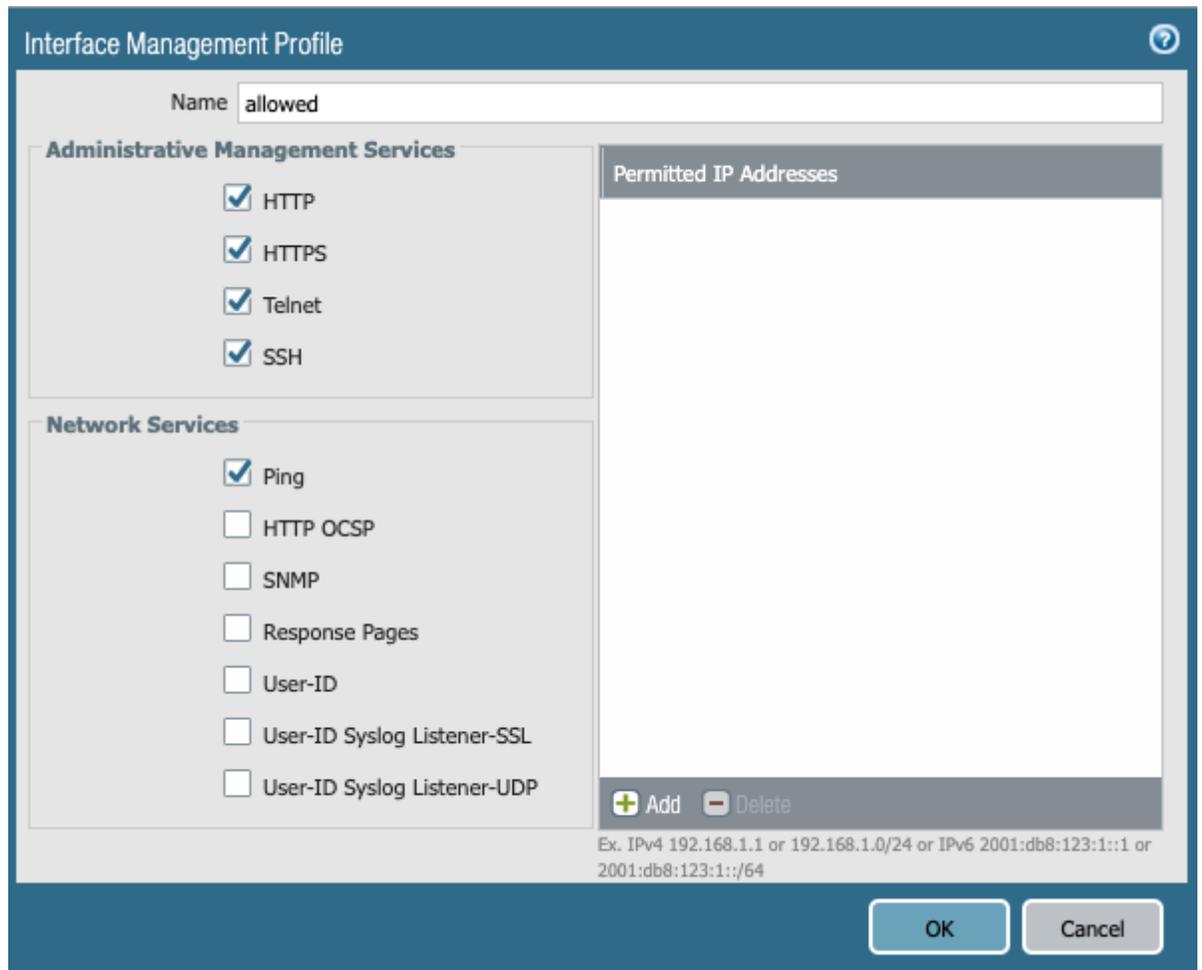
Network > **Network Profiles** > **Interface Management**.


Figure 88: Palo Alto Firewall Interface Management Profile Window

15. PING your interfaces and populate the IPARP and FDB tables on the switch.

16. Check the interface mapping against the switch MAC addresses. From the VM side, use the command:

```
admin@PA-VM> debug show vm-series interfaces all

Interface_name     Base-OS_port      Base-OS_MAC            PCI-ID          Driver
  Mgt                 eth0        52:54:00:7d:e5:c1                       virtio_net
 Ethernet1/1          eth1        48:9b:d5:eb:1e:42    0000:00:07.0     net_ixgbe
 Ethernet1/2          eth2        48:9b:d5:eb:1e:43    0000:00:08.0     net_ixgbe
```

Compare this to the switch mapping by the ExtremeXOS CLI.

17. Inspect the ARP table:

```
# show iparp
VR           Destination     Mac                 Age Static VLAN    VID    Port
VR-Default   192.168.1.100   48:9b:d5:eb:1e:42   6   NO     inside   10     57
VR-Default   10.10.100.100   48:9b:d5:eb:1e:43   1   NO     outside  100    58
```

18. Inspect the forwarding database:

```
# show fdb
MAC                    VLAN Name( Tag)    Age Flags    Port/Virtual Port List
--------------------------------------------------------------------------------
48:9b:d5:eb:1e:42      inside(0010) 0091   d     m            57
48:9b:d5:eb:1e:43      outside(0100) 0026  d     m            58
```

As each interface is mapped, activated, and used on the VM, they appear the IP ARP table and the switch forwarding database. Port management is shared with the front panel Management port and limited to 1 Gb/s. Ports 57 and 58 are connected directly to the forwarding plane on an X465. (A X695 has only one port connected to the forwarding plane and requires VLANs to instantiate multiple interfaces. Check the hardware guide for your switch for the number and port designations of the forwarding plane ports.)

ExtremeSwitching X695 series switches provide greater CPU and memory capacity, but have only one sideband port: port 63. This is a 10Gb/s port. The configuration of the firewall on the X695 requires the use of sub-interfaces or VLANs on the firewall to gain more than one firewall traffic port. The configuration is as above, but the two ports (Mgmt and port 63) are mapped. Mgmt provides the web UI and port 63 maps to Ethernet 1/1.

When using a ExtremeSwitching X695 switch for the above procedure, the following applies.

```
# sh vm PAN
VM Name:         PAN
    State:       Running
    Memory size: 8192 MB
    CPUs:        2
    Auto-start:  Disabled
    VNC:         127.0.0.1:1 (Port 5901)
    Disk:        vda
        Source:                 /mnt/vmdisk/.vm/PAN_PA-VM-KVM-9.1.2.qcow2
        Disk bus type:          virtio
        Allocated size in bytes: 64424509440 (60.00 GB)
        Physical size in bytes: 5405478912 (5.03 GB)
        Read requests:          48213
        Bytes read:             1188752896
        Write requests:         17699
        Bytes written:          1011475968
    Network interfaces:
        Attached switch ports:  mgmt,63
    CPU utilization:
        User:                   0.16%
        System:                 62.53%
    Memory utilization:
        Used:                   0.67 GB
        Available:              7.33 GB
```

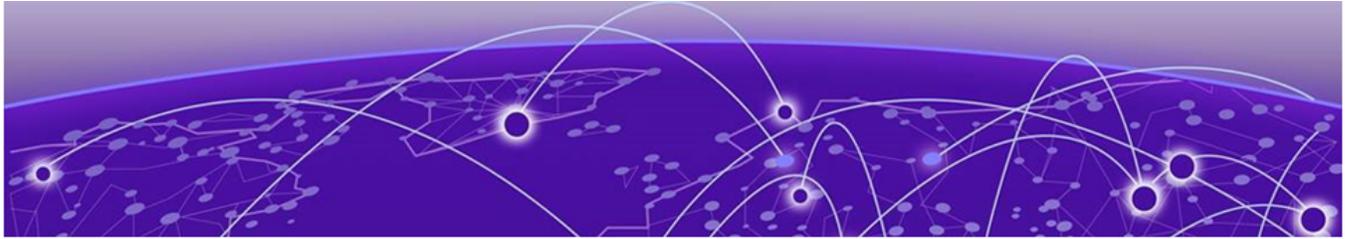
The VLAN configuration of the sideband port is as follows:

```
# sh ports 63 vlan
         Untagged
Port     /Tagged   VLAN Name(s)
-------- --------  ------------------------------------------------------------
```

```
Insight  Untagged  Default
         Tagged    v1, v2
```

They are mapped directly to interface Ethernet 1/1 (Default VLAN on 63), sub-interface Ethernet 1/1.10 (VLAN 10, v1), sub-interface Ethernet 1/1.20 (VLAN 20, v2).

Figure 89: Palo Alto Firewall Interface Management Profile Window for X695

The total availability of bandwidth for this VM is one 10Gb/s port: 10Gb/s in, 10Gb/s out.


Data Center Solutions

This chapter provides information about Extreme Network's Data Center Solutions. It provides an overview of data centers and provides information about how to configure and manage data center features, including DCBX, *Extreme Network Virtualization (XNV)*, VM Tracking, and Direct Attach to support VEPA.

Data Center Overview

Typical data centers support multiple Virtual Machines (VMs) on a single server. These VMs usually require network connectivity to provide their services to network users and to other VMs. The following sections introduce ExtremeXOS software features that support VM network connectivity:

> **Note**
> For additional information on using ExtremeXOS features to implement Data Center Bridging, see the application note titled *Enhanced Transmission Selection (ETS) Deployment and Configuration for ExtremeXOS* on the Extreme Networks website.

Introduction to Data Center Bridging

DCB (Data Center Bridging) is a set of IEEE 802.1Q extensions to standard Ethernet, that provide an operational framework for unifying Local Area Networks (LAN), Storage Area Networks (SAN) and Inter-Process Communication (IPC) traffic between switches and endpoints onto a single transport layer.

Data Center Bridging Exchange Protocol

The Data Center Bridging eXchange (DCBX) protocol is used by *DCB* devices to exchange DCB configuration information with directly connected peers. In an ExtremeXOS enabled switch, the switch uses DCBX to advertise its DCB configuration to end stations. The end stations can then configure themselves to use the switch DCB services. If the peers do not support a common configuration for one or more features, the switch generates messages to alert network management. The switch does not accept configuration change requests from end stations.

The DCBX protocol advertises the following types of information:

- DCBX version information, so that the peers can negotiate a common version to use.
- Enhanced Transmission Selection (ETS) information for _QoS (Quality of Service)_ parameters such as bandwidth allocation per traffic class (802.1p COS), priority for each traffic class, and the algorithm used for servicing traffic classes.
- Priority-based Flow Control (PFC) information for managing flow control between peers.
- Application priority information for prioritizing traffic for special applications that do not map directly to an established traffic class.

The ExtremeXOS software supports two versions of DCBX standards. The first version is a pre-standard version known as the baseline version, or more specifically as Baseline Version 1.01. The DCBX baseline version is specified in DCB Capability Exchange Protocol Base Specification Rev 1.01 and was developed outside of the IEEE and later submitted to the IEEE for standardization. The IEEE agreed to standardize DCBX as part of IEEE 802.1Qaz Enhanced Transmission Selection for Bandwidth Sharing Between Traffic Classes. While IEEE 802.1Qaz has progressed through the standards process, many companies have released support for the baseline version.

After you enable DCBX, the protocol collects most of the information to be advertised from other switch services such as QoS and PFC. The only DCBX feature that needs configuration is the application priority feature.

DCBX uses the _LLDP (Link Layer Discovery Protocol)_ (IEEE 802.1AB) to exchange attributes between two link peers. DCBX attributes are packaged into organizationally specific TLVs, which are different for the Baseline and IEEE 802.1Qaz versions. Information on the TLV support differences is provided in the ExtremeXOS Command Reference under the command description for the command: `show lldp {`**`port`** `[`**`all`** `|` _`port_list`_`]}` **`dcbx`** `{`**`ieee`**`|`**`baseline`**`} {`**`detailed`**`}`

Custom Application Support

The DCBX custom application support feature allows you to prioritize and manage traffic flow through the switch based on the application type. This feature allows you to configure DCBX handling of the following applications:

- Fiber Channel Over Ethernet (FCoE)
- Internet Small Computer System Interface (iSCSI)
- Any application that can be defined by:
  - Ethertype value
  - Layer 4 port number
  - TCP port number
  - UDP port number

When you configure a custom application, you define a priority number that applies to traffic related to that application. DCBX advertises this priority to end stations in an application TLV. End stations that support this feature use the priority number for communications with the switch. The priority number maps to an 802.1p value, which determines which _QoS_ profile in the switch manages the application traffic.

The software supports a maximum of eight application configurations.

Priority-based Flow Control

Priority flow control (PFC) is defined in the IEEE 802.1Qbb standard as an extension of the IEEE 802.3x flow control standard. When buffer congestion is detected, IEEE 802.3x flow control allows the communicating device to pause all traffic on the port, whereas PFC allows the device to pause just a portion of the traffic and allow other traffic on the same port to continue.

The rest of this section provides general guidelines for configuring the ExtremeXOS PFC feature for *DCB* operation. After you configure PFC, DCBX advertises the PFC compatible configuration to DCBX peers on all DCBX enabled ports.

• PFC configuration is controlled per-port using the following command:

  enable flow-control [**tx-pause** {**priority** *priority*} | **rx-pause** {**qosprofile** *qosprofile*}] **ports** [**all** | *port_list*]

  The **rx-pause** option is configured on the *QoS* profile.

  The PFC priority to which a QoS profile responds is fixed and is determined by the QoS profile number such that qpN responds to a PFC frame for priority N-1.

  For example, the following command enables PFC priority 4 for qp5 on ports 1-24:

  ```
  enable flow-control rx-pause qosprofile qp5 ports 1-24
  ```

  After the above command is entered, if a PFC frame is received indicating that priority 4 should be paused, then qp5 will be paused. Note that qp5 is paused regardless of whether the packets mapped to qp5 have priority 4 or other priorities. For example, if we enter the command configure dot1p type 3 qosprofile qp5, priority 3 packets are queued in qp5, and a PFC pause frame for priority 4 pauses priority 3 frames, which might not be desired. For this reason, you should be careful about mapping multiple priorities to the same QoS profile when PFC is enabled for that profile.

The **tx-pause** option is configured on the priority itself. For example, the following command enables the transmittal of PFC Pause frames for priority 4 when frames with priority 4 are congested:

```
enable flow-control tx-pause priority 4 ports 1-24
```

The tx-pause configuration determines what is advertised in the DCBX PFC TLV. In order for PFC to work correctly, it is important to ensure that all switches in the DCB network are receiving and transmitting PFC consistently for each priority on all ports.

In summary, the following three commands ensure that PFC is enabled for priority 4 traffic on ports 1-24:

```
configure dot1p type 4 qosprofile qp5
enable flow-control rx-pause qosprofile qp5 ports 1-24
enable flow-control tx-pause priority 4 ports 1-24
```

For more information on PFC, see IEEE 802.1Qbb Priority Flow Control on page 233.

Introduction to the XNV Feature

The _XNV_ feature, which is also known as Virtual Machine (VM) tracking, enables the ExtremeXOS software to support VM port movement, port configuration, and inventory on network switches. VM movement and operation on one or more VM servers is managed by a VM Manager (VMM) application. The XNV feature enables a network switch to respond to VM movement and report VM activity to network management software.

VM network access support enables a switch to support VMs as follows:
- Identify a VM by its MAC address and authenticate the VM connection to the network.
- Apply a custom port configuration in response to VM authentication.
- Remove a custom port configuration when a VM _FDB (forwarding database)_ entry ages out.
- Detect a VM move between switch ports or switches and configure the old and new ports appropriately.

To support VM mobility, the XNV feature requires that each VM use unique, static MAC and IP addresses. Switch port operation for a VM can be configured with a policy file or an _ACL (Access Control List)_.

VM Port Configuration

An important part of the _XNV_ feature is the ability to configure a switch port to support a particular VM. A Virtual Port Profile (VPP) identifies a policy file or _ACL_ rule to associate with a VM entry in the authentication database. You can define both ingress and egress policies in VPPs to configure a port separately for each direction. When the VPP is configured for a VM entry and the VM is detected on a port, any associated policy or rule is applied to the port in the specified direction.

The XNV feature supports two types of VPPs, Network VPPs (NVPPs) and Local VPPs (LVPPs).

NVPPs are stored on an FTP server called a repository server. The XNV feature supports file synchronization between XNV-enabled switches and the repository server. One of the advantages of the repository server is centralized storage for NVPPs.

LVPPs must be configured on each switch. LVPPs are a good choice for simple network topologies, but NVPPs offer easier network management for more complex network topologies.

VM Authentication Process

The _XNV_ feature supports three methods of authentication:
- NMS server authentication.
- Network authentication using a downloaded authentication database stored in the VMMAP file.
- Local authentication using a local database created with ExtremeXOS CLI commands.

The default VM authentication configuration uses all three methods in the following sequence: NMS server (first choice), network based VMMAP file (second choice), and finally, local database. If a service is not available, the switch tries the next authentication service in the sequence.

NMS Server Authentication

If NMS server authentication is enabled and a VM MAC address is detected on a VM-tracking enabled port, the software sends an Access-Request to the configured NMS server for authentication. When the switch receives a response, the switch does one of the following:

- When an Access-Accept packet is received with an NVPP specified, the policies are applied on VM enabled port.
- When an Access-Accept packet is received and no NVPP is specified, the port is authenticated and no policy is applied to the port.
- When an Access-Reject packet is received, the port is unauthenticated and no policy is applied.
- When an Access-Reject packet indicates that the NMS server timed-out or is not reachable, the switch tries to authenticate the VM MAC address based on the next authentication method configured, which can be either network authentication or local authentication.

The Access-Accept packet from the NMS server can include the following Vendor Specific Attributes (VSAs):

- VM name
- VM IP address
- VPP configured for the VM

An Access-Reject packet contains no VSA.

Network (VMMAP) Authentication

If network (VMMAP) authentication is enabled and a VM MAC address is detected on a VM-tracking enabled port, the switch uses the VMMAP file to authenticate the VM and applies the appropriate VPP.

Local Authentication

If local authentication is enabled and a VM MAC address is detected on a VM-tracking enabled port, the switch uses the local database to authenticate the VM and apply the appropriate VPP.

Authentication Failure

If all configured authentication methods fail, EMS messages are logged and no VPP is applied.

Possible remedies include:

- Fix the authentication process that failed. Look for misconfiguration or down segments.
- Configure UPM to take action on the related EMS message.

- If one or two authentication methods are configured, configure additional authentication methods.

Duplicate VM MAC Detected

Each VM MAC must be unique. If duplicate MAC addresses are detected on the switch, whether on the same _VLAN (Virtual LAN)_ or different VLANs, the switch supports only the last MAC detected.

File Synchronization

The _XNV_ feature supports file synchronization between XNV-enabled switches and the repository server. The files stored on the repository server include the .map, .vpp, and .pol files. One of the advantages of the repository server is that multiple XNV-enabled switches can use the repository server to collect the network VM configuration files. The XNV feature provides for access to a secondary repository server if the primary repository server is unavailable.

Through file synchronization, the network files are periodically downloaded to the XNV-enabled switches, which allows these switches to continue to support VM authentication when the NMS server is unavailable.

Network Management and Inventory

The _XNV_ feature is designed to support network management programs such as Extreme Management Center and Ridgeline. The ExtremeXOS software contains _SNMP (Simple Network Management Protocol)_ MIBs, which allow network management programs to view VM network configuration data, discover the VM inventory, and make configuration changes. We recommend that you use Extreme Management Center to manage VM network connectivity.

For instructions on managing the XNV feature using the switch CLI, see Managing the XNV Feature, VM Tracking on page 682.

Introduction to the Direct Attach Feature

The direct attach feature is a port configuration feature that supports VM-to-VM communication on a directly connected server that uses the Virtual Ethernet Port Aggregator (VEPA) feature on that server. Without VEPA and direct attach, a VM server must use a virtual Ethernet bridge or switch on the VM server to enable Ethernet communications between VMs. With VEPA, the VM server can rely on a directly connected switch to receive and reflect VM-to-VM messages between VMs on the same server.

The ExtremeXOS direct attach feature works with VEPA software on a VM server to intelligently forward unicast, flood, and broadcast traffic. Without direct attach, frames are never forwarded back out the same port on which they arrive. With direct attach, frames can be forwarded back out the ingress port, and VEPA software on the VM server ensures that the frames are forwarded appropriately.

For instructions on managing the Direct Attach feature, see Managing Direct Attach to Support VEPA on page 702.

Managing the DCBX Feature

Enabling DCBX on Switch Ports

DCBX uses *LLDP* to advertise *DCB* capabilities to DCB peers.

Use the following commands to enable LLDP and the DCBX feature on switch ports:

```
enable lldp ports [all | port_list] {receive-only | transmit-only}
```

```
configure lldp ports [all | port_list] [advertise | no-advertise]
vendor-specific dcbx {ieee|baseline}
```

Configuring DCBX Application Priority Instances

Each DCBX application priority instance maps traffic from one of the supported application types to a TC or PG priority, which selects a specific *QoS* profile for traffic management. Supported application types include:

- Fiber Channel Over Ethernet (FCoE)
- Internet Small Computer System Interface (iSCSI)

Use the following commands to add or delete DCBX application priority instances:

```
configure lldp ports [all | port_list] dcbx add application [name
application_name | ethertype ethertype_value | L4-port port_number |
tcp-port port_number | udp-port port_number] priority priority_value
```

```
configure lldp ports [all | port_list] dcbx delete application [all-
applications | name application_name | ethertype ethertype_value | L4-
port port_number | tcp-port port_number | udp-port port_number]
```

Displaying DCBX Configuration and Statistics

Use the following commands to display DCBX feature configuration and statistics:

```
show lldp {port [all | port_list]} {detailed}
```

```
show lldp {port [all | port_list]} dcbx {ieee|baseline} {detailed}
```

DCBX Configuration Example

The following is a sample DCBX configuration:

```
enable lldp ports 1
configure lldp port 1 advertise vendor-specific dcbx ieee
configure lldp port 1 advertise vendor-specific dcbx baseline

enable lldp ports 2
configure lldp port 2 advertise vendor-specific dcbx ieee
configure lldp port 2 advertise vendor-specific dcbx baseline
```

```
configure lldp ports 1 dcbx add application name iscsi priority 4
configure lldp ports 1 dcbx add application name fcoe priority 3
configure lldp ports 2 dcbx add application name iscsi priority 4
configure lldp ports 2 dcbx add application name fcoe priority 3
configure lldp ports 2 dcbx add application L4-port 25 priority 4
configure lldp ports 2 dcbx add application tcp-port 4500 priority 4
configure lldp ports 2 dcbx add application udp-port 45 priority 5
configure lldp ports 2 dcbx add application ethertype 2536 priority 4
```

Managing the XNV Feature, VM Tracking

Limitations

The following limitations apply to this release of the VM tracking feature:

- When VM tracking is configured on a port, all existing learned MAC addresses are flushed. MAC addresses will be relearned by the switch and the appropriate VPP (if any) for each VM will be applied.
- If a VM changes MAC addresses while moving between ports on a switch, the VM remains authenticated on the original port until the original MAC address ages out of the *FDB*.
- VM counters are cleared when a VM moves between ports on the same switch (because the *ACL*s are deleted and recreated).
- Each VPP entry supports a maximum of eight ingress and four egress ACL or policies.
- For Network VPP, only policy files can be mapped. For Local VPP, either ACL or policy files can be mapped. You cannot map a mixture of both ACL and policy files to a particular VPP.

Managing VM Tracking on the Switch

Use the following steps to manage VM tracking on the switch:

- Issue the following command to enable the VM tracking feature on the switch:

  `enable vm-tracking`

- Issue the following command to disable the VM tracking feature on the switch:

  `disable vm-tracking`

  > **Note**
  > When the VM tracking feature is disabled, file synchronization with the repository server stops.

- Issue the following command to view the VM tracking feature configuration and the list of authenticated VMs:

  show vm-tracking

Managing VM Tracking on Specific Ports

Before you enable the VM tracking feature on specific ports, you must enable VM tracking on the switch, configure the authentication method and sequence, and the VM authentication databases.

- When this configuration is complete, you can use the following command to enable VM tracking on one or more ports:

  ```
  enable vm-tracking ports port_list
  ```

- To disable the VM tracking feature on a group of ports, use the following command:

  ```
  disable vm-tracking ports port_list
  ```

- To view the VM tracking feature configuration on one or more ports, use the following command:

  ```
  show vm-tracking port port_list
  ```

Configuring the Authentication Method and Sequence

You can configure VM authentication through the following services:

- NMS server
- Network based VMMAP file
- Local database

The default VM authentication configuration uses all three methods in the following sequence: NMS server (first choice), network based VMMAP file (second choice), and finally, local database. If a service is not available, the switch tries the next authentication service in the sequence.

To configure one or more authentication methods and a preferred sequence, use the following command:

```
configure vm-tracking authentication database-order [[nms] | [vm-map] |
[local] | [nms local] | [local nms] | [nms vm-map] | [vm-maplocal] |
[local vm-map] | [nms vm-map local] | [localnmsvm-map]]
```

XNV and MLAG

Starting with ExtremeXOS 15.7 as part of Extreme Management Center NAC integration, as long as *MLAG (Multi-switch Link Aggregation Group)* peers have ISC connectivity, only one of the MLAG peers authenticates a VM that is learned on an MLAG port.

- When ISC connectivity between the MLAG peers is established, the peer with the highest IP address is chosen to be the authenticator. This peer will authenticate a VM based on the chosen authentication method.
- The result of the authentication is checkpointed by the authenticator to its peer so that the same VPP gets applied to the VM on both peers.
- When the MLAG peer that is the authenticator goes down, the other peer detects that the authenticator is down and re-authenticates the VM at the next authentication interval. Note that the peer that takes over as the authenticator does not re-authenticate the VMs immediately but waits for the re-authentication timer to expire.

- VMs learned on non-MLAG ports are authenticated by the detecting peer.
- All authentication-related configurations like _RADIUS (Remote Authentication Dial In User Service)_ address, repository for VMMAP, local DB, etc. must be identical on both peers. This is an existing requirement and there is no change to this requirement.

XNV Dynamic VLAN

Starting in release 15.3, when a virtual machine is detected, ExtremeXOS dynamically creates the _VLAN_ that is required for the VM to send traffic. If a virtual machine shuts down or is moved, its VLAN is pruned to preserve bandwidth. This feature creates an adaptive infrastructure in which the network responds to changes dynamically in the virtual machine network.

Enabling/Disabling XNV Dynamic VLAN

Enabling the _XNV_ dynamic VLAN feature must be done on a per-port basis. XNV requires that the port on which dynamic VLANs is enabled is part of the "default or "base" VLAN as untagged. This "default", or "base", VLAN for the port is the VLAN on which untagged packets are classified to when no VLAN configuration is available for the MAC. This default VLAN should be present, and you should manually add the port to this VLAN before you enable the feature. Enabling this feature on a port results in a failure if any of the following conditions are true:

- If XNV is not enabled, the command only results in a warning, and does not fail. XNV can be enabled later.
- The port is not an untagged member of any VLAN.

When a VLAN's MAC is detected on a port, XNV consults the configuration database to determine the VLAN configuration for the VM. For a case where the VM sends tagged traffic, the VLAN tag of the received frame is used to determine VLAN classification for the VM's traffic. If VLAN configuration exists for the VM and it conflicts with the actual tag present in received traffic, XNV reports an EMS message and does not trigger VLAN creation or port addition. However, if no configuration is present for the VM, XNV assumes that there are no restrictions for classifying traffic for the VM to the received VLAN.

For untagged traffic, XNV can determine the VLAN for the VM from any one of the three possible sources:

- VLAN configuration for the VM MAC entry.
- VLAN configuration for the VPP associated with the VM's MAC. The VPP can either be a network VPP or a local VPP.
- In case of untagged traffic from the VM, the "default" VLAN for the port that is specified as part of the dynamic VLAN enable configuration.

This list determines the order of precedence for VLAN classification for untagged traffic only. For tagged VLAN traffic, XNV validates the tag of the received traffic with then VLAN tag configuration for that VM.

In addition to the VLAN tag, you can specify the VR to which the dynamically created VLAN needs to be associated. The VR configuration is relevant only if a VLAN tag is configured for the VM.

Table 64: Associating Dynamically Created VLANS to VRs

Configured VR on Port	Configured VR for VM (from VM Mapping Entry or VPP)	VLAN Already Exists on the Switch	Dynamic VLANs VR
None	None	No	*VR-Default*
None	None	Yes	VLAN's VR
None	VR-X	No	VR-X (Configured VR for VM) if VR-X is valid.) Otherwise an EMS error is displayed indicating the VR-X is invalid.
None	VR-X	Yes	VLAN's VR. An EMS error is displayed if the VLAN's VR is not VR-X.
VR-X	None	No	VR-X (Port's VR).
VR-X	None	Yes	VR-X if VLAN's VR is VR-X. If it is not, an EMS error is displayed indicating the VR-X is invalid.
VR-X	VR-Y	No	Dynamic VLAN is not created when Port Level VR and VM-MAC VR are different, and *FDB* is learned on a system generated VMAN. An EMS warning is generated on the switch log, because a Dynamic VLAN cannot be created.
VR-X	VR-Y	Yes	VR-X if VLAN is part of VR-X. Otherwise, EMS error is displayed.

When you disable dynamic VLAN on a port, XNV does the following:

- Triggers deletion of MAC-based entries on that port in the hardware.
- If the port has been added to any VLAN by XNV, XNV triggers a flush for those VLANs.

- If the port has been added to an VLAN by XNV, XNV requests VLAN manager to remove the port from the VLAN.

  > **Note**
  > It is up to the VLAN manager to decide if the port actually needs to be removed from the VLAN.

On deleting the ports from base/default VLAN the below warning message will be thrown and XNV Dynamic vlan gets disabled on that port:

```
 Warning: Removing the untagged VLAN from a port may disrupt network connectivity. IDM and
VMT may not be functional on the port without an untagged VLAN.
```

> **Note**
> This behavior is in effect from ExtremeXOS 16.1.

Example

```
create vlan v1
con v1 add ports 1untagged
enable vm-tracking
enable vm-tracking ports 1
enable vm-tracking dynamic-vlan ports 1
con vlan v1 delete ports 1
Warning: Removing the untagged VLAN from a port may disrupt network connectivity. IDM
and VMT may not be functional on the port without an untagged VLAN.

show vm-tracking
--------------------------------------------------------
VM Tracking Global Configuration
--------------------------------------------------------
VM Tracking                       : Enabled
VM  Tracking authentication order: nms vm-map local
VM Tracking nms reauth  period   : 0 (Re-authentication disabled)
VM Tracking blackhole policy       : none
--------------------------------------------------------

Port                           : 1
VM Tracking                    : Enabled
VM Tracking Dynamic VLAN      : Disabled
```

When XNV is disabled on a port, the XNV dynamic VLAN feature is also disabled. The XNV dynamic VLAN configuration is not persistent, and needs to be re-enabled after XNV is re-enabled on that port.

Tracking XNV Per VM Statistics

Beginning in release 15.3, each local and network VPP has the option to specify whether a counter needs to be installed to count traffic matching the virtual machine MAC which gets the VPP mapping. You can choose to install a counter to collect statistics for ingress traffic only, egress traffic only, or traffic in both directions.

Once the ingress counter installation option is selected for a specific local or network VPP and the virtual machine which has this VPP mapping is detected on the switch, the counter is installed with the name "xnv_ing_dyn_cnt_vmxxxxxxxxxxxx" for the port on which the VM MAC is detected. In this case, xxxxxxxxxxxx denotes the virtual

machine MAC for which the counter is installed. In the same way, the egress counter is installed using the name "xnv_egr_dyn_cnt_vmxxxxxxxxxxxx" for that port.

You can view a list of packet/byte counts for this counter name using the command `show access dynamic-counter`. The counter is uninstalled only when the virtual machine MAC is deleted on the switch or the VPP is mapped to a virtual machine MAC which has the counter option set to none. If the VM MAC move happens then the counter installed on the previous port is uninstalled and the counter is installed on the new port. The counter values are not maintained during the MAC move.

Managing the Repository Server

Selecting the Repository Server Directory

All files for NMS and network authentication must be placed in the configured repository server directory. These files include the following:

- MANIFEST
- VMMAP
- NVPP policy files

By default, the *XNV* feature tries to access the FTP server with anonymous login and fetch the files from the pub directory within the FTP server root directory.

To configure a different directory for repository server files, use the following command:

`configure vm-tracking repository`

Creating the MANIFEST File

The MANIFEST file identifies the VMMAP, NVPP, and policy files that are to be used for either NMS or network authentication. The MANIFEST file is downloaded to the switch at the specified refresh interval. Each time the MANIFEST file is downloaded, the switch scans the file and compares the file entries and timestamps to those files on the switch. If the switch detects newer files, it downloads those files to the switch.

You can create the MANIFEST file with a text editor. The MANIFEST file must be placed on the repository server as described in Selecting the Repository Server Directory on page 687.

The format of MANIFEST files is:

```
File1 yyyy-mm-dd hh:mm:ss
File2 yyyy-mm-dd hh:mm:ss
```

Because the definition for each file in the MANIFEST includes a date and time, you must update the MANIFEST file every time you update the VMMAP file or a policy file.

The following is a sample MANIFEST file:

```
a1.map 2010-07-07 18:57:00
a1.vpp 2010-07-07 18:57:00
```

```
a2.map 2010-07-07 18:57:00
a2.vpp 2010-07-07 18:57:00
policy1.pol 2010-07-07 18:57:00
epolicy1.pol 2010-07-07 18:57:00
```

The file extensions for the files in the MANIFEST file identify the supported file types:

- .map—VMMAP files
- .vpp—VPP files
- .pol—Policy files

Creating a VMMAP File

Use a text editor to create a VMMAP file. VMMAP file entries must use the following XML format:

```
<VMLIST>
    <VM>
        <MAC>00:00:00:00:00:21</MAC>
        <NAME>network_vm1</NAME>
        <IPV4>10.10.10.10</IPV4>
        <VPP>nvpp1</VPP>
    </VM>
    <VM>
        <MAC>00:00:00:00:00:22</MAC>
        <NAME>network_vm2</NAME>
        <IPV4>20.20.20.20</IPV4>
        <VPP>nvpp2</VPP>
    </VM>
</VMLIST>
```

When creating VMMAP file entries, use the following guidelines:

- The VPP file supports up to 400 child nodes.
- The MAC address is required.
- If you do not want to specify a VM name, specify none.
- If you do not want to specify an IP address, specify 0.0.0.0.
- If you do not want to specify a VPP name, specify none.
- If a value such as the VM name contains any space characters, the entire value must be specified between double quotation marks (").

For information on where to place the VMMAP file, see Selecting the Repository Server Directory on page 687.

Creating VPP Files

Use a text editor to create a VPP file. VPP file entries must use the following XML format:

```
<vppList>
  <vpp>
    <name>nvpp1</name>
      <last-updated>2002-05-30T09:00:00</last-updated>
    <policy>
      <name>policy1</name>
      <direction>ingress</direction>
      <order>1</order>
```

```
          </policy>
          <policy>
            <name>policy4</name>
            <direction>ingress</direction>
            <order>4</order>
          </policy>
          <policy>
            <name>epolicy1</name>
            <direction>egress</direction>
            <order>1</order>
          </policy>
          <policy>
            <name>epolicy4</name>
            <direction>egress</direction>
            <order>4</order>
          </policy>
      </vpp>
 </vppList>
```

The VPP file supports up to 400 child nodes, and each VPP entry supports up to eight ingress and four egress _ACL_ or policies. If multiple policies are defined within a VPP entry for either ingress or egress, the switch uses the policy with the lowest order number. If two ingress or egress policies have the same order number, the switch selects the policy based on which name is lexicographically lower.

To refresh all policies which are all associated and applied to each VPP, use the following command:

```
refresh policy policy-name
```

The NVPP policy files must be placed on the repository server as described in

Creating Policy Files

For instructions on creating policy files, see

To display the policy file or _ACL_ associated with one or all VPPs, use the following command:

```
show vm-tracking vpp {vpp_name}
```

Managing Switch Access to the Repository Server

- To enable and configure file synchronization between an _XNV_-enabled switch and a repository server, use the following command:

```
configure vm-tracking repository [primary | secondary] server
[ipaddress | hostname] {vr vr_name} {refresh-interval seconds} {path-
name path_name} {user user_name {encrypted} password}
```

- To force file synchronization with the repository server, use the following command:

```
run vm-tracking repository sync-now
```

- To remove the configuration for one or both repository servers, use the following command:

```
unconfigure vm-tracking repository {primary | secondary}
```

- To display the repository server configuration and status, use the following command:

```
show vm-tracking repository {primary | secondary}
```

Manage NMS Server Authentication

NMS server authentication uses the *RADIUS* protocol to authenticate VM access to the network with the RADIUS server included with Extreme Management Center and Ridgeline. These products are designed to perform VM network management tasks, such as creating and associating NVPPs with VM authentication entries.

To use NMS authentication, you must do the following:

- Select NMS authentication as described in Configuring the Authentication Method and Sequence on page 683.
- Prepare the network repository server as described in Managing the Repository Server on page 687.
- Configure the NMS client software in the switch as described in Configure the NMS Client Software on page 691.
- Configure the NMS server as described in Configuring the NMS Server Software on page 690.

You can display NMS authenticated VMs as described in Displaying NMS Authenticated VMs on page 691.

Configuring the NMS Server Software

The Extreme Management Center and Ridgeline include a *RADIUS* server that you can use for NMS server authentication. To configure this server, do the following:

1. Add the IP address of each *XNV*-enabled switch as a RADIUS client.
2. Add each VM MAC address as a username (in upper case and should not contain semicolon) and add the MAC address as the password.
3. Add a remote access policy with the Extreme Networks VSAs:

   - Vendor code: 1916
   - VSA ID: 213 (EXTREME_VM_NAME)

     Example: MyVM1
   - VSA ID: 214 (EXTREME_VM_VPP_NAME)

     Example: nvpp1
   - VSA ID: 215 (EXTREME_VM_IP_ADDR)

     Example: 11.1.1.254

For instructions on configuring the Ridgeline RADIUS server, refer to the Ridgeline documentation.

Configure the NMS Client Software

- The switch uses NMS client software to connect to an NMS server for VM authentication. Use the following commands to configure the NMS client software in the switch:

```
configure vm-tracking nms [primary | secondary] server [ipaddress
| hostname] {udp_port} client-ip client_ip shared-secret {encrypted}
secret {vr vr_name}

configure vm-tracking nms timeout seconds

configure vm-tracking timers reauth-period reauth_period
```

- To remove the NMs client configuration for one or both NMS servers, use the following command:

```
unconfigure vm-tracking nms {server [primary | secondary]}
```

- To display the NMS client configuration, use the following command:

```
show vm-tracking nms server {primary | secondary}
```

Displaying NMS Authenticated VMs

To display the VMs and corresponding policies in the NMS authentication database, use the following command:

```
show vm-tracking network-vm
```

Managing Network Authentication (Using the VMMAP File)

To use network authentication, you must do the following:

1. Select network authentication as described in Configuring the Authentication Method and Sequence on page 683.
2. Prepare the network repository server as described in Managing the Repository Server on page 687.

To display the VMs and corresponding policies in the network authentication database, use the following command:

```
show vm-tracking network-vm
```

Manage Local Database Authentication

To use local database authentication, you must do the following:

1. Select local database authentication as described in Configuring the Authentication Method and Sequence on page 683.
2. Create and manage local VPPs (LVPPs) as described in Managing the Local VPP Database on page 692.
3. Create VM entries as described in Managing VM Entries in the Local Authentication Database on page 692.

Managing the Local VPP Database

> Only one dynamic *ACL* or policy can be added to a VPP. Ingress LVPPs apply to traffic flowing from the VM, into the switch port, and then to the client. Egress LVPPs apply to traffic flowing from the client, out the switch port, and to the VM.
>
> For instructions on creating policy files, see Policy Manager on page 776. For instructions on creating dynamic ACLs, see ACLs on page 781.
>
> - To create and configure entries in the LVPP database, use the following commands:
>
>   ```
>   create vm-tracking vpp vpp_name
>   ```
>   ```
>   configure vm-tracking vpp vpp_name add [ingress | egress] [policy
>   policy_name | dynamic-rule rule_name] {policy-order policy_order}
>   ```
>
> - To delete or unconfigure entries in the local VPP database, use the following commands:
>
>   ```
>   delete vm-tracking vpp {vpp_name}
>   ```
>   ```
>   unconfigure vm-tracking vpp vpp_name
>   ```
>
> - To display the policy file or ACL associated with one or more VPPs , use the following command:
>
>   ```
>   show vm-tracking vpp {vpp_name}
>   ```

Managing VM Entries in the Local Authentication Database

> - To create and configure entries in the local authentication database, use the following commands:
>
>   ```
>   create vm-tracking local-vm mac-address mac {name name | ipaddress
>   ipaddress vpp vpp_name }
>   ```
>   ```
>   configure vm-tracking local-vm mac-address mac [name name | ip-address
>   ipaddress | vpp vpp_name]
>   ```
>
> - To remove a configuration parameter for a local authentication database entry, or to remove an entry, use the following commands:
>
>   ```
>   unconfigure vm-tracking local-vm mac-address mac [name | ip-address |
>   vpp]
>   ```
>   ```
>   delete vm-tracking local-vm {mac-address mac}
>   ```
>
> - To display the local VPP database entries, use the following command:
>
>   ```
>   show vm-tracking local-vm {mac-address mac}
>   ```

Example XNV Configuration

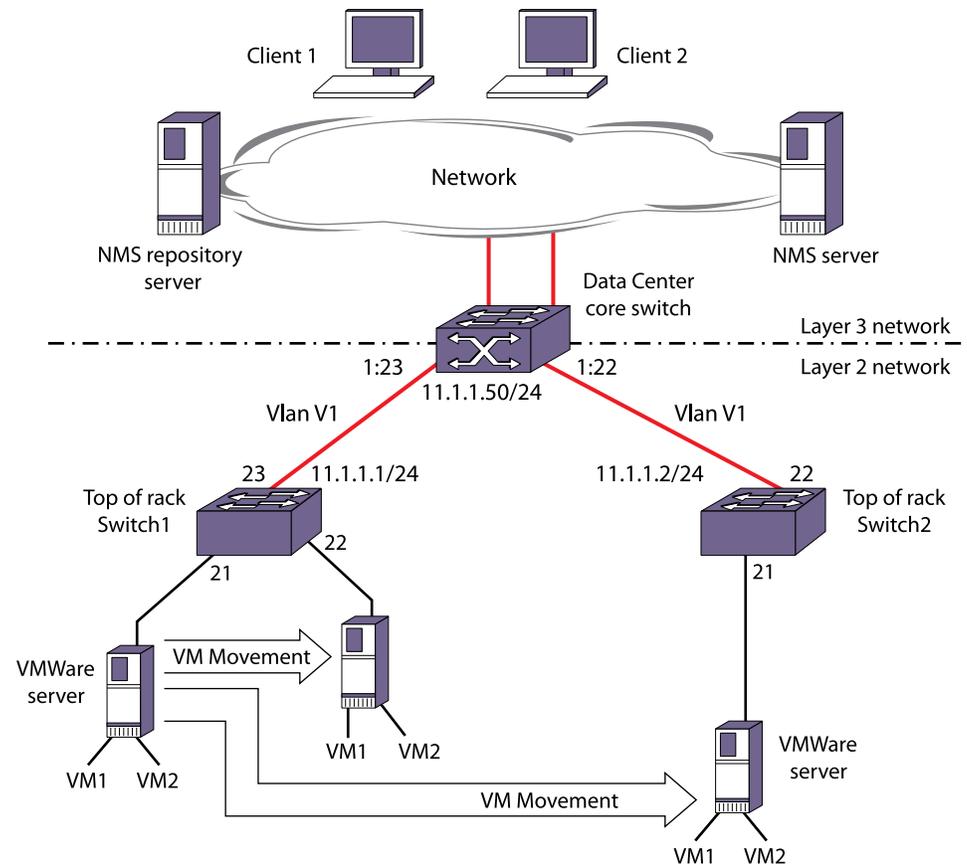
> Figure 90 displays a sample *XNV* topology that will be used for the examples in the following sections:


Figure 90: Sample XNV Topology

The example configuration supports the following:

- VM authentication using NMS server, network, or local authentication
- Ingress and egress port configuration for each VM
- VM movement from one switch port to another
- VM movement from one switch to another

> **Note**
>
> Ingress ACLs or policies apply to traffic flowing from the VM, into the switch port, and then to the client. Egress ACLs apply to traffic flowing from the client, out the switch port, and to the VM.

MAC and IP Addresses

The following are the MAC and IP addresses for the example topology:

```
VM1 MAC address: 00:04:96:27:C8:23
VM2 MAC address: 00:04:96:27:C8:24
VM1 IP address: 11.1.1.101
VM2 IP address: 11.1.1.102
Client1 MAC address: 00:04:96:00:00:01
Client2 MAC address: 00:04:97:00:00:02
Repository server IP address: 10.127.8.1
NMS server IP address: 10.127.5.221
```

General VLAN Configuration

The following is the core switch *VLAN* configuration:

```
create vlan v1
configure vlan v1 tag 100
configure vlan v1 add ports 1:22,1:23 tagged
configure vlan v1 ipaddress 11.1.1.50/24
```

The following is the Switch1 VLAN configuration:

```
create vlan v1
configure vlan v1 tag 100
configure vlan v1 add ports 21,22, 23 tagged
configure vlan v1 ipaddress 11.1.1.1/24
```

The following is the Switch2 VLAN configuration:

```
create vlan v1
configure vlan v1 tag 100
configure vlan v1 add ports 21,22 tagged
configure vlan v1 ipaddress 11.1.1.2/24
```

> **Note**
> For NMS server and network authentication, the NMS server and repository server must be accessible to all *XNV*-enabled switches through *VR-Mgmt*.

VMWare Server Setup

The VMWare servers must be connected to Switch1 and Switch2 and should have dual quad-core processors. The VMWare servers require the following software:

- VMWare server: ESXi license
- Vsphere EXSI client
- V-Center client

Each physical VMWare server should be configured with two VMs. Use the V-Center client to trigger Vmotion.

Repository Server Setup

The repository server setup for this topology is the same for NMS server authentication and network authentication. The following shows the FTP server setup:

```
FTP login: anonymous
Password: "" (no password)
Repository directory path: pub
[root@linux pub]# pwd
/var/ftp/pub
```

The following is an example MANIFEST file:

```
vm.map 2011-05-11 18:57:00
vpp.vpp 2011-05-11 18:57:00
nvpp1.pol 2011-05-11 18:57:00
nevpp1.pol 2011-05-11 18:57:00
nvpp2.pol 2011-05-11 18:57:00
nevpp2.pol 2011-05-11 18:57:00
```

The following is an example VMMAP file named vm.map:

```
<VMLIST>
  <VM>
    <MAC>00:04:96:27:C8:23</MAC>
    <NAME>vm_1</NAME>
    <IPV4>11.1.1.101</IPV4>
    <VPP>nvpp1</VPP>
    <CTag>1000</CTag>
    <VRName>Vr-Default</VRName>
  </VM>
  <VM>
    <MAC>00:04:96:27:C8:24</MAC>
    <NAME>vm_2</NAME>
    <IPV4>11.1.1.102</IPV4>
    <VPP>nvpp2</VPP>
  </VM>
</VMLIST>
```

The following is an example VPP file named vpp.vpp:

```
<vppList>
  <vpp>
    <name>nvpp1</name>
      <last-updated>2011-05-30T09:00:00</last-updated>
    <policy>
      <name>nvpp1.pol</name>
      <direction>ingress</direction>
      <order>1</order>
    </policy>
    <policy>

  </vpp>
</vppList>
```

The following is the nvpp1.pol file:

```
entry nvpp1 {
if match all {
    ethernet-destination-address 00:04:96:00:00:00 / ff:ff:ff:00:00:00 ;
} then {
  deny ;
```

```
   count host1
} }
```

The following is the nvpp2.pol file:

```
entry nvpp2 {
if match all {
    ethernet-destination-address 00:04:97:00:00:00 / ff:ff:ff:00:00:00 ;
} then {
  deny ;
  count host2
} }
```

The following is the nevpp1.pol file:

```
entry nevpp1 {
if match all {
    ethernet-source-address 00:04:96:00:00:00 / ff:ff:ff:00:00:00 ;
} then {
  deny ;
  count h1
} }
```

The following is the nevpp2.pol file:

```
entry nevpp2 {
if match all {
  ethernet-source-address 00:04:97:00:00:00 / ff:ff:ff:00:00:00 ;
} then {
  deny ;
  count h2
} }
```

Example ACL Rules

The following are some example ACL rules:

```
entry etherType1 {
    if {
      ethernet-source-address 00:a1:f1:00:00:01;
      }
    then {
      permit;
      count etherType1;
      }
    }
entry denyall {
    if {
        source-address 10.21.1.1/32;
        }
    then {
          deny;
          }
    }
entry allowall {
    if {
        source-address 11.1.1.1/32;
        source-address 12.1.0.0/16;
        }
    then {
```

```
        allow;
        }
    }
entry destIp {
    if {
        destination-address 192.20.1.0/24;
        protocol UDP;
        }
    then {
        deny;
      count destIp;
        }
    }
entry denyAll {
    if {
        }
    then {
         deny;
         count denyAll;
        }
    }
```

General Switch XNV Feature Configuration

The following configuration enables the *XNV* feature on the switch and the specified ports:

```
enable vm-tracking
enable vm-tracking ports 21-22
```

Local VM Authentication Configuration

If you only want to use local authentication, configure the *XNV*-enabled switches as follows:

```
configure vm-tracking authentication database-order local
```

To enable dynamic *VLAN*, issue the following command:

```
enable vm-tracking dynamic-vlan ports 19
```

To add Uplinkports to Dynamic VLAN:

```
configure vlan dynamic-vlan uplink-ports add ports port_no
```

To delete the uplink port:

```
configure vlan dynamic-vlan uplink-ports delete ports port_no
```

The following is the policy1.pol file for Port 21 in the ingress direction:

```
entry nvpp1 {
if match all {
ethernet-destination-address 00:04:96:00:00:00 / ff:ff:ff:00:00:00 ;
} then {
deny ;
count host1
} }
```

The following is the policy2.pol file for Port 21 in the egress direction:

```
entry nevpp1 {
if match all {
ethernet-source-address 00:04:96:00:00:00 / ff:ff:ff:00:00:00 ;
} then {
deny ;
count h1
} }
```

The following commands configure VM authentication in the local database:

```
create vm-tracking local-vm mac-address 00:04:96:27:C8:23
configure vm-tracking local-vm mac-address 00:04:96:27:C8:23 ip-address 11.1.1.101
configure vm-tracking local-vm mac-address 00:04:96:27:C8:23 name myVm1
create vm-tracking vpp vpp1
configure vm-tracking vpp vpp1 add ingress policy policy1
configure vm-tracking vpp vpp1 add egress policy policy2
configure vm-tracking local-vm mac-address 00:04:96:27:C8:23 vpp vpp1
```

The following commands used to create VM-mac with vlan-tag, and Vr for Dynamic vlan creation:

```
create vm-tracking local-vm mac-address 00:00:00:00:00:01
configure vm-tracking local-vm mac-address 00:00:00:00:00:01 vpp lvpp1
configure vm-tracking local-vm mac-address 00:00:00:00:00:01 vlan-tag 1000 vr VR-Default
configure vm-tracking vpp lvpp1 vlan-tag 2000
```

The following commands display the switch XNV feature status after configuration:

```
* Switch.67 # show vm-tracking local-vm

show vm-tracking nms server
VM Tracking NMS : enabled
VM Tracking NMS server connect time out: 3 seconds

Primary VM Tracking NMS server:
  Server name :
  IP address : 10.127.6.202
  Server IP Port: 1812
  Client address: 10.127.11.101 (VR-Mgmt)
  Shared secret : qijxou
Access Requests : 0 Access Accepts : 0
Access Rejects : 0 Access Challenges : 0
Access Retransmits: 0 Client timeouts : 0
Bad authenticators: 0 Unknown types : 0
Round Trip Time : 0
```

NMS Server Authentication Configuration

- If you only want to use NMS server authentication, configure the *XNV*-enabled switches as follows:

  ```
  configure vm-tracking authentication database-order nms
  ```

- Configure the NMS server as follows:

  a. Add Switch1 and Switch2 as *RADIUS* clients.

  b. Add the MAC addresses for VM1 and VM2 as users, and configure the passwords to match the user names.

  c. Add a remote access policy with the Extreme Networks VSAs:

     ◦ Vendor code: 1916

     ◦ VSA ID: 213 (EXTREME_VM_NAME)

        Example: MyVM1

     ◦ VSA ID: 214 (EXTREME_VM_VPP_NAME)

        Example: nvpp1

     ◦ VSA ID: 215 (EXTREME_VM_IP_ADDR)

        Example: 11.1.1.254

  > **Note**
  > For the Dynamic *VLAN* feature, the following VSAs are used:
  >
  > EXTREME_VM_VLAN_ID with VSA ID as 216
  > EXTREME_VM_VR_NAME with VSA ID as 217

- The following command configures the switch as an NMS server client:

  ```
  configure vm-tracking nms primary server 10.127.5.221 client-ip 10.127.8.12 shared-
  secret secret
  ```

After the repository server is configured (see Repository Server Setup on page 694), the following commands can be used to display the switch XNV feature status:

```
 * Switch.33 # show vm-tracking nms server
VM Tracking NMS : enabled
VM Tracking NMS server connect time out: 3 seconds
Primary VM Tracking NMS server:
 Server name   :

Managing Direct Attach to Support VEPA

You should only enable the Direct Attach feature on ports that directly connect to a VM server running VEPA software.

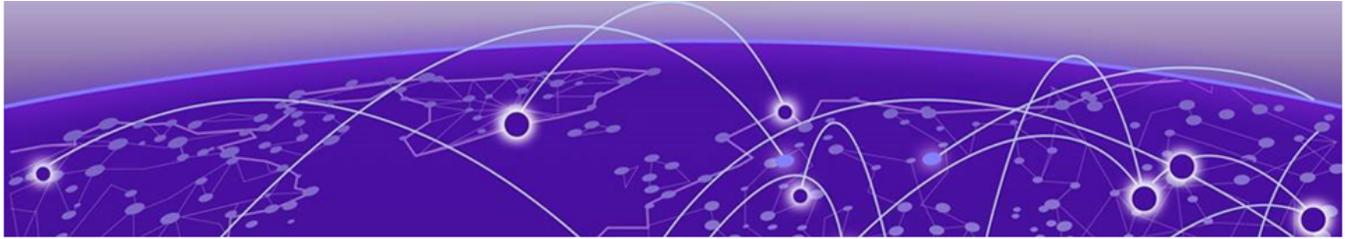
- To enable or disable the direct attach feature on a port, enter the command:

  configure port *port* **reflective-relay** [**on** | **off**]

- To see if the direct attach feature (reflective-relay) is enabled on a switch port, enter the command:

  show ports information detail

  📝 **Note**

  When the Direct Attach feature is configured on a port, the port number cannot be included in the port list for a static _FDB_ entry. For example, the Direct-Attach enabled port can be the only port number specified in a static FDB entry, but it cannot be included in a port-list range for a static FDB entry.


AVB

This chapter provides information about Audio Video Bridging support. It specifically discusses the AVB Feature Pack License, as well as how to configure and manage the AVB feature.

Overview

Audio Video Bridging (AVB) supports the deployment of professional quality audio and/or video (AV) over standard Ethernet while coexisting with other "legacy" (or non-AV) Ethernet traffic. This supports "Network Convergence," or using one simple standard Ethernet network for all communication needs.

To support AV applications, it is necessary for AVB systems to provide time synchronization and *QoS (Quality of Service)*.

Time Synchronization is needed so that multiple streams may be synchronized with respect to each other. For example:

- Voice and video
- Multiple audio streams for a multi-digital speaker deployment in a large venue
- Multiple Video streams in a security surveillance application

QoS is needed to ensure:

- Bandwidth guarantees sufficient for each application
- Worst Case Delay Bounds, particularly for interactive applications
- Traffic shaping to limit traffic burstiness and reduce buffering requirements

The time synchronization and QoS requirements for AVB systems are defined in the following set of IEEE Standards:

- IEEE 802.1AS: Timing and Synchronization for Time-Sensitive Applications in Bridged Local Area Networks (gPTP)
- IEEE 802.1Q
  - Clause 10: Multiple Registration Protocol (MRP) and Multiple MAC Registration Protocol (MMRP)
  - Clause 11: *VLAN (Virtual LAN)* Topology Management (MVRP)

- ◦ Clause 34: Forwarding and Queuing for Time-Sensitive Streams (FQTSS)
- ◦ Clause 35: Stream Reservation Protocol (SRP)
- IEEE 802.1BA: Audio Video Bridging (AVB) Systems

AVB Feature Pack License

The AVB feature (including AVB, gPTP and MSRP commands) requires the AVB Feature Pack. MRP and MVRP do not require the AVB Feature Pack.

The AVB feature is supported on all platforms.

The ExtremeSwitching X590 and X695 series switches have the AVB Feature License included in the Advanced Edge license. You do not need to separately purchase and install the AVB Feature License for these switches.

If you purchase the AVB Feature Pack license separately, use the `enable license` command to install it.

For more information about the AVB Feature Pack and licensing, see the *ExtremeXOS 32.4 Feature License Requirements*.

> **Note**
> The ExtremeSwitching X465 series switches support AVB on the front panel ports only, and only on the following VIMs (all ports):
> - VIM5-4X
> - VIM5-2Y
> - VIM5-4Y
> - VIM5-2Q

> **Note**
> The ExtremeSwitching X590 series switch supports AVB on all ports, except ports 25–36.

> **Note**
> The ExtremeSwitching X440-G2 series switches support AVB, but AVB support on 48-port models is limited to ports on the front-panel ports 1–24 and 51–52.

> **Note**
> In the 48-port models of ExtremeSwitching X440-G2 series switches, combo ports 51 and 52 do not support AVB when used as copper ports (as in RJ-45 interfaces.)

> **Note**
> AVB is not supported on SummitStacks.

> **Note**
> AVB is supported in ExtremeXOS 31.3 and later on the following X465 models: X465-24XE, X465-24S, and X465i-48W.

> **Note**
> AVB is not supported when MACsec is enabled.

> **Note**
> AVB is not supported when Network Timing Feature License is installed.

Configuring and Managing AVB

AVB is not enabled in the default configuration, and must be enabled both globally on the switch and on the ports where you want to use it. In the simplest case, when starting with a blank configuration, AVB may be enabled by executing the following two commands:

```
# enable avb

enable avb ports all
```

The status of AVB can be seen by using the following command:

```
# show avb
gPTP status        : Enabled
gPTP enabled ports : *1s     *2m     *10m    *11m    *12m
                     *13m    *14m    *15m    *16m    *17m
                     *18m    *19m    *20m    *21m

MSRP status        : Enabled
MSRP enabled ports : *1ab    *2ab    *10ab   *11ab   *12ab
                     *13ab   *14ab   *15ab   *16ab   *17ab
                     *18ab   *19ab   *20ab   *21ab

MVRP status        : Enabled
MVRP enabled ports : *1      *2      *10     *11     *12
                     *13     *14     *15     *16     *17
                     *18     *19     *20     *21

Flags:       (*) Active,                  (!) Administratively disabled,
             (a) SR Class A allowed,      (b) SR Class B allowed,
             (d) Disabled gPTP port role, (m) Master gPTP port role,
             (p) Passive gPTP port role,  (s) Slave gPTP port role
```

The `show avb` command displays high level information about each of the three main protocols (gPTP, MSRP, and MVRP). Each protocol section indicates that all three protocols are enabled both globally, and on ports 1,2 and 11-21. The "*" indicates that we have link on each of the ports.

The gPTP status indicates that port 1 is a slave port, which means that the Grand Master Clock (GMC) is reachable through port 1. The gPTP status also indicates that the rest of the ports are master ports. Furthermore, the fact that no ports are shown to be in the Disabled role means that gPTP is operational on all the ports.

ExtremeXOS provides static AVB configuration with the exception of of Best Master Clock Algorithm (BMCA), which runs as part of gPTP. The BMCA feature adds the ability to disable BMCA and to specify a slave port if desired. When BMCA functionality is on, BMCA is executed normally as described in IEEE 802.1AS. When BMCA is off, BMCA is not executed. In disabled mode, a port can be configured to be the slave-port. If no

ports are configured to be slave-port, then the switch will become the Grandmaster Clock and all network-gptp enabled ports will be master ports. The `show network-gptp` command displays whether BMCA is on or off.

The "ab" on the MSRP status indicates that all ports are members of both the class A and class B domain domains. The MVRP status simply shows which ports are enabled and active.

The user interface for AVB includes the following five protocols:

- gPTP
- MRP
- MVRP
- MSRP
- FQTSS

The "avb" commands shown above are part of a set of AVB macro commands provided to simplify the process of enabling and disabling AVB. The AVB macro commands have the form:

```
[ enable | disable | unconfigure ] avb { ports [ all | port_list ] }
```

Using one of the macro commands is the same as executing the following three commands:

```
[ enable | disable | unconfigure ] network-clock gptp { ports [ all | port_list ]}
```

```
[ enable | disable | unconfigure ] mvrp { ports [ all | port_list ]}
```

```
[ enable | disable | unconfigure ] msrp { ports [ all | port_list ]}
```

MRP does not need to be enabled or disabled, and the only MRP properties that may be configured are timer values. The defaults should be sufficient for most deployments, though it may be necessary to increase the leave-all and leave time values when supporting a large number of streams.

Multiple Registration Protocol/Multiple _VLAN_ Registration Protocol is used for dynamically creating VLANs and/or dynamically adding ports to VLANs. As per IEEE Std 802.1Q-2011, some VLANs can be marked as forbidden VLANs on some ports so that when MVRP PDU is received on the port with the particular forbidden VLAN Id, the VLAN is not created and if the VLAN is already there, the port is not added to the VLAN. This functionality was added in 15.3.2.

Link aggregation allows an increased bandwidth and resilience by using a group of ports to carry traffic in parallel between switches. Multiple ports can be aggregated into one logical port. MVRP can be enabled on the logical port. The MVRP control packets will be transmitted on any available physical port of the _LAG (Link Aggregation Group)_. The peer on the other side will receive the packet and process as if being received on

the logical port. MVRP supports both dynamic (LACP) as well as static load sharing. Some restrictions that apply are:

- The individual ports of the LAG, including the master port, should not have MVRP configuration prior to grouping.
- MVRP can be enabled / disabled only on master port. The individual links cannot be configured.
- Once sharing is disabled, MVRP configuration of the master port will be lost (default will be disabled).
- The statistics and counters shown on the MVRP show commands will be a cumulative counter for all links added together. We do not maintain per link counters.
- The actual load sharing of the traffic is beyond MVRP's domain and should take place as per the configured LAG setting. MVRP just adds the LAG port to the VLAN(s).
- MVRP only works with Rapid Spanning Tree Protocol [RSTP} and the Default VLAN.User-created STPD instances cannot be associated with the Default VLAN. The Default VLAN is always associated to STPD s0.

MVRP data structure is based on port Instance. All dynamic VLANs created or propagated for a given port will be stored for each port Instance. For normal ports, the port Instance will correspond to the PIF port instance, and for LAG ports, the port Instance will correspond to the LIF port Instance. The port instance is not shown in any of the standard CLI show commands, though it is available as a part of the debug commands. Once MVRP is enabled on the master port, addition / deletion of individual links is supported. MVRP packets received on the newly added link will be accounted instantaneously.

MVRP LAG configuration examples:

- `enable sharing 13 grouping 13,14,15`

- `enable mvrp port 13`

- `enable sharing 13 grouping 13,14`

- `enable mvrp port 13`

- `configure sharing 13 add ports 15`

The VLAN registration is of three types:

- Forbidden—Port is forbidden to be added to the VLAN
- Normal—Port is allowed to be added to the VLAN
- Fixed—Port is statically added to the VLAN

The forbidden / normal setting is only for dynamic addition of ports to VLANs. Any static addition of ports to the VLANs, overrides this setting and marks the status as fixed. The forbidden setting can be used to control MSRP advertisements, in typical scaling scenarios. In addition to support for forbidden VLANs, support for periodic timer and extended-refresh timer has been added in 15.3.2.

The FQTSS settings are managed by MSRP, and may not be configured directly.

The disable commands disable the AVB protocols globally or per port without changing any other configured settings, while the unconfigure commands reset all AVB settings to the initial states, and release all switch resources that were allocated when the protocols were enabled.

More detailed configuration options are provided on a per-protocol basis using the corresponding configure commands:

```
configure network-clock gptp
configure mvrp
configure msrp
configure mrp
```

If a topology contains redundant connections, *ELRP (Extreme Loop Recovery Protocol)* with dynamic VLAN feature should be enabled to prevent data loops in VLANs created by MVRP (see ELRP with Dynamic VLANs on page 2001). The ELRP with dynamic VLANs feature is supported starting with ExtremeXOS 22.2. In a MVRP-only environment, STP-based loop prevention method is not supported.

MRP/MSRP/MVRP LAG Support

As of ExtremeXOS 21.1, *LAG* is supported for MRP/MSRP. A LAG may have one or multiple member ports, thus providing redundancy as well as additional bandwidth.

There are two modes of how a LAG runs with MRP/MSRP. The two MRP/MSRP LAG modes are single-port and cumulative. The concept of effective bandwidth is used below to simulate the available bandwidth of a physical port (port speed). As in the case of the physical port, a configurable percentage, deltaBandwidth, which by default is 75%, of the effective bandwidth is the final bandwidth available for MSRP streams.

In single-port mode, the LAG is simply a way to provide redundancy. Therefore the effective bandwidth is set to the minimum bandwidth of all member ports.

```
effective bw = min (bw of all active member ports)

MSRP reservable bw = deltaBandwidth * effective bw
```

All LAG member ports on ExtremeXOS must have the same speed to aggregate. Therefore, the minimum bandwidth is equivalent to the bandwidth of any member port.

In cumulative mode, the LAG trades redundancy for extra bandwidth. To calculate the available bandwidth, all bandwidth of one active member and partial bandwidth of other member ports are used to calculate the effective bandwidth.

```
effective bw = min (bw of all active member ports) + beta * sum (bw of
all other active member ports)

MSRP reservable bw = deltalBandwidth * effective bw
```

For example, if the LAG has three 1GB member ports, and deltaBandwidth = 75%, then in the single-port mode, the effective bandwidth is 1GB, of which 75%, that is 0.75GB is reservable for MSRP, exactly the same as in the case of a physical port.

For the same LAG in the cumulative mode, if beta = 50%, then 100% of one member port and 50% bandwidth of other two member ports contributes to the effective bandwidth, therefore:

```
effective bw = 1GB (one active member port) + 50% * 1GB (the next active
member port) + 50% * 1GB (the last active member port) = 2GB

MSRP reservable bw = 75% x effective bw = 1.5GB
```

When a LAG runs in the cumulative mode, the streams are roughly evenly distributed on all member links. Even though beta percent bandwidth of the other member ports contributes to the effective bandwidth, it does not mean that reservation on that member port is limited to beta percent of its bandwidth. That is just the way to calculate an estimate of how much bandwidth can be provided with a LAG, with a balanced redundancy requirement. All member ports are treated equally and programmed in the same way.

As in the case of physical ports, if the `(total requested BW) <= deltaBandwidth * (effective BW)`, then assume the LAG is able to handle all streams safely and provide a comfortable level of redundancy if the streams are reasonably evenly distributed. In extremely polarized cases, where many streams are hashed to a certain member link, packet drop is inevitable. When `(total requested BW) > deltaBandwidth * (effective BW)`, then the LAG is not able to safely handle all streams, even though it may still be able to. At this time new reservation requests are declined.

The effective bandwidth is an aggregate of multiple physical ports and can exceed the bandwidth of any single physical port. The _QoS_ profile is configured on a physical port, so if the reservation bandwidth request is less than the delta bandwidth of the physical port, the QoS profile will be configured to the requested bandwidth. To prevent the QoS profile configuration from exceeding the physical port bandwidth, the QoS profile configuration is limited to delta bandwidth of the physical port (which is typically 75% of the port bandwidth).

Multiple _VLAN_ Registration Protocol (MVRP) is supported over _MLAG (Multi-switch Link Aggregation Group)_ (for more information, see Multiple VLAN Registration Protocol (MVRP) over Multi-switch Link Aggregation (MLAG) on page 270).

gPTP LAG Support

Starting in ExtremeXOS 21.1, configuration of gPTP on a _LAG_ port is supported. However, the protocol is still running on the member port, aka, physical port level. When gPTP is enabled on a LAG port, all member ports are enabled with the protocol, vice versa when it is disabled on the LAG port. All member ports share the same gPTP configurations. When adding or deleting LAG member port, gPTP is automatically enabled or disabled. Member ports go operational up/down when the physical port is administratively enabled/disabled.

It is recommended to perform configuration on the LAG level; however, the only keyword in the `enable/disable/configure network-gptp` CLIs allows per member port fine tuning. This per member port change is overwritten with the next LAG level

configuration. Unconfigure gPTP on a member port is not allowed though; otherwise, the newly added member port may not have the reference of the master port for gptp configuration.

In the CLI display, all member ports with gPTP enabled, regardless port operational status, are listed, but noted as a LAG member port. The LAG itself is not displayed because it does not participate the protocol.

Displaying AVB Information

The complete set of "show" commands are detailed in the *ExtremeXOS 32.4 Command Reference Guide*. Some of the more commonly used commands are outlined here.

gPTP

Detailed information about gPTP can be displayed using the following set of commands:

```
show network-clock gptp ...
```

For example, the `show network-clock gptp ports` command can be used to view the gPTP properties of a given port, and is useful for debugging when the `show avb` command shows that the port is not operational for gPTP.

```
# show network-clock gptp ports 1
Physical port number  : 1
gPTP port status                    : Enabled
Clock Identity                      : 00:04:96:ff:fe:51:ba:ea
gPTP Port Number                    : 1
IEEE 802.1AS Capable                : Yes
Port Role                           : 9 (Slave)
Announce Initial Interval           : 0 (1.000 secs)
Announce Current Interval           : 0 (1.000 secs)
Announce Receipt Timeout            : 3
Sync Initial Interval               : -3 (0.125 secs)
Sync Current Interval               : -3 (0.125 secs)
Sync Receipt Timeout                : 3
Sync Receipt Timeout Interval       : 375000000 ns
Measuring Propagation Delay         : Yes
Propagation Delay                   : 623 ns
Propagation Delay Threshold         : 3800 ns (auto)
Propagation Delay Asymmetry         : 0
Peer Delay Initial Interval         : 0 (1.000 secs)
Peer Delay Current Interval         : 0 (1.000 secs)
Peer Delay Allowed Lost Responses   : 3
Neighbor Rate Ratio                 : 1.000020
PTP Version                         : 2
```

MSRP

Detailed information about MSRP can be displayed using the following set of commands:

```
show msrp ...
```

Several that are commonly used are:

```
show msrp
show msrp streams
show msrp listeners
show msrp streams propagation
```

Examples of these commands are shown below.

The `show msrp` command displays the summary information included in the `show avb` command, but also displays the total number of streams and reservations on the switch.

```
# show msrp
MSRP Status  : Enabled
MSRP Max Latency Frame Size   : 1522
MSRP Max Fan-in Ports         : No limit
MSRP Enabled Ports            : *1ab    *2ab    *10ab    *11ab    12
                                 13      14      15       16       17
                                 18      19      20       21
Total MSRP streams            : 2
Total MSRP reservations       : 6
Flags:  (*) Active,             (!) Administratively disabled,
        (a) SR Class A allowed,  (b) SR Class B allowed
```

The `show msrp` streams command displays all of the streams that the switch is aware of.

```
# show msrp streams
Stream Id  Destination     Port  Dec    Vid  Cls/Rn    BW
---------------------  ----------------  ----  ----  ----  ------  ---------
00:50:c2:4e:db:02:00:00  91:e0:f0:00:ce:00    1   Adv      2   A/1       6.336 Mb
00:50:c2:4e:db:06:00:00  91:e0:f0:00:0e:82    2   Adv      2   A/1       6.336 Mb

Total Streams: 2
-------------------------------------------------------------------------------
BW       : Bandwidth,              Cls      : Traffic Class,
Dec      : Prop. Declaration Types, Rn       : Rank

MSRP Declaration Types:
   Adv   : Talker Advertise,       AskFail  : Listener Asking Failed,
   Fail  : Talker Fail,            RdyFail  : Listener Ready Failed,
   Ready : Listener Ready
```

The `show msrp listeners` command displays all of the listeners the switch is aware of. If the declaration type is either Ready or RdyFail, a reservation has been made, and the Stream Age will show the length of time this reservation has been active.

```
# show msrp listeners
    Stream Id             Port  Dec      Dir      State      Stream Age

                                                   App  Reg  (days,hr:mm:ss)
---------------------  -----  -------  -------  ---  ---  ----------------

MVRP

Other than the MVRP summary information displayed in the show avb command, information about dynamically created VLANs is shown using the "vlan" commands as follows.

In the `show vlan` command, it can be seen that SYS_VLAN_0002 is a dynamically created _VLAN_ due to the "d" flag.

```
# show vlan
-----------------------------------------------------------------------------------------

Layer 2 Tunneling and Filtering

This ExtremeXOS feature introduces the ability to tunnel and filter Layer 2 PDUs. Tunneling allows you to send Layer 2 PDUs across a service provider network, and be delivered to remote switches. It is useful when a network includes remote sites that are connected through a service provider network. Using tunneling, you can make the service provider network transparent to the customer network.

Filtering prevents Layer 2 PDUs from being received on a port.

Layer 2 Protocol Tunneling

Layer 2 protocol tunneling (L2PT) is achieved by encapsulating the PDUs at the ingress PE device before transmitting them over the service provider network. The encapsulation prevents the PDUs from being processed by the switches in the SP network. At the egress PE device, the encapsulated packets are de-encapsulated, and transmitted to the CE device.

The encapsulation used for different types of networks is as follows:

- *VLAN (Virtual LAN)*/VMAN – The Destination Address (DA) MAC of the Layer 2 PDU is changed to the L2PT DA MAC. The switch shall also add any VLAN tags that may be required to the Layer 2 PDU before transmitting over the SP network.

- VPLS/VPWS – The DA MAC of the Layer 2 PDU is changed to L2PT DA MAC. The Layer 2 PDU is then treated like any other data packet by the *MPLS (Multiprotocol Label Switching)* stack. The MPLS stack shall add the labels and L2 headers as per its configuration to the Layer 2 PDU before transmitting over the SP network.

- VXLAN – The DA MAC of the Layer 2 PDU is changed to L2PT DA MAC at the ingress remote tunnel end-point (RTEP). The modified packet is then encapsulated into a VXLAN packet and sent over the network. At the egress RTEP, the packet is lifted to the CPU for L2PT processing. After VXLAN decapsulation, the DA MAC is changed from L2PT MAC to the protocol MAC and is sent on the access ports of the tenant VLAN.

Tunneling is configured on a service by specifying a tunneling action for each interface of the service. The possible actions are:

- Tunnel – Configuring an interface of a service to **tunnel** for a protocol enables the interface to tunnel PDUs of the configured protocol that are received by the underlying port of the interface. Any PDUs that are received in its native format are tunneled instead of processing locally by the switch. Any PDUs of the protocol that are received in its encapsulated format are dropped by the switch (receiving an encapsulated packet on an interface configured to tunnel is considered proof of network misconfiguration, or loops).

- Encapsulate/Decapsulate – Configuring an interface of a service to encapsulate or de-encapsulate for a protocol enables the interface to transmit and receive PDUs of that protocol in its encapsulated format. Native PDUs of the protocol may still be received by the underlying port of the interface, but they will not be tunneled and instead are processed locally by the switch.

- None – Configuring an interface of a service to **none** for protocol marks the interface as not participating in tunneling for that protocol. Native PDUs of the protocol that are received on the underlying port of the interface shall either be processed locally by the switch or be tunneled by another service which is configured to tunnel that protocol. Encapsulated PDUs that are received on the interface are treated like any other L2 packet.

An operator can specify a _CoS (Class of Service)_ value for the tunneled PDUs. This can be useful since some L2 protocols may have a higher priority than others (for example, _STP (Spanning Tree Protocol)_ may be considered higher priority than _LLDP (Link Layer Discovery Protocol)_). If a CoS value is specified for a protocol for which tunneling is enabled, the switch will transmit the encapsulated PDUs for that protocol with the operator specified CoS towards the network. The CoS value specified by the operator is transmitted on the SP network as follows:

- VLAN/VMAN – The CoS value is written to the PRI bits of the outermost VLAN tag if available.

- VPLS/VPWS – The CoS value is written to the EXP bits of the outermost MPLS label. The action taken by the switch for PDUs of a protocol is as described in the following table.

- VXLAN – The CoS value configured on the profile attached to the access port is written to the PRI bits of the outer VLAN header of the VXLAN encapsulated frames before transmitting them to other RTEPs.

As VXLAN tunneled packets cross L3 boundaries in the underlay network, the CoS can get lost when traversing L3 boundaries. An operator may choose to configure a Differentiated Services Code Point (DSCP) that needs to be set in the outer IP header of the encapsulated packets. If the packet encapsulated into the VXLAN tunnel is an IP packet, the DSCP from inner IP header is typically copied to DSCP of the outer IP header. A configuration option is provided to overwrite this outer DSCP value. In case of

L2 protocols (which do not have an inner DSCP), the configured DSCP value is set in the outer IP header.

Table 65: L2 PDU Actions

Ingress Action	Egress Action	Switch Action
None or Encap/Decap	NA	Process locally
Tunnel	None	Discard PDU at egress
Tunnel	Tunnel	Tx PDU natively
Tunnel	Encap/Decap	Tx PDU encapsulated

The action taken by the switch for encapsulated PDUs for a protocol is as described in the following table.

Table 66: L2 Encapsulated PDU Actions

Service has at least one I/F with tunnel action	Ingress Action	Egress Action	Switch Action
No	None or Encap/Decap	None or Encap/Decap	Forward
Yes	None or Tunnel	NA	Discard packet at ingress
Yes	Encap/Decap	None	Discard packet at egress
Yes	Encap/Decap	Tunnel	Tx PDU natively
Yes	Encap/Decap	Encap/Decap	Tx PDU encapsulated

Protocol Tunneling

To make L2PT configuration easier, in ExtremeXOS you can create L2PT profiles. An L2PT profile specifies the tunneling action and other parameters for protocols (specified using protocol filters) that should be tunneled. You can then apply the profile to the interfaces of the service that are participating in L2PT. And you can also change the profile when it is already bound to an interface.

The L2PT parameters that can be configured through a profile include the following:
• Tunneling Action
• Tunneling CoS
• Tunneling DSCP for VXLAN case

The following validity checks are performed when an entry for a protocol filter is created in an L2PT profile:
• Ensure that all protocols in the protocol filter define a destination MAC address.
• Ensure that all protocols in the protocol filter define a protocol identifier.
• Ensure that all protocols in the protocol filter are unique within the L2PT profile.
• If the action for the protocol filter is 'encapsulate:
   ◦ Ensure that there are no entries with action as 'tunnel in the L2PT profile.

- ◦ Ensure that the service interface is either a tagged _VLAN_ port, a PW, or a VXLAN RTEP.
- If the action for the protocol filter is 'tunnel':
  - ◦ Ensure that there are no entries with action as 'encapsulate' in the L2PT profile.
  - ◦ For every service interface using the L2PT profile:
    - ▪ Ensure that none of the protocols in the protocol filter are filtered on the underlying port of the interface.
    - ▪ Ensure that none of the protocols in the protocol filter are tunneled on the underlying port of the interface.

The following validity checks are performed when a L2PT profile is bound to an interface of a service:

- If the profile specifies the action as 'tunnel' for protocol filter:
  - ◦ Ensure that the interface is not a PW or a VXLAN RTEP.
  - ◦ Ensure that none of the protocols in the L2PT profile are filtered on the underlying port of the interface.
  - ◦ Ensure that none of the protocols in the L2PT profile are tunneled on the underlying port of the interface.

Typically, you will want to configure the tunneling action for all customer facing interfaces of the service that participate in L2PT as tunnel, and the tunneling action for all network facing interfaces as encapsulate/decapsulate. Once any interface of the service is configured to tunnel a protocol, the switch will configure all tagged ports and PWs or VXLAN RTEPs of the service to encapsulate/decapsulate mode. You can override this implicit configuration by binding the RTEPs a profile to the service interface that specifies a different tunneling action.

For example, consider a VMAN service named c1 with customer facing ports 1, 2 and 3 and network facing ports 4, 5, 6. Ports 4, 5 and 6 are added as tagged to the VMAN and 1, 2 and 3 are added as untagged to the VMAN. The operator wants to tunnel LACP and EFM OAM on all customer facing ports at CoS 5. The configurations that he or she must make are as follows:

```
# Create a protocol filter
create protocol filter "my_slow_protocols_filter"

# Add LACP to the protocol filter
configure protocol filter "my_slow_protocols_filter"
add dest-mac 01:80:C2:00:00:02 etype 0x8809 field offset 14 value 01 mask FF

# Add EFM OAM to the protocol filter
configure protocol filter "my_slow_protocols_filter"
add dest-mac 01:80:C2:00:00:02 etype 0x8809 field offset 14 value 03 mask FF

# Create an L2PT profile for the customer facing ports named c1_l2pt_profile
create l2pt profile "c1_l2pt_profile"

# Enable CDP tunneling with CoS 5
configure l2pt profile "c1_l2pt_profile" add protocol filter
"my_slow_protocols_filter" action tunnel cos 5

# Enable CDP tunneling with CoS 3 and DSCP 38 in case of VXLAN tenant VLAN
configure l2pt profile "c1_l2pt_profile" add protocol filter
```

```
"my_slow_protocols_filter" action tunnel cos 5 dscp 38

# Bind c1_l2pt_profile to all customer facing ports
configure vman c1 ports 1,2,3 l2pt profile "c1_l2pt_profile"

# Please note that the network facing port 4, 5 and 6 don't have to be explicitly
# configured to encapsulate/decapsulate mode since the switch implicitly sets all
# tagged ports to encapsulate/decapsulate mode when an L2PT profile is bound to
# any port of the service.
```

The operator also has the option to configure the L2PT destination MAC address (i.e., the DA used by L2PT encapsulated PDUs). This is may be done using the following CLI command:

```
configure l2pt encapsulation dest-mac mac_address
```

The L2PT destination MAC address may only be changed when no L2PT profiles have been bound to any service interface. The default L2PT DA MAC is 01:00:0C:CD:CD:D0 (selected to be interoperable with Cisco and Juniper).

Use the following commands to view the status and statistics of L2PT:

```
show [vlan | vman] vlan_name {ports port_list} l2pt {detail}
```

```
show {l2vpn} [vpls vpls_name | vpws vpws_name] {peer ipaddress} l2pt
{detail}
```

```
show [[{vlan} vlan_name] {{vxlan {vr vr_name} rtep rtep_ipv4}}] l2pt
{detail}
```

Use the following commands to clear L2PT stats:

```
clear l2pt counters {[vlan | vman] vlan_name {ports port_list}}
```

```
clear l2pt counters {[vpls vpls_name {peer ipaddress} | vpws vpws_name]}
```

```
clear l2pt counters {[vlan] vlan_name {{vxlan {vr vr_name} rtep rtep_ipvs}}}
```

Implementing L2PT in ExtremeXOS

In ExtremeXOS, the L2PT data-plane is implemented almost entirely in software. When you attach a L2PT profile to a service interface, the following _ACL (Access Control List)_ rules are configured:

- An ACL rule is added to copy and drop all packets with a destination address equal to the L2PT destination MAC address, and an outer _VLAN_ ID equal to the VLAN tag of the service. In case of VXLAN tenant VLAN, the condition for VLAN ID is modified so that the packet is copied to CPU on any VLAN received. The traffic for the destined tenant VLAN ID can be received on any underlay L3 VLAN.

- For each protocol that is tunneled on the service interface, an ACL rule is added to copy and drop all packets with the same the destination address as the protocol. If the protocol defines an EtherType, then the rule is also qualified with the EtherType.

- If any protocol is tunneled on the service interface, an ACL rule is added to drop all packets received on the service interface with a destination address equal to the L2PT destination MAC address.

Protocol Filtering

You can enable filtering of PDUs of a protocol on any port. If you enable filtering for a protocol on a port, the switch discards PDUs of that protocol on that port.

Use the following command to view protocol filter status and statistics:

```
show ports [port_list | all] protocol filter {detail}
```

Use the following command to clear protocol filtering stats:

```
clear counters ports {port_list} protocol filter
```

Implementing Protocol Filtering in ExtremeXOS

In ExtremeXOS, the protocol filtering data-plane is implemented partially in hardware and partially in software. Filtering is performed only on the ingress. When a protocol filter is attached to a port, the following _ACL_ rules are configured:

- For each protocol in the protocol filter: If the protocol does not define a user-defined field, and the protocol identifier is EtherType, or does not have a protocol identifier:
  - An ACL rule is added to drop all packets on the port that match the destination address of the packet. The rule is also qualified with the EtherType of the protocol if it defines one.

  Else:
  - An ACL rule is added to copy and drop all packets on the port that match the destination address of the packet. The rule is also qualified with the EtherType of the protocol if it defines one.

The protocol filtering data-plane inspects all packets received from ports that have protocol filters attached, and drops any packet that matches any of the protocols configured in the protocol filter.

Protocol filtering is also supported for VXLAN tenant VLANs. However, filtering has to be configured on access ports only, and is not supported on RTEPs. This aligns with the existing behavior where filtering cannot be supported on pseudo wires.

Protocol Filters

Both L2PT and protocol filtering allow you to tunnel or filter many protocols on an interface. For this purpose, ExtremeXOS supports creating protocol filters. A protocol filter contains a number of protocols to which you can apply some action (like tunneling and filtering). Each protocol in a protocol filter is defined using the following fields:

- The destination MAC address of PDUs of the protocol. This field is mandatory for all protocols that are to be tunneled or filtered.

- The protocol id (EtherType, LLC, SNAP). This field is mandatory for all protocols that are to be tunneled.
- User defined field. This is an arbitrary field in the PDU of the protocol that is specified using the offset of the field from the start of the PDU, the value of the field and a mask.

For example, use the following command to create a protocol filter that includes LACP and EFM OAM:

```
# Create a protocol filter
create protocol filter my_slow_protocols_filter

# Add LACP to the protocol filter
configure protocol filter my_slow_protocols_filteradd dest-mac
01:80:C2:00:00:02 etype 0x8809 field offset 14 value 01 mask FF

# Add EFM OAM to the protocol filter
configure protocol filter my_slow_protocols_filteradd dest-mac
01:80:C2:00:00:02 etype 0x8809 field offset 14 value 03 mask FF
```

The following validity checks are performed when a protocol is added to a protocol filter:

- Ensure that the protocol does not already exist in the protocol filter.
- If the protocol filter is used by any L2PT profile:
  - Ensure that the protocol defines a destination MAC address.
  - Ensure that the protocol defines a protocol identifier.

- For every L2PT profile that is using the protocol filter:
  - Ensure that the protocol is unique within the L2PT profile. If the action for the protocol filter is 'tunnel' in the L2PT profile:
    - For every service interface using the L2PT profile: ensure that the protocol is not filtered on the underlying port of the service interface.
    - It ensures that the protocol is not tunneled on the underlying port of the service interface.

- If the protocol filter is used by any port for the purpose of protocol filtering (`configure ports port# protocol filter filter-name`):
  - Ensure that the protocol defines a destination MAC address.

- For every port that has the protocol filter attached for the purpose of protocol filtering:
  - Ensure that the protocol is not tunneled by a service on that port.

> **Note**
> Protocol filters may be used with features other than L2PT and protocol filtering (for example, Protocol Based VLANs). The validity tests listed above are only the ones relevant to L2PT and protocol filtering.

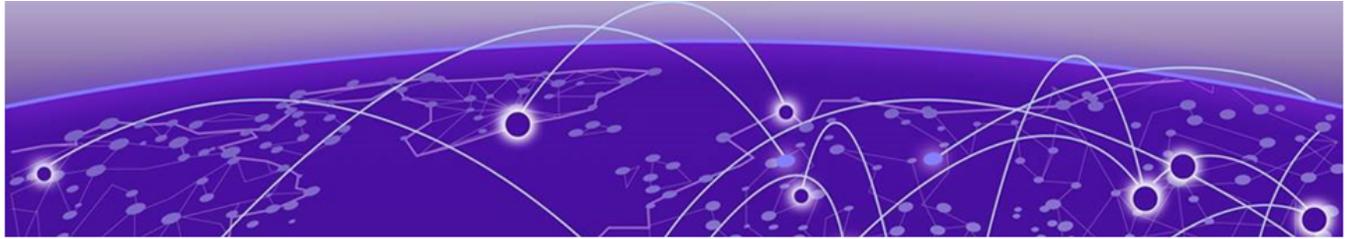
Protocol filters for the following protocols are created automatically by the switch when the switch is set to default configuration:

- Cisco Discovery Protocol (CDP)
- Unidirectional Link Detection (UDLD)

- *VLAN* Trunking Protocol (VTP)
- Port Aggregation Protocol (PAgP)
- Dynamic Trunking Protocol (DTP)
- Link Aggregation Control Protocol (LACP)
- *LLDP*
- *STP*
- *EDP (Extreme Discovery Protocol)*

L2PT Limitations

- L2PT and protocol filtering is implemented in software, so the number of frames that can be filtered or tunneled is limited.
- Both L2PT and protocol filtering can be configured only through CLI. Configuration through *SNMP (Simple Network Management Protocol)*/XML is not supported for this release.
- If L2PT configurations are made on PWs, these configurations are lost on a restart of the *MPLS* process unless the L2PT process is also restarted.
- If L2PT configurations are made on a VPLS or VPWS service, dot1p tag inclusion must be enabled on the VPLS/VPWS. Also, VPLS or VPWS service must have same *VLAN* IDs at each end of a PW.
- When tunneling protocols are point-to-point in nature, it is your responsibility to ensure that there are only two tunnel endpoints for the protocol.
- If a protocol that is configured to be tunneled on a service interface cannot be uniquely identified by its destination address and EtherType, then all packets with the same DA and EtherType of the protocol being tunneled (but that are not really PDUs of the protocol) will be slow path forwarded.
- Tagged protocol PDUs cannot be tunneled over VLANs. Tagged protocol PDUs can only be tunneled over VMANs (the VMAN can be the service VMAN for a VPLS/VPWS service, or a standalone VMAN). Untagged protocol PDUs can be tunneled over both VLANs and VMANs (the VLAN/VMAN can be standalone, or be the service VMAN for a VPLS/VPWS service).
- Untagged protocol PDUs cannot be bypassed if the ingress port is an untagged VMAN port with a default CVID. Untagged protocol PDUs can be bypassed if the ingress port is an untagged VMAN port without a default CVID.
- In VPLS, only full-mesh configuration is supported for L2PT.
- L2PT is not supported on VLAN ports that have a port specific tag.

Virtual Routers


This section provides information about Virtual Routers. It discusses how ExtremeXOS software supports Virtual Routers and VRFs, and provides specific information about how to configure and manage those virtual routers.

Overview of Virtual Routers

The ExtremeXOS software supports virtual routers (VRs). This capability allows a single physical switch to be split into multiple VRs. This feature separates the traffic forwarded by a VR from the traffic on a different VR.

Each VR maintains a separate logical forwarding table, which allows the VRs to have overlapping IP addressing. Because each VR maintains its own separate routing information, packets arriving on one VR are never switched to another.

> **Note**
> VRs should not be connected together through a Layer 2 domain. Since there is a single MAC address per switch in the ExtremeXOS software, this same MAC address is used for all VRs. If two VRs on the same switch are connected through a Layer 2 domain, the intermediate Layer 2 switches learn the same MAC address of the switch on different ports, and may send traffic into the wrong VR.

Ports on the switch can either be used exclusively by one VR, or can be shared among two or more VRs. One reason to configure a port for the exclusive use of a single VR is to be sure that only packets from that VR egress from that port. One reason to configure a port to be shared by multiple VRs is to pass traffic from multiple VRs across a shared link.

Each *VLAN (Virtual LAN)* can belong to only one VR.

Because a single physical switch supports multiple VRs, some commands in the ExtremeXOS software require you to specify to which VR the command applies. For example, when you use the ping command, you must specify from which VR the ping packets are generated. Many commands that deal with switch management use the

management VR by default. See the *ExtremeXOS 32.4 Command Reference Guide* for information on the defaults for individual commands.

> **Note**
>
> The term VR is also used with the *VRRP (Virtual Router Redundancy Protocol)*. VRRP uses the term to refer to a single *virtual router (VR)* that spans more than one physical router, which allows multiple switches to provide redundant routing services to users. For more information about VRRP, see VRRP Overview on page 1425.

Types of Virtual Routers

This section describes the types of Virtual Routers:

- System Virtual Routers on page 724
- User Virtual Routers on page 725
- VRFs on page 725
- Local-Only Virtual Routers on page 726
- Direct Route Leaking Between Virtual Routers on page 727

System Virtual Routers

The system VRs are the three VRs created at boot-up time. These system VRs cannot be deleted or renamed. They are named *VR-Mgmt*, *VR-Control*, and *VR-Default*. The following describes each system VR:

- **VR-Mgmt** enables remote management stations to access the switch through Telnet, SSH, and *SNMP (Simple Network Management Protocol)* sessions; it also owns the management port. No other ports can be added to VR-Mgmt, and the management port cannot be removed from it.

  The Mgmt *VLAN* is created in VR-Mgmt during ExtremeXOS system boot-up. No other VLAN can be created in this VR, and the Mgmt VLAN cannot be deleted from it.

  No routing protocol is running on or can be added to VR-Mgmt.

  VR-Mgmt is called VR-0 in ExtremeXOS releases before 11.0.

- **VR-Control** is used for internal communications between all the subsystems in the switch. It has no external visible ports, and you cannot assign any port to it.

  VR-Control has no VLAN interface, and no VLAN can be created for it.

  No routing protocol is running on or can be added to VR-Control.

  VR-Control is called VR-1 in ExtremeXOS releases before 11.0.

- **VR-Default** is the default VR created by the ExtremeXOS system. By default, all data ports in the switch are assigned to VR-Default. Any data port can be added to and deleted from VR-Default.

Users can create and delete VLANs in VR-Default. The Default VLAN is created in VR-Default during the ExtremeXOS system boot-up. The Default VLAN cannot be deleted from VR-Default.

One instance of each routing protocol is spawned for VR-Default during the ExtremeXOS system boot-up, and these routing instances cannot be deleted.

VR-Default is called VR-2 in ExtremeXOS releases before 11.0.

User Virtual Routers

User VRs are the VRs created by users in addition to the system VRs, and each user VR supports Layer 3 routing and forwarding.

The routing tables for each VR are separate from the tables for other VRs, so user VRs can support overlapping address space.

> **Note**
> User VRs are supported only on the platforms listed for the VR feature in the *ExtremeXOS 32.4 Feature License Requirements* document. When a SummitStack contains switches that do not support user VRs, the ports on those devices cannot be added to a user VR.

When a new user VR is created, by default, no ports are assigned, no *VLAN* interface is created, and no support for any routing protocols is added. User VRs support all switch routing protocols. When you add a protocol to a user VR, the user VR starts a process for that protocol. The ExtremeXOS software supports up to 63 user VRs, each of which supports protocols for that VR and all child Virtual Routers and Forwarding instances (VRFs).

> **Note**
> When using SNMPv2c for user created *VR*, "read community" in the *SNMP* tool should be set as "vr_name@community_name" where vr-name is user created virtual router name . Similarly for SNMPv3, "Context name" in SNMP tool should be set as "vr_name@community_name" where vr-name is user created virtual router name .

VRFs

Virtual Router and Forwarding instances (VRFs) are similar to VRs. VRFs are created as children of user VRs or *VR-Default*, and each VRF supports Layer 3 routing and forwarding. The routing tables for each VRF are separate from the tables for other VRs and VRFs, so VRFs can support overlapping address space. The primary differences between VRs and VRFs are:

- For each routing protocol added to a VRF, only one process is started in the user VR and VRF. The VRF protocol operates as one instance of the parent VR protocol, and additional child VRFs operate as additional instances of the same parent VR protocol process. VRFs allow a protocol process running in the parent VR to support many virtual router instances.
- ExtremeXOS supports up to 63 VRs and up to many more VRFs. For the maximum number of supported VRFs, see the *ExtremeXOS Release Notes*.

There are two types of VRFs:

VPN VRFs

Support BGP-based Layer 3 VPNs over *MPLS (Multiprotocol Label Switching)*. VPN VRF tables support entries for additional configuration parameters that enable Layer 3 VPN functionality over an BGP/MPLS backbone network.

Non-VPN VRFs

Support static routes, OSFPv3, and BGP.

Use VRFs instead of VRs when your network plan calls for more than 63 virtual routers or when you want to create Layer 3 VPNs. Use VRs instead of VRFs when the routing protocol you want to use is not supported on a VRF.

When a new VRF is created, by default, no ports are assigned, no *VLAN* interface is created, and no support for any routing protocols is added. When you add a protocol to a VRF, an instance of the protocol is created in the protocol process running in the parent VR, if the protocol process exists. If no protocol process is running in the parent VR, a process is started and a protocol instance corresponding to this VRF is created within that process.

The rest of this chapter uses the following terms to identify the different types of VRs and VRFs to which features and commands apply:

- VR—All VRs and VRFs
- VRF—VPN and non-VPN VRFs
- VPN VRF—VPN VRFs only
- Non-VPN VRF—Non-VPN VRFs only

> **Note**
> VRFs are supported only on the platforms listed for the VRF feature in the *ExtremeXOS 32.4 Feature License Requirements* document. When a SummitStack contains switches that do not support VRFs, the ports on those devices cannot be added to a VRF.

Local-Only Virtual Routers

Local-only virtual routers (VR) are a form of user-created VRs (User Virtual Routers on page 725) that allow for separate logical IP lookup tables, to be used only for IP packets to or from the switch's local IP addresses. Local-only user-created VRs allow for different gateways for routes to a host or subnet, based on the local VLANs on the switch.

Local-only VRs allow bidirectional monitoring of each individual path used to reach the switch itself, where each path may traverse, for example, a different firewall. Switches that support local-only VRs do not forward IP packets in local-only VRs in software or in hardware; they instead use separate lookup tables, including static routes, for packets to or from the switch's local IP addresses.

Supported Platforms

Local-only VRs are supported on the ExtremeSwitching X435, X440-G2, and X620 series switches and stacks with these series switches. Other ExtremeSwitching series switches support VRs in hardware, rather than support local-only VRs.

Limitations

IP forwarding is not permitted on local-only VRs, or on VLANs belonging to local-only VRs.

Local-only VRs default to having IP route compression disabled. Enabling IP route compression produces an error.

NEW!Direct Route Leaking Between Virtual Routers

Version 32.4 adds support for leaking direct routes of specified VLAN(s) to a different Virtual Router (VR). Adjacent (directly connected) hosts are also reachable in the specified VR.

> **Note**
> This feature is an additional method for achieving Inter-VR routing without an external router. You can also allow a static route's gateway to be in a different VR by entering the `configure iproute add` command and specifying **vlan** *egress_vlan*, or redistribute routes from one OSPF instance to another OSPF instance in a different VR by entering the `enable ospf export {`**vr**`}` command.

Leaked direct routes are created with origin **direct-inter-vr** in the leak-to-VR. These routes have a lower route priority than direct routes and a higher route priority than any other route type.

The route priority of **direct-inter-vr** can be modified using the **iproute priority** command. These routes can be redistributed to the OSPF protocol in the leak-to-VR like any other routes in the VR. OSPF's route redistribution command is also extended as part of this feature and includes the **direct-inter-vr** route type.

> **Note**
> To ping a directly attached host from the switch command line successfully, the **ping** command must specify the correct VR name (or use the correct command line **VR context**) containing the VLAN with that subnet. If another VR name or VR context is used, the ping will not be successful.

Direct Route Leaking CLI Commands

Use the `configure iproute add` **direct-inter-vr** {**ipv4**} [{**vlan**} *from_vlan_name* | **vlan** *from_vlan_list*] {{**vr**} *to_vr_name*} command to add the direct routes of a VLAN or set of VLANs to be leaked to the leak-to-VR.

Use the `configure iproute delete` **`direct-inter-vr`** `{`**`ipv4}`** `[{`**`vlan`**`}` *`from_vlan_name`* `|` **`vlan`** *`from_vlan_list`*`]` `{{`**`vr`**`}` *`to_vr_name`*`}` command to delete a direct route of a VLAN or set of VLANs previously leaked to the leak-to-VR.

Use the `show iproute` **`direct-inter-vr`** `{`**`ipv4`**`}` `{`**`from-vr`** *`from_vr_name`*`}` `{{`**`vr`**`}` *`to_vr_name`*`}` command to display the configuration of Inter-VR direct routes.

Direct Route Leaking Use Case

A typical use case for this feature is when you have a printer IP directly attached to a switch on a VLAN in VR1. For example, a printer IP 10.1.1.222 on a VLAN names "yellow10" in VR1, with an IP address of 10.1.1.1/24. In this scenario, you want all users in VR1 and VR2 to access the printer using the same IP 10.1.1.222, without requireing an external router.

To accomplish this, you can configure the direct route of VLAN "yellow10" with IP 10.1.1.1/24 to be leaked to VR2. You can create a reverse routed path by configuring the direct route of VLAN "red20" with IP 20.1.1.1/24 in VR2 to be leaked to VR1.

By configuring direct route leaking, hardware and slow path forwarding tables are augmented to include all IP ARP entries on that interface, such as 10.1.1.222, in VR2 in addition to VR1.

> **Note**
> In this scenario, you do not want users in VR3 to access 10.1.1.0/24, on VR1 and VR2.

Direct Route Leaking Example Configuration

The following example commands create or configure direct route leaking.

```
create vr VR1

create vlan yellow10 tag 10 vr VR1

configure yellow10 ipaddress 10.1.1.1/24

create vr VR2

create vlan red20 tag 20 vr VR2

configure red20 ipaddress 10.1.1.1/24

configure iproute add 30.1.1.0/24 20.1.1.254 vr VR2

create vr VR3

configure iproute add direct-inter-vr vlan yellow10 vr VR2

configure iproute add direct-inter-vr red20 VR1
```

Direct Route Leaking Example Show Output

The following example displays **show** command output for this feature:

```
# show iproute direct-inter-vr

Inter-VR Direct IPv4 Routes Leaked To Virtual Router: VR1

Leak From VLAN Name            VID  Primary IP Addr.   Leak From Virtual Router
------------------------------ ---- ----------------- -------------------------------
red20                          20   20.1.1.1      /24 VR2

Inter-VR Direct IPv4 Routes Leaked To Virtual Router: VR2

Leak From VLAN Name            VID  Primary IP Addr.   Leak From Virtual Router
------------------------------ ---- ----------------- -------------------------------
yellow10                       10   10.1.1.1      /24 VR1
```

The following examples display the "div" origin prefix showing Direct-Inter-VR information.

```
# show iproute vr vr1

Ori  Destination         Gateway         Mtr  Flags         VLAN        Duration
 d   10.1.1.0/24         10.1.1.1        1    -------um---- yellow10    0d:0h:3m:12s
 div 20.1.1.0/24         20.1.1.1        1    -------um---- red20       0d:0h:2m:17s
 s   30.1.1.0/24         20.1.1.254      1    -G---S-um---- red20       0d:0h:1m:59s

# show iproute vr vr2

```

VR Configuration Context

Each VR and VRF has its own configuration domain or context, in which you can enter commands to configure that VR. Some commands allow you to specify a VR to which the command applies.

For other commands, you must change context to that of the target VR or VRF before you execute the command. The current context is indicated in the command line interface (CLI) prompt by the name of the user VR or VRF. If no name appears in the prompt, the context is *VR-Default*.

For instructions on changing context, see

Commands that apply to the current VR context include all the *BGP (Border Gateway Protocol)*, *OSPF (Open Shortest Path First)*, *OSPFv3 (Open Shortest Path First version 3)*, PIM, IS-IS, *RIP (Routing Information Protocol)*, and *RIPng (Routing Information Protocol Next Generation)* commands, and the commands listed in the following table.

Commands that apply to the current VRF context are limited to BGP commands and the commands listed in Table 67.

Table 67: Virtual Router Commands

`[enable	disable] ipforwarding`
`configure iparp`
`configure iparp [`**`add`** `|` **`delete`**`]`
`[enable	disable] iparp`
`show iparp`
`configure iproute [`**`add`** `|` **`delete`**`]`
`show iproute`
`rtlookup`
`create [vlan	vman]` *`vlan-name`*
`[enable	disable] igmp`
`[enable	disable] igmp snooping`
`[enable	disable] ipmcforwarding`
`show igmp`
`show igmp snooping`
`show igmp group`
`show igmp snooping cache`

Managing Virtual Routers

This section describes the options for managing Virtual Routers.

Creating and Deleting User Virtual Routers

- To create a user VR, use the following command and do not include the type or vr attributes:

  `create virtual-router` *`vr-name`* `{`**`type`** `[`**`vrf`** `|` **`vpn-vrf`** `{`**`vr`** *`parent_vr_name`*`}]}`

  > **Note**
  > User VRs are supported only on the platforms listed for this feature in the *ExtremeXOS 32.4 Feature License Requirements* document.

  A VR name cannot be the same as a VLAN name. You cannot name a user VR with the names *VR-Mgmt*, *VR-Control*, or *VR-Default* because these are the existing default system VRs. For backward compatibility, user VRs also cannot be named VR-0, VR-1 or VR-2 because these three names are the names for the system VRs in ExtremeXOS releases before 11.0.

  If you exceed the maximum number of VRs supported on your platform, a message similar to the following appears:

```
Error: Maximum number of User VRs supported by the system is 63
```

- To create a local-only user VR (ExtremeSwitching X435, X440-G2, and X620 only), use the following command, and do not include the type or vr attributes:

```
create virtual-router vr-name local-only {type [vrf | vpn-vrf {vr
parent_vr_name}]}
```

- To display the virtual routers, use the following command:

```
show virtual-router {name}
```

- To delete a user VR, use the following command:

> **Note**
> Before you delete a VR, you must delete all VLANs and child VRFs created in that VR. All of the ports assigned to this VR are deleted and made available to assign to other VRs and VRFs. Any routing protocol that is running on the VR is shut down and deleted gracefully.

```
delete virtual-router vr-name
```

Creating and Deleting VRFs

- To create a VRF, use the following command and include the type attribute:

```
create virtual-router vr-name {type [vrf | vpn-vrf {vr
parent_vr_name}]}
```

> **Note**
> VRFs are supported only on the platforms listed for this feature in the *ExtremeXOS 32.4 Feature License Requirements* document. To support a Layer 3 VPN, a VPN VRF must be created under the parent VR that will run the *MPLS* protocol.

A VRF name cannot have the same name as a VLAN or VR.

- To create a local-only VRF (ExtremeSwitching X435, X440-G2, and X620 only), use the preceding command and include the **type** attribute:
- To display the VRFs, use the following command:

```
show virtual-router {name}
```

- To delete a VRF, use the following command:

> **Note**
> Before you delete a VRF, you must delete all VLANs and stop all protocols that are assigned to that VRF. All of the ports assigned to a deleted VRF are deleted and made available to assign to other VRs and VRFs. Any routing protocol instance that is assigned to the VRF is deleted gracefully.

```
delete virtual-router vr-name
```

Enabling and Disabling VRFs

VRFs are enabled when created. If you want to shut down a Layer 3 VPN, you can disable the corresponding VRF, which disables only the corresponding Layer 3 VPN and does not affect other routing services or Layer 3 VPNs.

To enable or disable a VRF, use the following commands:

```
enable virtual-router vrf-name
```

```
disable virtual-router vrf-name
```

Configuring and Removing a VR Description

A VR description is a text message that can be used to label the VR. The text message is for viewing and *SNMP* MIB reports only; it has no affect on VR operation.

To configure or remove a description, use the following commands:

```
configure vr name description string
```

```
unconfigure vr name description
```

Changing the VR Context

The VR context is introduced in

To switch to a context for a different VR, use the following command:

```
virtual-router {vr-name}
```

The CLI prompt displays the VR context.

Adding and Deleting Routing Protocols

When a user VR is created, no resources are allocated for routing protocols. You must add the routing protocols needed for your VR before you attempt to configure them. The maximum number of protocols supported is 64.

The commands that follow allow adding the following protocols:

- The basic seven protocols on *VR-Default* (*RIP*, *OSPF*, *BGP*, PIM, ISIS, *OSPFv3*, and RIPNG)
- 1 *MPLS* protocol instance on any VR (only on platforms that support MPLS)
- 56 additional protocols for user VRs. Any combination of the 7 protocols supported on user VRs (RIP, OSPF, BGP, PIM, ISIS, OSPFv3, and RIPNG) can be assigned to user VRs, up to a maximum number of 56.

When you add a protocol to a user VR, the software starts a process to support the protocol, but it does not enable that protocol. After you add a protocol to a user VR, you must specifically enable and configure that protocol before it starts.

When you add a protocol to a VRF, a protocol process is started in the parent VR (if it is not already started) and a protocol instance is created inside that process for this VRF.

> **Note**
> You must add, configure, and enable a protocol for a VR before you start unicast or multicast forwarding on the VR and before you configure any features (such as VLANs) to use the VR.

- To add a protocol to a VR, use the command:

  `configure vr` *vr_name* [**add** | **delete**] **protocol** [**ospf** | **ospfv3** | **rip** | **ripng** | **bgp** | **isis** | **pim** | **mpls**]

  If you add more than the maximum number of protocols, the following message appears:
  ```
  Error: Maximum number of Protocols that can be started in the system is 64
  ```

- To remove a protocol from a VR, use the command:

  `configure vr` *vr-name* **delete protocol** *protocol-name*

> **Note**
> Local-only VRs and VRFs do not use routing protocols.

Configuring Ports to Use One or More Virtual Routers

By default, all the user data ports belong to *VR-Default* and the default *VLAN*, Default. All these ports are used exclusively by VR-Default. To configure a port to use one or more virtual routers, you need to perform one or more of the tasks described in the following sections:

- Deleting Ports from a Virtual Router on page 733
- Adding Ports to a Single Virtual Router on page 733
- Adding Ports to Multiple Virtual Routers on page 734

Deleting Ports from a Virtual Router

To configure a port for exclusive use by another VR, or for use by multiple VRs, it must first be deleted from *VR-Default*. You must delete the port from any *VLAN* it belongs to before deleting it from a VR.

To delete a port from a VR, use the command:

`configure vr` *vr-name* **delete ports** *port_list*

> **Caution**
> Do not create Layer 2 connections between ports assigned to different VRs in the same switch. Because each switch supports just one MAC address, every VR in the switch uses the same MAC address. A Layer 2 connection between two VRs can cause external devices to direct traffic to the wrong VR.

Adding Ports to a Single Virtual Router

When you add a port to a VR, that port can only be used by that VR. To add a port to a single VR, use the command:

```
configure vr vr-name add ports port_list
```

The following example demonstrates how to remove all the ports on slot 3 from the Default _VLAN_ in _VR-Default_ and add them for the exclusive use of user VR helix:

```
configure vlan default delete ports 3:*
configure vr vr-default delete ports 3:*
configure vr helix add ports 3:*
```

Adding Ports to Multiple Virtual Routers

To use a port in multiple VRs, do not add the port to a VR as described in Adding Ports to a Single Virtual Router on page 733. Instead, add the port to a _VLAN_ in the desired VR.

To add the port to a VLAN in the desired VR, use the following command:

```
configure [ {vlan} vlan_name | vlan vlan_list] add ports [port_list |
all] {tagged tag | untagged} {{stpd} stpd_name} {dot1d | emistp | pvst-
plus}}
```

> **Note**
> See QoS for details about how multiple VRs per port can affect DiffServ and code replacement.
> You should configure any protocols you want to use on a user VR before you add a VLAN to the user VR. When IP multicast forwarding will be supported on a user VR, add the PIM protocol before you enable IP multicast forwarding.

The following example demonstrates how to add port 3:5 to user VRs VR-green and VR-blue.

The tagged VLAN bldg_200 was previously configured in VR-green, and the tagged VLAN bldg_300 was previously configured in VR-blue.

```
configure vlan default delete ports 3:5
configure vr vr-default delete ports 3:5
configure vlan bldg_200 add ports 3:5 tagged
configure vlan bldg_300 add ports 3:5 tagged
```

Displaying Ports and Protocols

To display the ports, protocols, and names of protocol processes for a VR, use the following command:

```
show virtual-router {name}
```

Configuring the Routing Protocols and VLANs

After a user VR is created, the ports are added, and support for any required routing protocols is added, you can configure the VR.

- To create a _VLAN_ in a VR, use the command:

```
create vlan vlan_name {description vlan-description} {vr name}
```

If you do not specify a VR in the create vlan command, the VLAN is created in the current VR context.

VLAN names must conform to the guidelines specified in Object Names on page 37.

> **Note**
> All VLAN names and VLAN IDs on a switch must be unique, regardless of the VR in which they are created. You cannot have two VLANs with the same name, even if they are in different VRs.

- To display the VLANs in a specific VR, use the command:

  `show vlan virtual-router vr-name`, which is a specific form of this command:

  `show vlan {`**`virtual-router`** `vr-name}`

You can also configure routing protocols by using the standard ExtremeXOS software commands. The routing configurations of the different VRs are independent of each other.

Configuration Tasks for Layer 3 VPNs

Layer 3 VPN Configuration Overview

To configure VR and VRF support for a Layer 3 VPN, do the following:

1. Configure the PE to PE interfaces as follows:
   a. Select the VR that to which the *MPLS* protocol will be added.
   b. Assign PE facing VLANs and ports to the VR.
2. Configure the PE to CE interface as follows:
   a. Create a VPN VRF as described in Creating and Deleting VRFs on page 731.
   b. Assign a VPN ID to the VPN VRF as described in Configuring a VPN ID on page 735.
   c. Assign an RD to the VPN VRF as described in Configuring the Route Distinquisher on page 735.
   d. Configure RTs for the VPN VRF as described in Configuring Route Targets on page 736.
   e. Assign CE facing VLANs and ports to the VRF.
   f. Configure *BGP* as described in Configuration Overview on page 1736.

Configuring a VPN ID

A VPN ID is an optional configuration parameter that you can use to associate a Layer 3 VPN ID label with a VRF.

To configure a VPN ID, use the command:

`configure vr vrf_name vpn-id 3_byte_oui:4_vpn_index`

Configuring the Route Distinquisher

The Route Distinquisher (RD) is added to the beginning of a VPN customer's IPv4 prefix to create a globally unique VPNv4 prefix for routing over the Layer 3 VPN. The IPv4

hosts that connect to a VRF must have unique IPv4 addresses. To eliminate duplicate IPv4 address issues between VRFs, configure a unique RD for each VRF.

To configure or unconfigure an RD, use the following commands:

```
configure vr vrf_name rd [2_byte_as_num:4_byte_number |
ip_address:2_byte_number | 4_byte_as_num:2_byte_number]

unconfigure vr vrf_name rd
```

Configuring Route Targets

Route Targets (RTs) are used by *BGP* as extended communities that define which VRFs will export and import learned routes. A VRF import RT will receive Layer 3 VPN routes from any PE VRF that is configured to export to that RT. To enable BGP Layer 3 VPN communications, you must configure import and export RTs on every VRF that will participate in the Layer 3 VPN.

To add, delete, or configure an RT, use the command:

```
configure vr vrf_name route-target [import | export | both] [add |
delete] [route_target_extended_community]
```

Enabling and Disabling Layer 3 VPN SNMP Traps for a VR

To enable or disable Layer 3 VPN *SNMP* traps for a VR, use the following commands:

```
enable snmp trap l3vpn {vr}
```

> **Note**
> You must enable this command in the parent VR of VPN-VRF.

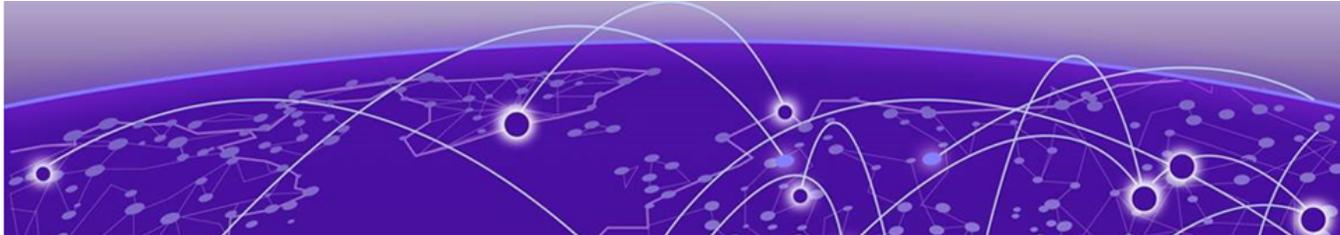
```
disable snmp trap l3vpn {vr}
```

Virtual Router Configuration Example

The following example demonstrates how to:

- Create a user VR named helix.
- Remove ports from the *VLAN* Default and *VR-Default*.
- Add ports to user VR helix.
- Add the *OSPF* protocol to user VR helix.
- Set the VR context to helix, so that subsequent VR commands affect VR helix.
- Create an incoming VLAN named helix-accounting-in.
- Create an outgoing VLAN named helix-accounting-out.
- Add ports that belong to user VR helix to the helix-accounting incoming and outgoing VLANs.

The CLI prompt is shown in this example to show how the VR context appears. At the end of the example, the VR is ready to be configured for OSPF, using ExtremeXOS software commands.

```
* BD10K.1 # create virtual-router helix
* BD10K.2 # configure vlan default delete ports 3:*
* BD10K.3 # configure vr vr-default delete ports 3:*
* BD10K.4 # configure vr helix add ports 3:*
* BD10K.5 # configure vr helix add protocol ospf
* BD10K.6 # virtual-router helix
* (vr helix) BD10K.8 # configure helix-accounting-in add ports 3:1
* (vr helix) BD10K.8 # configure helix-accounting-out add ports 3:2
* (vr helix) BD10K.9 #
```


Fabric Attach

The Fabric Attach feature allows attachment of non-SPB (Shortest Path Bridging) stations to an SPB network through a Fabric Attach server or it can act as a Fabric Attach server for _VXLAN (Virtual Extensible LAN)_ overlay networks.

Fabric Attach Overview

Fabric Attach uses the IEEE802.1ab _LLDP (Link Layer Discovery Protocol)_ extensions to automatically attach network devices to individual services in a IEEE 802.1aq Shortest Path Bridging (SPB) network. These network devices typically do not support SPB, MAC-in-MAC (802.1ah) or Network Services Identifier (NSI)/Individual Service Identifier (ISID) usage, and therefore cannot easily take advantage of the Fabric infrastructure without manual configuration of VLAN attachments to NSIs or ISIDs in multiple locations. Fabric Attach deals with this issue by facilitating automated network device discovery and the automatic configuration and teardown of NSI/ISID to VLAN associations at the edge of the network. Fabric Attach can also use the same LLDP extensions to allow Fabric Attach clients and proxy devices to connect to _VXLAN_ overlay networks.

> 📒 **Note**
> Both terms NSI and ISID are used in this document, with NSI being the preferred term. For ExtremeXOS, the NSI is an ISID in SPB fabrics, but the NSI could also be used to as an identifier for other (non-SPB) fabrics where it will not be an ISID.

Fabric Attach supports the following:

- Single _LAG (Link Aggregation Group)_ between any two devices
- SPBM networks: Fabric Attach client and proxy behavior
- VXLAN overlay networks: Fabric Attach client, proxy, and server behavior
- Connection to a single Fabric Attach server
- One-to-one mapping between a VLAN and an NSI/ISID
- Stacking
- _RADIUS (Remote Authentication Dial In User Service)_ authentication

Limitations

Mappings of VLANs to NSIs/ISIDs is limited to 94.

Fabric Attach does not support *MIB (Management Information Base)*s.

Fabric Attach Operation Modes

Fabric Attach has four modes of operation:
- Proxy mode—see Fabric Attach Proxy Mode on page 739.
- Server mode—see Fabric Attach Server Mode on page 739.
- Standalone proxy mode—see Fabric Attach Standalone Proxy Mode on page 739.
- Client mode—see Fabric Attach Client Mode on page 740.

Fabric Attach Proxy Mode

After the Fabric Attach proxy receives a Fabric Attach Element TLV from in an *LLDP* frame from a Fabric Attach server, the Fabric Attach Element TLV is included in all LLDP frames sent by the Fabric Attach proxy. The Fabric Attach Assignment TLV is included in LLDP frames to the Fabric Attach server if any VLAN to NSI mappings exist. The Fabric Attach Assignment TLV is included in LLDP frames sent to a Fabric Attach client if that client has requested at least one VLAN to NSI mapping. Mappings that are rejected by the server are placed in the "rejected" state in the LLDP database and remain in the database until they expire.

Supported Platforms

All platforms.

Fabric Attach Server Mode

Fabric Attach operates in server mode whenever BGP Auto-peering is configured or an LTEP (Local Tunnel End Point) is created. The Fabric Attach server may receive mapping requests from any of several sources (CLI, client/proxy requests using *LLDP*, BGP, OSPFv2, or network authentication services such as *RADIUS* and policy). Since the CLI prevents conflicting CLI-sourced mappings from being requested, a mapping request from the CLI is entered into the database as "accepted" and conflicting mappings in the database have their status set to "rejected". When a mapping is requested by a client or proxy, it is entered into the database.

Supported Platforms

All platforms.

Fabric Attach Standalone Proxy Mode

Fabric Attach standalone proxy allows for Fabric Attach proxy functionality in environments without a Fabric Attach server.

Fabric Attach standalone proxy operation supports standard Fabric Attach proxy processing as if a Fabric Attach server has been discovered. You can enable or disable Fabric Attach standalone proxy support (see Configuring Fabric Attach on page 750). By default, it is disabled. Enabling the Fabric Attach Standalone Proxy mode enables

immediate processing of pending NSI/VLAN bindings, if other configuration data, such as static uplink data allows the processing. Previously established settings based on Fabric Attach proxy operation, if present, are reset when Fabric Attach standalone proxy operation is enabled.

The Fabric Attach standalone proxy does not send provisioning requests upstream. A Fabric Attach standalone proxy automatically accepts requests from Fabric Attach clients and assumes that the upstream network has been provisioned appropriately. Disabling Fabric Attach standalone proxy mode resets configured NSI/VLAN binding data to its default state and enables full Fabric Attach Proxy operation (see Fabric Attach Proxy Mode on page 739). In Fabric Attach standalone proxy mode, you must provide the Fabric Attach server uplink information, which is typically gathered through Fabric Attach server discovery. After you provide this information, Fabric Attach standalone proxy mode operates as if a Fabric Attach server has been discovered and is accepting NSI/VLAN binding requests. The binding clean-up is similar to a Fabric Attach server timeout event, and occurs when the static uplink is deleted and when Fabric Attach standalone proxy operation is disabled.

Supported Platforms

All platforms.

Fabric Attach Client Mode

After booting up, Fabric Attach defaults to operation as a client and identifies as the Fabric Attach client type "switch". In Fabric Attach, there are element types for Fabric Attach server (both auth and non-auth), proxy (both auth and non-auth), and an unused element type of "Other". The rest of the values are all different variations of an Fabric Attach client. As an ExtremeXOS Fabric Attach client, all Fabric Attach devices are ignored, except proxy and server. If a proxy is detected, the client treats it like a server and sends any assignments (mappings) that it has to the proxy for relay to the server. If a server is detected (while operating as a client), the Fabric Attach database is cleared and proxy mode is activated. If connection to the server is lost, the switch will again become a client after the server connection times out.

Supported Platforms

All platforms.

Network Service Identifier Mappings

A Network Service Identifier (NSI) or Individual Service Identifier (ISID) to VLAN mapping entered into the database remains until one of the following events occurs:
- The mapping times out (client-requested mappings only).
- Mapped VLAN is removed.
- Switch is rebooted.
- A mapping request with higher precedence is received.
- The port on which the mapping was requested is administratively disabled.

There are three ways to configure an NSI/ISID mapping: CLI, *LLDP*, or *RADIUS*/Policy/ *NetLogin*. The Fabric Attach feature only allows a one-to-one mapping of NSI/ISID to

VLAN. However, it is possible for a mapping made through the CLI to conflict with mappings requested by a Fabric Attach client or by RADIUS. Conflicting mappings from multiple sources are resolved in the following precedence order (highest to lowest):

1. CLI (see Configuring Fabric Attach on page 750).
2. LLDP client request. (see LLDP on page 741).
3. RADIUS/Policy/NetLogin (see RADIUS/Policy/NetLogin on page 742).

> **Note**
> When operating as a Fabric Attach server, this precedence order is not observed, only the last request is accepted.

This precedence is implemented by sending only the highest precedence mapping for each VLAN to the Fabric Attach server in the Fabric Attach Assignment TLV. If the highest precedence mapping changes, the prior highest precedence mapping is no longer be sent to the Fabric Attach server and it is replaced with the "new" highest priority mapping. The Fabric Attach server rejects the new mapping until the prior mapping times out of the Fabric Attach server's database.

When a VLAN to NSI/ISID mapping is requested by a Fabric Attach client, LLDP determines if the requested mapping conflicts with an existing client or CLI manual mapping. If this is the first client-requested mapping for a VLAN, it is added to the LLDP database with a "pending" status and is added to the list of mappings that are sent to the Fabric Attach server.

Conflicts between mapping requests from the same source are handled as follows: A conflict arises when different NSI values are requested for a VLAN. When a conflict arises between Fabric Attach client requests, the NSI with the lowest numerical value is retained, overwriting the previous client requested value for the VLAN. This reduces flip-flopping between competing values, since these mappings are continuously requested by Fabric Attach clients through LLDP. The conflict is resolved when all Fabric Attach clients have been configured to request the same mapping. After the incorrect mapping is no longer requested by any Fabric Attach client, it times out of the database and is replaced by the correct value from the next Fabric Attach client request. The timeout value for the database on the FA proxy is 240 seconds and is not configurable. When a conflict arises because of RADIUS requests, the last NSI value received is used, overwriting any previous NSI from RADIUS for this VLAN. After the RADIUS configuration has been corrected so that authentications return the correct NSI value, the correct mapping is then provided by the next user authentication. RADIUS can be configured to re-authenticate users periodically, but this is not required and if there is no change to the data for a user, RADIUS provides no notification. Since RADIUS does not provide periodic confirmation of the mappings it has requested, these mappings do not time out.

LLDP

LLDP may receive mapping requests from the CLI and from attached Fabric Attach clients. The CLI prevents you from configuring multiple static (CLI sourced) mappings for a VLAN. When a VLAN to NSI/ISID mapping is configured through the CLI (see Configuring Fabric Attach on page 750), the mapping is entered into the database

and is persistent across device reboots, whereas mappings requested by Fabric Attach clients are not persistent.

RADIUS/Policy/NetLogin

RADIUS/Policy/NetLogin mappings are not persistent.

Actions when RADIUS is enabled::

- Policy maptable may be configured to use policy, tunnel, or both.
- RADIUS may return a policy name, a VLAN, and possibly an Network Service Identifier (NSI) mapping.

If RADIUS returns a VLAN/NSI mapping:

  ◦ Policy is **not** enabled: policy does not install an NSI mapping.
  ◦ Policy **is** enabled: the mapping is installed if the following conditions are met.
    ▪ Policy must be configured to make use of the RADIUS (RFC3580) VLAN, meaning:
      - The Policy maptable response must be set to "tunnel" or "both".
      - If the response is set to "policy" (the default), the VLAN/NSI is not used.
      - Vlanauthorization must be enabled.
    ▪ The VLAN and NSI must both be specified for the NSI to be used (see Defining VLAN/NSI Mappings with RADIUS Standards Attributes or VSAs on page 742).
    ▪ The authentication response is an initial authentication for the given user or a re-authentication of an existing user with a mapping that differs from the existing mapping.

Defining VLAN/NSI Mappings with RADIUS Standards Attributes or VSAs

There are two ways to define the VLAN/NSI mapping using a combination of RADIUS Standards (*RFC2868* and *RFC3580*) Attributes and/or Vendor Specific Attributes (VSAs).

1. The presently supported *RFC3580* VLAN can be associated with newly introduced Extreme Networks VSAs.
   - RFC2868 & RFC3580 RADIUS Attributes:
     ◦ Attribute 64: Tunnel-Type = VLAN (13)
     ◦ Attribute 65: Tunnel-Medium-Type = 802
     ◦ Attribute 81: Tunnel-Private-Group-Id=<VlanID>
   - Extreme Networks VSAs:
     ◦ Attribute 230: Extreme-NSI-Type
     ◦ Attribute 231: Extreme-NSI-ID

If configuring these attributes manually, care must be taken. Extreme-NSI-Type and Extreme-NSI-ID values require a "tag" byte to allow for multiple attribute pairs to be specified in the same RADIUS response (For example, in FreeRADIUS this is annotated with "has_tag"). At present, only one Type/ID pair is used. If more than one pair is present, the entry with the lowest tag value is used. This is associated with the Tunnel-Private-Group-Id's VLAN. Note that although the Tunnel-Private-Group-id attribute also supports an optional "tag" value as well, for backwards compatibility it is not currently used. Whether or not a "tag" value is specified in the Tunnel-Private-

Group-Id attribute, it is matched to the Extreme-NSI-ID. Future releases may place additional restrictions on mismatched tags between the Tunnel-Private-Group-Id attribute and the Extreme-NSI-ID attribute.

2. Alternatively, an existing Nortel/Avaya attribute can also be used. The attribute is of the form "VLAN:NSI". As the VLAN is specified within the attribute, *RFC2868* and *RFC3580* attributes are not required:

   • Attribute 171: Fabric-Attach-ISID

> **Note**
> If both attributes are present in the RADIUS attributes returned, the Extreme VSAs is used.

Starting with ExtremeXOS 22.5, policy can configure NSI mappings based on the RADIUS-returned "policy name". This allows the mappings to be derived from the RADIUS configuration and avoid configuration conflicts between users. This makes it easier for all users that match a policy profile to get the same mapping.

> **Note**
> Policy and RADIUS authentication is performed per-user, which means NSI mappings are also specified per user. Unless a common policy profile is used, you cannot prevent different users from mapping a VLAN to different NSI values.

Fabric Attach Automatic LAG Creation

When an switch receives Fabric Attach element TLVs on two or more ports that have same System-Id, same SMLT-Id, and have a Connection Type of SMLT, it automatically creates a LAG consisting of those ports. These LAGs:

• Do not persist after a reboot—after a reboot, TLVs must be received again to re-form the LAG.

• Do not require receipt of LACP PDUs—LACP PDUs are not sent.

• Require at least two ports to form the LAG—if a port is removed from the LAG, and the exiting LAG goes down to one port, it is torn down. When a LAG is initially created with two ports, the lowest numbered port is chosen as the master port of the LAG. If there are three or more ports on the LAG, and the port is not the master port, it is simply removed from the LAG. If it is the master port, the lag is torn down, and then re-created with the lowest port number of the remaining ports as the master port.

• Are supported in stacks—the dynamic LAG is checkpointed to support failover, etc.

A port is removed from a LAG under following circumstances:

• Port is administratively disabled—if port is later administratively enabled, it will not automatically be re-added to the LAG, it will take a receipt of a matching TLV.

• TLV with Connection Type other than MLT is received.

- TLV with a System-ID that is different from the one when the LAG was created is received.
- TLV with a SMLT-ID that is different from the one when the LAG was created is received.

> **Note**
> The last three situations indicate that you are not connected to same Fabric Attach server, or the same LAG on a Fabric Attach server, which are not valid scenarios.

> **Note**
> MLAG with Fabric Attach Automatic LAG is not supported in ExtremeXOS 31.1 and later. Do not enable MLAGs on ports where automatically created LAGs will be created.

To see a configuration example, see Fabric Attach Automatic LAG Configuration Example on page 773.

Fabric Attach Support over Multi-switch Link Aggregation Groups (MLAGs)

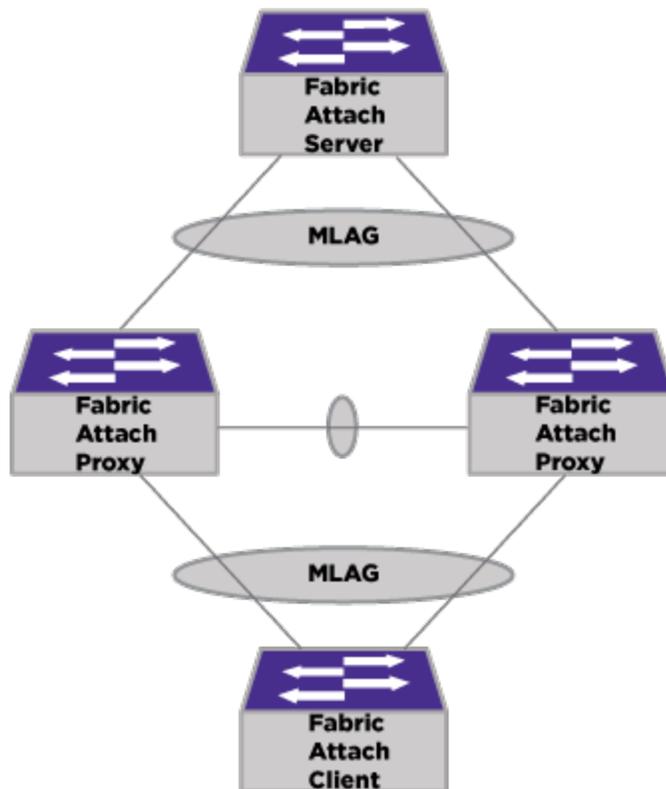
Starting with ExtremeXOS 30.2, Fabric Attach server and proxy can work over _MLAG (Multi-switch Link Aggregation Group)_. Starting with ExtremeXOS 30.4, Fabric Attach standalone proxy works over MLAG.


Figure 91: Fabric Attach with MLAG

Fabric Attach Proxy Support over MLAG

When an ExtremeXOS switch acts as a Fabric Attach proxy in an MLAG configuration, the VLAN/NSI mappings are sent on the master port of MLAG by the Fabric Attach client. The same mappings are sent on the slave ports of the MLAG by the Fabric Attach client in a delayed manner. This could result in data loss if the data packets are reaching the Fabric Attach proxy attached to the slave port of the MLAG. To address this, whenever VLAN/NSI mapping information is received on an MLAG port, the Fabric Attach proxy forwards this VLAN/NSI mappings to the Fabric Attach server for authentication, and also checkpoints the information to the peer Fabric Attach proxy attached to the same MLAG. Respective VLANs received are created; ISC ports and MLAG ports are added to the respective VLAN. VLAN/NSI mappings are sent to the server for approval. After receiving VLAN/NSI mappings over the ISC link, the MLAG peer Fabric Attach proxy processes the metadata and with the received MLAG ID, it gets the local MLAG port and creates respective VLANs and ISCs. Additionally, the MLAG port is added to the respective VLANs. VLAN/NSI mappings are sent to the server for authentication. By checkpointing the NSI values across MLAG peer, redundancy is provided even if any of the client ports or server ports in MLAG go down.

For more information about MLAGs, see MLAG Overview on page 267.

Fabric Attach Server Support over MLAG

Fabric Attach server mode is also supported over MLAG, which is similar to proxy support on client-facing port side.

Fabric Attach Support Over W-MLAG

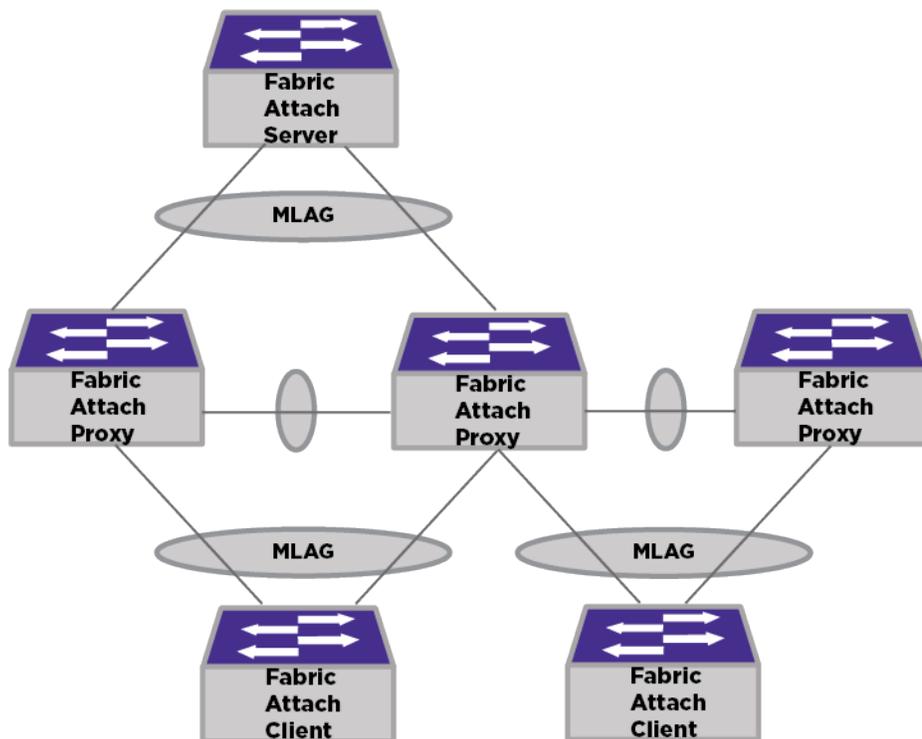
From ExtremeXOS 31.2, W-MLAG and single-homed MLAG support is provided for Fabric Attach (see Figure 92). Prior to ExtremeXOS 31.2, the mappings from MLAG clients were checkpointed to the proxy or server peer. But starting with ExtremeXOS 31.2, the mappings from non-MLAG clients are also checkpointed to the MLAG proxy or server peer node. If the proxy or server is part of a W-MLAG network, then the mapppings from all the clients, whether they are part of MLAG or not, are passed to all the peer nodes of the MLAG.


Figure 92: Fabric Attach with W-MLAG

Fabric Attach Authentication

By default, all ports are configured to the authentication disabled state. When enabled, the default key is used until otherwise configured. If the authentication fails, the Fabric Attach information is dropped whether or not authentication is enabled on the receiving port.

To set up Fabric Attach authentication, use the following command:

```
configure fabric attach ports [port_list | all] authentication [ disable
| enable | key {key | default | encrypted encrypted_key}]
```

You can set up authentication using either of the following methods:

- If you want to use the <u>default</u> key, enable authentication, and do not configure a key.
- To use a <u>unique</u> key (not the default), configure a key, and then enable authentication.

Be sure to configure authentication in the same manner on all applicable servers, proxies, and clients; and with MLAGs (Fabric Attach Support over Multi-switch Link Aggregation Groups (MLAGs) on page 744) on both peers.

RADIUS Vendor-Specific Attributes (VSAs) for Fabric Attach

To aid the proper authentication attributes sent from the RADIUS server to the device, several vendor-specific attributes (VSAs) exist to provide client-specific information from the device and information received from the Fabric Attach client at the time it connects to the network. ExtremeXOS provides support in Fabric Attach for the following VSAs.

> **Note**
> Attributes are sent only for NetLogin MAC- and Dot1x-based authentications.

Table 68: VSA Information

VSA	Vendor Type	Description
Switch Mode (FA-Switch-Mode)	180	Defines the configuration of the FA device itself. It can take on 6 different values. • 0 or not sent—Switch has no concept of SPB/Fabric Attach. • 1—Switch is a FA server with SPB disabled and FA Enabled. • 2—Switch is a FA server with SPB enabled. • 3—Switch is a FA proxy connected to a FA Server with SPB disabled and FA enabled. • 4—Switch is a FA proxy connected to a FA Server with SPB enabled. • 5—Switch is a FA proxy standalone.
Client Identifer (FA-Client-ID)	181	Contains the MAC address of the FA Client received from the FA LLDP messaging.

Table 68: VSA Information (continued)

VSA	Vendor Type	Description
Client Type (FA-Client-Type)	182	Informs the RADIUS server of what the user requesting authentication's primary purpose is. This can allow the RADIUS server to return a consistent set of attributes for clients who have a similar purpose. Accepted values are in the range of 6–17 (client types, not server or proxy types) for this attribute, though values 1–17 are defined. • 1—FA Element Type Other • 2—FA Server • 3—FA Proxy • 4—FA-Server No Authentication • 5—FA Proxy No Authentication • 6—FA Client Wireless AP Type 1 [clients direct network attachment] (for example: AP 9100) • 7—FA Client Wireless AP Type 2 [clients tunneled to controller] • 8—FA Client FA Switch • 9—FA Client FA Router • 10—FA Client IP Phone • 11—FA Client IP Camera • 12 - FA Client IP Video • 13—FA Client Security Device (13) [FW, IPD/IDS etc.] • 14—FA Client Virtual Switch • 15—FA Client Server/Endpoint • 16—FA Client ONA SDN • 17—FA Client ONA SPBoIP
Pre-shared Key (PSK) Status (FA-Client-PSK)	183	Used to inform the RADIUS server of the Pre-shared Key status of the client being authenticated. If sent, it can take one of 5 binary values, 0,10,11,100,101. • Not Sent—Pre-share Key (PSK) used unknown. • 0—FA PSK not enabled on Fabric Attach Switch Port • 10—Failed. FA PSK used is default key • 11—Passed. FA PSK used is default key

Table 68: VSA Information (continued)

VSA	Vendor Type	Description
		• 100—Failed. FA PSK used is user-defined • 101—Passed. FA PSK used is user-defined

Zero Touch Client

Zero Touch Client (ZTC) adds addition functionality that enhances Fabric Attach (FA) by allowing static mappings for client types. Normally, Network Service Identifier (NSI) or Virtual LAN (VLAN) mappings are received from the Client through Link Layer Discovery Protocol (LLDP), or are configured statically on a port. Zero Touch Client provides a method to configure a mapping for a specific client type, so that all devices of that type that are discovered will have the same mapping. For example, all LLDP neighbors defined as Fabric Attach Client Phones can be configured to be added to VLAN "phoneVlan." In this scenario, all phones are treated the same without the Client requiring knowledge of this. Zero Touch Client NSI or VLAN mappings are added to the VLAN as the untagged VLAN for the port.

Zero Touch Client can configure only one mapping per client type since there can be only one untagged port VLAN. Zero Touch Client provides a method to configure port priority. If no priority is provided, the statically configured dot1p priority will be used.

Base Zero Touch (ZT) auto-attach functionality allows a device to acquire management VLAN information and use this data to facilitate device manageability and network configuration download across the network. When you have enabled Base ZT auto-attach operation, it extracts management VLAN data from the primary FA Server advertisements, and potentially uses this data to update the in-use management VLAN. This information can also be cascaded to FA Clients. An FA proxy can disable management VLAN cascading to clients device-wide, and disable by port.

Configuring Zero Touch Client

To configure Fabric Attach Zero Touch Client, run the following command:

```
configure fabric attach zero-touch-client client [vlan [vlan_name |
vlan_id] [nsi nsi | isid isid] {priority [priority | dot1p]} {enable |
disable} | none] | enable | disable]
```

To show configured Fabric Attach Zero Touch Clients, run the following command:

```
show fabric attach zero-touch-client
```

Fabric Attach Triggered Signaling

Version 32.3 adds support for Fabric Attach triggered signaling that replaces LLDP timer triggers to create VLAN/NSI binding. This feature provides faster learning of

VLAN/NSI bindings when a switch or link recovers from failure. Fabric Attach triggered signaling of VLAN/NSI mappings occurs when:

- A link between the client and proxy flaps
- A client switch reboots
- A proxy switch reboots
- A link between the server and proxy flaps
- A server switch reboots
- A new VLAN/NSI mapping is added in the client

Limitations

A proxy switch sends out the maximum of 94 VLAN/NSI mapping requests to a server based on the time the mappings are created. Only the first 94 mappings added in the VLAN/NSI DB are sent to the server for approval.

Configuring Fabric Attach

An ExtremeXOS Fabric Attach device automatically detects and exchanges information with attached Fabric Attach devices, except that a proxy does not exchange information with another proxy).

The following are optional user-configurable items:
- Static VLAN/NSI assignments
- Fabric Attach authentication on either a proxy or server
- Management VLAN (Fabric Attach server only)
- Uplink port (Fabric Attach proxy only)

Static VLAN/NSI Assignments

You explicitly create static Fabric Attach VLANs. Static VLANs can be mapped to a Network Service Identifier (NSI) or Individual Service Identifier (ISID).

To map a VLAN to an NSI/ISID, use the following command:

```
configure [{vlan} vlan_name |vlan vlan_id] add [nsi nsi | isid isid]
```

Mappings created with this command are persistent across reboots, whereas mappings by Fabric Attach clients and mappings requested by RADIUS/Policy/NetLogin are not persistent.

> **Note**
> While it is possible to configure an NSI mapping using the command
> `configure virtual-network vn_name vxlan vni [ vni | none]`, it is not
> recommended to do so when using Fabric Attach.

To unmap a VLAN from an NSI/ISID, use the following command:

```
configure [{vlan} vlan_name |vlan vlan_id] delete [nsi nsi | isid isid]
```

To display VLAN to NSI/ISID information, use the following command:

```
show [{vlan} vlan_name | vlan {vlan_id}] fabric attach assignments
```

Fabric Attach Authentication

To set up authentication, use the following command:

```
configure fabric attach ports [port_list | all] authentication [ disable
| enable | key {key | default | encrypted encrypted_key}]
```

> **Note**
> When Fabric Attach authentication is configured on ports that are part of an *MLAG*, all ports on that MLAG must have the same Fabric Attach authentication configuration.

To view authentication information, use the following command:

```
show fabric attach ports [port_list | all] authentication {detail}
```

Standalone Proxy/Uplink Port

If there is no Fabric Attach-capable server available, configuring an uplink makes the device a standalone proxy. This works like a proxy, but without having discovered a Fabric Attach server. The uplink port is treated as the server port.

To enable standalone proxy mode and specify the uplink port, use the following command using the **port** keyword:

```
configure fabric attach uplink [port | none]
```

To disable standalone proxy mode, use the following command using the **none** keyword:

```
configure fabric attach uplink [port | none]
```

```
configure fabric attach ports [port_list | all] enable | disable]
```

Management VLAN

To specify the VLAN advertised to Fabric Attach clients for them to use as the management VLAN, use the following command:

```
configure fabric attach management-vlan [vlan_id | vlan_name | untagged
| none | forward [on | off] ]
```

```
configure fabric attach management-vlan ports [port_list | all] forward
[on | off]
```

The specified VLAN configuration on the Fabric Attach server is restricted to only tagged VLANs.

Zero Touch Server Management VLAN

Zero Touch Server enhances FA by allowing a management VLAN to be automatically propagated to FA proxy and FA clients. FA proxy and FA clients use the VLAN to obtain an IP address via Dynamic Host Configuration Protocol (DHCP) and connect to a management device.

Viewing Fabric Attach Information

To display known fabric attach statistics information, use the following command:

```
show fabric attach statistics
```

> **Note**
> To clear these statistics, use the `clear counters` command.

To display known fabric attach elements (neighbors) information, use the following command:

```
show fabric attach elements
```

To display known fabric attach assignments (mappings) information, use the following command:

```
show fabric attach {{vlan} | {vlan} vlan_name | vlan vlan_id}
assignments
```

To display known fabric attach agent information, use the following command:

```
show fabric attach agent
```

To display known Fabric Attach authentication information, use the following command:

```
show fabric attach ports [port_list | all] authentication {detail}
```

Warnings for MLAG Ports

```
5.2.2.8-FASvr-DUT1-switch.110 # configure fabric attach ports 1 3 5 53 disable

Port 1:1 is a member port of 1:5. Configuring all members the same is recommended.
Port 1:3 is a member port of 1:5. Configuring all members the same is recommended.
Port 1:5 is a master port. Configuring all members the same is recommended.
Port 1:53 is a member port of 1:5. Configuring all members the same is recommended.
```

Fabric Attach and Extended Edge Switching Configuration Examples

ExtremeXOS Fabric Attach (FA) supports FA servers and FA Proxies to be Extended Edge Switching controlling bridge (CB) nodes connected with bridge port extenders (BPEs) in two different topologies:

- Single-arm *MLAG* ring—see Single-ARM MLAG Ring Topology Configuration Examples on page 753.
- Cross-connect MLAG—see Cross-Connect MLAG Topology Configuration Examples on page 765.

Limitations

Trusted ports on BPEs cannot be used to connect FA clients.

Single-ARM MLAG Ring Topology Configuration Examples

The following are three combinations through which you can connect FA clients to FA elements, such as FA proxies and FA servers:

- FA Clients Connected to BPEs with Extended Edge Switching Ring MLAG-Connected CBs FA Server Peers **on page 753**—FA server CB MLAG peers detect FA clients connected to BPE ports. CBs will add ISC ports and extended port to dynamic VLAN matching received VLAN/NSI mappings.
- FA Clients Connected to BPEs with Extended Edge Switching Ring MLAG-Connected CB FA Proxy Peers **on page 758**—FA server can be VSP or ExtremeXOS switches. BPEs and FA servers are attached by MLAGs.
- FA Clients Connected to BPEs with Extended Edge Switching Ring MLAG-Connected CB FA Standalone Peers **on page 761**—FA standalone proxy CB MLAG peers detect FA clients connected to BPE port. CBs will add ISC port and extended port to dynamic VLAN matching received VLAN/NSI mappings.

FA Clients Connected to BPEs with Extended Edge Switching Ring MLAG-Connected CBs FA Server Peers

This configuration example shows how to configure a Fabric Attach (FA) server Controlling Bridge (CB) to receive and approve VLAN/NSI mappings from an FA client connected to a bridge port extender (BPE).

In the following example:

- The FA proxy/client connected to BPE port sent VLAN/NSI mappings.
- The FA server CB MLAG peers see their LLDP neighbor as FA client.
- When mappings are received on BPE port, the FA server CB creates a dynamic VLAN and adds ISC ports and extended port to the dynamic VLAN matching received VLAN/NSI mappings.
- The FA server approves the mappings and moves the VLAN/NSI mapping to the active state in FA database.

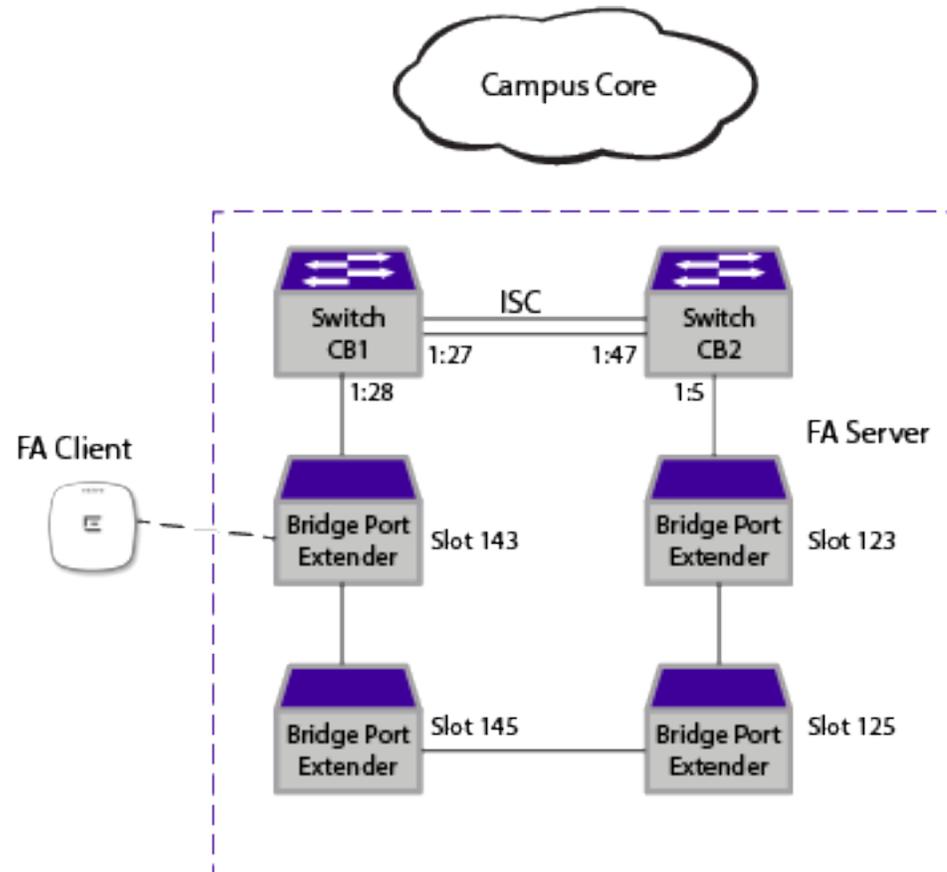
- The FA server CB Extended Edge Switching ring peers act as VXLAN VTEPs.
- When creation of dynamic virtual networks is enabled (`configure virtual-network dynamic on`), Extended Edge Switching MLAG ring CB peers create dynamic virtual networks for VLAN-VNI pair that match the VLAN/NSI(I-SID) mappings in the FA database.


Figure 93: FA Clients Connect to BPE with Ring MLAG-Connected FA Server Peers

FA Client/Proxy Connected to BPE

Create VLAN/NSI mappings on the FA client switch connected to a BPE:

```
create vlan "VLAN_0505"
configure vlan VLAN_0505 tag 505
create vlan "VLAN_0707"
configure vlan VLAN_0707 tag 707
create vlan "VLAN_4004"
configure vlan VLAN_4004 tag 4004
configure vlan VLAN_0505 add nsi 5050
configure vlan VLAN_0707 add nsi 70707
configure vlan VLAN_4004 add nsi 41414
```

```

FA Clients Connected to BPEs with Extended Edge Switching Ring MLAG-Connected CB FA Proxy Peers

This configuration example shows how to configure Fabric Attach (FA) proxy controlling bridge (CB) Extended Edge Switching *MLAG* Ring CB peers to receive and approve VLAN/NSI mappings from FA clients connected to BPEs.

In the following example:

- The FA proxy/client connected to BPE port sent VLAN/NSI mappings.
- The FA proxy CB MLAG peers see its LLDP neighbor as FA client.
- When mappings are received on a BPE port, the FA proxy CB creates a dynamic VLAN and adds ISC ports, uplink MLAG ports, and extended port to the dynamic VLAN that matches received VLAN/NSI mappings.
- The FA server approves the mappings and moves the VLAN/NSI mapping to the active state in FA database.
- The FA server MLAG peers act as VXLAN VTEPs.
- When creation of dynamic virtual networks is enabled (`configure virtual-network dynamic on`), Extended Edge Switching MLAG ring CB peers create dynamic virtual networks for VLAN-VNI pair that match the VLAN/NSI(I-SID) mappings in the FA database.

FA Clients Connected to BPEs with Extended Edge Switching Ring MLAG-Connected CB FA Standalone Peers

Fabric Attach (FA) standalone proxy introduces FA proxy functionality in environments without an FA server. FA provisions VLANs on the FA standalone proxy switch for itself, and for connected FA clients, and then adds the VLAN membership to the uplink port facing the core (non-FA) switch or router for connection to existing services. The provisioned VLANs at the access layer switch *must* match the VLANs on the opposite end of the link at the core/aggregation layer switch for communications to operate. You can use this design with an existing legacy core network infrastructure (any vendor).

This configuration example shows how to configure FA standalone CB Extended Edge Switching MLAG peers over a ring to receive and approve VLAN/NSI mappings from an FA client connected to BPEs.

In the following example:

- FA client connected to BPE port sent VLAN/NSI mappings.
- The FA standalone proxy CB MLAG peers see their LLDP neighbor as FA client.
- When mappings are received on BPE ports, the FA standalone proxy CB creates a dynamic VLAN, and adds ISC port and extended port to the dynamic VLAN that matches received VLAN/NSI mappings.
- The command `show fabric attach` **statistics** using the **assignments** option shows ISID/NSI as N/A on Extended Edge Switching standalone CBs.

Cross-Connect MLAG Topology Configuration Examples

Cross-Connect MLAG Topology Configuration Example

In the following example:

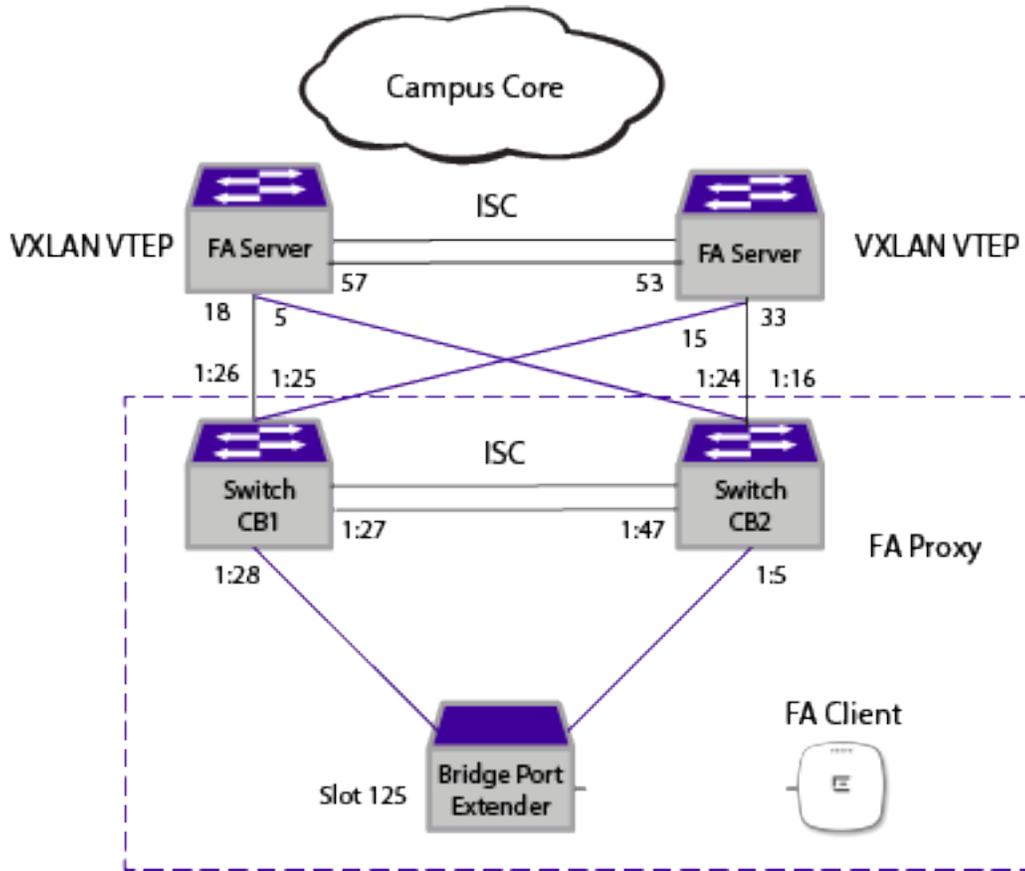
- The Fabric Attach (FA) client connected to bridge port extender (BPE) port sends VLAN/NSI mappings to the FA proxy controlling bridge (CB) *MLAG* peers connected in cross-connect topology.
- The FA proxy CB MLAG peers see their LLDP neighbor as the FA client.
- When mappings are received on a BPE port, the FA proxy CB creates a dynamic VLAN, and adds ISC port, extended port, and uplink server port to the dynamic VLAN that matches the received VLAN/NSI mappings.
- Uplink ports connected to the FA server MLAG peers on the CB MLAG peers should be MLAG enabled.
- FA server peers in following example are non-Extended Edge Switching nodes, which can be ExtremeXOS or VSP switches.
- The FA server approves the mappings and moves the VLAN/NSI mapping to the active state in FA database. The ExtremeXOS FA server MLAG peers act as VXLAN VTEPs.
- When creation of dynamic virtual networks is enabled (`configure virtual-network dynamic on`), MLAG peers create dynamic virtual networks for the VLAN-VNI pair that matches the VLAN/NSI(I-SID) mappings in the FA database.


Figure 96: Cross-Connect MLAG Topology

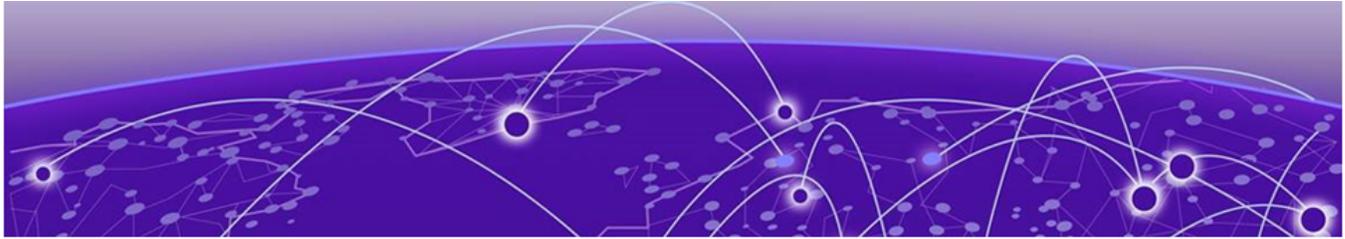
Policy Manager

This chapter provides information about how ExtremeXOS implements policy statements. It includes an overview of the Policy Manager, as well as specific information about how to create, edit, check, and apply policies.


Policy Manager and Policies Overview

One of the processes that make up the ExtremeXOS system is the policy manager. The policy manager is responsible for maintaining a set of policy statements in a policy database and communicating these policy statements to the applications that request them.

Policies are used by the routing protocol applications to control the advertisement, reception, and use of routing information by the switch. Using policies, a set of routes can be selectively permitted (or denied) based on their attributes, for advertisements in the routing domain. The routing protocol application can also modify the attributes of the routing information, based on the policy statements.

Policies are also used by the *ACL (Access Control List)* application to perform packet filtering and forwarding decisions on packets. The ACL application will program these policies into the packet filtering hardware on the switch. Packets can be dropped, forwarded, moved to a different *QoS (Quality of Service)* profile, or counted, based on the policy statements provided by the policy manager.

Creating and Editing Policies

A policy is created by writing a text file that contains a series of rule entries describing match conditions and actions to take.

Policies are created by writing a text file on a separate machine and then downloading it to the switch. Once on the switch, the file is then loaded into a policy database to

be used by applications on the switch. Policy text files can also be created and edited directly on the switch.

> **Note**
> Although ExtremeXOS does not prohibit mixing _ACL_ and routing type entries in a policy file, it is best to use separate policy files for ACL and routing policies instead of mixing the entries.

When you create a policy file, name the file with the policy name that you will use when applying the policy, and use " .pol" as the filename extension. For example, the policy name "boundary" refers to the text file "boundary.pol".

Using the Edit Command

A VI-like editor is available on the switch to edit policies. There are many commands available with the editor. For information about the editor commands, use any tutorial or documentation about VI. The following is only a short introduction to the editor.

The editor operates in one of two modes: command and input.

1. To edit a policy file on the switch by launching the editor, enter the command:

   `edit policy` _filename_`.pol`

   When a file first opens, you are in the command mode.
2. To write in the file, use the keyboard arrow keys to position your cursor within the file, then press one of the following keys to enter input mode:

   a. **[i]**—Inserts text ahead of the initial cursor position.
   b. **[a]**—Appends text after the initial cursor position.
3. To escape the input mode and return to the command mode, press the **[Esc]** key.

Several commands can be used from the command mode. The following commands are the most commonly used:

- **[dd]**—Deletes the current line.
- **[yy]**—Copies the current line.
- **[p]**—Pastes the line copied.
- **[:w]**—Writes (saves) the file.
- **[:q]**—Quits the file if no changes were made.
- **[:q!]**—Forcefully quits the file without saving changes.
- **[:wq]**—Writes and quits the file.

Using a Separate Machine to Edit Policies

You can also edit policies on a separate machine. Any common text editor can be used to create a policy file. The file is then transferred to the switch using TFTP and then applied.

To transfer policy files to the switch, enter the command:

```
tftp [ ip-address | host-name ] { -v vr_name } { -b block_size } [ -g
| -p ] [ -l local-file { -r remote-file } | -r remote-file { -l local-
file } ]
```

Checking Policies

A policy file can be checked to see if it is syntactically correct. This command can only determine if the syntax of the policy file is correct and can be loaded into the policy manager database. Since a policy can be used by multiple applications, a particular application may have additional constraints on allowable policies.

To check the policy syntax, enter the command:

```
check policy policy_name
```

Refreshing Policies

When a policy file is changed (such as adding, deleting an entry, adding/deleting/ modifying a statement), the information in the policy database does not change until the policy is refreshed. The user must refresh the policy so that the latest copy of policy is used. When the policy is refreshed, the new policy file is read, processed, and stored in the server database.

Any clients that use the policy are updated.

- To refresh the policy, enter the command:

  ```
  refresh policy policy_name
  ```

  For _ACL_ policies only, during the time that an ACL policy is refreshed, packets on the interface are blackholed, by default. This is to protect the switch during the short time that the policy is being applied to the hardware. It is conceivable that an unwanted packet could be forwarded by the switch as the new ACL is being set up in the hardware. You can disable this behavior.

  > **Note**
  > Performing a refresh on multiple ports requires the original and modified policy to coexist at the same time in the intermittent state. If this is not possible due to slice limitations, the refresh will fail with "ACL slice full" error.

- To control the behavior of the switch during an ACL refresh, enter the commands:

  ```
  enable access-list refresh blackhole
  disable access-list refresh blackhole
  ```

  In releases previous to ExtremeXOS 11.4, when ACLs were refreshed, all the ACL entries were removed, and new ACL entries were created to implement the newly applied policy.

  Beginning in release 11.4, the policy manager uses Smart Refresh to update the ACLs. When a change is detected, only the ACL changes needed to modify the ACLs are sent to the hardware, and the unchanged entries remain. This behavior avoids having to blackhole packets because the ACLs have been momentarily cleared. Smart Refresh works well up for up to 200 changes. If the number of changes

exceeds 200, you will see this message: Policy file has more than 200 new rules. Smart refresh can not be carried out. Following this message, you will see a prompt based on the current blackhole configuration. If blackhole is disabled you will see the following prompt:

```
Note, the current setting for Access-list Refresh Blackhole is Disabled. WARNING: If
a full refresh is performed, it is possible packets that should be denied may be
forwarded through the switch during the time the access list is being installed.
Would you like to perform a full refresh?
```

If blackhole is enabled, you will see the following prompt:

```
Note, the current setting for Access-list Refresh Blackhole is Enabled.
Would you like to perform a full refresh?
```

> **Note**
> ACL refresh may take additional time if the ACL is applied on multiple VLANs with several ACL slices already in the filled state. Additionally, in SummitStack, ACL refresh happens sequentially, such that after successful installation on one node, it will be applied to other nodes one-by-one, causing a slight delay in refresh operation.

To take advantage of Smart Refresh, disable access-list refresh blackholing.

Applying Policies

ACL policies and routing policies are applied using different commands.

Applying ACL Policies

A policy intended to be used as an *ACL* is applied to an interface, and the CLI command option is named `aclname`.

Supply the policy name in place of the `aclname` option.

- To apply an ACL policy, enter the command:
  ```
  configure access-list aclname [any | ports port_list ] {ingress |
  egress}
  ```

  When you use the **any** keyword, the ACL is applied to all the interfaces and is referred to as the wildcard ACL. This ACL is evaluated for any ports without specific ACLs, and it is also applied to any packets that do not match the specific ACLs applied to the interfaces.

  When an ACL is already configured on an interface, the command is rejected and an error message is displayed.
- To remove an ACL from an interface, enter the command:
  ```
  unconfigure access-list policy_name {any | ports port_list } {ingress
  | egress}
  ```
- To display the interfaces that have ACLs configured and the ACL that is configured on each. enter the command:
  ```
  show access-list {any | ports port_list } {ingress | egress}
  ```

Applying Routing Policies

To apply a routing policy, use the command appropriate to the client. Different protocols support different ways to apply policies, but there are some generalities.

Commands that use the keyword **import-policy** are used to change the attributes of routes installed into the switch routing table by the protocol. These commands cannot be used to determine the routes to be added to the routing table.

To remove a routing policy, use the **none** option in the command.

The following are examples for the _BGP (Border Gateway Protocol)_ and _RIP (Routing Information Protocol)_ protocols:

```
configure bgp import-policy [policy-name |none]

configure rip import-policy [policy-name |none]
```

Commands that use the keyword **route-policy** control the routes advertised or received by the protocol. Following are examples for BGP and RIP:

```
configure bgp neighbor [remoteaddr |all] {address-family [ipv4-unicast |
ipv4-multicast |ipv6-unicast |ipv6-multicast |vpnv4]} route-policy [in |
out] [none | policy]

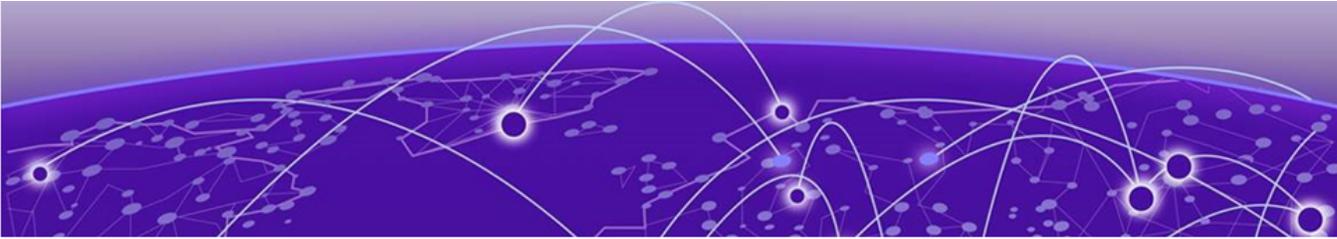
configure bgp peer-group peer-group-name {address-family [ipv4-unicast |
ipv4-multicast | ipv6-unicast | ipv6-multicast |vpnv4]} route-policy [in
|out] [none | policy]

configure rip vlan [vlan_name | all] route-policy [in |out] [policy-name
| none]
```

Other examples of commands that use route policies include:

```
configure ospf area area-identifier external-filter [policy-map |none]

configure ospf area area-identifier interarea-filter [policy-map |none]

configure rip vlan [vlan_name |all] trusted-gateway [policy-name |none]
```


ACLs

This chapter discusses *ACL (Access Control List)*s.

ACLs Overview

An *ACL* is used to define packet filtering and forwarding rules for traffic traversing the switch. Each packet arriving on an ingress port and/or *VLAN (Virtual LAN)* is compared to the access list applied to that interface and is either permitted or denied. Packets egressing an interface can also be filtered on the platforms listed for this feature in the *ExtremeXOS 32.4 Feature License Requirements* document. However, only a subset of the filtering conditions available for ingress filtering are available for egress filtering.

In addition to forwarding or dropping packets that match an ACL, the switch can also perform additional operations such as incrementing counters, logging packet headers, mirroring traffic to a monitor port, sending the packet to a *QoS (Quality of Service)* profile, and metering the packets matching the ACL to control bandwidth. (Metering is supported only on the platforms listed for this feature in the *ExtremeXOS 32.4 Feature License Requirements* document.) Using ACLs has no impact on switch performance (with the minor exception of the mirror-cpu action modifier).

ACLs are typically applied to traffic that crosses Layer 3 router boundaries, but it is possible to use access lists within a Layer 2 virtual LAN (VLAN).

ACLs in ExtremeXOS apply to all traffic. For example, if you deny all the traffic to a port, no traffic, including control packets, such as *OSPF (Open Shortest Path First)* or

RIP (Routing Information Protocol), will reach the switch and the adjacency will be dropped.

> **Note**
> Some locally CPU-generated packets are not subject to egress ACL processing.

You must explicitly allow those types of packets (if desired).

ACLs are created in two different ways. One method is to create an ACL policy file and apply that ACL policy file to a list of ports, a VLAN, or to all interfaces. The second method to create an ACL is to use the CLI to specify a single rule, called a dynamic ACL; this is the default.

> **Note**
> ACLs applied to a VLAN are actually applied to all ports on the switch, without regard to VLAN membership. The result is that resources are consumed per chip.

An ACL policy file is a text file that contains one or more ACL rule entries. This first method creates ACLs that are persistent across switch reboots, can contain a large number of rule entries, and are all applied at the same time. See ACL Rule Syntax on page 786 for information about creating ACL rule entries.

Policy files are also used to define routing policies. Routing policies are used to control the advertisement or recognition of routes communicated by routing protocols. ACL policy files and routing policy files are both handled by the policy manager, and the syntax for both types of files is checked by the policy manager.

> **Note**
> Although ExtremeXOS does not prohibit mixing ACL and routing type entries in a policy file, it is strongly recommended that you do not mix the entries and do use separate policy files for ACL and routing policies.

Dynamic ACLs persist across reboots; however, you can configure non-persistent dynamic ACLS that disappear when the switch reboots. Dynamic ACLs consist of only a single rule. Multiple dynamic ACLs can be applied to an interface. See Layer-2 Protocol Tunneling ACLs on page 808 for information about creating dynamic ACLs. The precedence of ACLs can be configured by defining zones and configuring the priority of both the zones and the ACLs within a zone. See Configuring ACL Priority on page 812 for more information.

Two-Stage ACL

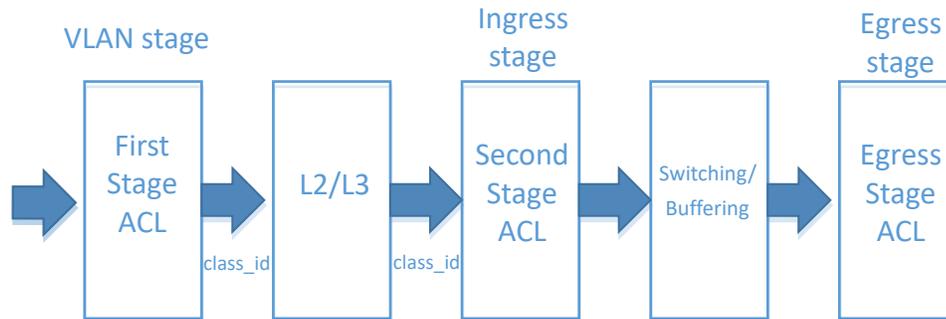
The following diagram shows the three *ACL* processors available that can be used for filtering the packets at various stages of processing:


Figure 97: ACL Stages

First Stage ACL / _VLAN_ Processor: is used to filter packets before ingress processing. It can be used to assign the VLAN, set a CLASS ID, or perform other more traditional ACL actions, such as drop or count. In general, this stage's scale, actions, and match criteria are more limited than the ingress stage. However, the high-level architecture of the first stage ACL is the same as the second stage ACL in that it is composed of a series of slices, or individual TCAM elements. First stage ACL rules are included in the policy file or dynamic ACLs in the same way as regular second stage ACL rules. To specify that a rule is to be added to the first stage ACL table, use the "class-id <class-id>" action.

Second Stage ACL / Ingress Filter Processor: is used to filter packets for ingress processing and is the primary hardware resource used for ingress user ACLs. While this stage follows the L2 and L3 lookups, the packet data presented to this stage is pre-modified, except in the case of tunneling. In general, this stage is the most capable and scalable of the 3 stages. Second stage ACL rules can additionally match the class-id specified as an action in a first stage ACL rule. This is done by listing "class-id <class-id>" in the match clause of the rule.

Egress ACL: is used to filter egressing packets after packet switching, queuing, and buffering operations have been performed. It can be used to deny or modify (e.g. 802.1p, DSCP) packets but cannot be used to redirect or change _QoS_. In general, this stage's scale, actions, and match criteria are more limited than the ingress stage.

The two-stage ingress classification is supported for static user ACL policies, dynamic CLI-driven user ACLs, and dynamic API-driven ACLs.

Platform Support

This feature is supported on the following platforms:
- ExtremeSwitching X440-G2
- ExtremeSwitching X450-G2
- ExtremeSwitching X460-G2
- ExtremeSwitching X465
- ExtremeSwitching X620

- ExtremeSwitching X590
- ExtremeSwitching X695

Feature Description

Rules in the first classifier are set up with an action to set class_id. Rules in the second classifier are setup to use the class_id as the key to match on the identity specific policies. The class_id is the common attribute between the two classifiers/ tables, uniquely identifies the role of the identity.

This feature introduces one new _ACL_ action modifier for specifying the class-id from the first stage that will be input into the second stage. It also introduces one new ACL match criteria for matching the class-id within the second stage.

When a rule is installed in the first stage ACL table, it will be accounted for in the "Stage: LOOKUP" section of `show access-list usage acl-slice port` _port_ . When a rule is installed in the second stage ACL table, it is accounted for in the "Stage: INGRESS" section of this command. For example:

```
# show access-list usage acl-slice port 1
Ports 1-54
Stage: INGRESS
Slices:          Used: 0  Available: 16
Virtual Slice  * (physical slice  0) Rules:   Used:      0  Available:    256
Virtual Slice  * (physical slice  1) Rules:   Used:      0  Available:    256
Virtual Slice  * (physical slice  2) Rules:   Used:      0  Available:    256
Virtual Slice  * (physical slice  3) Rules:   Used:      0  Available:    256
Virtual Slice  * (physical slice  4) Rules:   Used:      0  Available:    256
Virtual Slice  * (physical slice  5) Rules:   Used:      0  Available:    256
Virtual Slice  * (physical slice  6) Rules:   Used:      0  Available:    256
Virtual Slice  * (physical slice  7) Rules:   Used:      0  Available:    256
Virtual Slice  * (physical slice  8) Rules:   Used:      0  Available:    256
Virtual Slice  * (physical slice  9) Rules:   Used:      0  Available:    256
Virtual Slice  * (physical slice 10) Rules:   Used:      0  Available:    256
Virtual Slice  * (physical slice 11) Rules:   Used:      0  Available:    256
Virtual Slice  * (physical slice 12) Rules:   Used:      0  Available:    256
Virtual Slice  * (physical slice 13) Rules:   Used:      0  Available:    256
Virtual Slice  * (physical slice 14) Rules:   Used:      0  Available:    256
Virtual Slice  * (physical slice 15) Rules:   Used:      0  Available:    256
Stage: EGRESS
Slices:          Used: 0  Available: 4
Virtual Slice  * (physical slice  0) Rules:   Used:      0  Available:    256
Virtual Slice  * (physical slice  1) Rules:   Used:      0  Available:    256
Virtual Slice  * (physical slice  2) Rules:   Used:      0  Available:    256
Virtual Slice  * (physical slice  3) Rules:   Used:      0  Available:    256
Stage: LOOKUP
Slices:          Used: 0  Available: 4
Virtual Slice  * (physical slice  0) Rules:   Used:      0  Available:    512
Virtual Slice  * (physical slice  1) Rules:   Used:      0  Available:    512
Virtual Slice  * (physical slice  2) Rules:   Used:      0  Available:    512
Virtual Slice  * (physical slice  3) Rules:   Used:      0  Available:    512
Stage: EXTERNAL

Virtual Slice :  (*) Physical slice not allocated to any virtual slice.
X460G2-48x-10G4.10 #
```

Limitations

- The second stage ACL will always override any qosprofile set in the First stage.
- A first stage ACL rule will not work for untagged traffic when "vlan-id" is used as a matching condition or when applied to a vlan .
- Matching "arp-sender-address" OR "arp-target-address" in the first stage ACL is not supported. However, matching both conditions is supported on select platforms.
- L4 port ranges are not supported in the first stage ACL.

Table 69: First-Stage ACL Support Actions

Platform	Permit	Deny	Count	Replace-dot1p-value	qosprofile	Replace-dot1p
ExtremeSwitching X450-G2	Y	Y	Y	Y	Y	Y
ExtremeSwitching X460-G2	Y	Y	Y	Y	Y	Y
ExtremeSwitching X440-G2	Y	Y	N	Y	Y	Y
ExtremeSwitching X465	Y	Y	Y	Y	Y	Y
ExtremeSwitching X620	Y	Y	N	Y	Y	Y
ExtremeSwitching X590	Y	Y	Y	Y	Y	Y
ExtremeSwitching X695	Y	Y	Y	Y	Y	Y

Two-Stage Policy Example

The following example policy demonstrates how these new tokens can be used to create "user profiles" where each user is identified by source MAC address:

```
twostage_example1.pol:
 # First stage rules:

 entry firststage_1 {
if{
    ethernet-source-address 00:00:00:00:00:01;
} then {
    class-id 7;
}}
entry firststage_2 {
if {
    ethernet-source-address 00:00:00:00:00:02;
} then {
    class-id 8;
}}entry firststage_3 {
if {
    ethernet-source-address 00:00:00:00:00:03;
} then {
    class-id 7;
}}
```

```
 # Second stage rules:

entry secondstage_1 {
 if{
    class-id 7;
    destination-address 10.68.9.0/24;
} then {
    permit;
}}

entry secondstage_2 {
if {
    class-id 8;
    destination-address 10.68.0.0/16;
} then {
    permit;
}}entry secondstage_3 {
if {
} then
{entry permit_arp {
if {
ethernet-type 0x0806;
} then {
permit;
}
}
    deny;
    }}
```

The above example policy would have the following resulting behavior:

1. MAC addresses 00:00:00:00:00:01 and 00:00:00:00:00:03 would be permitted to access subnet 10.68.9.0/24
2. MAC address 00:00:00:00:00:02 would be permitted to access subnet 10.68.0.0/16
3. All other traffic would be dropped.

ACL Rule Syntax

An *ACL* rule entry consists of:

- A rule entry name, unique within the same ACL policy file or among Dynamic ACLs.
- Zero or more match conditions.
- Zero or one action (permit or deny). If no action is specified, the packet is permitted by default.
- Zero or more action modifiers.

Each rule entry uses the following syntax:

```
entry <ACLrulename>{
    if  {
        <match-conditions>;
    } then {
        <action>;
        <action-modifiers>;
    }
}
```

The following is an example of a rule entry:

```
entry  udpacl {
    if  {
        source-address 10.203.134.0/24;
        destination-address 140.158.18.16/32;
        protocol  udp;
        source-port 190;
        destination-port  1200 - 1250;
    } then {
        permit;
    }
}
```

An ACL rule is evaluated as follows:

• If the packet matches all the match conditions, the action and any action modifiers in the then statement are taken.

• For ingress ACLs, if a rule entry does not contain any match condition, the packet is considered to match and the action and any action modifiers in the rule entry's "then" statement are taken. For egress ACLs, if a rule entry does not contain any match condition, no packets will match. See Matching All Egress Packets on page 788 for more information.

• If the packet matches all the match conditions, and if there is no action specified in the then statement, the action permit is taken by default.

• If the packet does not match all the match conditions, the action in the then statement is ignored.

> **Note**
>
> For the ExtremeSwitching X695 series switches, egress ACL user rules or policy with an OuterVlanId qualifier do not match packets egressing untagged member ports of a given VLAN. Matching does occur as expected if the egress port is a tagged member of the given VLAN. The OuterVlanId qualifier might be explicitly present, or a rule/policy is applied to a VLAN.
>
> **Workaround**: (Using dynamic ACL rule) To achieve the same functionality for untagged member ports, use the following workaround. It installs an additional ACL on the untagged member ports with the same actions:
>
> ```
> vlan v1 tag 100
>  ports 1,2,3 are tagged members of vlan v1
>  port 5 is untagged members of vlan v1
>
>  original rule (will match only on tagged ports (1,2,3)):
>  create access-list test "source-address 10.10.10.10/24" "count cnt"
>  configure access-list add test first vlan v1 egress
>
>  additional rule (will match on untagged port(s))
>  create access-list test2 "vlan-format untagged; source-address 10.10.10.10/24"
> "count cnt2"
>  configure access-list add test2 last port 5 egress
> ```

Matching All Egress Packets

Unlike ingress _ACL_s, for egress ACLs you must specify either a source or destination address, instead of writing a rule with no match conditions.

For example, an ingress ACL deny all rule could be:

```
entry DenyAllIngress{
    if {
    } then {
        deny;
    }
}
```

The previous rule would not work as an egress ACL.

The following is an example of an egress ACL deny all rule:

```
entry DenyAllEgress{
    if {
        source-address 0.0.0.0/0;
    } then {
        deny;
    }
}
```

Comments and Descriptions in ACL Policy Files

In _ACL_ policy files, there are two types of textual additions that have no effect on the ACL actions: comments and descriptions. A comment is ignored by the policy manager and resides only in the policy file. Comments are not saved in the switch configuration and are not displayed by the show policy command. A description is saved in the policy manager and is displayed when the ACL is displayed.

- You can display the ACL using the following two commands:

  show policy {_policy-name_ | **detail**}

  show access-list {**any** | **ports** _port_list_ | **vlan** _vlan_name_} {**ingress** | **egress**}

  For example, the following policy, saved in the file denyping.pol, contains both a comment and a description:

```
 # this line is a comment
 @description "This line is a description for the denyping.pol"
 entry ping_deny_echo-request {
     if {
         protocol icmp;
         icmp-type echo-request;
     } then {
         deny;
         count pingcount_deny;
     }
 }
```

  Note that the description begins with the tag @description and is a text string enclosed in quotes.

- You can apply the policy to port 1 using the following command:

```
configure access-list denyping port 1
```

- and display the policy using the following command:

```
show policy denyping
```

The output of this command is similar to the following:

```
Policies at Policy Server:
Policy: denyping
@description This line is a description for the denyping.pol
entry ping_deny_echo-request {
if match all {
protocol icmp ;
icmp-type echo-request ;
}
Then {
deny  ;
count pingcount_deny ;
}
}
Number of clients bound to policy: 1
Client: acl bound once
```

Types of Rule Entries

In ExtremeXOS, each rule can be one of the following types:

- L2 rule—A rule containing only Layer 2 (L2) matching conditions, such as Ethernet MAC address and Ethernet type.
- L3 rule—A rule containing only Layer 3 (L3) matching conditions, such as source or destination IP address and protocol.
- L4 rule—A rule containing both Layer 3 (L3) and Layer 4 (L4) matching conditions, such as TCP/UDP port number.

Match Conditions

You can specify multiple, single, or zero match conditions. If you do not specify a match condition, all packets match the rule entry. Commonly used match conditions are:

- `ethernet-source-address` [*mac-address* | *pre-defined-mac*] *mask*—Ethernet source address
- `ethernet-destination-address` [*mac-address* | *pre-defined-mac*] *mask*—Ethernet destination address and mask
- `ethernet-type` *value* {**mask** *value*}—Ethernet type, accepts an optional mask.
- `source-address` *prefix*—IP source address and mask
- `destination-address` *prefix*—IP destination address and mask
- `destination-port` *value* {**mask** *value*}—IP destination port, accepts optional mask
- `source-port` [*value* {**mask** *value*}|*range*]—TCP or UDP source port with optional mask or TCP or UDP source port range

- `destination-port [`*`port`*` {`**`mask`** *`value`*`} |`*`range`*`]`—TCP or UDP destination port with optional mask or TCP or UDP destination port range
- `ttl` *`value`* `{`**`mask`** *`value}`*—condition with optional mask that matches IPv4 Time-To-Live and IPv6 Hop Limit.
- `ip-tos` *`value`* `{`**`mask`** *`value}`*—this condition accepts optional masks
- `vlan-format`—matches packets based on their _VLAN_ format. Can be one of the following values:
  - untagged—all untagged packets
  - single-tagged—all packets with only a single tag
  - double-tagged—all packets with a double tag
  - outer-tagged—all packets with at least one tag; for example, single tag or double tag
- `fragments`—matches any fragment of fragmented packet, including the first fragment
- `first-fragments`—matches only the first fragment of a fragmented packet.
- `l4-match` *`value`* **`offset`** *`offset`* **`mask`** *`mask value`*—generic bit-matching pattern starting at the Layer 4 header of four separate chunks of 32-bits, each fully bit-maskable with a unique offset. Unlike others, this match criteria can appear up to four times in a single rule, each specified as a logical AND, to match up to four separate chunks of 32-bits. Each chunk is fully bit-maskable with a unique offset. The matching data must be within the first 128 bytes of the packet. This match criteria is intended for advanced users only.
  - *`value`*—32-bit value
  - *`offset`*—number of bytes from the start of the Layer 4 header (for example, TCP header)
  - *`mask`*—32-bit mask value applied to *`value`* for matching. Mask is optional. The default is 0xffffffff.

> **Note**
> On ExtremeSwitching X620 and X440-G2 series switches, l4-match cannot be combined with other Layer 3 match criteria, such as source-address.

Table 70 on page 796 describes all the possible match conditions.

Actions

The actions are:

- `permit`—The packet is forwarded.
- `deny`—The packet is dropped.

The default action is permit, so if no action is specified in a rule entry, the packet is forwarded.

The following actions are supported on all platforms:

- `deny-cpu`—Prevents packets that are copied or switched to the CPU from reaching the CPU. The data-plane forwarding of these packets is unaffected. For example, use this action to match broadcast packets and prevent them from reaching the CPU, but still allow them to be flooded to other _VLAN_ members. You can also use this action to match Spanning Tree Protocol packets and prevent them from reaching the CPU, and instead flood them to other VLAN members in certain configurations where Spanning Tree is enabled.

- `copy-cpu-off`—Prevents packets that are copied to the CPU from reaching the CPU. The data-plane forwarding of these packets is unaffected. For example, use this action to cancel the "mirror-cpu" action in another rule. This action does not prevent packets that are switched to the CPU (for example, broadcast, layer-3 unicast miss) from reaching the CPU.

- `copy-cpu-and-drop`—Overrides the above action to facilitate the above action in a "catch-all" rule. It sends matching packets only to the CPU.

- `add-vlan-id`—Adds a new outer VLAN ID. If the packet is untagged, it adds a VLAN tag to the packet. If the packet is tagged, it adds an additional VLAN tag. Only supported in VLAN lookup stage (VFP).

  > **Note**
  > The ExtremeSwitching X695 does not support adding an additional (third) VLAN tag to a double-tagged packet.

- `replace-dscp-value`—Replaces the existing DSCP value of the packet

- `do-ipfix`—Records the matching packet. Can be used on both ingress and egress. Attempting to install a policy with this action on an unsupported chip will result in failure in HAL. The ExtremeSwitching X435, X465, X590, X695 series switches do not support this action.

- `do-not-ipfix`—Cancels recording for the matching packet. Can be used to reduce demand on egress IPFIX capacity (and to reduce recording loss) during packet flooding situations. Attempting to install a policy with this action on an unsupported chip will result in failure in HAL. The ExtremeSwitching X435, X465, X590, X695 series switches do not support this action.

- `redirect-port-copy-cpu-allowed`—Redirects a packet out of an output port, but does not enforce a requirement that Copy to CPU must be cancelled.

- `redirect-port-list-copy-cpu-allowed`—Redirects a packet out of an output port to a list of ports, but does not enforce a requirement that Copy to CPU must be cancelled.

Action Modifiers

Additional actions can also be specified, independent of whether the packet is dropped or forwarded. These additional actions are called action modifiers. Not all action

modifiers are available on all switches, and not all are available for both ingress and egress ACLs. The action modifiers are:

- `class-id` *`value 0-4095`*—Signifies that the rule will be installed in the LOOKUP stage access-list resource. Class-id range varies from platform to platform.

- `count` *`countername`*—Increments the counter named in the action modifier.

  > **Note**
  > The CLEAR-Flow counters work when the ACL is applied to a VLAN, but not if applied to a port or wildcard.

  ◦ ingress— All platforms
  ◦ egress— All platform. On egress, count does not work in combination with deny action.

  > **Note**
  > On egress, count does not work in combination with deny action in some platforms

- `add-vlan-id`—Adds a new outer *VLAN* ID. If the packet is untagged it will add a VLAN tag to the packet. If the packet is tagged, it will add an additional VLAN tag. Only supported in VLAN Lookup stage (VFP).

- `byte-count` *`byte counter name`*—Increments the byte counter named in the action modifier

- `packet-count` *`packet counter name`*—Increments the packet counter named in the action modifier.

- `log`—Logs the packet header.

- `log-raw`—Logs the packet header in hex format.

- `meter` *`metername`*—Takes action depending on the traffic rate. (Ingress and egress meters are supported on the platforms listed for these features in the *ExtremeXOS 32.4 Feature License Requirements* document.

- `mirror`—Rules that contain mirror as an action modifier will use a separate slice.

- `mirror-cpu`—Mirrors a copy of the packet to the CPU in order to log it. It is supported only in ingress.

- `qosprofile` *`qosprofilename`*—Forwards the packet to the specified *QoS* profile.

  ◦ ingress—all platforms
  ◦ egress—does not forward the packets to the specified qosprofile. If the action modifier "replace-dot1p" is present in the ACL rule, the dot1p field in the packet is replaced with the value from associated qosprofile. ExtremeSwitching X460-G2, X435, X465, X590, X695 series switches only.

- `redirect` *`ipv4 addr`*—Forwards the packet to the specified IPv4 address.

- `redirect-no-replace-l2-sa` *`IP nexthop address`*—Forwards the packet to the specified IPv4 address without changing the source MAC address. Only apply to "L3 routable" traffic. Layer-2 traffic is not subject to matching.

- `redirect-port` *`port`*—Overrides the forwarding decision and changes the egress port used. If the specified port is part of a load share group then this action will apply the load sharing algorithm.
- `redirect-port-list` *`port_list`*—Supports multiple redirect ports as arguments. When used in an ACL, matching packets are now redirected to multiple ports as specified in the ACL while overriding the default forwarding decision. Maximum number of ports that can be mentioned in this list is 64.
- `redirect-port-no-sharing` *`port`*—Overrides the forwarding decision and changes the egress port used. If the specified port is part of a load share group then this action overrides the load sharing algorithm and directs matching packets to only this port.
- `redirect-name` *`name`*—Specifies the name of the flow-redirect that must be used to redirect matching traffic.
- redirect-vlan—Redirects the traffic to all ports in the matching VLAN. With L3 unicast routing, floods on the egress VLAN members.
- `replace-dscp`—Replaces the packet's DSCP field with the value from the associated QoS profile.
  - ingress
  - egress
- `replace-dot1p`—Replaces the packet's 802.1p field with the value from the associated QoS profile.
  - ingress
  - egress
- `replace-dot1p-value` *`value`*—Replaces the packet's 802.1p field with the value specified without affecting the QoS profile assignment.
  - ingress
  - egress
- `replace-ethernet-destination-address` *`mac-address`*—Replaces the packet's destination MAC address; this is applicable only to layer-2 forwarded traffic.
- `replace-vlan-id` —Replaces an outer VLAN ID in a double-tagged packet or a single VLAN tag in a single-tagged packet.
  - ingress
  - egress

Counting Packets and Bytes

When the ACL entry match conditions are met, the specified counter is incremented.

- The counter value can be displayed by the command:

  `show access-list counter {`*`countername`*`} {`**`any`** `|` **`ports`** *`port_list`* `|` **`vlan`** *`vlan_name`*`} {`**`ingress`** `|` **`egress`**`}`

ExtremeSwitching series switches can use ACL byte counters as an alternative to ACL packet counters. See ACL Byte Counters on page 808 for more information.

> **Note**
> The maximum number of packets that can be counted with token packet-count or count is 18,446,744,073,709,551,616. The maximum number of bytes that can be counted with byte-count is also 18,446,744,073,709,551,616, which is equivalent to 288,230,376,151,711,744 packets that are sized at 64 bytes.

> **Note**
> Each packet increments only one counter in the egress direction. When there are multiple ACLs with action "count" applied in the port, only single counter based on the slice priority work.

Logging Packets

Packets are logged only when they go to the CPU, so packets in the fastpath are not automatically logged. You must use both the mirror-cpu action modifier and the log or log-raw action modifier if you want to log both slowpath and fastpath packets that match the *ACL* rule entry. Additionally, Kern.Info messages (or Kern.Card.Info on SummitStack) are not logged by default. You must configure an EMS filter to log these messages, for example, `configure log filter DefaultFilter add event kern.info`. See the Status Monitoring and Statistics chapter for information about configuring EMS.

Metering Packets

The `meter metername` action modifier applies a meter to the traffic defined by an *ACL*. For more information, see Meters on page 877.

Mirroring Packets

You must enable port-mirroring on your switch. If you attempt to apply a policy that requires port-mirroring, the mirror action will be disabled until you enable the port-mirroring.

On ExtremeSwitching X450-G2 and X460-G2 series switches, mirroring can be configured on the same port as egress ACLs. Mirroring can send packets to port x and you can install your rule at egress port x, and the rule should match your mirrored traffic.

Starting with ExtremeXOS 30.1, a single ACL can have up to four mirror actions (each with a different mirror instance) to accomplish mirroring the same packet to multiple destinations (port, ERSPAN/remote-ip, RSPAN/remote-tag, etc). This capability is not supported on ExtremeSwitching X620 and X440-G2 series switches.

Redirecting Packets

Packets are forwarded to the IPv4 address specified, without modifying the IP header (except the TTL is decremented and the IP checksum is updated). The IPv4 address must be in the IP ARP cache, otherwise the packet is forwarded normally. Only fast

path traffic can be redirected. This capability can be used to implement Policy-Based Routing.

You may want to create a static ARP entry for the redirection IP address, so that there will always be a cache entry. See Policy-Based Routing on page 842 for more information.

Replacing DSCP or 802.1p Fields

Specify a *QoS* profile for matching packets. The field values are replaced with the value associated with that profile. In the following example, DiffServ replacement is configured such that QP8 is mapped to code point 56. Matching packets are sent to QP8, and the DSCP value in the packet is set to 56.

```
entry voice_entry {
if {
source-address 2.2.2.2/32;
} then {
qosprofile qp8;
replace-dscp;
}
}
```

See Quality of Service on page 862 for more details about QoS profiles, and 802.1p and DSCP replacement.

ACL Rule Syntax Details

The following table lists the match conditions that can be used with *ACLs*, and whether the condition can be used for ingress ACLs only, or with both ingress and egress. The conditions are not case-sensitive; for example, the match condition listed in the table as TCP-flags can also be written as tcp-flags. Within Table 70 are five different data types used in matching packets.

Table 70 lists general match conditions that apply to all traffic, unless otherwise noted. Table 71 on page 805 the data types and details on using them.

Table 70: ACL Match Conditions

Match Conditions	Description	Applicable IP Protocols/ Direction
`ethernet-type` *`number`*	Ethernet packet type. In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): ETHER-P-IP (0x0800), ETHER-P-8021Q (0x8100), ETHER-P-IPV6 (0x86DD).	Ethernet/ Ingress and Egress
[**ethernet-source-address** | **ethernet-destination-address**][*mac-address | pre-defined-mac*] { [**mask** | /] *mask* }	Match Ethernet source MAC address or Ethernet destination MAC address. The mask is optional, and is in the same format as the MAC address for example: `ethernet-source-address 00:01:02:03:01:01 mask ff:ff:ff:ff:00:00 or ethernet-source-address 00:01:02:03:01:01 / ff:ff:ff:ff:00:00` *Pre-defined-mac* can be any one of the following: `cdp-mac, csp-mac (Port Extender Control and Status Protocol), eaps-flush-fdb-mac, eaps-mac, eaps-ver1-mac, eaps-ver2-mac, edp-mac, elrp-dst-mac, elrpsrc-mac, elsm-mac, erps-mac, esrp-mac, lacp-mac, lldp-mac, msrp-mac, pvstp-mac, stp-mac, system-lla-mac and system-mac` Example with pre-defined-mac: `ethernet-source-address edp-mac mask ff:ff:ff:ff:00:00 or ethernet-source-address edp-mac / ff:ff:ff:ff:00:00` Only those bits of the MAC address whose corresponding bit in the mask is set to 1 will be used as match criteria. Therefore, the preceding example matches 00:01:02:03:xx:xx. If the mask is not supplied, it is assumed to be ff:ff:ff:ff:ff:ff. In other words, all bits of the MAC address are used for matching.	Ethernet/ Ingress and Egress
`source-address` *`prefix`*	IP source address and mask. Use either all IPv4 or all IPv6 addresses in an ACL. On ExtremeSwitching series switches, using arbitrary mask arguments is supported. Masks are not restricted to be of a subnet type. Examples of arbitrary IPv4 and IPv6 masks include 10.22.3.4 and 1:0:0:ffff:2:4. The 1s in the mask indicate the corresponding bits of the source-address that should be used as part of the match criteria.	All IP/ Ingress and Egress

---

[1] However, packets using the Ethernet type for VMANs, 0x88a8 by default, are handled by VMAN ACLs.

Table 70: ACL Match Conditions (continued)

Match Conditions	Description	Applicable IP Protocols/ Direction
`destination-address` *`prefix`*	IP destination address and mask. On ExtremeSwitching series switches, using arbitrary mask arguments is supported. Masks are not restricted to be of a subnet type. Examples of arbitrary IPv4 and IPv6 masks include 10.22.3.4 and 1:0:0:ffff:2:4. The 1s in the mask indicate the corresponding bits of the destination-address that should be used as part of the match criteria.	All IP/ Ingress and Egress
`source-port` *`number`*	TCP or UDP source port. You must also specify the protocol match condition to determine which protocol is being used on the port, any time you use the this match condition. In place of the numeric value, you can specify one of the text synonyms listed under destination port. If no source-port is specified, the default source-port is "any."	TCP, UDP/ Ingress and Egress
`source-port` *`range`*	TCP or UDP source port. You must also specify the protocol match condition to determine which protocol is being used on the port, any time you use the this match condition. In place of the numeric value, you can specify one of the text synonyms listed under destination port. If no source-port is specified, the default source-port is "any."	TCP, UDP/ Ingress
`source-port number { `**`mask`** *`value`* ` }`	TCP or UDP port and mask. The mask is optional, and it can be decimal value or a hexadecimal value.	TCP,UDP/ Ingress and Egress

Table 70: ACL Match Conditions (continued)

Match Conditions	Description	Applicable IP Protocols/ Direction
`destination-port` *number*	TCP or UDP destination port. You must also specify the protocol match condition to determine which protocol is being used on the port, any time you use the this match condition. In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): afs(1483), bgp(179), biff(512), bootpc(68), bootps(67), cmd(514), cvspserver(2401), dhcp(67), domain(53), eklogin(2105), ekshell(2106), exec(512), finger(79), ftp(21), ftp-data(20), http(80), https(443), ident(113), imap(143), kerberos-sec(88), klogin(543), kpasswd(761), krbprop(754), krbupdate(760), kshell(544), ldap(389), login(513), mobileip-agent(434), mobileip-mn(435), msdp(639), netbiosdgm(138), netbios-ns(137), netbios-ssn(139), nfsd(2049), nntp(119), ntalk(518), ntp(123), pop3(110), pptp(1723), printer(515), radacct(1813), radius(1812), rip(520), rkinit(2108), smtp(25), snmp(161), snmptrap(162), snpp(444), socks(1080), ssh(22), sunrpc(111), syslog(514), tacacs-ds(65), talk(517), telnet(23), tftp(69), timed(525), who(513), xdmcp(177), zephyrclt(2103), or zephyr-hm(2104).	TCP, UDP/ Ingress and Egress
`destination-port` *range*	TCP or UDP destination port. You must also specify the protocol match condition to determine which protocol is being used on the port, any time you use the this match condition. In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): afs(1483), bgp(179), biff(512), bootpc(68), bootps(67), cmd(514), cvspserver(2401), dhcp(67), domain(53), eklogin(2105), ekshell(2106), exec(512), finger(79), ftp(21), ftp-data(20), http(80), https(443), ident(113), imap(143), kerberos-sec(88), klogin(543), kpasswd(761), krbprop(754), krbupdate(760), kshell(544), ldap(389), login(513), mobileip-agent(434), mobileip-mn(435), msdp(639), netbiosdgm(138), netbios-ns(137), netbios-ssn(139), nfsd(2049), nntp(119), ntalk(518), ntp(123), pop3(110), pptp(1723), printer(515), radacct(1813), radius(1812), rip(520), rkinit(2108), smtp(25), snmp(161), snmptrap(162), snpp(444), socks(1080), ssh(22), sunrpc(111), syslog(514), tacacs-ds(65), talk(517), telnet(23), tftp(69), timed(525), who(513), xdmcp(177), zephyrclt(2103), or zephyr-hm(2104).	TCP, UDP/ Ingress

Table 70: ACL Match Conditions (continued)

Match Conditions	Description	Applicable IP Protocols/ Direction
`destination-port number {`**`mask value`**`}`	TCP or UDP port and mask. The mask is optional, and it can be decimal value or a hexadecimal value. Only those bits of the destination-port whose corresponding bit in the mask is set to 1 will be used as match criteria.	TCP,UDP/ Ingress and Egress
`TCP-flags` *`bitfield`*	TCP flags. Normally, you specify this match in conjunction with the protocol match statement. In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): ACK(0x10), FIN(0x01), PUSH(0x08), RST(0x04), SYN(0x02), URG(0x20), SYN_ACK(0x12).	TCP/Ingress and Egress
`IGMP-msg-type` *`number`*	IGMP message type. Possible values and text synonyms: v1-report(0x12), v2-report(0x16), v3-report(0x22), V2-leave (0x17), or query(0x11).	IGMP/ Ingress only
`ICMP-Type` *`number`*	ICMP type field. Normally, you specify this match in conjunction with the protocol match statement. In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): echo-reply(0), echo-request(8), info-reply(16), info-request(15), mask-request(17), mask-reply(18), parameter-problem(12), redirect(5), router-advertisement(9), router-solicit(10), source-quench(4), time-exceeded(11), timestamp(13), timestamp-reply(14), or unreachable(3), v6-echo-request(128), v6-echo-reply(129), v6-mld-query(130), v6-mld-report(131), v6-mld-reduction(132), v6-router-soliciation(133), v6-router-advertisement(134), v6-neighbor-solicitation(135), v6-neighbor-advertisement(136), v6-redirect(137), v6-node-info-query(139), v6-node-info-reply(140), v6-unreachable(1), v6-packet-too-big(2), v6-time-exceeded(3), v6-parameter-problem(4), v6-echo-request(128), v6-echo-reply(129), v6-mld-query(130), v6-mld-report(131), v6-mld-reduction(132), v6-router-soliciation(133), v6-router-advertisement(134), v6-neighbor-solicitation(135), v6-neighbor-advertisement(136), v6-redirect(137), v6-node-info-query(139), v6-node-info-reply(140) v6-unreachable(1), v6-packet-too-big(2), v6-time-exceeded(3), v6-parameter-problem(4), v6-echo-request(128), v6-echo-reply(129), v6-mld-query(130), v6-mld-report(131), v6-mld-reduction(132), v6-router-soliciation(133), v6-router-advertisement(134), v6-neighbor-solicitation(135), v6-neighbor-advertisement(136), v6-redirect(137), v6-node-info-query(139), v6-node-info-reply(140).	ICMP/ Ingress only

Table 70: ACL Match Conditions (continued)

Match Conditions	Description	Applicable IP Protocols/ Direction
ICMP-Code *number*	ICMP code field. This value or keyword provides more specific information than the icmp-type. Because the value's meaning depends upon the associated icmp-type, you must specify the icmp-type along with the icmp-code (only available in IPv4). In place of the numeric value, you can specify one of the following text synonyms (the field values also listed); the keywords are grouped by the ICMP type with which they are associated: Parameter-problem: ip-header-bad(0), required-option-missing(1) Redirect: redirect-for-host (1), redirect-for-network (2), redirect-for-tos-and-host (3), redirect-for-tos-and-net (2) Time-exceeded: ttl-eq-zero-during-reassembly(1), ttl-eq-zero-during-transit(0) Unreachable: communication-prohibited-by-filtering(13), destination-host-prohibited(10), destination-host-unknown(7), destination-network-prohibited(9), destination-network-unknown(6), fragmentation-needed(4), host-precedence-violation(14), host-unreachable(1), host-unreachable-for-TOS(12), network-unreachable(0), network-unreachable-for-TOS(11), port-unreachable(3), precedence-cutoff-in-effect(15), protocol-unreachable(2), source-host-isolated(8), source-route-failed(5)	IPv4 only/ ICMP/ Ingress only
source-sap	SSAP is a 1 byte field with possible values 0-255 decimal. The value can be specified in decimal or hexadecimal. The SSAP field can be found at byte offset 15 in 802.3 SNAP and LLC formatted packets.	Ethernet/ Ingress Only
destination-sap	DSAP is a 1 byte field with possible values 0-255 decimal. The value can be specified in decimal or hexadecimal. The DSAP field can be found at byte offset 14 in 802.3 SNAP and LLC formatted packets. (Available on ExtremeSwitching series switches, SummitStack.)	Ethernet/ Ingress Only
snap-type	SNAP type is a 2 byte field with possible values 0-65535 decimal. The value can be specified in decimal or hexadecimal. The SNAP type field can be found a byte offset 20 in 802.3 SNAP formatted packets.	Ethernet/ Ingress Only

Table 70: ACL Match Conditions (continued)

Match Conditions	Description	Applicable IP Protocols/ Direction
`ttl number {`**`mask`** `value}`	Time To Live with mask.The mask is optional, and it can be decimal value or a hexadecimal value.Only those bits of the ttl whose corresponding bit in the mask is set to 1 will be used as match criteria.This can be used to match IPv4 Time-To-Live and IPv6 Hop Limit.	All IP/ Ingress and Egress.
`IP-TOS number`	IP TOS field. In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): minimize-delay 16 (0x10), maximize-reliability 4(0x04), minimize-cost2 (0x02), and normal-service 0(0x00).	All IP/ Ingress and Egress
`IP-TOS number {mask value}`	IP-TOS and mask.The mask is optional, and it can be decimal value or a hexadecimal value.Only those bits of the IP-TOS whose corresponding bit in the mask is set to 1 will be used as match criteria.	All IP/ Ingress and Egress
`dscp value`	DSCP field. In place of the value, you can specify one of the DSCP numeric values (for example, 8, 16, or 24).	All IP/ Ingress and Egress
`fragments`	IP fragmented packet including first fragment. FO = 0 (FO = Fragment Offset in IP header)	All IP, no L4 rules/ Ingress only
`first-fragment`	Matches only first fragmented packet. FO==0.	All IP/ Ingress only
`protocol number`	IP protocol field. For IPv6, this matches the Next Header field in the packet. In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): egp(8), gre(47), icmp(1), igmp(2), ipip(4), Ipv6 over ipv4(41), ospf(89), pim(103), rsvp(46), st(5), tcp(6), or udp(17).	All IP/ Ingress and Egress
`vlan-format format`	VLAN-format matches packets based on its vlan format. Can be one of the 4 values: untagged - will match all untagged packets single-tagged - will match all packets with only single tag. double-tagged - will match all packets with double tag outer-tagged - will match all packets with at least one tag ex. single tag or double tag.	Ethernet/ Ingress and Egress

---

2 See the section Fragmented packet handling for details,
3 See the section IPv6 Traffic with L4 Match Conditions for details about specifying a protocol/ port match with IPv6.

Table 70: ACL Match Conditions (continued)

Match Conditions	Description	Applicable IP Protocols/ Direction
`vlan-id` *number*	Matches the VLAN tag number or the VLAN ID which is given to a VLAN when created. The ACL rule can only be applied to ports or any, and not VLANs. The following restriction applies to all platforms: The vlan-id match condition matches on the "outer" tag of a VMAN.The vlan-id ACL keyword can be used in egress ACL.	Ethernet/ Ingress and Egress
`vlan-id number {`**`mask`** *`value`*`}`	VLAN-id and mask.The mask is optional, and it can be decimal value or a hexadecimal value.Only those bits of the Vlan tag Number or vlan id whose corresponding bit in the mask is set to 1 will be used as match criteria.	Ethernet/ Ingress and Egress
`vxlan-vni` *vni number*	VNI on an egress-terminated VXLAN packet (egress VTEP scenario) or on a transit switch. Available for both static and dynamic ingress ACLs.	Ethernet/ Egress
`dot1p` *priority tag*	Creates an ACL with 802.1p match conditions, allowing the ACL to take action based on the VLAN tag priority. (Available on all platforms.)	All IP/ Ingress
`arp-sender-address` *prefix* and `arp-target-address` *prefix*	Matches the ARP sender protocol address and target protocol address respectively. *prefix* => *IPv4 address* / *mask length*. They cannot be combined with an Ethernet-source-address or Ethernet-destination-address in the same rule. They can be used only when the ACL hardware database is configured to be internal for those platforms that support "external-table" ACL databases.	ARP packets/ Ingress
ccos	Matches customer 802.1p on UNI or NNI ports. Available on all platforms. `ccos <ccos value>`	

Table 70: ACL Match Conditions (continued)

Match Conditions	Description	Applicable IP Protocols/ Direction
`cvid`	Use this match criteria in the following scenarios: Tagged VMAN ports: installing an ACL matching "cvid" on ingress or egress will match the inner vlan-id of a double tagged packet on a tagged VMAN port. Untagged VMAN ports: installing an ACL matching "cvid" on ingress or egress will match the single VLAN tag on an untagged VMAN port. CEP VMAN ports (with or without VPLS): installing an ACL matching "cvid" on ingress or egress will match the single VLAN tag on a CEP VMAN port (without translation). CEP VMAN ports with cvid translation (with or without translation): installing an ACL matching "cvid" on ingress will match the post-translation cvid. Installing an ACL matching "cvid" on egress will match the post-translation cvid.	Ethernet/ Ingress and Egress
`class-id`	This match condition can be specified on any rule within a policy file or within a list of dynamic access-lists. A rule cannot both match a class-id and specify a class-id as an action. When a "class-id" match criteria is specified, the associated rule will be programmed into the normal "INGRESS stage" access-list hardware resource. The range of valid class-id values varies per platform.	Ingress only.
unknown-l2-unicast	Matches the unknown L2 unicast packets	Ingress only
unknown-l2-multicast	Matches the unknown L2 multicast packets	Ingress only
unknown-l3-multicast	Matches the unknown L3 multicast packets	Ingress only
l2-da-hit	Matches the known L2 unicast packets	Ingress only
l2-match	Generic bit-matching pattern starting at the Layer 4 header of four separate chunks of 32-bits, each fully bit-maskable with a unique offset.	Ingress only
`ospf {msg-type} {version}`	Matches OSPF messages types and optionally OSPF version. If version is not specified, the rule matches both OSPFv2 and OSPFv3 packets. Valid OSPF message types are: `hello` `db-desc` `ls-request` `ls-update` `ls-ack` Valid OSPF version keywords are: `v2` `v3`	OSPF/ Ingress and Egress

Table 70: ACL Match Conditions (continued)

Match Conditions	Description	Applicable IP Protocols/ Direction
pim *msg-type*	Matches PIM message types. Valid PIM message types are: *hello* *register* *register-stop* *join-prune* *boot-strap* *assert* *graft* *graft-ack* *crp-advt* *state-refresh* *df-election* *ecmp-redirect* *pim-flooding*	PIM / Ingress and Egress
packet-resolution *type*	Valid packet types are: *l2-broadcast* *known-l2-unicast* *unknown-l2-unicast* *known-l2-multicast* *unknown-l2-multicast* *known-l3-unicast* *unknown-l3-unicast* *known-l3-multicast* *unknown-l3-multicast*	Ingress only
packet-lookup-status *status1* {, *status2* {, *status3*}}	Matches if the packet's lookup status satisfies all the statuses listed in the match condition. The lookup status value can be one of the following: • destination-mac-hit or destination-mac-miss • source-mac-miss or source-mac-hit or source-mac-move • source-mac-static For example: packet-lookup-status destination-mac-hit packet-lookup-status destination-mac-miss, source-mac-hit packet-lookup-status source-mac-move, source-mac-static	Ingress only

> **Note**
> When you use a configured ACL that contains a match condition with any MAC address, IGMP snooping stops working and IGMP joins are flooded to all ports in a VLAN. When you unconfigure the ACL, IGMP joins stop flooding.

> **Note**
> An ACL that matches the EAPS `ethernet-destination-address`
> (`00:e0:2b:00:00:04`) or `ethernet-source-address` (`00:e0:2b:00:00:01`)
> match condition with the permit action should not be applied to an EAPS
> master node on EAPS ring ports. Doing so causes an EAPS PDU loop. For the
> EAPS master node, you should use the `copy-cpu-and-drop` action with either
> of these match conditions.

> **Note**
> Directed ARP response packets cannot be blocked with ACLs from reaching
> the CPU and being learned.

Along with the data types described in Table 71, you can use the operators <, <=, >, and
>= to specify match conditions. For example, the match condition, `source-port 190`,
will match packets with a source port greater than 190. Be sure to use a space before
and after an operator.

Table 71: ACL Match Condition Data Types

Condition Data Type	Description
prefix	IP source and destination address prefixes. To specify the address prefix, use the notation prefix/prefix-length. For a host address, prefix-length should be set to 32.
number	Numeric value, such as TCP or UDP source and destination port number, IP protocol number.
range	A range of numeric values. To specify the numeric range, use the notation: number - number
bit-field	Used to match specific bits in an IP packet, such as TCP flags and the fragment flag.
mac-address	6-byte hardware address.

IPv6 Traffic with L4 Match Conditions

If you apply an *ACL* policy using ACL that specifies L4 conditions, both IPv4 and IPv6
traffic will be matched. For example, the following ACL will match both IPv4 and IPv6
TCP packets that have their L4 destination port in the range of 120–150:

```
if {
protocol tcp;
destination-port 120 - 150;
}
Then {
permit;
count destIp;
}
}
```

Fragmented Packet Handling

Two keywords are used to support fragmentation in ACLs:

- **`fragments`**—FO field = 0 (FO means the fragment offset field in the IP header). This will match first fragment also (packets with FO = 0).
- **`first-fragments`**—FO == 0.

Policy file syntax checker

The **`fragments`** keyword cannot be used in a rule with L4 information. The syntax checker will reject such policy files.

The following rules are used to evaluate fragmented packets or rules that use the **`fragments`** or **`first-fragments`** keywords.

With no keyword specified, processing proceeds as follows:

- An L3-only rule that does not contain either the fragments or first-fragments keyword matches any IP packets.
- An L4 rule that does not contain either the fragments or first-fragments keyword matches non-fragmented or initial-fragment packets.

With the **`fragments`** keyword specified:

- An L3-only rule with the fragments keyword only matches fragmented packets.
- An L4 rule with the fragments keyword is not valid (see above).

With the **`first-fragments`** keyword specified:

- An L3-only rule with the first-fragments keyword matches initial fragment packets.
- An L4 rule with the first-fragments keyword matches initial fragment packets.

Wide Key ACLs

Wide key capability provides greater capacity for rules than single-wide key *ACL*s.

For example, a double-wide match key provides a 362-bit capacity, instead of a standard 181-bit single-wide key to be used with match conditions. A double-wide key allows you to add more match conditions to an ACL. It also allows matching on a full destination-source IPv6 address.

All ExtremeSwitching Series Switches

- Single-wide key
- Double-wide key

On all platforms, key width is configured manually (see Configuring Wide Key ACL Modes on page 807) and applies to all ACLs on the switch. An individual switch cannot be configured to operate in a mixed double- and single-wide mode. However, a SummitStack can have a mixture of modules and switches with some of them operating in a single-wide mode and some in a double-wide mode.

Double wide key ACLs allow additional condition combinations than single-wide ACLs. The existing supported condition combinations are described in Table 74 on page 835.

The double-wide condition combinations that can be appended under the set union operation to the single-wide condition combinations are as follows:

- OVID, DIP, SIP, IpInfo(First-Fragment,Fragments), IP-Proto, DSCP, TCP-Flag, L4SP, L4DP
- SIPv6, IP-Proto, DSCP, TCP-Flag, L4SP, L4DP

For example, your single-wide mode supports condition combination A, B, and C, and the double-wide mode adds condition combinations D1 and D2. Then in a single-wide mode, the conditions of your rule should be a subset of either {A}, or {B}, or {C} and in a double-wide mode, the conditions of your rule should be a subset of either {A U D1}, or {A U D2}, or {B U D1}, or {B U D2}, or {C U D1}, or {C U D2}.

Limitations

The following are limitations associated with wide keys:

- Wide keys provides richer condition combinations. However, there is a tradeoff in ACL capacity; wide key ACLs consume more space.
- Only ingress ACLs support this feature. Egress and external ACLs do not support it.

Supported Platforms

Wide key ACLs are available on ExtremeSwitching X450-G2, X460-G2, X440-G2, X465, X590, X620, X695 series switches.

Configuring Wide Key ACL Modes

To configure the TCAM width of a switch (standalone or SummitStack), use the following command:

```
configure access-list width [double | single] [slot slotNo | all]
```

You must reboot for the configuration to take effect.

When switching from single-wide key mode to double-wide key mode and rebooting, the following conditions apply:

- Configurations that have less that one-half the number of *ACL* rules that the single-wide key mode supports, reboot successfully.
- Configurations that have more than one-half the number of ACL rules that the single-wide key mode supports, fail after the reboot.

When switching from double-wide key mode to single-wide key mode and rebooting, the following conditions apply:

- Configurations that do not use the additional condition combinations that double-wide key mode offers, reboot successfully.
- Configurations that use the additional condition combinations that the double-wide key mode offers, fail after the reboot.

To display the wide key mode settings, use the following command:

```
show access-list width [slot slotNo | all]
```

Layer-2 Protocol Tunneling ACLs

Three _ACL_ match conditions and one ACL action interoperate with vendor-proprietary Layer-2 protocol tunneling on the platforms listed for this feature in the _ExtremeXOS 32.4 Feature License Requirements_ document.

The following fields within 802.3 Subnetwork Access Protocol (SNAP) and LLC formatted packets can be matched:

- Destination service access point (SAP)
- Source SAP

The following field can be matched within Subnetwork Access Protocol (SNAP) packets only:

- SNAP type

The following ACL action is added to the specified switches:

- Replacement of the Ethernet MAC destination address

This action replaces the destination MAC address of any matching Layer-2 forwarded packets on the supported platforms. This action can be used to effectively tunnel protocol packets, such as _STP (Spanning Tree Protocol)_, across a network by replacing the well-known protocol MAC address with a different proprietary or otherwise unique MAC address. After tunnel egress, the MAC destination address can be reverted back to the well-known MAC address.

> **Note**
> The "replace-ethernet-destination-address" action applies only to Layer-2 forwarded packets.

ACL Byte Counters

An _ACL_ byte counter associated with a particular rule, either dynamic or static, shows how many bytes of traffic have matched that ACL rule. You can use ACL byte counters as an alternative to packet counters on the platforms listed for this feature in the _ExtremeXOS 32.4 Feature License Requirements_ document..

A new ACL action token has been added to associate a byte counter with an ACL, and a new corresponding token for a packet counter.

Following are the two new tokens:

```
byte-count byte counter name

packet-count packet counter name
```

An ACL rule specifying both packet and byte counter is rejected.

Below is an example of an ACL rule that uses a byte counter:

```
entry CountBytes {
    if {
```

```
        ethernet-source-address 00:aa:00:00:00:10;
    } then {
        byte-count CountBytes;
        permit;
    }
}
```

Below are two examples of ACL rules that use packet counters. The "packet-count" token is a synonym of the existing "count" token.

```
entry CountPacket1 {
    if {
        ethernet-source-address 00:aa:00:00:00:10;
    } then {
        count CountPacket1;
        permit;
    }
}

entry CountPacket2 {
    if {
        ethernet-source-address 00:aa:00:00:00:10;
    } then {
        packet-count CountPacket2;
        permit;
    }
}
```

The output of the `show access-list counter` and `show access-list dynamic counter` commands has been changed to include a new "Byte Count" column in addition to the "Packet Count" column. When a rule utilizes a byte counter, the "Byte Count" field is incremented and the "Packet Count" field stays at zero. If a rule utilizes a packet counter, the "Packet Count" field is incremented and the "Byte Count" field stays at zero.

> **Note**
> Byte counters and packet counters cannot be used at the same time in the same rule.

Dynamic ACLs

Dynamic _ACL_s are created using the CLI. They use a similar syntax and can accomplish the same actions as single rule entries used in ACL policy files. More than one dynamic ACL can be applied to an interface, and the precedence among the dynamic ACLs can be configured. By default, the priority among dynamic ACLs is established by the order in which they are configured.

> **Note**
> Dynamic ACLs have a higher precedence than ACLs applied using a policy file.

The steps involved in using a dynamic ACL on an interface are:

* Creating the Dynamic ACL Rule
* Configuring the ACL Rule on the Interface.

- Configuring ACL Priority
- Network-Zone Support in ACLs

Creating the Dynamic ACL Rule

Creating a dynamic _ACL_ rule is similar to creating an ACL policy file rule entry. You specify the name of the dynamic ACL rule, the match conditions, and the actions and action-modifiers. You can configure a dynamic ACL to be persistent or non-persistent across system reboots. User-created access-list names are not case sensitive. The match conditions, actions, and action-modifiers are the same as those that are available for ACL policy files (see ACL Rule Syntax on page 786). In contrast to the ACL policy file entries, dynamic ACLs are created directly in the CLI. Use the following command to create a dynamic ACL:

```
create access-list dynamic_rule conditions actions {non_permanent}
```

As an example of creating a dynamic ACL rule, compare an ACL policy file entry with the CLI command that creates the equivalent dynamic ACL rule.

The following ACL policy file entry will drop all _ICMP (Internet Control Message Protocol)_ echo-requests:

```
entry  icmp-echo {
    if  {
        protocol  icmp;
        icmp-type  echo-request;
    } then {
        deny;
    }
}
```

To create the equivalent dynamic ACL rule, use the following command:

```
create access-list icmp-echo "protocol icmp;icmp-type echo-request"
"deny"
```

Notice that the _conditions_ parameter is a quoted string that corresponds to the match conditions in the if { ... } portion of the ACL policy file entry. The individual match conditions are concatenated into a single string. The _actions_ parameter corresponds to the then { ... } portion of the ACL policy file entry.

From the command line you can get a list of match conditions and actions by using the following command:

```
check policy attribute {attr}
```

The ACL rule shown in the example will be saved when the save command is executed, because the optional keyword **non-permanent** was not configured. This allows the rule to persist across system reboots.

Note also that the sample ACL rule does not specify an application to which the rule belongs. The default application is CLI.

Limitations

Dynamic ACL rule names must be unique, but can be the same as used in a policy file-based ACL. Any dynamic rule counter names must be unique. CLEAR-FLow rules can be specified only in policy files and therefore apply only to rules created in a policy file.

Configuring the ACL Rule on the Interface

After a dynamic *ACL* rule has been created, it can be applied to a port, *VLAN*, or to the wildcard any interface. When the ACL is applied, you specify the precedence of the rule among the dynamic ACL rules. To configure the dynamic ACL rule on an interface, use the following command:

```
configure access-list add dynamic_rule [ [[first | last] {priority
p_number} {zone zone} ] | [[before | after] rule] | [ priority p_number
{zone zone} ]] [ any | vlan vlan_name | ports port_list ] {ingress |
egress}
```

To remove a dynamic ACL from an interface, use the following command:

```
configure access-list delete ruleName [ any | vlan vlan_name | ports
port_list | all] {ingress | egress}
```

An ACL can be created to be used when an edge port detects a loop. This ACL acts to block looped frames while allowing the port to remain in a forwarding state rather than shutting down. To configure a dynamic ACL for blocking looped *STP* BPDUs on port 6, for example, use the following:

```
create access-list bpdu1 "ethernet-destination-address     \
                          01:80:C2:00:00:00;" "deny; count bpdu1"
conf access-list add "bpdu1" first ports 6 ingress
```

To configure a dynamic ACL for blocking PVST frames on port 6, use the following:

```
create access-list bpdu2 "ethernet-destination-address \
                              01:00:0c:cc:cc:cd;" "deny; count bpdu2"
 conf access-list add "bpdu2" first ports 6 ingress
```

To unconfigure the STP ACL, use the following:

```
conf access-list del "bpdu1" ports 6
del access-list "bpdu1"
```

Configuring ACLs on a Management Port

Hardware *ACL* support is not possible on the management port. Untagged packets that are received on the management port are processed in software and can be filtered using ACLs. ACLs applied to the management port/vlan are installed only in software and not in the hardware.

For example, to block an *ICMP* echo-request on a management port, use the following:

```
create access-list echo "protocol icmp; icmp-type echo-request;" "deny; count echo"
conf access-list add "echo" first vlan "Mgmt" ingress
```

To unblock ICMP echo request on a management port, use the following:

```
conf access-list del "echo" vlan "Mgmt"
del access-list "echo"
```

To show ACL dropped packet counters, use the following command:

```
show access-list dynamic counter
```

Configuring ACL Priority

Management of *ACL*s is flexible, with configurable priority for dynamic ACLs. This includes ACLs inserted by internal and external applications, as well as those inserted using the CLI. The priority is assigned by a system of zones, and within zones by numeric codes.

Zones are of two types:

*   System Space—The System Space zones include the following:
    ◦   SYSTEM_HIGH—This zone always has the highest priority.
    ◦   SYSTEM_LOW—This zone always has the lowest priority.

    The priorities cannot be changed.

    No configuration is allowed by the user into System Space.

    Hal is the only application in a System Space zone.
*   User Space—The User Space zones include the following:
    ◦   DOS—This is the denial of service zone.
    ◦   SYSTEM—This is the zone for applications that require a CPU-copy or mirror and for redirect ACLs.
    ◦   SECURITY—This is the zone for ACLs installed by security appliances and internal security processes.

    User Space zones consist of default zones and created zones. Default zones group like functions and cannot be deleted.

    The administrator has the ability to create new zones and configure the priority of both default and created zones. See Configuring User Zones on page 813 for discussion of created zones and applications. Applications insert ACLs into zones.

To view both System Space and User Space zones, use the `show access-list zone` command.

Table 72 shows the priority of System Space zones and User Space zones together with the default assignments and priority of applications by zone.

Table 72: Default Assignment and Priority of Applications, by Zone

Zone/Default Application	Default Priority	Platform
SYSTEM SPACE ZONES		
hal	1	
USER SPACE ZONES		
DOS	2	
hal	1	All platforms
Dos	2	All platforms
SYSTEM	3	
Cli	1	All platforms
IpSecurity	2	All platforms
NetLogin	6	All platforms
SECURITY	4	
GenericXml (Allows configuration of one additional external application)	4	All platforms
SYSTEM SPACE ZONES		
hal	1	

> **Note**
> The priority of static ACLs is determined by the order they are configured, with the first rule configured having the highest priority.

Configuring User Zones

There is a configurable process for applications to insert an *ACL* into a zone according to the priority of the application within that zone. Applications can occupy multiple zones. For example, you can add the Cli application to the DOS zone, and assign it a higher priority than the Dos application. The DOS zone then has two applications, Cli and Dos application, and within the DOS zone, an ACL created by the Cli has a higher priority than an ACL inserted by the Dos application.

Another way to configure ACL priority is by creating new zones. For example, you might create a zone called MY_HIGH_ZONE, and assign that zone a priority below the DOS zone and above the System zone. You can add applications to that zone and assign their priority.

The example below shows the ACL zone priority that would result from adding the MacInMac and Cli applications to MY_HIGH_ZONE:

1. SYSTEM_HIGH_ZONE

   hal

2. DOS Zone

    hal

    DoS

3. MY_HIGH_ZONE

    MacInMac

    Cli

4. SYSTEM Zone

    Dot1Ag

    Dot1AgDefault

    MacInMac

    Cli

    NetLogin

5. SECURITY Zone

    FlowVSR

    FlowVSRTS

    Generic Xml

6. SYSTEM_LOW_ZONE

    hal

Applications can insert an ACL into any of the zones to which the application belongs.

If an application attempts to insert an ACL into a zone where the application is not configured, an error message appears, and the ACL is not installed. Therefore, you have full control of ACL priorities and you can configure the switch to install ACLs from an application at any priority level. In the example above, the application Cli can insert an ACL into either MY_HIGH_ZONE or the SYSTEM zone. The location of the ACL within the zone depends on the priority assigned by the application. An application can assign priority to an ACL using:

•   priority attributes (first or last)

•   relative priority

•   priority numbers

The priority attributes first (highest priority) and last (lowest priority) can be applied to an ACL to establish its position within a zone.

Relative priority sets the ACL priority relative to another ACL already installed by the application in the same zone.

Priority numbers allow an application to specify the priority of an ACL within a zone. The priority numbers are unsigned integers from 0 to 7; a lower number represents a higher priority. This means that if an application adds an ACL at priority 5 and later adds another ACL at priority 3, the second ACL has higher priority.

If an application assigns the same priority number to two ACLs, the ACL added most recently has the higher priority. It is inserted in the priority map immediately ahead of the older ACL that has the same priority number. This effectively allows the application to create sub-zones within a zone. The attributes first and last can be used

in combination with priority numbers to prioritize the ACLs within a sub-zone. For example, an ACL could be configured with the first attribute, along with the same priority number as other ACLs in the same zone, effectively assigning that ACL the highest priority within a sub-zone.

The `show configuration` command shows the current configuration of the entire switch in the form of CLI commands which can later be played back to configure the switch.

The `show configuration acl` command shows the current configuration of the ACL manager.

The new **application** keyword allows you to specify the application to which the ACL will be bound. Typically, applications create and insert ACLs on the switch; however the administrator can install ACLs "on behalf" of an application by specifying the **application** keyword. (This keyword is also used with the show config acl command to enable CLI playback). If no application is specified, the default application is CLI.

This means you have the ability to create, delete, and configure ACLs for any application.

- To create a zone, use the following command:

  `create access-list zone` *name* **zone-priority***number*

- To configure the priority of zones, use the following command:

  `configure access-list zone` *name* **zone-priority** *number*

- To add an application to a zone at a particular priority, or to change the priority of an application within a zone, use the following command:

  `configure access-list zone` *name* {**add**} **application***appl-name* **application_priority** *number*

  An application must occupy at least one zone.

- To move an application within a zone or to another zone, use the following command:

  `configure access-list zone` *name* **move-application***appl-name* to-zone*number* **application-priority***number*

  All applications can be configured to go into any and all zones.

  A change in the zone list results in a change in the order of dynamic ACLs that have been applied per interface. The changes in hardware are achieved by uninstalling and then reinstalling the dynamic ACLs in the new positions. There is a possibility, due to hardware constraints, that some ACLs will not be reinstalled. These occurrences are logged.

- To delete an application from a zone, use the following command:

  `configure access-list zone` *name* **delete application** *appl-name*

When you delete an application from a zone, any ACLs that have been inserted into that zone for the deleted application are moved to the next higher zone in which the application appears.

- To delete a zone, use the following command:

```
delete access-list zone name
```

You must remove all applications from a zone before you can delete the zone. You cannot delete the default zones.

Network-Zone Support in ACLs

ExtremeXOS Network-Zone support allows you to create a network-zone, add multiple IP addresses and/or MAC addresses to it, and use the network-zone in policy files.

This feature provides the ability to add a single attribute "source-zone," or "destination-zone" to an entry of a policy file. This entry is then expanded into multiple entries depending upon the number of IP and/or MAC addresses configured in that particular zone. If the zone is added to the policy with the keyword "source-zone," the attributes that are configured in that particular zone are added as either a "source-address" or an "ethernet-source-address" in the policy. Conversely, if the network-zone is added as a "destination-zone," the attributes are added to the policies as a "destination-address," or an "ethernet-destination-address."

After you make changes in the zones and issue a refresh of a specific zone, or all the zones, the policies that have the corresponding zones configured as source-zone or destination-zone in their entries are expanded and refreshed in the hardware.

If you configure the following policy to a port or *VLAN*, or through applications like IdMgr or *Extreme Network Virtualization (XNV)*,

```
Policy: test
entry e1 {
if match all {
source-zone zone1 ;
}
Then {
permit  ;
}
}
```

and the network-zone "zone1" that is part of the policy is configured as below:

```
create access-list network-zone zone1
configure access-list network-zone zone1 add ipaddress 10.1.1.1 255.255.255.255
configure access-list network-zone zone1 add ipaddress 10.1.1.1 255.255.255.240
configure access-list network-zone zone1 add ipaddress 12.1.1.0 255.255.255.0
```

When you refresh the network-zone "zone1," the policy is expanded as follows, and is applied in the hardware:

```
entry Cl0:0_10.1.1.1_E1 {
if match all {
```

```
source-address 10.1.1.1 / 32 ;
} then {
permit  ;
}
}
entry Cl0:0_10.1.1.1_E2 {
if match all {
source-address 10.1.1.1 / 28 ;
} then {
permit  ;
}
}

entry Cl0:0_12.1.1.0_E3 {
if match all {
source-address 12.1.1.0 / 24 ;
} then {
permit  ;
}
}
```

When the policy is configured with the network-zone, the zone may or may not have attributes configured in it. In cases where the network-zone does not have any attributes, the policy is created with entries that do not have the network-zone attribute alone.

So, if you create the following policy:

```
Policy: test2
entry e1 {
if match all {
source-zone zone2 ;
protocol udp ;
}
Then {
permit  ;
}
}
entry e2 {
if match all {
protocol tcp ;
}
Then {
permit  ;
}
}
```

And the network-zone "zone2" is just created, but is not configured with any attributes, the policy appears as follows and has only the second entry "e2," and not "e1".

```
entry e2 {
protocol tcp;
}
Then {
permit;
}
}
```

Once the network-zone "zone2" is configured with one or more attributes, and refreshed, the policy is updated accordingly. In this instance, the name of the entries

that have a source-zone or a destination-zone are changed. This is because each entry in the original policy that has a source-zone/destination-zone is converted to a maximum of eight entries in the new policy.

A single policy can have one or more network-zones configured in it. It can also have the same network-zone in multiple entries with different combinations, as well as support for other attributes in the policy file. Similarly, the same network-zone can be configured to multiple policies. In cases where the policy has multiple network-zones, and only some of those network-zones are refreshed, the entries that correspond to those specific network-zones are alone refreshed, and not entries that correspond to the other network-zones.

After you refresh a network-zone, all the policies that have the specified network-zone are modified, and a refresh for each of those policies is sent to the hardware. The command succeeds only after receiving a successful return for all the policies that have this particular network-zone. If for some reason one of the policy's refresh fails in the hardware, all the policies that are supposed to refresh are reverted back to their previous successful state, and the command is rejected.

Additionally, the configuration or refresh can fail if the attributes in the network-zone are not compatible with the attributes in the corresponding entries of the policy. For example, in platforms that do not support wide-key or UDF, a policy entry cannot have Layer 2 attributes and Layer4 attributes. In such cases, if the entry has "protocol tcp" and a network-zone that has an ethernet source address, the configuration fails in the hardware.

In cases where the refresh fails, the content of the policy and the content of the network-zone may go out of sync, because the policy reverts back to the last successful state, whereas the network-zone will contain the last configured values.

Here is an example:

```
create access-list network-zone zone1
configure access-list network-zone zone1 add ipaddress 10.1.1.1/32
configure access-list network-zone zone1 add ipaddress 10.1.1.1/28
```

Once this configuration is refreshed and is successfully installed in the hardware, the policy will look like the following:

```
entry Cl0:0_10.1.1.1_E1 {
if match all {
source-address 10.1.1.1 / 32 ;
} then {
permit  ;
}
}
entry Cl0:0_10.1.1.1_E2 {
if match all {
source-address 10.1.1.1 / 28 ;
} then {
permit  ;
}
}
```

If you remove 10.1.1.1/28, and adds 10.1.1.1/24 to the network-zone and perform a refresh,

```
configure access-list network-zone zone1 delete ipaddress 10.1.1.1/28
configure access-list network-zone zone1 add ipaddress 12.1.1.0/24
```

and if for some reason the policy refresh fails, the policy and the network-zone will look like this:

```
entry Cl0:0_10.1.1.1_E1 {
if match all {
source-address 10.1.1.1 / 32 ;
} then {
permit  ;
}
}
entry Cl0:0_10.1.1.1_E2 {
if match all {
source-address 10.1.1.1 / 28 ;
} then {
permit  ;
}
}

create access-list network-zone zone1
configure access-list network-zone zone1 add ipaddress 10.1.1.1 255.255.255.255
configure access-list network-zone zone1 add ipaddress 12.1.1.0 255.255.255.0
```

Configuring Network-Zone Support in ACLs

Use the following command to configure the network-zone support in ACLs.:

Creating a Network-Zone

To create a network-zone with the specified name, enter the command below. You can then associate this network-zone with the policy file using either the `source-zone` or `destination-zone` attribute.

```
create access-list network-zone zone_name
```

Here is an example:

```
Switch# create access-list network-zone zone1
```

If you try to create a network-zone that is already created, the following error message is displayed on the console, and the command is rejected:

```
Switch# create access-list network-zone zone1
Error:  Network Zone "zone1" already exists.
```

Deleting a Network-Zone

To delete a network-zone, and all the configurations that belong to the zone, enter the following command:

```
delete access-list network-zone zone_name
```

Here is an example:

```
Switch# delete access-list network-zone zone1
```

If you try to delete a network-zone that is bound with one or more policy files, the following error message is displayed, and the command is rejected:

```
Switch# delete access-list network-zone zone1
Error:  Network Zone "zone1" - Unable to delete zone. Zone has one
or more policies.
```

Adding or Removing Network-Zone Attributes

To add or remove IP/MAC addresses to or from the network-zone, enter the following command:

configure access-list network-zone *zone_name* [**add** | **delete**] [**mac-address** *macaddress* {*macmask*} | **ipaddress** [*ipaddress* {*netmask*} | *ipNetmask* | *ipv6_address_mask*]]

Here is an example:

```
Switch# configure access-list network-zone zone1 add ipaddress 11.1.1.1/24
```

If you try to add the same IP/MAC with the same or narrow mask, the configuration is rejected, with the following error message:

```
Switch# configure access-list network-zone "zone1" add ipaddress 11.1.1.1/32
Error:  Network Zone "zone1" - Zone already has the same entity value with same or wider
mask.
```

If the you try to add more than eight attributes to a network-zone, the following error message is issued:

```
Switch# configure access-list network-zone "zone1" add ipaddress 11.1.1.1/24
Error:  Network Zone "zone1" - Reached maximum number of attributes. Unable to add more.
```

Refreshing Network-Zones

To refresh a specific network-zone, or all the network-zones, enter the following command:

refresh access-list **network-zone** [*zone_name* | **all**]

Here is an example:

```
Switch# refresh access-list network-zone zone1
```

> **Note**
> When you issue the command to refresh a network-zone, or all network-zones, it can take a long time to clear the CLI because each individual policy must be converted before it is refreshed. The command succeeds, or fails, only after it receives a success response for all policy refresh, or when a first refresh failure is received from the hardware.

If the refresh fails for a specific zone, the following error message is printed on the console.

```
Switch# refresh access-list network-zone zone1
Error: Refresh failed for network-zone "zone1".
```

Monitoring Network-Zone Support in ACLs

show access-list network-zone

To monitor various network statistics, use the `show access-list network-zone` command. This command's output displays the network-zones configured, the number of attributes configured, and the number of policy files that has the specific zones in it.

Example

```
Switch# sh access-list network-zone
=============================================================
Network Zone                        No. of    No. of Policies
Entities      Bound
=============================================================
zone1                                  5            2
zone2                                  3            1
zone3                                  0            0
=============================================================
Total Network Zones : 3
```

The following example displays detailed information about a specific network zone, the attributes configured in the zone, and the policies bound to the zone:

```
Switch# show access-list network-zone zone1
Network-zone     : zone1
Total Attributes : 3
Attributes       : 10.1.1.1 / 32
10.1.1.1 / 30
10.1.1.0 / 24
No. of Policies  : 1
Policies         : test
Switch # sh access-list network-zone zone2
Network-zone     : zone2
No. of Entities  : 3
Entities         : 00:00:00:00:00:22 / ff:ff:ff:ff:ff:ff
00:00:00:00:00:23 / ff:ff:ff:ff:00:00
00:00:00:00:00:24 / ff:ff:ff:ff:ff:00
No. of Policies : 0
```

CVID ACL Match Criteria

This feature adds support for the EXOS *ACL* match criteria "cvid." It provides the ability to specify access-lists that filter on the inner-*VLAN*-id field of a double tagged packet, the customer VLAN id field of a single tagged packet entering a VMAN UNI/CEP port, or the port-cvid inserted into an untagged packet entering a VMAN UNI port. You can use this feature to perform service-level, or customer-level (cvid) rate-limiting and accounting.

You can utilize this match criteria in the following scenarios:

- Tagged VMAN ports: installing an ACL matching "cvid" on ingress or egress will match the inner vlan-id of a double tagged packet on a tagged VMAN port.
- Untagged VMAN ports: installing an ACL matching "cvid" on ingress or egress will match the single VLAN tag on an untagged VMAN port.

- CEP VMAN ports (with or without VPLS): installing an ACL matching "cvid" on ingress or egress will match the single VLAN tag on a CEP VMAN port (without translation).
- CEP VMAN ports with cvid translation (with or without translation): installing an ACL matching "cvid" on ingress will match the post-translation cvid. Installing an ACL matching "cvid" on egress will match the post-translation cvid.

As an example of CEP VMAN ports, consider the following configuration:

```
create vman vm1 tag 100
config vman vm1 add port 1 cep cvid 7 translate 8
config vman vm1 add port 2 tag
```

Now consider the following ACL policy applied to "access" port 1:

```
      test.pol:
      entry one {
        if {
            cvid 7;
          } then {
              count count7;
          }
      }
      entry two {
         if {
            cvid 8;
          } then {
              count count8;
          }
      }
      config access-list test port 1
      config access-list test port 1 egress
```

This results in "count8" incrementing for ingress, and "count7" incrementing on egress.

Here is another example policy:

```
entry one {
        if{
          cvid 7;
          vlan-id 100;    #SVID
        } then {
            count foo;
        }
      }
```

And here's an example that allow you to perform service-level, or customer-level (cvid) rate-limiting and accounting:

```
doubletag.pol:
            entry customer1 {
              if{
                 cvid 8;
              } then{
                  count cust1;
              }
            }
create vman vm1 tag 100
config vman vm1 add port 21
config vman vm1 add port 22 tag
config access-list doubletag port 21
config access-list doubletag port 21 egress
```

Limitations

The CVID ACL match criteria support has the following limitations:

- Any platform that does not support egress ACLs will not support this match criteria on egress.
- Using "cvid" with an egress ACL will not match egress packets matching the port-cvid (since the cvid will be stripped).
- Using "cvid" does not provide symmetrical results when you apply them to VMAN CEP ports that also enable cvid translation. Ingress ACLs match the CVID after ingress translation, while egress ACLs also match the CVID after egress translation.

Supported Platforms

CVID ACl match criteria is supported on all platforms.

CCOS ACL Match Criteria

This feature adds support for the ExtremeXOS *ACL* match criteria `ccos`. It provides the ability to specify access-lists that filter on the inner-dot1p field of double tagged packet.

```
entry one {

if {

ccos 3;
} then {

meter m1;
count c1;
}
}
```

ACL Evaluation Precedence

The section Precedence on page 823 describes *ACL* evaluation precedence for different platforms.

Precedence

This section describes the precedence for evaluation among *ACL* rules for ExtremeSwitching series switches. In many cases there will be more than one ACL rule entry for an interface. This section describes how multiple rule entries are evaluated.

Multiple rule entries do consume hardware resources. If you find that your situation runs up against those limits, there are steps you can take to conserve resources by modifying the order of the ACL entries that you create. For details, see ACL Mechanisms on page 829.

Rule Evaluation

When there are multiple rule entries applied to an interface, evaluation proceeds as follows:

- A packet is compared to all the rule entry match conditions at the same time.
- For each rule where the packet matches all the match conditions, the action and any action modifiers in the then statement are taken. If there are any actions or action modifiers that conflict (deny vs. permit, etc), only the one with higher precedence is taken.
- If a packet matches no rule entries in the *ACL*, it is permitted.

Often there will be a lowest-precedence rule entry that matches all packets. This entry will match any packets not otherwise processed, so that the user can specify an action to overwrite the default permit action. This lowest-precedence rule entry is usually the last entry in the ACL policy file applied to the interface.

Precedence of Dynamic ACLs

Dynamic ACLs have a higher precedence than any ACLs applied using policy files. The precedence among any dynamic ACLs is determined as they are configured. The precedence of ACLs applied using policy files is determined by the rule's relative order in the policy file.

Precedence of L2/L3/L4 ACL Entries

Rule precedence is solely determined by the rule's relative order. L2, L3, and L4 rules are evaluated in the order found in the file or by dynamic *ACL* configuration.

Precedence Among Interface Types

As an example of precedence among interface types, suppose a physical port 1:2 is a member port of the *VLAN* yellow. *ACL*s could be configured on the port, either singly or as part of a port list, on the VLAN yellow, and on all ports in the switch (the wildcard ACL). For all packets crossing this port, the port-based ACL has highest precedence, followed by the VLAN-based ACL and then the wildcard ACL.

Precedence with Egress ACLs

Egress *ACL*s are supported on ExtremeSwitching X450-G2, X460-G2, X465, X440-G2, X590, X620, X695 series switches. For these, egress ACL lookup happens at egress, and diffserv, dot1p and other non-ACL feature examination happen at ingress. Therefore, egress ACL happens at the last moment and has precedence.

Redundant Rules

For ExtremeSwitching series switches, eliminate redundant rules (any with the EXACT same match criteria) in the policy file. If two rules have identical match conditions, but different actions, the second rule is rejected by the hardware.

For example, the two following *ACL* entries are not allowed:

```
entry DenyNMR {
    if {
        protocol 17;
        destination-port 161;
```

```
    } then {
        deny;
        count denyNMR;
    }
}
entry DenyNIC {
    if {
        protocol 17;
        destination-port 161;
    } then {
        deny;
        count denyNIC;
    }
}
```

Applying ACL Policy Files

A policy file intended to be used as an *ACL* is applied to a port, *VLAN*, or to all interfaces (the any keyword). Use the name of the policy file for the `aclname` parameter in the CLI command. To apply an ACL policy, use the following command:

configure access-list *aclname* [**any** | **ports** *portlist* | **vlan** *vlanname*] {**ingress** | **egress**}

If you use the **any** keyword, the ACL is applied to all the interfaces and is referred to as the wildcard ACL. This ACL is evaluated for any ports without specific ACLs, and it is also applied to any packets that do not match the specific ACLs applied to the interfaces.

If an ACL is already configured on an interface, the command will be rejected and an error message displayed.

To remove an ACL from an interface, use the following command:

unconfigure access-list *aclname* [**any** | **ports** *portlist* | **vlan** *vlanname*] {**ingress** | **egress**}

To display which interfaces have ACLs configured, and which ACL is on which interface, use the following command:

show access-list *aclname* [**any** | **ports** *portlist* | **vlan** *vlanname*] {**ingress** | **egress**}

> **Note**
> If an ACL needs to be installed for traffic that is L3 routed, and the ingress/ egress ports are on different packet-processing units or different slots, and any of the following features are enabled, we recommend that you install the policy on a per-port basis rather than applying it as a wildcard, or VLAN-based ACL.
> - *MLAG (Multi-switch Link Aggregation Group)*
> - PVLAN
> - Multiport-*FDB (forwarding database)*

Displaying and Clearing ACL Counters

To display the *ACL* counters, use the following command:

```
show access-list counter {countername} {any | ports port_list | vlan
vlan_name} {ingress | egress}
```

To clear the access list counters, use the following command:

```
clear access-list {dynamic} counter {countername} {any | ports port_list
| vlan vlan_name} {ingress | egress}
```

Example ACL Rule Entries

The following entry accepts all the UDP packets from the 10.203.134.0/24 subnet that are destined for the host 140.158.18.16, with source port 190 and a destination port in the range of 1200 to 1250:

```
entry  udpacl {
    if  {
        source-address 10.203.134.0/24;
        destination-address 140.158.18.16/32;
        protocol  udp;
        source-port 190;
        destination-port  1200 - 1250;
    } then {
        permit;
    }
}
```

The following rule entry accepts TCP packets from the 10.203.134.0/24 subnet with a source port larger than 190 and ACK & SYN bits set and also increments the counter tcpcnt. The packets will be forwarded using *QoS* profile QP3.

```
entry  tcpacl {
    if  {
        source-address 10.203.134.0/24;
        protocol  TCP;
        source-port > 190;
        tcp-flags  syn_ack;
    } then {
        permit;
        count tcpcnt ;
        qosprofile qp3;
    }
}
```

The following example denies *ICMP* echo request (ping) packets originating from the 10.203.134.0/24 subnet, and increments the counter icmpcnt:

```
entry  icmp {
    if  {
        source-address 10.203.134.0/24;
        protocol  icmp;
        icmp-type  echo-request;
    } then {
        deny;
        count icmpcnt;
    }
}
```

The following example prevents TCP connections from being established from the 10.10.20.0/24 subnet, but allows established connections to continue, and allows TCP connections to be established to that subnet. A TCP connection is established by sending a TCP packet with the SYN flag set, so this example blocks TCP SYN packets.

```
entry  permit-established {
    if  {
        source-address 10.10.20.0/24;
        protocol  TCP;
        tcp-flags  syn;
    } then {
        deny;
    }
}
```

The following entry denies every packet and increments the counter default:

```
entry  default {
    if  {
    } then {
        deny;
        count default;
    }
}
```

The following entry permits only those packets with destination MAC addresses whose first 32 bits match 00:01:02:03:

```
entry rule1 {
    if {
        ethernet-destination-address 00:01:02:03:01:01 ff:ff:ff:ff:00:00 ;
    } then {
        permit  ;
    }
}
```

The following entry denies IPv6 packets from source addresses in the 2001:db8:c0a8::/48 subnets and to destination addresses in the 2001:db8:c0a0:1234::/64 subnets:

```
entry ipv6entry {
    if {
        source-address 2001:DB8:C0A8:: / 48;
        destination-address 2001:DB8:C0A0:1234:: / 64;
    } then {
        deny;
    }
}
```

Access lists have entries to match an Ethernet type, so be careful when configuring access lists to deny all traffic. For example, the following rule entries permit traffic only to destination 10.200.250.2 and block any other packet.

```
entry test_policy_4 {
    if {
        source-address 0.0.0.0/0;
```

```
          destination-address 10.200.250.2/32;
     } then {
          permit;
          count test_policy_permit;
     }
}
# deny everyone else
entry test_policy_99 {
     if {
     } then {
          deny;
          count test_policy_deny;
     }
}
```

Since the deny section does not specify an Ethernet type, all traffic other than IP packets destined to 10.200.250.2/32 are blocked, including the ARP packets. To allow ARP packets, add an entry for the Ethernet type, 1x0806, as shown below.

```
entry test_policy_5 {
     if {
          ethernet-type 0x0806;
     } then {
          permit;
          count test_policy_permit;
     }
}
```

The following entries use vlan-ids to set up meters based on individual VLANs.

```
myServices.pol
     entry voiceService {
          if {
               vlan-id 100;
          } then {
               meter voiceServiceMeter;
          }
     }
     entry videoService {
          if {
               vlan-id 101;
          } then {
               meter videoServiceMeter;
          }
     }
…and so on.
```

To bind this ACL to a port with vlan-id match criteria use the following command:

```
config access-list myServices port <N>
```

The following entry shows how to take action based on *VLAN* tag priority information. In this example, the **dot1p** match keyword is used to allow and count every tagged packet with a VLAN priority tag of 3.

```
entry count_specific_packets {
     if {
          dot1p 3;
     } then {
          count allowed_pkts;
```

```
        permit;
    }
}
```

ACL Mechanisms

For many applications of _ACL_s, it is not necessary to know the details of how ACLs work. However, if you find that your application of ACLs is constrained by hardware limitations, you can often rearrange the ACLs to use the hardware more efficiently. The following sections go into some detail about how the ACLs use hardware resources, and provide some suggestions about how to reorder or rewrite ACLs to use fewer resources.

- ACL Slices and Rules.
- ACL Counters—Shared and Dedicated.

ACL Slices and Rules

The ExtremeSwitching series switches use a mechanism different from the earlier ExtremeSwitching series to implement _ACL_s. The same architecture and guidelines apply to both platforms.

Instead of the per port masks used in earlier switches, these platforms use slices that can apply to any of the supported ports. An ACL applied to a port may be supported by any of the slices.

The slice support is as follows:
- ExtremeSwitching X450-G2 switches—
  - Each group of 48 ports has 4 slices with each slice having enough memory for 256 egress rules, which adds up to 1024 rules.
  - Each group of 48 ports has 16 slices with each slice having enough memory for 256 ingress rules, which adds up to 4,096 ingress rules.
- ExtremeSwitching X460-G2 switches—
  - Each group of 48 ports has 4 slices with each slice having enough memory for 256 egress rules, which adds up to 1,024 rules.
  - Each group of 48 ports has 16 slices with each slice having enough memory for 256 ingress rules , which adds up to 4,096 ingress rules.
- ExtremeSwitching X440-G2 switches—
  - Each group of 24 ports has 4 slices with each slice having enough memory for 128 egress rules, which adds up to 512 rules.
  - Each group of 24 ports has 8 slices with each slice having enough memory for 256 ingress rules, which adds up to 2,048 ingress rules.
- ExtremeSwitching X620 switches—
  - Each group of 10/16 ports has 4 slices with each slice having enough memory for 128 egress rules, which adds up to 512 rules.
  - Each group of 10/16 ports has 8 slices with each slice having enough memory for 256 ingress rules, which adds up to 2,048 ingress rules.

- ExtremeSwitching X590 switches—
  - Four slices of 256 egress rules, for a total of 1,024 rules.
  - Each group of 48 ports has up to 12 slices with a total capacity of 8K single-wide rules ingress rules.
- ExtremeSwitching X465 switches—
  - Four slices of 256 egress rules, for a total of 1,024 rules.
  - Each group of 48 ports has up to 12 slices with a total capacity of 8K single-wide rules ingress rules.
- ExtremeSwitching X435 switches—
  - 1,024 single-wide rules, for 128 per slice.
- ExtremeSwitching X695 switches—
  - Four VLAN look-up stage slices with 1,024 rules.
  - Twelve ingress stage slices with 18,000 rules.
  - Four egress stage slices with 2,000 rules.

ACL Allocation to Slices—All Platforms

A single slice can implement ACLs that are applied to more than one port. When an ACL entry is applied, if its match conditions do not conflict with an already existing ACL, the entry is added to the rule memory of an already populated slice.

When ACLs are applied, the system programs each slice to select parts of the packet information to be loaded into it. For example, one possible way a slice can be programmed allows it to hold the information about a packet's ingress port, source and destination IP address, IP protocol, source and destination Layer 4 ports, DSCP value, TCP flag, and if it is a first fragment. Any rule entry that consists of match conditions drawn from that list is compatible with that slice. This list of conditions is just one example. A complete description of possible ways to program a slice is discussed in Compatible and Conflicting Rules on page 832.

In the following example, the two rule entries are compatible and require only one slice in hardware even though they are applied to different ports. The following entry is applied to port 1:

```
entry ex_A {
    if {
        source-address 10.10.10.0/24 ;
        destination-port 23 ;
        protocol tcp ;
    } then {
        deny ;
    }
}
```

and the following entry is applied to port 2:

```
entry ex_B {
    if {
        destination-address 192.168.0.0/16 ;
        source-port 1000 ;
        protocol tcp ;
    } then {
```

```
         deny ;
    }
}
```

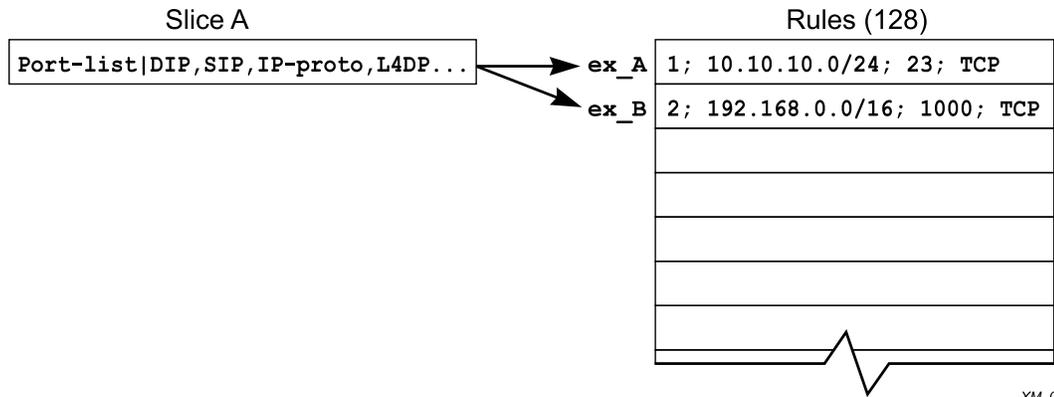
Both of these ACLs could be supported on the same slice, since the match conditions are taken from the example list discussed earlier. This example is shown in the following figure. In the example, we refer to slice A, even though the slices are numbered. Slice A just means that one slice is used, but does not specify a particular slice. Some rules require more than one slice, so we use letters to show that different slices are used, but not which specific slices.


Figure 98: ACL Entry ex_A and ex_B

There are cases where compatible ACLs require using a different slice. If the memory associated with a slice is filled with rule entries, then another slice will be used to process any other compatible entries.

For example, consider the following 129 rule entries applied to ports 3-7:

```
entry one {
    if {
        source-address 10.66.10.0/24 ;
        destination-port 23 ;
        protocol tcp ;
    } then {
        deny ;
    }
}
entry two {
    if {
        destination-address 192.168.0.0/16 ;
        source-port 1000 ;
        protocol tcp ;
    } then {
        deny ;
    }
}
entry three {
    if {
        source-address 10.5.2.246/32 ;
        destination-address 10.0.1.16/32 ;
        protocol udp ;
        source-port 100 ;
        destination-port 200 ;
    } then {
        deny ;
```

```
        }
    }
    ....
    [The 125 intervening entries are not displayed in this example]
    ....
    entry onehundred_twentynine {
        if {
            protocol udp ;
            destination-port 1714 ;
        } then {
            deny ;
        }
    }
```

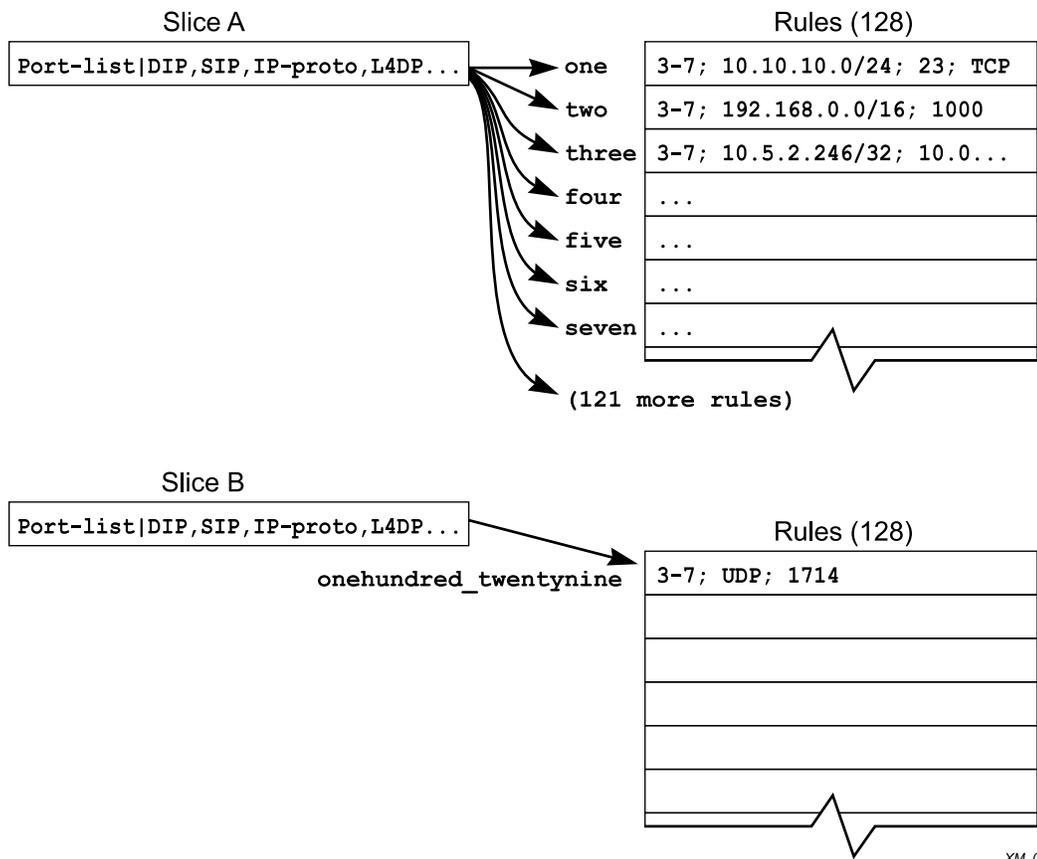
The following figure shows the result of applying the 129 entries; 128 of the entries are applied to one slice, and the final entry is applied to a different slice. If another compatible entry is applied from another port, for example, it will use Slice B.


Figure 99: ACL Entry one Through onehundred_twentynine

As entries are configured on the switch, the slices are programmed to implement the rules, and the rule memory is filled with the matching values for the rules. If a compatible slice is available, each entry is added to that slice.

Compatible and Conflicting Rules

The slices can support a variety of different *ACL* match conditions, but there are some limitations on how you combine the match conditions in a single slice. A slice is divided up into fields, and each field uses a single selector. A selector is a combination of

match conditions or packet conditions that are used together. To show all the possible combinations, the conditions in Table 73 are abbreviated.

Table 73: Abbreviations Used in Field Selector Table

Abbreviation	Condition
Ingress	
DIP	destination address <prefix> (IPv4 addresses only)
DIPv6/128	destination address <prefix> (IPv6 address with a prefix length longer than 64)
DIPv6/64	destination address <prefix> (IPv6 address with a prefix length up to 64)
DSCP	dscp <number>
Etype	ethernet-type <number>
First Fragment	first ip fragment
FL	IPv6 Flow Label
Fragments	fragments
IP-Proto	protocol <number>
L4DP	destination-port <number> (a single port)
L4-Range	A Layer 4 port range. For example, if you specify "protocol UDP" and "port 200 - 1200" in an entry, you have used a Layer 4 range. There are a total of sixteen Layer 4 port ranges. Also, you can have a source port range, or a destination port range, but not both kinds of ranges together in the same entry.
L4SP	source-port <number> (a single port)
MACDA	ethernet-destination-address <mac-address> <mask>
MACSA	ethernet-source-address <mac-address>
NH	IPv6 Next Header field. Use protocol <number> to match. See IP-Proto
OVID	This is not a match condition used in ACLs, but is used when an ACL is applied to VLANs. An ACL applied to a port uses a different field selector than an ACL applied to a VLAN. VLAN IDs are outer VLAN IDs unless specified as inner VLAN IDs.
packet-type	This selector is used internally and not accessible by users through explicit ACLs.
Port-list	This is not a match condition used in ACLs, but is used when an ACL is applied to ports, or to all ports (the wildcard ACL). An ACL applied to a port uses a different field selector than an ACL applied to a VLAN.
SIP	source address <prefix> (IPv4 addresses only)
SIPv6/128	source address <prefix> (IPv6 address with a prefix length longer than 64)
SIPv6/64	source address <prefix> (IPv6 address with a prefix length up to 64)

Table 73: Abbreviations Used in Field Selector Table (continued)

Abbreviation	Condition
TC	IPv6 Traffic Class field. Use dscp <number>
TCP-Flags	TCP-flags <bitfield>
TPID	802.1Q Tag Protocol Identifier
TTL	Time-to-live
UDF	User-defined field. This selector is used internally and not accessible by users through explicit ACLs.
VID-inner	Inner VLAN ID
VRF	virtual router and forwarding instance
Egress	
DestIPv6	destination-address <ipv6>
DIP	destination-address
Etype	ethernet-type
IP-Proto	protocol
L4DP	destination-port. Support only single L4 ports and not port ranges.
L4SP	source-port. Support only single L4 ports and not port ranges.
MACDA	ethernet-destination-address
MACSA	ethernet-source-address
NH	IPv6 Next Header field.
SIP	source-address
SIPv6	source-address <ipv6>
TC	IPv6 Traffic Class field.
Tcp-Flags	tcp-flags
TOS	ip-tos or diffserv-codepoint
VlanId	vlan-id

The following ingress conditions are not supported on egress:

- fragments
- first-fragment
- IGMP-msg-type
- ICMP-type
- ICMP-code

Table 74 lists all the combinations of match conditions that are available. Any number of match conditions in a single row for a particular field may be matched. For example if Field 1 has row 1 (Port-list) selected, Field 2 has row 8 (MACDA, MACSA, Etype,

OVID) selected, and Field 3 has row 7 (Dst-Port) selected, any combination of Port-list, MACDA, MACSA, Etype, OVID, and Dst-Port may be used as match conditions.

If an ACL requires the use of field selectors from two different rows, it must be implemented on two different slices.

Table 74: Field Selectors for ExtremeSwitching Series Switches

Fixed Field	Field 1	Field 2	Field 3
Port-list	OVID, VID-inner	DIP, SIP, IP-Proto, L4DP, L4SP, DSCP, IPFlag, TCP-Flag	OVID
	Etype, OVID	DIP, SIP, IP-Proto, L4DP, L4SP, DSCP, IpInfo(First-Fragment, Fragments) TCP-Flag	OVID, IpInfo(First-Fragment, Fragments)
	VID-inner	DIPv6/128	OVID, VID-inner
	IpInfo(First-Fragment, Fragments), OVID	SIPv6/128	OVID, Etype
	OVID	DIPv6/64, IP-Proto, DSCP, FL, TCP-Flag	VID-Inner
	IP-Proto, DSCP	MACDA, MACSA, OVID, Etype	L4-Range
	"User Defined Field" 1b	MACSA, OVID, Etype, SIP	FL
		MACDA, OVID, Etype, DIP, IP-Proto	UDF1[95..64]
		"User Defined Field" 1	
		"User Defined Field" 2	
		DIPv6/64, SIPv6/64	

Egress ACLs

Each of the four egress slices can be configured to one of the three combinations below. The rules that can be installed into a particular slice should be a subset of the combination to which that slice is configured.

The following are available combinations:

- Combination 1:

```
<vlan-id, ethernet-source-address, ethernet-destination-address,
ethernet-type>
```

- Combination 2:

```
<vlan-id, diffserv-codepoint/ip-tos, destination-address, source-
address, protocol, destination-port, source-port, tcp-flags>
```

- Combination 3:

```
<vlan-id, ip-tos, destination-address<ipv6>, source-address<ipv6>,
protocol>
```

Use the the tables inCompatible and Conflicting Rules on page 832 to determine which *ACL* entries are compatible. If the entries are compatible, they can be on the same slice.

For example, the earlier example entries are applied to ports:

```
entry ex_A {
    if {
        source-address 10.10.10.0/24 ;
        destination-port 23 ;
        protocol tcp ;
    } then {
        deny ;
    }
}
entry ex_B {
    if {
        destination-address 192.168.0.0/16 ;
        source-port 1000 ;
    } then {
        deny ;
    }
}
```

Entry ex_A consists of the following conditions (using the abbreviations from the following table), SIP, L4DP, and IP-Proto. Entry ex_B is DIP, L4SP. Since they are applied to ports, the selector for Field 1 is Port-list (the first item). The selector for Field 2 would be the first item, and Field 3 could be any item.

Our other example entries are also compatible with the entries ex_A and ex_B:

```
entry one {
    if {
        source-address 10.66.10.0/24 ;
        destination-port 23 ;
        protocol tcp ;
    } then {
        deny ;
    }
}
entry two {
    if {
        destination-address 192.168.0.0/16 ;
        source-port 1000 ;
    } then {
        deny ;
    }
}
entry three {
    if {
        source-address 10.5.2.246/32 ;
        destination-address 10.0.1.16/32 ;
        protocol udp ;
        source-port 100 ;
        destination-port 200 ;
    } then {
        deny ;
    }
}
```

Entry one is SIP, L4DP, and IP-Proto; entry two is DIP, and L4SP; entry three is SIP, DIP, IP-Proto, L4SP, and L4DP. All of these examples can use the first item in Field 2 in the tables.

However, if we add the following entry:

```
entry alpha {
    if {
        ethernet-destination-address 00:e0:2b:11:22:33 ;
    } then {
        deny ;
    }
}
```

This will not be compatible with the earlier one. Entry alpha is MACDA, and there is no MACDA in the first item for Field 2. Any entry with MACDA will have to use selector 7 or 8 from the following table (or 6 or 7 from the following table, depending on the platform). If an entry requires choosing a different selector from the table, it is not compatible and must go into a different slice.

Single Virtual Group for User ACLs

Prior to ExtremeXOS 16.1, when two user rules in two separate slices are matched by a packet, the non-conflicting actions from both of the rules are executed. This feature allows you to put all user rules into a single virtual group. When rules are in a single virtual group, even when two rules in two separate virtual slices are matched, only the actions of the highest precedence rule are executed. In effect, in this mode, multiple slices behave as a big single virtual slice.

Normally _ACL_ hardware works in the following way: on arrival of a packet, all N slices are searched in parallel to find a possible match in each of these N slices. In each slice, upon finding the first match, the search within that slice stops. In other slices the search continues until a match is found or the end of the slice is reached. Thus, a single slice can produce only a single match, but all N slices combined together can produce up to N matches for a given packet.

In the case of multiple matches in multiple slices, all the actions of the rule in the highest priority virtual slice are executed. In addition, all the actions from the lower priority rules from the lower priority virtual slices are executed if those additional actions do not conflict with the actions of the highest priority rule. An example of non-conflicting with each other actions would be "permit" and "count". An example of conflicting with each other actions would be "permit" and "deny".

However, in more recent chipsets a new mode of operation was introduced where you can combine a few virtual slices into one big virtual group. In this mode of operation, even if a packet gets multiple matches from multiple virtual slices within the same virtual group, only the actions of the highest priority rule are executed, whereas the actions from the lower priority rules are not executed at all, even if those actions do not conflict with the actions of the highest priority rule.

This feature allows choosing between the old way of operation where every virtual slice is in its own virtual group and multiple matches are possible, and the new way, where

all user ACL's virtual slices are in the same virtual group and multiple matches are not possible.

> **Note**
> Some platforms that do not support virtual groups. On those chipsets even if single virtual group feature is enabled, ACL will operate in the old way and multiple matches would be still possible.

Rule Evaluation and Actions

When a packet ingresses the switch, its header is loaded into all the slices, and the header value is compared with the rule values. If the values match, the rule action is taken. Conflicting actions are resolved by the precedence of the entries. However, if rule entries are on different slices, then ACL counters can be incremented on each slice that contains a counter-incrementing rule.

Slice and Rule Use by Feature

A number of slices and rules are used by features present on the switch. You consume these resources when the feature is enabled.

- dot1p examination - enabled by default - 1 slice, 8 rules per chip
  - Slice A (F1=Port-list, F2=MACDA, MACSA, Etype, VID, F3=packet-type)
- IGMP (Internet Group Management Protocol) snooping - enabled by default - 2 slice, 2 rules
  - Slice A (F1=Port-list, F2=MACDA, MACSA, Etype, VID, F3=packet-type)
  - Slice B (F1=Port-list, F2=MACDA, MACSA, Etype, VID, F3=IP-Proto, TOS)
- VLAN without IP configured - 2 rules - 2 slices
  - Slice A (F1=Port-list, F2=MACDA, MACSA, Etype, VID, F3=packet-type)
  - Slice C (F1=Port-list, F2=SIP, DIP, IP-proto, L4SP, L4DP, DSCP, F3=packet-type)
- IP interface - disabled by default - 2 slices, 3 rules (plus IGMP snooping rules above)
  - Slice A (F1=Port-list, F2=MACDA, MACSA, Etype, VID, F3=packet-type)
  - Slice C (F1=Port-list, F2=SIP, DIP, IP-proto, L4SP, L4DP, DSCP, F3=packet-type)
- VLAN QoS - disabled by default - 1 slice, n rules (n VLANs)
  - Slice A or B (F1=Port-list, F2=MACDA, MACSA, Etype, VID, F3=anything)
- port QoS - disabled by default - 1 slice, 1 rule
  - Slice D (F1=anything, F2=anything, F3=anything)
- VRRP (Virtual Router Redundancy Protocol) - 2 slices, 2 rules
  - Slice A (F1=Port-list, F2=MACDA, MACSA, Etype, VID, F3=packet-type)
  - Slice A or B (F1=Port-list, F2=MACDA, MACSA, Etype, VID, F3=anything)
- EAPS (Extreme Automatic Protection Switching) - 1 slice, 1 rule (master), n rules (transit - n domains)
  - Slice A or B (F1=Port-list, F2=MACDA, MACSA, Etype, VID, F3=anything)
- ESRP (Extreme Standby Router Protocol) - 2 slices, 2 rules
  - Slice A (F1=Port-list, F2=MACDA, MACSA, Etype, VID, F3=packet-type)
  - Slice A or B (F1=Port-list, F2=MACDA, MACSA, Etype, VID, F3=anything)

- IPv6 - 2 slices, 3 rules
  - Slice A or B (F1=Port-list, F2=MACDA, MACSA, Etype, VID, F3=anything)
  - Slice (F1=Port-list, F2=DIPv6, IPv6 Next Header Field, TC, F3=anything)
- Netlogin - 1 slice, 1 rule
  - Slice A or B (F1=Port-list, F2=MACDA, MACSA, Etype, VID, F3=anything)
- VLAN Mirroring - 1 slice, n rules (n VLANs)
  - Slice E (F1=Port-list, F2=MACDA, MACSA, Etype, VID, F3=anything)
- Unicast Multiport *FDB*
  - 1 slice, 1+n rules in 24 port ExtremeSwitching series switches
  - 1 slice, 2+ n rules in 48 port ExtremeSwitching series and G48Ta, G48Pe cards
- VLAN Aggregation
  - 1 slice, 4 rules for the first subvlan configured and 1 slice, 2 rules for subsequent subvlan configuration
- Private VLAN
  - 2 slices, 3 rules when adding an non-isolated VLAN with loop-back port a to private VLAN
  - 1 slice, 3 rules when adding an isolated subscriber VLAN (without loopback port) to a private VLAN. 3 additional rules when a loopback port is configured in the above isolated subscriber VLAN
- ESRP Aware - 1 slice, 1 rule
  - Field 1: {Drop, OuterVlan, EtherType, PacketFormat, HiGig, Stage, StageIngress, Ip4, Ip6}
  - Field 2: {SrcIp, DstIp, L4SrcPort, L4DstPort, IpProtocol, DSCP, Ttl, Ip6HopLimit, TcpControl, IpFlags}
  - Field 3: {RangeCheck}
- *ACL* rule with mirror action is installed in a separate slice, and this slice cannot be shared by other rules without a mirror action.

> **Note**
> The user ACLs may not be compatible with the slice used by this ESRP rule. This may result in the reduction the number of rules available to the user by 127.

> **Note**
> Additional rule is created for every active IPv6 interface and for routes with prefix greater than 64 in following cards for Black Diamond. These rules occupy a different slice. G48Ta,10G1xc,G48Te, G48Pe, G48Ta, G48Xa, 10G4Xa, 10G4Ca, G48Te2, G24Xc, G48Xc, G48Tc, 10G4Xc, 10G8Xc, S-G8Xc, S-10G1Xc.

To display the number of slices used by the ACLs on the slices that support a particular port, use the following command:

```
show access-list usage acl-slice port port
```

To display the number of rules used by the ACLs on the slices that support a particular port, use the following command:

```
show access-list usage acl-rule port port
```

To display the number of Layer 4 ranges used by the ACLs on the slices that support a particular port, use the following command:

```
show access-list usage acl-range port port
```

System Configuration Example

The following example shows incremental configurations and their corresponding *ACL* resource consumption taken on a switch.

- Default configuration including: dot1p examination and *IGMP* snooping:
  - ◦ 2 slices, 10 rules
- Add an IP interface to the configuration:
  - ◦ 2 slices, 13 rules
- Add port-based *QoS* to the configuration:
  - ◦ 2 slices, 14 rules
- Add *VLAN*-based QoS to the configuration:
  - ◦ 2 slices, 15 rules
- Add *VRRP* to the configuration:
  - ◦ 2 slices, 17 rules
- Add *EAPS* (Master mode) to the configuration:
  - ◦ 2 slices, 18 rules
- Add *ESRP* to the configuration:
  - ◦ 2 slices, 21 rules
- Add IPv6 routing (slowpath) to the configuration:
  - ◦ 4 slices, 24 rules
- Add Netlogin to the configuration:
  - ◦ 5 slices, 25 rules

ACL Error Messages

Errors may happen when installing an *ACL* policy on a port, *VLAN*, or all interfaces (wildcard). Following is a list of the most common error conditions and their resulting CLI error message:

- `Error: ACL install operation failed - slice hardware full for port 3:1`

  Slice resource exceeded: This happens when all slices are allocated for a given chip and an additional incompatible rule (see Egress ACLs on page 835) is installed which requires allocation of another slice.
- `Error: ACL install operation failed - rule hardware full for port 3:1`

  Rule resource exceeded: This happens when all slices are allocated for a given chip and there is an attempt to install a compatible rule to the lowest precedence slice which already has 128 rules. This condition can be triggered with less than the full capacity number of rules installed. For example, if 15 of the slices each have less than 128 rules and there is an attempt to install 129 compatible rules, this error message will be displayed.

- `Error: ACL install operation failed - layer-4 port range hardware full for port 3:1`

  Layer-4 port range exceeded: This happens when more than 32 Layer 4 port ranges are installed on a single chip.
- `Error: ACL install operation failed - conditions specified in rule "r1" cannot be satisfied by hardware on port 3:1`

  Incompatible fields selected: This happens when the selected conditions can not be satisfied by the available single-slice field selections described in Compatible and Conflicting Rules on page 832.
- `Error: ACL install operation failed - user-defined-field (UDF) hardware full for port 3:1`

  UDF exceeded: This happens in the rare case that the two available user-defined fields are exceeded on a given chip. UDF fields are used to qualify conditions that are not natively supported by the hardware. Some ACL rules that use UDF are: Source MAC address + Destination IP address combination, Destination MAC address + Source IP address combination, *ICMP* Type, and ICMP Code.

ACL Counters-Shared and Dedicated

You can configure rule compression in *ACL*s to be either shared or dedicated.

In the dedicated mode, ACL rules that have counters are assigned a separate rule space and the counter accurately shows the count of matching events. If the ACL with counter is applied to ports 1 and 2, and 10 packets ingress via port 1 and 20 packets ingress via port 2, the ACL counter value for ports 1 and 2 is 10 and 20 packets respectively. More space is used and the process is slower than shared. Dedicated is the default setting.

In the shared mode, ACL space is reused even with counters. ACL counters count packets ingressing via all ports in the whole unit. If the ACL with the counter is applied to ports 1 and 2, and 10 packets ingress via port 1, and 20 packets ingress via port 2, the ACL counter value is 30 each of ports 1 and 2 instead of 10 and 20. The process is faster—as fast as applying an ACL without the counters—and saves space.

> **Note**
> Port-Counter shared mode will not work when ports are on across slots and units.

The shared/dedicated setting is global to the switch; that is, the option does not support setting some ACL rules with shared counters and some with dedicated counters.

Use the following command to configure the shared or dedicated mode:

```
configure access-list rule-compression port-counters [shared |
dedicated]
```

Use the following command to view the configuration:

```
show access-list configuration
```

The shared or dedicated mode does not affect any ACLs that have already been configured. Only ACLs entered after the command is entered are affected.

> **Note**
> To configure all ACLs in the shared mode, enter the command before any ACLs are configured or have been saved in the configuration when a switch is booted.

Policy-Based Routing

> **Note**
> Policy-Based Routing is available only on the platforms listed for this feature in the *ExtremeXOS 32.4 Feature License Requirements* document. Refer to Load Sharing Rules and Restrictions for All Switches on page 261 for information on applying ACLs to *LAG (Link Aggregation Group)* ports.

Layer 3 Policy-Based Redirect

Policy-Based Routing allows you to bypass standard Layer 3 forwarding decisions for certain flows. Typically, in a Layer 3 environment, when an IP packet hits an Ethernet switch or router, the Layer 3 processing determines the next-hop and outgoing interface for the packet (based only on the packet's destination address). The Layer 3 processing does so by looking up the IP Forwarding Table; this forwarding table itself is populated either by static routes or by routes learned dynamically from routing protocols such as *OSPF* and *RIP*.

With Policy-Based Routing, you can configure policies to use a different next-hop than what the routing lookup would have chosen. The switch first compares packets to the *ACL* rule entries. If there is a match, the packet is forwarded to the destination identified by the redirect action modifier. If there is no match, the packet is forwarded based on normal routing, in other words, by looking up a route in the IP Forwarding Table.

When there is a match with a redirect ACL rule, the matched traffic is redirected to the next-hop specified in the action.

> **Note**
> The IP packet itself is not modified, but only redirected to the port where the next-hop entry resides. The original IP destination address and source address are retained in the packet. The TTL is decremented and the IP checksum is recalculated.

The applications for Policy-Based Routing are quite diverse, since the functionality can be used to set policies on how flows identified by any Layer 2 to Layer 7 field (bounded by the switch's ACL syntax) are forwarded.

Deployment scenarios include:

- Forwarding flows for certain applications, for example, all HTTP traffic to designated server(s).
- Redirecting flows from certain source IP addresses for security and other applications.

Policy-Based Routing is implemented using ACLs, so it inherits the capabilities and limitations of ACLs. All the matching conditions used for ACLs can be used for Policy-Based Routing. The destination IP address must be an IPv4 unicast address. For IPv6 scenarios refer the section on Policy-Based Redirection Redundancy on page 846.

When a switch finds a matching ACL rule, it forwards the packet to the redirect IP address as specified in the rule without modifying the packet (except as noted above).

The traffic flow is redirected only after applying the ACL to the port and only when the redirect IP address's adjacency is resolved. When the ARP or NDP table does not have the information to reach the redirect IP address, the packet is routed based on the Layer 3 routing table. When the switch does not know how to reach the redirect IP address in the rule, the rule is installed with a warning, and traffic is not redirected until the address is resolved in the ARP or NDP table. After the address is resolved, the traffic is redirected.

To configure Policy-Based Routing, you configure an ACL on your switch. You can apply an ACL policy file, or use a dynamic ACL.

The following is an example ACL rule entry that redirects any TCP traffic with a destination port of 81 to the device at IP address 3.3.3.2:

```
entry redirect_port_81 {
    if {
        protocol tcp;
        destination-port 81;
    } then {
        redirect 3.3.3.2;
    }
}
```

Use the following procedure:

1. Issue the following command to prevent the redirect IP address from clearing from the ARP or NDP table due to a timeout: `enable iparp refresh`
2. Configure the ACL, either by applying an ACL policy file similar to the example, or a dynamic ACL.
3. Ping or send traffic so that the redirect IP adjacency is resolved.

You may want to create a static ARP or NDP entry for the redirect IP address, so that there will always be a cache entry.

> **Note**
> An ACL can be rejected on switches that support Policy-Based Routing, because these have different amounts of hardware resources and one switch has exhausted its resources.

Layer 2 Policy-Based Redirect

This feature allows matching packets to override the normal forwarding decision and be Layer 2 switched to the specified physical port. This is accomplished using an additional packet _ACL_ lookup. While similar to the Layer 3 Policy-Based Redirect feature, it differs in that the packet is not modified for Layer 3 routing based on a new IP redirect next-hop. Instead, the packet uses the packet format based on the forwarding decision. When the packet is Layer 2-switched, the packet egresses the redirect port unmodified. When the packet is Layer 3-switched, the packet egresses with the Layer 3 packet modifications of the next-hop found by the normal Layer 3 forwarding lookups.

The following ACL actions are added in support of this feature:

`redirect-port` _port_; `redirect-port-list` _port-list_

> **Note**
> The `redirect-port` or `redirect-port-list` commands will not work for L3 switched packets matching ACL, if distributed IP ARP feature is turned ON.

You must specify the _port_ argument in the correct format for the switch platform. On supporting switches, this argument must be in the format _slot:port_ and this argument must be in the format _port_.

The _port-list_ argument is simply a comma-separated list of _port_ arguments. White space between _port_ arguments is not allowed.

Here is an example of valid _port-list_ syntax:

```
redirect-port-list 2:1,2:5,5:3; and redirect-port-list 3,24,5;
```

Here is an example of **invalid** _port-list_ syntax :

```
redirect-port-list 2:1 2:5 5:3;
redirect-port-list 2, 4, 5;
```

The policy shown below redirects any TCP traffic with source Layer 4 port 81 to physical port 3:2.

```
entry one {
    if {
        protocol tcp;
        source-port 81;
        destination-port 200 ;
    } then {
        count num_pkts_redirected;
        redirect-port 3:2;
    }
```

The policy shown below redirects any in-profile traffic as defined by the meter configuration to physical port 14. The out-of-profile traffic is subject to the action specified in the meter "out-action" configuration.

```
entry one {
    if {
```

```
    } then {
        meter redirected_traffic;
        count num_pkts_redirected;
        redirect-port 14;
    }
```

The policy shown below redirects all traffic with source IP matching 192.168.1.1/24; to physical ports 2:10 and 4:7.

```
entry one {
if {
source-address 192.168.1.1/24;
} then {
count num_pkts_redirected;
redirect-port-list 2:10,4:7;
}
```

If an incorrect port format is used or if the port number specified is out of range, the following error message is displayed:

```
switch.5 # check policy l2pbr
Error:  Policy l2pbr has syntax errors
Line 7 : 12:3 is not a valid port.
switch.6 # check policy l2pbr
Error:  Policy l2pbr has syntax errors
Line 7 : 77 is not a valid port.
```

When this feature is used on ExtremeSwitching switches, the traffic egressing the redirect-port can be either tagged or untagged depending on the redirect-port *VLAN* configuration. The following table provides the details.

Table 75: VLAN Format of Traffic Egressing Redirect-Port

ACL Hardware Type	Redirect-Port Not in Egress VLAN	Redirect-Port Tagged in Egress VLAN	Redirect-Port Untagged in Egress VLAN
ExtremeSwitching Switches	Dropped	VLAN Tagged	Untagged

Be aware of the following important implementation notes:

- Using the "redirect-port" action with a disabled port causes traffic to be dropped.
- For systems with a- and e- series hardware that has the larger table size, packets with IP options do not match ACLs using the "redirect-port" action. Systems with hardware that has the smaller table size do not have this capability. On these systems, packets with IP options will match ACLs that use the "redirect-port" action, and will be dropped.
- The redirect-port-list action modifier is targeted towards L2 scenarios. This action is not supported in slow path ACLs. The following list summarizes the behavior of the redirect-port-list action modifier under certain situations.

The following list summarizes the behavior of redirect-port-list action modifier under certain situations.

- ◦ When a Unicast packet matches the applied ACL, the packet is redirected to all ports specified in the redirect port-list as long as these ports are part of the true egress VLAN.
- ◦ When a Broadcast/Multicast packet matches the applied ACL, the packet is redirected only to ports specified in the redirect port-list that are part of the ingress VLAN. Matched multicast packets will get L2 switched.
- ◦ When a *LAG* port is part of redirect-port-list, then packets matching applied ACL will be load shared between LAG member ports based on Layer 2 source and destination MAC addresses.

LAG Port Selection

This feature allows you to apply an *ACL* that causes matching packets to egress a specific port in a link aggregation (or load-sharing) group.

The following ACL action is added in support of this feature:

```
redirect-port-no-sharing port
```

The ACL overrides any load-sharing algorithm hash that is generated based on the lookup results.

Limitations include the following:

- If the selected port in a load-sharing group is down, the packets will be dropped.
- Like the redirect-port action, the specified port must be a member of the egress *VLAN*.

Following is an example of a configuration and ACL policy that directs traffic matching 10.66.4.10 to LAG port 3:

```
enable sharing 2 group 2,3
radiomgmt.pol:
entry one {
if {
destination-address 10.66.4.10/32;
} then {
redirect-port-no-sharing 3;
}
}
config access-list radiomgmt any
```

This example would direct inband management traffic to specific radios connected to specific ports within a load-sharing group.

Policy-Based Redirection Redundancy

Multiple Next-hop Support

As discussed above, Layer 3 and Layer 2 policy-based redirect support only one next-hop for one policy-based entry. Multiple next-hops with different priorities can be

configured. A higher priority is denoted with a higher number; for example, "priority 5" has a higher precedence than "priority 1." When a high priority next-hop becomes unreachable, another preconfigured next-hop, based on priority, replaces the first. This is done by first creating a flow-redirect name that is used to hold next-hop information. User-created flow-redirect names are not case-sensitive.

> **Note**
> As of ExtremeXOS 16.1, there is no limitation in creating the flow-redirects. Number of Next hops has been increased to 4,096 next hops. If more than 4,096 next hops are attempted to be created, an error message appears.

Use the following command:

```
create flow-redirect flow_redirect_name
```

To delete the flow-redirect name, use:

```
delete flow-redirect flow_redirect_name
```

Then information for each next-hop, including a defined priority, is added one by one to the new flow-redirect name. Use the following command:

```
configure flow-redirect flow_redirect_name add nexthop ipaddress
priority number
```

> **Note**
> You can add IPv4 or IPv6 next-hops to a flow-redirect policy, but both types are not supported in the same policy.

To delete a next-hop, use the following command:

```
configure flow-redirect flow_redirect_name delete nexthop {ipaddress |
all }
```

Because an _ACL_ does not recognize the virtual routing concept, one policy-based routing is used for multiple virtual routing entries when a _VLAN_-based _virtual router (VR)_ is used for one port. Configuring a virtual router into a flow-redirect allows policy-based routing to work for only one specific virtual router. Use the following command:

```
configure flow-redirect flow_redirect_name vr vr_name
```

> **Note**
> Flow-redirect does not work on user-created virtual routers.

Finally, a new action modifier, redirect-name, is used to specify the flow-redirect name in an ACL rule entry.

```
entry redirect_redundancy {
    if match all {
        source-address 1.1.1.100/24 ;
    } then            {
        permit ;
        redirect-name <name>
    }
}
```

Health Checking for ARP, NDP, and Ping

Policy-based redirection redundancy requires the determination of the reachability or unreachability of the active next hop and the other configured next hops. This feature can use ARP, NDP or Ping checking to make the determination.

> **Note**
> IPv6 Policy-Based Routing is not supported for traffic with Hop-by-Hop extension headers. Traffic will continue to be hardware forwarded, and will not be processed in slow path.

To configure health checking for a specific flow-redirect-name, use the following command:

```
configure flow-redirect flow_redirect_name health-check [ping | arp |
neighbor-discovery]
```

To configure the ping interval, miss count, and success count for a next-hop, use the following command:

```
configure flow-redirect flow_redirect_name nexthop ip_address ping
health-check interval seconds miss number {success successes}
```

Packet Forward/Drop

The default behavior for policy-based routing when all next-hops are unreachable is to route packets based on the routing table. Policy-based routing redundancy adds an option to drop the packets when all next-hops for the policy-based routing become unreachable.

To configure this option, use the following command:

```
configure flow-redirect flow_redirect_name no-active [drop|forward]
```

Configuring Packet Forward Drop

Traffic from the Source IP = 211.10.15.0/24, 211.10.16.0/24 network blocks should be redirected into two routers: 192.168.2.2 and 192.168.2.3. The 192.168.2.2 router is preferred to 192.168.2.3. If router 192.168.2.2 is not reachable, 192.168.2.3 should be used. If both routers are not reachable, the default route is used.

1. Create a flow-redirect to keep next-hop IP address and health check information.

   ```
   create flow-redirect premium_subscriber
   ```

   ```
   config flow-redirect premium_subscriber add next-hop 192.168.2.2
   priority 200
   ```

   ```
   config flow-redirect premium_subscriber add next-hop 192.168.2.3
   priority 100
   ```

2. Add an ACL entry with a flow-redirect name action to the existing ACL policy

   For example: premium_user.pol:

   ```
   entry premium_15 {
   if match {
   source-address 211.10.15.0/24;
   } then {
   ```

```
      permit;
      redirect-name premium_subscriber;
      }
      }
      entry premium_16 {
      if match {
      source-address 211.10.16.0/24;
      } then {
      permit;
      redirect-name premium_subscriber;
      }
      }
```

3. Apply the modified ACL policy file or dynamic ACL into a port, VLAN, or VLAN and Port.

   For example: user1 VLAN: 192.168.1.0/30, user2 VLAN: 192.168.1.4/30.

   ```
   config access-list premium_user vlan user1 ingress
   config access-list premium_user vlan user2 ingress
   ```

4. Finally, check the current flow-redirect status.

```
BD-8810.47 # show flow-redirect "premium_subscriber"
Name         : premium_subscriber          VR Name         : VR-Default
NO-ACTIVE NH : FORWARD                      HC TYPE         : PING
NH COUNT    : 2                             ACTIVE IP       : 192.168.2.3
Index     STATE     Pri        IP ADDRESS               STATUS INTERVAL MISS
=============================================================================
0         ENABLED   200        192.168.2.2              DOWN
2
          2
1         ENABLED   100        192.168.2.3              UP        2       2

BD-8810.48 # show flow-redirect
Flow-Redirect Name    NH_CNT     ACTIVE IP    VR Name         D/F  HC
=====================================================================
premium_subscriber    2          192.168.2.3  VR-Default       F   PING
```

ACL Troubleshooting

The following commands are designed to help troubleshoot and resolve *ACL* configuration issues:

- `show access-list usage acl-mask port` *port*

- `show access-list usage acl-range port` *port*

- `show access-list usage acl-rule port` *port*

- `show access-list usage acl-slice port` *port*

The **acl-mask** keyword is not relevant for the a-series or e-series models.

If you enter this command and specify an a-series or e-series port, the following error message appears:

```
This command is not applicable to the specified port.
```

Use the **acl-rule** keyword to display the total number of ACL rules that are available and consumed for the specified port.

If this keyword is specified on an a-series or e-series port, the first part of the command output details the port list using this resource because the ACL hardware rules are shared by all ports on a given ASIC (24x1G ports). If you enter the same command and specify any of the listed ports, the command output is identical.

```
*switch# show access-list usage acl-rule port 4:1 Ports 4:1-4:12, 4:25-4:36
Total Rules:     Used: 46  Available: 2002
```

The **acl-slice** keyword is used to display ACL resource consumption for each of the independent TCAMs, or slices, that make up the hardware ACLs.

Each slice is a 128-entry TCAM. The command output displays the number of consumed and available TCAM rules for each slice as follows.

```
*switch# show access-list usage acl-slice port 4:1
Ports 4:1-4:12, 4:25-4:36
Slices:            Used: 8  Available: 8
Slice 0 Rules:    Used: 1  Available: 127
Slice 1 Rules:    Used: 1  Available: 127
Slice 2 Rules:    Used: 1  Available: 127
Slice 3 Rules:    Used: 8  Available: 120
Slice 4 Rules:    Used: 8  Available: 120
Slice 5 Rules:    Used: 2  Available: 126
Slice 6 Rules:    Used: 1  Available: 127
Slice 7 Rules:    Used: 24 Available: 104
```

Use the **acl-range** keyword to view the Layer-4 port range hardware resource on an a-series or e-series model switch.

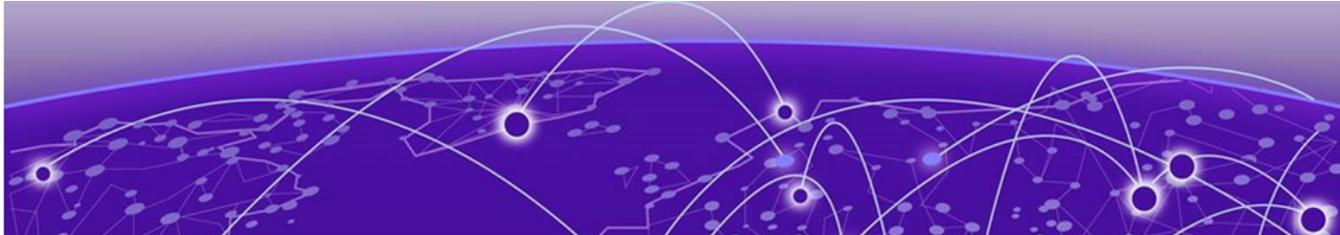
Each a-series and e-series ASIC has 16 Layer-4 port range checkers that are shared among the 24 1G ports. The first part of the command output lists the ports that utilizes this resource. The second part of the command output lists the number of range checkers that are consumed and the number available for use.

```
switch # show access-list usage acl-range port 4:1
Ports 4:1-4:12, 4:25-4:36
L4 Port Ranges:  Used: 0  Available: 16
```

If the **acl-slice** or **acl-range** keyword is specified with an e-series port, the following error message will appear:

```
This command is not applicable to the specified port.
```

Routing Policies

This chapter provides information about Routing Policies. It includes an overview, specific information about Routing Policy File Syntax, how to apply Routing Policies, and offers some Policy examples.


Routing Policies Overview

Routing policies are used to control the advertisement or recognition of routes communicated by routing protocols, such as _RIP (Routing Information Protocol)_, _OSPF (Open Shortest Path First)_, Intermediate System-Intermediate System (IS-IS) and _BGP (Border Gateway Protocol)_.

Routing policies can be used to "hide" entire networks or to trust only specific sources for routes or ranges of routes. The capabilities of routing policies are specific to the type of routing protocol involved, but these policies are sometimes more efficient and easier to implement than access lists.

Routing policies can also modify and filter routing information received and advertised by a switch.

A similar type of policy is an _ACL (Access Control List)_ policy, used to control, at the hardware level, the packets accessing the switch. ACL policy files and routing policy files are both handled by the policy manager and the syntax for both types of files is checked by the policy manager.

> **Note**
> Although ExtremeXOS does not prohibit mixing ACL and routing type entries in a policy file, it is strongly recommended that you do not mix the entries, and you use separate policy files for ACL and routing policies.

Routing Policy File Syntax

A routing policy file contains one or more policy rule entries. Each routing policy entry consists of:

- A policy entry rule name, unique within the same policy.
- Zero or one match type. If no type is specified, the match type is all, so all match conditions must be satisfied.
- Zero or more match conditions. If no match condition is specified, then every routing entity matches.
- Zero or more actions. If no action is specified, the packet is permitted by default.

Each policy entry in the file uses the following syntax:

```
entry <routingrulename>{
    if <match-type> {
        <match-conditions>;
    } then {
        <action>;
    }
}
```

The following is an example of a policy entry:

```
entry ip_entry {
    if match any {
        nlri   10.203.134.0/24;
        nlri   10.204.134.0/24;
    } then {
        next-hop   192.168.174.92;
        origin   egp;
    }
}
```

Policy entries are evaluated in order, from the beginning of the file to the end, as follows:

- If a match occurs, the action in the then statement is taken:
  - if the action contains an explicit permit or deny, the evaluation process terminates.
  - if the action does not contain an explicit permit or deny, the action is an implicit permit, and the evaluation process terminates.
- If a match does not occur, the next policy entry is evaluated.
- If no match has occurred after evaluating all policy entries, the default action is deny.

Often a policy has a rule entry at the end of the policy with no match conditions. This entry matches anything not otherwise processed, so that the user can specify an action to override the default deny action.

Policy match type, match conditions and action statements are discussed in the following sections:

- Policy Match Type on page 853
- Policy Match Conditions on page 853

-
-

Policy Match Type

The two possible choices for the match type are:

- match all—All the match conditions must be true for a match to occur. This is the default.
- match any—If any match condition is true, then a match occurs.

Policy Match Conditions

Table 76 lists the possible policy entry match conditions.

Table 76: Policy Match Conditions

Match Condition	Description
as-path [<as-number> | <as-path-regular-expression>];	Where <as-number> is a valid 2-byte AS number in the range of 1 to 65535 or a 4-byte AS number in the range of 65536 to 4294967294. Where <as-path-regular-expression> is a multi-character regular expression (with 2-byte unsigned Integer being an Atom). Regular expression will consist of the AS-Numbers and various regular expression symbols. Regular expressions must be enclosed in double quotes ("").
community [no-advertise | no-export | no-export-subconfed | number <community_num> | <community_regular_expression> | <as_num> : <num>];	Where no-advertise, no-export and no-export-subconfed are the standard communities defined by RFC. <community_num> is a four-byte unsigned integer, <as_num> is a two-byte or four-byte AS-Number and <num> is the 2-bytes community number. Community regular expression is a multi-character regular expression (with four byte unsigned integer being an Atom). Regular expression is enclosed in double quotes ("").
med <number>;	Where <number> is a 4-byte unsigned integer.
next-hop [<ipaddress> | <ipaddress-regular-expression>];	Where <ipaddress> is a valid IP address in dotted decimal format.

Table 76: Policy Match Conditions (continued)

Match Condition	Description
nlri [*ipaddress* | any] *mask-length* {exact}; nlri [*ipaddress* | any] mask *mask* {exact}; nlri [*ipv6address* | any-ipv6]/ *mask-length* {exact};	Where *ipaddress* and *mask* are IPv4 addresses and masks, *mask-length* is an integer with maximum value of 32 for IPv4 addresses. The keyword **any** matches any IPv4 address with a given (or larger) mask/ mask-length. Similarly *ipv6address* is an IPv6 address and *masklength* is an integer with a maximum value of 128 for IPv6 addresses. The keyword **any-ipv6** matches any IPv6 address with a given (or larger) mask-length.
origin [igp | egp | incomplete];	Where igp, egp and incomplete are the *BGP* route origin values.
tag <number>;	Where <number> is a 4-byte unsigned number. **Note:** The tag match condition only works with export policy.
route-origin [direct | static | icmp | egp | ggp | hello | rip | isis | esis | cisco-igrp | ospf | bgp | idrp | dvmrp | mospf | pim-dm | pim-sm | ospf-intra | ospf-inter | ospf-extern1 | ospf-extern2 | bootp | e-bgp | i-bgp | mbgp | i-mbgp | e-mbgp | isis-level-1 | isis-level-2 | isis-level-1-external | isis-level-2-external];	Matches the origin (different from BGP route origin) of a route. A match statement "route-origin bgp" will match routes whose origin are "I-bgp" or "e-bgp" or "I-mbgp" or "e-mbgp". Similarly, the match statement "route-origin ospf" will match routes whose origin is "ospf-inta" or "ospf-inter" or "ospf-as-external" or "ospf-extern-1" or "ospf-extern-2"

> **Note**
> When entering an AS number in a policy file, you must enter a unique 2-byte or 4-byte AS number. The transition AS number, AS 23456, is not supported in policy files.

Autonomous System Expressions

The **AS-path** keyword uses a regular expression string to match against the autonomous system (AS) path. Table 77 lists the regular expressions that can be used in the match conditions for BGP AS path and community. It also shows examples of regular expressions and the AS paths they match.

Table 77: AS Regular Expression Notation

Character	Definition
N	As number
N1 - N2	Range of AS numbers, where N1 and N2 are AS numbers and N1 < N2

Table 77: AS Regular Expression Notation (continued)

Character	Definition
[Nx ... Ny]	Group of AS numbers, where Nx and Ny are AS numbers or a range of AS numbers
[^Nx ... Ny]	Any AS numbers other than the ones in the group
.	Matches any number
^	Matches the beginning of the AS path
$	Matches the end of the AS path
_	Matches the beginning or end, or a space
-	Separates the beginning and end of a range of numbers
*	Matches 0 or more instances
+	Matches 1 or more instances
?	Matches 0 or 1 instance
{	Start of AS SET segment in the AS path
}	End of AS SET segment in the AS path
(	Start of a confederation segment in the AS path
)	End of a confederation segment in the AS path

Table 78: Policy Regular Expression Examples

Attribute	Regular Expression	Example Matches
AS path is 64496	"64496"	64496
Zero or more occurrences of AS number 1234	"64496*"	64496 64496 64496
Start of AS path set	"64496 64500 { 64505"	64496 64500 64505 { 64511 64509 64496 64500 { 64505 64507
End of AS path set	"64500 } 64505"	64500 } 64505 56
Path that starts with 99 followed by 34	"^64511 64505 "	64511 64505 45
Path that ends with 99	"64511 $"	45 66 64511
Path of any length that begins with AS numbers 64496 64497 64498	"64496 64497 64498 .*"	64496 64497 64498 64499 64500 64501 64502 64503 64504
Path of any length that ends with AS numbers 64496 64497 64498	".* 64496 64497 64498 $"	64496 64497 64498 64502 64503 64504 64496 64497 64498

Following are additional examples of using regular expressions in the AS-Path statement.

The following AS-Path statement matches AS paths that contain only (begin and end with) AS number 64511:

```
as-path "^64511$"
```

The following AS-Path statement matches AS paths beginning with AS number 64500, ending with AS number 64511, and containing no other AS paths:

```
as-path "^64500 64511$"
```

The following AS-Path statement matches AS paths beginning with AS number 64496, followed by any AS number from 65500 - 65505, and ending with either AS number 65507, 65509, or 65511:

```
as-path "^64496 65500-65505 [65507 65509 65511]$"
```

The following AS-Path statement matches AS paths beginning with AS number 65511 and ending with any AS number from 65500 - 65505:

```
as-path "65511 [65500-65505]$"
```

The following AS-Path statement matches AS paths beginning with AS number 65511 and ending with any additional AS number, or beginning and ending with AS number 65511:

```
as-path "65511 .?"
```

Policy Action Statements

Table 79 lists policy action statements. These are the actions taken when the policy match conditions are met in a policy entry.

Table 79: Policy Actions

Action	Description
as-path "<as_num> {<as_num1> <as_num2> <as_num3> …. <as_numN>}";	Prepends the entire list of as-numbers to the as-path of the route.
community set [no-advertise | no-export | noexport- subconfed | <community_num> | <as_num> : <community_num>];	Replaces the existing community attribute of a route by the community specified by the action statement. Community must be enclosed in double quotes ("").
community [add | delete] [no-advertise | no-export | no-export-subconfed | <community_num> {<community_num1> <community_num2> …. <community_numN>} | <as_num> : <community_num> {<as_num1> <community_num1> <as_num2> <community_num2> ….}];	Adds/deletes communities to/from a route's community attribute. Communities must be enclosed in double quotes ("").
community remove;	Strips off the entire community attribute from a route. Communities must be enclosed in double quotes ("").
cost <cost(0-4261412864)>;	Sets the cost/metric for a route.

Table 79: Policy Actions (continued)

Action	Description
cost-type {ase-type-1 | ase-type-2 | external | internal};	Sets the cost type for a route.
dampening half-life <minutes (1-45)> reuse-limit <number (1-20000)> suppress-limit <number (1-20000)> max-suppress <minutes (1-255)>;	Sets the *BGP* route flap dampening parameters.
deny;	Denies the route.
local-preference <number>;	Sets the BGP local preference for a route.
med {add | delete} <number>;	Performs MED arithmetic. Add means the value of the MED in the route will be incremented by <number>, and delete means the value of the MED in the route will be decremented by <number>.
med {internal | remove};	Internal means that the Interior Gateway Protocol (IGP) distance to the next hop will be taken as the MED for a route. Remove means take out the MED attribute from the route.
med set <number>;	Sets the MED attribute for a route.
next-hop <ipv4 address | ipv6 address>;	Sets the next hop attribute for a route.
nlri [<ipaddress> | any]/<mask-length> {exact};nlri [<ipaddress> | any] mask <mask> {exact};	These set statements are used for building a list of IP addresses. This is used by PIM to set up the RP list.
origin {igp | egp | incomplete};	Sets the BGP route origin values.
permit;	Permits the route.
tag <number>;	Sets the tag number for a route.
weight <number>	Sets the weight for a BGP route.

> **Note**
> Multiple communities couldn't be used in "community set" attribute in the BGP policy file. The way to set multiple communities in BGP policy file could be accomplished by two set of attributes as given in below example:

```
entry permit-anything-else {
    if {
    } then {
      community set "2342:6788";
      community add "2342:6789 2342:6790";
  permit;
    }
}
```

Applying Routing Policies

To apply a routing policy, use the command appropriate to the client. Different protocols support different ways to apply policies, but there are some generalities.

Commands that use the keyword **import-policy** are used to change the attributes of routes installed into the switch routing table by the protocol. These commands cannot be used to determine the routes to be added to the routing table. The following are examples for the *BGP* and *RIP* protocols:

```
configure bgp import-policy [policy-name | none]
```

```
configure rip import-policy [policy-name | none]
```

Commands that use the keyword **route-policy** control the routes advertised or received by the protocol. For BGP and RIP, here are some examples:

```
configure bgp neighbor [remoteaddr | all] {address-family [ipv4-unicast
| ipv4-multicast |ipv6-unicast | ipv6-multicast |vpnv4]} route-policy
[in | out] [none | policy]
```

```
configure bgp peer-group peer-group-name {address-family [ipv4-unicast |
ipv4-multicast |ipv6-unicast | ipv6-multicast |vpnv4]} route-policy [in
|out] [none | policy]
```

```
configure rip vlan [vlan_name | all] route-policy [in | out] [policy-
name | none]
```

Other examples of commands that use routing policies include:

```
configure ospf area area-identifier external-filter [policy-map |none]
```

```
configure ospf add vlan [vlan-name | all] area area-identifier {passive}
{vr vrf_name}
```

```
configure rip vlan [vlan_name | all] trusted-gateway [policy-name |
none]
```

To remove a routing policy, use the **none** option in the command.

> **Note**
> When exporting a route into BGP with an export policy, the AS-Path is limited to a maximum of 15 AS numbers.

Policy Examples

Translating an Access Profile to a Policy

```
entry  entry-5  {
```

```
    If  {
        nlri    22.16.0.0/14;
    }
    then  {
        permit;
    }
}
entry  entry-10  {
    if  {
        nlri    192.168.0.0/18 exact;
    }
    then  {
        permit;
    }
}
entry  entry-15  {
    if  {
        nlri    any/8;
    }
    then  {
        deny;
    }
}
entry  entry-20  {
    if  {
        nlri    10.10.0.0/18;
}
Then  {
    permit;
}
}
entry  entry-25  {
    if  {
        nlri    22.44.66.0/23  exact;
    }
    then  {
        deny;
    }
}
```

The policy above can be optimized by combining some of the if statements into a single expression.

The compact form of the policy looks like this:

```
entry  permit_entry  {
    If match any {
        nlri    22.16.0.0/14;
        nlri    192.168.0.0/18 exact ;
        nlri    10.10.0.0/18;
    }
    then  {
        permit;
    }
}
entry  deny_entry  {
    if match any {
        nlri    any/8;
        nlri    22.44.66.0/23  exact;
    }
    then  {
        deny;
```

```
        }
}
```

Translating a Route Map to a Policy

```
entry  entry-10  {
    If  {
        origin    incomplete;
    }
    then  {
        permit;
    }
}
entry  entry-20  {
    if  {
        community   6553800;
    }
    then  {
        deny;
    }
}
entry  entry-30  {
    if  {
        med   30;

Quality of Service

This chapter discusses the Quality of Service (QoS) feature, and allows you to configure a switch to provide different levels of service to different groups of traffic. In this section you will find both overview information, as well as specific information on how to configure and monitor the QoS feature.

QoS Overview

Quality of Service (QoS) is a feature that allows you to configure a switch to provide different levels of service to different groups of traffic. For example, QoS allows you to do the following:

- Give some traffic groups higher priority access to network resources.
- Reserve bandwidth for special traffic groups.
- Restrict some traffic groups to bandwidth or data rates defined in a Service Level Agreement (SLA).
- Count frames and packets that exceed specified limits and optionally discard them (rate limiting).
- Queue or buffer frames and packets that exceed specified limits and forward them later (rate shaping).
- Modify QoS related fields in forwarded frames and packets (remarking).

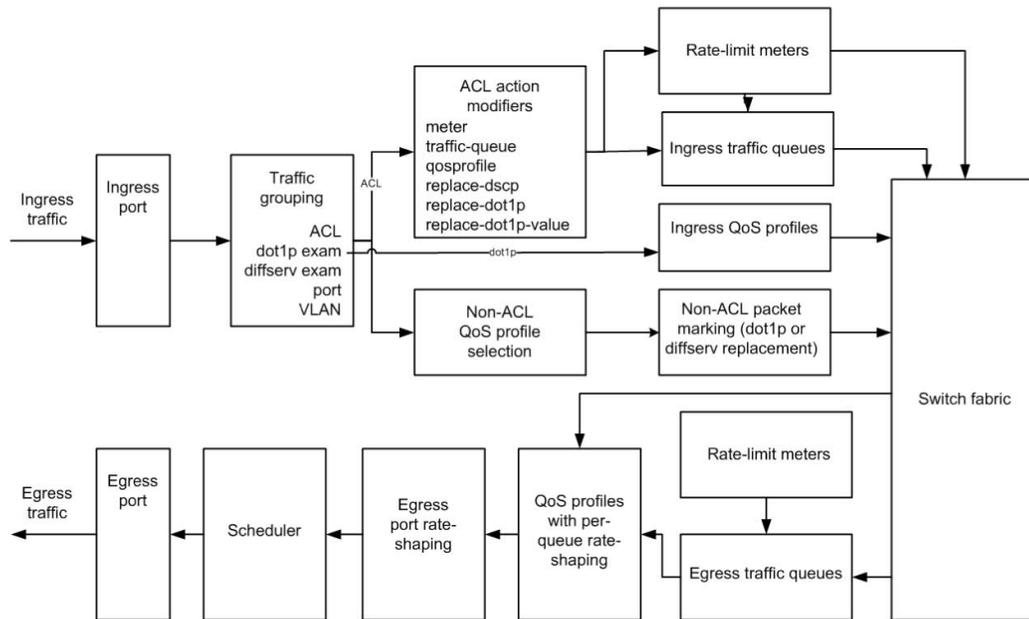
Figure 100 shows the QoS components that provide these features on Extreme Networks switches.


Figure 100: QoS on Extreme Networks Switches

Data enters the ingress port and is sorted into traffic groups, which can be classified as either ACL-based or non-ACL-based.

The ACL-based traffic groups provide the most control of QoS features and can be used to apply ingress and egress rate limiting and rate shaping as follows:

- Subject ingress traffic to rate limit meters
- Specify ingress hardware queues (QoS profiles) for rate limiting and rate shaping
- Specify ingress software traffic queues for rate limiting and rate shaping (these can be associated with egress traffic queues for additional QoS control)
- Specify egress software traffic queues for rate limiting and rate shaping
- Specify egress QoS profiles for rate limiting and rate shaping
- Change the dot1p or Differential Services (DiffServ) values in egress frames or packets

Non-ACL-based traffic groups specify an ingress or egress QoS profile for rate limiting and rate shaping. These groups cannot use ingress or egress software traffic queues. However, non-ACL-based traffic groups can use the packet marking feature to change the dot1p or DiffServ values in egress frames or packets.

The ingress rate-limiting and rate-shaping features allow you to apply QoS to incoming traffic before it reaches the switch fabric. If some out-of-profile traffic needs to be dropped, it is better to drop it before it consumes resources in the switch fabric.

All ingress traffic is linked to an egress traffic queue or QoS profile before it reaches the switch fabric. This information is forwarded with the traffic to the egress interface, where it selects the appropriate egress traffic queue or QoS profile. Egress traffic from all traffic queues and QoS profiles is forwarded to the egress port rate-shaping feature, which applies QoS to the entire port. When multiple QoS profiles are contending for egress bandwidth, the scheduler determines which queues are serviced.

The following sections provide more information on QoS:

Applications and Types of QoS

Different applications have different *QoS (Quality of Service)* requirements. Table 80 on page 864 summarizes the QoS guidelines for different types of network traffic.

Table 80: Traffic Type and QoS Guidelines

Traffic Type	Key QoS Parameters
Voice	Minimum bandwidth, priority
Video	Medium bandwidth, priority, buffering (varies)
Database	Minimum bandwidth
Web browsing	Minimum bandwidth for critical applications, maximum bandwidth for noncritical applications
File server	Minimum bandwidth

Consider these parameters as general guidelines and not as strict recommendations. After QoS parameters have been set, you can monitor the performance of the application to determine if the actual behavior of the applications matches your expectations. It is very important to understand the needs and behavior of the particular applications you want to protect or limit. Behavioral aspects to consider include bandwidth needs, sensitivity to latency and jitter, and sensitivity and impact of packet loss.

> **Note**
> Full-duplex links should be used when deploying policy-based QoS. Half-duplex operation on links can make delivery of guaranteed minimum bandwidth impossible.

Voice Applications

Voice applications, or voice over IP (VoIP), typically demand small amounts of bandwidth. However, the bandwidth must be constant and predictable because voice applications are typically sensitive to latency (inter-packet delay) and jitter (variation in inter-packet delay). The most important *QoS* parameter to establish for voice applications is minimum bandwidth, followed by priority.

Video Applications

Video applications are similar in needs to voice applications, with the exception that bandwidth requirements are somewhat larger, depending on the encoding. It is important to understand the behavior of the video application being used. For example, in the playback of stored video streams, some applications can transmit large amounts of data for multiple streams in one spike, with the expectation that the end stations will buffer significant amounts of video-stream data. This can present a problem to the network infrastructure, because the network must be capable of buffering the transmitted spikes where there are speed differences (for example, going from gigabit Ethernet to Fast Ethernet). Key *QoS* parameters for video applications include minimum bandwidth and priority, and possibly buffering (depending upon the behavior of the application).

Critical Database Applications

Database applications, such as those associated with Enterprise Resource Planning (ERP), typically do not demand significant bandwidth and are tolerant of delay. You can establish a minimum bandwidth using a priority less than that of delay-sensitive applications.

Web Browsing Applications

QoS needs for web browsing applications cannot be generalized into a single category. For example, ERP applications that use a browser front-end might be more important than retrieving daily news information. Traffic groupings can typically be distinguished from each other by their server source and destinations. Most browser-based applications are distinguished by the dataflow being asymmetric (small dataflows from the browser client, large dataflows from the server to the browser client).

An exception to this might be created by some Java™-based applications. In addition, web-based applications are generally tolerant of latency, jitter, and some packet loss; however, small packet loss might have a large impact on perceived performance because of the nature of TCP. The relevant parameter for protecting browser applications is minimum bandwidth. The relevant parameter for preventing non-critical browser applications from overwhelming the network is maximum bandwidth.

File Server Applications

With some dependencies on the network operating system, file serving typically poses the greatest demand on bandwidth, although file server applications are very tolerant of latency, jitter, and some packet loss, depending on the network operating system and the use of TCP or UDP.

Traffic Groups

A traffic group defines the ingress traffic to which you want to apply some level of _QoS_. You can use the ExtremeXOS software to define traffic groups based on the following:

- Frame or packet header information such as IP address or MAC address
- _CoS (Class of Service)_ 802.1p bits in the frame header
- DiffServ information in a packet header
- Ingress port number
- _VLAN (Virtual LAN)_ ID

Traffic groups that are defined based on frame or packet information are usually defined in Access Control Lists (ACLs). The exception to this rule is the CoS and DiffServ information, which you can use to define traffic groups without ACLs.

The function of the CoS and DiffServ traffic groups is sometimes referred to as explicit packet marking, and it uses information contained within a frame or packet to explicitly determine a class of service. An advantage of explicit packet marking is that the class of service information can be carried throughout the network infrastructure, without repeating what can be complex traffic group policies at each switch location. Another advantage is that end stations can perform their own packet marking on an application-specific basis. Extreme Networks switch products have the capability of observing and manipulating packet marking information with no performance penalty.

The CoS and DiffServ capabilities (on supported platforms) are not impacted by the switching or routing configuration of the switch. For example, 802.1p information can be preserved across a routed switch boundary and DiffServ code points can be observed or overwritten across a Layer 2 switch boundary.

During QoS configuration, you configure the QoS level first by configuring QoS profiles, traffic queues, and meters, and then you define a traffic group and assign the traffic group to the QoS configuration.

ACL-Based Traffic Groups

An _ACL (Access Control List)_-based traffic group allows you to use ACL rules in an ACL policy file to define the traffic to which you want to apply _QoS_. An ACL-based traffic group requires more effort to create, but the ACL rules give you more control over which traffic is selected for the traffic group. For example, you can use an ACL to add traffic to a traffic group based on the following frame or packet components:

- MAC source or destination address
- Ethertype
- IP source or destination address
- IP protocol
- TCP flag
- TCP, UDP, or other Layer 4 protocol
- TCP or UDP port information
- IP fragmentation

Depending on the platform you are using, traffic in an ACL traffic group can be processed as follows:

- Assigned to an ingress meter for rate limiting
- Marked for an egress QoS profile for rate shaping
- Marked for an egress traffic queue for rate shaping
- Marked for DSCP replacement on egress
- Marked for 802.1p priority replacement on egress
- Assigned to an egress meter for rate limiting

When you are deciding whether to use an ACL-based traffic group or another type of traffic group, consider what QoS features you want to apply to the traffic group. Some QoS features can only apply to ACL-based traffic groups.

> **Note**
> ACLs are discussed in detail in the ACLs chapter.

CoS 802.1p-Based Traffic Groups

CoS 802.1p-based traffic groups forward traffic to QoS features based on the three 802.1p priority bits in an Ethernet frame. The 802.1p priority bits are located between the 802.1Q type field and the 802.1Q VLAN ID as shown in Figure 101.

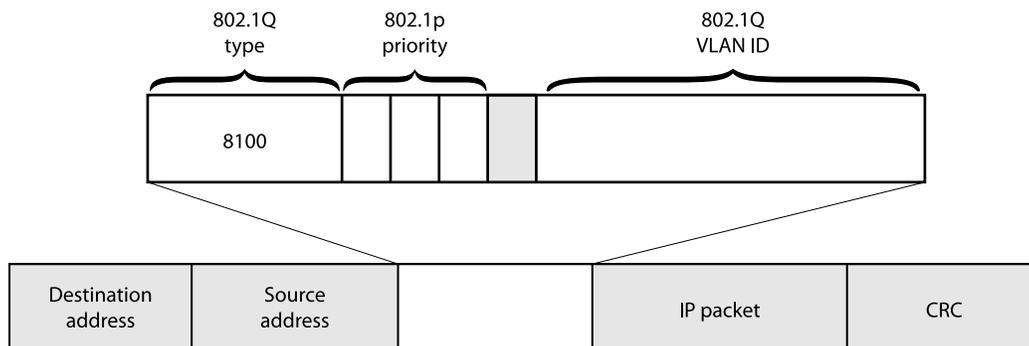
Typically CoS will be used in conjunction with policy, however it may also work independently. In a policy-enabled system, policy may use any CoS index setting (0-255) to configure ACLs to assign a qosprofile, meter, dot1p replacement and TOS-rewrite value. By default, 802.1p priorities 0-7 are mapped to CoS indices 0-7.


Figure 101: 802.1p Priority Bits

The three 802.1p priority bits define up to eight traffic groups that are predefined in the ExtremeXOS software.

On SummitStack and ExtremeSwitching series switches, the traffic groups direct traffic to egress QoS profiles for egress rate shaping (see the following table).

You do not need to define 802.1p-based traffic groups. You can enable or disable the use of these traffic groups by enabling or disabling the 802.1p examination feature. You can also configure which 802.1p values map to which QoS profiles.

A related feature is the 802.1p replacement feature, which allows you to configure the software to replace the 802.1p bits in an ingress frame with a different value in the egress frame. For more information on 802.1p replacement, see Configuring 802.1p or DSCP Replacement on page 884.

DiffServ-Based Traffic Groups

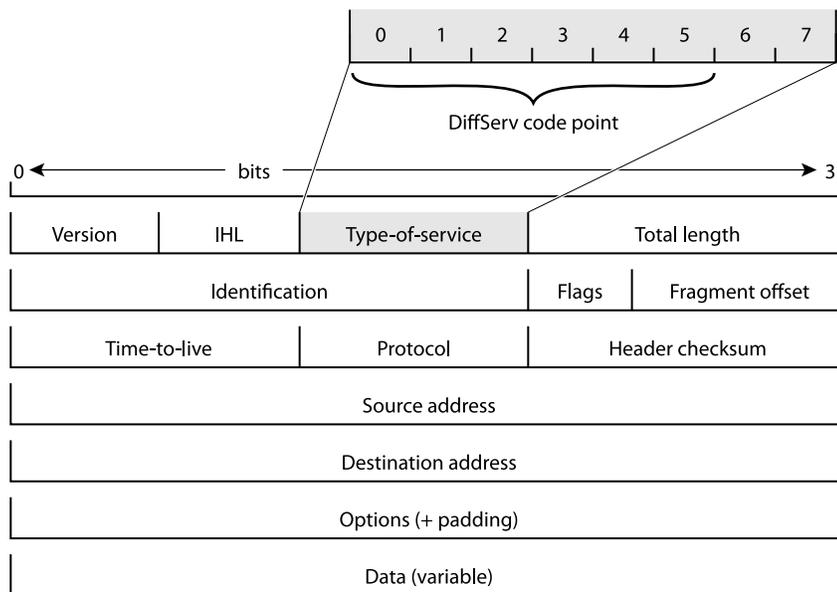
DiffServ-based traffic groups forward traffic to egress *QoS* profiles based on the type-of-service (TOS) or traffic class (TC) information in an IP packet. In many systems, this TOS or TC information is replaced with a DiffServ field that uses six of the eight bits for a *DSCP (Differentiated Services Code Point)*, as shown in Figure 102. (The other two bits are not used.)


Figure 102: DiffServe Code Point

Because the DSCP uses six bits, it has 64 possible values ($2^6 = 64$). By default, the values are grouped and assigned to the default QoS profiles as listed in Table 81.

Table 81: Default DSCP-to-QoS-Profile Mapping

Traffic Group Code Point	SummitStack and ExtremeSwitching Switches QoS Profile
0-7	QP1
8-15	QP1
16-23	QP1
24-31	QP1
32-39	QP1
40-47	QP1

Table 81: Default DSCP-to-QoS-Profile Mapping (continued)

Traffic Group Code Point	SummitStack and ExtremeSwitching Switches QoS Profile
48-55	QP1
56-63	QP8

> **Note**
> The default DiffServ examination mappings apply on ports in more than one virtual router. If you attempt to configure DiffServe examination or replacement on a port that is in more than one virtual router, the system returns the following message:
> ```
> Warning: Port belongs to more than one VR. Port properties related to diff serv
> and code replacement will not take effect.
> ```

You do not need to define these traffic groups. You can enable or disable the use of these traffic groups by enabling or disabling the DiffServ examination feature as described in Configuring a DiffServ-Based Traffic Group on page 891. You can also configure which DSCP values map to which queues.

> **Note**
> When DiffServ examination is enabled on 1 Gigabit Ethernet ports, 802.1p replacement is enabled and cannot be disabled. The ingress 802.1p value is replaced with the 802.1p value assigned to the egress QoS profile.

A related feature is the DiffServ replacement feature, which allows you to configure the software to replace the DSCP in an ingress frame with a different value in the egress frame. For more information on DiffServ replacement, see Configuring 802.1p or DSCP Replacement on page 884.

Port-Based Traffic Groups

Port-based traffic groups forward traffic to egress *QoS* profiles based on the incoming port number. There are no default port-based traffic groups; you must configure each port-based traffic group.

> **Note**
> Port-based traffic groups apply to all packets.

VLAN-Based Traffic Groups

VLAN-based traffic groups forward traffic to egress *QoS* profiles based on the VLAN membership of the ingress port. There are no default VLAN-based traffic groups; you must configure each VLAN-based traffic group.

> **Note**
> VLAN-based traffic groups apply to all packets.

Precedence of Traffic Groups

The ExtremeXOS software allows you to define multiple traffic groups, and you can configure traffic groups in such a way that multiple traffic groups apply to an ingress frame or packet. When an ingress frame or packet matches two or more traffic groups, the software chooses one traffic group based on the precedence defined for the switch platform. In general, the more specific traffic group definition takes precedence. Table 82 on page 870 shows the traffic group precedence for the supported switch platforms (number 1 is the highest precedence).

> **Note**
> Beginning in ExtremeXOS 16.1, the port, _VLAN_ and DiffServ-based traffic groups will only work if 802.1p examination is disabled.

Table 82: Traffic Group Precedence

SummitStack and ExtremeSwitching Switches
1. _ACL_-based traffic groups for IP packets (specifies IP address information)   2. ACL-based traffic groups for Ethernet frames (specifies MAC address information)   3. _CoS_ 802.1p-based traffic groups   4. Port-based traffic groups   5. VLAN-based traffic groups   6. DiffServ-based traffic groups

Introduction to Rate Limiting, Rate Shaping, and Scheduling

The terms _rate limiting_ and _rate shaping_ are used throughout this chapter to describe _QoS_ features. Some QoS features perform both rate limiting and rate shaping. Rate limiting is the process of restricting traffic to a peak rate (PR). Rate shaping is the process of reshaping traffic throughput to give preference to higher priority traffic or to buffer traffic until forwarding resources become available.

Both rate limiting and rate shaping allow you to take action on traffic that exceeds the configured limits. These actions include forwarding traffic, dropping traffic, and marking the excess traffic for possible drops later in the communication path. Software counters allow you to record traffic statistics such as total packets forwarded and total packets dropped.

Single-Rate QoS

Single-rate _QoS_ defines a single rate for traffic that is subject to QoS. Single-rate QoS is the most basic form of rate limiting and is well suited for constant rate traffic flows such as video or where more complex dual-rate QoS is not needed. The traffic that meets the rate requirement is considered in-profile. Traffic that does not meet the specified rate is considered out-of-profile. A two-color system is often used to describe or mark the single-rate QoS result. In-profile traffic is marked green, and out-of-profile traffic is marked red.

Single-rate rate-limiters pass traffic that is in-profile or marked green. Out-of-profile traffic (marked red) is subject to whatever action is configured for out-of-profile traffic. Out of profile traffic can be forwarded if bandwidth is available, dropped, or marked for a possible drop later in the communication path.

All traffic that arrives at or below the PR is considered in-profile and marked green. All traffic that arrives above the PR is considered out-of-profile and marked red. When the traffic exceeds the capacity of the rate-limiting component, all traffic that is marked red is dropped.

Another type of single-rate QoS is used on SummitStack and ExtremeSwitching series switches. A committed information rate (CIR) establishes a reserved traffic rate, and a peak burst size (PBS) establishes a maximum size for a traffic stream. If a traffic stream is at or below the CIR and the PBS, it is considered to be within profile and marked green. If a traffic stream exceeds either the CIR or the PBS, it is considered out-of-profile and marked red. On these switches, you can configure the single-rate rate-limiting components to drop traffic marked red or set a drop precedence for that traffic. You can also specify a DSCP value to mark the out-of-profile traffic.

Dual-rate QoS

Dual-rate *QoS* defines two rates for traffic that is subject to QoS. The lower of the two rates is the CIR, which establishes a reserved traffic rate. The higher of the two rates is the peak rate, which establishes an upper limit for traffic. Dual-rate QoS is well suited to bursty traffic patterns which are common with typical data traffic. Dual-rate QoS is widely used in legacy Frame Relay and ATM leased lines.

> **Note**
> You must configure the peak rate higher than the committed rate.

A three-color system is used with dual-rate QoS. As with single-rate QoS, traffic at or below the CIR is considered in-profile, marked green, and forwarded. The traffic that is above the CIR and below the PIR is out-of-profile and marked yellow. Traffic above the PIR is also out-of-profile and marked red. When incoming traffic is already marked yellow and is out of profile, it is marked red. Different switch platforms take different actions on the traffic marked yellow or red.

Rate Specification Options

The ExtremeXOS software allows you to specify the CIR and PR in gigabits per second (Gbps), megabits per second (Mbps), or kilobits per second (Kbps). Most commands also allow you to specify the CIR and PR as a percentage of the maximum port bandwidth using the `minbw` (CIR) and `maxbw` (PR) options. The default value on all minimum bandwidth parameters is 0%, and the default value on all maximum bandwidth parameters is 100%.

QoS can be applied at different locations in the traffic path using the following rate-limiting and rate-shaping components:

- Ingress meters
- Egress traffic queues
- Egress meters
- Egress *QoS* profiles
- Egress ports

The CIR or minimum bandwidth configuration for a rate-limiting or rate-shaping component is a bandwidth guarantee for that component at a particular location in the traffic path. The guarantees for all components at a specified location should add up to less than 100% and should account for the traffic needs of the other components. For example, if you configure 25% minimum bandwidth for four out of eight queues at a particular location, there will be no available bandwidth for the remaining four queues when traffic exceeds the port capacity. Bandwidth unused by a queue can be used by other queues.

The rate-shaping configuration is configured at the location to which it applies on most platforms.

Disabling Rate Limiting and Rate Shaping

All switch platforms provide multiple *QoS* components in the traffic path that provide rate limiting or rate shaping. These components give you control over where and how the rate shaping is applied. However, your application might not require rate shaping at every component. The default configuration for most components provides no rate shaping. When rate shaping is disabled on a component, the CIR is set to 0 (minbw=0%) and the PR is set to the maximum bandwidth (maxbw=100%). This setting reserves no bandwidth for the component and allows the component to use 100% of the port bandwidth. If you need to remove rate shaping from a QoS component, configure these settings on that component.

Scheduling

Scheduling is the process that determines which traffic is forwarded when multiple *QoS* components are competing for egress bandwidth. The ExtremeXOS software supports the following scheduling methods:

- Strict priority queuing: All higher priority queues are serviced before lower priority queues. This ensures that high priority traffic receives access to available network bandwidth immediately, but can result in lower priority traffic being starved. As long as a queued packet remains in a higher-priority queue, any lower-priority queues are not serviced.
- Weighted fair queuing: All queues are given access to a relative amount of bandwidth based on the weight assigned to the queue. When you configure a QoS profile with a weight of 4, that queue is serviced four times as frequently as a queue with a weight of 1. The hardware services higher-weighted queues more frequently, but lower-weighted queues continue to be serviced at all times. Initially, the weight

for all queues is set to 1, which gives them equal weight. If all queues are set to 4, for example, all queues still have equal weight, but each queue is serviced for a longer period.

- Round-robin priority: All queues are given access based on the configured priority level and a round-robin algorithm.

Scheduling takes place on the egress interface and includes consideration for the color-marking of egress frames and packets. Green-marked traffic has the highest priority and is forwarded based on the scheduling method. When multiple queues are competing for bandwidth, yellow-marked traffic might be dropped or remarked red. Red-marked traffic is dropped when no bandwidth is available. If yellow-marked traffic is forwarded to the egress port rate-shaping component, it can be dropped there if the egress port is congested.

Introduction to WRED

The weighted random early detection (WRED) feature is supported on some platforms to avoid congestion in traffic queues or *QoS* profiles. WRED improves upon the TCP congestion control mechanism.

The TCP congestion control mechanism on hosts detects congestion when packets are lost and lowers the packet transmission rate in response. At the switch, packets are dropped when a queue is full. When multiple hosts forward packets that are dropped, multiple hosts reduce the transmission rate. This creates a global synchronization problem as multiple hosts overwhelm a queue and then simultaneously lower their transmission rate and under utilize the queue.

WRED is an extension to random early detection (RED), which calculates an average queue size and randomly discards packets in proportion to the queue usage. At low usage levels, no packets are discarded. As the average queue size exceeds configured thresholds, packets are discarded in proportion to the queue usage. Discarding packets early causes some (but not all) hosts to reduce their transmission rate, which reduces queue congestion. The random nature of the discard process reduces the global synchronization problem.

WRED extends RED by applying different discard rules for different types of traffic. Typically, WRED is used on core routers and takes action based on the packet contents established at edge routers. Edge routers can use the IP precedence or DSCP value to mark packets as committed (green), conforming (yellow), or exceeded (red). The marking process and these colors are described in Introduction to Rate Limiting, Rate Shaping, and Scheduling on page 870.

The ExtremeXOS WRED implementation varies per platform and allows you to configure the following:

- Minimum threshold for dropped packets.
- Maximum threshold for dropped packets.
- Maximum drop rate.
- An average weight control that determines how WRED calculates the average queue size.

WRED does not drop packets at calculated average queue sizes below the minimum threshold (although packets would be dropped if the queue fills).

When the calculated average queue size rises above the maximum threshold, WRED drops packets at the maximum drop rate. When the calculated average falls between the minimum and maximum thresholds, packets are randomly dropped at a proportional rate between zero and the maximum drop rate. As the queue fills, more packets are dropped.

The average weight parameter provides some control over how the average queue size is calculated and the probability of packet drop. Increasing the avg_weight value reduces the probability that traffic is dropped. Conversely, decreasing the avg_weight value increases the probability that traffic is dropped.

On ExtremeSwitching X450-G2, X460-G2, X465, X590, X620, X695 series switches, you can configure up to four WRED profiles or configurations per QoS profile, enabling you to create custom WRED configurations for up to 32 traffic flows (4 WRED profiles x 8 QoS profiles).

Each QoS profile supports WRED profiles for the following colors of traffic:

- TCP green
- Non-TCP green
- TCP red
- Non-TCP red

Without support for non-TCP traffic management, non-TCP traffic could monopolize a QoS profile in which TCP traffic is regulated, effectively giving non-TCP traffic priority over TCP traffic. With support for both TCP and non-TCP traffic, WRED allows you to regulate different types of traffic independently, giving you greater control over which type of traffic is dropped first and most frequently.

The typical WRED configuration establishes the lowest probability for packet drop for green traffic, which conforms to established limits along the transmission path. A typical WRED configuration establishes a higher probability for packet drop for red colored traffic, because it has already exceeded established limits earlier in the transmission path. All traffic (green and red) is dropped when the queue is full, so the goal is to configure the WRED settings for each color in such a way as to prevent the queue from filling frequently.

Explicit Congestion Notification (ECN)

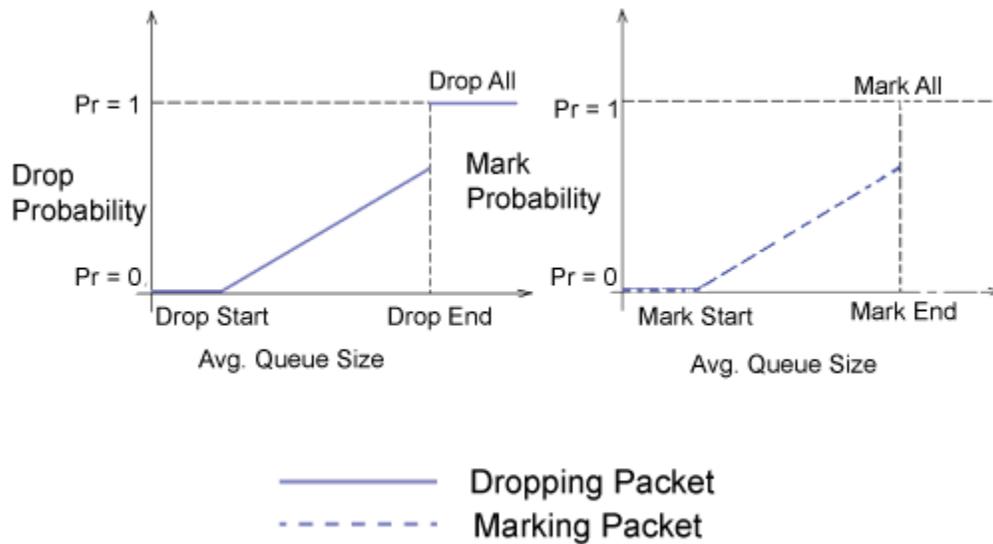
Weighted Random Early Detection (WRED) drops packets based on the average length exceeding a specific threshold value to indicate congestion. Explicit Congestion Notification (ECN) is an extension to WRED that marks the drop-eligible packets, instead of dropping, using the same criteria of minimum threshold, maximum threshold, and drop probability. Figure 103 shows the WRED behavior without ECN and with ECN.


Figure 103: WRED Behavior with and without ECN

The current WRED implementation prevents tail dropping of packets that are queued in the output queue by selectively dropping packets early. This avoids dropping of all packets at once when congestion occurs. With ECN functionality, routers are no longer limited to packet drops to indicate congestion. Routers can instead set the CE (Congestion Experienced) codepoint in the IP header of packets from ECN-capable transport entities. The transport endpoints use the ECE and CWR bits of the TCP header to mitigate congestion.

RFC 3168 states that the two-bit ECN field comprises an ECT bit and a CE bit that are used to implement ECN. The ECT bit and the CE bit can be combined into four possible ECN field values 00 to 11. The first number is ECT bit and the second number is the CE bit. Table 83 shows the possible combination.

Table 83: ENC Field Values

ECT Bit Value	CE Bit Value	Combined Inference
0	0	Not ECN capable. Packet is not using ECN.
0	1	Endpoints are ECN capable.
1	0	Data senders use these values to indicate that the endpoints are ECN capable. Routers treat the two values identically.
1	1	Congestion experienced.

Table 84 indicates the processing applied on incoming packets that are identified as drop-eligible in various ECN scenarios.

Table 84: ECN Processing

Incoming ECN Bits	ECN Configuration	Action if Packet Is Drop-Eligible	Outgoing ECN bits
00 (Non-ECT)	On/Off	Drop.	N/A (packet dropped).
ECT (01 or 10)	Off	Drop.	N/A (packet dropped).
ECT (01 or 10)	On	Not dropped. CE bit is marked.	11 indicates "Congestion Experienced".
CE (11)	Off	Drop.	N/A (packet dropped).
CE (11)	On	Not dropped. Packet already marked, just forward.	11 indicates "Congestion Experienced".

To configure ECN capability as on or off, use the following command:

```
configure qosprofile egress qp_num wred ecn [on | off] ports [port_list
| all]
```

To view ECN information, use the following commands:

```
show wredprofile {ports [port_list | all]}
```

```
show ports port_list wred ecn {no-refresh | refresh}
```

To clear the ECN counters, use the following commands:

```
clear counters wred ecn
```

Supported Platforms

This feature is available on ExtremeSwitching X460-G2, X465, X590, X695 series switches.

Limitations

- TCP yellow traffic color is not supported.
- ECN over VXLAN is not supported. Any tunneling protocol implemented with double headers is not supported.
- The ECN counters showing the number of marked packets is not available yet, so those appear as 0.
- This implementation is limited to ECN pass-through. End points having TCP/DCTCP/RoCEv2 capabilities can use the ECN services.

Meters

Meters are used to define ingress rate-limiting and rate-shaping. Some platforms also support meters for egress traffic. The following sections provide information on meters for specific platforms.

The SummitStack and standalone switches use a single-rate meter to determine if ingress traffic is in-profile or out-of-profile.

On all ExtremeSwitching switches, you can also use single-rate meters to determine if egress traffic is in-profile or out-of-profile.

When _ACL_ meters are applied to a _VLAN_ or to any, the rate limit is applied to each port group. To determine which ports are contained within a port group, use any of the following commands:

```
show access-list usage acl-range port port
```

```
show access-list usage acl-rule port port
```

```
show access-list usage acl-slice port port
```

The out-of-profile actions are drop, set the drop precedence, mark the dot1p, or mark the DSCP with configured value. Additionally, each meter has an associated out-of-profile counter that counts the number of packets that were above the committed-rate (and subject to the out-of-profile-action).

Prior to ExtremeXOS 21.1, when traffic exceeded the specified meter rate, the traffic could be marked with a user-specified diffserv code point. As of ExtremeXOS 21.1, this out-of-profile marking capability is enhanced to additionally include the option of marking the 802.1p value. The 802.1p value that is marked will be the outer 802.1p value in both VLAN and VMAN tagging scenarios. In the latter, the SVLAN's 802.1p value will be modified. Like the existing dscp out-of-profile meter action, this out-of-profile action will work on global and per-port meters.

On ExtremeSwitching series switches, the meters are a per-chip, per-slice resource (see ACLs for complete information.)

> **Note**
> If set-drop-precedence is used as a meter out-of-profile action, you should configure WRED on the egress port so that red packets marked by the meter are dropped in case of egress congestion.

QoS Profiles

QoS profiles are queues that provide ingress or egress rate limiting and rate shaping. The following sections provide more information on QoS profiles.

Egress Qos Profiles

Egress _QoS_ profiles are supported on all ExtremeXOS switches and allow you to provide dual-rate egress rate-shaping for all traffic groups on all egress ports. Any configuration you apply to an egress QoS profile is applied to the same egress QoS profile on all other ports, unless a QoS profile parameter has been overridden for a port.

When you are configuring _ACL_-based traffic groups, you can use the qosprofile action modifier to select an egress QoS profile. For DiffServ-, port-, and _VLAN_-based traffic groups, the traffic group configuration selects the egress QoS profile. For _CoS_ dot1p traffic groups on all platforms, the dot1p value selects the egress QoS profile.

Egress QoS profile operation depends on the switch type and is described in the following sections.

SummitStack and ExtremeSwitching series switches have two default egress QoS profiles named QP1 and QP8. You can configure up to six additional QoS profiles (QP2 through QP7) on the switch. However, on a SummitStack, you cannot create QoS profile QP7, as this profile is reserved for system control traffic. The default settings for egress QoS profiles are summarized Table 85 on page 878.

Table 85: Default QoS Profile Parameters on all Platforms

Ingress 802.1p Priority Value	Egress QoS Profile Name	Queue Service Priority Value	Buffer	Weight	Notes
0-6	QP1	1 (Low)	100%	1	This QoS profile is part of the default configuration and cannot be deleted.
	QP2	2 (LowHi)	100%	1	You must create this QoS profile before using it.
	QP3	3 (Normal)	100%	1	You must create this QoS profile before using it.
	QP4	4 (NormalHi)	100%	1	You must create this QoS profile before using it.
	QP5	5 (Medium)	100%	1	You must create this QoS profile before using it.
	QP6	6 (MediumHi)	100%	1	You must create this QoS profile before using it.
	QP7	7 (High)	100%	1	You must create this QoS profile before using it. You cannot create this QoS profile on SummitStack.
7	QP8	8 (HighHi)	100%	1	This QoS profile is part of the default configuration and cannot be deleted.

---

[4] The QoS Profile Name cannot be changed.
[5] The Queue Service Priority value cannot be changed.

For CoS 802.1p traffic groups, the ingress 802.1p priority value selects a specific QoS profile as shown in Table 85. This mapping can be changed as described in Changing the 802.1p Priority to QoS Profile Mapping on page 891. For traffic groups other than 802.1p-based groups, the traffic group configuration selects a specific egress QoS profile by name.

The default dual-rate QoS configuration is 0% for minimum bandwidth and 100% for maximum bandwidth.

The QoS profile for each port receives a default buffer reservation. All unreserved buffer space is part of a buffer pool, which can be used by QoS profiles when reserved space runs out, provided that the configuration for that QoS profile and port allows it.

You can increase the size of the shared buffer pool by reducing the global buffer reservation for a QoS profile on all switch ports. You can restrict buffer usage for a QoS profile in amounts ranging from 1 to 100%, in whole integers.

You can also override the global buffer reservation to increase or decrease the buffer space allotment for a specific QoS profile on one or more ports. Using the buffer override feature, you can override the global setting to use from 1–10,000% of the configured global allotment. The system does not drop any packets as long as reserved packet buffer memory for the port and QoS profile or shared packet memory for the port (`configure port` *port_list* **shared-packet-buffer** command) remains available.

> **Note**
>
> In a SummitStack, the scheduling algorithm is automatically programmed by ExtremeXOS for the stacking links only, and might be different from the algorithm you select.
>
> Use of all eight queues on all ports can result in insufficient buffering to sustain zero packet loss throughput during full-mesh connectivity with large packets.

When multiple QoS profiles are contending for port bandwidth and the egress traffic in each profile is within profile, the scheduler determines how the QoS profiles are serviced as described in Scheduling on page 872. In strict-priority mode, the queues are serviced based on the queue service priority value. In weighted fair-queuing mode, the queues are serviced based on the configured weight.

When configured to do so, the priority of a QoS profile can determine the 802.1p bits used in the priority field of a forwarded frame (see Introduction to Rate Limiting, Rate Shaping, and Scheduling on page 870). The priority of a QoS profile can determine the DiffServ code point value used in an IP packet when the packet is forwarded (see Replacement of DSCP on Egress on page 886).

A QoS profile change does not alter the behavior of the switch until it is assigned to a traffic group.

Egress Port Rate Limiting and Rate Shaping

Egress port rate limiting and rate shaping allow you to define limits for all egress traffic coming from the egress *QoS* profiles and traffic queues.

You can apply single-rate rate-limiting and control shared packet buffer space (`configure port` *port_list* **shared-packet-buffer** command) for each port.

You can also configure ports to pass an unlimited flow as described in .

Configuring Overhead-Bytes in Calculating Rate-Limiting and Rate-Shaping

You can configure the size of overhead-bytes used in the calculation of rate-limiting and rate-shaping. Overhead-bytes include size of preamble and inter-frame gap. In releases earlier than 21.1, ExtremeXOS included these overhead-bytes during traffic rate-limit and shaping techniques. Now, you can configure overhead-bytes using the `configure forwarding rate-limit overhead-bytes <bytes>` command.

For example, if the frame size is 68 bytes configuring overhead-bytes of 0, the switch calculates rate-limit and shaping techniques with 68 bytes as the frame size. If 20 is the configured overhead-bytes size, the switch calculates rate-limit and shaping techniques with 88 bytes as the frame size. This configuration is applicable for ingress meters, egress *QoS* profile, egress port rate-limiting, and rate-shaping configurations.

Class of Service (CoS)

CoS provides a means to configure 802.1p-based traffic grouping, *QoS* rate-shaping and scheduling, ingress and egress metering and flood rate-limiting via *SNMP (Simple Network Management Protocol)*. The CoS MIB is fully integrated with ONEPolicy to provide a solution to management entities such as Extreme Management Center for QoS on ExtremeXOS

Class of Service (CoS) Settings

Each of the 256 *CoS* entries, indexed 0-255, are mapped to a 802.1p priority (0-7), ToS value (0-255), virtual txq-reference (0-15) and virtual irl-reference (0-31). A virtual reference is used to abstract the hardware capabilities from the CoS row. This allows for the management entity such as Extreme Management Center to create user CoS profiles based on the user and not multiple user profiles for each hardware platform. The virtual references are then mapped to actual hardware resources. On ExtremeXOS, the txq-reference mappings 0-7 are fixed to *QoS* profiles 1-8 and txq-reference 8-15 map to QoS profile 8. The irl-reference mappings are also fixed to the per-port ingress meters. This mapping is dependent on the number of per-port ingress meters supported on the platform.CoS entries 0-7 are equivalent to the dot1p traffic groupings for priorities 0-7.

Port Groups

Port groups allow the user to define ports by similar functionality or role. The user can create port groups and use them to configure *QoS* profiles, ingress meters and flood rate-limiters for ports that share the same role. In addition, Extreme Management Center will create and manipulate port groups through the *CoS* MIB via *SNMP*. These groups will be used to configure the Extreme Management Center-specified CoS resources that are mapped to QoS profiles, ingress meters and flood rate-limiters. Since the Extreme Management Center CoS feature is port group- oriented, extremeXOS QoS entities (e.g. QoS profiles, ingress meter, and flood rate-limiting) that are configured on a per-port basis are not exposed through the CoS MIB via SNMP.

CoS Port Resource

The TXQ, IRL and Flood Control port resource tables in *CoS* are configured using the *QoS* profile, ingress meter and rate-limit flood resource commands in the CLI. These port resources are mapped to CoS when the resources in the CLI are configured using a port group.

CoS Global Enable Action

An *SNMP* set to enable *CoS* will automatically enable per-port dot1p examination and diffserv replacement controls as needed for the functionality of CoS. Diffserv replacement is enabled for a *QoS* profile on all ports if the corresponding tosValue for CoS index 0-7 is configured. Otherwise, diffserv replacement is disabled for the corresponding QoS profile on all ports. Dot1p replacement is disabled for all QoS profiles on all ports. In addition, all QoS profiles are created and the dot1p examination to QoS profile mapping are fixed to match the TXQ reference mapping for CoS indexes 0-7. The internal CoS state is used to warn the user in the CLI in the event that the controls setup by CoS are modified. A subsequent SNMP set to disable CoS disables the internal CoS state. This turns off the warning messages in the CLI; however, it does not restore the configuration to its original state before the global enable action occurred.

When the internal CoS state is enabled, the global enable action is performed on any new switch that is inserted into the stack.

Meter and Flood Actions

ExtremeXOS 16.1 has been expanded to implement the syslog, trap, and disable-port out-actions for meters and flood rate-limiters. This requires additional counters and a polling task to periodically check the thresholds for the configured events.

Meter and Flood Limitations

Port-Meter Out-of-profile Limitations

The *CoS* MIB supports an out-of-profile status and counter for each per-port meter on each port. On all 16.1 supported platforms, the hardware only supports a global counter for each per-port meter. The out-of-profile status is supported for each per-port meter on each port; however, the status is only valid while the meter is out-of-profile. When

the per-port meter rate is no longer exceeded, the out-of-profile status is automatically cleared in the hardware. The ability to detect an out-of-profile per-port meter on a given port is dependent on the out-of-profile status of the per-port meter at the time of the software polling interval.

Due to this limitation, the out-of-profile actions can only accurately be performed if the exceeded per-port meter rate is sustained for the duration of the software polling interval. Any change in the global out-of-profile counter for the per-port meter will be evenly distributed between the ports that indicate an out-of-profile status at the time of the software polling interval. This should give a rough approximation of the out-of-profile count of the per-port meter on each port.

Flood Out-of-profile Limitations

The CoS MIB supports an out-of-profile status and counter on each port for each flood type (unknown unicast, multicast, and broadcast). On all ExtremeXOS 16.1 supported platforms, the hardware only supports a single counter and status per port for all flood types. Any out-of-profile actions configured for one flood type on a given port will be performed if any flood type is out-of-profile on that port. The out-of-profile counter will be the aggregate count of all flood types on a given port.

Configuring QoS

Configuring QoS on SummitStack and ExtremeSwitching Switches

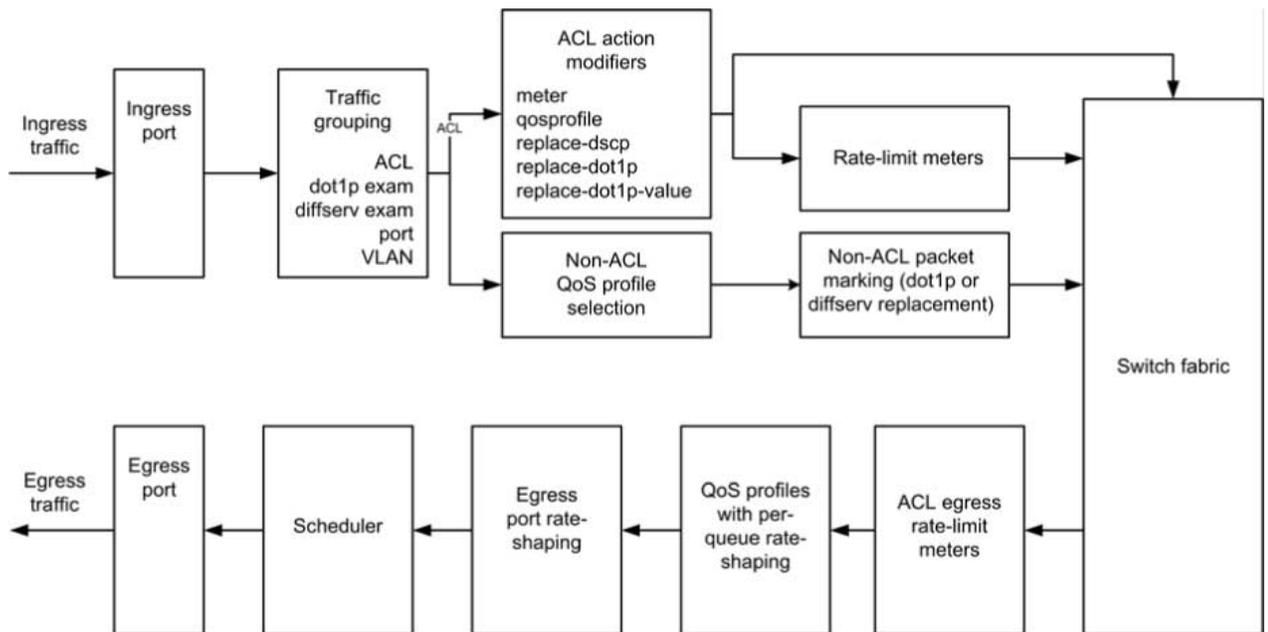
Figure 104 shows the *QoS* configuration components for SummitStack and ExtremeSwitching switches.


Figure 104: QoS on SummitStack and ExtremeSwitching Switches

The considerations below apply to QoS on SummitStack and ExtremeSwitching switches:

- The following QoS features share resources:
    - *ACL*s
    - dot1p
    - *VLAN*-based QoS
    - Port-based QoS
- You might receive an error message when configuring a QoS feature in the above list; it is possible that the shared resource is depleted. In this case, unconfigure one of the other QoS features and reconfigure the one you are working on.
- On a SummitStack, you cannot create QoS profile QP7. This QoS profile is reserved for system control traffic.
- These switches allow dynamic creation and deletion of QoS queues, with QP1 and QP8 always available.
- ACL egress rate-limit meters are supported only on all platforms.

Configuration Summary

Use the following procedure to configure *QoS*:

1. Configure basic Layer 2 connectivity (prerequisite).
2. Configure QoS scheduling, if needed, as described in Selecting the QoS Scheduling Method on page 884.
3. Configure ingress and egress rate-limiting as needed:
   a. Create a meter as described in Creating Meters on page 893.
   b. Configure the meter as described in Configuring a Meter on page 893.
   c. Apply the meter to ingress traffic as described in Applying a Meter to Ingress Traffic on page 893.
4. Configure non-*ACL*-based egress QoS profile selection as described in the following sections:
   - Configuring a CoS 802.1p-Based Traffic Group on page 890
   - Configuring a DiffServ-Based Traffic Group on page 891
   - Configuring a Port-Based Traffic Group on page 892
   - Configuring a VLAN-Based Traffic Group on page 892
5. Configure 802.1p or DiffServ packet marking as described in Configuring 802.1p or DSCP Replacement on page 884.
6. Configure egress QoS profile rate shaping as needed:
   a. Create egress QoS profiles as described in Creating or Deleting an Egress QoS Profile on page 888.
   b. Configure egress QoS profile rate shaping parameters as described in Configuring an Egress QoS Profile on page 888.
7. Configure egress port rate shaping as described in Configuring Egress Port Rate Limits on page 889.
8. Finalize ACL traffic-based group configuration as described in Configuring an ACL-Based Traffic Group on page 890.

9. Verify the configuration using the commands described in Displaying QoS Configuration and Performance on page 894.

Selecting the QoS Scheduling Method

QoS scheduling determines the order of QoS profile service and varies between platforms. SummitStack and ExtremeSwitching series switches support three scheduling methods: strict-priority, weighted-round-robin, and weighted-deficit-round-robin. These scheduling methods are described in Scheduling on page 872. Scheduling can be applied globally or on a per-port or per-PortGroup basis. If no port_list or port_group is specified in the command, the global scheduling algorithm is set and applied to ports that are not configured via a port_list or port_group. Specifying a port_list or port_group in the command configures the scheduling algorithm for specific ports.

QoS profiles can also be overriden on a global, per-port or per-port_group basis. If no port_list or port_group is specified, the global qosprofile configuration is changed and applied to all ports that are not configured on a per-port or per-port_group basis.

1. Select the QoS scheduling method for a switch.

   ```
   configure qosscheduler [strict-priority | weighted-round-robin |
   weighted-deficit-round-robin ] {ports [port_list | port_group | all ]}
   ```

   > **Note**
   > In a SummitStack, the scheduling algorithm is automatically programmed by ExtremeXOS for the stacking links only, and will likely be different than the algorithm you select.

2. Override the weighted-round-robin switch configuration on a specific QoS profile.

   ```
   configure qosprofile qosprofile use-strict-priority
   ```

Configuring 802.1p or DSCP Replacement

Replacement of 802.1p Priority Information on Egress

By default, 802.1p priority information is not replaced or manipulated, and the information observed on ingress is preserved when forwarding the frame. This behavior is not affected by the switching or routing configuration of the switch. However, the switch is capable of inserting and/or overwriting 802.1p priority information when it transmits an 802.1Q tagged frame as described below.

Replacement in ACL-Based Traffic Groups

If you are using ACL-based traffic groups, you can use the `replace-dot1p` action modifier to replace the ingress 802.1p priority value with the 802.1p priority value of

the egress *QoS* profile as listed in the following table. To specify a specific 802.1p priority value on egress, use the `replace-dot1p-value` action modifier.

> **Note**
> If you are using ACL-based traffic groups, you must use ACL action modifiers to replace the 802.1p priority. Traffic that meets any ACL match conditions is not subject to non-ACL-based 802.1p priority replacement.

Replacement in Non-ACL-Based Traffic Groups

For non-ACL-based traffic groups, you can enable or disable 802.1p priority replacement on specific ingress ports. When 802.1p priority replacement is enabled, the default egress 802.1p priority value is set to the priority value of the egress QoS profile as listed in Table 86.

Table 86: Default Queue-to-802.1p Priority Replacement Value

Egress QoS Profile	802.1p Priority Replacement Value
QP1	0
QP2	1
QP3	2
QP4	3
QP5	4
QP6	5
QP7	6
QP8	7

To enable 802.1p priority replacement on egress, use the following command:

```
enable dot1p replacement ports [port_list | all]
```

> **Note**
> The port in this command is the ingress port.

To disable this feature, use the following command:

---

6 You cannot direct traffic to this QoS profile in a SummitStack.

```
disable dot1p replacement ports [port_list | all]
```

> **Note**
>
> If only DiffServ traffic groups are enabled, then 802.1p priority enforcement for 802.1q tagged packets continues for non-IP packets using the default 802.1p map shown in the following table.
>
> Only QP1 and QP8 exist by default; you must create QP2 to QP7 (QP2 to QP5 in a SummitStack). If you have not created these QPs, the replacement feature will not take effect.
>
> When DiffServ examination is enabled on 1 Gigabit Ethernet ports, 802.1p replacement is enabled and cannot be disabled. The ingress 802.1p value is replaced with the 802.1p value assigned to the egress QoS profile.

Replacement of DSCP on Egress

The switch can be configured to change the DSCP in a packet before forwarding the packet. This is done with no impact on switch performance and can be configured as described in the following sections:

Replacement in ACL-Based Traffic Groups

If you are using ACL-based traffic groups, you can use the replace-dscp action modifier to replace the ingress DSCP value with the DSCP value of the egress *QoS* profile as listed in Table 87. This action modifier functions for both IPv4 and IPv6 traffic.

> **Note**
>
> If you are using ACL-based traffic groups, you must use ACL action modifiers to replace the DSCP. Traffic that meets any ACL match conditions is not subject to non-ACL-based DSCP priority replacement. For all platforms, we recommend that you use ACL-based traffic groups when configuring DSCP replacement.

Replacement in Non-ACL-Based Traffic Groups

For non-ACL-based traffic groups, you can enable or disable DSCP replacement on specific ingress ports. When DSCP replacement is enabled, the DSCP value used on egress is determined by either the QoS profile or the 802.1p priority value. Table 87 shows the default mappings of QoS profiles and 802.1p priority values to DSCPs.

Table 87: Default QoS Profile and 802.1p Priority Value Mapping to DiffServ Code Points

QoS Profile	802.1p Priority Value	DSCP
QP1	0	0
	1	8
	2	16
	3	24
	4	32
	5	40

Table 87: Default QoS Profile and 802.1p Priority Value Mapping to DiffServ Code Points (continued)

QoS Profile	802.1p Priority Value	DSCP
	6	48
QP8	7	56

Replacing a DSCP on Egress

- To replace DSCPs by enabling DiffServ replacement, use the command:

  ```
  enable diffserv replacement ports [port_list | all]
  ```

  > **Note**
  > The port in this command is the ingress port.

- To disable this feature, use the command:

  ```
  disable diffserv replacement ports [port_list | all]
  ```

- To view the current DiffServ replacement configuration, use the command:

  ```
  show diffserv replacement
  ```

- To change the DSCP mapping, use the commands:

  ```
  configure diffserv replacement [{qosprofile} qosprofile | priority
  priority] code-point code_point
  unconfigure diffserv replacement
  ```

DiffServ Example

In this example, we use DiffServ to signal a class of service throughput and assign any traffic coming from network 10.1.2.x with a specific DSCP. This allows all other network switches to send and observe the DSCP instead of repeating the same *QoS* configuration on every network switch.

To configure the switch:

1. Using ACLs, assign a traffic grouping for traffic from network 10.1.2.x to QP3:

   ```
   configure access-list qp3sub any
   ```

   The following is a sample policy file example:

   ```
   #filename: qp3sub.pol
   entry QP3-subnet {
       if {
           source-address 10.1.2.0/24
       } then {
           Qosprofile qp3;
           replace-dscp;
           }
   ```

2. Configure the switch so that other switches can signal calls of service that this switch should observe.

```
enable diffserv examination ports all
```

> **Note**
> The switch only observes the DSCPs if the traffic does not match the configured access list. Otherwise, the *ACL* QoS setting overrides the QoS DiffServ configuration.

Configuring Egress QoS Profile Rate Shaping

Creating or Deleting an Egress QoS Profile

The default configuration for most platforms defines eight egress *QoS* profiles. The default configuration defines two egress QoS profiles.

- Use the following command to create an additional egress QoS profile:

  ```
  create qosprofile [QP2| QP3 | QP4 | QP5 | QP6 | QP7]
  ```

- Use the following command to delete an egress QoS profile:

  ```
  delete qosprofile [QP2| QP3 | QP4 | QP5 | QP6 | QP7]
  ```

Configuring an Egress QoS Profile

- Egress *QoS* profile rate shaping is disabled by default on all ports. On all platforms, use the following commands to configure egress QoS profile rate shaping on one or more ports:

  ```
  configure qosprofile egress qosprofile [{minbw minbw_number} {maxbw
  maxbw_number} | {peak_rate peak_bps [K | M]}] [ports [port_list |
  all]]
  ```

  ```
  configure qosprofile qosprofile [{minbw minbw_number} {maxbw
  maxbw_number} | {{committed_rate committed_bps [K | M]} {peak_rate
  peak_bps [K | M]} | [ports [port_list | all]]
  ```

  ```
  configure {qosprofile} qosprofile [[{maxbuffer buffer_percentage}
  {use-strict-priority}] | [maxbuffer buffer_percentage ports [port_list
  | all]]]
  ```

  > **Note**
  > You must use these commands on all platforms if you want to configure the buffer size or weight value. Otherwise, you can use the command in the following description.
  > You cannot configure the priority for the QoS profile.

- To remove the limit on egress bandwidth per QoS profile per port, re-issue this command using the default values.
- To display the current configuration for the QoS profile, use the following command.

  ```
  show qosprofile [ all | port_list | port_group]
  ```

Configuring WRED on an Egress QoS Profile

- To configure or unconfigure WRED on an egress *QoS* profile, use the following commands:

  ```
  configure {qosprofile} {egress} qosprofile [wred [{color [tcp [green |
  red] | non-tcp [any|red]] [{min-threshold min_thresh} {max-threshold }
  {max-drop-rate max_drop_rate}]} | avg-weight avg_weight]] ports
  [port_list | all]
  ```

  ```
  unconfigure qosprofile wred {ports [port_list | all]}
  ```

- To display the WRED configuration settings, use the following command:

  ```
  show wredprofile {ports [port_list | all]}
  ```

Configuring Egress Port Rate Limits

Configuring Egress Traffic

- The default behavior is to have no limit on the egress traffic per port. To configure egress rate limiting, use the following command:

  ```
  configure ports [port_list | port_group]rate-limit egress [no-limit |
  cir-rate [Kbps | Mbps | Gbps] {max-burst-size burst-size [Kb | Mb]}]
  ```

- To view the configured egress port rate-limiting behavior, use the following command.

  ```
  show port {mgmt | port_list | tag tag} information {detail}
  ```

  You must use the *detail* parameter to display the egress port rate configuration and, if configured, the maximum burst size. Refer to Displaying Port Information on page 311 for more information on the `show ports information` command.

  You can also display this information using the following command:

  ```
  show configuration vlan
  ```

  The following is sample output from the show configuration vlan command for configured egress rate limiting:

  ```
  # Module vlan configuration.
  #
  configure vlan Default tag 1
  config port 3:1 rate-limit egress 128 Kbps max-burst-size 200 Kb
  config port 3:2 rate-limit egress 128 Kbps
  config port 3:10 rate-limit egress 73 Kbps max-burst-size 128 Kb
  configure vlan Default add ports 3:1-48 untagged
  ```

  > **Note**
  > Refer to FDB on page 646 for more information on limiting broadcast, multicast, or unknown MAC traffic ingressing the port.

Configuring Traffic Groups

Configuring an ACL-Based Traffic Group

ACL-based traffic groups are introduced in ACL-Based Traffic Groups on page 866. An ACL can implement multiple QoS features, so it is usually best to finalize the ACL after all other features have been configured.

To configure an ACL-based traffic group, do the following:

1. Create an ACL policy file and add rules to the file using the following guidelines:
   a. Use ACL match conditions to identify the traffic for the traffic group.
   b. Use ACL action modifiers to apply QoS features such as ingress meter or traffic queue selection, egress QoS profile or traffic queue selection, and 802.1p priority replacement to the traffic group.
2. Apply the ACL policy file to the ports where you want to define the traffic groups. You can apply the file to specific ports, all ports, or all ports in a VLAN.

> **Note**
> ACLs are described in detail in the ACLs chapter.

Configuring a CoS 802.1p-Based Traffic Group

As described in CoS 802.1p-Based Traffic Groups on page 867, the default switch configuration defines CoS 802.1p-based traffic groups. The configuration options for these groups are described in the following sections:

- Enabling and Disabling 802.1p Examination on page 890
- Changing the 802.1p Priority to QoS Profile Mapping on page 891

> **Note**
> If you are using ACL-based traffic groups, use the `qosprofile` or `traffic-queue` action modifier to select a forwarding queue. Traffic that meets any ACL match conditions is not evaluated by other traffic groups.

Enabling and Disabling 802.1p Examination

CoS 802.1p examination is supported on all platforms and enabled by default. However, you can only disable and enable this feature. To free ACL resources, disable this feature

whenever another *QoS* traffic grouping is configured. (See ACLs for information on available ACL resources.)

> **Note**
> If you disable this feature when no other QoS traffic grouping is in effect, 802.1p priority enforcement of 802.1q tagged packets continues. If only DiffServ traffic groups are enabled, then 802.1p priority enforcement for 802.1q tagged packets continues for non-IP packets using the default 802.1p map shown in the following table.

- To disable the 802.1p examination feature, use the following command.

  ```
  disable dot1p examination ports [port_list | all]
  ```

  > **Note**
  > 802.1p examination cannot be disabled for 802.1p priority level 6 in a SummitStack. When 802.1p examination is disabled on a SummitStack, the precedence for the remaining examination becomes lower than that of all other traffic groupings.

- To re-enable the 802.1p examination feature, use the following command:

  ```
  enable dot1p examination ports [port_list | all]
  ```

- To display whether the 802.1p examination feature is enabled or disabled, use the following command:

  ```
  show ports {mgmt | port_list | tag tag} information {detail}
  ```

Changing the 802.1p Priority to QoS Profile Mapping

To view the current 802.1p priority to *QoS* profile mapping on a switch, enter the following command:

```
show dot1p
```

To change the mapping, enter the following command:

```
configure dot1p type dot1p_priority {qosprofile} qosprofile
```

Configuring a DiffServ-Based Traffic Group

As described in DiffServ-Based Traffic Groups on page 868, the default switch configuration defines DiffServ-based traffic groups. The configuration options for these groups are described in the following sections:

- Enabling and Disabling Diffserv Examination on page 892
- Changing the DSCP to QoS Profile Mapping on page 892

> **Note**
> If you are using *ACL*-based traffic groups, use the `qosprofile` or `traffic-queue` action modifier to select a forwarding queue. Traffic that meets any ACL match conditions is not evaluated by other traffic groups.

Enabling and Disabling Diffserv Examination

When a packet arrives at the switch on an ingress port and Diffserv examination is enabled, the switch uses the DSCP value to select the egress *QoS* profile that forwards the packet. The QoS profile configuration defines the forwarding characteristics for all traffic assigned to the QoS profile.

- The DiffServ examination feature is disabled by default. To enable DiffServ examination, use the following command:

  ```
  enable diffserv examination ports [port_list | all]
  ```

  > **Note**
  > When DiffServ examination is enabled on 1 Gigabit Ethernet ports for ExtremeSwitching series switches, 802.1p replacement is enabled and cannot be disabled. The ingress 802.1p value is replaced with the 802.1p value assigned to the egress QoS profile.

- To disable DiffServ examination, use the following command:

  ```
  disable diffserv examination ports [port_list | all]
  ```

Changing the DSCP to QoS Profile Mapping

- You can change the egress *QoS* profile assignment for each of the 64 code points. To view the current DSCP to QoS profile mapping, use the following command:

  ```
  show diffserv examination
  ```

- Use the following commands to change the DSCP to QoS profile mapping:

  ```
  configure diffserv examination code-point code_point {qosprofile}
  qosprofile
  ```

  ```
  unconfigure diffserv examination
  ```

  After a QoS profile is assigned, the rest of the switches in the network prioritize the packet using the characteristics specified by the QoS profile.

Configuring a Port-Based Traffic Group

A port-based traffic group links a physical ingress port to an egress *QoS* profile for traffic forwarding.

To configure a port-based traffic group, use the following command:

```
configure ports port_list {qosprofile} qosprofile
```

> **Note**
> If you are using *ACL*-based traffic groups, use the `qosprofile` or `traffic-queue` action modifier to select a forwarding queue. Traffic that meets any ACL match conditions is not evaluated by other traffic groups.
> Port-based traffic groups apply to all packets.

Configuring a VLAN-Based Traffic Group

A *VLAN*-based traffic group links all ports in a VLAN to an egress *QoS* profile for traffic forwarding. All intra-VLAN switched traffic and all routed traffic sourced from the named VLAN uses the specified QoS profile.

To configure a VLAN-based traffic group, use the following command:

```
configure vlan vlan_name {qosprofile} qosprofile
```

> **Note**
>
> If you are using _ACL_-based traffic groups, use the `qosprofile` or `traffic-queue` action modifier to select a forwarding queue. Traffic that meets any ACL match conditions is not evaluated by other traffic groups.
> VLAN-based traffic groups apply to all packets.

Creating and Managing Meters

You can configure meters to define bandwidth requirements on SummitStack and ExtremeSwitching series switches.

Creating Meters

- To create a meter, use the following command:

  ```
  create meter meter-name
  ```

- To display the meters already configured on the switch, use the command:

  ```
  show meter meter_name
  ```

ExtremeXOS now creates 8 to 16 default ingress meters that are used for per-port metering. These are named "ingmeter<n>" where n is 0-15.

Configuring a Meter

After you create a meter, you can configure the meter using the command for the platform you are using. To configure a _QoS_ meter on all platforms, use the following command:

```
configure meter metername {committed-rate cir [Gbps | Mbps | Kbps |
Pps]} {max-burst-size burst-size [Kb | Mb | packets]} {out-actions
[{disable-port} {drop | set-drop-precedence {dscp [none | dscp-value]}
{dot1p [ none | dot1p-value ]}} {log} {trap}]} {ports [port_group |
port_list]}
```

> **Note**
>
> The disable-port, log, and trap options are only allowed for per-port meters (i.e. ingmeter0, ingmeter1,...).

Applying a Meter to Ingress Traffic

You can apply a meter to ingress traffic using an _ACL_ on SummitStack and ExtremeXOS switches.

Use rules within the ACL to identify the ingress traffic to which you want to apply the meter. Apply the meter by specifying the meter name with the `meter metername` action modifier. For information on completing the ACL configuration, see Configuring an ACL-Based Traffic Group on page 890.

Deleting a Meter

To delete a meter, use the following command:

```
delete meter meter-name
```

> **Note**
> The associated meters are not deleted when you delete any type of traffic queue. Those meters remain and can be associated with other traffic queues. To display the configured meters, use the `show meter meter_name` command.

Adjusting the Byte Count Used to Calculate Traffic Rates

You can configure a per-packet byte adjustment that the system uses to calculate the ingress traffic rate, traffic utilization, and traffic statistics. You configure either the number of bytes you want subtracted from each packet ingressing the specified ports or the number of bytes you want added to the packet ingressing the specified ports.

By default, all bytes are counted for the ingressing traffic rate. After you issue this command, the default number of bytes removed is 0; you can add or subtract from one to four bytes from each ingressing packet on the specified ports for calculating the ingressing traffic rate.

- To display the number of bytes added to or subtracted from the packet to calculate the ingressing traffic rate, traffic utilization, and traffic statistics, enter the command:

  ```
  show ports port_list information detail
  ```

  > **Note**
  > You must use the `detail` keyword to display this information.

- To unconfigure this setting, re-issue the command and enter the value `0`.

Controlling Flooding, Multicast, and Broadcast Traffic on Ingress Ports

You can control ingress flooding of broadcast and multicast traffic and traffic for unknown destination MAC addresses.

To control ingress flooding of broadcast and multicast traffic and traffic for unknown destination MAC addresses, enter the command:

```
configure ports port_list | port_group rate-limit flood [broadcast |
multicast | unknown-destmac] [no-limit | pps]
```

Displaying QoS Configuration and Performance

Displaying Traffic Group Configuration Data

Displaying 802.1p Priority to QoS Profile Mappings

To display the 802.1p priority to egress *QoS* profile mappings, enter the command:

```
show dot1p
```

Displaying DiffServ DSCP to QoS Profile Mappings

To display the DiffServ DSCP to egress *QoS* profile mappings, enter the command:

```
show diffserv examination
```

Displaying Port and VLAN QoS Settings

To display *QoS* settings assigned to ports or *VLAN*s, enter the command:

```
show port {mgmt | port_list | tag tag} information {detail}
```

> **Note**
> To ensure that you display the QoS information, you must use the **detail** keyword.

This command displays which QoS profile, if any, is configured.

Displaying Performance Statistics

Displaying QoS Profile Traffic Statistics

After you have created *QoS* policies that manage the traffic through the switch, you can use the QoS monitor to determine whether the application performance meets your expectations.

The QoS monitor allows you to display the traffic packet counts in a real-time or a snapshot display for the specified ports.

- View QoS profile traffic statistics entering the command:.

  ```
  show ports port_list qosmonitor {congestion} {no-refresh}
  ```
- View or clear the WRED statistics by entering the command:

  ```
  show ports port_list wred {no-refresh}
  clear counters wred
  ```

Displaying Congestion Statistics

- To display a count of the packets dropped due to congestion on a port, use the command:

  ```
  show ports port_list congestion {no-refresh}
  ```
- To display a count of the packets dropped due to congestion in the *QoS* profiles for a port, use the command:

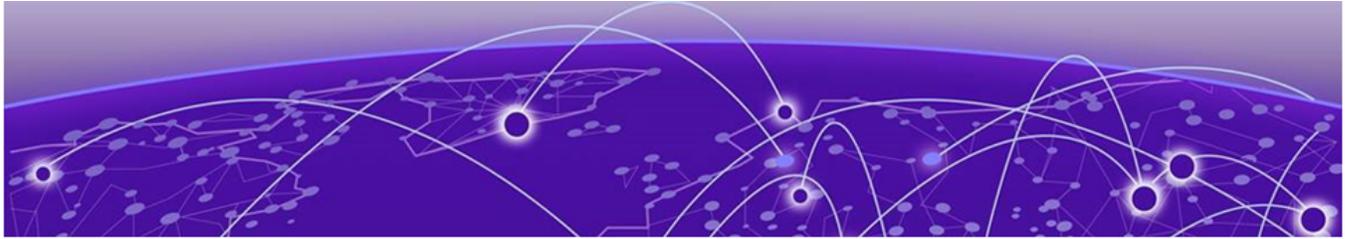
  ```
  show ports port_list qosmonitor {congestion} {no-refresh}
  ```
- To display traffic counts for each profile on the specified stacking ports, use the command:

  ```
  show ports stack-ports stack_port_list qosmonitor {no-refresh | refresh} {port-number}
  ```

- To display packet counts or dropped-traffic counts for each profile on the specified stacking ports, use the command:

  show ports **stack-ports** *stack_port_list* **qosmonitor congestion** {**no-refresh** | **refresh**} {**port-number**}

- To display the stacking port congestion statistics (dropped packets) for the specified ports on the front panel, use the command:

  show ports **stack-ports** *stack_port_list* **congestion** {**no-refresh** | **refresh**} **port-number**


Network Login

This chapter offers information about Network Login procedures. This section provides an overview, specific configuration information, and specific information about Local Database Authentication, 802.1X Authentication, Web-based Authentication, and MAC-based Authentication.

Network Login Overview

Network login controls the admission of user packets into a network by allowing MAC addresses from users that are properly authenticated. Network login is controlled on a per-port basis.

When network login is enabled on a port, that port does not forward any packets until authentication takes place.

Unknown broadcast/unicast/multicast (BUM) traffic is not allowed on the egress side of network login-enabled ports until authentication is successful. To allow BUM traffic to egress on network login-enabled, unauthenticated ports, use `configure netlogin` **ports** [*port_list* | **all**] **allow egress-traffic** [**none** | **unicast** | **broadcast** | **all_cast**] .

Network login is capable of three types of authentication: web-based, MAC-based, and 802.1X. In addition, network login has two different modes of operation: campus mode and ISP mode. The authentication types and modes of operation can be used in any combination.

When web-based network login is enabled on a switch port, that port is placed into a non-forwarding state until authentication takes place. To authenticate, a user must open a web browser and provide the appropriate credentials. These credentials are either approved, in which case the port is placed in forwarding mode, or not approved,

in which case the port remains blocked. You can initiate user logout by submitting a logout request or closing the logout window.

The following capabilities are included with network login:

- Web-based login using HTTP available on each port.
- Web-based login using HTTPS—if you install SSL—available on each port.
- Multiple supplicants for web-based, MAC-based, and 802.1X authentication on each port.

ExtremeXOS *NetLogin* provides the *AAA (Authentication, Authorization, and Accounting)* functionality, which is an important block of the network infrastructure and security and provides a model or framework to determine who is requesting network access, network resources that can be accessed by the requesting party, and when the resources are used. NetLogin supports all popular methods of authentication: MAC-based, Web-based, and IEEE 802.1X. NetLogin can help network administrators to control access into the network; it also provides flexibility to configure specific backend resources to which user access is allowed.

Together with IP Security, administrators can enhance security in the network by controlling access to upstream network and resources by the hosts or clients. IP Security is a collection of powerful features that allow network administrators to design security in combination with standard authentication and authorization techniques. IP Security features as ExtremeXOS 15.2 include:

- *DHCP (Dynamic Host Configuration Protocol)* Snooping and concept of trusted DHCP Servers
- Source IP Lockdown
- ARP Learning and Validation
- Gratuitous ARP Protection

When NetLogin and IP Security features are enabled on a port, NetLogin performs the first or the basic function of authenticating and authorizing the user. Further course of

action is determined by IP Security in case a violation is detected. The violation action
will then determine further access to the network.

Scenario	Notes	Expected Behavior
NetLogin + DHCP Snooping and trusted DHCP Servers/Ports. Violation: DHCP Server Packets seen on netlogin enabled ports (i.e. a host is masquerading post authentication).	We recommend that you enable NetLogin on the client-facing ports. Enabling DHCP Snooping on all ports, including client/host facing ports and ports connected to the upstream network automation and provisioning infrastructure, ensures that all DHCP messages are processed by the switch and a DHCP binding database is maintained. For the combination of NetLogin and DHCP Security to work correctly, we recommend that you configure at least one uplink (or server facing port) as a trusted port. This ensures that all other ports (normally client-facing ports) automatically become untrusted, and can be monitored for any violations that might occur. You can configure more than one uplink port as "trusted" as this allows flexibility in network design. In addition to controlling which DHCP Servers can communicate with the downstream clients, the trusted DHCP Server configuration can be used.	Action: None NetLogin authenticates the client, and IP Security flags a violation. No action is taken because of configuration. Action: Drop-packet The packet is dropped, and an EMS event is logged. Action: block-mac NetLogin initially authenticates the client, and subsequently when the violation occurs, IP Security reports violation, which causes the MAC address to be blocked either permanently or for a configured duration on the switch. The _FDB (forwarding database)_ will be flushed after FDB entry ages out and the netlogin entry is unauthenticated and removed from the switch. Action: block-port NetLogin initially authenticates the client, and subsequently when the violation occurs, IP Security reports the violation, which causes the port to be administratively disabled. As a result, all authenticated clients on the ports are immediately unauthenticated and removed from the switch. This can occur either for a certain configured duration or permanently. We do not recommend that you use this configuration if there are multiple supplicants on the port (for example, conference rooms, groups of users, etc. accessing the network through an intermediate port extender, or hub). In addition, for network troubleshooting and debugging purposes, an _SNMP (Simple Network Management Protocol)_ trap can be sent to a central network manager

Scenario	Notes	Expected Behavior
		such as Extreme Management Center or Ridgeline.
NetLogin + Source IP Lockdown Violation: After a client/host successfully authenticates to the network, it performs a source IP address violation.	The Source IP lockdown feature can determine if a client/host should be allowed access to the network based on inspection of the source IP address used in the packets. If a client is not using an IP address present in DHCP binding database, a violation is flagged for the client and further action is determined by configuration. This helps prevent clients from using source addresses not assigned by a centralized network automation and provisioning infrastructure. By default the switch denies all IP traffic from clients when source IP lockdown is enabled. In order for the clients to get a valid IP address, DHCP packets are allowed to be forwarded through the switch. NetLogin authentication (all three forms) will still proceed, and clients presenting the valid credentials (per authentication scheme) are authenticated. Post authentication (and authorization - for membership to a _VLAN (Virtual LAN)_), once a valid DHCP binding is found for the client, access control lists are automatically (dynamically) applied to permit traffic from the client.	It is not mandatory to configure specific violation actions in DHCP Snooping (which is a prerequisite to this feature). If configured, DHCP Snooping filters and violation actions take precedence over source IP lockdown. This is to ensure that successfully authenticated clients (with NetLogin) do not masquerade as rogue DHCP servers post authentication. In this case, DHCP violation is detected and actions are determined per configuration for vilation-action.

Scenario	Notes	Expected Behavior
NetLogin + DHCP Secured ARP	DHCP Secured ARP allows administrators to control how the ARP table is populated. By default, the switch learns IP ARP bindings and builds the ARP table by tracking the ARP requests and replies. When DHCP Secured ARP is used for design, IP ARP learning method can be disabled. This is recommended for security purposes. When combined with NetLogin, this feature ensures that a client (even after success authentication) cannot override the ARP entry on the switch, thereby preventing duplicate addresses and ensuring proper network operation. ARP entries populated from DHCP are known as Secure ARP entries and are flushed/removed only when the address is released.	Same behavior as expected in the case of "NetLogin + DHCP Snooping and Trusted Ports/Server". Apart from securing the IP ARP table, in this case, violations detected as part of DHCP Snooping and validation is flagged and actions are determined by configuration.

Scenario	Notes	Expected Behavior
NetLogin + ARP Validation	ARP Validation helps check different fields in the ARP packet. Source MAC, Destination MAC, and Source IP addresses can be checked for validity. For a complete reference to the different checks performed, please refer to ARP Validation Options. All checks are performed post authentication.	Violation actions are same as the options presented in the DHCP Snooping and Validation Cases. Same expected behavior and functionality as in the case of "NetLogin + DHCP Snooping and Trusted Ports/Server".
NetLogin + Gratuitous ARP Protection	Gratuitous ARP is a method by which a client/host can resolve its own IP address, and is useful in scenarios where duplicate addresses need to be detected, or a host can announce that it has either used an IP address on a different NIC card, or even if a client has moved from one location to another. While ExtremeXOS supports Gratuitous ARP, protection can also be enabled to mitigate any risk or threats that can arise because of any m-i-m attacks. The switch will automatically send ARP packets to not only protect its own IP address but to also safeguard addresses of any NetLogin authenticated clients on the switch. For this, it is recommended that both DHCP Secured ARP and Gratuitous ARP protection be enabled on the switch. It is not mandatory that DHCP Snooping be enabled for this feature, but becomes a prerequisite if DHCP Secured ARP is also configured.	ARP Packets are sent out when a violation is detected. For all other violations detected by DHCP Snooping and Trust, the corresponding violation actions are determined by configuration, and expected behavior is the same as the case of "NetLogin + DHCP Snooping and Trusted Servers/Ports".

Web-Based, MAC-Based, and 802.1X Authentication

Authentication is handled as a web-based process, MAC-based process, or as described in the IEEE 802.1X specification.

Web-based network login does not require any specific client software and can work with any HTTP-compliant web browser. By contrast, 802.1X authentication may require additional software installed on the client workstation, making it less suitable for a user walk-up situation, such as a cybercafé or coffee shop. A workstation running Windows 7 or Windows 8 supports 802.1X natively, and does not require additional authentication

software. Extreme Networks supports a smooth transition from web-based to 802.1X authentication.

> **Note**
> When both HTTP and HTTPS are enabled on the switch and sending HTTP requests from the Netlogin client, HTTPS takes preference and the switch responds with a HTTPS response.

MAC-based authentication is used for supplicants that do not support a network login mode, or supplicants that are not aware of the existence of such security measures, for example an IP phone.

If a MAC address is detected on a MAC-based enabled network login port, an authentication request is sent once to the AAA application. AAA tries to authenticate the MAC address against the configured Remote Authentication Dial In User Server (*RADIUS (Remote Authentication Dial In User Service)*) server and its configured parameters (timeout, retries, and so on) or the configured local database.

The credentials used for this are the supplicant's MAC address in ASCII representation and a locally configured password on the switch. If no password is configured, the MAC address is also used as the password. You can also group MAC addresses together using a mask (`configure netlogin add mac-list [`*`mac {mask}`* `|` **`default`**`]` `{`**`encrypted`** `{`*`encrypted_password | password`*`}` `{`**`ports`** *`port_list`*`}` `).

DHCP is required for web-based network login because the underlying protocol used to carry authentication request-response is HTTP. The client requires an IP address to send and receive HTTP packets before the client is authenticated; however, the only connection that exists is to the authenticator. As a result, the authenticator must be furnished with a temporary DHCP server to distribute the IP address.

The switch responds to DHCP requests for unauthenticated clients when DHCP parameters such as *`dhcp-address-range`* and *`dhcp-options`* are configured on the network login *VLAN*. The switch can also answer DHCP requests following authentication if DHCP is enabled on the specified VLAN. If network login clients are required to obtain DHCP leases from an external DHCP server elsewhere on the network, DHCP should not be enabled on the VLAN.

Also, enabling DHCP on post authentication VLANs is not be saved in the switch configuration, since the port movement is dynamic. The following warning message appears when enabling DHCP on post authentication VLAN and network login VLAN:

```
Warning: DHCP server configuration will not be saved for netlogin-enabled ports: 1

After reboot/port removal the dhcp config should be reconfigured again
```

The DHCP allocation for network login has a short time duration of 10 seconds and is intended to perform web-based network login only. The Netlogin lease timer can be extended using the command: `configure vlan` *`vlan_name`* **`netlogin-lease-timer`** *`seconds`* . As soon as the client is authenticated, it is deprived of this address. The client must obtain an operational address from another DHCP server in the network. DHCP is not required for 802.1X, because 802.1X uses only Layer 2 frames (EAPOL) or MAC-based network login.

URL redirection (applicable to web-based mode only) is a mechanism to redirect any HTTP request to the base URL of the authenticator when the port is in unauthenticated mode. In other words, when the user tries to log in to the network using the browser, the user is first redirected to the network login page. Only after a successful login is the user connected to the network. URL redirection requires that the switch is configured with a DNS client.

Web-based, MAC-based, and 802.1X authentication each have advantages and disadvantages, as summarized in Advantages of Web-Based Authentication.

Advantages of Web-Based Authentication:

- Works with any operating system that is capable of obtaining an IP address using DHCP. There is no need for special client side software; only a web browser is needed.

Disadvantages of Web-Based Authentication:

- The login process involves manipulation of IP addresses and must be done outside the scope of a normal computer login process. It is not tied to a Windows login. The client must bring up a login page and initiate a login.
- Supplicants cannot be re-authenticated transparently. They cannot be re-authenticated from the authenticator side.
- This method is not as effective in maintaining privacy protection.

Advantages of MAC-Based Authentication:

- Works with any operating system or network enabled device.
- Works silently; the user, client, or device does not know that it gets authenticated.
- Ease of management - set of devices can easily be grouped by the vendor part of the MAC address.

Disadvantages of MAC-Based Authentication:

- Security is based on the MAC address of the client, so the network is more vulnerable to spoofing attacks.

Advantages of 802.1X Authentication:

- In cases where the 802.1X is natively supported, login and authentication happens transparently.
- Authentication happens at Layer 2. It does not involve getting a temporary IP address and subsequent release of the address to obtain a permanent IP address.
- Allows for periodic, transparent re-authentication of supplicants.

Disadvantages of 802.1X Authentication:

- 802.1X native support is available only on newer operating systems, such as Windows 7 or Windows 8.
- 802.1X requires an EAP-capable RADIUS Server. Most current RADIUS servers support EAP, so this is not a major disadvantage.

- Transport Layer Security (TLS) and Tunneled TLS (TTLS) authentication methods involve Public Key Infrastructure (PKI), which adds to the administrative requirements.

Multiple Supplicant Support

An important enhancement over the IEEE 802.1X standard is that ExtremeXOS supports multiple supplicants (clients) to be individually authenticated on the same port.

This feature makes it possible for two or more client stations to be connected to the same port, with some being authenticated while others are not. A port's authentication state is the logical "OR" of the individual MAC's authentication states. In other words, a port is authenticated if any of its connected clients is authenticated. Multiple clients can be connected to a single port of authentication server through a hub or Layer 2 switch.

Multiple supplicants are supported in ISP mode for web-based, 802.1X, and MAC-based authentication. In addition, multiple supplicants are supported in Campus mode if you configure and enable network login MAC-based VLANs. For more information, see Configuring Network Login MAC-Based VLANs on page 943.

The choice of web-based versus 802.1X authentication is again on a per-MAC basis. Among multiple clients on the same port, it is possible that some clients use web-based mode to authenticate, and some others use 802.1X, but the restriction is that they must be in the same untagged _VLAN_. This restriction is not applicable if you configure network login MAC-based VLANs. For more information, see Configuring Network Login MAC-Based VLANs.

> **Note**
> With multiple supplicant support, after the first MAC is authenticated, the port is transitioned to the authenticated state and other unauthenticated MACs can listen to all data destined for the first MAC. Be aware of this as unauthenticated MACs can listen to all broadcast and multicast traffic directed to a network login-authenticated port.

Network Login Multiple Authentication Support

The client or supplicant connected to the NetLogin-enabled port(s) are authenticated by only one authentication protocol. If enabled globally and at the port, MAC-based authentication takes precedence if enabled globally and at the port. Dot1x takes precedence over MAC-based authentication if Dot1x is supported by the supplicant. In this case the MAC-based authentication information is cleared as the client gets authenticated via Dot1x. Web-based authentication happens only when the port belongs to the NetLogin _VLAN_. The final authentication method used with its associated actions is applied while any previous authenticated protocol information is cleared.

This feature supports multiple authentication protocols on a NetLogin-enabled port. The user must specify the authentication protocol priority or order per port which

dictates the action for the client or supplicant that is getting authenticated on this port. Use the CLI to configure the authentication protocol order (`configure netlogin` **authentication protocol-order** [[**dot1x** [**web-based** | **mac** | **cep**]] | [**mac** [**dot1x** | **web-based** | **cep**]] | [**web-based** [**dot1x** | **mac** | **cep**]] | [**cep** [**dot1x** | **web-based** | **mac**]]]). By default the protocol precedence order for a NetLogin-enabled port is:

1. Dot1x
2. Web-based
3. MAC
4. CEP

For example, if the following is the authentication protocol order configured on a NetLogin-enabled port in which three authentication protocols are enabled:

1. Dot1x
2. MAC
3. Web-based

> **Note**
> Precedence order does not work when MAC and web-based are enabled on the same port. If you want to authenticate by web-based, do not use MAC and other protocols.

When user "john" tries to authenticate with his login credentials through Dot1x-enabled supplicant or client, it sends the EAPOL packet to the ExtremeXOS switch or authenticator. Upon receipt of the EAPOL packet, the ExtremeXOS kernel *FDB* module informs the user interface FDBMgr about the new MAC detection. The FDBMgr in turn informs the NetLogin process about the new MAC or client. The NetLogin process tries to authenticate the client/MAC through *RADIUS*. On receiving the authentication result from AAA process, the NetLogin process checks for the protocol precedence configured by the user for that port and also finds if this client is being authenticated by any other authentication protocol. In this case, no other authentication protocol has authenticated this MAC address yet and the NetLogin process applies the action (VLAN movement, UPM security profile, etc.;) corresponding to MAC-based authentication.

The ExtremeXOS switch or authenticator then sends the credentials of user "john" to the authentication server (RADIUS) a second time for Dot1x protocol authentication, After the authentication result is received, the NetLogin process again checks the protocol precedence to find that the user "john's" host/MAC is already authenticated using MAC-based authentication. Since Dot1x is configured as the highest precedence protocol for this port the NetLogin process remove MAC-based authentication actions for this client and apply the Dot1x protocol action for "john" on this port. The MAC-based authenticated client continues to exist and performs the periodic re-authentication for the configured time. The `show netlogin` output shows the client's highest precedence protocol or action applied authentication protocol details only.

When another user "sam" tries to authenticate from the same host or MAC through web-based authentication method (provided the NetLogin-enabled port is still present in NetLogin VLAN) the user "sam" gets authenticated, but the web-based authentication protocol action is not applied, since user "john" is already authenticated

from this MAC address with user-configured highest precedence Dot1x protocol on this port.

> **Note**
>
> After changing the protocol precedence, the action for the current highest precedence protocol (if client is authenticated by this protocol) takes effect immediately.

> **Note**
>
> After disabling the highest precedence protocol on this port, the next precedence protocol (if client is authenticated by this protocol) action takes effect immediately.

Support for Attaching and Detaching the UPM profile

When the user or device gets authenticated the netlogin process will check for the protocol precedence configured by the user in this port and apply or remove the action accordingly. From the previous example when the user "john" tries to authenticate using Dot1x the ExtremeXOS switch or authenticator will authenticate the MAC using MAC based authentication and apply the action corresponding to the MAC based authentication protocol which includes applying UPM profile, creating *VLAN* (if netlogin dynamic VLAN is enabled on this port), VLAN movement etc.; when the user "john" then gets authenticated through Dot1x the ExtremeXOS switch or authenticator determines that Dot1x is the highest precedence protocol configured by the user in this port and removes the actions of MAC based authentication protocol and applies the Dot1x authentication protocol action that includes applying UPM profile, creating VLAN (if netlogin dynamic VLAN is enabled on this port), VLAN movement etc.; the MAC based authenticated client details still remains and continues to get reauthenticated for the configured time.

The netlogin process does the following when the user or MAC is being unauthenticated:

1. Sends accounting stop message to *RADIUS* through AAA.
2. Logs unauthentication EMS message for this client for this authentication protocol.
3. Sends "extremeNetloginUserLogout" SNMP trap message for this authentication protocol.
4. Informs IDM about unauthentication of this client for this authentication protocol.
5. Informs UPM about the client's unauthentication for this protocol.

After performing the above actions, the netlogin process applies the highest precedence authentication protocol action configured for this port.

Campus and ISP Modes

Network login supports two modes of operation, Campus and ISP.

Campus mode is intended for mobile users who tend to move from one port to another and connect at various locations in the network. ISP mode is meant for users who connect through the same port and *VLAN* each time (the switch functions as an ISP).

In Campus mode, the clients are placed into a permanent VLAN following authentication with access to network resources. For wired ports, the port is moved from the temporary to the permanent VLAN.

In ISP mode, the port and VLAN remain constant. Before the supplicant is authenticated, the port is in an unauthenticated state. After authentication, the port forwards packets.

You do not explicitly configure the mode of operation; rather, the presence of any Extreme Networks Vendor Specific Attribute (VSA) that has a VLAN name or VLAN ID (any VLAN attribute) in the _RADIUS_ server determines the mode of operation. If a VLAN attribute is present, it is assumed to be Campus mode. If a VLAN attribute is not present, it is assumed to be ISP mode.

> **Note**
>
> When a client is authenticated in multiple VLANs using campus mode: 1) If any of the authenticated VLANs are deleted manually from a port or globally, the client is unauthenticated from all VLANs; and 2) If traffic is not seen on a particular VLAN then the _FDB_ entry ages out and is deleted; the client itself remains authenticated and the FDB entry is reinstalled either when traffic is detected on that VLAN or when the client reauthenticates. For additional information on Campus and ISP mode operation on ports that support network login and _STP (Spanning Tree Protocol)_, see Exclusions and Limitations.

Spanning Tree Protocol (STP) Support with NetLogin Campus Mode

ExtremeXOS provides support for _STP_ with NetLogin campus mode.

If NetLogin is authenticating a client in campus mode on a port, then that port is moved/added to list of authentication _VLAN_s (provided in VLAN VSA), and as a consequence the port could be removed from the VLANs where it is currently present. Due to this constant port/VLAN movement in campus mode, any STP configuration on the port could be lost; so to protect the port by STP, autobind needs to be configured on the list of authentication VLANs provided in VLAN VSA.

For example, configure RSTP with autobind on VLANs V1, V2, and V3 assuming that there are no ports associated to any of those VLANs. NetLogin moves the ports to the VLANs as when clients get authenticated. As the ports are added to the VLAN, RSTP inherits only tagged ports or untagged ports, depending on the default encapsulation configured for the S1 domain. If S1 is configured with default-encapsulation PVST+ or EMISTP, and if NetLogin adds port P1 to V1 (tagged), then RSTP inherits port P1. This occurs dynamically, and if port P1 is removed from VLAN V1, then port P1 is automatically removed from S1.

This feature is generic and applicable to all STP operational modes.

Supported Platforms

All ExtremeSwitching switches.

Network Login and Hitless Failover

When redundancy is available in a SummitStack, one node assumes the role of primary and the another node assumes the role of backup node.

The primary node executes the switch's management functions, and the backup node acts in a standby role. Hitless failover transfers switch management control from the primary node to the backup node.

> **Note**
> Not all platforms support hitless failover in the same software release. To verify if the software version you are running supports hitless failover, see Protocol Support for Hitless Failover on page 95. For more information about protocol and platform support for hitless failover, see Understanding Hitless Failover Support on page 94.

Network login supports hitless failover by relaying current client authentication information from the master node to the backup node. For example, if a client moves to the authenticated state, or moves from an authenticated state to an unauthenticated state, the primary node conveys this information to the backup node. If failover occurs, your authenticated client continues to operate as before the failover.

Backup nodes do not show reauthentication timer in the output of the show netlogin command as in master. Only the authenticated clients details appear in show netlogin in backup.

> **Note**
> If you use 802.1X network login, authenticated clients remain authenticated during failover; however, shortly after failover, all authenticated clients automatically re-authenticate themselves. Re-authentication occurs without user intervention.

If failover occurs during the authentication or re-authentication of a client, the client must repeat the authentication process.

> **Note**
> Before initiating failover, review the section Synchronizing Nodes on page 1982 to confirm that your switch (or SummitStack) and both (or all) nodes are running software that supports the synchronize command.

Initial Hitless Failover

To initiate hitless failover on a network that uses network login:

1. Confirm that the nodes are synchronized and have identical software and switch configurations using the show switch {detail} command.

   If the primary and backup nodes, are not synchronized and both nodes are running a version of ExtremeXOS that supports synchronization, proceed to Step 2.

   If the primary and backup nodes, are synchronized, proceed to Step 3 on page 910.

   The output displays the status of the primary and backup nodes, with the primary node showing MASTER and the backup node showing BACKUP (InSync).

2. If the primary and backup nodes, are not synchronized, use the synchronize command to replicate all saved images and configurations from the primary to the backup.

    After you confirm that the nodes are synchronized, proceed to Step 3.

3. If the nodes are synchronized, use the show ports tdm information command to initiate failover.

For more detailed information about verifying the status of the nodes and system redundancy, see Understanding System Redundancy on page 89. For more information about hitless failover, see Understanding Hitless Failover Support on page 94.

Network Login over LAG

When *NetLogin* is enabled on a sharing group, user credentials for the *LAG (Link Aggregation Group)* are forwarded to AAA server for authentication. Once authenticated, the LAG is moved to the *VLAN* configured as the destination VLAN for NetLogin, and the learned MAC address is installed over the LAG in the *FDB* on the NetLogin's destination VLAN.

All NetLogin configurations should be done on the LAG master port. For example:

```
enable sharing 24 grouping 24, 25, 26

enable netlogin ports 24 mac
```

For MAC-based authentication (see MAC-Based Authentication on page 937), when NetLogin is enabled on a sharing group, software-based learning is enabled for each member port of the sharing group. Similarly, when member ports are removed from the sharing group, software-based learning is disabled on that member port.

> **Note**
> • When a LAG is removed, all the NetLogin configurations related to that LAG are removed. Before deleting a sharing group, disable NetLogin on the LAG port.
> • The master port cannot be removed from the LAG.
> • The maximum number of authenticated users per LAG group is 1,024.
> • If OnePolicy is enabled, NetLogin global protocol configurations and NetLogin VLAN configurations are lost, and then the LAG port is authenticated using OnePolicy by enabling NetLogin protocols globally.

Network Login over MLAG

Starting with ExtremeXOS 22.4, NetLogin MAC-based authentication and 802.1X authentication are supported in policy mode (NetLogin web-based authentication is not supported) over *MLAG (Multi-switch Link Aggregation Group)* ports. If an MLAG peer goes down, supplicants remain authenticated on the other MLAG peers and continue to send data traffic thereby providing redundancy.

After successful authentication, NetLogin passes the necessary information to the policy module (such as the port, MAC address, policy profile, and authentication result) for further processing, such as movement of the port to VLAN and insertion of MAC address in the FDB.

> **Note**
> ISC port must be added to the destination VLAN for all dynamic VLANs on the switch.

Limitations

- Web-based authentication is not supported.
- Supported in policy mode only.

MLAG Support for Change of Authentication (CoA)

Starting with ExtremeXOS 30.4, MLAG support for Netlogin is extended for dynamic authorization and disconnect (CoA). CoA support (introduced in ExtremeXOS 22.1), which was implemented directly in the policy module, now moves to NetLogin.

The CoA messages that were previously handled directly by the policy module are now handled by the NetLogin module. With ExtremeXOS 30.4, the AAA module, on receiving the CoA messages from the RADIUS server, passes the data to NetLogin. Netlogin checks for the availability of the client, and the mode of authentication. If it finds a valid client, the CoA message is passed to policy for further processing. Additionally, NetLogin takes care of updating the MLAG peer about the dynamic authorization changes or disconnect. The NetLogin module on the MLAG peer passes the message to the policy module of that switch.

Limitations

- CoA support is not provided for web-based clients.
- The CoA server is aware of only the MLAG authenticator, so if the ISC link is down, one MLAG peer might have a client in a different profile with respect to the other MLAG node. This is resolved after the ISC link becomes active. This is a limitation of the CoA server.

Configuring Network Login

This section provides a general overview of the commands used for:

For more detailed information about a specific mode of network login, including configuration examples, see the following sections:

- 802.1X Authentication on page 919
- Web-Based Authentication on page 929
- MAC-Based Authentication on page 937

> **Note**
> When *STP* with Edge-safeguard and the Network login feature are enabled on same port, the port moves to a disabled state when it detects a loop in the network.

Enabling or Disabling Network Login on the Switch

By default, network login is disabled. To enable or disable network login and specify the authentication method, use the following commands:

- `configure netlogin` **vlan** *vlan_name*
- `enable netlogin [{`**dot1x**`} {`**mac**`} {`**web-based**`}]`
- `disable netlogin [{`**dot1x**`} {`**mac**`} {`**web-based**`}]`

Enabling or Disabling Network Login on a Specific Port

Network login must be disabled on a port before you can delete a *VLAN* that contains that port.By default, all methods of network login are disabled on all ports.

- To enable network login on a port to specify the ports and the authentication method, use the following command:

  `enable netlogin ports` *ports* `[{dot1x} {mac} {web-based}]`

  > **Note**
  > When network login and *STP* are enabled on the same port, network login operates only when the STP port is in the forwarding state.

- To disable network login, use the following command:

  `disable netlogin ports` *ports* `[{dot1x} {mac} {web-based}]`

Configuring the Move Fail Action

If network login fails to perform Campus mode login, you can configure the switch to authenticate the client in the original *VLAN* or deny authentication even if the user name and password are correct. For example, this may occur if a destination VLAN does not exist.

To configure the behavior of network login if a VLAN move fails, use the following command:

`configure netlogin move-fail-action [`**authenticate** `|` **deny**`]`

By default, the setting is deny.

The following describes the parameters of this command if two clients want to move to a different untagged VLAN on the same port:

- **authenticate**—Network login authenticates the first client that requests a move and moves that client to the requested VLAN. Network login authenticates the second client but does not move that client to the requested VLAN. The second client moves to the first client's authenticated VLAN.
- **deny**—Network login authenticates the first client that requests a move and moves that client. Network login does not authenticate the second client.

The dot1x client is not informed of the VLAN move-fail because it always receives EAP-Success or EAP-Fail directly based on the authentication result, not based on both authentication and the VLAN move result.

Displaying Network Login Settings

To display the network login settings and parameters, use the following command:

```
show netlogin {port portlist vlan vlan_name} {dot1x {detail}}
```

Setting Netlogin Traps

To set NetLogin trap setting for ports, use the following command:

```
configure netlogin ports [all | port_list] [allowed-users allowed_users
| authentication mode [optional | required] | trap [all-traps | no-traps
| [{success} {failed} {terminated} {max-reached}]]]
```

To set NetLogin system traps, use the following command:

```
configure netlogin trap max-users [enable | disable]
```

Exclusions and Limitations

The following are limitations and exclusions for network login:

- When using *NetLogin* MAC-based *VLAN* mode, moving a port as untagged from a pre-authentication VLAN to a post-authentication VLAN is not supported when both VLANs are configured with Protocol Filter IP.
- All unauthenticated MACs will be seeing broadcasts and multicasts sent to the port if even a single MAC is authenticated on that port.
- Network login must be disabled on a port before that port can be deleted from a VLAN.
- In Campus mode on all switches with untagged VLANs and the network login ports' mode configured as port-based-VLAN, after the port moves to the destination VLAN, the original VLAN for that port is not displayed.
- A network login VLAN port should not be a part of following protocols:
  - *EAPS (Extreme Automatic Protection Switching)*
  - *ESRP (Extreme Standby Router Protocol)*

- Network login and *STP* operate on the same port as follows:
  - At least one VLAN on the intended port should be configured both for network login and STP.
  - When STP blocks a port, network login does not process authentication requests and BPDUs are the only traffic in and out of the port. All user data forwarding stops.
  - When STP places a port in forwarding state, network login operates and BPDUs and user data flow in and out of the port. The forwarding state is the only STP state that allows network login and user data forwarding.
  - If a network login client is authenticated in ISP mode and STP blocks one of the authenticated VLANS on a given port, the client is unauthenticated only from the port or VLAN which is blocked.
  - All clients that are going through authentication and are learned on a blocked port or VLAN are cleared.

  > **Note**
  > When STP with edge-safeguard and network login feature is enabled on the same port, the port goes into the disabled state after detecting a loop in the network. NetLogin campus mode and STP can be configured together on a port with the autobind feature.

- The maximum re-authentication period configured using CLI commands is 86,400 seconds for MAC and Dot1x authentication methods. There is no limitation for the re-authentication period (session timeout) sent using RADIUS server for Netlogin authentication.
- When in non-policy mode, NetLogin is not supported on user VRs. In non-policy mode, it is supported only on VR-Default.

  Enabling NetLogin on ports that are not part of VR-default produces the following error
  ```
  WARNING: Ports that are not part of the current Virtual Router were ignored.
  ```
- When in policy mode, system-wide, only one NetLogin base VLAN can be configured and this VLAN can be part of any VR.
- If you want to scale to 65,000 authenticated users, use a session timeout value of at least 300 minutes.
- NetLogin is not supported on user VRs in non-policy mode. NetLogin is supported only on VR-Default in non-policy mode.

Authenticating Users

Network login uses two types of databases to authenticate users trying to access the network:

- *RADIUS* servers
- Local database

All three network login protocols, web-based, MAC-based, and 802.1X, support RADIUS authentication. Only web-based and MAC-based network login support local database authentication.

> **Note**
> Beginning in ExtremeXOS 16.1, when RADIUS authentication is listed first and sends an access-reject it is honored and the local user database is not consulted - the bullet points listed just below indicate when the local database is used. .

The network login authenticated entry is cleared when there is an _FDB_ timeout. This applies to web-based, MAC-Based, and 802.1X authentication.

Local Database Authentication

You can configure the switch to use its local database for web-based and MAC-based network login authentication.

802.1X network login does not support local database authentication. Local authentication essentially mimics the functionality of the remote _RADIUS_ server locally. This method of authentication is useful in the following situations:

- If both the primary and secondary (if configured) RADIUS servers timeout or are unable to respond to authentication requests.
- If no RADIUS servers are configured.
- If the RADIUS server used for network login authentication is disabled.

If any of the above conditions are met, the switch checks for a local user account and attempts to authenticate against that local account.

For local authentication to occur, you must configure the switch's local database with a user name and password for network login. We recommend a maximum of 64 local accounts. If you need more than 64 local accounts, we recommend using RADIUS for authentication. You can also specify the destination _VLAN_ to enter upon a successful authentication. You can also specify a UPM profile in the local database when creating a local user.

You can also use local database authentication in conjunction with network login MAC-based VLANs. For more detailed information about network login MAC-based VLANs, see Configuring Network Login MAC-Based VLANs on page 943.

Creating a Local Network Login Account--User Name and Password Only

We recommend creating a maximum of 64 local accounts. If you need more than 64 local accounts, we recommend using _RADIUS_ for authentication. For information about RADIUS authentication, see Configuring the RADIUS Client on page 1161.

User names are not case-sensitive. Passwords are case-sensitive. User names must have a minimum of one character and a maximum of 32 characters. Passwords must have a minimum of zero characters and a maximum of 32 characters. If you use RADIUS

for authentication, we recommend that you use the same user name and password for both local authentication and RADIUS authentication.

- To create a local network login user name and password, use the following command and specify the parameter: *user-name*

  ```
  create netlogin local-user user-name {encrypted} {password} {vlan-vsa
  [[{tagged | untagged} [vlan_name] | vlan_tag]]} {security-profile
  security_profile}
  ```

  If you attempt to create a user name with more than 32 characters, the switch displays the following messages:
  ```
  %% Invalid name detected at '^' marker.
  %% Name cannot exceed 32 characters.
  ```
  If you attempt to create a password with more than 32 characters, the switch displays the following message after you re-enter the password:
  ```
  Password cannot exceed 32 characters
  ```
  The encrypted option is used by the switch to encrypt the password. Do not use this option through the command line interface (CLI).

- After you enter a local network login user name, press **[Enter]**. The switch prompts you twice to enter the password.

The following example:

- Creates a new local network login user name.
- Creates a password associated with the local network login user name.

```
# create netlogin local-user megtest
password: <Enter the password. The switch does not display the password.>
Reenter password: <Re-enter the password. The switch does not display the password.>
```

For information about specifying the destination *VLAN*, see the section Specifying a Destination VLAN on page 916.

> **Note**
> If you do not specify a password or the keyword **encrypted**, you are prompted for one.

Specifying a Destination VLAN

If you configure a local network login account with a destination *VLAN*, upon successful authentication, the client transitions to the permanent, destination VLAN.

You can specify the destination VLAN when you initially create the local network login account or at a later time.

Adding VLANs when Creating a Local Network Login Account

- To specify the destination *VLAN* when creating the local network login account, use the following command and specify the **vlan-vsa** option with the associated parameters:
  ```
  create netlogin local-user user-name {encrypted} {password} {vlan-vsa
  [[{tagged | untagged} [vlan_name] | vlan_tag]]} {security-profile
  security_profile}
  ```

Where the following is true:

- ◦ **tagged**—Specifies that the client be added as tagged.
- ◦ **untagged**—Specifies that the client be added as untagged.
- ◦ **vlan_name**—Specifies the name of the destination VLAN.
- ◦ **vlan_tag**—Specifies the VLAN ID, tag, of the destination VLAN.

The following example:

- Creates a new local network login user name.
- Creates a password associated with the local network login user name.
- Adds the VLAN test1 as the destination VLAN.

The following is a sample display from this command:

```
create netlogin local-user megtest vlan-vsa "test1"
password: <Enter the password. The switch does not display the password.>
Reenter password: <Re-enter the password. The switch does not display the password.>
```

Adding VLANs at a Later Time

To specify the destination VLAN after you created the local network login account, use the following command:

```
configure netlogin local-user user-name {vlan-vsa [[{tagged | untagged}
[vlan_name | vlan_tag]] | none]}
```

Where the following is true:

- **tagged**—Specifies that the client be added as tagged
- **untagged**—Specifies that the client be added as untagged
- **vlan_name**—Specifies the name of the destination VLAN
- **vlan_tag**—Specifies the VLAN ID, tag, of the destination VLAN
- **none**—Specifies that the VSA 211 wildcard (*) is applied, only if you do not specify tagged or untagged

The following example:

- Modifies a previously created local network login account.
- Specifies that clients are added as tagged to the VLAN.
- Adds the VLAN blue as the destination VLAN.

```
configure netlogin local-user megtest vlan-vsa tagged "blue"
```

Modifying an Existing Local Network Login Account

After you create a local network login user name and password, you can update the following attributes of that account:

- Password of the local network login account.
- Destination VLAN attributes including: adding clients tagged or untagged, the name of the VLAN, and the VLAN ID.

If you try modifying a local network login account that is not present on the switch, or you incorrectly enter the name of the account, output similar to the following appears:

```
  * Switch # configure netlogin local-user purplenet
 ^
%% Invalid input detected at '^' marker.
```

To confirm the names of the local network login accounts on your switch, use the following command:

```
show netlogin local-users
```

Updating the Local Network Login Password

Passwords are case-sensitive. Passwords must have a minimum of zero characters and a maximum of 32 characters.

1. Update the password of an existing local network login account with the following command:

   ```
   configure netlogin local-user user_name
   ```

   where *user_name* specifies the name of the existing local network login account.
2. After you enter the local network login user name, press **[Enter]**.

   The switch prompts you to enter a password.
3. At the prompt, enter the new password and press **[Enter]**.

   The switch then prompts you to reenter the password.

   If you attempt to create a password with more than 32 characters, the switch displays the following message after you re-enter the password:

   ```
   Password cannot exceed 32 characters
   ```

   The following example modifies the password for the existing local network login account megtest.The following is a sample display from this command:

   ```
   configure netlogin local-user megtest
   password: <Enter the new password. The switch does not display the password.>
   Reenter password: <Re-enter the new password. The switch does not display the
   password.>
   ```

After you complete these steps, the password has been updated.

Updating VLAN Attributes

You can add a destination *VLAN*, change the destination VLAN, or remove the destination VLAN from an existing local network login account.

To make any of these VLAN updates, use the following command:

```
configure netlogin local-user user-name {vlan-vsa [[{tagged | untagged}
[vlan_name | vlan_tag]] | none]}
```

Where the following are true:

- *user_name*—Specifies the name of the existing local network login account
- **tagged**—Specifies that the client be added as tagged

- **untagged**—Specifies that the client be added as untagged
- *vlan_name*—Specifies the name of the destination VLAN
- *vlan_tag*—Specifies the VLAN ID, tag, of the destination VLAN
- **none**—Specifies that the VSA 211 wildcard (*) is applied, only if you do not specify tagged or untagged

Displaying Local Network Login Accounts

To display a list of local network login accounts on the switch, including *VLAN* information, use the following command:

```
show netlogin local-users
```

Deleting a Local Network Login Account

To delete a local network login user name and password, use the following command:

```
delete netlogin local-user user-name
```

> **Note**
> You cannot mass delete all local users. You can only remove them one at a time by specifying each name.

802.1X Authentication

802.1X authentication methods govern interactions between the supplicant (client) and the authentication server.

The most commonly used methods are Transport Layer Security (TLS); Tunneled TLS (TTLS), which is a Funk/Certicom standards proposal; and PEAP.

TLS is the most secure of the currently available protocols, although TTLS is advertised to be as strong as TLS. Both TLS and TTLS are certificate-based and require a Public Key Infrastructure (PKI) that can issue, renew, and revoke certificates. TTLS is easier to deploy, as it requires only server certificates, by contrast with TLS, which requires client and server certificates. With TTLS, the client can use the RSA Data Security, Inc. *MD5 (Message-Digest algorithm 5)* Message-Digest Algorithm mode of user name/password authentication.

If you plan to use 802.1X authentication, refer to the documentation for your particular *RADIUS* server and 802.1X client on how to set up a PKI configuration.

> **Note**
> If you do not configure the reauthentication timer in non-policy mode, or the reauthentication or idle timer for policy mode, Dot1x clients remain active and are not removed when switching between machine authentication and user authentication (by logging out of a VM, and then logging back into the VM) or when switching between two users using the same VM.

Interoperability Requirements

For network login to operate, the user (supplicant) software and the authentication server must support common authentication methods.Not all combinations provide the appropriate functionality.

Supplicant Side

The supported 802.1X supplicants (clients) are Windows 7 and Windows 8 native clients, and Meetinghouse AEGIS.

A Windows 7 or Windows 8 802.1X supplicant can be authenticated as a computer or as a user. Computer authentication requires a certificate installed in the computer certificate store, and user authentication requires a certificate installed in the individual user's certificate store.

By default, the Windows 7 or Windows 8 machine performs computer authentication as soon as the computer is powered on, or at link-up when no user is logged into the machine. User authentication is performed at link-up when the user is logged in.

Windows 7 or Windows 8 also supports guest authentication, but this is disabled by default. Refer to relevant Microsoft documentation for further information. You can configure a Windows 7 or Windows 8 machine to perform computer authentication at link-up even if a user is logged in.

Authentication Server Side

The *RADIUS* server used for authentication must be EAP-capable. Consider the following when choosing a RADIUS server:

- Types of authentication methods supported on RADIUS, as mentioned previously.
- Need to support VSAs. Parameters such as `Extreme-Netlogin-Vlan-Name` (destination vlan for port movement after authentication) and `Extreme-NetLogin-Only` (authorization for network login only) are brought back as VSAs.
- Need to support both EAP and traditional user name-password authentication. These are used by network login and switch console login respectively.

> **Note**
>
> For information on how to use and configure your RADIUS server, refer to Configuring the RADIUS Client on page 1161 and to the documentation that came with your RADIUS server.

Enabling and Disabling 802.1X Network Login

Network Login must be disabled on a port before you can delete a *VLAN* that contains that port. You can set a reauthentication maximum counter value to indicate the number of reauthentication trials after which the supplicant is denied access or given limited access.

- To enable 802.1X network login on the switch, use the following command:

  `enable netlogin dot1x` Any combination of types of authentication can be enabled on the same switch. At least one of the authentication types must be specified on the CLI.

- To disable 802.1X network login on the switch, use the following command:

  `disable netlogin dot1x`

- To enable 802.1X network login on one or more ports, use the following command:

  `enable netlogin ports `*`portlist`*` dot1x`

- To disable 802.1X network login on one or more ports, use the following command:

  `disable netlogin ports `*`portlist`*` dot1x`

- To configure the reauthentication counter values, use the following command:

  `configure netlogin dot1x timers`

802.1X Network Login Configuration Example

The following configuration example shows the Extreme Networks switch configuration needed to support the 802.1X network login example.

> **Note**
> In the following sample configuration, any lines marked (Default) represent default settings and do not need to be explicitly configured.

```
create vlan "temp"
create vlan "corp"
configure vlan "default" delete ports 4:1-4:4
# Configuration Information for VLAN corp
# No VLAN-ID is associated with VLAN corp.
configure vlan "corp" protocol "ANY" (Default)
configure vlan "corp" ipaddress 10.203.0.224 255.255.255.0
# Configuration Information for VLAN Mgmt
configure vlan "Mgmt" ipaddress 10.10.20.30 255.255.255.0
# Network Login Configuration
configure netlogin vlan "temp"
enable netlogin dot1x
enable netlogin ports 1:10-1:14, 4:1-4:4 dot1x
# RADIUS Configuration
configure radius netlogin primary server 10.0.1.2 1812 client-ip 10.10.20.30 vr "VR-Mgmt"
configure radius netlogin primary shared-secret purple
enable radius
```

The following example is for the FreeRADIUS server; the configuration might be different for your *RADIUS* server:

```
#RADIUS Server Setting, in this example the user name is eaptest
eaptest Auth-Type := EAP, User-Password == "eaptest"
Session-Timeout = 120,
Termination-Action =1
```

For information about how to use and configure your RADIUS server, refer to Configuring the RADIUS Client on page 1161 and the documentation that came with your RADIUS server.

Configuring Guest VLANs

Ordinarily, a client that does not respond to 802.1X authentication remains disabled and cannot access the network.

802.1X authentication supports the concept of "guest _VLANs_" that allow such a supplicant (client) limited or restricted network access. If a supplicant connected to a port does not respond to the 802.1X authentication requests from the switch, the port moves to the configured guest VLAN. A port always moves untagged into the guest VLAN.

> 📋 **Note**
> The supplicant does not move to a guest VLAN if it fails authentication after an 802.1X exchange; the supplicant moves to the guest VLAN only if it does not respond to an 802.1X authentication request.

When the authentication server sends an 802.1X request to the supplicant, there is a specified time interval for the supplicant to respond. By default, the switch uses the supplicant response timer to authenticate the supplicant every 30 seconds for a maximum of three tries. If the supplicant does not respond within the specified time, the authentication server sends another request. After the third 802.1X request without a supplicant response, the port is placed in the guest VLAN, if the guest VLAN feature has been configured for the port. The number of authentication attempts is not a user-configured parameter.

If a supplicant on a port in the guest VLAN becomes 802.1X-capable, the switch starts processing the 802.1X responses from the supplicant. If the supplicant is successfully authenticated, the port moves from the guest VLAN to the destination VLAN specified by the _RADIUS_ server. If the RADIUS server does not specify a destination VLAN, the port moves to the VLAN it belonged to before it was placed in the guest VLAN. After a port has been authenticated and moved to a destination VLAN, it is periodically re-authenticated. If the port fails authentication, it moves to the VLAN it belonged to originally.

> 📋 **Note**
> A guest VLAN is not a normal network login VLAN. A guest VLAN performs authentication only if authentication is initiated by the supplicant.

Using Guest VLANs

Suppose you have a meeting that includes company employees and visitors from outside the company.

In this scenario, your employees have 802.1X enabled supplicants but your visitors do not. By configuring a guest _VLAN_, when your employees log into the network, they are granted network access (based on their user credentials and 802.1X enabled supplicants). However, when the visitors attempt to log into the network, they are granted limited network access because they do not have 802.1X enabled supplicant. The visitors might be able to reach the Internet, but they are unable to access the corporate network.

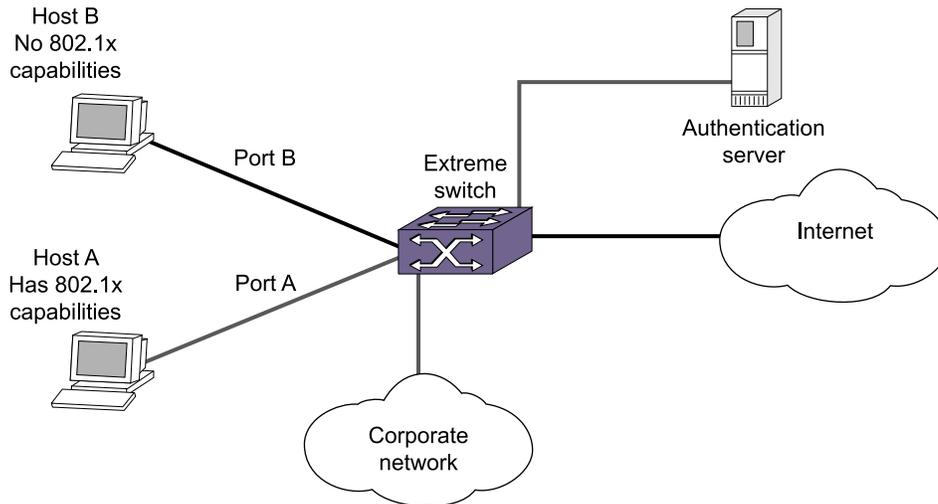
For example, in Figure 105 Host A has 802.1x capability and Host B does not. When Host A is authenticated, it is given full access to the network. Host B does not have 802.1X capability and therefore does not respond to 802.1X requests from the switch. If port B is configured with the guest VLAN, port B is moved to the guest VLAN. Then Host B will be able to access the Internet but not the corporate network. After Host B is equipped with 802.1X capability, it can be authenticated and allowed to be part of the corporate network.


Figure 105: Guest VLAN for Network Login

Guidelines for Configuring Guest VLANs

Keep in mind the following guidelines when configuring guest *VLAN*s:

- You must create a VLAN and configure it as a guest VLAN before enabling the guest VLAN feature.
- Configure guest VLANs only on network login ports with 802.1x enabled.
- Movement to guest VLANs is not supported on network login ports with MAC-based or web-based authentication.
- 802.1x must be the only authentication method enabled on the port for movement to guest VLAN.
- No supplicant on the port has 802.1x capability.

Creating Guest VLANs

If you configure a guest *VLAN*, and a supplicant has 802.1X disabled and does not respond to 802.1X authentication requests from the switch, the supplicant moves to the guest VLAN. Upon entering the guest VLAN, the supplicant gains limited network access.

> **Note**
> You can configure guest VLANs on a per port basis, which allows you to configure more than one guest VLAN per VR. In ExtremeXOS 11.5 and earlier, you can only configure guest VLANs on a per VR basis, which allows you to configure only one guest VLAN per VR.

To create a guest VLAN, use the following command:

```
configure netlogin dot1x guest-vlan vlan_name {ports port_list}
```

Enabling Guest VLANs

To enable the guest _VLAN_, use the following command:

```
enable netlogin dot1x guest-vlan ports [all | ports]
```

Modifying the Supplicant Response Timer

The default supplicant response timeout is 30 seconds, and the range is 1-120 seconds. The number of authentication attempts is not a user-configured parameter.

To modify the supplicant response timer, use the following command and specify the **supp-resp-timeout** parameter:

```
configure netlogin dot1x timers [{server-timeout server_timeout}
{quiet-period quiet_period} {reauth-period reauth_period {reauth-max
max_num_reauths}} {supp-resp-timeout supp_resp_timeout}]
```

Disabling Guest VLANs

To disable the guest _VLAN_, use the following command:

```
disable netlogin dot1x guest-vlan ports [all | ports]
```

Unconfiguring Guest VLANs

To unconfigure the guest _VLAN_, use the following command:

```
unconfigure netlogin dot1x guest-vlan {ports port_list | vlan_name}
```

Displaying Guest VLAN Settings

To display the guest _VLAN_ settings, use the following command:

```
show netlogin guest-vlan {vlan_name}
```

If you specify the `vlan_name`, the switch displays information for only that guest VLAN.

The output displays the following information in a tabular format:
- Port—Specifies the 802.1X enabled port configured for the guest VLAN.
- Guest-vlan—Displays guest VLAN name and status: enable/disable.
- Vlan—Specifies the name of the guest VLAN.

Post-authentication VLAN Movement

After the supplicant has been successfully authenticated and the port has been moved to a _VLAN_, the supplicant can move to a VLAN other than the one it was authenticated on.

This occurs when the switch receives an Access-Accept message from the *RADIUS* server with a VSA that defines a new VLAN. The supplicant remains authenticated during this transition. This occurs on both untagged and tagged VLANs. For example, suppose a supplicant submits the required credentials for network access; however, it is not running the current, approved anti-virus software or it does not have the appropriate software updates installed. If this occurs, the supplicant is authenticated but has limited network access until the problem is resolved. After you update the supplicant's anti-virus software, or install the software updates, the RADIUS server re-authenticates the supplicant by sending ACCESS-ACCEPT messages with the accompanying VLAN attributes, thereby allowing the supplicant to enter its permanent VLAN with full network access.

This is normal and expected behavior; no configuration is necessary.

802.1X Authentication and Network Access Protection

802.1X authentication in combination with Microsoft's Network Access Protection (NAP) provide additional integrity checks for end users and supplicants that attempt to access the network.

NAP allows network administrators to create system health policies to ensure supplicants that access or communicate with the network meet administrator-defined system health requirements. For example, if a supplicant has the appropriate software updates or anti-virus software installed, the supplicant is deemed healthy and granted network access. On the other hand, if a supplicant does not have the appropriate software updates or anti-virus software installed, the supplicant is deemed unhealthy and is placed in a quarantine *VLAN* until the appropriate update or anti-virus software is installed. After the supplicant is healthy, it is granted network access. For more information about NAP, please refer to the documentation that came with your Microsoft Windows or Microsoft Server software.

To configure your network for NAP, the minimum required components are:
- Extreme Networks switches running ExtremeXOS 11.6 or later.
- *RADIUS* server that supports NAP (Microsoft Windows Vista operating system refers to this as a network policy server (NPS), formerly known as the internet authentication server (IAS)).
- Remediation servers that receive unhealthy supplicants. The remediation servers contain the appropriate software updates, anti-virus software, and so on to make a supplicant healthy.

In addition to the required hardware and software, you must configure NAP-specific VSAs on your RADIUS server. By configuring these VSAs, you ensure supplicant authentication and authorization to the network and the switch creates dynamic Access Control Lists (ACLs) to move unhealthy supplicants to the quarantine VLAN for remediation. For more information see, Using NAP-Specific VSAs to Authenticate 802.1X Supplicants on page 928.

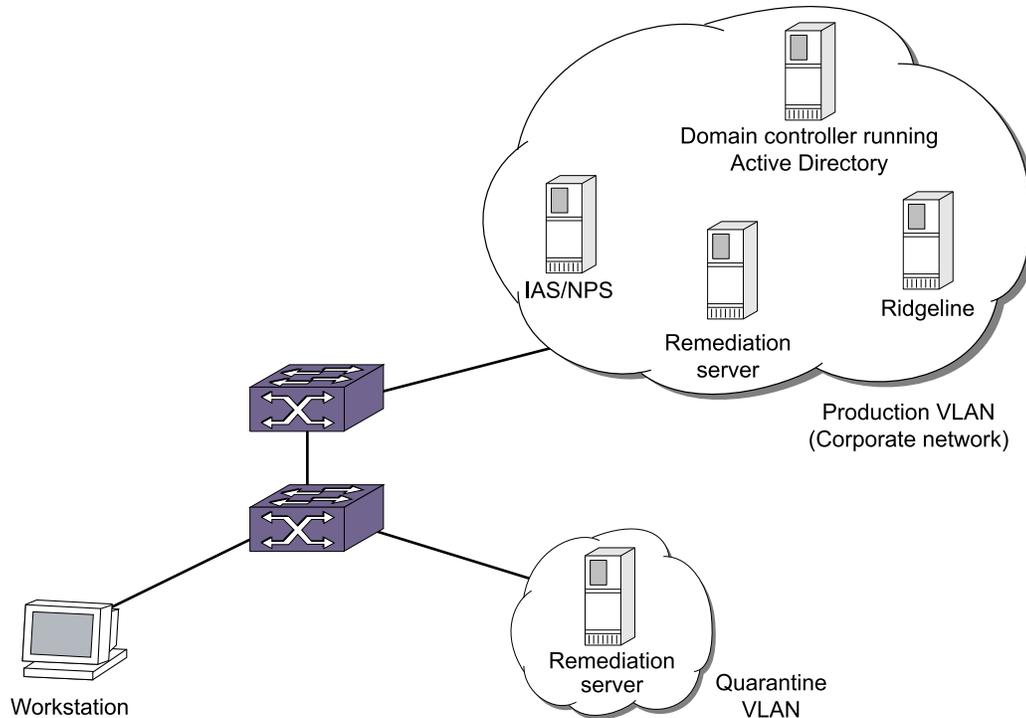
Figure 106 displays a sample network that uses NAP to protect the network.


Figure 106: Sample Network Using NAP to Provide Enhanced Security

Example Scenarios Using NAP

Using the following figure, the following two scenarios describe some sample actions taken when an 802.1X-enabled supplicant initiates a connection to the network.

The scenarios assume the following:

- Scenario 1 has a healthy 802.1X-enabled supplicant.
- Scenario 2 has an unhealthy 802.1X-enabled supplicant.
- 802.1X network login has been configured and enabled on the switch.
- The *RADIUS* server has been configured using the NAP-specific VSAs for authenticating supplicants.
- The remediation servers have been configured with the appropriate software updates, anti-virus software, and so on.
- The Extreme Management Center and Ridgeline servers have been configured to receive traps from the switch. The traps sent from the switch inform Ridgeline of the state of the supplicant. In these scenarios, you configure the NMS as the syslog target.
- *VLAN*s Production and Quarantine have already been created and configured.

> **Note**
>
> You can dynamically create the quarantine VLAN if you configure dynamic VLAN creation on the switch. For more information see, Configuring Dynamic VLANs for Network Login on page 945.

Scenario 1--Healthy Supplicant

The steps to authenticate a healthy supplicant are:

1. The 802.1X supplicant initiates a connection to the 802.1X network access server (NAS), which in this scenario is the Extreme Networks switch.
2. The supplicant passes its authentication credentials to the switch using PEAP and an inner authentication method such as MS-CHAPv2.
3. The _RADIUS_ server requests a statement of health (SoH) from the supplicant. Only NAP-capable supplicants create an SoH, which contains information about whether or not the supplicant is compliant with the system health requirements defined by the network administrator.
4. If the SoH indicates that the supplicant is healthy, the RADIUS server sends an Access-Accept message with a RADIUS VSA indicating which _VLAN_ the healthy supplicant is moved to (in this example, the Production VLAN).
5. The switch authenticates the supplicant and moves it into the Production VLAN.
6. The switch sends a trap to the NMS indicating that the supplicant has been successfully authenticated and the VLAN into which it has been moved.

Scenario 2--Unhealthy Supplicant

The steps to authenticate an unhealthy supplicant are:

1. The 802.1X supplicant initiates a connection to the 802.1X network access server (NAS), which in this scenario is the Extreme Networks switch.
2. The supplicant passes its authentication credentials to the switch using PEAP and an inner authentication method such as MS-CHAPv2.
3. The _RADIUS_ server requests a statement of health (SoH) from the supplicant. Only NAP-capable supplicants create an SoH, which contains information about whether or not the supplicant is compliant with the system health requirements defined by the network administrator.
4. If the SoH indicates that the supplicant is unhealthy, the RADIUS server sends an Access-Accept message with RADIUS VSAs indicating which:
   - _VLAN_ the unhealthy supplicant is moved to (in this example, the Quarantine VLAN).
   - the remediation server(s) from which the supplicant can get software updates, anti-virus software and so on to remediate itself.
5. When the switch receives the VLAN and remediation server information from the RADIUS server, the switch:
   - Moves the supplicant into the Quarantine VLAN.
   - Applies ACLs to ensure the supplicant in the Quarantine VLAN can access only the remediation servers
   - Drops all other traffic not originating/destined from/to the remediation servers
   - sends a trap to Ridgeline indicating that the supplicant has been authenticated but has restricted access in the Quarantine VLAN for remediation.
6. The supplicant connects to the remediation server to get software updates, anti-virus software, and so on to get healthy.
7. After the supplicant is healthy, it restarts the authentication process and is moved to the Production VLAN, as a healthy supplicant with full network access.

Using NAP-Specific VSAs to Authenticate 802.1X Supplicants

Table 88 contains the VSA definitions for 802.1X network login in conjunction with devices and servers that support NAP.

The Microsoft Vendor ID is 311.

> **Note**
> For more information about NAP and the VSAs supported by NAP, please refer to the documentation that came with your Microsoft operating system or server.

Table 88: NAP-Specific VSA Definitions for 802.1X Network Login

VSA	Vendor Type	Type	Sent-in	Description
MS-Quarantine-State	45	Integer	Access-Accept	Indicates the network access level that the *RADIUS* server authorizes the user. The network access server (the switch) also enforces the network access level. A value of "0" gives the user full network access. A value of "1" gives the user limited network access. A value of "2" gives the user full network access within a specified time period.
MS-IPv4-Remediation-Servers	52	Integer	Access-Accept	Indicates the IP address(es) of the remediation server(s) that an unhealthy supplicant moves to in order to get healthy.

ACLS for Remediation Servers

The NAP VSA, MS-IPv4-Remediation-Servers, contains a list of IP addresses that an unhealthy and therefore quarantined supplicant should be allowed access to so that it can remediate itself and become healthy.

The way a quarantine is implemented on the switch is simply by moving the client/port to a user-designated 'quarantine' *VLAN* whose VLANID/Name is sent in the Access-Accept message. It is up to the user to ensure that the quarantine VLAN does indeed have limited access to the rest of the network. Typically, this can be done by disabling IP forwarding on that VLAN so no routed traffic can get out of that VLAN. Also, with dynamic VLAN creation, the quarantine VLAN being supplied by *RADIUS* could be dynamically created on the switch, once dynamic VLAN creation is enabled on it. The remediation server(s) would need to be accessible via the uplink port, regardless of whether the quarantine VLAN is pre-configured or dynamically created, since IP forwarding is not enabled on it.

To get around this restriction, network login has been enhanced so when a MS-Quarantine-State attribute is present in the Access-Accept message with extremeSessionStatus being either 'Quarantined' or 'On Probation,' then a 'deny all traffic' dynamic *ACL (Access Control List)* will be applied on the VLAN. If such an ACL is already present on that VLAN, then no new ACL will be applied.

When the last authenticated client has been removed from the quarantine VLAN, then the above ACL will be removed.

Additionally, if the MS-IPv4-Remediation-Servers VSA is present in the Access-Accept message, for each IP address present in the VSA a 'permit all traffic to/from this IP address' ACL will be applied on the quarantine VLAN. This will allow traffic to/from the remediation servers to pass unhindered in the Quarantine VLAN while all other traffic will be dropped.

Web-Based Authentication

This section describes web-based network login.

For web-based authentication, you need to configure the switch DNS name, default redirect page, session refresh, and logout-privilege. URL redirection requires the switch to be assigned a DNS name. The default name is network-access.com. Any DNS query coming to the switch to resolve switch DNS name in unauthenticated mode is resolved by the DNS server on the switch in terms of the interface (to which the network login port is connected).

> **Note**
> When both HTTP and HTTPS are enabled on the switch and sending HTTP requests from the Netlogin client, HTTPS takes preference and the switch responds with a HTTPS response.

Enabling and Disabling Web-Based Network Login

- To enable web-based network login on the switch, use the following command:

  ```
  enable netlogin web-based
  ```

  Any combination of types of authentication can be enabled on the same switch. At least one of the authentication types must be specified on the CLI.
- To disable web-based network login on the switch, use the following command:

  ```
  disable netlogin web-based
  ```
- To enable web-based network login on one or more ports, use the following command:

  ```
  enable netlogin ports portlist web-based
  ```

  Network Login must be disabled on a port before you can delete a _VLAN_ that contains that port.
- To disable web-based network login on one or more ports, use the following command:

  ```
  disable netlogin ports portlist web-based
  ```

Configuring the Base URL

- To configure the network login base URL, use the following command:

  ```
  configure netlogin base-url url
  ```

where `url` is the DNS name of the switch.

For example, configure netlogin base-url network-access.com makes the switch send DNS responses back to the network login clients when a DNS query is made for network-access.com.

Configuring the Redirect Page

To configure the network login redirect page, use the following command:

```
configure netlogin redirect-page url
```

Where `url` defines the redirection information for the users after they have logged in. You must configure a complete URL starting with http:// or https://. By default, the redirect URL value is "http://www.extremenetworks.com" and default re-direction will take maximum of 20 seconds i.e default netlogin-lease-timer + 10 seconds. Re-direct time can be changed by tuning netlogin-lease-timer.

You can also configure the redirect value to a specific port number, such as 8080. For example, you can configure the network login redirect page to the URL value "http://www.extremenetworks.com:8080". The default port value is 80.

This redirection information is used only in case the redirection info is missing from _RADIUS_ server. For example, configure netlogin base-url http://www.extremenetworks.com redirects all users to this URL after they get logged in.

For more information about SSH2, see Secure Shell 2 on page 1193.

Configuring Proxy Ports

To configure the ports to be hijacked and redirected, use the following command:

```
configure netlogin add proxy-port tcp_port {http | https}

configure netlogin delete proxy-port
```

For each hijacked or proxy port, you must specify whether the port is to be used for HTTP or HTTPS traffic. No more than five hijack or proxy ports are supported for HTTP in addition to port 80 (for HTTP) and port 443 (for HTTPS), both of which cannot be deleted.

Configuring Session Refresh

To enable or disable the network login session refresh, use the following commands:

```
enable netlogin session-refresh {refresh_minutes}

disable netlogin session-refresh
```

Where `minutes` ranges from 1 - 255. The default setting is 3 minutes. The commands `enable netlogin session-refresh` and `configure netlogin session-refresh`

make the logout window refresh itself at every configured time interval. Session refresh is enabled by default. When you configure the network login session refresh for the logout window, ensure that the _FDB_ aging timer is greater than the network login session refresh timer.

> **Note**
> If an attempt is made to authenticate the client in a non-existent _VLAN_, and the move fail action setting is authenticate, then the client is successfully authenticated in the port's original VLAN, but subsequent session refreshes fail and cause the client to become unauthenticated.

When web-based Network Login is configured with proxy ports and session-refresh are also enabled, you must configure the web browser to bypass the web proxy server for the IP address of the VLAN into which the client moves after authentication.

Configuring Logout Privilege

- To enable or disable network login logout privilege, use the following commands:

  ```
  enable netlogin logout-privilege
  disable netlogin logout-privilege
  ```

  These commands turn the privilege for network login users to logout by popping up (or not popping up) the logout window. Logout-privilege is enabled by default.
- You can configure the number of times a refresh failure is ignored before it results in the client being unauthenticated by using the following commands:

  ```
  configure netlogin allowed-refresh-failures
  unconfigure netlogin allowed-refresh-failures
  ```

  You can set the number of failures to be from between 0 and 5. The default number of logout failures is 0.

Configuring the Login Page

You can fully customize the HTML login page and also add custom embedded graphical images to it. This page and the associated graphics must be uploaded to the switch so that they can be served up as the initial login page at the base URL. Both HTTP and HTTPS are supported as a means of authenticating the user via the custom page.

In general, the steps for setting up a custom login page and graphical images (if any) are as follows:

1. Write the custom webpage.
2. TFTP the page and any embedded JPEG or GIF graphical images that it references onto the switch.
3. Enable and configure web-based Network Login on the switch. When the custom page is present on the switch, it will override the configured banner.

Configuring a Network Login Banner

- To configure a banner on a network login screen, use the following command:

  ```
  configure netlogin banner banner
  ```

- To display configured banners from the network login screen, use the following command:

  ```
  show netlogin banner
  ```

- To clear configured network login banners, use the following command:

  ```
  unconfigure netlogin banner
  ```

Login Page Contents

The customized web-page must have the file name `netlogin_login_page.html`.

While the contents of the page are left up to the customer, they must contain the following elements:

- An HTML submit form with action="/hello" and method="post" that is used to send the Network Login username and password to the switch. The form must contain the following:
  - A username input field with name="extremenetloginuser"
  - A password input field with name="extremenetloginpassword"

- Optionally, one or more graphical images embedded using the tags

  ```
  <img src="netlogin_<xxx>.jpg"> or
  ```

  ```
  <img src="netlogin_<xxx>.jpeg"> or
  ```

  ```
  <img src="<netlogin_<xxx>.gif">
  ```

  where <xxx> is user-configurable.

The following is a sample custom page, where the embedded graphical image is named netlogin_welcome.jpg:

```
<html lang="en">

<head>
<title>Network Login Page</title>
</head>
<body>
<form action="/hello" method="post">
<img src="netlogin_welcome.jpg">
<br/>
Please log in:

<br/>
User:

<input type="text" name="extremenetloginuser" />
<br/>
Password:

<input type="password" name="extremenetloginpassword" />
<br/>
<input type="submit" value="Submit" />
</form>
```

```
</body>
</html>
```

Uploading the Login File to the Switch

To upload the page and the JPEG/GIF files, the switch TFTP command must be used.

For example, assuming the page resides on a TFTP server with IP address 10.255.49.19, the command used would be:

```
BD-8810.1 # tftp get 10.255.49.19 netlogin_login_page.html
```

General Guidelines

The following general guidelines are applicable to the login page:

- When the custom web page is not present on the switch, the system falls back to the using the default banner. The web page may be added (or removed) from the switch at any time, at which point the switch will stop (or start) using the banner.
- The graphical image file names referenced in the web page must not have any path information prepended.
- Both uppercase and lowercase names (or a mixture) for the graphical image filenames are supported, but the user and password tag names should be either all uppercase or all lowercase, not a mixture of the two.
- More than one form may exist on the page. This can be useful when, for example, in addition to the main username and password that is typed in by the user, an additional special username and password needs to be auto-filled and sent. This could be used when end users without a valid username or password need to be given restricted access to the network.

Limitations

The following limitations apply to the login page:

- When the client is in the unauthenticated state, any embedded URLs in the custom page are inaccessible to it.
- Only JPEG and GIF graphical images are supported.
- It is the web page writer's responsibility to write the HTML page correctly and without errors.
- Only TFTP is supported as a method to upload the web-page and graphical images to the switch.

Customizable Authentication Failure Response

In the event of web-based network login authentication failure, you can use a custom authentication failure page to recover.

When a customized login page is in effect, by default, any authentication failure results in the following failure response being delivered to the browser:
```
Login Incorrect. Click here to try again.
```

Clicking on the indicated link will bring the user back to the initial custom login page.

You may choose to override the above default response with a custom one. This custom failure response page must be uploaded to the switch using TFTP with the name `netlogin_login_fail_page.html`. When authentication fails, the switch responds with this page. If the page is deleted from the switch, the response reverts back to the default.

The same graphical images that are uploaded to the switch for the custom login page can also be embedded in the custom authentication failure page.

> **Note**
> The custom authentication failure page can be used only when authentication is being done via the custom login page.

Customizable Graphical Image in Logout Popup Window

You can embed a graphical image in the logout popup window.

This image appears in the window in addition to the text that is displayed. The image must be TFTPed to the switch in the same manner as the custom login image, and must have the filename `netlogin_logout_image.jpg` or `netlogin_logout_image.gif` (depending on whether the image is JPEG or GIF). If no such image is present on the switch, then the logout popup contains only text.

Web-Based Network Login Configuration Example

The following configuration example shows both the Extreme Networks switch configuration and the *RADIUS* server entries needed to support the example.

VLAN corp is assumed to be a corporate subnet which has connections to DNS, WINS servers, network routers, and so on. VLAN temp is a temporary VLAN and is created to provide connections to unauthenticated network login clients. Unauthenticated ports belong to the VLAN temp. This kind of configuration provides better security as unauthenticated clients do not connect to the corporate subnet and will not be able to send or receive any data. They have to get authenticated in order to have access to the network.

- **ISP Mode**—Network login clients connected to ports 1:10–1:14, VLAN corp, will be logged into the network in ISP mode. This is controlled by the fact that the VLAN in which they reside in unauthenticated mode and the RADIUS server Vendor Specific Attributes (VSA), Extreme-Netlogin-Vlan, are the same, corp. So there will be no port movement. Also if this VSA is missing from RADIUS server, it is assumed to be ISP Mode.
- **Campus Mode**—On the other hand, clients connected to ports 4:1–4:4, VLAN temp, will be logged into the network in Campus mode since the port will move to the VLAN corp after getting authenticated. A port moves back and forth from one VLAN to the other as its authentication state changes.

Both ISP and Campus mode are not tied to ports but to a user profile. In other words, if the VSA Extreme:Extreme-Netlogin-Vlan represents a VLAN different from the one in which the user currently resides, then VLAN movement will occur after login and after

logout. In following example, it is assumed that campus users are connected to ports 4:1–4:4, while ISP users are logged in through ports 1:10–1:14.

> **Note**
> In the following sample configuration, any lines marked (Default) represent default settings and do not need to be explicitly configured.

```
create vlan "temp"
create vlan "corp"
configure vlan "default" delete ports 4:1-4:4
enable ipforwarding
# Configuration Information for VLAN temp
# No VLAN-ID is associated with VLAN temp.
configure vlan "temp" ipaddress 198.162.32.10 255.255.255.0
# Configuration Information for VLAN corp
# No VLAN-ID is associated with VLAN corp.
configure vlan "corp" ipaddress 10.203.0.224 255.255.255.0
configure vlan "corp" add port 1:10 untagged
configure vlan "corp" add port 1:11 untagged
configure vlan "corp" add port 1:12 untagged
configure vlan "corp" add port 1:13 untagged
configure vlan "corp" add port 1:14 untagged
# Network Login Configuration
configure vlan "temp" dhcp-address-range 198.162.32.20 - 198.162.32.80
configure vlan "temp" dhcp-options default-gateway 198.162.32.1
configure vlan "temp" dhcp-options dns-server 198.162.32.10
configure vlan "temp" dhcp-options wins-server 10.0.1.85
configure netlogin vlan "temp"
enable netlogin web-based
enable netlogin ports 1:10-1:14,4:1-4:4 web-based
configure netlogin base-url "network-access.com" (Default)
configure netlogin redirect-page http://www.extremenetworks.com (Default)
enable netlogin logout-privilege (Default)
disable netlogin session-refresh  3 (Default)
# DNS Client Configuration
configure dns-client add name-server 10.0.1.1
configure dns-client add name-server 10.0.1.85
#RADIUS Client Configuration
configure radius netlogin primary server 10.0.1.2 1812 client-ip 10.10.20.30 vr "Vr-Mgmt"
configure radius netlogin primary shared-secret purple
enable radius
```

For this example, the following lines (for a FreeRADIUS server) should be added to the RADIUS server users file for each user:

```
Extreme:Extreme-Netlogin-Only = Enabled (if no CLI authorization)
Extreme:Extreme-Netlogin-Vlan = "corp" (destination vlan for CAMPUS mode network login)
```

> **Note**
> For information about how to use and configure your RADIUS server, refer to Configuring the RADIUS Client on page 1161 and the documentation that came with your RADIUS server.

Web-Based Authentication User Login

To use web-based authentication:

1. Set up the Windows IP configuration for DHCP.

2. Plug into the port that has web-based network login enabled.
3. Log in to Windows.
4. Release any old IP settings and renew the DHCP lease.

   This is done differently depending on the version of Windows the user is running:

   - **Windows 9x**—Use the winipcfg tool. Choose the Ethernet adapter that is connected to the port on which network login is enabled. Use the buttons to release the IP configuration and renew the DHCP lease.
   - **Windows 7 or Windows 8**—Use the ipconfig command line utility. Use the command ipconfig/release to release the IP configuration and ipconfig/renew to get the temporary IP address from the switch. If you have more than one Ethernet adapter, specify the adapter by using a number for the adapter following the `ipconfig` command. You can find the adapter number using the command `ipconfig/all`. At this point, the client will have its temporary IP address. In this example, the client should have obtained an IP address in the range 198.162.32.20–198.162.32.80.

   > **Note**
   > The idea of explicit release/renew is required to bring the network login client machine in the same subnet as the connected _VLAN_. When using web-based authentication, this requirement is mandatory after every logout and before login again as the port moves back and forth between the temporary and permanent VLANs.

5. Bring up the browser and enter any URL as `http://www.123.net or http://1.2.3.4` or switch IP address as `http://<IP address>/login` (where IP address could be either temporary or Permanent VLAN Interface for Campus mode).

   URL redirection redirects any URL and IP address to the network login page. This is significant where security matters most, as no knowledge of VLAN interfaces is required to be provided to network login users, because they can login using a URL or IP address.

   > **Note**
   > URL redirection requires that the switch be configured with a DNS client.

   A page opens with a link for Network Login.
6. Click the Network Login link.

   A dialog box opens requesting a user name and password.
7. Enter the user name and password configured on the _RADIUS_ server. After the user has successfully logged in, the user will be redirected to the URL configured on the RADIUS server. During the user login process, the following takes place:

   a. Authentication is done through the RADIUS server.
   b. After successful authentication, the connection information configured on the RADIUS server is returned to the switch:

      - The permanent VLAN
      - The URL to be redirected to (optional)
      - The URL description (optional)

    c. The port is moved to the permanent VLAN.

    d. You can verify this using the `show vlan` command. For more information on the `show vlan` command, see Displaying VLAN Information on page 599.

After a successful login has been achieved, there are several ways that a port can return to a non-authenticated, non-forwarding state:

- The user successfully logs out using the logout web browser window.
- The link from the user to the switch's port is lost.
- There is no activity on the port for 20 minutes.
- An administrator changes the port state.

> **Note**
> Because network login is sensitive to state changes during the authentication process, we recommend that you do not log out until the login process is complete. The login process is complete when you receive a permanent address.

MAC-Based Authentication

MAC-based authentication is used for supplicants that do not support a network login mode, or supplicants that are not aware of the existence of such security measure (for example, an IP phone).

If a MAC address is detected on a MAC-based enabled network login port, an authentication request is sent once to the AAA application. AAA tries to authenticate the MAC address against the configured *RADIUS* server and its configured parameters (timeout, retries, and so on) or the local database.

In a MAC-based authentication environment, the authentication verification is done only after at MAC address detection. However, forced re-authentication is allowed through the Session-Timeout VSA when supplied along with Termination-Action attribute "RADIUS-Request" by RADIUS. When this VSA with Termination-Action attribute "RADIUS-Request" is present the switch, re-authenticates the client based on the value supplied by the VSA. If no VSA is present, there is no re-authentication. If Session-Timeout VSA is supplied and no Termination-Action attribute or "Default" Termination-Action attribute is specified, the client is unauthenticated. You can also force re-authentication by configuring the MAC re-authentication timers using the CLI (see Configuring Reauthentication Period on page 940). If MAC re-authentication timers are configured using the CLI and RADIUS sends a different session timeout value, the RADIUS session timeout has higher precedence.

The credentials used for this are the MAC address of the supplicant in ASCII representation, and a locally configured password on the switch. If no password is configured, the MAC address is used as the password. ExtremeXOS 30.3 provides an option to send the MAC address in either uppercase or lowercase for the user name or password to provide compatibility with the requirements of the RADIUS server (see Configuring MAC Authentication Case Option for User Name and Password on page 940).You can also group MAC addresses together using a mask.

You can configure a MAC list or a table of MAC entries to filter and authenticate clients based on their MAC addresses. If a match is found in the table of MAC entries, authentication occurs. If no match is found in the table of MAC entries, and a default entry exists, the default will be used to authenticate the client. All entries in the list are automatically sorted in longest prefix order. All passwords are stored and showed encrypted.

You can associate a MAC address with one or more ports. By learning a MAC address, the port confirms the supplicant before sending an authorization request to the RADIUS server. This additional step protects your network against unauthorized supplicants because the port accepts only authorization requests from the MAC address learned on that port. The port blocks all other requests that do not have a matching entry.

> **Note**
> When ONEPolicy is enabled and authentication required mode is configured with a static macsource rule applied, even if a MAC address fails authentication, traffic is forwarded.

> **Note**
> With ONEPolicy enabled, admin-profile port rule configured, and authentication required mode set, traffic is not forwarded by the admin profile VLAN when MAC authentication fails.

Limitations

Web-based authentication is not supported on Extended Edge Switching extended ports.

Enabling and Disabling MAC-Based Network Login

Network Login must be disabled on a port before you can delete a *VLAN* that contains that port.

- To enable MAC-based network login on the switch, use the following commands:

```
configure netlogin vlan vlan_name

enable netlogin mac
```

Any combination of types of authentication can be enabled on the same switch. At least one of the authentication types must be specified on the CLI.

If **enable netlogin mac** is entered, **configure netlogin add mac-list default** configuration is added by default. This added mac-list config will not be removed if **disable netlogin mac** is entered. Instead, **configure netlogin delete mac-list default** must be entered to remove the mac-list config.

- To disable MAC-based network login on the switch, use the following command:

```
disable netlogin mac
```

- To enable MAC-based network login on one or more ports, use the following command:
  ```
  enable netlogin ports portlist mac
  ```
- To disable MAC-based network login on one or more ports, use the following command:
  ```
  disable netlogin ports portlist mac
  ```

Associating a MAC Address to a Specific Port

You can configure the switch to accept and authenticate a client with a specific MAC address. Only MAC addresses that have a match for the specific ports are sent for authentication. For example, if you associate a MAC address with one or more ports, only authentication requests for that MAC address received on the port(s) are sent to the configured *RADIUS* server or local database. The port(s) block all other authentication requests that do not have a matching entry. This is also known as secure MAC.

- To associate a MAC address with one or more ports, specify the **ports** option when using the following command:
  ```
  configure netlogin add mac-list [mac {mask} | default] {encrypted}
  {password} {ports port_list}
  ```

  You must enable MAC-based network login on the switch and the specified ports.

  If MAC-based network login is not enabled on the specified port(s), the switch displays a warning message similar to the following:
  ```
  WARNING: Not all specified ports have MAC-Based NetLogin enabled.
  ```

For a sample configuration, see Securing MAC Configuration Example on page 941.

Adding and Deleting MAC Addresses

- To add a MAC address to the table, use the following command:
  ```
  configure netlogin add mac-list [mac {mask} | default] {encrypted}
  {password} {ports port_list}
  ```
- To remove a MAC address from the table, use the following command:
  ```
  configure netlogin delete mac-list [mac {mask} | default]
  ```

Displaying the MAC Address List

To display the MAC address table, use the following command:

```
show netlogin mac-list
```

When a client needs authentication the best match will be used to authenticate to the server.

MAC-based authentication is VR aware, so there is one MAC list per VR.

Assume we have a supplicant with MAC address 00:04:96:05:40:00, and the switch has the following table:

```
MAC Address/Mask       Password (encrypted)    Port(s)
-------------------    ----------------------  --------------
00:00:00:00:00:10/48   <not configured>        1:1-1:5
00:00:00:00:00:11/48   <not configured>        1:6-1:10
00:00:00:00:00:12/48   <not configured>        any
00:01:30:70:0C:00/48   yaqu                    any
00:01:30:32:7D:00/48   ravdqsr                 any
00:04:96:00:00:00/24   <not configured>        any
```

The user name used to authenticate against the *RADIUS* server would be
"000496000000," as this is the supplicant's MAC address with the configured mask
applied. Although this is the default, ExtremeXOS 16.1 allows for a hyphenated mac
address to be sent - `configure netlogin mac username format hyphenated`.

Note that the commands are VR aware, and therefore one MAC list table exists per VR.

Configuring MAC Authentication Case Option for User Name and Password

If a RADIUS server is case-sensitive and it expects the user name and password only in
lowercase, then MAC Authentication will fail due to the case mismatch, since whenever
a MAC address is used as user name and password, by default the MAC address is sent
only in uppercase.

ExtremeXOS 30.3 provides an option to send the Network Login (NetLogin) MAC
Authentication MAC address in either upper or lower case for the user name or
password.

To change the MAC case, use the following command:

`configure` **`netlogin mac username case`** `(`**`lower`** `|` **`upper`**`}`

Configuring Reauthentication Period

The reauthentication timer is applicable for all the cases when session timeout is not
sent by *RADIUS*. Clients moved to authentication success, authentication failure VLAN,
and service unavailable VLANs can be reauthenticated using this timer. If the switch
receives the session-timeout attribute during authentication, the switch uses that value
to set the reauthentication period.

To configure the reauthentication period for network login MAC-based authentication,
use the following command:

`configure netlogin mac timers reauth-period`

For more information about RADIUS server attributes, see Configuring the RADIUS
Client on page 1161.

Securing MAC Configuration Example

The following configuration example shows how to configure secure MAC on your Extreme Networks switch. To configure secure MAC:

1. Create a _VLAN_ used for network login.
2. Configure the VLAN for network login.
3. Enable MAC-based network login on the switch.
4. Enable MAC-based network login on the ports used for authentication.
5. Specify one or more ports to accept authentication requests from a specific MAC address.

   In the following example, authentication requests from MAC address:

   - 00:00:00:00:00:10 are only accepted on ports 1:1 through 1:5
   - 00:00:00:00:00:11 are only accepted on ports 1:6 through 1:10
   - 00:00:00:00:00:12 are accepted on all other ports

```
create vlan nlvlan
configure netlogin vlan nlvlan
enable netlogin mac
enable netlogin ports 1:1-1:10 mac
configure netlogin add mac-list 00:00:00:00:00:10 ports 1:1-1:5
configure netlogin add mac-list 00:00:00:00:00:11 ports 1:6-1:10
configure netlogin add mac-list 00:00:00:00:00:12
```

To view your network login configuration, use the following commands:

```
show netlogin {port portlist vlan vlan_name} {dot1x {detail}} {mac}
{web-based}

show netlogin mac-list
```

MAC-Based Network Login Configuration Example

The following configuration example shows the Extreme Networks switch configuration needed to support the MAC-based network login example.

```
create vlan "temp"
create vlan "corp"
configure vlan "default" delete ports 4:1-4:4
# Configuration Information for VLAN corp
# No VLAN-ID is associated with VLAN corp.
configure vlan "corp" ipaddress 10.203.0.224 255.255.255.0
# Network Login Configuration
configure netlogin vlan "temp"
enable netlogin mac
enable netlogin ports 4:1-4:4 mac
configure netlogin add mac-list default <password>
# RADIUS Client Configuration
configure radius netlogin primary server 10.0.1.2 1812 client-ip 10.10.20.30 vr "VR-Mgmt"
configure radius netlogin primary shared-secret purple
enable radius
```

The following example is a user's file entry for a specific MAC address on a FreeRADIUS server:

```
00E018A8C540 Auth-Type := Local,  User-Password == "00E018A8C540"
```

> **Note**
> For information about how to use and configure your *RADIUS* server, refer to Configuring the RADIUS Client on page 1161 and the documentation that came with your RADIUS server.

MAC-Based Authentication Delay

Prior to ExtremeXOS 21.1, the default behavior was to authenticate the client with all enabled authentication methods on that port for backward compatibility. To delay MAC authentication the user must configure the MAC authentication delay period using the CLI. The MAC authentication delay period's default value is 0 seconds for backward compatibility. The MAC authentication delay period configurable range is 0 to 120 seconds.

The following example explains both the pre-ExtremeXOS 21.1 behavior and the added MAC Authentication Delay feature:

Assume MAC, dot1X and Web-based authentication methods are enabled on a port. When the client is connected to the port the first packet from the client triggers ExtremeXOS to do MAC authentication, authenticates the client using *RADIUS*, and applies the action. When the user "Adam" tries to do the dot1X authentication, ExtremeXOS triggers the dot1X authentication, authenticates "Adam" using RADIUS, and applies the high preferred authentication method's action. If dot1x authentication is configured as preferred over MAC authentication, then the MAC authentication action is unapplied and the dot1X authentication action is applied. In this case the switch authenticates the client using both MAC and dot1x authentication method. This is the existing behavior in which the MAC authentication delay interval is 0 second.

If the customer requirement is to delay/bypass the MAC authentication then the the MAC authentication delay period must be configured on a per port basis. In this case, the moment ExtremeXOS detects the first packet from the client connected port it will wait for the MAC authentication delay period for other authentication methods to be triggered to authenticate the client. In this case the user "Adam" will do dot1X authentication to authenticate himself. The time ExtemeXOS waits for the dot1X authentication to trigger is termed as MAC authentication delay period and it is user configurable.

Additional Network Login Configuration Details

This section describes additional, optional network login configurations.These configurations are not required to run network login; however, depending on your network settings and environment, you can use the commands described in this section to enhance your network login settings.

Review the earlier sections of this chapter for general information about network login and information about MAC-based, web-based, and 802.1X authentication methods.

Configuring Network Login MAC-Based VLANs

Currently, network login allows only a single, untagged _VLAN_ to exist on a port. This limits the flexibility for untagged supplicants because they must be in the same VLAN.

ExtremeSwitching series switches support network login MAC-based VLANs. Network login MAC-based VLANs allow a port assigned to a VLAN to operate in a MAC-based fashion. This means that each individual untagged supplicant, identified by its MAC address, can be in different VLANs.

Network login MAC-based VLAN utilizes VSA information from both the network login local database and the _RADIUS_ server. After successfully performing the Campus mode operation, the supplicant is added untagged to the destination VLAN.

To support this feature, you must configure the network login port's mode of operation.

Network Login MAC-Based VLANs Rules and Restrictions

This section summarizes the rules and restrictions for configuring network login MAC-based VLANss:

* You must configure and enable network login on the switch and before you configure network login MAC-based VLANs.

  If you attempt to configure the port's mode of operation before enabling network login, the switch displays an error message similar to the following:

  ```
  ERROR: The following ports do not have NetLogin enabled; 1
  ```
* If you attempt to configure network login MAC-based VLANs on 10 Gigabit Ethernet ports, the switch displays an error message similar to the following:
  ```
  ERROR: The following ports do not support the MAC-Based VLAN mode; 1, 2, 10
  ```

  In ExtremeXOS version 12.0 and later, you can configure MAC-based-VLANs on 10 Gigabit Ethernet ports.
* You can have a maximum of 1,024 MAC addresses per switch.

Configuring the Port Mode

To support network login MAC-based VLANs on a network login port, you must configure that port's mode of operation.

Specify MAC-based operation using the following command and specifying mac-based-vlans:

```
configure netlogin ports [all | port_list] mode [mac-based-vlans | port-
based-vlans]
```

By default, the network login port's mode of operation is port-based-vlans. If you modify the mode of operation to mac-based-vlans and later disable all network login protocols on that port, the mode of operation automatically returns to port-based-vlans.

When you change the network login port's mode of operation, the switch deletes all currently known supplicants from the port and restores all VLANs associated with that port to their original state. In addition, by selecting mac-based-vlans, you are unable

to manually add or delete untagged VLANs from this port. Network login now controls these VLANs.

With network login MAC-based operation, every authenticated client has an additional _FDB_ flag that indicates a translation MAC address. If the supplicant's requested VLAN does not exist on the port, the switch adds the requested VLAN.

Configuring Ingress Filtering

Ingress filtering is disabled by default when MAC-based VLANs are enabled on the port. To toggle the ingress filtering setting for MAC-based VLANs, use the following command:

- `configure ports `_`port_list`_` **mac-based-vlans ingress-filtering** [**on**|**off**]`

   The configuration is specific to MAC-based VLANs, and only takes effect if MAC-based VLANs are enabled on the port. If the command is executed on a port that does not have MAC-based VLANs enabled, the command will be accepted, but it will not be applied until MAC-based VLANs are enabled.

Displaying Network Login MAC-Based VLAN Information

The following commands display important information for network login MAC-based _VLAN_s.

FDB Information

To view _FDB_ entries, use the following command:

```
show fdb netlogin [all | mac-based-vlans]
```

By specifying netlogin, you see only FDB entries related to network login or network login MAC-based _VLAN_s.

The flags associated with network login include:
- v—Indicates the FDB entry was added because the port is part of a MAC-Based virtual port/VLAN combination
- n—Indicates the FDB entry was added by network login

VLAN and Port Information

- To view the _VLAN_s that network login adds temporarily in MAC-based mode, use the following command:
  ```
  show ports port_list information detail
  ```

   By specifying **information** and **detail**, the output displays the temporarily added VLANs in network login MAC-based mode.

   This command will also show port information for ingress filtering for MAC-based VLANs.
- To confirm this, review the following output of this command:

   VLAN cfg—The term "MAC-based" appears next to the tag number.

Netlogin port mode—This output was added to display the port mode of operation. "Mac-based" appears and the network login port mode of operation.

- To view information about the ports that are temporarily added in MAC-based mode for network login, due to discovered MAC addresses, use the following command:

```
show vlan detail
```

By specifying **detail**, the output displays detailed information including the ports associated with the VLAN.

The flags associated with network login include:

- ◦ a—Indicates that egress traffic is allowed for network login
- ◦ u—Indicates that egress traffic is not allowed for network login.
- ◦ m—Indicates that the network login port operates in MAC-based mode.

> **Note**
> If network login is enabled together with _STP_, the 'a' and 'u' flags are controlled by network login only when the STP port state is 'Forwarding.'

Network Login MAC-Based VLAN Example

The following example configures the network login MAC-based _VLAN_ feature:

```
create vlan users12
create vlan nlvlan
configure netlogin vlan nlvlan
enable netlogin mac
enable netlogin ports 1:1-1:10 mac
configure netlogin ports 1:1-1:10 mode mac-based-vlans
configure netlogin add mac-list default MySecretPassword
```

Expanding upon the previous example, you can also utilize the local database for authentication rather than the _RADIUS_ server:

```
create netlogin local-user 000000000012 vlan-vsa untagged default
create netlogin local-user 000000000010 vlan-vsa untagged users12
```

For more information about local database authentication, see Local Database Authentication on page 915.

Configuring Dynamic VLANs for Network Login

During an authentication request, network login receives a destination _VLAN_ (if configured on the _RADIUS_ server) to put the authenticated user in.

The VLAN must exist on the switch for network login to authenticate the client on that VLAN.

You can configure the switch to dynamically create a VLAN after receiving an authentication response from a RADIUS server. A dynamically created VLAN is only a Layer 2 bridging mechanism; this VLAN does not work with routing protocols to forward traffic. If configured for dynamic VLAN creation, the switch automatically creates a supplicant VLAN that contains both the supplicant's physical port and one

or more uplink ports. After the switch unauthenticates all of the supplicants from the dynamically created VLAN, the switch deletes that VLAN.

> **Note**
> Dynamically created VLANs do not support the session refresh feature of web-based network login because dynamically created VLANs do not have an IP address.

By dynamically creating and deleting VLANs, you minimize the number of active VLANs configured on your edge switches. In addition, the dynamic VLAN name can be stored on the RADIUS server and supplied to the switch during authentication, simplifying switch management. A key difference between dynamically created VLANs and other VLANs is that the switch does not save dynamically created VLANs. Even if you use the save command, the switch does not save a dynamically created VLAN.

After you configure network login on the switch, the two steps to configure dynamic VLANs are:

- Specifying the tagged uplink port(s) to be added to each dynamically created VLAN.
- Enabling the switch to create dynamic VLANs.

Specifying the Uplink Ports

The uplink ports send traffic to and from the supplicants from the core of the network. Uplink ports should not be configured for network login (network login is disabled on uplink ports).

To specify one or more ports as tagged uplink ports that are added to the dynamically created *VLAN*, use the following command:

```
configure netlogin dynamic-vlan uplink-ports [port_list | none]
```

By default, the setting is none.

If you specify an uplink port with network login enabled, the configuration fails and the switch displays an error message similar to the following:

```
ERROR: The following ports have NetLogin enabled: 1, 2
```

If this occurs, select a port with network login disabled.

Enabling Dynamic VLANs for Network Login

By default, the setting is disabled.

To enable the switch to create dynamic *VLAN*s, use the following command:

```
configure netlogin dynamic-vlan [disable | enable]
```

When enabled, the switch dynamically creates VLANs. Remember, dynamically created VLANs are not permanent nor are user-created VLANs. The switch uses the VLAN ID supplied by the *RADIUS* attributes (as described below) to create the VLAN. The switch only creates a dynamic VLAN if the requested VLAN, indicated by the VLAN ID, does not currently exist on the switch.

The RADIUS server uses VSAs to forward VLAN information.The forwarded information can include only a VLAN ID (no VLAN name). The following list specifies the supported VSAs for configuring dynamic VLANs:

- Extreme: Netlogin-VLAN-ID (VSA 209)
- Extreme: Netlogin-Extended-VLAN (VSA 211)
- IETF: Tunnel-Private-Group-ID (VSA 81)

Extreme-specific VSAs have greater precedence than IETF Tunnel-Private-Group-Id attribute if both are sent using RADIUS Access-Accept. For example, if Extreme-Netlogin-Extended-Vlan 211: Uv1;Tcorp and Tunnel-Private-Group-Id:200 are both sent, MAC is authenticated on VLAN v1 and corp, and not on vlanid 200.

> **Note**
> If the ASCII string contains only numbers, it is interpreted as the VLAN ID. Dynamic VLANS support only numerical VLAN IDs; VLAN names are not supported.

The switch automatically generates the VLAN name in the following format: SYS_VLAN_TAG where *TAG* specifies the VLAN ID. For example, a dynamic VLAN with an ID of 10 has the name `SYS_VLAN_0010`.

> **Note**
> Like all VLAN names, dynamic VLAN names are unique. If you create a VLAN and use the name of an existing dynamic VLAN, the switch now sees the dynamic VLAN as a user-created VLAN and will save this VLAN to the switch configuration. If this occurs, the switch does not delete the VLAN after the supplicants are authenticated and moved to the permanent VLAN.

For more information on Extreme Networks VSAs, see Extreme Networks VSAs on page 1169.

Dynamic VLAN Example with Web-Based Network Login

After you finish the web-based network login configuration as described in Web-Based Network Login Configuration Example on page 934, complete the dynamic *VLAN* configuration by:

- Assigning one or more non-network-login ports as uplink ports

> **Note**
> Do not enable network login on uplink ports. If you specify an uplink port with network login enabled, the configuration fails and the switch displays an error message.

- Enabling the switch to dynamically create VLANs

Whether you have MAC-based, web-based, or 802.1X authentication, you use the same two commands to configure dynamic VLANs on the switch.

The following example configures dynamic VLANs on the switch:

```
configure netlogin dynamic-vlan uplink ports 2:1-2:2
configure netlogin dynamic-vlan enable
```

Displaying Dynamic VLAN Information

- To display summary information about all of the *VLAN*s on the switch, including any dynamically VLANs currently operating on the switch, use the following command:

  `show vlan`

  If the switch has dynamically created VLANs, the VLAN name begins with `SYS_NLD_`.

- To display the status of dynamic VLAN configuration on the switch, use the following command:

  `show netlogin`

  The switch displays the current state of dynamic VLAN creation (enabled or disabled) and the uplink port(s) associated with the dynamic VLAN.

Configuring Network Login Port Restart

You can configure network login to restart specific network-login-enabled ports when the last authenticated supplicant unauthenticates, regardless of the configured authentication methods on the port.

This feature, known as *network login port restart*, is available with all network login authentication methods although is most practical with web-based network login. This section describes how this feature behaves with web-based network login; MAC-based and 802.1X network login do not experience any differences in behavior if you enable network login port restart.

Currently with web-based network login, if you have an authenticated supplicant and log out of the network, you must manually release the IP address allocated to you by the *DHCP* server. The DHCP server dynamically manages and allocates IP addresses to supplicants. When a supplicant accesses the network, the DHCP server provides an IP address to that supplicant. DHCP cannot renegotiate their leases, which is why you must manually release the IP address.

For example, if the idle timer expires on the switch, the switch disconnects your network session. If this occurs, it may be unclear why you are unable to access the network. After you manually renew the IP address, you are redirected to the network login login page and can log back into the network. To solve this situation in a single supplicant per port environment, port restart triggers the DHCP client on the PC to restart the DHCP address assignment process.

Guidelines for Using Network Login Port Restart

Configure network login port restart on ports with directly attached supplicants.

If you use a hub to connect multiple supplicants, only the last unauthenticated supplicant causes the port to restart. Although the hub does not inflict harm to your network, in this situation, the previously unauthenticated supplicants do not get the benefit of the port restart configuration.

Enabling Network Login Port Restart

To enable network login port restart, use the following command:

```
configure netlogin ports [all | port_list] restart
```

Disabling Network Login Port Restart

To disable network login port restart, use the following command:

```
configure netlogin [ports port_list | all] allow egress-traffic
{all_cast | broadcast | none | unicast}
```

```
configure netlogin ports [all | port_list] no-restart
```

Displaying the Port Restart Configuration

To display the network login settings on the port, including the configuration for port restart, use the following command:

```
show netlogin port port_list
```

Output from this command includes the enable/disable state for network login port restart.

Authentication Failure and Services Unavailable Handling

ExtremeXOS provides the following features for handling network login authentication failures, and for handling instances of services unavailable:

- Configure Authentication Failure VLAN
- Configure Authentication Services Unavailable VLAN
- Configure Reauthentication Period (`configure netlogin mac ports [port_list | all] timers [{reauth-period [reauth_period]} {reauthentication [on| off]} {delay [delay_period]}])`

You can use these features to set and control the response to network login authentication failure and instances of services unavailable.

Configuring Authentication Failure VLAN

When a network login client fails authentication, it is moved to authentication failure *VLAN* and given restricted access.

To configure the authentication failure VLAN, use the following commands:

```
configure netlogin authentication failure vlan
```

```
unconfigure netlogin authentication failure vlan
```

```
enable netlogin authentication failure vlan ports
```

```
disable netlogin authentication failure vlan ports
```

Use the command `enable netlogin authentication failure vlan` to configure authentication failure VLAN on network-login-enabled ports. When a supplicant fails authentication, it is moved to the authentication failure VLAN and is given limited access until it passes the authentication.

Through either a *RADIUS* or local server, the other database is used to authenticate the client depending on the authentication database order for that particular network login method (mac, web, or dot1x). If the final result is authentication failure and if the authentication failure VLAN is configured and enabled on that port, then the client is moved there.

For example, if the network login MAC authentication database order is local, radius and the authentication of a MAC client fails through local database, then the RADIUS server is used to authenticate. If the RADIUS server also fails authentication, the client is moved to the authentication failure VLAN. This applies for all authentication database orders (radius,local; local,radius; radius; local).

In the above example if authentication through local fails but passes through the RADIUS server, the client is moved to appropriate destination VLAN. If the local server authentication fails and the RADIUS server is not available, the client is not moved to authentication failure VLAN.

Only when Radius Access-Reject is received, the client moves to auth fail vlan in Netlogin Mac. 802.1x Authentication: Client will move to auth fail vlan for access rejection and for cases where Radius Access Challenge is received without reject from the Radius Server. After the expiration of the timeout period, client will move to auth fail vlan.

Dependency on authentication database order

There are four different authentication orders which can be configured per authentication method. These four orders are the following:

- RADIUS
- Local
- RADIUS, Local
- Local, RADIUS

For each authentication order, the end result is considered in deciding whether to authenticate the client through the authentication failure *VLAN* or the authentication service unavailable VLAN (if configured).

For example, if the authentication order is radius, local, with the RADIUS server unavailable, and local authentication failed, the client is authenticated in the authentication failure VLAN (if one is configured on the port).

For local authentication, the following cases are considered as authentication failure.
- If the user is not created in the local database.
- If the user is configured, but the password does not match.

If the user is configured, but the password does not match, it is considered an authentication failure.

For RADIUS server authentication, if for some reason the user cannot be authenticated due to problems with the RADIUS configuration, the RADIUS server not running, or some other problem then it is considered as an authentication service unavailable. If the actual authentication fails then it is considered as an authentication failure.

Configuring Authentication Service-Unavailable VLAN

When the authentication service is not available for authentication, the supplicant is moved to authentication service-unavailable _VLAN_ and given restricted access.

Starting with ExtremeXOS 30.2, you can configure multiple (10 maximum) service-unavailable VLANs per port.

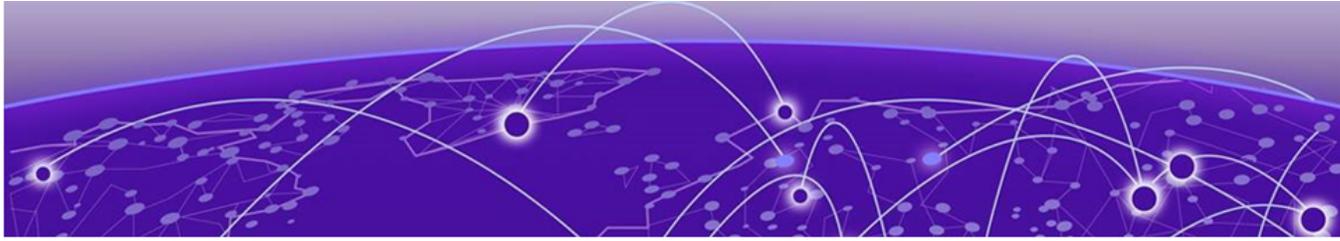
To configure the authentication services unavailable VLAN, use the following commands:

```
configure netlogin authentication service-unavailable [{add} | {delete}
| {{vlan vlan_name} {ports port_list {tagged | untagged}}}]
```

```
unconfigure netlogin authentication service-unavailable vlan vlan_name
{ports port_list}
```

```
enable netlogin authentication service-unavailable vlan ports [ports |
all]
```

```
disable netlogin authentication service-unavailable vlan ports [ports |
all]
```

If a NetLogin port has web enabled, authentication-failure VLAN and authentication service-unavailable VLAN configuration are not applicable to MAC and Dot1x clients connected to that port. For example, if port 1:2 has NetLogin MAC and web authentication enabled and the service-unavailable VLAN is configured and enabled on it, and if a MAC client connected to that port fails authentication, it is not moved to service-unavailable VLAN.


ONEPolicy

ONEPolicy provides for the configuration of role-based profiles for securing and provisioning network resources based upon the role the user or device plays within the enterprise. By first defining the user or device role, network resources can be granularly tailored to a specific user, system, service, or port-based context by configuring and assigning rules to the policy role. A policy role can be configured for any combination of Class of Service, *VLAN (Virtual LAN)* assignment, or default behavior based upon L2, L3, and L4 packet fields. Hybrid authentication allows either policy or dynamic VLAN assignment, or both, to be applied through *RADIUS (Remote Authentication Dial In User Service)* authorization.

> **Note**
> The software only allows policy to be enabled if all the devices in the stack support policy. At the time of configuration the device will provision the lowest common denominator of functionality. If a device attempts to join the stack after policy is enabled, it must be able to support the existing level of functionality or it will not be allowed to participate in policy. For more detailed information about lowest common denominator, see Policy and Lowest Common Denominator Stacking on page 967.

ONEPolicy Overview

The three primary benefits of using policy in your network are provisioning and control of network resources, security, and centralized operational efficiency. Policy provides for the provisioning and control of network resources by creating policy roles that allow you to determine network provisioning and control at the appropriate network layer, for a given user or device. With a role defined, rules can be created based upon up to 15 traffic classification types for traffic drop or forwarding. A *CoS (Class of Service)* can be associated with each role for purposes of setting priority, forwarding queue, rate limiting, and rate shaping.

Security can be enhanced by allowing only intended users and devices access to network protocols and capabilities. Some examples are:

- Ensuring that only approved stations can use *SNMP (Simple Network Management Protocol)*, preventing unauthorized stations from viewing, reading, and writing network management information
- Preventing edge clients from attaching network services that are appropriately restricted to data centers and managed by the enterprise IT organization such as *DHCP (Dynamic Host Configuration Protocol)* and DNS services
- Identifying and restricting routing to legitimate routing IP addresses to prevent DoS, spoofing, data integrity and other routing related security issues
- Ensuring that FTP/TFTP file transfers and firmware upgrades only originate from authorized file and configuration management servers
- Preventing clients from using legacy protocols

Extreme Management Center Policy Manager provides a centralized point and click configuration, and one click pushing of defined policy out to all network elements. Use Extreme Management Center Policy Manager for ease of initial configuration and response to security and provisioning issues that may come up during real-time network operation.

> **Note**
> Any configurations which require the use of the first stage ACL/VLAN processor, do not operate when OnePolicy is enabled. This includes, but is not limited to, certain MPLS, PSTag, VXLAN, and OAM/CFM configurations.

> **Note**
> Configuration changes on existing policy mux entries (changing the policy profile for a convergence endpoint to 0 or a different value, disabling *LLDP (Link Layer Discovery Protocol)* or CDP, etc.) do not take effect until re-authorization. As a result, existing CEP connections remain active and *FDB (forwarding database)* is still learned on policy profile even though CDP/LLDP neighbor times out and `show cdp neighbor {`**`detail`**`}` and `show lldp neighbors` is empty. You can force re-authorization by clearing a CEP connection: `configure policy convergence-endpoint clear` **`ports`** [*port_list* | **all**].

> **Note**
> IDM and ONEPolicy are not supported together and it is not recommended to enable both, since handling rule/role-based actions is not supported, except to support Kerberos Authentication with NAC as a RADIUS server and can be used in conjunction with IDM XML event triggers.

> **Note**
> In ONEPolicy mode, when enabling NetLogin web-based, the following warning message appears when the port is not part of any default VLAN:
> `WARNING: The following netlogin enabled ports 1 are not part of any VLAN. The port has to be part of some VLAN for Web-Based netlogin to work.`
> For NetLogin web to work, the port must be part of a default VLAN.

> **Note**
>
> Restarting the NetLogin process is not supported when policy is enabled. Doing so results in indeterminate behavior.

> **Note**
>
> If Convergence End Point (CEP) (see Convergence End Point (CEP) Detection on page 955) is configured and you have multiple authentication types configured, failure of a higher priority authentication results in the lower priority authentication being used.

```

Extreme Management Center Policy Manager

Extreme Management Center Policy Manager is a management GUI that automates the definition and enforcement of network-wide policy rules. It eliminates the need to configure policies on a device-by-device basis using complex CLI commands. The Policy Manager's GUI provides ease of classification rule and policy role creation, because you only define policies once using an easy to understand point and click GUI— and regardless of the number of moves, adds or changes to the policy role, Policy Manager automatically enforces roles on Extreme security-enabled infrastructure devices.

This section presents policy configuration from the perspective of the CLI. Though it is possible to configure policy from the CLI, CLI policy configuration in even a small network can be complex from an operational point of view. It is highly recommended that policy configuration be performed using the Extreme Management Center Policy Manager.

The Extreme Management Center Policy Manager provides:

- Ease of rule and policy role creation.
- The ability to store and retrieve roles and policies.
- The ability, with a single click, to enforce policy across multiple devices.

Implementing Policy

To implement policy:

1. Identify the roles of users and devices in your organization that access the network.
2. Create a policy role for each identified user role (see Policy Roles on page 971 and Table 100 on page 995).
3. Associate classification rules and administrative profiles with each policy role (see Classification Rules on page 974 and Table 101 on page 997).
4. Optionally, configure a class of service and associate it directly with the policy role or through a classification rule (see Assigning a Class of Service to Policy Role on page 973, Classification Rules on page 974, and Table 100 on page 995).
5. Optionally, enable hybrid authentication, which allows *RADIUS* filter-ID and tunnel attributes to be used to dynamically assign policy roles and VLANs to authenticating users (see Applying Policy Using Hybrid Authentication Mode on page 993).
6. Optionally, set device response to invalid policy (see Device Response to Invalid Policy on page 959).
7. Optionally, set captive portal to use HTTP redirection to force a client's web browser to be redirected to a particular administrative web page for authentication purposes (user login and password), payment (for example, at an airport hotspot), or use-policy enforcement (installing necessary software, agreeing to terms of service (TOS), etc.) (see Captive Portal Redirection on page 957 and Table 104 on page 1001).

ONEPolicy Features

Convergence End Point (CEP) Detection

Convergence End Point (CEP) is a mechanism to detect remote IP telephony or video devices on a port and dynamically apply a policy based on the type of CEP device discovered. CEP is only active when ONEPolicy is enabled and configured on the switch. When a CEP device is detected on a port, the configured policy for that device is applied to the user on that port. The switch detects a CEP by inspecting devices on CDP- and *LLDP*-configured ports. CEP interacts with LLDP, CDP, and ONEPolicy through callbacks and/or inter-process messaging to initiate detection and apply policy.

LLDP and CDP

LLDP and CDP are required to call into CEP to add detected IP telephony devices with the following data:

- MAC—MAC address of detected device
- Port—port origin of detection
- Type—the type of detected device (Cisco, LLDP)

- inetAddr—IP address of end point device
- inetType—IP address type of end point device (IPv4, IPv6)
- inetLen—length of inetAddr

ONEPolicy

- CEP initializes with, and exists in, the ONEPolicy process and calls directly to modify policy muxRule entries.
- CEP leverages ONEPolicy port add/del/mod callback integration, satisfying CEP platform port requirements.

For information about configuring CEP detection, see Table 103 on page 1000.

> **Note**
>
> When both CEP and *NetLogin* are enabled on the same port, the policy profile name is "active" for both CEP and NetLogin sessions with session applied as "false" for CEP and "true" for NetLogin. If NetLogin authentication is successful, the session applied is false for CEP and true for NetLogin. NetLogin takes higher precedence than the CEP profile.

Learning of CEP entries depends on the LLDP/CDP update on active ports and on disabling and enabling CEP. New entries are learned only after receiving new LLDP/CDP information, and not from existing LLDP neighbors and CDP neighbors table.

For example:

```
# configure policy convergence-endpoint disable

# show fd

> **Note**
>
> After CEP devices are mapped to a profile, changing the index value to "0" or to some other policy profile name, the existing CEP connections are still be mapped to the old profile that was configured initially when the CEP devices were detected. To force a refresh of existing detected devices, disable, and then enable, CEP (see `configure policy convergence-endpoint [`**enable** `| `**disable**`]`) or disable, and then enable, the port(s) (see `disable port [port_list | `**all**`]` and `enable port [port_list | `**all**`]`).

Captive Portal Redirection

Captive Portal Redirection uses HTTP redirection to force a client's web browser to be redirected to a particular administrative web page. You can use this feature for such web-based purposes as:

• Authentication—request a user login and password

• Payment—for example, at an airport hotspot

• Use-policy enforcement—require installing necessary software, agreeing to terms of service (TOS), etc.

Captive Portal Redirection is an extension of the ONEPolicy feature. You can configure policy roles that can force redirection of HTTP traffic by specifying a web redirection class index that associates it with up to two redirection servers. The HTTP traffic to potentially redirect is identified based on a destination captive portal server absolute

URL address containing an IPv4 address, TCP port, and path. For traffic that is placed into one of these policy roles (through authentication or policy admin-profile rules) actions are taken based upon the contents of the policy profile.

If the incoming traffic is on the configured L4 port and is not destined for the configured captive portal server IP, the switch causes an HTTP redirect message (code 307) to be sent back to the client. If the incoming traffic is destined for the configured captive portal server IP, or it is not on one of the configured listening L4 ports, the traffic is handled according to the rest of the policy role configuration.

Configuring this feature occurs through the etsysPolicyProfileMIB and the ONEPolicy command set. There are two tables in the MIB, one that allows configuration of the listening ports and one that allows configuration of the captive portal servers. You can configure up to three ports on which ONEPolicy listens for client traffic that is (potentially) subject to HTTP redirection. A URL that explicitly identifies the server by an IPv4 address, TCP port, and path is configured along with the ports on which the Captive Portal feature listens for client traffic (for example: `configure policy captive-portal listening 80,8080`).

You can configure up to ten web-redirect groups of two captive portal servers. They can be used to redirect traffic in different roles to different servers. These web-redirect groups are identified by associating a web redirection class index with the server ID. The policy roles used for captive portal redirection each have a non-zero web redirection class index configured (for example, `configure policy profile 1 web-redirect 5`). The default captive portal web redirection class index for any given role (profile) is 0, or unset. To enable captive portal, there must be a role defined that has a valid captive portal web redirection class index with a value between 1–10.

In addition to the captive portal configuration, this policy role should also have rules to handle the traffic that is not handled by the captive portal web redirection.

> **Note**
> When there are two servers configured in a web-redirect, the switch uses the following algorithm to pick which server to use for redirection:
> ((Last byte of the client's source MAC address)%(numServers)) + 1
> For example, (mac = 00:00:00:00:00:03) and where numServers is 2. (0x03%2) + 1 = 2 (This MAC uses server 2.)

> **Note**
> Captive portal does not work with tagged frames.

> **Note**
> HTTPS redirection is not supported in Captive Portal redirection.
> Redirection to the portal does not happen if the user (guest-user or unauthenticated user) tries to connect to an HTTPS website. This feature only handles HTTP traffic. However, you can configure redirection to a captive portal URL based on HTTPS.

If not specified to do otherwise, ONEPolicy programs its captive portal-related rules outside of the reserved ACL rule space for ONEPolicy. This results in additional ACL slice usage. Starting with ExtremeXOS 30.4, you can specify that these rules are programmed within the already reserved ACL rule space at the expense of IPv4 rule capacity (see Table 100 on page 995).

For information about configuring Captive Portal Redirection, see Table 104 on page 1001.

For an example Captive Portal Redirection configuration, see Captive Portal Redirection Example on page 1018.

VLAN/VXLAN to Policy Mapping

VLAN-to-Policy mapping manually configures VLAN-to-policy associations that create a policy maptable entry between the specified VLAN and the specified policy role. When an incoming tagged VLAN packet is seen by the switch, a lookup of the policy maptable determines whether a VLAN-to-policy mapping exists. This feature can be used at the distribution layer in environments where non-policy-capable edge switches are deployed and you cannot apply Extreme policy at the edge. Tagged frames received at the distribution layer interface for a VLAN with an entry in the policy maptable have the associated policy applied to the frame.

To create a policy maptable entry associating a policy to a VLAN, use the following command specifying a single VLAN ID or range of IDs and the policy profile-index:

```
configure policy maptable [response [tunnel | policy | both] | vlan_list
profile_index]
```

Starting with ExtremeXOS 22.5, you can map VXLAN (Virtual Extensible LAN)s by applying the VXLAN identifier (VNI) to a profile using the command, where NSI = VNI:

```
configure policy profile profile_index {name name} {pvid pvid}
{pvid-status pvid_status} {cos cos} {cos-status cos_status} {egress-
vlans egress_vlan_list}{forbidden-vlans forbidden_vlans} {untagged-vlans
untagged_vlans} {append | clear} {tci-overwrite tci_overwrite}
{precedence [precedence | default]} {auth-override auth_override} {nsi
[nsi | none]} {web-redirect web_redir_index} {access-list [unassigned |
list_name | list_name_placeholder]}
```

You can then create the maptable entry, using the previous maptable command.

Device Response to Invalid Policy

The action that the device should take when asked to apply an invalid or unknown policy can be specified. The available actions are:

- Ignore the result and search for the next policy assignment rule. If all rules are missed, the default policy is applied.
- Block traffic.
- Forward traffic as if no policy has been assigned using 802.1D/Q rules.

Use the `configure policy invalid action` command to specify a default action to take when asked to apply an invalid or unknown policy.

Policy-Based Mirrors

You can apply mirrors to policy profile rules by using a "control group" mirror referenced by a unique control index number. These control group mirrors are etsysMirrorDestinationControlEntry entries in the ENTERASYS-MIRROR-CONFIG-MIB (Mirror MIB) (see ENTERASYS-MIRROR-CONFIG-MIB on page 2057). A Mirror MIB instance (designated by a control index) can be associated with up to four "physical" mirrors, each being one destination port (or tunnel).

For information about configuring policy-based mirrors, see Table 105 on page 1002.

Limitations

- Mirrors with multiple destination ports are not supported.
- A maximum of four concurrently enabled mirrors is supported.
- A maximum of four control group (Mirror MIB) instances can be created using the CLI.
- Mirrors on admin profile rules is not supported.
- Mirroring cannot be enabled on LAG and MLAG ports.
- Mirroring index cannot be assigned for default mirrors.

Rule Trap and Syslog for ONEPolicy

You can be notified when a policy rule is used by enabling "Syslog" or "trap" actions:

- The Syslog action sends an entry in the log after first rule use with the EMS tag "Policy.LogRuleHit".
- The trap action sends an etsysPolicyRulePortHitNotification SNMP trap to the configured trap receiver.

By default, the Syslog and trap actions only occur when the rule is first used. However, for the Syslog action, you can configure the system to send messages every time the rule is used at a maximum rate of once every five seconds.

Additionally, a rule counter tracks the number of times a packet triggers a rule. By default, the counter is enabled for all rules.You can set an interval for how often this counter is cleared, or manually clear it at any time.

For information about configuring rule trap/Syslog, and the rule counter, see Table 106 on page 1003.

Limitations

Not supported on admin profile rules.

VCAP Partitioning

ExtremeXOS allows multiple applications (Layer 7 policy, user-based dynamic ACLs) to share a pool of VCAP slices. This area is called the "shared pool." The TCI overwrite-enabled case is configurable to use its own pool of VCAP slices and the "shared pool"

is allocated for the other applications. VCAP slices not allocated for policy usage are available for general system use.

TCI overwrite-enabled profiles use their own resource pool of slices (0–4) for VLAN assignment (translation). Allocating less TCI overwrite-enabled VCAP space means fewer rules available for users to have their VLAN tags overwritten.

Supported Platforms

All platforms, except the ExtremeSwitching X435 series switches.

Layer 7 Policy/Application Signature

Policy rules are used to assign incoming traffic to a specific policy profile. Layer 7 policy/ application signature provides an additional traffic classification capability. This layer 7 classification is accomplished by the snooping of DNS packets for pre-defined traffic application signatures. The snooping feature is activated automatically when policy is enabled and an application signature (AS) rule is created. It is deactivated if all AS rules are removed or if policy is disabled. Layer 7 policy uses shared look-up stage TCAM resources that must be configured first (see VCAP Partitioning on page 960). The number of signature rules is dependent upon the availability of this shared space.

Dynamic policy rules are created in hardware using DNS-discovered destination IP addresses for the host name. The IP addresses ultimately map the traffic to a particular application traffic signature pattern. IP addresses and their associated dynamic rules are timed out per the TTL of the snooped IP address. The application traffic signatures are defined in groups of one or more signature names, where each signature name consists of one or more signature patterns.

Layer 7 policy is based on the use of the enterasys-application-signature-mib (see ENTERASYS-APPLICATION-SIGNATURE-MIB on page 2035).

Supported Platforms

ExtremeSwitching X450-G2, X460-G2, X440-G2, X465, X590, X620, and X695 series switches.

Limitations

- V6 is not supported.
- Rule creation and deletion are controlled by a time-to-live (TTL) 5 second timer.
- TTL value is configurable in terms of 1 min., 5 mins., and 10 mins.
- When VCAP space runs out, any IP rule not already installed in hardware is not created. New attempts to install previously uninstalled rules occur after the 5 second TTL timer interval and are dependent upon the space made available by other rules that have timed out.

Signatures

Starting with ExtremeXOS 30.4, policy rules have an additional traffic classification of application signature group and name. There is a fixed, defined set of signature groups available. Each group has a subset of pre-defined/built-in signature names; these can be enhanced with additional ones that can be created by commands or

MIB. Additionally, each application signature name is defined by one or more signature patterns.

The signatures are arranged into two hierarchical levels, group and name.

Group examples: Advertising, Storage, Education

Names examples: Etrade, Skype, AOL, Facebook, Twitter, Google

Example Signature Groups

Built-in signatures:
* Social Networking
  ◦ Facebook
    ▪ facebook.com
    ▪ facebook.net
* Search Engines
  ◦ Google
    ▪ google.co
    ▪ google.ca
    ▪ google.it
    ▪ google.fr

User-defined signatures:
* News and Information
  ◦ Flipboard
    ▪ flipboard.com
* E-commerce
  ◦ Warehouse
    ▪ bjs.com
    ▪ costco.com

Pattern examples:
* wireshark.org
* mysql.com

ACL Style Policy

Traditional ONEPolicy architecture uses a hierarchical approach to rule precedence where rule type dictates precedence. In addition, rule look-ups occur per role, per action type. This means, for example, that triggering a forward/drop rule without an explicit Class of Service (CoS) action results in applying the forward/drop action, and then continuing searching until a rule with CoS action matches. This hierarchical approach is implemented in hardware by maintaining one list for forward/drop actions, and one list for CoS actions. This implementation often results in underused resources, because not every rule has both forward/drop and CoS actions.

With ACL Style Policy, a mode of operation with a single ordered list per role is maintained. Rule look-ups occur in the provided ACL order per role. A match applies all actions specified, and the search stops. This approach can potentially double the advertised scale of classification rules as compared to the traditional model. It also provides a more standard approach to policy classification rules.

Default policy rule-model is hierarchical, unless you are upgrading from ExtremeXOS 30.5 with a saved configuration that is set to access list.

For information about configuring ACL Style Policy, see

Limitations

SNMP for configuration of ACL Style Policy classification rules is not supported.

Traditional Versus ACL Style Policy Classification Rule Scaling

The following table compares the overall classification rule scale between "traditional" and ACL Style policy:

Table 89: Traditional Versus ACL Style Policy Classification Rule Scaling

Switch Model(s)	Traditional	ACL Style*
X435	Default: 184 Less System ACL: 184	Default: 440 Less System ACL: N/A
X450-G2 X460-G2	Default: 952 Less System ACL: 1,464	Default: 3,000 Less System ACL: N/A
X440-G2 X620	Default: 440 Less System ACL: 440	Default: 952 Less System ACL: N/A
X590 X465	Default: 1,976 Less System ACL: 1,976	Default: 4,024 Less System ACL: N/A
X695	Default: 1,976 Less System ACL: 1,976	Default: 3,512 Less System ACL: N/A

** - Applies to role-based DACLs as well as static ACLs created via the Policy CLI, which are also associated with a profile. User-based DACLs may achieve lower ACL Style numbers.

ACL Style Classification Rule Architecture

- Single ordered list per role.
- Rule look-ups done in provided ACL order.
- Rule look-up match applies all actions, and then the search stops.
- 5-tuple rule match support.
- Layer 4 port range.
- Rule types: application, ipsourcesocket, ipdestsocket, ipfrag, udpsourceportIP, udpdestportIP, tcpsourceportIP, tcpdestportIP, icmptype, icmp6type, ipttl, iptos, ipproto, ether.
- Rule actions: permit/deny, CoS (prio, tos, rate-limit, shape, etc), mirror, Syslog, and count.

RESTful API Support

ACL Style Policy implements a new RESTful API for configuration of classification rules.

> **Note**
> RESTful API is not supported for Dynamically-created ACLs via RADIUS and COA.

Dynamic Access Control Lists (ACL)

The user-based dynamic policy access control lists (ACL) feature uses the existing RADIUS Access-Accept and change of authorization (CoA) mechanism to override existing policy rules associated with a user by including a new vendor specific attribute (VSA) in the CoA and Access-Accept. When a CoA request or Access-Accept response to apply a particular set of match conditions and actions (or an action-set) is received, a look-up is performed to determine which policy profile the specified user was authenticated in, and the action-set ID specified in the CoA/Access-Accept is applied in that user's profile.

> **Note**
> You must configure VCAP partitioning to use dynamic ACL (see VCAP Partitioning on page 960).

If ACL style policy is not selected, or if the specified action-set does not exist, or if insufficient resources are available, the dynamic ACL rules are not applied and a NAK response to the RADIUS CoA request are returned. The maximum number of Dynamic ACL rules per user is 64. Access-Accept can include multiple adds using the += operation (this operation is not supported as part of RADIUS CoA request). Access-Accept usage does not support delete operation is ignored. Dynamic ACL rules can be deleted using an explicit CoA delete or are deleted when the dynamic session associated with the user is deleted.

> **Note**
> The maximum length of a RADIUS packet size is 4096 (both UDP and TLS), which can prevent the Dynamic ACLs from being sent to get trimmed via VSA 232 due to the lengthier ACL lists.

Dynamic ACLs and Layer 7 policy share the slices not used by TCI overwrite-enabled as one shared resource pool (see VCAP Partitioning on page 960). Dynamic ACLs have a higher priority to override Layer 7 policy (DNS) entry matches.

Beginning with Release 32.1, masking IPv4 addresses, L4 ports, and IP protocol numbers are supported. The mask is a required value and must be greater than zero and less than or equal to the maximum number of bits in the field being masked. For example, an IPv4 address mask value must be between 1 and 32.

The following match conditions can be used with user-based ACLs:

- `ipv4src` *ipv4source/mask-length*
- `ipv4dst` *ipv4dest/mask-length*
- `ipproto` *ipproto* (TCP, UDP, ICMP, or protocol number)

- `l4srcport` *l4sourceport/mask-length* (requires ipproto; range is role-based only with no mask)
- `l4dstport` *l4destport-i4sourceportend/mask-length* (requires ipproto; range is role-based only with no mask)
- `ether` (role-based only)
- `any`

The following actions can be used:
- CoS (not valid if "drop" is specified)
- Drop (not valid if "forward" is specified)
- Forward (not valid if "drop" is specified)
- Syslog
- Mirror

To see an example of dynamic ACL VSA string, see Example Dynamic ACL VSA String on page 1019.

Supported Platforms

ExtremeSwitching X450-G2, X460-G2, X440-G2, X465, X590, X620, X695 series switches.

Limitations

- TCI overwrite is not supported on X435 switches.
- Layer 7 policy (DNS) is not supported on X435 switches.
- Dynamic Access-List is not supported on X435 switches.
- DNS is not supported on Extended Edge switches with Controlling Bridges on the ExtremeSwitching X695 series switch.
- ACL style policy must be selected.
- Only a subset of the existing policy rules is allowed.
- SNMP is not supported.
- Controlling Bridge does not support tci-overwrite on policy profiles for the ExtremeSwitching X695 series switch.

Role-based ACLs

Beginning with Release 32.1, the dynamic ACL rule(s) can be user-based or role-based. User-based rules are treated as higher priority than any other statically provisioned rules. Policy roles and the DACLs associated with them are dynamically created as needed based on the incoming RADIUS Filter-Id attribute. This attribute is automatically deleted when the last authenticated user associated with the role is removed.

When a set of role-based rules is installed for a given role or profile, they cannot be changed until that role is no longer in use. Role-based rules are shared by any other user who authenticates to the same role or profile. While both user based and role-based DACLs can be used on the device at the same time, a mix of user based and role-based DACLs are not permitted for a given user.

A role-based operation has a type 'r' and requires a preceding add operation (a,r). Each role requires a profile pre-configured with a unique name and access-list configuration.

A role-based with create operation has a type 'c' and also requires a preceding add operation (a,rc). The role or profile is dynamically created if it does not already exist. If created dynamically, the role or profile will be deleted when no longer in use.

A **delete-all** operation has a type of 'da' and no **match**, **action**, or **index** fields are permitted. When used, the **delete-all** must be the first entry in the list. When present, this operation removes all existing rules associated with the user or role. Neither the action field nor the index field is permitted and will be ignored if present.

The following match conditions can be used with role-based ACLs:

- `ipv4src` *`ipv4source/mask-length`*
- `ipv4dst` *`ipv4dest/mask-length`*
- `ipproto` *`ipproto`* (TCP, UDP, ICMP, or protocol number)(ICMP and protocol number as of Release 32.1)
- `l4srcport` *`l4sourceport-l4sourceportend/mask-length`* (requires ipproto; range is role-based only and no mask)
- `l4dstport` *`l4destport-l4destportend/mask-length`* (requires ipproto; range is role-based only and no mask)
- `ether` (role-based only)
- `any` (as of Release 32.1)

Supported Platforms

All ExtremeSwitching X435, X450-G2, X460-G2, X440-G2, X465, X590, X620, X695 series switches.

Limitations

- TCI overwrite is not supported on X435 switches.
- Layer 7 policy (DNS) is not supported on X435 switches.
- Role-based Dynamic Access-List is supported on X435 switches, but without action set IDs mentioned in the VSA (Action-set ID CLI is not supported on X435).
- User-based ACLs, which requires slice sharing by running the **configure policy slices shared number** command, is not supported on X435.
- DNS is not supported on Extended Edge switches with Controlling Bridges on the ExtremeSwitching X695 series switch.
- ACL style policy must be selected.
- Only a subset of the existing policy rules is allowed.
- SNMP is not supported.
- Role-based ACLs are supported for Controlling Bridge, which does not support tci-overwrite profiles.
- User-based ACLs are not supported for Controlling Bridge, which does not support tci-overwrite policy profiles.

Policy and Lowest Common Denominator Stacking

When devices are stacked that have different capacities, we sink to the lowest common level of capacities and functionality when possible. If the stack already has an existing configuration that exceeds the new lower capacity policy will disallow the ports on the new unit to become policy enabled.

Note

In some cases policy capacities of a device have been determined to be so low that they are deigned non-useful for any practical policy deployment. In these cases the ports on the device are never allowed to become policy enabled.

The following algorithm is used to determine the lowest common denominator when stacking:

```
(A) More Capable device(s)
(B) Less Capable device(s)

- (A) is running and (B) is added

   If (A) is currently using less or equal resources to the maximum
   capacity (B) provides.
       - Policy will reduce the system maximum capacity
         to match (B).
   If (A) is currently using more resources than the maximum capacity (B)
provides.
       - Policy will not be enabled on the ports of (B).
       - A message will be printed that indicates the condition to the
         customer. If the resources being used by (A) are reduced to less or equal the
maximum capacity of (B)
       the ports on (B) will become policy enabled. A message will be printed that
indicates the condition to the customer and thereafter every
       5 minutes as the condition exists. If the resources being used by (A) are reduced
to less or equal the maximum capacity of (B)
       a message will be printed that indicates this slot can fully function with policy
pending a
       reboot of (B). This message will repeat every 5 minutes until (B) is
       rebooted.              - (B) is running and
       (A) is added      o The
       system maximum capacity will continue to match (B)
       - If (B) is removed (A) will revert to its higher capacity.              -
(A) and (B) brought
       up at the same time.      o The
       system maximum capacity will be the lower capacity of (B)- If (B) is removed
       (A) will revert to its higher maximum capacity.
```

Standard and Enhanced Policy Considerations

This section itemizes additional policy considerations for the stackable and standalone platforms, and provides a table cross-referencing standard and enhanced policy capability and policy capability to traffic classification rules.

Not all stackable fixed switch platforms support policy. On some stackable and standalone fixed switch platforms policy support requires a purchased license. See the software release notes that come with your device for policy support.

Table 90 provides a listing of policy capabilities by standard and enhanced support level. Standard policy capabilities are further granulated based upon traffic classification support. See Table 91 on page 968 for a cross-reference of traffic classification to policy capability support.

Table 90: Standard and Enhanced Policy Capability Cross-Reference

Policy Support Level	Policy Capability
Standard	• Dynamic PID Assign Rule – The ability to dynamically assign a policy based upon a traffic classification (macsource and port-string). See **Dynamic** in Table 91 on page 968. • Admin PID Assign Rule – The ability to administratively assign a policy based upon a traffic classification (macsource and port-string). See **Admin** in Table 91 on page 968. • *VLAN* Forwarding – The ability to assign a forwarding VLAN rule through the default profile/role PVID only. • Deny – The ability to assign a drop traffic rule. See **Drop** in Table 91 on page 968. • Permit – The ability to assign a forward traffic rule. See **Forward** in Table 91 on page 968. • *CoS* Assign Rule – The ability to assign a CoS rule. See **CoS** in Table 91 on page 968. • Priority – The ability to assign traffic priority using a CoS assignment. See **CoS** in Table 91 on page 968. • Longest Prefix Rules – The ability to always look at the highest bit mask for an exact traffic classification match.
Enhanced	• TCI Overwrite – The ability to overwrite user priority and other VLAN tag TCI field classification information. • Invalid Policy Action – The ability to set a drop, forward, or default-policy behavior based upon an invalid action.

Table 91 provides a cross-reference of standard ( ) and enhanced (X) policy capability to traffic classification rule.

Table 91: Policy Capability to Traffic Classification Rule Cross-Reference

Traffic Classification Rule	Dynamic	Admin	VLAN	CoS	Drop	Forward	Syslog	Trap	Mirror
MAC Source Address [a]	X	X		X	X	X	X	X	X
MAC Destination Address [a]				X	X	X	X	X	X
IPX Source Address							X	X	X

Table 91: Policy Capability to Traffic Classification Rule Cross-Reference (continued)

Traffic Classification Rule	Dynamic	Admin	VLAN	CoS	Drop	Forward	Syslog	Trap	Mirror
IPv6 Destination Address [a]				X	X	X	X	X	X
IPX Destination Address							X	X	X
IPX Source Socket							X	X	X
IPX Destination Socket							X	X	X
IPX Transmission Control							X	X	X
IPX Type Field							X	X	X
IP Source Address				X	X	X	X	X	X
IP Destination Address				X	X	X	X	X	X
IP Fragmentation				X	X	X	X	X	X
UPD Port Source				X	X	X	X	X	X
UDP Port Destination				X	X	X	X	X	X
TCP Port Source				X	X	X	X	X	X
TCP Port Destination				X	X	X	X	X	X
ICMP (Internet Control Message Protocol) Packet Type							X	X	X
Time-To-Live (TTL)				X	X	X	X	X	X
IP Type of Service				X	X	X	X	X	X
IP Protocol				X	X	X	X	X	X

Table 91: Policy Capability to Traffic Classification Rule Cross-Reference (continued)

Traffic Classification Rule	Dynamic	Admin	VLAN	CoS	Drop	Forward	Syslog	Trap	Mirror
Ether II Packet Type				X	X	X	X	X	X
LLC DSAP/SSAP/CTRL							X	X	X
VLAN Tag							X	X	X
TCI-Overwrite							X	X	X
Port String	X	X		X	X	X	X	X	X

Terms and Definitions

Table 92 lists terms and definitions used in this policy configuration discussion.

Table 92: Policy Configuration Terms and Definitions

Term	Definition
Administrative Profile	A logical container that assigns a traffic classification to a policy role.
CoS	A logical container for packet priority, queue, and forwarding treatment that determines how the firmware treats a packet as it transits the link.
Filter-ID	A string that is formatted in the *RADIUS* access-accept packet sent back from the authentication server to the switch during the authentication process. In the Extreme policy context, the string contains the name of the policy role to be applied to the authenticating user or device.
