AdminStat	Specifies the administrative status for the OSPFv3 interface. If you enable the status, it is advertised as an internal route to some areas. If you disable the status, the interface is external to OSPFv3. The default is enabled.
RtrPriority	Specifies the priority of this interface. Multiaccess networks use the priority in the designated router election. A higher priority value increases the chance the router becomes the designated router. A value of zero (0) indicates the router cannot become the designated router for the network. If more than one router uses the same priority value, the router ID determines the designated router. The default is 1.
TransitDelay	Specifies the estimated number of seconds to transmit a link-state-update packet over this interface. The default is 1.
RetransInterval	Specifies the number of seconds between retransmission of link-state advertisements for the adjacencies that belong to this interface, and for database description and link-state request packets. The default is 5.
HelloInterval	Specifies the number of seconds between the hello packets that the router sends on this interface. You must configure this field to the same value for all routers attached to a common network. The default is 10.
RtrDeadInterval	Specifies the number of seconds after which to declare a router down if no hello packets are received. You must configure this field to the same value for all routers attached to a common network. The default is 40.

Name	Description
PollInterval	Specifies the number of seconds between hello packets sent to an inactive NBMA neighbor. The default is 120.
State	Shows the state of the OSPFv3 interface as one of the following: <ul style="list-style-type: none"> • down • loopback • waiting • pointToPoint • designatedRouter • backupDesignatedRouter • otherDesignatedRouter
DesignatedRouter	Shows the router ID for the designated router.
BackupDesignatedRouter	Shows the router ID for the backup designated router.
MetricValue	Specifies the cost for the interface. The default value for a brouter port or VLAN is 1. The default value for a tunnel is 100. Note: If you do not specify a cost for the interface, the switch dynamically updates the interface cost with the configured global OSPF default cost. The global OSPF default cost depends on the speed of the interface.
LinkLsaSuppression	Specifies whether Link LSA suppression is enabled.
BfdEnable	Enables Bidirectional Forwarding Detection (BFD) for OSPF.

Create an OSPF Interface on a Tunnel

Configure the OSPF protocol on an IPv6 interface to support dynamic routing on the interface. Perform this procedure to create an OSPF interface on a tunnel.

If you want to modify existing OSPFv3 interfaces, see [Modify an OSPFv3 Interface](#) on page 2214. To configure OSPFv3 on an IPv6 VLAN, see [Create an OSPF VLAN Interface](#) on page 2204.

Before You Begin

- The IPv6 interface must exist.

Procedure

1. In the navigation pane, expand the **Configuration > IPv6** folders.
2. Select **Tunnel**.
3. Select the **Tunnel Config** tab.
4. Select a configured tunnel.

5. Select **IPv6 OSPF**.
6. Select **Insert**.
7. Select the area ID.
8. Select **enabled**.
9. Select **Insert**.

OSPF Interface Field Descriptions

Use the data in the following table to use the **OSPF Interface** tab.

Name	Description
Index	Shows the interface index for the IPv6 interface on which OSPFv3 is configured.
Areaid	Specifies the area ID to which the IPv6 interface connects. Use 0.0.0.0 for the OSPFv3 backbone.
Type	Specifies the OSPFv3 interface type as one of the following: <ul style="list-style-type: none"> • broadcast • NBMA • point-to-point • point-to-multipoint
AdminStat	Specifies the administrative status for the OSPFv3 interface. If you enable the status, it is advertised as an internal route to some areas. If you disable the status, the interface is external to OSPFv3. The default is enabled.
RtrPriority	Specifies the priority of this interface. Multiaccess networks use the priority in the designated router election. A higher priority value increases the chance the router becomes the designated router. A value of zero (0) indicates the router cannot become the designated router for the network. If more than one router uses the same priority value, the router ID determines the designated router. The default is 1.
TransitDelay	Specifies the estimated number of seconds to transmit a link-state-update packet over this interface. The default is 1.
RetransInterval	Specifies the number of seconds between retransmission of link-state advertisements for the adjacencies that belong to this interface, and for database description and link-state request packets. The default is 5.
HelloInterval	Specifies the number of seconds between the hello packets that the router sends on this interface. You must configure this field to the same value for all routers attached to a common network. The default is 10.

Name	Description
RtrDeadInterval	Specifies the number of seconds after which to declare a router down if no hello packets are received. You must configure this field to the same value for all routers attached to a common network. The default is 40.
PollInterval	Specifies the number of seconds between hello packets sent to an inactive NBMA neighbor. The default is 120.
State	Shows the state of the OSPFv3 interface as one of the following: <ul style="list-style-type: none"> • down • loopback • waiting • pointToPoint • designatedRouter • backupDesignatedRouter • otherDesignatedRouter
DesignatedRouter	Shows the router ID for the designated router.
BackupDesignatedRouter	Shows the router ID for the backup designated router.
MetricValue	Specifies the cost for the interface. The default value for a brouter port or VLAN is 1. The default value for a tunnel is 100. Note: If you do not specify a cost for the interface, the switch dynamically updates the interface cost with the configured global OSPF default cost. The global OSPF default cost depends on the speed of the interface.
LinkLsaSuppression	Specifies whether Link LSA suppression is enabled.

Viewing the AS-scope link-state database

View the AS-scope link-state database (LSDB) to see the LSAs that are flooded through the routing domain. The AS scope is used for AS external-LSAs.

Before You Begin

- Change the VRF instance as required to view OSPFv3 on a specific VRF instance.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **OSPFv3**.
3. Click the **AS-scope LSDB** tab.

AS-scope LSDB field descriptions

Use the data in the following table to use the **AS-scope LSDB** tab.

Name	Description
Type	Shows the type of the link-state advertisement. Each link state type has a separate advertisement format. AS-scope LSAs not recognized by the router may be stored in the database.
RouterId	Shows the 32 bit number that uniquely identifies the originating router in the autonomous system.
Lsid	Identifies the piece of the routing domain that is being described by the advertisement.
Sequence	Shows a signed 32-bit integer that detects old and duplicate link-state advertisements. The larger the sequence number, the more recent the advertisement.
Age	Shows the age of the link-state advertisement in seconds.
Checksum	Indicates the checksum of the complete contents of the advertisement, except the age field. The age field is not affected so that the advertisement age value increments without updating the checksum. The checksum used is the same for ISO connectionless datagrams, the Fletcher checksum.

Viewing the area-scope LSDB

View the area-scope LSDB to see the LSAs that are flooded in a single OSPFv3 area. Area scope is used in router LSAs, network LSAs, Inter-Area-Prefix-LSAs, Inter-Area-Router LSAs, and Intra-Area-Prefix-LSAs.

Before You Begin

- Change the VRF instance as required to view OSPFv3 on a specific VRF instance.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IPv6**.
2. Click **OSPFv3**.
3. Click the **Area-scope LSDB** tab.

Area-scope LSDB field descriptions

Use the data in the following table to use the **Area-scope LSDB** tab.

Name	Description
AreaId	Identifies the area ID from which the LSA is received. Area ID 0.0.0.0 is the OSPF backbone.
Type	Identifies the type of the link-state advertisement. Each link-state type has a separate advertisement format. Area-scope LSAs unrecognized by the router are also stored in this database.
RouterId	Identifies the originating router in the autonomous system.
Lsid	Identifies the piece of the routing domain that is described by the advertisement.
Sequence	Shows a signed 32-bit integer that detects old and duplicate link-state advertisements. The larger the sequence number, the more recent the advertisement.
Age	Shows the age of the link-state advertisement in seconds.
Checksum	Indicates the checksum of the complete contents of the advertisement, except the age field. The age field is not affected so that the advertisement age value increments without updating the checksum. The checksum used is the same for ISO connectionless datagrams, the Fletcher checksum.

Viewing the link-scope LSDB

View the link-scope LSDB to view the LSAs that are not flooded beyond the local link.

Before You Begin

- Change the VRF instance as required to view OSPFv3 on a specific VRF instance.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IPv6**.
2. Click **OSPFv3**.
3. Click the **Link-scope LSDB** tab.

Link-scope LSDB field descriptions

Use the data in the following table to use the **Link-scope LSDB** tab.

Name	Description
IfIndex	Shows the identifier of the link from which the LSA was received.
Type	Shows the type of the link-state advertisement. Each link state type has a separate advertisement format. Link-scope LSAs not recognized by the router may be stored in the database.

Name	Description
RouterId	Shows the 32 bit number that uniquely identifies the originating router in the autonomous system.
Lsid	Identifies the piece of the routing domain that is being described by the advertisement.
Sequence	Shows a signed 32-bit integer that detects old and duplicate link-state advertisements. The larger the sequence number, the more recent the advertisement.
Age	Shows the age of the link-state advertisement in seconds.
Checksum	Indicates the checksum of the complete contents of the advertisement, except the age field. The age field is not affected so that the advertisement age value increments without updating the checksum. The checksum used is the same for ISO connectionless datagrams, the Fletcher checksum.

Adding an NBMA neighbor

Add an NBMA neighbor for each interface that is eligible to become the DR.

An NBMA interface with a positive nonzero router priority is eligible to become the DR for the NBMA network and is configured with the identification of all attached routers, IPv6 addresses, and router priorities.

Before You Begin

- Identify the following information:
 - specific interfaces to include in the NBMA network
 - the IPv6 address for each interface
 - the router priority for each interface
 - the hello interval for the network
 - the router dead interval for the network
 - the poll interval for the network
- Change the VRF instance as required to configure OSPFv3 on a specific VRF instance.

About This Task

In contrast to a broadcast network where switches multicast (send to AllSPFRouters and AllDRouters) certain OSPF protocol packets, switches replicate and send NBMA packets to each neighboring router as unicast. NBMA networks drop all OSPF packets with destination addresses AllSPFRouters and AllDRouters. Because the NBMA network does not broadcast, you must manually configure a list of neighbors and priorities for all routers in the network that can become the DR. Potential DRs use a positive nonzero router priority.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.

2. Click **OSPFv3**.
3. Click the **NBMA Neighbors** tab.
4. Click **Insert**.
5. Select the IPv6 port or VLAN interface.
6. Specify the IPv6 address for the neighbor.
7. Specify the priority for the neighbor.
8. Click **Insert**.

NBMA Neighbors field descriptions

Use the data in the following table to use the **NBMA Neighbors** tab.

Name	Description
IfIndex	Specifies the link ID for the link over which the switch reaches the neighbor.
Address	Specifies the IPv6 address of the neighbor.
Priority	Specifies the priority to use for this neighbor in the designated router election process. A value of 0 indicates the neighbor cannot become the designated router. The higher the priority value, the higher chance the switch will win the election process. The default is 1.
RtrId	Identifies the neighboring router in the autonomous system. The value is 0.0.0.0 until the switch receives a hello message from the neighbor.
State	Identifies the state of the relationship with the neighbor. The state can be one of the following: <ul style="list-style-type: none"> • down • attempt • init • twoWay • exchangeStart • exchange • loading • full

Configuring Route Redistribution to OSPFv3

Configure a redistribute entry to announce routes of a certain source protocol into the OSPFv3 domain. Optionally, use a route policy to control the redistribution of routes.

About This Task

Important

Changing the OSPFv3 redistribute context is a process-oriented operation that can affect system performance and network reachability while you perform this procedure. As a best practice, change the default preferences for an OSPFv3 redistribute context, you must do so before you enable the protocols.

Before You Begin

- Enable OSPFv3 globally.
- Ensure that a route policy exists if you intend to use a route policy.
- Change the VRF instance as required to configure OSPFv3 on a specific VRF instance. The VRF must have an RP trigger of OSPFv3. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IPv6**.
2. Click **OSPFv3**.
3. Click the **Redistribute** tab.
4. Click **Insert**.
5. Select an option for the route source.
6. Select the **enable** option button.
7. Select a route policy.
8. Configure the metric type.
9. Click **Insert**.

Redistribute Field Descriptions

Use the data in the following table to use the **Redistribute** tab.

Name	Description
DstVrfId	Specifies the destination virtual router forwarding instance. You cannot configure this variable.
Protocol	Specifies the dynamic routing protocol that receives the external routing information.
SrcVrfId	Specifies the source VRF instance. You cannot configure this variable.
RouteSource	Specifies the route source protocol for the redistribution entry.
Enable	Enables (or disables) an OSPF redistribute entry for a specified source type.
RoutePolicy	Configures the route policy (by name) to use for detailed redistribution of external routes from a specified source into an OSPF domain. Click the ellipsis (...) button and choose from the list in the dialog box.

Name	Description
Metric	Configures the OSPF route redistribution metric for basic redistribution. The value can be a range from 0–65535. A value of 0 indicates to use the original cost of the route.
MetricType	Configures the OSPF route redistribution metric type. The default is type 2. The cost of a type 2 route is the external cost, regardless of the interior cost. A type 1 cost is the sum of both the internal and external costs.

Modify an OSPFv3 Interface

Configure the OSPF protocol on IPv6 interface to support dynamic routing on the interface. The IPv6 interface can be a tunnel, port, or VLAN.

Before You Begin

- The OSPFv3 interface must exist.

Procedure

- In the navigation pane, expand **Configuration > IPv6**.
- Select **OSPFv3**.
- Select the **Interfaces** tab.
- Double-click a cell to edit the value.
- Select **Apply**.

Interfaces field descriptions

Use the data in the following table to use the **Interfaces** tab.

Name	Description
Index	Specifies the interface index for the IPv6 interface on which OSPFv3 is configured.
Areald	Specifies the area ID to which the IPv6 interface connects. Use 0.0.0.0 for the OSPFv3 backbone.
Type	Specifies the OSPFv3 interface type as one of the following: <ul style="list-style-type: none"> broadcast NBMA point-to-point point-to-multipoint passive
AdminStat	Specifies the administrative status for the OSPFv3 interface. If you enable the status, it is advertised as an internal route to some areas. If you disable the status, the interface is external to OSPFv3. The default is enabled.

Name	Description
RtrPriority	Specifies the priority of this interface. Multiaccess networks use the priority in the designated router election. A higher priority value increases the chance the router becomes the designated router. A value of zero (0) indicates the router cannot become the designated router for the network. If more than one router uses the same priority value, the router ID determines the designated router. The default is 1.
TransitDelay	Specifies the estimated number of seconds to transmit a link-state-update packet over this interface. The default is 1.
RetransInterval	Specifies the number of seconds between retransmission of link-state advertisements for the adjacencies that belong to this interface, and for database description and link-state request packets. The default is 5.
HelloInterval	Specifies the number of seconds between the hello packets that the router sends on this interface. You must configure this field to the same value for all routers attached to a common network. The default is 10.
RtrDeadInterval	Specifies the number of seconds after which to declare a router down if no hello packets are received. You must configure this field to the same value for all routers attached to a common network. The default is 40.
PollInterval	Specifies the number of seconds between hello packets sent to an inactive NBMA neighbor. The default is 120.
State	Shows the state of the OSPFv3 interface as one of the following: <ul style="list-style-type: none"> • down • loopback • waiting • pointToPoint • designatedRouter • backupDesginatedRouter • otherDesignatedRouter
DesignatedRouter	Shows the router ID for the designated router.
BackupDesignatedRouter	Shows the router ID for the backup designated router.

Name	Description
MetricValue	Specifies the cost for the interface. The default value for a brouter port or VLAN is 1. The default value for a tunnel is 100. Note: If you do not specify a cost for the interface, the switch dynamically updates the interface cost with the configured global OSPF default cost. The global OSPF default cost depends on the speed of the interface.
LinkLsaSuppression	Specifies whether Link LSA suppression is enabled.

Viewing OSPFv3 neighbors

View OSPFv3 neighbors to see routers with interfaces to a common network.

The OSPFv3 hello protocol maintains and dynamically discovers neighbor relationships.

The exception is an NBMA network; you manually configure permanent neighbors on each router eligible to become the designated router (DR).

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **OSPFv3**.
3. Click the **Neighbors** tab.

Neighbors field descriptions

Use the data in the following table to use the **Neighbors** tab.

Name	Description
IfIndex	Displays the local-link ID of the link over which the neighbor can be reached.
RtrId	Identifies the neighboring router in the Autonomous System. The value is the router ID of the neighboring router, which in OSPF uses the same format as an IPv6 address but identifies the router independent of IPv6 address.
Address	Displays the IPv6 address for the neighbor associated with the local link.
Options	Displays the bit mask that corresponds to the options field on the neighbor.

Name	Description
State	Displays the state of the relationship with the neighbor. The value can be one of the following: <ul style="list-style-type: none"> • down • attempt • init • twoWay • exchangeStart • exchange • loading • full
NbrIfId	Displays the interface ID that the neighbor advertises in its hello packets on this link.
DeadIntCnt	Displays the Dead interval Count or TTL (time to live) field that indicates how many seconds remain before the system declares the Neighbor down. The starting value is the Router Dead Interval value and it decrements to 0 if no Hello is received for that neighbor within the interval. If no Hello is received within the interval, then the system declares the neighbor down. When a hello is received for the neighbor, the system resets the value to the Router Dead Interval value.

Viewing virtual neighbors

View information about the neighbors on the virtual link to the OSPFv3 backbone.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **OSPFv3**.
3. Click the **Virtual Neighbors** tab.

Virtual Neighbors field descriptions

Use the data in the following table to use the **Virtual Neighbors** tab.

Name	Description
Area	Shows the ID for the transit area.
RtrId	Shows the ID for the neighboring router in the autonomous system.
LocalIfIndex	Shows the local interface ID for the virtual link over which the switch can reach the neighbor.

Name	Description
AddressType	Shows the type of address as one of the following: <ul style="list-style-type: none"> • ipv4 • ipv6 • ipv4z • ipv6z • dns ipv4z and ipv6z indicate a scope zone.
Address	Shows the IPv6 address that this virtual neighbor advertises. This value must be a global scope address.
Options	Shows a bit mask that corresponds to the OSPF options field of the neighbor.
State	Shows the state of the virtual neighbor relationship. The value can be one of the following: <ul style="list-style-type: none"> • down • attempt • init • twoWay • exchangeStart • exchange • loading • full

View OSPFv3 Statistics

View OSPF statistics to analyze trends. You can also graph statistics for all OSPF packets transmitted by the switch.

Procedure

1. In the navigation pane, expand the **Configuration > IPv6** folders.
2. Select **OSPFv3**.
3. Select **Stats**.

Stats Field Descriptions

Use the data in the following table to use the **Stats** tab.

Name	Description
TxPackets	Shows the count of sent packets.
RxPackets	Shows the count of received packets.
TxDropPackets	Shows the count of sent, dropped packets.
RxDropPackets	Shows the count of received, dropped packets.
RxBadPackets	Shows the count of received, bad packets.

Name	Description
SpfRuns	Shows the count of intra-area route table updates with calculations using this area link-state database.
LastSpfRun	Shows the count of the most recent SPF run.
LsdbTblSize	Shows the size of the link state database table.
BadLsReqs	Shows the count of bad link requests.
SeqMismatches	Shows the count of sequence mismatched packets.
Routes	Shows the number of OSPF routes added to the routing table.
Adjacencies	Shows the number of existing adjacencies.
Areas	Shows the number of configured areas.
Nbrs	Shows the number of OSPF neighbors.

OSPFv3 Configuration Example

This section shows an example of OSPFv3 configuration. The following figure shows the network.

Figure 196: OSPFv3 configuration

To complete the configuration, you must perform the following actions:

- Configure an IPv6 VLAN (VLAN 2) with port member 1/1.
- Configure an IPv6 brouter port (1/2).
- Use IPv6 address 2001:100:102::/64.

Configure VLAN 2 and add port members.

```
vlan create 2 type port-mstprstp 0
vlan mlt 2 4
vlan members 2 1/1 portmember
interface vlan 2
ipv6 interface
ipv6 interface enable
ipv6 interface address 2001:100:102:202:0:0:0:1/64
exit
```

Enable OSPFv3 on VLAN 2.

```
# IPV6 OSPF VLAN CONFIGURATION
interface vlan 2
ipv6 ospf area 0.0.0.0
```

```

ipv6 ospf poll-interval 0
ipv6 ospf enable
exit

```

Create router port 1/2 with IPv6 and OSPFv3.

```

interface gigabitethernet 1/2
ipv6 interface vlan 3999
ipv6 interface enable
ipv6 interface address 2001:100:102:201:0:0:0:1/64
ipv6 ospf area 0.0.0.0
ipv6 ospf enable
exit

```

Verification

The following example shows the Global Router example for OSPFv3 Area configuration:

```

Switch:1#show ipv6 ospf area

=====
                        OSPF Area - GlobalRouter
=====
AREA_ID          STUB_AREA  NSSA   IMPORT_SUM  TRANS_ROLE  TRANS_STATE
-----
0.0.0.0          false     false  true        always      disabled
STUB_METRIC STUB_METRIC_TYPE  SPF_RUNS  BDR_RTR_CNT  ASBDR_RTR_CNT  LSA_CNT  LSACK_SUM
-----
10              ospfV3Metric     0         0             0             0         0

```

The following example shows the VRF example for OSPFv3 Area configuration:

```

Switch:1#show ipv6 ospf area vrf vrf1

=====
                        OSPF Area - VRF vrf1
=====

Port Performance Management

[Digital Diagnostic Monitoring on page 2222](#)

[Port Performance Management Using CLI on page 2222](#)

[Port Performance Management using EDM on page 2227](#)

Digital Diagnostic Monitoring

Use Digital Diagnostic Monitoring (DDM) to monitor laser operating characteristics such as temperature, voltage, current, and power. This feature works at any time during active laser operation without affecting data traffic.

The following optical transceivers support DDM:

- 1 Gbps Small Form Factor Pluggable (SFP)
- 10 Gbps Small Form Factor Pluggable plus (SFP+)
- 25 Gbps Small Form Factor Pluggable 28 (SFP28)
- 40 Gbps Quad Small Form Factor Pluggable plus (QSFP+)
- 100 Gbps Quad Small Form Factor Pluggable 28 (QSFP28)

Digital Diagnostic Interface (DDI) is an interface that supports DDM. These devices provide real-time monitoring of individual DDI transceivers. The DDM software provides warnings or alarms after the temperature, voltage, laser bias current, transmitter power or receiver power fall outside of vendor-specified thresholds during initialization.

For information about optical transceivers, see [Extreme Optics](#) website

Port Performance Management Using CLI

This section contains procedures to monitor individual DDI transceivers using the CLI.

Configure DDM

Configure Digital Diagnostic Monitoring to get information concerning the status of the transmitted and received signals to allow better fault isolation and error detection.

About This Task

When you enable DDM, you see the internal performance condition (temperature, voltage, bias, Tx power and Rx power) of the pluggable transceiver. The default is disabled.

For information about how to reset a transceiver for troubleshooting purposes, see [Reset a QSFP+ or QSFP28 Transceiver](#) on page 3197.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. (Optional) Configure an alarm to occur if the port goes down:

```
pluggable-optical-module ddm-alarm-portdown
```
3. (Optional) Configure the DDM interval:

```
pluggable-optical-module ddm-monitor-interval <5-60>
```
4. (Optional) Enable the sending of trap messages when an alarm occurs:

```
pluggable-optical-module ddm-traps-send
```
5. Enable DDM:

```
pluggable-optical-module ddm-monitor
```

Example

Configure the interval to 10 seconds and enable DDM.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#pluggable-optical-module ddm-monitor-interval 10
Switch:1(config)#pluggable-optical-module ddm-monitor
```

Variable Definitions

Use the data in the following table to use the **pluggable-optical-module** command

Variable	Value
<i>ddm-alarm-portdown</i>	When enabled, the port goes down when any alarm occurs. The default is disabled.
<i>ddm-monitor</i>	Enables DDM. When enabled, you see the internal performance condition (temperature, voltage, bias, Tx power and Rx power) of the pluggable transceiver. The default is disabled.
<i>ddm-monitor-interval</i> <5-60>	Configures the DDM monitor interval. If an alarm occurs, the log message is received within the specific interval. The default value is 5 seconds.
<i>ddm-traps-send</i>	Enables or disables the sending of trap messages. When enabled, the trap message is sent to the device manager any time the alarm occurs. The default is enabled.

View DDI Port Information

Perform this procedure to view basic manufacturing information and characteristics, and the current configuration.

About This Task

This command displays information for DDI transceivers.

Note

Transceiver support differs across hardware platforms. For information about supported parts, see [Extreme Optics](#) website.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. View basic manufacturing information and characteristics:

```
show pluggable-optical-modules basic [{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]]
```
3. View configuration information:

```
show pluggable-optical-modules config
```
4. View detailed manufacturing information and characteristics:

```
show pluggable-optical-modules detail [{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]]
```

Examples

```
Switch:1#show pluggable-optical-modules config
=====
Pluggable Optical Module Global Configuration
=====
                ddm-monitor : disabled
dmm-monitor-interval : 5
                ddm-traps-send : enabled
dmm-alarm-portdown : disabled
```

The following example includes Extreme extended diagnostic information. Not all parts support this information. A value of 254 indicates the part has not been initialized.

```
Switch:1#show pluggable-optical-modules detail 1/29
=====
Pluggable Optical Module Info 1/29 Detail

Variable Definitions

Use the data in the following table to use the **show pluggable-optical-modules basic** and **show pluggable-optical-modules detail** commands.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

View DDI Temperature Information

About This Task

This command displays information for DDI transceivers.

Note

Transceiver support differs across hardware platforms. For information about supported parts, see [Extreme Optics](#) website.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. View temperatures:

```
show pluggable-optical-modules temperature [{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]]
```

Example

```
Switch:1#show pluggable-optical-modules temperature
```

```

Port Performance Management using EDM

This section contains procedures to monitor individual DDI transceivers using EDM.

View DDI Information**About This Task**

You can view DDI information, for example, port information, temperature, and voltages for DDI transceivers.

**Note**

Transceiver support differs across hardware platforms. For information about supported parts, see [Extreme Optics](#) website.

Procedure

1. On the Physical Device view, select one or more ports.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **DDI/SFP** tab.

DDI/SFP Field Descriptions

Use the data in the following table to use the **DDI/SFP** tab.

Name	Description
ConnectorType	Indicates the type of connector.
SupportsDDM	Indicates if the transceiver supports DDM.
DdmStatusMask	Indicates the DDM status. A value other than ddm-ok represents a specific error.
CLEI	Indicates the Telcordia register assignment CLEI code.
VendorName	Indicates the name of the manufacturer.
VendorPartNumber	Indicates the part number for the transceiver.
VendorRevNumber	Indicates the manufacturer revision level for the transceiver.
VendorSN	Indicates the manufacturer serial number for the transceiver.
VendorDateCode	Indicates the manufacturer date code for the transceiver.
Wavelength	Indicates the wavelength in nm. This field is valid for optical transceivers only.
Calibration	Indicates if the calibration is internal or external.
PowerMeasure	Indicates Rx power measurement as average or OMA.
Aux1Monitoring	Indicates if auxiliary monitoring is implemented for the transceiver.
Aux2Monitoring	Indicates if auxiliary monitoring is implemented for the transceiver.
TemperatureLowAlarmThreshold	Indicates the low alarm threshold in degrees Celsius.
TemperatureLowWarningThreshold	Indicates the low warning threshold in degrees Celsius.
Temperature	Indicates the current temperature in degrees Celsius of the transceiver.
TemperatureHighWarningThreshold	Indicates the high warning threshold in degrees Celsius.
TemperatureHighAlarmThreshold	Indicates the high alarm threshold in degrees Celsius.
TemperatureStatus	Indicates if any temperature thresholds were exceeded.
VoltageLowAlarmThreshold	Indicates the low alarm threshold in volts.
VoltageLowWarningThreshold	Indicates the low warning threshold in volts.
Voltage	Indicates the current voltage in volts.

Name	Description
VoltageHighWarningThreshold	Indicates the high warning threshold in volts.
VoltageHighAlarmThreshold	Indicates the high alarm threshold in volts.
VoltageStatus	Indicates if any voltage thresholds were exceeded.
BiasLowAlarmThreshold	Indicates the bias current low alarm threshold in mA.
BiasLowWarningThreshold	Indicates the bias current low warning threshold in mA.
Bias	Indicates the laser bias current in mA.
BiasHighWarningThreshold	Indicates the bias current high warning threshold in mA.
BiasHighAlarmThreshold	Indicates the bias current high alarm threshold in mA.
BiasStatus	Indicates if any bias thresholds were exceeded.
TxPowerLowAlarmThreshold	Indicates the low alarm threshold in dBm for the Tx power.
TxPowerLowWarningThreshold	Indicates the low warning threshold in dBm for the Tx power.
TxPower	Indicates the current Tx power in dBm.
TxPowerHighWarningThreshold	Indicates the high warning threshold in dBm for the Tx power.
TxPowerHighAlarmThreshold	Indicates the high alarm threshold in dBm for the Tx power.
TxPowerStatus	Indicates if any Tx power thresholds were exceeded.
RxPowerLowAlarmThreshold	Indicates the low alarm threshold in dBm for the Rx power.
RxPowerLowWarningThreshold	Indicates the low warning threshold in dBm for the Rx power.
RxPower	Indicates the current Rx power in dBm.
RxPowerHighWarningThreshold	Indicates the high warning threshold in dBm for the Rx power.
RxPowerHighAlarmThreshold	Indicates the high alarm threshold in dBm for the Rx power.
RxPowerStatus	Indicates if any Rx power thresholds were exceeded.
Aux1LowAlarmThreshold	Indicates the low alarm threshold auxiliary 1 reading.
Aux1LowWarningThreshold	Indicates the low warning threshold auxiliary 1 reading.
Aux1	Indicates the current auxiliary 1 reading.
Aux1HighWarningThreshold	Indicates the high warning threshold auxiliary 1 reading.
Aux1HighAlarmThreshold	Indicates the high alarm threshold auxiliary 1 reading.
Aux1Status	Indicates if any auxiliary 1 thresholds were exceeded.
Aux2LowAlarmThreshold	Indicates the low alarm threshold auxiliary 2 reading.
Aux2LowWarningThreshold	Indicates the low warning threshold auxiliary 2 reading.
Aux2	Indicates the current auxiliary 2 reading.

Name	Description
Aux2HighWarningThreshold	Indicates the high warning threshold auxiliary 2 reading.
Aux2HighAlarmThreshold	Indicates the high alarm threshold auxiliary 2 reading.
Aux2Status	Indicates if any auxiliary 2 thresholds were exceeded.
PowerOnCounter	Tracks the power-on-life of the part. This value increments by 1 every 48 hours of consecutive power. This value is never decremented or cleared. If you remove or reinsert the part, reset or reboot the chassis, reset the slot, or channelize or dechannelize the port, then the 48-hour time period restarts.
TxDdmInitial	Indicates the Tx dB from low alarm, which is the difference between the TxPower dBm and the TxPower low alarm. The host provides the value after the first 48 consecutive hours of operation.
TxDdmLastGasp	Indicates the last gasp of Tx dB from low alarm. The host updates this value every 48 hours.
RxDdmInitial	Indicates the Rx dB from low alarm, which is the difference between the RxPower dBm and the RxPower low alarm. The host provides the value after the first 48 consecutive hours of operation after a power cycle.
RxDdmLastGasp	Indicates the last gasp of Rx dB from low alarm. The host updates this value every 48 hours.
ExtremeExtraFeatures	Indicates if the device supports the extra Extreme features.

Note

1. Threshold and actual values for TxBias, TxPower, and RxPower are provided for all 4 channels in QSFP+ and QSFP28 optical transceivers.
2. Auxiliary monitoring does not apply to QSFP+s or QSFP28s.

Power over Ethernet (PoE) is the implementation of IEEE 802.3af, IEEE 802.3at, and IEEE 802.3bt (Type 3 and Type 4), which allows for both data and power to pass over a copper Ethernet LAN cable. Typical power devices include wireless Access Points and VoIP telephones.

Depending on the technology and application requirements, PoE is classified into classes. Depending on the power requirements, the PoE devices are categorized by type. Classes range from Class 0 to 8 whereas types range from Type 1 to 4. Each type associates with an IEEE 802.3 PoE standard. These standards provide signaling between the power sourcing equipment (PSE) and the powered device (PD). PSE devices, such as switches, provide power on the network cable. The devices that PSE provides power to are called PDs, such as VoIP phones, wireless access points, and IP surveillance cameras.

To know which ports support PoE, see the following documents:

- [ExtremeSwitching 5320 Series Hardware Installation Guide](#)
- [ExtremeSwitching 5420 Series Hardware Installation Guide](#)
- [ExtremeSwitching 5520 Series Hardware Installation Guide](#)

The switch uses the Dynamic Power Allocation scheme when supplying power to devices. Only the power being consumed by the device is allocated, improving efficiency and enabling support for more number of devices.

You can configure PoE from CLI and Enterprise Device Manager (EDM).

PoE Overview

You can plug any IEEE 802.3af-compliant, 802.3at-compliant, or 802.3bt-compliant (Type 3 and Type 4) for PWR+ powered device into a front-panel port and receive power in that port. Data also can pass simultaneously on that port. This capability is called PoE.

For more information about PoE and power supplies, see your hardware documentation.

The IEEE 802.3af draft standard regulates a maximum of 15.4 W of power for each port; that is, a power device cannot request more than 15.4 W of power. As different network devices require different levels of power, the overall available power budget of the switch depends on your power configuration and the particular connected network devices. If you connect an IP device that requires more than 16 W of power, you see an error on that port notifying you of an overload.

The switch automatically detects each IEEE 802.3af-compliant powered device attached to each front-panel port and immediately sends power to that appliance. The switch also automatically detects how much power each device requires and supply the required DC voltage at a set current based on the load conditions and current availability. The switch supports both PoE and standard LAN devices.

Similarly, the switch automatically detects any IEEE 802.3at-compliant (maximum 25.5 W) or IEEE 802.3bt-compliant (maximum 60W for Type 3, maximum 90W for Type 4) powered device attached to any PoE front panel port and immediately sends power to that appliance.

The power detection function of the switch operates independently of the data link status. A device that is already operating the link for data or a device that is not yet operational can request power. That is, the switch provides power to a requesting device even if the data link for that port is disabled. The switch monitors the connection and automatically disconnects power from a port when you remove or change the device, as well as when a short occurs.

The switch automatically detects devices that require no power connections from them, such as laptop computers or other switching devices, and sends no power to those devices. You control the supply of power to specific ports by setting the maximum allowed power to each port in 1 W increments, from 3 W to 98W.

**Important**

Wait for 30 seconds between unplugging and replugging an IP device to the switch to enable the IP device to discharge. If you attempt to connect earlier, the switch cannot detect the IP device.

The switch provides the capability to set a PoE power threshold, which lets you set a percentage of the total PoE power usage at which the switch sends a warning message. If the power consumption is below the threshold, the switch logs an information message.

**Important**

- After you enable Fast PoE or Perpetual PoE or both, you must save the running configuration file.
- If Fast PoE or Perpetual PoE are enabled and you change any other global or port-specific PoE settings (for example, power limits, or port power priority), you must resave the running configuration file.

PoE Detection Types

The following table identifies product support for the different PoE types.

Table 159: PoE type support

Product	Highest PoE Standard
5320-16P-4XE 5320-16P-4XE-DC 5320-24P-8XE 5320-48P-8XE	802.3at Type 2 PoE (30W) on BASE-T ports
5420F-48P-4XE 5420F-48P-4XL 5420F-24P-4XE	802.3at Type 2 PoE (30W)
5420F-8W-16P-4XE	802.3bt Type 4 PoE (90W) on 8 ports 802.3at Type 2 PoE (30W) on 16 ports
5420F-16W-32P-4XE 5420F-16MW-32P-4XE	802.3bt Type 4 PoE (90W) on 16 ports 802.3at Type 2 PoE (30W) on 32 ports
5420M-24W-4YE 5420M-48W-4YE	802.3bt Type 4 PoE (90W)
5420M-16MW-32P-4YE	802.3bt Type 4 PoE (90W) on 16 ports 802.3at Type 2 PoE (30W) on 32 ports
5520-12MW-36W	802.3bt Type 4 PoE (90W)
5520-24W	802.3bt Type 4 PoE (90W)
5520-48W	802.3bt Type 4 PoE (90W)

The global configured detection type specifies the following versions of the IEEE standard to support. Standards are arranged from oldest (top) to newest (bottom).

Detection Type	Power Mode
802.3af	Normal
802.3af and legacy	Normal
802.3at	High
802.3at and legacy	High
802.3bt type 3	Normal
802.3bt type 4	Normal
802.3bt and legacy	Normal

By default, 802.3at (including legacy) is the POE PD detection type. In this high power mode, Class 4 PDs receive up to 32 watts of power.

Note

802.3at is backwards compatible with 802.3af. Therefore, both normal power and high power devices are supported in this mode.

802.3af (maximum 15.4 W) and 802.3at (maximum 25.5W) are the older standards.

Note

Changing from a newer IEEE standard to an older IEEE standard is permitted, however power delivery is interrupted during this operation, and all PoE devices are reset. There is no service interruption when changing from an older IEEE standard to a newer IEEE standard.

Power Usage Threshold

The power usage threshold is a chassis configurable percent of the total power available on the switch. When the POE power consumption exceeds this threshold, a log message is generated to warn such an event. When power consumption transitions below the threshold, an informational log message is logged. The default threshold is 80%.

Port Power Limit

Each PoE port has a configurable power limit. This configuration attribute limits the amount of power supplied on a particular port and varies across different hardware platforms. If a PD requires more than the configured limit, the device will not connect properly or is forced to run at a lower limit.

The following table lists the power limit for different hardware platforms:

Table 160: Power Limits

Platform	Power Limit
5320 Series	32 watts
5420 Series	32 watts: <ul style="list-style-type: none"> • 5420F-24P-4XE • 5420F-48P-4XE • 5420F-48P-4XL 98 watts: <ul style="list-style-type: none"> • 5420F-8W-16P-4XE • 5420F-16W-32P-4XE • 5420M-24W-4YE • 5420M-48W-4YE • 5420M-16MW-32P-4YE
5520 Series	98 watts

Port Power Priority

You can configure the power priority of each port by choosing low, high, or critical power priority settings.

The switch automatically drops low-priority ports when the power requirements exceed the available power budget. When the power requirements become lower than the switch power budget, the power returns to the dropped port. When several ports have the same priority and the power budget is exceeded, the ports with the highest interface number are dropped until the consumption is within the power budget.

The priority methods are:

1. Port configured PoE priority

- Low: (default) standard priority for standard devices
- High: higher priority than low for important devices
- Critical: highest priority for critical devices like wireless APs

2. Port number priority where the lower port numbers have a higher priority.

PD Classification

The PDs are classified during initial connection establishment as defined in IEEE 802.3 standards. The classification defines the amount of power a device is expected to consume.

Table 161: Classification Chart for Various Standards

Name	Standard	Class	Type	PSE Min Output Power (in W)	PD Min Input Power (in W)	Example of Supported PDs
PoE	IEEE 802.3af	0	1	15.4	12.95	Static surveillance camera, VoIP phones, wireless access points
		1	1	4	3.84	IP phones
		2	1	7	6.49	IP camera
		3	1	15.4	12.95	Wireless access points
PoE+	IEEE 802.3at	4	2	30	25.5	High power PD
PoE++	IEEE 802.3bt	5	3	45	40	Video conferencing equipment, multi-radio wireless access points
		6	3	60	51	
PoE++	IEEE 802.3bt	7	4	75	62	Laptops, flat screens
		8	4	90	73	

PoE/PoE+ Allocation Using LLDP

Power over Ethernet/Power over Ethernet Plus allocation using Link Layer Discovery Protocol (LLDP) supports Ethernet switches, which do not support hardware-level power negotiation. With this feature, these switches support IEEE-based PoE and play the role of power sourcing equipment (PSE).

The devices that are powered using PoE, such as IP Phone and Video Surveillance Cameras, are classified as Powered Devices (PD). The maximum allowed continuous output power per cable for each standard is:

- IEEE 802.3af: 15.4 W
- IEEE 802.3at: 25.5 W
- IEEE 802.3bt Type 3: 60 W
- IEEE 802.3bt Type 4: 90 W

The negotiation of actual power supply and demand between a PSE and a PD can be executed at either the physical layer or at the data link layer. After the link is established at the physical layer, the PSE can use the IEEE 802.1AB LLDP protocol to repeatedly query the PD to discover its power needs.

Communication using LLDP allows for a finer control of power allocation, making it possible for the PSE to dynamically supply the exact power levels needed by individual PDs, and globally for all PDs that are attached. Using LLDP is optional for the PSE, however, it is mandatory for a Type 2 PD that requires more than 12.95 watts of power.

Important

LLDP supports PoE discovery and power allocation because some switches do not support hardware-level power negotiation. This allows Type 2 PDs such as PTZ (pan-tilt-zoom) Video Surveillance Cameras to be fully functional when connected to one of these switches. This functionality is enabled by default and is not configurable.

Note

Some switches feature a hardware design that supports hardware-level detection. Therefore, they do not require LLDP.

Fast PoE and Perpetual PoE

Fast PoE minimizes the PoE controller recovery time in case of a power failure. With Fast PoE, the PoE controller initializes the moment the switch powers on, which results in a faster recovery period.

Perpetual PoE provides uninterrupted power to all connected devices during a switch reboot.

Important

- After you enable Fast PoE or Perpetual PoE or both, you must save the running configuration file.
- If Fast PoE or Perpetual PoE are enabled and you change global or port-specific PoE configuration, you must save the running configuration file.

PoE Ports in EDM

The front panel view of Enterprise Device Manager (EDM) provides additional information for Power over Ethernet (PoE) ports for switches that support PoE.

This additional information is in the form of a colored **P** that displays inside the graphical representation of the port. This colored P represents the current power aspect of the PoE port.

Table 162: Power Aspect color codes

Color	Description
Green	The port is currently delivering power.
Red	The power and detection mechanism for the port is disabled.
Orange	The power and detection mechanism for the port is enabled. The port is not currently delivering power.
White/Gray	The power and detection mechanism for the port is unknown.

Important

The data and power aspect coloring schemes are independent of each other. You can view the initial status for both data and power aspect for the port. To refresh the power status, right-click the unit, and then select **Refresh Port Tooltips** from the shortcut menu.

Power over Ethernet Configuration using CLI

This section provides details to configure PoE settings using CLI.

Important

- After you enable Fast PoE or Perpetual PoE or both, you must save the running configuration file.
- If Fast PoE or Perpetual PoE are enabled and you change any other global or port-specific PoE settings, you must resave the running configuration file.

Disabling PoE on a port

About This Task

Perform the following procedure to disable PoE on a port. The Ethernet connected device does not receive any power over Ethernet if you shutdown PoE on the port.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Disable PoE on the port:

```
poe poe-shutdown [port <portlist>]
```

<portlist> is the port on which you want to disable PoE. The default is enable.

What to Do Next

To return power to the port, enter `no poe-shutdown [port <portlist>]`.

Configure PoE Detection Type

Perform the following procedure to configure the PoE powered device (PD) detection type. You can enable either 802.3af and Legacy compliant PD detection methods, or 802.3at and Legacy compliant PD detection methods. The default detection type is 802.3at and legacy.

- 802.3af : normal power mode
- 802.3af and legacy
- 802.3at : high power mode
- 802.3at and legacy
- 802.3bt Type 3 : normal power mode
- 802.3bt Type 4 : normal power mode

802.3at is backwards compatible with 802.3af. Therefore, normal power and high power devices are supported in 802.3at.

**Important**

Changing from a newer IEEE standard to an older IEEE standard is permitted, however power delivery is interrupted during this operation, and all PoE devices are reset. There is no service interruption when changing from an older IEEE standard to a newer IEEE standard.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure PoE detection type:

```
poe poe-pd-detect-type {802dot3af | 802dot3af_and_legacy | 802dot3at |
802dot3at_and_legacy | 802dot3bt_type3 | 802dot3bt_type4}
```

Variable Definitions

The following table defines parameters for the **poe-pd-detect-type** command.

Variable	Value
{802dot3af 802dot3af_and_legacy 802dot3at 802dot3at_and_legacy 802dot3bt_type3 802dot3bt_type4}	<p>Configures the detection type to one of the following values:</p> <ul style="list-style-type: none"> • 802dot3af: Set PD detection mode in 802.3af • 802dot3af_and_legacy: Set PD detection mode in 802.3af and legacy • 802dot3at: Set PD detection mode in 802.3at • 802dot3at_and_legacy: Set PD detection mode in 802.3at and legacy • 802dot3bt_type3: Set PD detection mode in 802dot3bt Type3 • 802dot3bt_type4: Set PD detection mode in 802dot3bt Type4

Configuring PoE Power Usage Threshold

About This Task

Perform the following procedure to configure the PoE power usage threshold limit globally as a percentage on the switch. The switch logs a warning message when a PoE PD power usage exceeds the configured threshold. The switch logs an informational message when a PoE PD power usage is below the configured threshold.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure the power usage threshold:

```
poe poe-power-usage-threshold <1-99>.
```

Variable Definitions

The following table defines parameters for the **poe-power-usage-threshold** command.

Variable	Value
<1-99>	Specifies the PoE usage threshold in the range of 1–99 percent.

Configure Power Limits for Channels

About This Task

Perform the following procedure to configure the PoE power limit for specific ports or channels. You can limit the PoE wattage available from an individual port or list of ports.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure PoE channel limits:

```
poe poe-limit [port <portlist>] <power_limit>
```

Variable definitions

The following table defines parameters for the **poe-limit** command.

Variable	Value
<i><portlist></i>	Identifies the ports on which the limit is set.
<i><power_limit></i>	Specifies the configurable power limit, in watts on a particular port. To see the available range for the switch, use the CLI Help.

Configuring Port Power Priority

About This Task

Perform the following procedure to configure the PoE power priority for a port or list of ports. You can configure the PoE power priority of ports to manage availability of the connected PDs. If the switch needs to shut down PDs because PoE exceeds the power limit threshold, low priority devices are shut down before high priority, and high priority are shut down before critical.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure port power priority:

```
poe poe-priority [port <portlist>] {critical| high| low}
```

Variable Definitions

The following table defines parameters for the **poe-priority** command.

Variable	Value
<i><portlist></i>	Identifies the ports to set priority for.
<i>{low high critical}</i>	Identifies the PoE priority.

Enable Fast PoE Globally

About This Task

Perform this procedure to enable Fast PoE on the switch. After you enable Fast PoE, you must save the running configuration file.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable Fast PoE:

```
poe fast-poe-enable
```

3. Save the configuration file:

```
save config
```

Enable Perpetual PoE Globally

About This Task

Perform this procedure to enable Perpetual PoE on the switch. After you enable Perpetual PoE, you must save the running configuration file.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable Perpetual PoE:

```
poe perpetual-poe-enable
```
3. Save the configuration file:

```
save config
```

Enable Fast PoE on a Port

About This Task

Perform this procedure to enable Fast PoE on a specific copper port of the switch. After you enable Fast PoE, you must save the running configuration file.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
```

```
[,...]}
```
2. Enable Fast PoE on the copper port:

```
poe fast-poe-enable [port {slot/port[/sub-port] [-slot/port[/sub-port]]
```

```
[,...]}
```
3. Save the configuration file:

```
save config
```

Variable Definitions

The following table defines parameters for the **fast-poe-enable** command.

Variable	Value
<code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Specifies the port or ports to be configured.

Enable Perpetual PoE on a Port

About This Task

Perform this procedure to enable Perpetual PoE on a specific copper port of the switch. After you enable Perpetual PoE, you must save the running configuration file.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable

configure terminal

interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```
2. Enable Fast PoE on the copper port:

```
poe perpetual-poe-enable [port {slot/port[/sub-port] [-slot/port[/sub-
port]] [,...]}]
```
3. Save the configuration file:

```
save config
```

Variable Definitions

The following table defines parameters for the **fast-poe-enable** command.

Variable	Value
<code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Specifies the port or ports to be configured.

Display Global PoE Configuration

About This Task

Perform the following procedure to display the global PoE configuration. You can view the global PoE status, power consumption, power limit threshold, and more.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. View the global configuration:

```
show poe-main-status
```

Example

```
Switch:1#show poe-main-status
=====
                        PoE Main Status - Stand-alone
=====
Available DTE Power      : 1855 Watts
DTE Power Status         : NORMAL
DTE Power Consumption    : 92 Watts
DTE Power Usage Threshold : 80
PD Detect Type           : 802.3at and Legacy
Power Source Present     : AC Only
Primary Power Status     : Present and operational
Redundant Power Status   : Present and Operational
Fast POE Status          : Enabled
```

```
Perpetual POE Status      : Enabled
POE Firmware Version:    : 3.0.0.6
```

Displaying PoE Port Status

About This Task

Perform the following procedure to display the PoE status for each port. You can use this information to view the status, classification, watts, and priority for each PoE port.

Procedure

1. Enter Privileged EXEC mode:
enable
2. View the port status:
show poe-port-status

Example

```
Switch:1#show poe-port-status
=====
                        POE Port Status
=====
      ADMIN  CURRENT          LIMIT          FAST PERPETUAL
PORT  STATUS  STATUS          CLASSIFICATION (Watts) PRIORITY POE      POE
-----
Port mgmt does not support DTE power
-----
1/1   Enable  DeliveringPower Class0          98      Low    Disable  Disable
1/2   Enable  DeliveringPower Class0          98      Low    Disable  Disable
1/3   Enable  DeliveringPower Class0          98      High   Disable  Disable
1/4   Enable  Searching        Class0          98      Low    Disable  Disable
1/5   Enable  Searching        Class0          98      Low    Disable  Disable
1/6   Enable  Searching        Class0          98      Low    Disable  Disable
1/7   Enable  Searching        Class0          98      Low    Disable  Disable
1/8   Enable  Searching        Class0          98      Low    Disable  Disable
1/9   Enable  Searching        Class0          98      Low    Disable  Disable
1/10  Enable  Searching        Class0          98      Low    Disable  Disable
```

Note

The PoE status of all ports is displayed. The preceding output is a sample of the full output.

Displaying Port Power Measurement

About This Task

Perform the following procedure to display the PoE power measurement. You can view the voltage, amperage, and wattage for every PoE port. PoE ports without a PD in use are measured as zeros.

Procedure

1. Enter Privileged EXEC mode:
enable
2. View measurement information:
show poe-power-measurement

Example

```
Switch:1#show poe-power-measurement
=====
                                POE Port Measurement
=====
PORT  Volt (V)  CURRENT (mA)  POWER(Watt)
-----
1/1   34.0      117           6.200
1/2   34.0      94            5.000
1/3   34.0      535           28.500
1/4   0.0       0             0.000
1/5   0.0       0             0.000
1/6   34.0      525           27.900
1/7   34.0      152           8.100
1/8   34.0      49            2.600
```

**Note**

The PoE port measurement for all ports is displayed. The preceding output is a sample of the full output.

Power over Ethernet configuration using EDM

This section provides details to configure PoE settings using EDM.

Configure PoE Globally

About This Task

Configure PoE usage threshold and device type settings, and enable Fast PoE and Perpetual PoE globally on a switch.

**Important**

- After you enable Fast PoE or Perpetual PoE or both, you must save the running configuration file.
- If Fast PoE or Perpetual PoE are enabled and you change any other global or port-specific PoE settings, you must resave the running configuration file.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Chassis**.
3. Select the **PoE** tab.
4. Configure the fields as required.
5. Select **Apply**.

PoE Field Descriptions

Use the data in the following table to use the **PoE** tab.

Name	Description
Power(watts)	Specifies the nominal power of the Power Sourcing Entity expressed in Watts.
OperStatus	Specifies the operational status of the main Power Sourcing Entity.
ConsumptionPower(watts)	Specifies the measured usage power expressed in Watts.
UsageThreshold%	Configures the usage threshold in percent for comparing the measured power and initiating an alarm if the threshold is exceeded.
PoweredDeviceDetectType	Configures the mechanism used to detect powered ethernet devices attached to a powered ethernet port. The options are: <ul style="list-style-type: none"> • 802.3af • 802.3afAndLegacySupport • 802.3at • 802.3atAndLegacySupport • 802.3bt Type 3 • 802.3bt Type 4
PowerPresent	Specifies the current power source present on the switch. Available power sources are AC and DC. A value of acOnly indicates that the only power supply is AC. A value of dcOnly indicates that the only power supply is DC. A value of acDc indicates that the two power supplies, AC and DC are supplying power.
FastPoeEnable	Enables Fast PoE on the switch. The default is disabled.
PerpetualPoeEnable	Enables Perpetual PoE on the switch. The default is disabled.

Configure PoE on Ports

About This Task

Enable or disable PoE on a port, and configure PoE priority and power limit settings.

**Important**

If Fast PoE or Perpetual PoE are enabled and you change any other global or port-specific PoE settings, you must resave the running configuration file.

Procedure

1. In the Device Physical View, select one or more ports that support PoE. For information about which ports support PoE, see your hardware documentation.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **PoE** tab.
5. Configure the fields as required.
6. Click **Apply**.

PoE Field Descriptions

Use the data in the following table to use the **PoE** tab.

Name	Description
AdminEnable	Enabled or disables PoE on this port.
FastPoeEnable	Enables or disables Fast PoE on this port. The default is disabled.
PerpetualPoeEnable	Enables or disables Perpetual PoE on this port. The default is disabled.
DetectionStatus	Specifies the operational status of the power device detecting mode on this port: <ul style="list-style-type: none"> • Disabled—detecting function disabled • Searching—detecting function is enabled and the system is searching for a valid powered device on this port • DeliveringPower—detection found a valid powered device and the port is delivering power • Fault (OtherFault)—a power-specific fault has been detected on the port • Test—detecting device is in test mode
PowerClassifications	Specifies the power classification of the device connected to this port. Power classification tags different terminals on the Power over LAN network according to their power consumption. Devices such as IP telephones, WLAN access points, and others can be classified according to their power requirements.
PowerPriority	Configures the power priority for this port: <ul style="list-style-type: none"> • critical • high • low
PowerLimit(Watts)	Configures the maximum power that the switch can supply to a port.
Voltage(volts)	Specifies the power measured in volts.
Current(amps)	Specifies the power measured in amps.
Power(Watts)	Specifies the power measured in watts.

Power Savings

[Energy Saver](#) on page 2251

[Energy Efficient Ethernet](#) on page 2253

[Power Savings Configuration Using CLI](#) on page 2253

[Power Savings Configuration Using EDM](#) on page 2262

Power savings allow you to reduce network infrastructure power consumption during periods of low data activity without impacting network connectivity.

Depending on the power saving option you choose, you can implement power savings on a switch-wide, or on a per-port basis. The following power saving options are supported:

- Energy Saver (switch-wide or per-port)
- Energy Efficient Ethernet (EEE) (per-port only)

You must choose either Energy Saver, or Energy Efficient Ethernet (EEE)—you cannot use both options together.

The following sections describe the Energy Saver and Energy Efficient Ethernet (EEE) features, and how to configure them.

Energy Saver

Table 163: Energy Saver product support

Feature	Product	Release introduced
Energy Saver	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4 Switch models: 5420F-24T-4XE, 5420F-24P-4XE, 5420F-48T-4XE, 5420F-48P-4XE, 5420F-48P-4XL, 5420F-8W-16P-4XE, 5420F-16W-32P-4XE, 5420F-16MW-32P-4XE, 5420M-24W-4YE, 5420M-48W-4YE, 5420M-24T-4YE, 5420M-48T-4YE, 5420M-16MW-32P-4YE
	5520 Series	VOSS 8.2.5 All fixed ports on 5520-24T, 5520-24W, 5520-48T, 5520-48W, and 5520-12MW-36W

To reduce direct power consumption by up to 40%, Energy Saver uses intelligent-switching capacity reduction in off-peak mode by controlling port link speeds and optionally powering off low priority PoE devices during off-peak periods. You can schedule Energy Saver to activate during multiple specific time periods. These time periods can be as short as one minute, or can last a week, a weekend, or individual days.

Note

- Energy Saver is supported only on copper ports that have auto-negotiation enabled on them.
- If auto-negotiation is disabled on a port and a custom port speed is configured, Energy Saver will not change the speed of that port.

**Important**

- Configuring the port link speed to a low value impacts the overall network performance. The best practice is to use the Energy Saver feature during the hours when the network is not overburdened.
- If a switch is reset while Energy Saver is activated, the PoE power-saving calculation might not accurately reflect the power saving, and in some cases might display zero savings. This problem occurs because the switch did not have sufficient time to record PoE usage between the reset of the switch and the reactivation of Energy Saver. When Energy Saver is next activated, the PoE power saving calculation is correctly updated.
- When Energy Saver is active and you replace a unit, that unit will not be in Energy Saver mode. You must configure Energy Saver directly after replacing a unit.

Interaction with PoE

Energy Saver can use Power over Ethernet (PoE) port-power priority levels to shut down low-priority PoE ports and provide power savings. The power consumption savings of each switch is determined by the number of ports with Energy Saver enabled, and by the power consumption of PoE ports that are powered off. If Energy Saver is disabled on a port, the port is not powered off, irrespective of the PoE configuration. Energy Saver turns off the power to a port only when PoE is enabled globally, the port Energy Saver is enabled, and the PoE priority for the port is configured to Low.

Configuration Fundamentals

To fully configure and use Energy Saver, you must first enable Energy Saver on ports, create a schedule, and then enable Energy Saver globally.

Alternatively, you can configure Energy Saver using the Efficiency Mode quick configuration method, which enables Energy Saver on all ports, creates a default schedule, and enables Energy Saver globally.

You can manually deactivate and reactivate Energy Saver at any time, without affecting the port configurations.

**Note**

- Energy Saver is supported only on copper ports that have auto-negotiation enabled.
- Network Time Protocol (NTP) must be enabled and configured to use Energy Saver.

Energy Efficient Ethernet

Table 164: Energy Efficient Ethernet product support

Feature	Product	Release introduced
Energy Efficient Ethernet (EEE)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4 All fixed ports on 5420F-24T-4XE, 5420F-24P-4XE, 5420F-48T-4XE, 5420F-48P-4XE, 5420F-48P-4XL, 5420F-8W-16P-4XE, 5420F-16MW-32P-4XE, 5420M-24W-4YE, 5420M-48W-4YE, 5420M-24T-4YE, 5420M-48T-4YE, 5420M-16MW-32P-4YE
	5520 Series	VOSS 8.2.5 All fixed ports on 5520-24T, 5520-24W, 5520-48T, 5520-48W, and 5520-12MW-36W

Energy Efficient Ethernet (EEE) supports the IEEE 802.3az standard for power savings in Ethernet networks for a select group of physical layer devices. A physical device that can support low power idle (LPI) mode is considered EEE-capable. Legacy devices that do not support EEE can be made EEE-compliant with an EEE-compliant PHY and an SDK version that allows the MAC device to interact with the PHY EEE functionality.

In a typical configuration, the EEE protocol communicates with the switch and the physical device to determine when to enter LPI mode during a period of inactivity, and to exit LPI mode when data transmission resumes.

Note

EEE is supported only on copper ports that have auto-negotiation enabled on them.

Power Savings Configuration Using CLI

Configure Energy Saver or Energy Efficient Ethernet using the command line interface (CLI).

Enable Energy Saver on Ports

About This Task

Perform this procedure to enable Energy Saver on a specific port or range of ports.

Before You Begin

- If you have previously enabled Energy Saver globally, you must disable it globally before enabling Energy Saver on individual ports.
- If you have previously enabled Efficiency Mode, you must disable it before enabling Energy Saver on individual ports.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable Energy Saver on the specified port:

Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port).

```
energy-saver port {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} enable
```

Example

Enable energy savings on slot 1 port 2:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface GigabitEthernet 1/2
Switch:1(config-if)#energy-saver port 1/2 enable
```

What to Do Next

Configure an Energy Saver schedule.

Variable Definitions

The following table defines parameters for the **energy-saver** command.

Variable	Value
<i>enable</i>	Enables energy savings on ports. The default is disabled.
<i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Create an Energy Saver Schedule

About This Task

Perform this procedure to configure scheduled time intervals during which the switch will operate in low power state. This time interval can be for a week, weekend, or individual days.

Note

You can configure a maximum of 84 entries in the Energy Saver schedule.

Before You Begin

- If you have previously enabled Energy Saver globally, you must disable it globally before creating a schedule.
- If you have previously enabled Efficiency Mode, you must disable it before creating a schedule. You cannot change the default Efficiency Mode schedule entries when Efficiency Mode is enabled.
- You must enable Energy Saver on every port affected by the schedule.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the Energy Saver schedule:

```
energy-saver schedule {friday | monday | saturday | sunday | thursday  
| tuesday | wednesday | weekday | weekend} <hhmm> {activate |  
deactivate}
```

Example

Configure an Energy Saver schedule:

```
Switch:1>enable  
Switch:1# configure terminal  
Switch:1(config)#energy-saver schedule weekend 0735 activate  
Switch:1(config)#energy-saver schedule monday 0600 deactivate
```

What to Do Next

Enable Energy Saver globally.

Variable Definitions

The following table defines parameters for the **energy-saver schedule** command.

Variable	Value
<code>{activate deactivate}</code>	Activates or deactivates the scheduled event.
<code><hhmm></code>	Specifies the hour and minutes to enable Energy Saver feature on the switch.
<code>{friday monday saturday sunday thursday tuesday wednesday weekday weekend}</code>	Specifies the day(s) to enable Energy Saver feature on the switch.

Enable Energy Saver Globally

About This Task

Perform this procedure to enable Energy Saver globally on the switch. You can optionally configure PoE power savings, to power off low priority PoE devices during off-peak times.

Before You Begin

- You must enable Energy Saver on individual ports.
- You must create an Energy Saver schedule.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. (Optional) Configure PoE power savings:

```
energy-saver poe-power-saving
```

Note

You must configure PoE power savings before you enable Energy Saver globally.

3. Enable Energy Saver:

```
energy-saver enable
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#energy-saver poe-power-saving
Switch:1(config)#energy-saver enable
```

Variable Definitions

The following table defines parameters for the **energy-saver** command.

Variable	Value
<i>enable</i>	Enables Energy Saver feature. The default is disabled.
<i>poe-power-saving</i>	Enables PoE power saving. The default is disabled.

Enable and Configure Energy Saver using Quick Configuration

About This Task

Perform this procedure to enable and configure Energy Saver globally using the quick configuration Efficiency Mode. Efficiency Mode automatically configures the following:

- enables Energy Saver on all ports.
- creates a default schedule with a weekday schedule of Energy Saver activated from 6:00 p.m. to 7:30 a.m., and during weekends. You cannot change this default schedule while Efficiency Mode is enabled.
- enables Energy Saver globally.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable efficiency mode:

```
energy-saver efficiency-mode
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#energy-saver efficiency-mode
```

Variable Definitions

The following table defines parameters for the **energy-saver** command.

Variable	Value
<i>efficiency-mode</i>	Enables efficiency mode. The default is disabled.

Activate or Deactivate Energy Saver Manually

About This Task

Perform this procedure to activate or deactivate Energy Saver on the switch at any time. Energy Saver is deactivated by default.

Activating Energy Saver reduces the port speed to the minimum value supported by the switch and enables PoE power saving, even if PoE is globally disabled. Deactivating Energy Saver restores the previous configuration.

Before You Begin

Before you can change any previously saved Energy Saver settings, you must disable Energy Saver globally.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Activate or deactivate Energy Saver:
energy-saver {activate | deactivate}

Example

```
Switch:1> enable
```

Activate Energy Saver:

```
Switch:1# energy-saver activate
```

Deactivate Energy Saver:

```
Switch:1# energy-saver deactivate
```

Variable Definitions

The following table defines parameters for the **energy-saver** command.

Variable	Value
<i>activate</i>	Activates Energy Saver manually.
<i>deactivate</i>	Deactivates Energy Saver manually.

Energy Saver Show Commands

Use the procedures in this section to display specific information about Energy Saver configuration on the switch.

Display Energy Saver Global Information

About This Task

Perform this procedure to display information about Energy Saver global configuration.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display global configuration:
show energy-saver global

Example

```
Switch:1#show energy-saver global
Energy Saver:                               Disabled
Energy Saver PoE Power Saving Mode:         Disabled
Energy Saver Efficiency-Mode Mode:         Disabled
Day/Time:                                    Wednesday 02:31:12
Current Energy Saver state:                 Energy Saver is Inactive
```

*Display Energy Saver Interface Information***About This Task**

Perform this procedure to display information about Energy Saver configuration on the ports.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Display information about all ports or specify a particular port:

```
show energy-saver interface [{slot/port[/sub-port] [-slot/port[/sub-
port]] [,...]]
```

Example

```
Switch:1>enable
Switch:1#show energy-saver interface
Port ES State PoE Savings PoE Priority
-----
1/1      Enabled  Enabled  Low
1/2      Enabled  Enabled  Low
1/3      Enabled  Enabled  Low
1/4      Enabled  Enabled  Low
1/5      Enabled  Enabled  Low
1/6      Enabled  Enabled  Low
1/7      Enabled  Enabled  Low
1/8      Enabled  Enabled  Low
1/9      Enabled  Enabled  Low
1/10     Enabled  Enabled  Low
1/11     Enabled  Enabled  Low
1/12     Enabled  Enabled  Low
1/13     Disabled N/A      N/A
1/14     Disabled N/A      N/A
1/15     Disabled N/A      N/A
```

*Display Energy Saver Power Savings Information***About This Task**

Perform this procedure to display information about Energy Saver power savings on the switch.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Display information about energy savings:

```
show energy-saver savings
```

Example

```
Switch:1#show energy-saver savings
-----
Unit Model          Switch Capacity      Saving PoE Saving
-----
8404C                0.0 watts            N/A
=====
```

*Display Energy Saver Schedule Information***About This Task**

Perform this procedure to display information about Energy Saver schedules configured on the switch.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display information about Energy Saver schedules:
show energy-saver schedule

Example

```
Switch:1#show energy-saver schedule
-----
Day      Time  Action
-----
Monday   18:00 Activate
Monday   07:00 Deactivate
```

Enable Energy Efficient Ethernet (EEE)**About This Task**

Perform this procedure to enable Energy Efficient Ethernet (EEE) on a port. The default is disabled.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:
enable

configure terminal

interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable Energy Efficient Ethernet:
energy-saver eee enable

Display Energy Efficient Ethernet (EEE) Statistics

About This Task

Perform this procedure to display information about Energy Efficient Ethernet (EEE) statistics for all ports on a switch, or for a specific port.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about all ports or specify a particular port:

```
show energy-saver eee statistics [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]
```

Example

```
Switch:1>show energy-saver eee statistics
```

EEE Port Status					
PortId	EEE Status	Tx LPI Events	Tx Idle Duration (micro seconds)	Rx LPI Events	Rx Idle Duration (micro seconds)
1/1	enabled	847	963657920	115	965100020

Variable Definitions

Use the data in following table to use the `show energy-saver eee statistics` command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Clear Energy Efficient Ethernet (EEE) Statistics

About This Task

Perform this procedure to clear information about Energy Efficient Ethernet (EEE) statistics for all ports on a switch, or for a specific port.

Procedure

1. Enter Privileged EXEC mode:
2. Clear Energy Efficient Ethernet statistics on all ports or specify a particular port:

```
enable
clear energy-saver eee stats [port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]
```

Variable Definitions

Use the data in following table to use the `clear energy-saver eee stats` command.

Variable	Value
<code>port</code>	Specifies one or more ports.
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Power Savings Configuration Using EDM

Use the following procedures to configure either Energy Saver or Energy Efficient Ethernet EEE using Enterprise Device Manager (EDM).

Enable Energy Saver Globally

About This Task

Perform this procedure to enable Energy Saver globally.

Procedure

1. In the navigation pane, expand **Configuration > Power Management**.
2. Click **Energy Saver**.
3. Click the **Energy Saver Globals** tab.
4. Configure the fields as required.
5. Click **Apply**.

Energy Saver Globals Field Descriptions

Name	Description
EnergySaverEnabled	Enables Energy Saver globally on the switch. The default is disabled.
PoePowerSavingEnabled	Enables Energy Saver PoE power saving. The default is disabled.
EfficiencyModeEnabled	Enables Energy Saver efficiency mode. The default is disabled. Efficiency mode enables Energy Saver globally and on all ports, it also enables PoE power saving. It also creates a weekday schedule that starts at 6:00 p.m. and ends at 7:30 a.m., and during the weekend Energy Saver is always activated.
EnergySaverActive	Activates Energy Saver on the switch. Energy Saver is deactivated by default.

Configure Energy Saver Schedule

About This Task

Perform this procedure to configure a scheduled time interval during which the switch will operate in low power state. This time interval can be for a week, weekend, or individual days.

Note

- You can configure maximum 84 entries in the Energy Saver schedule.
- If efficiency mode is enabled, you cannot configure any other entries in the Energy Saver schedule.

Before You Begin

- You must disable Energy Saver globally.
- You must enable Energy Saver on every port affected by the schedule.
- You must deactivate Energy Saver efficiency-mode.

Procedure

1. In the navigation pane, expand **Configuration > Power Management**.
2. Click **Energy Saver**.
3. Click the **Energy Saver Schedules** tab.
4. Click **Insert**.
5. Configure the fields as required.
6. Click **Insert**.
7. Click **Apply**.

Energy Saver Schedules Field Descriptions

Name	Description
ScheduleDay	Specifies the day on which Energy Saver is activated or deactivated. The options are: <ul style="list-style-type: none"> • monday • tuesday • wednesday • thursday • friday • saturday • sunday • weekdays • weekend
ScheduleHour	Specifies the hour at which Energy Saver is activated or deactivated. The range is 0 to 23. Note: 0 is equivalent to 12 a.m., and 12 is equivalent to 12 p.m.

Name	Description
ScheduleMinute	Specifies the minute at which Energy Saver is activated or deactivated. The range is 0 to 59.
ScheduleAction	Specifies if Energy Saver is activated or deactivated. The options are: <ul style="list-style-type: none"> • activate • deactivate

Enable Energy Saver or EEE on Ports

You can enable Energy Saver or EEE using the Energy Saver tab accessed by the Edit navigation path, or the Power Management navigation path. Use one of the following procedures to enable either Energy Saver or EEE on ports.

Enable Energy Saver or EEE on Ports

About This Task

Perform this procedure to enable Energy Saver or EEE on one or more ports.

Procedure

1. On the Device Physical View tab, select one or more ports.
2. In the navigation pane, expand **Edit > Port**.
3. Select **General**.
4. Select the **Energy Saver** tab.
5. Enable either Energy Saver or EEE:
 - To enable Energy Saver, select **EnergySaverEnabled**.
 - To enable EEE, select **EnergySaverEEEEnable**.
6. Select **Apply**.

Energy Saver Field Descriptions

Use the data in the following table to use the **Energy Saver** tab.

Name	Description
Port	Specifies the port number.
EnergySaverEnabled	Configures whether Energy Saver is enabled on the specific port.
EnergySavedPoeStatus	Specifies the Energy Saver PoE status for the specific port.
EnergySaverEEEEnable	Configures whether EEE is enabled on the specific port.

Enable Energy Saver or EEE on Ports

About This Task

Perform this procedure to enable Energy Saver or EEE on one or more ports.

Procedure

1. In the navigation pane, expand **Configuration > Power Management**.
2. Select **Energy Saver**.
3. Select the **Ports** tab.
4. Enable either Energy Saver or EEE:
 - To enable Energy Saver, in the **EnergySaverEnabled** column, double-click the field associated with the specific ports, and then select **true**.
 - To enable EEE, in the **EnergySaverEEEEEnable** column, double-click the field associated with the specific ports, and then select **true**.
5. Select **Apply**.

Energy Saver Field Descriptions

Use the data in the following table to use the **Energy Saver** tab.

Name	Description
Port	Specifies the port number.
EnergySaverEnabled	Configures whether Energy Saver is enabled on the specific port.
EnergySaverPoEStatus	Specifies Energy Saver PoE status for the specific port.
EnergySaverEEEEEnable	Configures whether EEE is enabled on the specific port.

View Energy Savings

About This Task

Perform this procedure to view the amount of switch capacity and PoE power being saved on the units.

Procedure

1. In the navigation pane, expand **Configuration > Power Management**.
2. Click **Energy Saver**.
3. Click the **Energy Savings** tab.

Energy Savings field descriptions

Name	Description
UnitIndex	Specifies the unit number.
UnitSavings(1/10 watts)	Specifies the amount of switch capacity power being saved on the specific unit.
PoeSavings(1/10 watts)	Specifies the amount of PoE power being saved on the specific unit.

Display Energy Efficient Ethernet Statistics

Perform this procedure to display information about Energy Efficient Ethernet (EEE) statistics for all ports on a switch, or for a specific port.

Procedure

1. In the navigation pane, expand **Configuration** > **Power Management**.
2. Select **Energy Saver**.
3. Select the **EEE Statistics** tab.
4. (Optional) Select **Clear Stats** to clear information about EEE statistics.

EEE Statistics Field Descriptions

The following table describes parameters on the **EEE Statistics** tab.

Name	Description
Port	Shows the port number.
State	Shows the state of Energy Efficient Ethernet (EEE) on the port.
TxEvents	Shows the EEE Tx event count for the port.
TxDuration	Shows the EEE Tx durations for the port.
RxEvents	Shows the EEE Rx event count for the port.
RxDuration	Shows the EEE Rx durations for the port.

Quality of Service

[QoS fundamentals on page 2267](#)

[Basic DiffServ configuration using CLI on page 2292](#)

[Basic DiffServ configuration using EDM on page 2297](#)

[QoS configuration using CLI on page 2299](#)

[QoS configuration using EDM on page 2313](#)

QoS fundamentals

Use the information in this section to help you understand Quality of Service (QoS).

This section describes a range of features that you can use on the switch to manage traffic flowing through your network. You can configure your network to prioritize specific types of traffic to ensure that the traffic receives the appropriate QoS level. For those cases where traffic levels are so high that congestion occurs despite management, the switch provides additional congestions handling features that are described in this section.

QoS refers to the ability to control network flows either by prioritizing traffic or by guaranteeing performance levels. QoS does not refer to a specifically achieved service quality. To provide QoS, you can use some combination of the switch's traffic management tools to help deliver provisioned network QoS. It is up to the network administrator to accurately analyze a given situation and select the proper tool(s) for the task.

Introduction to QoS

The switch comes with a set of traffic management tools that you can use to provide QoS for Layer 2 (bridged) or Layer 3 (routed) traffic flows. Many of these flows are multiplexed across a set of network switches and compete for network resources at convergence points. Without traffic management, the congested data flows compete for resources and the result is unpredictable. The resulting QoS can only be described as best-effort. The opposite is also true, without congestion there are sufficient network resources for all traffic to pass without competition. Without congestion, traffic management is not required. In this sense, you cannot separate discussions about QoS and traffic management from those on congestion. The switch provides a set of tools that you can use to provide network services that are far superior to best-effort thereby enabling the delivery of provisioned QoS.

To deliver QoS, the switch uses two types of traffic management tools:

- Congestion management
- Congestion handling

Congestion management acts to prevent congestion by prioritizing traffic flows through priority queuing and priority-aware servicing methods. Other functions, such as policing, are also considered congestion management. Policing indirectly prioritizes some traffic by limiting the rates of other traffic.

Congestion handling alleviates existing congestion by dropping lower priority traffic before higher priority traffic. The switch handles the congestion by queue-specific tail dropping. The basic QoS architecture of the switch identifies three primary functional areas:

- Ingress QoS identification and classification
- the switch's internals and queuing architecture
- QoS marking/remarking for downstream use

Important

Remarking packets with an ACL filter does not change the internal QoS level of the packets. You must add the **permit internal-qos [value]** statement to the ACL filter.

The QoS architecture is coherent end-to-end across a network. The QoS at any particular network element can be marked in the relevant Layer 2 or Layer 3 protocol fields and provided to the next hop. The receiving next hop can then use this information to classify its own ingress traffic, apply its specific internal traffic management features, and remark the results for subsequent hops.

Depending on the product, the QoS implementation on the switch can support the following options:

1. Ingress priority mappings including: DSCP to internal QoS, 802.1p-bits to internal QoS, and port-level QoS configuration.
2. Egress priority mappings including: internal QoS to DSCP and internal QoS to 802.1p-bits.
3. Port-based rate limiting or ingress policers
4. Port-based broadcast and multicast rate limiting
5. Port-based egress shaping
6. Egress queue rate limiting

For information about feature support, see [Fabric Engine Feature Support Matrix](#).

Traffic management

Prioritized traffic handling requires QoS classification first. The switch typically classifies traffic by using the endpoint switch configuration in conjunction with the protocol elements of the incoming frame such as *priority*. You can add additional classification by using access control lists (ACLs) and other filtering functionality.

The switch's internal traffic management functions use the results of classification to determine the prioritization of traffic. Examples of internal functions that prioritize traffic would be both strict and weighted round robin (WRR) queue scheduling. These mechanisms prioritize data by favorable scheduling or weighting.

The disposition of a particular data frame is not necessarily fully determined as a result of classification. You can apply additional traffic management functions such as Ingress Port Rate Limiting or Policing depending on your switch features. Ingress Port Rate Limiting is a congestion management mechanism to limit the traffic rate accepted by the specified ingress port. Policing is a congestion management method that limits incoming traffic at the ingress that could cause congestion at the egress. While queuing strategies affect prioritization by favoring some traffic; policing is essentially the opposite.

Policing works not by favoring some traffic, but by penalizing the bursty traffic. Queue scheduling and policing are only two of the available tools for congestion management. Additional details are presented in subsequent sections of this document.

In addition to the traffic management tools which aid in the prevention of congestion, tools are also provided to handle congestion as it occurs. Congestion handling tools monitor congestion levels at convergence points in the switch and selectively discard frames if congestion begins to increase. Per queue tail dropping is the primary congestion handling function of the switch. You can also use ACLs and filtering as congestion handling tools.

Differentiated Services (DiffServ)

Table 165: Differentiated Services product support

Feature	Product	Release introduced
Differentiated Services (DiffServ) including Per-Hop Behavior	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5

Differentiated Services (DiffServ) is a traffic management tool that classifies network traffic into eight traffic classes, and then gives each class differentiated treatment. DiffServ networks map the traffic's class into a set of packet forwarding behavior, referred to as a *Per-Hop Behavior (PHB)*. A PHB could specify which egress queue to use. For example, a switch may classify a packet by determining its protocol to be IPv4, subsequently extract the DSCP value, and apply a PHB by directing the packet to a specific queue. DiffServ does not prescribe a set of traffic classes and does not predetermine which types of traffic should be handled by a given class. DiffServ simply provides a generic means of classifying packets so they may be treated differently.

DiffServ applies to IP packets only.

DiffServ Access and DiffServ Core

A fundamental characteristic of DiffServ networks is the distinction made between switches at the network edges and those residing in the network interior. The switch refers to this distinction as DiffServ Access (edge) and DiffServ Core (interior), respectively.

It is important to note that the switch operates simultaneously as both a DiffServ Access switch and a DiffServ Core switch. The architectural premise is that the edge or access nodes perform the bulk of the work (classification, policing, etc.) and mark the packet for downstream processing. In theory this would permit the interior or core switches to bypass much of the edge processing as they would "trust" the classification and marking performed by the access switch. The notion of trust is key to the access/core switch distinction.

- If you configure a port as an access port, the system does not trust packet markings.
- If you configure a port as a core port, the system trusts packet markings.

On the access side, malicious users can send packets into a network with intent to cause serious harm (e.g., denial of service attacks). However, on core switches, the only traffic sources are one's own upstream switches. As such, a core switch has the opportunity to trust the classification, markings (and implied PHB) determined by the previous hop.

The following figure shows DiffServ network operations. The devices are on the network edge where they perform classification, marking, policing, and shaping functions.

Figure 197: DiffServ network core and edge devices

Use a DiffServ Access port at the edge of a DiffServ network. The access port classifies traffic according to port QoS. Outgoing packet DSCP and 802.1p values are derived from port QoS and QoS maps. The system strips Dot1Q headers at ingress, and adds them back at egress only if you configure the egress port as a tagged or trunk port.

A DiffServ Core port does not change packet classification or markings; the port trusts the incoming traffic markings. A core port preserves the DSCP marking of all incoming packets, and uses these markings to assign the packet to an internal QoS level. For tagged packets, the port honors the 802.1p bits within a Dot1Q header, and uses these bits to classify ingress traffic. You can control the honoring (or not) of 802.1p bits by configuring the 802.1p override.

Per-Hop Behavior (PHB)

Traffic entering the DiffServ network enter a queue according to their marking, which determines the PHB of the packets. For example, if the system marks a video stream to receive the highest priority, it enters a high-priority queue. As these packets traverse the DiffServ network, the system forwards the video stream before other packets.

As a standard, DiffServ is described in the context of Layer 3. Classification is accomplished by mapping a packet priority field from the packet and then applying a per-hop behavior. DiffServ standards define the IPv4 header's Differentiated Services Code Point (DSCP) field to determine classification and subsequent per-hop behavior.

The RFC2598 standard provides only the following four fundamental per-hop behaviors:

- Default (DF) — This PHB provides best-effort forwarding behavior.
- Expedited Forwarding (EF) — This PHB provides performance-critical forwarding.
- Assured Forwarding (AF) — This PHB classifies traffic based upon **class** (priority) only.

Important

The switch never classifies nor takes action based upon drop precedence. In response to congestion, the only drops available for a given traffic class are tail drops.

- Class Selector (CS) — This PHB provides a simple mapping of a DSCP to one of eight traffic classes. While the switch provides all four PHBs, the CS PHB is most analogous to the switch's internal processing – classification occurs to derive priority, which subsequently determine the per-hop behavior (e.g., queuing).

DiffServ and filters

QoS (DiffServ) and filters operate independently; you do not have to use filters to provide QoS. However, filters can override QoS operations. For more information, see [Traffic filtering fundamentals](#) on page 2956.

Traffic traversing the switch

The switch's traffic management capabilities are best understood by examining the functionality that is invoked as packets flow from ingress ports, through the switch, to egress ports. The following list includes the set of features and processing that the switch performs as flows traverse the switch:

- Classification and ingress mapping
- Filtering
- Rate Limiting or Policing
- Queueing
- Remarking
- Shaping

The switch classifies packets to determine their priority. While DiffServ is traditionally defined as Layer 3 functionality, the switch extends the logical concept to Layer 2. The switch can, based upon user configuration, determine a packet's priority from either its Layer 2 (p-bits) or Layer 3 (DSCP) information.

- If the packet arrives on an untrusted port (DiffServ Access), then the packet's priority comes from user-configured parameters such as port priority.
- If the packet arrives on a trusted port, priority comes from information contained in the packet's header (p-bits or DSCP).

After the switch determines the packet's configured or marked priority, it maps that value to be used internally. The QoS level used by the switch is referred to as the **Internal QoS Level (IQL)**. The IQL is the internal numerical value that the switch uses to determine the packets per-hop behaviors such as queue selection and bandwidth guarantee.

The following list identifies the order of DiffServ operations for a packet:

- Packet classification: IEEE 802.1p and DSCP markings classify (map) the packet to its appropriate PHB and QoS level.
- Remarking: The switch can remark packets according to QoS actions you configure on the switch (internal QoS mappings).
- Shaping: The switch provides port-based shaping. Port-based shaping shapes all outgoing traffic to a specific rate.

Classification and mapping

Traffic classification includes functions that examine a packet to determine further actions according to defined rules. Classification involves identifying flows so that the router can modify the packet contents or Per-Hop Behavior (PHB), apply conditioning treatments to the packet, and determine how to forward the packet to the egress interface. Packet classification depends on the service type of the packet and the point in the traffic management process where the classification occurs.

The device classifies traffic as it enters the DiffServ network, and assigns appropriate PHB based on the classification. To differentiate between classes of service, the device marks the DiffServ (DS) parameter in the IP packet header, as defined in RFC2474 and RFC2475. The DSCP marking defines the forwarding treatment of the packet at each network hop. This marking (or classification) occurs at the edge of the DiffServ domain, and is based on the policy (or filter) associated with the particular microflow or aggregate flow.

You can configure the mapping of DSCP-to-forwarding behaviors and DSCP re-markings. Re-marking the DSCP resets the treatment of packets based on new network specifications or desired levels of service.

Layer 3 marking uses the DSCP parameter. Layer 2 (Ethernet) marking involves the 802.1p-bits parameter.

For Layer 2 packets, priority bits (or 802.1p bits) define the traffic priority of the Ethernet packet. You can configure an interface to map DSCP or 802.1p bits to internal QoS levels on ingress. You can configure an interface to map internal QoS levels to DSCP or 802.1p bits at egress. 802.1p bit mapping provides the Ethernet VLAN QoS requirements.

Within the network, a packet PHB associated with the DSCP determines how a device forwards the packet to the next hop—if at all. Consequently, nodes can allocate buffer and bandwidth resources to each competing traffic stream. The initial DSCP value is based on network policies for the type of service required. The objective of DSCP-to-Service Class mapping is to translate the QoS characteristics defined by the packet DSCP marker to a Service Class. The DSCP-to-Service Class mapping occurs at ingress. For each received packet, the mapping function assigns a Service Class.

The switch maintains four mapping tables. These tables translate the ingress 802.1p-bits or DSCP markings to an internal QoS level, and then retranslate the internal QoS level to an egress DSCP or 802.1p-bits marking as follows:

- ingress 802.1p-bits to QoS level
- ingress DSCP to QoS level
- QoS level to egress 802.1p-bits
- QoS level to egress DSCP

Service classes

Service classes define a standard architecture to provide end-to-end QoS on a broad range of Ethernet switching and voice products. They function as default QoS policies built into the product. They incorporate the various QoS technologies to provide a complete end-to-end QoS behavioral treatment. The switch includes a built-in QoS implementation for service classes.

The switch includes eight preconfigured queues (corresponding to the eight service classes) on each port of an interface module.

A service class domain classifies traffic as one of the following:

- Network control traffic (Critical/Network)
- Subscriber traffic (Premium, Metal, or Standard)

Queue 7 — Critical/Network Service Class (PHB of CS6/CS7)

The switch uses the Critical/Network Service Class for traffic within a single administrative network domain. If such traffic does not get through, the network cannot function.

Queue 6 — Premium Service Class (PHB of CS5/EF)

The switch uses the Premium Service Class for IP telephony services, and provides the low latency and low jitter required to support such services. IP telephony services include Voice over IP (VoIP), voice signaling, Fax over IP (FoIP), and voice-band data services over IP (for example, analog modem). The switch can also use the Premium Service Class for Circuit Emulation Services over IP (CESoIP).

Metal Service Classes

The Platinum, Gold, Silver, and Bronze Service Classes are collectively referred to as the metal classes. The metal Service Classes provide a minimum bandwidth guarantee and are for variable bit rate or bursty types of traffic. Applications that use the metal Service Class support mechanisms that dynamically adjust their transmit rate and burst size based on congestion (packet loss) detected in the network. The following list describes the individual metal classes:

- Queue 5 — Platinum Service Class (PHB of CS4/AF41)

The switch uses the Platinum Service Class for applications that require low latency, for example, real-time services such as video conferencing and interactive gaming. Platinum Service Class traffic provides the low latency required for interhuman (interactive) communications. The Platinum Service Class provides a minimum bandwidth assurance for Assured Forwarding (AF) 41 and Class Selector (CS) 4-marked flows.

- Queue 4 — Gold Service Class (PHB of CS3/AF31)

The switch uses the Gold Service Class for applications that require near-real-time service and are not as delay-sensitive as applications that use the Platinum service. Such applications include streaming audio and video, video on demand, and surveillance video.

The Gold Service Class assumes that traffic buffers at the source and destination and, therefore, the traffic is less sensitive to delay and jitter. By default, the Gold Service Class provides a minimum bandwidth assurance for AF31, AF32, AF33 and CS3-marked flows.

- Queue 3— Silver Service Class (PHB of CS2/AF21)

The switch uses the Silver Service Class for responsive (typically client- and server-based) applications. Such applications include Systems Network Architecture (SNA) terminals (for example, a PC or Automatic Teller Machine) to mainframe (host) transactions that use Data Link Switching (SNA over IP), Telnet sessions, web-based ordering and credit card processing, financial wire transfers, and Enterprise Resource Planning applications.

Silver Service Class applications require a fast response and have asymmetrical bandwidth needs. The client sends a short message to the server and the server responds with a much larger data flow back to the client. For example, after a user clicks a hyperlink (that sends a few dozen bytes) on a webpage, a new webpage opens (that downloads kilobytes of data). The Silver Service Class provides a minimum bandwidth assurance for AF21 and CS2-marked flows.

The Silver Service Class favors short-lived, low-bandwidth TCP-based flows.

- Queue 2 — Bronze Service Class (PHB of CS1/AF11)

The switch uses the Bronze Service Class for longer-lived TCP-based flows, such as file transfers, e-mail, or noncritical Operation, Administration, and Maintenance (OAM) traffic. The Bronze Service Class provides a minimum bandwidth assurance for AF11 and CS1-marked flows. As a best practice, use the Bronze Service Class for noncritical OAM traffic with the CS1 DSCP marking.

Queue 1 and 0 — Standard (PHB of CS0/DF) and Custom Service Classes

The switch uses the Standard and Custom Service Classes for best-effort services. Delays, loss, or jitter guarantees for these service classes are not specified. However, the Standard Service Class has more forwarding resources than the custom service classes.

Internal QoS level

The internal QoS level or effective QoS level is a key element in the switch QoS architecture. The internal QoS level specifies the kind of treatment a packet receives. The switch classifies every packet that enters and assigns it an internal QoS level.

Internal QoS levels map to the queues on a port. For example, for an access port the internal QoS level is derived from the port QoS level. For Layer 3 trusted (core) ports, the system honors incoming DSCP or type of service (TOS) bits. The system assigns the internal QoS level using the ingress DSCP to QoS level map.

Important

Remarking packets with an ACL filter does not change the internal QoS level of the packets. You must add the **permit internal-qos [value]** statement to the ACL filter. For more information, see [Internal QoS Level and Remarking](#) on page 2969.

Ingress mappings

The system uses ingress maps to translate incoming packet QoS markings to the internal QoS level. The system uses the internal QoS level to classify packets.

Ingress mappings include

- 802.1p to (internal) QoS level
- DSCP to (internal) QoS level

The following logical table shows how the system performs ingress mappings for data packets and for control packets not destined for the Control Processor (CP).

Table 166: Data packet ingress mapping

DSCP	Layer 2 trusted	Layer 3 trusted (DiffServ enabled and Access-diffserv disabled)	IP packet	Routed packet	Ingress tagged	Internal QoS
x	No	x	No	x	x	Use port QoS
x	Yes	x	No	x	No	Use port QoS

Table 166: Data packet ingress mapping (continued)

DSCP	Layer 2 trusted	Layer 3 trusted (DiffServ enabled and Access-diffserv disabled)	IP packet	Routed packet	Ingress tagged	Internal QoS
x	Yes	x	No	x	Yes	Use ingress p-bits mapping
0x1B	x	x	Yes	x	x	4
0x23	x	x	Yes	x	x	5
0x29	x	x	Yes	x	x	5
0x2F	x	x	Yes	x	x	6
x	No	No	x	x	x	Use port QoS
x	No	Yes	Yes	x	x	Use ingress DSCP mapping
x	Yes	No	Yes	x	No	Use port QoS
x	Yes	No	Yes	x	Yes	Use ingress p-bits mapping
x	Yes	Yes	Yes	No	No	Use ingress DSCP mapping
x	Yes	Yes	Yes	No	Yes	Use ingress p-bits mapping
x	Yes	Yes	Yes	Yes	Yes	Use ingress DSCP mapping

**Important**

On a tagged port that is Layer-2 trusted, Layer-3 trusted and DiffServ enabled, all multicast packets honor the ingress DSCP value.

The QoS level for control packets destined for the CPU is assigned internally to ensure timely packet processing and scaling numbers. You cannot configure the QoS level for these control packets. The system assigns the highest QoS-level to time-critical protocols.

The following table shows ingress IEEE 802.1p to QoS level mappings.

Table 167: Default ingress 802.1p to QoS mappings

Ingress IEEE 802.1p	PHB	QoS Level	Network Service Class (NSC)
0	CS0/DF	1	Standard
1	Custom	0	Custom
2	CS1/AF11	2	Bronze
3	CS2/AF21	3	Silver
4	CS3/AF31	4	Gold
5	CS4/AF41	5	Platinum
6	CS5/EF	6	Premium/EF
7	CS6/CS7	7	Network/Critical

The following table shows DSCP to internal QoS level mappings.

Table 168: Default ingress DSCP to QoS mapping

Ingress				Internal QoS level	PHB level
DSCP (decimal)	DSCP (binary)	DSCP (hexadecimal)	TOS (hexadecimal)		
00	000000	00	00	1	CS0/DF
00	000000	00	00	1	DF

Egress mappings

Egress mappings include:

- QoS level to IEEE 802.1p mappings
- QoS level to DSCP mappings

When a packet is forwarded by the switch, the software does the following:

- Always performs 802.1p remarking before the packet egresses.
- If the ingress port has **enable-diffserv** and **access-diffserv** enabled, then the IP packet is DSCP remarked before the packet egresses.

If the ingress port is not configured this way, the packets are not DSCP remarked.

The following table shows egress QoS level to IEEE 802.1p mappings.

Table 169: Default egress QoS level to IEEE 802.1p mappings

QoS level	PHB	Default 1p remarking on egress	Network Service Class (NSC)
0	Custom	1	Custom
1	CS0/DF	0	Standard
2	CS1/AF11	2	Bronze

Table 169: Default egress QoS level to IEEE 802.1p mappings (continued)

QoS level	PHB	Default 1p remarking on egress	Network Service Class (NSC)
3	CS2/AF21	3	Silver
4	CS3/AF31	4	Gold
5	CS4/AF41	5	Platinum
6	CS5/EF	6	Premium/EF
7	CS6/CS7	7	Network/Critical

The following table shows QoS level to DSCP mappings.

Table 170: Default egress QoS level to DSCP mappings

Egress

Table 171: Port-Based Rate Limiting, Policing, and Shaping product support (continued)

Feature	Product	Release introduced
QoS ingress port rate limiter	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5

The switch QoS implementation supports the following two features for bandwidth management and traffic control:

- ingress port-based rate limiting—a mechanism to limit the traffic rate accepted by the specified ingress port
- egress port-based shaping—the process by which the system delays and transmits packets to produce an even and predictable flow rate

Each port has eight unicast and multicast queues, Class of Service (CoS) 0 to CoS 7. Traffic shaping exists on the egress CoS 6 and CoS 7, but you cannot change the configuration. CoS 6 and CoS 7 are strict priority queues, with traffic shaping for CoS 6 at 50 percent and CoS 7 to five percent of line rate.

Each feature is important to deliver DiffServ within a QoS network domain.

Some hardware platforms support an ingress flow-based policer for ACLs. For information about Ingress Flow-based Policer, see [Ingress Bandwidth Rate Limiter](#) on page 2974.

Token Buckets

Tokens are a key concept in traffic control. A port-based rate limiter, policer, shaper, or an ingress flow-based policer calculates the number of packets that passed, and at what data rate. Each packet corresponds to a token, and the port-based rate limiter, policer, shaper, or an ingress flow-based policer transmits or passes the packet if the token is available. For more information, see [Figure 198](#).

The token container is like a bucket. In this view, the bucket represents both the number of tokens that a port-rate limiter, policer, or shaper can use instantaneously (the depth of the bucket) and the rate at which the tokens replenish (how fast the bucket refills).

Each policer has two token buckets: one for the peak rate and the other for the service rate. The following figure shows the flow of tokens.

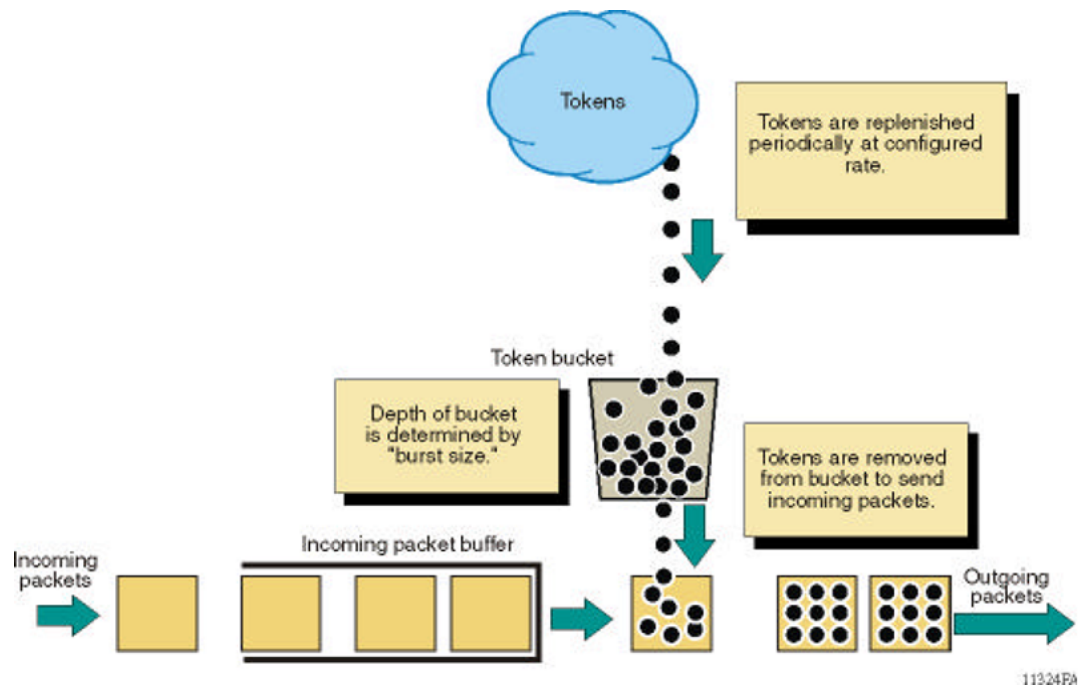

Figure 198: Token flow

Ingress port-rate limiter

Ingress port-rate limiter limits the traffic rate accepted by the specified ingress port. The port drops or re-marks violating traffic. The line rate of the port is the maximum rate that can be set.

For more information on ingress port-rate limiter, see:

- [View the Ingress Port-Rate Limit Information](#) on page 2303
- [Configuring the ingress port-rate limiter](#) on page 2302

Note

If Ingress Flow policer and Ingress port rate limiter features are configured together it might result in more traffic drop than expected. Since both are partially incompatible, best practice is to not configure both together that could affect same traffic. Below are the best practices:

- If ACL type is inPort, do not configure Qos Port Limiter on any of the ports that are part of ACL
- If ACL type is inVlan, do not configure Qos Port Limiter on ports that are part of any VLAN in the ACL
- If ACL type is inVsn, do not configure Qos Port Limiter on ports that are part of any VSN in the ACL

Queuing

Queuing is a congestion-avoidance function that prioritizes packet delivery. Queuing ensures discriminate packet discard during network congestion, and can delay a packet in memory until the scheduled transmission.

You can use queuing to manage congestion. Congestion management involves the creation of queues, assignment of packets to the queues based on the classification of the packet, and scheduling of the packets in a queue for transmission.

The system schedules packets for transmission according to their assigned priority and the queuing mechanism configured for the interface. The scheduler determines the order of packet transmission by controlling how the system services queues with respect to each other. The switch uses 16 CPU queues (used by traffic destined to the CPU), and eight unicast and eight multicast queues for each port. The deepest queue does not go beyond 60,000 packets.

A scheduler services the eight queues for each port, using a combination of strict priority and round-robin. Queue zero through five use round robin, and queues six and seven drain completely, or up to certain rate limits.

There are eight priorities on each egress port. Each Weighted Round Robin (WRR) queue has a minimum guaranteed weight to ensure fair bandwidth allocation for each queue in case all QoS queues are utilized and there is congestion. With the default profile, Class of Service (CoS) 0 to CoS 5 are WRR, and the default weights are 10, 20, 30, 40, 50, and 50 respectively. CoS 6 and CoS 7 are strict priority queues. The switch subjects CoS 6 and CoS 7 to traffic shaping at 50 per cent and five per cent of line rate respectively.

All packets destined for the CPU are sent as unicast packets.

Front panel ports also have 8 queues. When a front panel port is oversubscribed with both unicast and multicast packets, the bandwidth is divided so that the unicast packets receive 80% of the bandwidth and multicast packets 20% of the bandwidth.

If there are no multicast packets using the reserved 20%, the bandwidth is evenly distributed between COS levels 0 to 6. This results in approximately 3.3% more bandwidth for each level. If a specific COS level is not oversubscribed, the unused bandwidth is evenly distributed between the other COS levels. The CLI provides commands to map ingress packets to specific COS levels.

Note

Unicast packets will be tail dropped on the ingress card. Multicast packets will be dropped at egress card.

Among the WRR queues, the approximate bandwidth percentage is relative to the remaining bandwidth after subtracting the Strict Priority queues. The following tables provide the approximate bandwidth percentage based on queue congestion.

Table 172: Bandwidth for Queue 0 to 5 congestion

Queue	Approximate bandwidth percentage*
0	5%
1	10%
2	15%
3	20%
4	25%

Table 172: Bandwidth for Queue 0 to 5 congestion (continued)

Queue	Approximate bandwidth percentage*
5	25%
* The approximate value assumes that all queues 0 to 5 are congested and similar packet sizes. Any queue that does not require bandwidth results in adding more bandwidth to the WRR queues. Percentage is relative to the total bandwidth minus the bandwidth consumed by Cos 6 and 7 (strict queues).	

Table 173: Bandwidth for Queue 0 to 7 congestion

Queue	Approximate bandwidth percentage*
0	2.25%
1	4.5%
2	6.75%
3	9%
4	11.25%
5	11.25%
6	50%
7	5%
* The approximate value assumes that all queues 0 to 7 are congested and similar packet sizes.	

CPU Queues

This section provides information about CPU traffic and queues.

The following table outlines the CPU traffic, and which queue it uses.

Queue description	Queue ID	Queue pps, burst size	Traffic type
Other	0	1400 pps, 100 kbps	Others
BC_Other	1	1400 pps, 100 kbps	Broadcast
HI_CPU looper	2	4000 pps, 100 kbps	IP_COS01
HI_CPU	3	4000 pps, 100 kbps	IP_COS23, Multicast Data
HI_CPU	4	4000 pps, 100 kbps	IP_COS4
HI_CPU	5	4000 pps, 100 kbps	IP_COS5, IGMP, PIM Unicast
HI_CPU	6	4000 pps, 100 kbps	ARP, RARP, ND Multicast and Unicast, MLD
HI_CPU	7	4000 pps, 100 kbps	IP_COS6, Telnet, SSH
mgmt	8	4000 pps, 200 kbps	IP_COS7, OSPF

Queue description	Queue ID	Queue pps, burst size	Traffic type
Low rate looper	9	4000 pps, 6000 kbps	OSPF Multicast, PIM Multicast, RIP_v1, RIP_v2
Low rate 1	10	4000 pps, 12000 kbps	ISIS
Low latency	11	4000 pps, 1000 kbps	ISIS Hello, LLDP, EAP, IST Control
Low latency	12	500 pps, 32 kbps	VRRP, CFM
Low latency	13	256 pps, 32 kbps	SLPP
Low latency	14	100 pps, 32 kbps	BPDU
Low latency	15	250 pps, 32 kbps	LACP, VLACP, TUNI-extract

Queue profiles

Table 174: Queue Profiles product support

Feature	Product	Release introduced
QoS per queue rate limiting	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5

This section identifies optional ways to customize the egress queues and scheduling depending on your need to override the default configuration. You can also enable egress queue rate limiting, if desired.

Use a queue profile to apply configured egress queue parameters and modify each queue individually. You can use the queue profile to configure a minimum weight for the queue and to enable rate limiting for the queue. The queue profile applies to all ports in the switch.

Note

If you enable rate limiting for all queues, the scheduler treats all queues as strict priority queues. If all queues are strict priority, the scheduler services the highest priority queue first until the maximum bandwidth is met, and then it services the next highest priority queue. Queue 0 is the lowest priority queue, which means that when over-subscribed, the lower priority queues are serviced last, or not at all.

The switch supports six queue profiles. The default queue profile, with the name default and ID 1, is automatically created during system startup and cannot be deleted.

Note

The egress queues with rate limiting enabled must be contiguous. For example, you can configure queues 3-6, but you cannot configure 3 and 6.

After you make a configuration change to a queue profile, you must apply the profile before the changes take effect.

Configuration considerations

If you modify the QoS configuration for a port that is a member of MultiLink Trunking (MLT), all ports in the MLT inherit the same configuration. If you remove the port from the MLT, it keeps the QoS configuration it inherited from the MLT.

QoS support for 10 GbE interface in 1GbE mode

If you use QoS with a 10 gigabit Ethernet (GbE) interface and re-purpose the interface as a 1 GbE interface, you must make the necessary configuration changes to accommodate the new link speed.

Check your rate limiting and shaping settings, if you choose to change the port link speed from 10 GbE to 1 GbE.

Review the following commands to ensure proper configuration for the port speed you use.

Command	Description
<code>qos if-rate-limiting [port {slot/port}] rate <1000-40000000></code>	Configures ingress port rate limiting in kbps. Note: The range can vary depending on your hardware platform.
<code>rate-limit broadcast {<1-65535> <50-65000000>}</code>	Configures ingress port broadcast rate limiting in packets/second. Note: The range can vary depending on your hardware platform.
<code>rate-limit multicast {<1-65535> <50-65000000>}</code>	Configures ingress port multicast rate limiting in packets/second. Note: The range can vary depending on your hardware platform.
<code>qos if-shaper [port {slot/port[/sub-port]} [-slot/port[/sub-port]][, ...]] shape-rate <shape-rate></code>	Specifies the shaping rate in Kb/s. Different hardware platforms support different egress rate limits, depending on the port with the highest speed available on the platform. If you try to configure a limit that is too high for the port speed, the switch displays the following message: <code>Error: port slot/port, The QOS Egress shaper rate can not exceed the port capability.</code>

802.1p and 802.1Q Best Practices

In a network, to map the 802.1p user priority bits, use 802.1Q-tagged encapsulation on customer-premises equipment (CPE). You require encapsulation because the switch does not provide classification when it operates in bridging mode.

To ensure consistent Layer 2 QoS boundaries within the service provider network, you must use 802.1Q encapsulation to connect a CPE directly to the switch access node. If you do not require packet classification, use Ethernet Routing Switch 5600 to connect to the access node. In this case, configure the traffic classification functions in the Ethernet Routing Switch 5600.

At the egress access node, packets are examined to determine if their IEEE 802.1p or DSCP values must be re-marked before leaving the network. Upon examination, if the packet is a tagged packet, the IEEE 802.1p tag is configured based on the QoS level-to-IEEE 802.1p-bit mapping. For bridged packets, the DSCP is re-marked based on the QoS level.

Network congestion and QoS design

When you provide QoS in a network, one of the major elements you must consider is congestion, and the traffic management behavior during congestion. Congestion in a network is caused by many different conditions and events, including node failures, link outages, broadcast storms, and user traffic bursts.

At a high level, three main types or stages of congestion exist:

1. No congestion
2. Bursty congestion
3. Severe congestion

In a noncongested network, QoS actions ensure that delay-sensitive applications, such as real-time voice and video traffic, are sent before lower-priority traffic. The prioritization of delay-sensitive traffic is essential to minimize delay and reduce or eliminate jitter, which has a detrimental impact on these applications.

A network can experience momentary bursts of congestion for various reasons, such as network failures, rerouting, and broadcast storms. The switch has sufficient capacity to handle bursts of congestion in a seamless and transparent manner. If the burst is not sustained, the traffic management and buffering process on the switch allows all the traffic to pass without loss.

Severe congestion is defined as a condition where the network or certain elements of the network experience a prolonged period of sustained congestion. Under such congestion conditions, congestion thresholds are reached, buffers overflow, and a substantial amount of traffic is lost.

When you perform traffic engineering and link capacity analysis for a network, the standard design rule is to design the network links and trunks for a maximum average-peak utilization of no more than 80%. This value means that the network peaks to up to 100% capacity, but the average-peak utilization does not exceed 80%. The network is expected to handle momentary peaks above 100% capacity.

Layer 2 and Layer 3 trusted and untrusted ports

You can configure interface module ports as trusted or untrusted at both Layer 2 (802.1p) or Layer 3 (DSCP) for ingress packet classification.

The switch provides eight internal QoS levels. These eight levels, numbered zero to seven, map to the queues through

- the ingress 8021p to (internal) QoS mapping table
- the ingress DSCP to (internal) QoS mapping table

To configure a port as trusted or untrusted, use the commands and the parameter values as shown in the following tables:

Layer 2 Trusted	Layer 2 Untrusted
802.1p-override	802.1p-override
disable	enable

Layer 3 Trusted		Layer 3 Untrusted	
enable-diffserv	access-diffserv *	enable-diffserv	access-diffserv *
enable	disable	disable	disable
		disable	enable
		enable	enable **

* Configure **access-diffserv** as either a core or access port. If enabled, this command specifies an access port and overrides incoming DSCP bits. If disabled, it specifies a core port that honors and services incoming DSCP bits.
 ** If the ingress port has **enable-diffserv** and **access-diffserv** enabled, then the packet is DSCP remarked at egress.

Layer 2 untrusted and Layer 3 untrusted

To configure a port as Layer 2 untrusted and Layer 3 untrusted, refer to the tables above and assign the parameter values accordingly.

For more information, see [Table 166](#) on page 2274.

Layer 2 untrusted and Layer 3 trusted

To configure a port as Layer 2 untrusted and Layer 3 trusted, refer to the tables above and assign the parameter values accordingly.

Use these configuration options to classify packet QoS through the DSCP parameter for all IP packets, whether tagged or untagged. Use this configuration when another QoS or DiffServ enabled and configured switch marks the IP packets at the edge. These already-marked packets arrive Layer 3 trusted, and the switch continues with the trust (DiffServ core port operation). For tagged packets, the system does not examine the 802.1p bits. For non-IP packets, this configuration causes classification by port QoS settings.

Note

For IP switched and tagged packets, use the 802.1p bits to derive the internal QoS. For untagged or routed packets, use the DSCP to derive the internal QoS.

For more information, see [Table 166](#) on page 2274.

Layer 2 trusted and Layer 3 trusted

To configure a port as Layer 2 trusted and Layer 3 trusted, refer to the tables above and assign the parameter values accordingly.

Use these configuration options to classify packet QoS through DSCP for all IP packets, and through 802.1p for all tagged non IP packets. If it is an IP packet, DSCP is used. If it is a tagged non IP packet, 802.1p bits are used. If it is an untagged non IP packet, the port QoS is used.

For more information, see [Table 166](#) on page 2274.

Layer 2 trusted and Layer 3 untrusted

To configure a port as Layer 2 trusted and Layer 3 untrusted, refer to the tables above and assign the parameter values accordingly.

Use these configuration options to classify packet QoS through 802.1p for all tagged packets, and port QoS levels for all untagged (IP or non-IP) packets. If the packet is an IP packet, the system does not modify or examine the DSCP parameter bits.

For more information, see [Table 166](#) on page 2274.

DiffServ disabled

If you disable the DiffServ parameter, the system ignores the Layer 3 DSCP parameter. For more information, see [Table 166](#) on page 2274.

Broadcast and multicast traffic bandwidth limiters per ingress port

Interface modules support bandwidth limiters for ingress broadcast and multicast traffic. The system drops traffic that violates the bandwidth limit. Enable this feature and configure the rate limit on an individual port basis.

QoS and VoIP

VoIP traffic requires low latency and jitter.

If you use edge routers, configure ingress ports as core ports to treat VoIP traffic appropriately. In this case, the system trusts QoS markings that apply to VoIP traffic, and the system does not re-mark QoS settings. However, if this configuration is not sufficient, you can also apply filters, route policies, or re-mark traffic.

QoS re-marking on a Transparent Port UNI

A Transparent Port UNI port is normally configured as a Layer 2 trusted port. The T-UNI port honors incoming customer 802.1p bits and derives an internal QoS level. The 802.1p bit marking of the Backbone VLAN (B-VLAN) is derived from the internal QoS level. If the T-UNI port is set as a Layer 2 untrusted port, a best-effort queue is assigned. Customer packet headers are not modified.

The T-UNI port QoS configurations are:

- DiffServ = disable
- Layer3Trusted = access (for EDM configuration)
- access-diffserv enable (for CLI configuration)

QoS considerations when a port is associated with a T-UNI I-SID

- You cannot configure `access-diffserv` and `enable diffserv` on a T-UNI port.
- When a port is associated with a T-UNI I-SID, the T-UNI QoS configuration automatically takes effect.
- When the port is removed from the T-UNI I-SID, the default port QoS configuration takes effect.

QoS considerations when an MLT is associated with a T-UNI I-SID

- When an MLT, static or LACP, is added to a T-UNI I-SID, the T-UNI QoS configuration take effect on all the ports of the MLT.
- When an MLT, static or LACP, is removed from a T-UNI I-SID, the port default QoS configuration is configured on all the member ports of the MLT.
- If a port is added dynamically to a T-UNI MLT, static or LACP, the port inherits the QoS properties of the T-UNI MLT ports.
- If a port is dynamically removed from a T-UNI MLT, static or LACP, the port retains the QoS configuration inherited from the MLT.

QoS and channelization

Use channelization to configure a single port to operate as four subports. By default, the ports are not channelized.

You can enable or disable channelization on a channelization-capable port. Enabling or disabling channelization on a port resets the port QoS configuration to default values. For more information on channelization, see [Enable Channelization](#) on page 494.

QoS examples and Best Practices

The sections that follow present QoS network scenarios for bridged and routed traffic over the core network.

Bridged traffic

If you bridge traffic over the core network, you keep customer VLANs separate (similar to a Virtual Private Network). Normally, a service provider implements VLAN bridging (Layer 2) and no routing. In this case, the 802.1p-bit marking determines the QoS level assigned to each packet. If DiffServ is active on core ports, the level of service received is based on the highest of the DiffServ or 802.1p settings.

The following cases provide sample QoS design guidelines you can use to provide and maintain high service quality in a network.

If you configure a core port, you assume that, for all incoming traffic, the QoS value is properly marked. All core switch ports simply read and forward packets; they are not re-marked or reclassified. All initial QoS markings are performed at the customer device or on the edge devices.

The following figure illustrates the actions performed on three different bridged traffic flows (that is VoIP, video conference, and email) at access and core ports throughout the network.

Figure 199: Trusted bridged traffic

For bridged, untrusted traffic, if you configure the port to access, mark and prioritize traffic on the access node using global filters. Reclassify the traffic to ensure it complies with the class of service specified in the SLA.

For Resilient Packet Ring (RPR) interworking, you can assume that, for all incoming traffic, the QoS configuration is properly marked by the access nodes. The core switch ports, configured as core or trunk ports, perform the RPR interworking. These ports preserve the DSCP marking and re-mark the 802.1p bit to match the 802.1p bit of the RPR. The following figure shows the actions performed on three different traffic flows (VoIP, video conference, and email) over an RPR core network.

Figure 200: RPR QoS internetworking

Routed traffic

If you route traffic over the core network, VLANs are not kept separate.

If you configure the port to core, you assume that, for all incoming traffic, the QoS configuration is properly marked. All core switch ports simply read and forward packets. The switch does not re-mark or classify the packets. The customer device or the edge devices perform all initial QoS markings.

The following figure shows the actions performed on three different routed traffic flows (that is VoIP, video conference, and email) at access and core ports throughout the network.

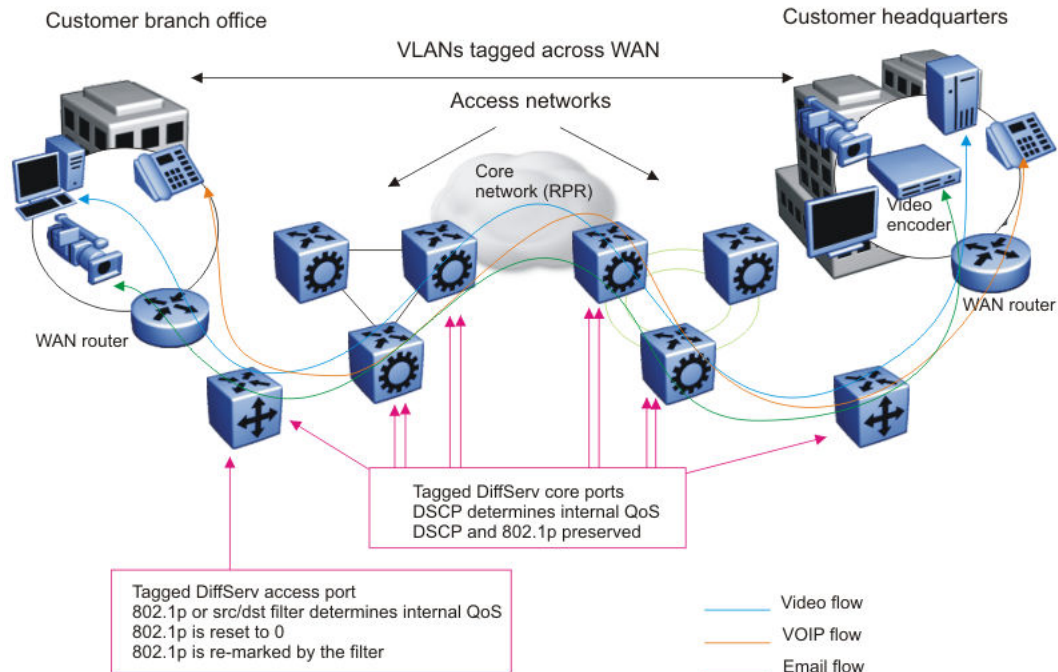

Figure 201: Trusted routed traffic

For routed, untrusted traffic, in an access node, packets that enter through a tagged or untagged access port exit through a tagged or untagged core port.

Basic DiffServ configuration using CLI

Use Differentiated Services (DiffServ) to provide appropriate Quality of Service (QoS) to specific traffic types.

Enabling DiffServ on a port

Enable DiffServ so that the system provides DiffServ-based QoS on the port. By default, DiffServ is enabled.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable DiffServ:

```
enable-diffserv [port {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}] [enable]
```

3. Disable Diffserv:

```
no enable-diffserv [port {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}] [enable]
```

Variable definitions

Use the data in the following table to use the **enable-diffserv** command.

Variable	Value
<i>enable</i>	Enables DiffServ for the specified port. The default is enabled.
<i>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Configuring Layer 3 trusted or untrusted ports

Configure a port as trusted or untrusted to determine the Layer 3 QoS actions the switch performs. A trusted (core) port honors incoming Differentiated Services Code Point (DSCP) markings. An untrusted (access) port overrides DSCP markings. The default configuration is trusted.

Before You Begin

Enable DiffServ.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the port as an access port, use one of the following options:

```
no enable-diffserv [port {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]] [enable]
```

OR configure both parameters:

```
enable-diffserv [port {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]] [enable]
```

```
access-diffserv [port {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]] [enable]
```

3. Configure the port as a core port:

```
no access-diffserv [port {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]] [enable]
```

Variable definitions

Use the data in the following table to use the **access-diffserv** commands.

Variable	Value
<i>enable</i>	If enabled, specifies an access port and overrides incoming DSCP bits. If disabled, specifies a core port that honors and services incoming DSCP bits.
<i>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Configuring Layer 2 trusted or untrusted ports

Configure a port as trusted or untrusted to determine the Layer 2 QoS actions the switch performs. A trusted port (override disabled) honors incoming 802.1p bit markings. An untrusted port (override enabled) overrides 802.1p bit markings.

Before You Begin

Enable DiffServ.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the port as Layer 2 untrusted:

```
qos 802.1p-override [enable]
```

3. Configure the port as Layer 2 trusted:

```
no qos 802.1p-override [enable]
```

Variable Definitions

Use the data in the following table to use the `qos 802.1p-override` command.

Variable	Value
<i>enable</i>	If you use this variable, the port overrides incoming 802.1p bits; if you do not use this variable, the port honors and services incoming 802.1p bits. The default is disable (Layer 2 trusted).

Viewing the port 802.1p override status

Use this procedure to view the port 802.1p override status. The system displays the port and 801.1p override status.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. View the port 802.1p override status:

```
show qos 802.1p-override
```

Example

```
Switch:1# show qos 802.1p-override
```

```
=====
Port 802.1p-Override Status
=====
PORT      802.1P OVERRIDE
=====
```

```

1/1    DISABLED
1/2    DISABLED
1/3    DISABLED
1/4    DISABLED
1/5    DISABLED
1/6    DISABLED
1/7    DISABLED
1/8    DISABLED
1/9    DISABLED
1/10   DISABLED
1/11   DISABLED
1/12   DISABLED
1/13   DISABLED
1/14   DISABLED
1/15   DISABLED
1/16   DISABLED

```

Configuring the port QoS level

Configure the port QoS level to assign a default QoS level for all traffic if the packet does not match an access control list (ACL) that re-marks the packet. If you configure port QoS levels, Layer 2 and Layer 3 traffic from the same port use the same QoS level. The default value is 1.

About This Task

For VoIP traffic, as a best practice, use QoS level 6.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the port QoS level:

```
qos level [port {slot/port[sub-port]}] <0-6>
```

Variable definitions

Use the data in the following table to use the **qos level** command.

Variable	Value
<0-6>	Specifies the default QoS level for the port traffic. The system reserves QoS level 7 for network control traffic. The default is 1.
<i>port {slot/port[/sub-port]}</i>	Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Basic DiffServ configuration using EDM

Use DiffServ to implement classification and mapping functions at the network boundary or access points to regulate packet behavior. You can configure a port as a trusted (core) or an untrusted (access) port at both Layer 2 and Layer 3.

You can also perform many of the procedures in this section on the Interface tab for the selected port. The procedures in this section show only one configuration method.

Enabling DiffServ for a port

Enable DiffServ so that the switch provides DiffServ-based Quality of Service (QoS) on the port.

About This Task

Procedure

1. In the navigation tree, expand the following folders: **Configuration > QOS**.
2. Click **Port QoS Config**.
3. In the row for the port, double-click the cell in the **DiffServ** column.
4. Select **true**.
5. Click **Apply**.

QoS Port Config field descriptions

Use the data in the following table to use the **Port QoS Config** tab.

Name	Description
Index	Specifies an index value that uniquely identifies a port.
DiffServ	Specifies whether DiffServ is enabled (true) or disabled (false) on the port. The default is true. This variable works in conjunction with Layer3Trust. The DiffServ variable is a global parameter that affects QoS DSCP operations. If the DiffServ parameter is false (DiffServ disabled), the system does not use the DSCP parameter for classification or modify it. If this variable is true, it activates the Layer3Trust parameter.
Layer3Trust	Configures the Layer 3 trusted port as an access or core port. The default is core. Core configures the port to a trusted state and access configures the port to an untrusted state. The DiffServ parameter determines the operation of this variable. If DiffServ is false, Layer3Trust has no effect; no modification of the DSCP or TOS bits occurs. If DiffServ is true, the core and access configuration take effect.

Name	Description
Layer2Override8021p	Specifies whether Layer 2 802.1p override is enabled (true) or disabled (false) on the port. The default is false. This variable primarily affects tagged packet treatment. If Layer2Override8021p is false, the port trusts the 802.1p-bits portion of a Q-tagged packet. The port trusts the 802.1p-bits marking regardless of the port setting (tagged or untagged); however, if the discard tagged packets parameter (DiscardTaggedFrames) on an untagged port is true, the system discards the packet. If Layer2Override8021p is true, the port does not trust the 802.1p bit marking. In this case, the QoS operation depends on other parameters, such as the port QoS level.
QoSLevel	Specifies the QoS level to use when the system processes packets carried on this port. Values range from level 0-6 (the system reserves 7 for network control traffic). The default is 1.

Configuring Layer 3 trusted or untrusted ports

Configure a port as trusted or untrusted to determine the Layer 3 QoS actions the switch performs. A trusted port honors incoming DSCP markings. An untrusted port overrides DSCP markings. The default is trusted.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > QOS**.
2. Click **Port QoS Config**.
3. In the row for the port, double-click the cell in the **Layer3Trust** column.
4. Select **core** (trusted) or **access** (untrusted) as the port setting.
5. Click **Apply**.

Configuring Layer 2 trusted or untrusted ports

Configure a port as trusted or untrusted to determine the Layer 2 QoS actions the switch performs. A trusted port (override false) honors incoming 802.1p bit markings. An untrusted port (override true) overrides 802.1p bit markings.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > QOS**.
2. Click **Port QoS Config**.
3. In the row for the port, double-click the cell in the **Layer2 Override 8021p** column.
4. To configure the port as a Layer 2 untrusted port, select **true**. To configure it as a Layer 2 trusted port, select **false**.
By default, all ports are Layer 2 trusted (Layer2 Override 8021p is false).
5. Click **Apply**.

Configuring the port QoS level

Use the default port QoS level to assign a default QoS level for all traffic, if the packet does not match an access control list (ACL) to remark the packet.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > QOS**.
2. Click **Port QoS Config**.
3. In the row for the port, double-click the cell in the **QoSLevel** column.
4. Select the new level.
5. Click **Apply**.

QoS configuration using CLI

Use the procedures in this section to configure Quality of Service (QoS) on the switch.

Configuring broadcast and multicast bandwidth limiting

Configure broadcast and multicast bandwidth limiting to limit the amount of ingress broadcast and multicast traffic on a port. The switch drops traffic that violates the bandwidth limit.

You can configure broadcast and multicast bandwidth limiting through CLI only; you cannot use Enterprise Device Manager (EDM).

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure broadcast bandwidth limiting:

```
rate-limit [port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]
broadcast <1-65535>
```

3. Configure multicast bandwidth limiting:

```
rate-limit [port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]
multicast <1-65535>
```

Variable definitions

Use the data in the following table to use the **rate-limit** command.

Variable	Value
<1-65535>	Specifies the bandwidth limit for broadcast and multicast traffic from 1-65535 packets per second.
<i>port</i> { <i>slot/port</i> [/ <i>sub-port</i>] [- <i>slot/port</i> [/ <i>sub-port</i>]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Viewing the port-based shaper information

About This Task

Use this procedure to view the port-based shaper information. The system displays the port, egress rate limit in Kbps, and the rate limit status.

Procedure

1. Enter Privileged EXEC mode:
enable
2. View the ingress port-rate limit information:
show qos shaper interface gigabitEthernet [{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]]

Example

```
Switch:1#show qos shaper interface gigabitEthernet 1/1
=====
                        Port Egress Rate-Limiting(Shape)
=====
-----
PORT      EGRESS RATE-LIMIT(kbps)   ENABLED/DISABLED
-----
1/1      0                          DISABLED
```

Configuring the port-based shaper

Use port-based shaping to rate-limit all outgoing traffic to a specific rate.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure port-based shaping:

```
qos if-shaper [port {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]] shape-rate <shape-rate>
```

Variable definitions

Use the data in the following table to use the **qos if-shaper** command.

Variable	Value
<code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Specifies the slot and port number to which to apply shaping. This variable is optional. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<code>shape-rate <shape-rate></code>	Specifies the shaping rate in Kb/s. Different hardware platforms support different egress rate limits, depending on the port with the highest speed available on the platform. If you try to configure a limit that is too high for the port speed, the switch displays the following message: <code>Error: port slot/port, The QoS Egress shaper rate can not exceed the port capability.</code> The default is 0, which means shaping is disabled on the port.

Configuring a port-based policer

Use a port policer to bandwidth-limit incoming traffic. The port drops or re-marks violating traffic.

**Note**

This command does not apply on all hardware platforms.

About This Task

The interface policer has two configurable rates: peak rate (PIR) and service or committed rate (CIR). Traffic above PIR is marked as red. Traffic above CIR is qualified as yellow. Normally, CIR is lower than PIR. However, in CLI you can configure these rates to equal values. Each rate has a maximum burst size

associated with it, peak burst size (PBS) and committed burst size (CBS) respectively. You cannot configure the burst sizes. These values ensure maximum traffic fairness between the ports; the CBS value is lower than the PBS value. Depending on the traffic pattern, this configuration can result in a small percentage of traffic qualified as yellow or above CIR, but not red or above PIR, even if the rates are equal.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the policing limit:

```
qos if-policer [port {slot/port[-slot/port] [,...]}] peak-rate
<64-100000000> svc-rate <64-100000000>
```

Example

Configure the policing limit to a peak-rate of 10000 and the service rate limit to 5000 for port 4/10:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitethernet 4/10
Switch:1(config-if)#qos if-policer port 4/10 peak-rate 10000 svc-rate 5000
```

Variable Definitions

Use the data in the following table to use the **qos if-policer** command.

Variable	Value
<code>peak-rate<64-100000000></code>	Specifies the peak rate limit in Kbps.
<code>port {slot/port[-slot/port] [,...]}</code>	Identifies the slot and the port.
<code>svc-rate<64-100000000></code>	Specifies the service rate limit in Kbps.

Configuring the ingress port-rate limiter

Use the ingress port-rate limiter to limit the traffic rate accepted by the specified ingress port. The port drops or re-marks violating traffic.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the ingress port-rate limit:

```
qos if-rate-limiting [port {slot/port[/sub-port] [-slot/port[/sub-
port]] [,...]] rate <1000-40000000>
```

3. Disable the ingress port-rate limit:

```
no qos if-rate-limiting [port {slot/port[/sub-port] [-slot/port[/sub-
port]] [,...]]
```

Variable definitions

Use the data in the following table to use the **qos if-rate-limiting** command.

Variable	Value
<i>1000-40000000</i>	Specifies the ingress rate limit in Kbps. The range is 1000-40000000.
<i>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

View the Ingress Port-Rate Limit Information

Use this procedure to view the ingress port-rate limit information. The system displays the port, rate limit in Kbps, and rate limit status.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. View the ingress port-rate limit information:

```
show qos rate-limiting interface gigabitEthernet [{slot/port[/sub-
port] [-slot/port[/sub-port]] [,...]]
```

Example

```
Switch:1# show qos rate-limiting interface gigabitEthernet 1/1
```

```

=====

=====
-----
PORT      RATE (kbps)      ENABLED/DISABLED
-----
1/1       0                 DISABLED
-----

```

Variable definitions

Use the data in the following table to use the **show qos rate-limiting interface gigabitEthernet** command.

Variable	Value
<code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Viewing Ingress Port-rate Limit Statistics

Use this procedure to view the ingress port-rate limit statistics. The system displays the statistics of the dropped packets and bytes.

**Note**

This command is not available on all hardware platforms.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. View the ingress port-rate limit statistics:

```
show interfaces gigabitEthernet statistics rate-limiting [port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

Example

```
Switch:1# show interfaces gigabitEthernet statistics rate-limiting 1/1
```

```

-----

```

Variable Definitions

Use the data in the following table to use the **show interfaces gigabitethernet statistics rate-limiting** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Configuring ingress mappings

You can modify the ingress mappings to change traffic priorities. However, as a best practice, use the default mappings.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure 802.1p bit to QoS ingress mappings:

```
qos ingressmap 1p <0-7> <0-6>
```
3. Configure DSCP to QoS ingress mappings:

```
qos ingressmap ds <0-63> <0-6>
```
4. Ensure the configuration is correct:

```
show qos ingressmap [1p <0-7>]

show qos ingressmap [ds <0-63>]
```

Variable Definitions

Use the data in the following table to use the **qos ingressmap** command.

Variable	Value
<code>1p <0-7> <0-6></code>	<p>Maps the IEEE 802.1p bit to QoS level. Each QoS level has a default IEEE 1P value:</p> <ul style="list-style-type: none"> • level 0—1 • level 1—0 • level 2—2 • level 3—3 • level 4—4 • level 5—5 • level 6—6 <p>The system reserves level 7 for Network Control. To use the default configuration, use the default option in the command: <code>default qos ingressmap 1p</code></p>
<code>ds <0-63> <0-6></code>	<p>Maps the DS byte to QoS level. The system reserves level 7 for Network Control. To use the default configuration, use the default option in the command: <code>default qos ingressmap ds</code></p>

Configuring egress mappings

You can modify the egress mappings to change traffic priorities. However, as a best practice, use the default mappings.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Configure QoS to 802.1p bit egress mappings:
`qos egressmap 1p <0-6> <0-7>`
3. Configure QoS to DSCP egress mappings:
`qos egressmap ds <0-7> WORD<1-6>`
4. Ensure the configuration is correct:
`show qos egressmap [1p <0-7>]`
`show qos egressmap [ds <0-7>]`

Variable Definitions

Use the data in the following table to use the **qos egressmap** command.

Variable	Value
<code>1p <0-6> <0-7></code>	<p>Maps the QoS level to IEEE 802.1p bit. Each QoS level has a default IEEE 1P value:</p> <ul style="list-style-type: none"> • level 0—1 • level 1—0 • level 2—2 • level 3—3 • level 4—4 • level 5—5 • level 6—6 <p>The system reserves level 7 for Network Control. To use the default configuration, use the default option in the command:</p> <pre>default qos egressmap 1p</pre>
<code>ds <0-7> WORD<1-6></code>	<p>Maps the QoS level to DS byte. You can specify the DSCP in either hexadecimal, binary, or decimal format. To use the default configuration, use the default option in the command:</p> <pre>default qos egressmap ds</pre>

View Port Egress CoS Queue Statistics

View the port egress CoS queue statistics. The system displays the statistics of the forwarded packets and bytes, and the dropped packets and bytes.

About This Task

If you disable rate limiting on queue 6, bandwidth is shared based on the weights from queues 0 through 6. Based on equal weights assigned for queues 4 through 6, equal amounts of traffic egress queues 4 through 6. The system displays Queue 6 to provide much lower throughput than 50% of port bandwidth.

Note

If there is egress congestion when you enable the **boot config flags flow-control-mode** command, then the system does not drop the packets at egress, and does not increment the counters under the **show qos cosq-stats interface {slot/port[/sub-port]} [-slot/port[/sub-port]] [, ...]** command output. Instead, the system drops the packets at the ingress port and the system counts them under the INDISCARD column of **show interfaces gigabitEthernet error {slot/port[/sub-port]} [-slot/port[/sub-port]] [, ...]** command output.

Procedure

1. Enter Privileged EXEC mode:
enable

- View the port egress CoS queue statistics:

```
show qos cosq-stats interface <PT_PORT>
```

Variable Definitions

Use the data in the following table to use the **show qos cosq-stats interface <PT_PORT>** command.

Variable	Value
<PT_PORT>	PT indicates the slot number; PORT indicates the port number.

Clearing port egress CoS queue statistics

Clear the port egress CoS queue statistics in the hardware.

Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

- Clear the port egress CoS queue statistics:

```
clear qos cosq-stats interface <PT_PORT>
```

Variable Definitions

Use the data in the following table to use the **clear qos cosq-stats interface <PT_PORT>** command.

Variable	Definition
<PT_PORT>	PT indicates the slot number; PORT indicates the port number.

View CPU Queue Statistics

View the statistics of the forwarded packets and bytes, and the dropped packets and bytes for the traffic sent toward CP. The queue assignment is based on the protocol types, not on the internal CoS value. These statistics are useful for debugging purposes.

When a neighbor transitions to the STALE state, to initiate Neighbor Unreachability detection (NUD), a duplicate copy of the traffic destined to this neighbor is sent to the switch Control Processor (CP) on a low priority queue (queue 0). The original packet is forwarded to this neighbor. Once NUD is initiated, the hardware records are updated and the traffic is no longer sent to the CP. When a high rate of such traffic is sent to CP, the switch can drop some of these packets due to the in built CP rate limiting feature, which protects the CP from DOS attacks.

Use the command **show qos cosq-stats cpu-port** to view drop statistics on the CPU queue. This design does not result in loss of traffic.

Use the command `ipv6 nd reachable-time <0-3600000>` to increase the default value of 3000 milliseconds which in turn delays the scenario of data path sending STALE neighbor destined packets to the CP.

About This Task

Note

If you disable rate limiting on queue 6, bandwidth is shared based on the weights from queues 0 through 6. Based on equal weights assigned for queues 4 through 6, equal amounts of traffic egress queues 4 through 6. The system displays Queue 6 to provide much lower throughput than 50% of port bandwidth.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. View the CPU queue statistics:
`show qos cosq-stats cpu-port`

Clearing CPU queue statistics

Clear the CPU queue statistics.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Clear CPU queue statistics:
`clear qos cosq-stats cpu-port`

Configure an Egress QoS Queue Profile

Configure a queue profile to apply the configured egress queue parameters to queues and ports.

About This Task

After you make a configuration change to a queue profile, you must apply the profile before the changes take effect.

Note

The switch supports six queue profiles. The default queue profile, with the name default and ID 1, is automatically created during system startup and cannot be deleted.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure the minimum weight for a specific queue:

```
qos queue-profile queue <1-6> <0-7> min-weight <1-100>
```
3. Enable rate limiting on a weighted queue:

```
qos queue-profile queue <1-6> <0-7> rate-limit-enable
```
4. Add a queue-profile port member:

```
qos queue-profile <1-6> member add {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```
5. Add a queue-profile name:

```
qos queue-profile <1-6> name WORD<0-64>
```
6. Apply the queue profile:

```
qos queue-profile <1-6> apply
```
7. Verify the egress queue configuration:

```
show qos queue-profile [<1-6> queue <0-7>|all]
```
8. (Optional) Configure the default settings for an egress queue:
 - Configure the default minimum weight using one of the following commands:

```
default qos queue-profile queue <1-6> <0-7> min-weight

no qos queue-profile queue <1-6> <0-7> min-weight
```
 - Configure the default rate limiting on a weighted queue using one of the following commands:

```
default qos queue-profile queue <1-6> <0-7> rate-limit-enable

no qos queue-profile queue <1-6> <0-7> rate-limit-enable
```

Examples

Configure the queue profile for queue 6 to use a weight of 20.

```
Switch:1(config)#qos queue-profile 6
Switch:1(config)#qos queue-profile queue 6 1 min-weight 20
Switch:1(config)#qos queue-profile 6 apply
```

View the queue profile configuration.

```
Switch:1#show qos queue-profile
```

```
=====
                                     Qos Queue Profile
=====

Profile Profile      Profile
ID       Name         Port List
-----
1        default      1/1-1/42,2/1-2/42
6                               profile-6
```

The value in the `Weight Applied` column is the maximum bandwidth for Strict Priority queues (Rate Limit Enabled) and the weight in the WRR scheduling algorithm applied per queue. Strict Priority queues are serviced first and limited to the configured percentage of bandwidth. WRR queues (no rate limit applied) have no upper boundary, other than the delta between the available bandwidth per port and the one consumed by Strict Priority queues. For WRR queues, there is no association with the bandwidth percentage servicing this queue; the bandwidth that can be served is relative to the available bandwidth at a certain moment and the load of other queues.

```
Switch:1(config)#show qos queue-profile 1 queue 1
```

```
=====
                        Qos Queue Profile Table
=====
```

1	default	2	30	30	DISABLE	DISABLE
1	default	3	40	40	DISABLE	DISABLE
1	default	4	50	50	DISABLE	DISABLE
1	default	5	50	50	DISABLE	DISABLE
1	default	6	50	50	DISABLE	ENABLE
1	default	7	5	5	ENABLE	ENABLE

Variable Definitions

The following table defines parameters for the `qos queue-profile queue` command.

Variable	Value
<1-6>	Specifies the queue profile ID. Note: The switch supports six queue profiles. The default queue is 1.
<0-7>	Specifies the egress queue to configure.

Variable	Value
<code>min-weight</code> <1-100>	Configures the queue weight for weighted round robin (WRR), or the rate-limit in percentage of the link rate for queue shaping enabled on the queue. For rate-limit-enabled queues, 50 indicates 50% bandwidth. The overall rate-limit-enabled queues cannot sum higher than 100 min-weight. If rate-limiting is not enabled, this parameter configures the weight in the WRR scheduler. These values are not associated with bandwidth percentage. The following list identifies the default minimum weight for each queue: <ul style="list-style-type: none"> • Queue 0 – 10 • Queue 1 – 20 • Queue 2 – 30 • Queue 3 – 40 • Queue 4 – 50 • Queue 5 – 50 • Queue 6 – Rate limited to 50% of configured shaper rate • Queue 7 – Rate limited to 5% of configured shaper rate
<code>member add</code> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Specifies a port member of the queue-profile to add or remove.
<code>name</code> WORD<0-64>	Specifies a profile name.
<code>rate-limit-enable</code>	Enables rate limiting on the queue. By default, rate limiting is enabled for queues 6 and 7 only; it is disabled for queues 0 through 5.

The following table defines parameters for the **show qos queue-profile** command.

Variable	Value
<1-6>	Specifies the queue profile ID. If you do not include a queue profile ID, the command output displays all configured profiles. Note: The switch supports six queue profiles. The default queue is 1.
<0-7>	Specifies the egress queue. Displays configuration settings of the specified egress queue.
<code>all</code>	The command output displays the configuration settings of all eight egress queues of the queue profile.

Viewing Logical Interface CoS Queue Statistics

View the QoS CoS queue statistics for IS-IS logical interfaces. These statistics are useful for debugging purposes.

Procedure

1. Enter Privileged EXEC mode:
enable

2. View the logical interface queue statistics:

```
show qos cosq-stats logical-intf [isis <1-255>]
```

Clearing Logical Interface CoS Queue Statistics

Clear the QoS CoS queue statistics for IS-IS logical interfaces.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Clear the logical interface queue statistics:

```
clear qos cosq-stats logical-intf [isis <1-255>]
```

QoS configuration using EDM

Configure Quality of Service (QoS) to allocate network resources where you need them most.

Configuring port-based shaping

Configure egress port-based shaping to bind the maximum rate at which traffic leaves the port.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand the **Configuration > Edit > Port** folders.
3. Click **General**.
4. Click the **Interface** tab.
5. From **EgressRateLimitState**, select **enable**.
6. In the **EgressRateLimit** box, type an egress rate limit in kilobits per second (Kb/s).
7. Click **Apply**.

Configure Port-Based Policing

Use a port-based policer to bandwidth-limit ingress traffic. The system drops or re-marks violating traffic.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation tree, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **Interface** tab.
5. From **IngressRatePeak**, type the value for the peak rate in Kbps.
The peak rate must be greater than or equal to the service rate.
6. From **IngressRateSvc**, type the value for the service rate in Kbps.
7. Select **Apply**.

Configuring ingress port-rate limiter

Use the ingress port-rate limiter to limit the traffic rate accepted by the specified ingress port. The system drops or re-marks violating traffic.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand the **Configuration > Edit > Port** folders.
3. Click **General**.
4. Click the **Interface** tab.
5. From **IngressRateLimit**, type the value in Kbps to set the traffic rate limit.
The ingress rate limit must be between 1000 and 40000000.
6. Click **Apply**.

Graphing Stat Rate Limit Statistics for a Port

View stat rate limit statistics to view the total dropped packets and bytes.

Procedure

1. In the Device Physical View, select a port.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Port**.
4. Click the **Stat Rate Limit** tab.
5. Select one or more values.
6. Click the type of graph to create.

Stat Rate Limit Field Descriptions

Use the data in the following table to use the **Stat Rate Limit** tab.

Name	Description
DropPktRate	Indicates the drop packet rate.
DropByteRate	Indicates the drop byte rate.
DropTotalBytes	Indicates the total bytes dropped.
DropTotalPkts	Indicates the total packets dropped.

Modifying ingress 802.1p to QoS mappings

Modify the ingress mappings to change traffic priorities. As a best practice, use the default mappings.

About This Task

Do not change the default values. If you change the values, make sure that the values are consistent on all other devices in the network. Inconsistent mapping of table values can result in unpredictable service levels.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > QOS**.
2. Click **Mapping Tables**.
3. Click the **Ingress 8021p to QoS** tab.
4. Double-click a QoSLevel field to change the value.
5. Click **Apply**.

Ingress 8021p To QoS field descriptions

Use the data in the following table to use the **Ingress 8021p to QoS** tab.

Name	Description
InIeee8021P	Specifies the value of the IEEE 802.1p bit of the incoming packet.
QoSLevel	Specifies the equivalent egress QoS level (0–7).

Modifying ingress DSCP to QoS mappings

Modify the ingress Differentiated Services Code Point (DSCP) to QoS mappings to change traffic priorities. As a best practice, use the default mappings. Changes to the mapping table take effect after you restart the system.

About This Task

Do not change the default values. If you change the values, make sure that the values are consistent on all other devices in the network. Inconsistent mapping of table values can result in unpredictable service levels.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > QOS**.
2. Click **Mapping Tables**.
3. Click the **Ingress Dscp To QoS** tab.
4. Double-click a QoSLevel field to change the value.
5. Click **Apply**.

Ingress Dscp To QoS field descriptions

Use the data in the following table to use the **Ingress Dscp To QoS** tab.

Name	Description
InDscp	Specifies the value of the DiffServ codepoint (in decimal format) in the IP header of the incoming packet.
InDscpBinaryFormat	Specifies the value of the DiffServ codepoint (in binary format) in the IP header of the incoming packet.
QoSLevel	Specifies the equivalent QoS level.

Modifying egress QoS to 802.1p mappings

Modify the egress mappings to change the mappings between the QoS levels and the IEEE 802.1p bits.

About This Task

Do not change the default values. If you change the values, make sure that the values are consistent on all other devices in the network. Inconsistent mapping of table values can result in unpredictable service levels.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > QOS**.
2. Click **Mapping Tables**.
3. Click the **Egress QoS to 8021p** tab.
4. Double-click the Outleee8021P field to change the value.
5. Click **Apply**.

Egress QoS to 8021p field descriptions

Use the data in the following table to use the **Egress QoS to 8021p** tab.

Name	Description
QoSLevel	Specifies the QoS level of the outgoing packet.
Outleee8021P	Specifies the equivalent value of the IEEE 802.1p bit.

Modifying egress QoS to DSCP mappings

Modify the egress QoS to DSCP mappings to change traffic priorities. As a best practice, use the default mappings.

About This Task

Do not change the default values. If you change the values, make sure that the values are consistent on all other devices in the network. Inconsistent mapping of table values can result in unpredictable service levels.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > QOS**.
2. Click **Mapping Tables**.
3. Click the **Egress QoS To Dscp** tab.
4. Double-click the OutDscp file to change the value.
5. Click **Apply**.

Egress QoS To Dscp field descriptions

Use the data in the following table to use the **Egress QoS To Dscp** tab.

Name	Description
QoSLevel	Specifies the QoS level of the outgoing packet.
OutDscp	Specifies the equivalent value of the DiffServ code point (in decimal format).
OutDscpBinaryFormat	Specifies the equivalent value of the DiffServ code point (in binary format).

Viewing port egress CoS queue statistics

Use the following procedure to retrieve the port egress CoS queue statistics. The system displays the statistics of the forwarded packets and bytes, and the dropped packets and bytes.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > QOS**.
2. Click **CoS Queue Stats**.
3. Select the **Interface** tab.

Interface Field Descriptions

The following table describes the fields from the CoS Queue Stats **Interface** tab.

Name	Description
Index	Indicates the loopback port number from 192(1/1) to 241(1/50).
ClearStat	Clears the port egress statistics.
Que<0-7>OutPackets	Indicates the out packets by CoS queue number 0-7.
Que<0-7>OutBytes	Indicates the out bytes by CoS queue number 0-7.
Que<0-7>DropPackets	Indicates the drop packets by CoS queue number 0-7.
Que<0-7>DropBytes	Indicates the drop bytes by CoS queue number 0-7.

Clearing CPU statistics for the chassis

Use the following procedure to clear the CPU statistics for the chassis.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > QOS**.
2. Click **CoS Queue Stats**.
3. Select the **CPU-Stats-Clear** tab.
4. Select the **CpuStatsClear** check box.

5. Click **Apply**.

Viewing CPU queue statistics

Use the following procedure to retrieve the statistics of the forwarded packets and bytes, and the dropped packets and bytes for the traffic sent toward CP. The queue assignment is based on the protocol types, not on the internal CoS value. These statistics are useful for debugging purposes.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **QOS**.
2. Click **CoS Queue Stats**.
3. Select the **CPU-Port** tab.

CPU-Port Field Descriptions

Use the data in the following table to use the **CPU-Port** tab.

Name	Description
Index	Indicates the CoS queue number.
OutPackets	Indicates the out packets for the CPU port.
OutBytes	Indicates the out bytes for the CPU port.
DropPackets	Indicates the drop packets for the CPU port.
DropBytes	Indicates the drop bytes for the CPU port.

Configuring an egress QoS queue profile

Configure a queue profile to apply the configured egress queue parameters to queues and ports. You must apply the profile before the changes take effect.

About This Task

The switch supports six queue profiles. The default queue profile, with the name default and ID 1, is automatically created during system startup and cannot be deleted.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **QoS**.
2. Click **Queue Profile**.
3. Click the **Queue Profile** tab.
4. Click **Insert**.
5. In the **Id** field, type the queue profile value.
6. In the **Name** field, specify a name for the queue profile.
7. To add a port to this queue, click the **PortList** ellipsis (...), choose a port or ports, and then click **Ok**.
8. Select the **Apply** check box.
9. Click **Insert**.

Queue Profile field descriptions

Use the data in the following table to use the **Queue Profile** tab.

Field	Description
Id	Specifies the ID for the queue profile.
Name	Specifies the queue profile name.
Apply	Applies the queue profile.
PortList	Indicates the port members of the queue profile.

Editing queue profile information

About This Task

Use the following procedure to edit queues of a queue profile, to configure a queue weight or enable rate limiting on the queue.

Note

After you make the configuration changes, you must apply the queue profile before the changes take effect.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > QoS**.
2. Click **Queue Profile**.
3. Update a queue to configure queue weight or rate limiting.
 - a. Click the **Queue** tab.
 - b. Edit the **AdminWeight** and **AdminRateLimitStatus** fields by double-clicking on them, and then selecting or typing the new value.
 - c. Click **Apply**.
4. Apply the queue profile for the queue configuration to take effect.
 - a. Click the **Queue Profile** tab.
 - b. In the **Apply** field, double-click and select **true**.
 - c. Click **Apply**.
5. Click the **Queue** tab again, to verify updates to the **OperWeight** and the **OperRateLimitStatus** fields, for the respective queue.

Queue field descriptions

Use the data in the following table to use the **Queue** tab.

Field	Description
PId	Displays the queue profile ID.
Id	Displays the queue ID.

Field	Description
AdminWeight	<p>Configures the queue weight for weighted round robin (WRR), or the rate-limit in percentage of the link rate for queue shaping enabled on the queue. For rate-limit-enabled queues, 50 indicates 50% bandwidth. The overall rate-limit-enabled queues cannot sum higher than 100 min-weight. If rate-limiting is not enabled, this field configures the weight in the WRR scheduler. These values are not associated with bandwidth percentage. The following list identifies the default minimum weight for each queue:</p> <ul style="list-style-type: none"> • Queue 0 – 10 • Queue 1 – 20 • Queue 2 – 30 • Queue 3 – 40 • Queue 4 – 50 • Queue 5 – 50 • Queue 6 – Rate limited to 50% of configured shaper rate • Queue 7 – Rate limited to 5% of configured shaper rate
OperWeight	Displays the operational weight of the profile, described as a percentage.
AdminRateLimitStatus	Enables rate limiting on the queue. By default, rate limiting is enabled (true) for queues 6 and 7 only; it is disabled (false) for queues 0 through 5.
OperRateLimitStatus	Displays the operational status of the queue rate limit.

Configuring Rate Limits

About This Task

Configure the rate limit of broadcast or multicast packets to determine the total bandwidth limit on the port.

Procedure

1. On the Device Physical View, select a port or multiple ports.
2. In the navigation pane, expand the **Configuration > Edit > Port** folders.
3. Click **General**.
4. Click the **Rate Limiting** tab.
5. Configure the parameters as required.
6. Click **Apply**.

Rate Limiting *Field Descriptions*

Use the data in the following table to use the **Rate Limiting** tab.

Name	Description
Index	The port number.
TrafficType	The type of traffic being rate limited, either broadcast or multicast traffic. The default is broadcast.
AllowedRatePps	This variable is the allowed traffic rate limit for the port in packets per second. 1 to 25 configures the limit in a percentage of the total bandwidth on the port from 1-25 percent. On gigabit ports and MDAs, there can be up to a 2 percent difference between the configured and actual rate limiting values. 1-65535 configures the limit in packets for each second.
Enable	Double-click in the field and select to enable (True) or disable (False) rate limiting. The default is false.

RADIUS Fundamentals

Remote Access Dial-In User Services (RADIUS) is a distributed client/server system that assists in securing networks against unauthorized access, allowing a number of communication servers and clients to authenticate users identity through a central database. The database within the RADIUS server stores information about clients, users, passwords, and access privileges including the use of shared secret.

RADIUS is a fully open and standard protocol, defined by two Requests for Comments (RFC) (Authentication: RFC2865, Accounting: RFC2866). You use RADIUS authentication to get secure access to the system (console/Telnet/SSH/EDM), and RADIUS accounting to track the management sessions (CLI only).

RADIUS Server Support for IPv6

RADIUS supports both IPv4 and IPv6 with no differences in functionality or configuration in all but the following case. When you add or update a RADIUS server in Enterprise Device Manager (EDM) you must specify if the address type is an IPv4 or an IPv6 address.

How RADIUS Works

A RADIUS application has two components:

<ul style="list-style-type: none"> RADIUS server 	A computer equipped with server software (for example, a UNIX workstation) that is located at a central office or campus. The server has authentication and access information in a form that is compatible with the client. Typically, the database in the RADIUS server stores client information, user information, password, and access privileges, including the use of a shared secret. A network can have one server for both authentication and accounting, or one server for each service.
<ul style="list-style-type: none"> RADIUS client 	A device, router, or a remote access server, equipped with client software, that typically resides on the same local area network (LAN) segment as the server. The client is the network access point between the remote users and the server.

The two RADIUS processes are

- RADIUS authentication—Identifies remote users before you give them access to a central network site.
- RADIUS accounting—Performs data collection on the server during a remote user's dial-in session with the client.

Configuration of the RADIUS Server and Client

For more information about how to configure a RADIUS server, see the documentation that came with the server software.

The switch software supports BaySecure Access Control (BSAC) and the Merit Network servers. To use these servers, you must first obtain the software for the server you will use. Also, you must make changes to one or more configuration files for these servers.

RADIUS Authentication

You can use RADIUS authentication to use a remote server to authenticate logons. The RADIUS server also provides access authority. RADIUS assists network security and authorization by managing a database of users. The device uses this database to verify user names and passwords as well as information about the type of access priority available to the user.

When the RADIUS client sends an authentication request requesting additional information such as a SecurID number, it sends it as a challenge-response. Along with the challenge-response, it sends a reply-message attribute. The reply-message is a text string, such as `Please enter the next number on your SecurID card:`. The RFC defined maximum length of each reply-message attribute is 253 characters. If you have multiple instances of reply-message attributes that together form a large message that displays to the user, the maximum length is 2000 characters.

You can use additional user names to access the device, in addition to the six existing user names of `ro`, `L1`, `L2`, `L3`, `rw`, and `rwa`. The RADIUS server authenticates the user name and assigns one of the existing access priorities to that name. Unauthenticated user names are denied access to the device. You must add user names `ro`, `L1`, `L2`, `L3`, `rw`, and `rwa` to the RADIUS server if you enable authentication. Users not added to the server are denied access.

The limitation on the number of characters in a username for users logging into CLI or EDM configured with RADIUS authentication is 64 characters.

Note

RADIUS server used-by snmp does not support authentication.

The following list shows the user configurable options of the RADIUS feature:

- Up to 10 RADIUS servers in each device for fault tolerance (each server is assigned a priority and is contacted in that order).
- A secret key for each server to authenticate the RADIUS client
- The server UDP port

- Maximum retries allowed
- Time-out period for each attempt

**Note**

If you enable enhanced secure mode with the **boot config flags enhancedsecure-mode** command, you enable different access levels, along with stronger password complexity, length, and minimum change intervals. With enhanced secure mode enabled, the switch supports the following access levels for RADIUS authentication:

- Administrator
- Privilege
- Operator
- Auditor
- Security

The switch associates each username with a certain role and appropriate authorization rights to view and configure commands. For more information on system access fundamentals and configuration, see [System Access](#) on page 2881.

Use of RADIUS to Modify User Access to CLI Commands

The switch provides CLI command access based on the configured access level of a user. However, you can use RADIUS to override CLI command access provided by the switch.

To override user access to CLI commands, you must configure the `command-access-attribute` on the switch and on the RADIUS server. (The switch uses decimal value 194 as the default for this parameter.) On the RADIUS server, you can then define the commands that the user can or cannot access.

**Important**

When you enable RADIUS on the switch and configure a RADIUS server to be used by CLI or EDM, the server authenticates the connection, whether it is FTP, HTTPs, SSH, or TELNET. However, in the event that the RADIUS server is unresponsive or is unreachable, the switch falls back to the local authentication, so that you can access the switch using your local login credentials.

Regardless of the RADIUS server configuration, you must configure the user's access on the switch based on the six platform access levels.

RADIUS Accounting

RADIUS accounting logs all of the activity of each remote user in a session on the centralized RADIUS accounting server.

Session-IDs for each RADIUS account generate as 12-character strings. The first four characters in the string form a random number in hexadecimal format. The last eight characters in the string indicate the number of user sessions started since the last restart, in hexadecimal format.

The Network Address Server (NAS) IP address for a session is the address of the device interface to which the remote session is connected over the network. For a console session, modem session, and sessions running on debug ports, this value is set to 0.0.0.0, as is the case with RADIUS authentication.

The following table summarizes the events and associated accounting information logged at the RADIUS accounting server.

Table 176: Accounting Events and Logged Information

Event	Accounting information logged at server
Accounting is turned on at router	<ul style="list-style-type: none"> Accounting on request: NAS IP address
Accounting is turned off at router	<ul style="list-style-type: none"> Accounting off request: NAS IP address
User logs on	<ul style="list-style-type: none"> Accounting start request: NAS IP address Session ID User name
More than 40 CLI commands are executed	<ul style="list-style-type: none"> Accounting interim request: NAS IP address Session ID CLI commands User name
User logs off	<ul style="list-style-type: none"> Accounting stop request: NAS IP address Session ID Session duration User name Number of input octets for session Number of octets output for session Number of packets input for session Number of packets output for session CLI commands

When the device communicates with the RADIUS accounting server, the following actions occur:

1. If the server sends an invalid response, the response is silently discarded and the server does not make an attempt to resend the request.
2. User-specified number of attempts are made if the server does not respond within the user-configured timeout interval. If a server does not respond to any of the retries, requests are sent to the next priority server (if configured). You can configure up to 10 RADIUS servers for redundancy.

Note

RADIUS server used-by endpoint-tracking does not support accounting.

RFC 4675 RADIUS Attributes: Egress VLAN

Egress VLAN controls egress traffic. Egress VLAN supports two standard RADIUS attributes as defined in RFC 4675:

- Egress-VLANID

- Egress-VLAN-Name

RADIUS attributes control the 802.1Q tagging for traffic egressing a port where RADIUS authentication is performed for a connected EAP or NEAP client.

Egress VLANs are standard attributes, therefore the RADIUS server supports the attributes by default and offer the ability to configure the attributes. Each attribute has two parts:

1. Indicates if the frames on the VLAN egress must be tagged or untagged
2. Specifies the VLAN name or VLAN ID

The switch applies the VLAN received in the Egress-VLAN attributes to the port where the client is authenticated through RADIUS and then sets the tagging rules (tagged or untagged) accordingly.

The switch processes the Egress-VLAN attributes when decoding the RADIUS packet, therefore the switch adds the port to the VLANs first and then sets the proper tagging for the VLANs. You must create VLANs in advance on the switch.

In the MultiVlan operation mode, the EAP applies ingress hardware rules to ensure untagged traffic from each authenticated client goes into its own VLAN. The unauthenticated clients send traffic to the Guest VLAN, which matches the default VLAN ID.

For more information, see [VLAN RADIUS Attributes](#) on page 2382.

RADIUS Server Reachability

Configure up to 10 EAP RADIUS servers on the switch to manage fault tolerance. Each server is assigned a priority and is contacted in the priority order. If the first server is unavailable, the switch tries the second server, and so on, until the switch establishes a successful connection. Higher priority means lower integer value.

RADIUS server reachability prevents clients from trying to establish a connection with non reachable servers. RADIUS server reachability runs a periodic check in the background to identify the available servers. The switch is aware of the first available EAP RADIUS server without going through each of the servers and wait for time-outs.

Use RADIUS server reachability to configure the switch to use RADIUS requests to determine the reachability of the RADIUS server. The switch regularly performs the reachability test to determine if the switch should fail over to the secondary RADIUS server or activate the Fail Open VLAN, if configured on the switch.

Use one of the following modes to configure RADIUS reachability:

- status-server mode: Status-Server packets provide a standard-compliant alternative to configuring dummy RADIUS requests. You can configure the switch to send status-server packets when the keep-alive timer or the unreachable timer expires. In order to use status-server mode, the configured RADIUS servers must support RFC5997.
- use-radius mode: Configure user-radius mode if any of the RADIUS servers do not support RFC5997. In user-radius mode, the switch regularly generates a dummy RADIUS request with the username `reachme` and password `reachme`. The switch interprets either Request Accept or Request Reject responses as a confirmation for server reachability, therefore it is not necessary to add the

credentials on the server to test server reachability. You can configure the username and password for the dummy account through CLI. Use-radius is the default mode for RADIUS reachability.

You can configure the RADIUS reachability mode in either CLI or EDM.

Note

RADIUS server reachability is enabled on the switch and is not a configurable option. The reachability process starts when at least one RADIUS server used by EAP is configured, and RADIUS is enabled globally.

Based on the number of EAP RADIUS servers configured, the switch performs the following:

- If the highest priority EAP RADIUS server is reachable, the server status is updated to reachable and further authentication will use this server. As long as the highest priority EAP RADIUS server is reachable, the rest of the EAP RADIUS servers are not tested for reachability.
- If the highest priority EAP RADIUS server is not reachable, then the switch tests the rest of the EAP RADIUS servers for reachability. The servers are checked one by one for reachability based on their priority from highest to lowest. The first server that is reachable is used for authentication and the rest of the lower priority EAP RADIUS servers if any, are skipped from the reachability test.
- If all the EAP RADIUS servers are unreachable, then no further authentication occurs until the next successful reachability check.

The intervals between two consecutive reachability checks can be configured. The default values are as follows:

- one minute, if the last check result was unreachable
- three minutes, if the last check result was reachable

A server is marked as unreachable after a number of retries and time-outs. The default number of retries is 1 and the default time-out value is 8 seconds, but you can also configure these values in CLI.

RFC 3580 RADIUS Attributes: IEEE 802.1X Remote Authentication Dial In User Service

RFC 3580 provides support for EAP and NEAP clients for the following RADIUS attributes:

- Called-Station ID attribute: For IEEE 802.1X authenticators, the Called-Station ID stores the bridge or access point MAC address in upper case ASCII format, with octet values separated by a hyphen (-). For example: 00-10-A4-23-19-C0.

In IEEE 802.11, where the SSID is known, the SSID must be appended to the access point MAC address and separated from the MAC address with a colon (:). For example: 00-10-A4-23-19-C0:AP1.

- Calling-Station ID: For IEEE 802.1X authenticators, the Calling-Station ID is used to store the supplicant MAC address in upper case ASCII format, with octet values separated by a hyphen (-). For example: 00-10-A4-23-19-C0.
- NAS-Port ID: The NAS-Port ID is used to identify the IEEE 802.1X Authenticator port which authenticates the Supplicant. The NAS-Port-Id differs from the NAS-Port in that it is a string of variable length whereas the NAS-Port is a 4 octet value.

RFC 5176 — Dynamic Session Change

RFC 5176 allows you to dynamically change the following user session characteristics:

- You can disconnect an authenticated user on a port and remove all associated session context.

If the RADIUS server issues a disconnect command to the switch and the switch identifies a user (that satisfies all attributes of the RADIUS server request) on a port that has enabled RADIUS dynamic extensions commands, the switch performs the following actions:

- Notify the user of the disconnect by sending an 802.1x disconnect message to the client.
 - Remove all session context from the port.
 - Remove the port from the RADIUS-assigned VLAN, if applicable.
 - Send the disconnect response Disconnect-ACK to the RADIUS server if the user session is disconnected and all steps successfully performed.
 - Send the Disconnect-NAK response to the RADIUS server if the user session is not found or if the Network Access Server (NAS) cannot disconnect the session and discard the session context.
- You can use the Change of Authorization command to dynamically change the VLAN used by the RADIUS server.

If the RADIUS server issues a Change of Authorization command to the switch and the switch identifies a user (that satisfies all attributes of the RADIUS server request) on a port that has enabled RADIUS dynamic extensions commands, the switch performs the following actions:

- If the Change of Authorization command specifies a valid VLAN ID for a port, the port is removed from the VLAN specified by RADIUS and added to the VLAN specified in the request.
 - A CoA-ACK response is sent to the RADIUS server.
 - If the user session is not found or an error is encountered in processing the Change of Authorization command, then a CoA-NAK response is sent to the RADIUS server.
 - If the Change of Authorization request specifies a VLAN that is not port-based, a CoA-NAK response is sent to the RADIUS server.
- You can dynamically initiate client re-authentication.

Re-authenticate requests can be made with Change of Authorization or Disconnect packet IDs, but they must have the Re-authentication Request Vendor-Specific Attributes (VSA) set to True.

Dynamic session changes are directed to specific user sessions, as identified by RADIUS attributes.

To enable dynamic session changes, configure the following:

- You must enable EAP or Endpoint Tracking globally and at the port level.
- You must enable RADIUS dynamic extensions commands at the port level.

You can use the **show radius dynamic-server statistics** command to view statistics about dynamic session changes.

```
Switch:1#enable
Switch:1#show radius dynamic-server statistics

=====
                        RADIUS Dynamic Authorization Global Statistics

-----
```

RADSec

Remote Access Dial-In User Services (RADIUS) Security (RADSec) provides secure communication between RADIUS peers using Transport Layer Security (TLS) encryption over Transmission Control Protocol (TCP), or Datagram Transport Layer Security (DTLS) encryption over User Datagram Protocol (UDP).

RADSec peers use certificates to establish trust relationships. Certificates are specified in the RADSec profile on the switch, which can be the default profile or a profile that you configure. You must configure the client and secure server with the same certificate authority (CA) certificate file, server certificate, certificate key file and password to establish a RADSec connection. The password is used for packet encryption and decryption.

You can configure the RADSec security mode to use TLS protocol or DTLS protocol. Both TLS and DTLS modes support IPv4 addresses, but IPv6 addresses are supported only by TLS mode.

RADSec uses radsecproxy to encrypt packets sent between RADIUS clients and a secure server. A radsecproxy process starts when radius and secure-mode are enabled both globally and for the current server. Radsecproxy uses multiple instances on the switch, one for each one for each security-configured RADIUS server. The maximum number of radsecproxy instances is 10, which is equivalent to the maximum number of radius servers you can configure on the switch.

Note

You must use radsecproxy version 1.8.1 or later. Using an earlier version of radsecproxy can result in authentication failures.

The following events cause all radsecproxy processes to restart:

- A Segmented Management Instance interface is deleted, enabled, or disabled.
- An IPv4 address or route is changed.
- An IPv6 address or route is changed.
- RADIUS global enable and secure-enable change.

The following changes only affect a radsecproxy instance and result only in the associated process restarting:

- Enabling or disabling the RADIUS server state or secure state.
- Modifying the RADIUS server secure mode, associated profile, or secure log level.

A RADSec profile configuration change causes all processes associated with the profile to restart.

A RADSec process automatically stops when the corresponding RADIUS server entry is deleted, or if RADIUS or secure mode is disabled for the server.

If one of the global radius flags (radius state, radius secure state) is disabled, all radsecproxy instances stop.

RADIUS configuration using CLI

You can configure Remote Access Dial-In User Services (RADIUS) to secure networks against unauthorized access, and allow communication servers and clients to authenticate users identity through a central database.

The database within the RADIUS server stores client information, user information, password, and access privileges, including the use of shared secret.

RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration using CLI.

RADIUS is a fully open and standard protocol, defined by RFCs (Authentication: RFC2865, accounting RFC2866). With the switch, you use RADIUS authentication to secure access to the device (console/Telnet/SSH), and RADIUS accounting to track the management sessions for Command Line Interface (CLI) only.

RADIUS authentication allows the remote server to authenticate logons. RADIUS accounting logs all of the activity of each remote user in a session on the centralized RADIUS accounting server.

Configure RADIUS Attributes

Configure RADIUS to authenticate user identity through a central database.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Configure RADIUS access priority:
`radius access-priority-attribute <192-240>`
3. Configure RADIUS accounting:
`radius accounting {attribute-value <192-240>|enable|include-cli-commands}`
4. Configure the RADIUS authentication info attribute value:
`radius auth-info-attr-value <0-255>`
5. Clear RADIUS statistics:
`radius clear-stat`
6. Configure the value of the CLI commands:
`radius cli-commands-attribute <192-240>`
7. Configure the value of the command access attribute:
`radius command-access-attribute <192-240>`
8. Configure the maximum number of servers allowed:
`radius maxserver <1-10>`
9. Configure the multicast address attribute:
`radius mcast-addr-attr-value <0-255>`

10. Enable RADSec globally:

```
radius secure-flag
```

11. Configure the RADSec profile:

```
radius secure-profile WORD<1-16> [ca-cert-file | cert-file | key-file  
| key-pwd]
```

Example

```
Switch:1>enable  
Switch:1#configure terminal
```

Configure RADIUS access priority:

```
Switch:1(config)#radius access-priority-attribute 192
```

Configure RADIUS accounting to include CLI commands:

```
Switch:1(config)#radius accounting include-cli-commands
```

Variable Definitions

The following table defines parameters for the **radius** command.

Variable	Value
<i>access-priority-attribute</i> <192-240>	Specifies the value of the access priority attribute in the range of 192 to 240. The default is 192.
<i>accounting</i> { <i>attribute-value</i> <192-240> <i>enable</i> <i>include-cli-commands</i> }	Configures the accounting attribute value, enable accounting, or configure if accounting includes CLI commands. The default is false. Use the no option to disable the accounting attribute value: no radius accounting enable .
<i>auth-info-attr-value</i> <0-255>	Specifies the value of the authentication information attribute in the range of 0 to 255. The default is 91.
<i>clear-stat</i>	Clears RADIUS statistics.
<i>cli-cmd-count</i> <1-40>	Specifies how many CLI commands, from 1 to 40, before the system sends a RADIUS accounting interim request. The default value is 40.
<i>cli-commands-attribute</i> <192-240>	Specifies the value of CLI commands attribute in the range of 192 to 240. The default is 195.
<i>cli-profile</i>	Enable RADIUS CLI profiling. CLI profiling grants or denies access to users being authenticated by way of the RADIUS server. You can add a set of CLI commands to the configuration on the RADIUS server, and you can specify the command-access more for these commands. The default is false.
<i>command-access-attribute</i> <192-240>	Specifies the value of the command access attribute in the range of 192 to 240. The default is 194.
<i>enable</i>	Enable RADIUS authentication globally on the switch.
<i>maxserver</i> <1-10>	Specific to RADIUS authentication, configures the maximum number of servers allowed for the device. The range is between 1 and 10. The default is 10.

Variable	Value
<i>mcast-addr-attr-value</i> <0-255>	Specifies the value of the multicast address attribute in the range of 0 to 255. The default is 90.
<i>secure-flag</i>	Specifies whether RADIUS Security (RADSec) is globally enabled. The default is disabled.

Variable	Value
<i>secure-profile</i>	Specifies the RADSec profile name.
<i>server host WORD<0-46> key WORD<0-32> [used-by {cli snmp web} [acct-enable] [acct-port <1-65536>] [enable] [port <1-65536>] [priority <1-10>] [retry <0-6>secure-enablesecure-log-level {critical debug error info warning}secure-mode{dtls tls}secure-profileWORD<1-16>] [timeout <1-60>]</i>	<ul style="list-style-type: none"> • <i>host WORD<0-46></i> Creates a host server. WORD<0-46> signifies an IP address. • <i>key WORD<0-32></i> Specifies a secret key in the range of 0-32 characters. • <i>used-by {cli eapol endpoint-tracking snmp web}</i> Specifies how the server functions. Configures the server for: <ul style="list-style-type: none"> ◦ cli authentication ◦ eapol authentication ◦ endpoint-tracking authentication ◦ snmp accounting ◦ web authentication • <i>acct-enable</i> Enables RADIUS accounting on this server. The system enables RADIUS accounting by default. • <i>acct-port <1-65536></i> Specifies a UDP port of the RADIUS accounting server (1 to 65536). The default value is 1816. The UDP port value set for the client must match the UDP value set for the RADIUS server. • <i>enable</i> Enables the server. The default is true. • <i>port <1-65536></i> Specifies a UDP port of the RADIUS server. The default value is 1812. • <i>priority <1-10></i> Specifies the priority value for this server. The default is 10. • <i>retry <0-6></i> Specifies the maximum number of authentication retries. The default is 3. • <i>secure-enable</i> Enable secure mode on the server. • <i>secure-log-level {critical debug error info warning}</i> Specifies the RADIUS secure server log severity level. • <i>secure-mode {dtls tls}</i>

Variable	Value
	<p>Specifies the protocol for establishing the secure connection with the server. IPv4 supports both dtls and tls modes. IPv6 only supports tls mode.</p> <ul style="list-style-type: none"> <code>secure-profileWORD<1-16></code> <p>Specifies the secure profile name.</p> <ul style="list-style-type: none"> <code>timeout <1-60></code> <p>Specifies the number of seconds before the authentication request times out. The default is 3.</p>

Configuring RADIUS profile

Use RADIUS CLI profiling to grant or deny CLI command access to users being authenticated by way of the RADIUS server. You can add a set of CLI commands to the configuration file on the radius server, and you can specify the command-access mode for these commands. The default is false.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable RADIUS CLI profiling:

```
radius cli-profile
```

Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# radius cli-profile
```

Enabling RADIUS authentication

About This Task

Enable or disable RADIUS authentication globally on the device to allow further configuration to take place. Use the no option to disable RADIUS authentication globally. The default is false or disabled.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable RADIUS authentication globally on the switch:

```
radius enable
```

Enabling RADIUS accounting

Before You Begin

- You must configure a RADIUS server before you can enable RADIUS accounting.

About This Task

Enable Remote Access Dial-in User Services (RADIUS) accounting to log all of the activity of each remote user in a session on the centralized RADIUS accounting server.

Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
- Enable RADIUS accounting globally:

```
radius accounting enable
```
- Include or exclude CLI commands in RADIUS accounting updates:

```
radius accounting include-cli-commands
```
- Specify the integer value of the CLI commands attribute:

```
radius accounting attribute-value <192-240>
```

Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# radius accounting enable
Switch:1(config)# radius accounting include-cli-commands
```

Variable Definitions

The following table defines parameters for the **radius accounting** command.

Variable	Value
<i>enable</i>	Enable RADIUS globally.
<i>include-cli-commands</i>	Include CLI commands in RADIUS accounting updates.
<i>attribute-value</i> <192-240>	Specify the integer value of the CLI commands attribute.

Enabling RADIUS-SNMP accounting

Before You Begin

- You must configure a RADIUS server before you can enable RADIUS-SNMP accounting.

About This Task

Enable Remote Access Dial-in User Services (RADIUS) Simple Network Managing Protocol (SNMP) accounting globally. Use SNMP to remotely collect management data. An SNMP agent is a software process that monitors the UDP port 161 for SNMP messages. Each SNMP message sent to the agent contains a list of management objects.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable RADIUS Simple Network Management Protocol (SNMP) accounting globally:

```
radius-snmp acct-enable
```
3. Set a timer to send a stop accounting message for RADIUS Simple Network Management Protocol (SNMP):

```
radius-snmp abort-session-timer <30-65535>
```
4. Set the timer for re-authentication of the SNMP session:

```
radius-snmp re-auth-timer <30-65535>
```
5. Specify the user name for SNMP access:

```
radius-snmp user WORD <0-20>
```

Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# radius-snmp acct-enable
Switch:1(config)# radius-snmp abort-session-timer 30
```

Variable Definitions

The following table defines parameters for the **radius-snmp** command.

Variable	Value
<i>acct-enable</i>	Enables RADIUS accounting globally. You cannot enable RADIUS accounting before you configure a valid server. The system disables RADIUS accounting by default. The default is false. Use the no option to disable RADIUS accounting globally: no radius-snmp acct-enable
<i>abort-session-timer</i> <30-65535>	Set the timer, in seconds, to send a stop accounting message. The default is 180.
<i>re-auth-timer</i> <30-65535>	Sets timer for re-authentication of the SNMP session. The timer value ranges from 30 to 65535 seconds. The default is 180.
<i>user</i> WORD <0-20>	Specifies the user name for SNMP access. WORD <0-20> specifies the user name in a range of 0 to 20 characters. The default is snmp_user.

Configuring RADIUS accounting interim request

About This Task

Configure RADIUS accounting interim requests to create a log whenever a user executes more than the number of CLI commands you specify.

If the packet size equals or exceeds 1.8 KB, an interim request packet is sent even if the configured limit is not reached. Therefore, the trigger to send out the interim request is either the configured value or a packet size greater than, or equal to 1.8 KB, whichever happens first.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure RADIUS accounting interim requests:

```
radius cli-cmd-count <1-40>
```
3. Include or exclude CLI commands in RADIUS accounting:

```
radius accounting include-cli-commands
```

Important

You must configure the **radius accounting include-cli-commands** command for accounting interim requests to function.

Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# radius cli-cmd-count 30
Switch:1(config)# radius accounting include-cli-commands
```

Variable Definitions

The following table defines parameters for the **radius cli-cmd-count** command.

Variable	Value
<1-40>	Specifies how many CLI commands, from 1 to 40, before the system sends a RADIUS accounting interim request. The default value is 40.

Configure RADIUS Authentication and RADIUS Accounting Attributes

About This Task

Configure RADIUS authentication and RADIUS accounting attributes to determine the size of the packets received.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure the RADIUS authentication attribute value:

```
radius command-access-attribute <192-240>
```
3. Configure the RADIUS accounting attribute value:

```
radius accounting attribute-value <192-240>
```

Example

```
Switch:1>enable
Switch:1#configure terminal
```

```
Switch:1(config)#radius command-access-attribute 192
Switch:1(config)#radius accounting attribute-value 192
```

Variable Definitions

The following table defines parameters for the **radius** command.

Variable	Value
<code>access-priority-attribute <192-240></code>	Specifies the value of the access priority attribute in the range of 192 to 240. The default is 192.
<code>accounting {attribute-value <192-240> enable include-cli-commands}</code>	Configures the accounting attribute value, enable accounting, or configure if accounting includes CLI commands. The default is false. Use the no option to disable the accounting attribute value: no radius accounting enable .
<code>auth-info-attr-value <0-255></code>	Specifies the value of the authentication information attribute in the range of 0 to 255. The default is 91.
<code>clear-stat</code>	Clears RADIUS statistics.
<code>cli-cmd-count <1-40></code>	Specifies how many CLI commands, from 1 to 40, before the system sends a RADIUS accounting interim request. The default value is 40.
<code>cli-commands-attribute <192-240></code>	Specifies the value of CLI commands attribute in the range of 192 to 240. The default is 195.
<code>cli-profile</code>	Enable RADIUS CLI profiling. CLI profiling grants or denies access to users being authenticated by way of the RADIUS server. You can add a set of CLI commands to the configuration on the RADIUS server, and you can specify the command-access more for these commands. The default is false.
<code>command-access-attribute <192-240></code>	Specifies the value of the command access attribute in the range of 192 to 240. The default is 194.
<code>enable</code>	Enable RADIUS authentication globally on the switch.
<code>maxserver <1-10></code>	Specific to RADIUS authentication, configures the maximum number of servers allowed for the device. The range is between 1 and 10. The default is 10.
<code>mcast-addr-attr-value <0-255></code>	Specifies the value of the multicast address attribute in the range of 0 to 255. The default is 90.
<code>secure-flag</code>	Specifies whether RADIUS Security (RADSec) is globally enabled. The default is disabled.

Variable	Value
<i>secure-profile</i>	Specifies the RADSec profile name.
<pre>server host WORD<0-46> key WORD<0-32> [used-by {cli snmp web} [acct-enable] [acct-port <1-65536>] [enable] [port <1-65536>] [priority <1-10>] [retry <0- 6>secure-enablesecure-log- level {critical debug error info warning}secure-mode{dtls tls}secure- profileWORD<1-16>] [timeout <1-60>]</pre>	<ul style="list-style-type: none"> • <i>host WORD<0-46></i> Creates a host server. WORD<0-46> signifies an IP address. • <i>key WORD<0-32></i> Specifies a secret key in the range of 0-32 characters. • <i>used-by {cli eapol endpoint-tracking snmp web}</i> Specifies how the server functions. Configures the server for: <ul style="list-style-type: none"> ◦ cli authentication ◦ eapol authentication ◦ endpoint-tracking authentication ◦ snmp accounting ◦ web authentication • <i>acct-enable</i> Enables RADIUS accounting on this server. The system enables RADIUS accounting by default. • <i>acct-port <1-65536></i> Specifies a UDP port of the RADIUS accounting server (1 to 65536). The default value is 1816. The UDP port value set for the client must match the UDP value set for the RADIUS server. • <i>enable</i> Enables the server. The default is true. • <i>port <1-65536></i> Specifies a UDP port of the RADIUS server. The default value is 1812. • <i>priority <1-10></i> Specifies the priority value for this server. The default is 10. • <i>retry <0-6></i> Specifies the maximum number of authentication retries. The default is 3. • <i>secure-enable</i> Enable secure mode on the server. • <i>secure-log-level {critical debug error info warning}</i> Specifies the RADIUS secure server log severity level. • <i>secure-mode {dtls tls}</i>

Variable	Value
	<p>Specifies the protocol for establishing the secure connection with the server. IPv4 supports both dtls and tls modes. IPv6 only supports tls mode.</p> <ul style="list-style-type: none"> <code>secure-profileWORD<1-16></code> <p>Specifies the secure profile name.</p> <ul style="list-style-type: none"> <code>timeout <1-60></code> <p>Specifies the number of seconds before the authentication request times out. The default is 3.</p>

Add a RADIUS Server

About This Task

Add a RADIUS server to provide RADIUS service on the switch.

RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration using CLI.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Add a RADIUS server:

```
radius server host WORD <0-46> key WORD<0-32> [used-by {cli|eapol|
endpoint-tracking|snmp|web}] [acct-enable][acct-port <1-65536>]
[enable] [port <1-65536>][priority <1-10>][retry <0-6>] [secure-
enable] [secure-log-level] [secure-mode] [secure-profile] [timeout
<1-60>]
```

Example

Add a RADIUS server:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#radius server host 4717:0000:0000:0000:0000:7933:0001 key testkey1
used-by snmp port 12 retry 5 timeout 10 enable
```

Variable Definitions

The following table defines parameters for the **radius server host** command.

Variable	Value
<i>used-by {cli eapol endpoint-tracking snmp web}</i>	<p>Configures how the server functions:</p> <ul style="list-style-type: none"> cli—configure the server for CLI authentication. eapol—configure the server for EAPoL authentication. endpoint-tracking—configure the server for Endpoint Tracking authentication. snmp—configure the server for SNMP accounting. web—configure the server for HTTP(s) authentication. <p>Use the no option to remove a host server: no radius server host WORD<0-46> used-by {cli eapol endpoint-tracking snmp web}. The default is cli. The default command is: default radius server host WORD<0-46> used-by {cli eapol endpoint-tracking snmp web}.</p>
<i>host WORD <0-46></i>	Configures a host server. WORD <0-46> signifies an IPv4 address in the format A.B.C.D or an IPv6 address in the format x:x:x:x:x:x. RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration using CLI.
<i>acct-enable</i>	Enables RADIUS accounting on this server. The system enables RADIUS accounting by default.
<i>acct-port <1-65536></i>	<p>Configures the UDP port of the RADIUS accounting server (1 to 65536). The default value is 1813.</p> <p>Important: The UDP port value set for the client must match the UDP value set for the RADIUS server.</p>
<i>enable</i>	Enables the RADIUS server. The default is true.
<i>key WORD<0-32></i>	Configures the secret key of the authentication client.
<i>port <1-65536></i>	Configures the UDP port of the RADIUS authentication server. The default value is 1812.
<i>priority <1-10></i>	Configures the priority value for this server. The default is 10.
<i>retry <0-6></i>	Configures the number of authentication retries the server will accept. The default is 3.
<i>secure-enable</i>	Enable RADIUS Security (RADSec).
<i>secure-log-level</i>	<p>Specifies the log severity level. Possible values are :</p> <ul style="list-style-type: none"> critical debug error info warning
<i>secure-mode</i>	Specifies the protocol used for secure connection to the server.
<i>secure-profile</i>	Configures the secure profile for the server.
<i>timeout <1-180></i>	Configures the number of seconds before the authentication request times out. The default is 8.

Modify RADIUS Server Settings

About This Task

Change a specified RADIUS server value without having to delete the server and recreate it again.

RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration using CLI.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Modify a RADIUS server:

```
radius server host WORD <0-46> used-by {cli|eapol|endpoint-tracking|
snmp|web} [key WORD<0-32>] [port 1-65536] [priority <1-10>] [retry
<0-6>] [timeout <1-180>] [enable] [acct-port <1-65536>] [acct-enable]
```

Example

Modify a RADIUS server:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#radius server host 4717:0000:0000:0000:0000:0000:7933:0001 used-by snmp
port 12 retry 5 timeout 10 enable
```

Variable Definitions

The following table defines parameters for the **radius server host** command.

Variable	Value
<i>used-by</i> {cli eapol endpoint-tracking snmp web}	<p>Configures how the server functions:</p> <ul style="list-style-type: none"> • cli—configure the server for CLI authentication. • eapol—configure the server for EAPoL authentication. • endpoint-tracking—configure the server for Endpoint Tracking authentication. • snmp—configure the server for SNMP accounting. • web—configure the server for HTTP(s) authentication. <p>Use the no option to remove a host server: no radius server host WORD<0-46> used-by {cli eapol endpoint-tracking snmp web}. The default is cli. The default command is: default radius server host WORD<0-46> used-by {cli eapol endpoint-tracking snmp web}.</p>
<i>host</i> WORD <0-46>	<p>Configures a host server. WORD <0-46> signifies an IPv4 address in the format A.B.C.D or an IPv6 address in the format x:x:x:x:x:x. RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration using CLI.</p>

Variable	Value
<i>acct-enable</i>	Enables RADIUS accounting on this server. The system enables RADIUS accounting by default.
<i>acct-port</i> <1-65536>	Configures the UDP port of the RADIUS accounting server (1 to 65536). The default value is 1813. Important: The UDP port value set for the client must match the UDP value set for the RADIUS server.
<i>enable</i>	Enables the RADIUS server. The default is true.
<i>key</i> WORD<0-32>	Configures the secret key of the authentication client.
<i>port</i> <1-65536>	Configures the UDP port of the RADIUS authentication server. The default value is 1812.
<i>priority</i> <1-10>	Configures the priority value for this server. The default is 10.
<i>retry</i> <0-6>	Configures the number of authentication retries the server will accept. The default is 3.
<i>secure-enable</i>	Enable RADIUS Security (RADSec).
<i>secure-log-level</i>	Specifies the log severity level. Possible values are : <ul style="list-style-type: none"> critical debug error info warning
<i>secure-mode</i>	Specifies the protocol used for secure connection to the server.
<i>secure-profile</i>	Configures the secure profile for the server.
<i>timeout</i> <1-180>	Configures the number of seconds before the authentication request times out. The default is 8.

View RADIUS Information

View the global status of RADIUS information to ensure you configured the RADIUS feature according to the needs of the network.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View the global status of RADIUS information:

```
show radius
```

Example

```
Switch:1>show radius
  acct-attribute-value : 193
      acct-enable      : false
  acct-include-cli-commands : false
  access-priority-attribute : 192
      auth-info-attr-value : 91
```

```

command-access-attribute : 194
cli-commands-attribute : 195
  cli-cmd-count : 40
  cli-profile-enable : false
    enable : false
  igap-passwd-attr : standard
igap-timeout-log-fsize : 512
  maxserver : 10
mcast-addr-attr-value : 90
  sourceip-flag : false
supported-vendor-ids : 1584, 562, 1916
  secure-flag : false

```

View RADIUS Server Information

If your system is configured with a RADIUS server you can display the RADIUS server information.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. To view the RADIUS server information enter the following command:

```
show radius-server
```

Note

If no RADIUS server is configured, the system displays the following message:
no RADIUS server configured

Example

```

=====
                        Radius Server Entries
=====

```

NAME	USED BY	SECRET	PORT	PRI	RETRY	TIMEOUT	ENABLED	SECURE ENABLED	SECURE MODE	SECURE INSTANCE	SECURE PROFILE	SECURE LOG-LEVEL	ACCT PORT	ACCT ENABLED

192.0.2.14	cli	*****	1812	10	1	8	true	true	tls	0	radsecp	error	1813	true
192.0.2.15	cli	*****	1812	10	1	8	true	false	tls	-1	default	error	1813	true

Showing RADIUS Server Statistics

About This Task

You cannot collect the following network statistics from a console port: the number of input and output packets, and the number of input and output bytes. All other statistics from console ports are available to assist with debugging.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display RADIUS server statistics:
show radius-server statistics

3. Clear server statistics:

```
clear radius statistics
```

Example

```
Switch:1#show radius-server statistics
```

```
Responses with invalid server address: 0
```

```
Radius Server(UsedBy) : 192.0.2.58 (cli)
```

```
-----  
Access Requests : 52  
Access Accepts : 0  
Access Rejects : 0  
Bad Responses : 52  
Client Retries : 52

Nas Ip Address : 192.0.2.32
```

```
--More-- (q = quit)
```

Configuring RADIUS server reachability

About This Task

Use this procedure to configure the RADIUS server reachability settings.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure the RADIUS keep-alive timer:

```
radius reachability keep-alive-timer <30-600>
```
3. Configure the RADIUS reachability mode:

```
radius reachability mode <status-server | use-radius>
```
4. If you selected `use-radius` as the RADIUS reachability mode, configure the RADIUS request username and password:

```
radius reachability username WORD<1-16> password WORD<1-16>
```
5. Configure the RADIUS reachability unreachable timer:

```
radius reachability unreachable-timer <30-600>
```

Example

Configure values for RADIUS server reachability:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
```

Configure the RADIUS keep-alive timer:

```
Switch:1(config)#radius reachability keep-alive-timer 30
```

Configure the RADIUS reachability mode:

```
Switch:1(config)#radius reachability mode status-server
```

Configure the RADIUS reachability unreachable timer:

```
Switch:1(config)#radius reachability unreachable-timer 30
```

Variable Definitions

The following table defines parameters for the **radius reachability** command.

Variable	Value
keep-alive-timer <30-600>	Specifies, in seconds, the interval between checks when radius server is reachable. The default is 180 seconds.
mode <status-server use-radius>	Specifies status-server mode or use-radius mode. Status-server mode provides a standard-compliant method for RADIUS reachability. Use-radius mode requires the configuration of dummy packets that are sent to RADIUS servers. The default is use-radius mode.
password WORD<1-16>	Configures the RADIUS request password. The default is extremenetworks.

Variable	Value
unreachable-timer <30-600>	Specifies, in seconds, the interval between checks when radius server is unreachable. The default is 60 seconds.
username <i>WORD</i> <1-16>	Configures the RADIUS request username. The default is extremenetworks.

Displaying RADIUS server reachability

About This Task

Use this procedure to display the RADIUS server reachability settings.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the RADIUS server reachability settings:

```
show radius reachability
```

Example

Display the RADIUS server reachability settings.

```
Switch:1#show radius reachability
EAP RADIUS reachability mode      : use-radius
EAP RADIUS reachability status    : RADIUS is disabled globally
EAP RADIUS reachable server       : none
Time until next check             : N/A
RADIUS username                   : reachme
RADIUS password                   : reachme
RADIUS keep-alive-timer           : 180
RADIUS unreachable-timer          : 60
```

Showing RADIUS SNMP configurations

Display current RADIUS SNMP configurations.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the current RADIUS server SNMP configurations:

```
show radius snmp
```

Example

```
Switch:1>show radius snmp
abort-session-timer : 180
acct-enable         : false
user                : snmp_user
enable              : false
re-auth-timer      : 180
```

Displaying RADIUS dynamic server information

About This Task

Use the following procedure to display information about the configuration of RADIUS dynamic session changes.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about dynamic change configuration:

```
show radius dynamic-server [client | statistics]
```

Example

```
Switch:1#show radius dynamic-server
```

```
=====
                        RADIUS Dynamic Authorization General Info
=====
CLIENT                UDP        CLIENT    SECRET
ADDRESS               PORT      ENABLED   KEY
-----
192.0.2.15            1026     Disabled *****
192.0.2.16            1027     Disabled *****
-----

All 2 out of 2 Total Num of RADIUS Dynamic Authorization clients displayed
```

Display dynamic server statistics:

```
Switch:1#show radius dynamic-server statistics
```

```
=====
                        RADIUS Dynamic Authorization Global Statistics
=====
Disconnects From Invalid Client Addresses:    0
CoAs From Invalid Client Addresses:           0
-----
```

Variable Definitions

The following table defines parameters for the **show radius dynamic-server** command.

Variable	Value
client WORD<0-46>	Display RADIUS Dynamic Authorization configuration values for the specified client.
statistics	Display statistics for RADIUS Dynamic Authorization clients.

Configuring a RADIUS dynamic-server client

About This Task

Configure a client to allow processing of dynamic session changes.

Before You Begin

You must enable EAPOL globally and at the port level.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure values for client IP address, port, and secret key:

```
Switch:1(config)#radius dynamic-server client WORD<0-46> port
<1024-65535> secret WORD<0-32> enable
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#radius dynamic-server client 192.0.2.15 port 1025 secret 123 enable
```

Variable Definitions

The following table defines parameters for the **radius dynamic-server** command.

Variable	Value
client WORD<0-46>	Specifies the client address.
enable	Enable processing of dynamic session changes.
port <1024-65535>	Specifies the port value.
secret WORD<0-32>	Specifies a value for secret key.

RADSec Configuration Using CLI

This section contains procedures for configuring RADSec using Command Line Interface (CLI).

Create and Configure a RADIUS Secure Profile

You configure RADIUS secure profiles with certificate information, certificate key information, and password information, which enables RADSec peers to establish connections.

About This Task

Note

- All the files (certificates and keys) must be in .pem format and copy it to flash /intflash directory.
- A new profile directory is created for each new profile in the flash/intflash/.radsec/profile/radsec directory.
- Profile configuration file “profile_info.cfg” is available in /intflash/.radsec/profile directory.
- You can configure a maximum of 10 RADSec profiles.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure a name for the RADIUS profile:

```
radius secure-profile WORD<1-16>
```

3. Configure the full file path of the certificate authority (CA) certificate for the RADIUS secure profile:

```
radius secure-profile WORD<1-16> CA-cert-file WORD<0-128>
[WORD<1-128>]
```

4. Configure the full path of the server certificate for the RADIUS secure profile:

```
radius secure-profile WORD<1-16> cert-file WORD<0-128> [WORD<1-128>]
```

5. Configure the full path of the private key file for the RADIUS secure profile:

```
radius secure-profile WORD<1-16> key-file WORD<0-128> [WORD<1-128>]
```

6. Configure the private key password for the RADIUS secure profile:

```
radius secure-profile WORD<1-16> key-pwd WORD<0-255>
```

Variable Definitions

The following table defines parameters for the **radius secure-profile** command.

Variable	Value
WORD<1-16>	Specifies the RADIUS secure profile name.
CA-cert-file WORD<0-128>	Specifies the full file path of the certificate authority (CA) certificate.
cert-file WORD<0-128>	Specifies the full file path of the server certificate.
key-file WORD<0-128>	Specifies the full file path of the private key file.
WORD<1-128>	Specifies the file name.
key-pwd WORD<0-255>	Specifies the private key password.

Display RADIUS Secure Profile information

About This Task

Use the following procedure to display information about the configuration of RADIUS secure profiles.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. Display information about RADIUS secure profile configuration:
`show radius secure-profile`

Example

```
Switch:1>enable
Switch:1#show radius secure-profile
```

```
=====
                        Secure RADIUS profile
=====
Profile default:
  Name : default
  RootCert : n/a
  Cert : n/a
  Key : n/a
  Password : *****
```

Associate a RADSec Profile with a RADIUS Server

Before You Begin

Add a RADIUS Server. For more information, see [Add a RADIUS Server](#) on page 2341.

About This Task

RADSec peers use certificates to establish trust relationships. You must associate a RADSec profile with a RADIUS server in order to use certificates.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Associate a RADSec profile with a RADIUS server:
`radius server host WORD<0-46> used-by {cli | eapol | endpoint-tracking
| snmp | web} secure-profile WORD<1-16>`

Variable Definitions

The following table defines parameters for the **radius server host** command.

Variable	Value
WORD<0-46>	Specifies the IPv4 address or the IPv6 address of the RADIUS server.
used-by	Specifies how the server functions. Configures the server for one of the following: <ul style="list-style-type: none"> cli authentication eapol authentication endpoint-tracking authentication snmp accounting web authentication
secure-enable	Enables RADSec on the RADIUS server.

Configure RADSec Secure Mode

About This Task

Configure the secure mode for RADSec as either Transport Layer Security (TLS) protocol or Datagram Transport Layer Security (DTLS) protocol.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the secure mode:

```
radius server host WORD<0-46> used-by {cli | eapol | endpoint-tracking
| snmp | web} secure-mode {tls | dtls}
```

Variable Definitions

The following table defines parameters for the **radius server host** command.

Variable	Value
<i>WORD<0-46></i>	Specifies the IPv4 address or the IPv6 address.
<i>used-by</i>	Specifies how the server functions. Configures the server for one of the following: <ul style="list-style-type: none"> cli authentication eapol authentication endpoint-tracking authentication snmp accounting web authentication
<i>secure-mode</i>	Specifies the RADSec security mode. Possible values are: <ul style="list-style-type: none"> tls - Transport Layer Security (TLS) encryption over Transmission Control Protocol (TCP) dtls - Datagram Transport Layer Security (DTLS) encryption over User Datagram Protocol (UDP) <p>The default is tls.</p>

Enable RADSec

About This Task

You must enable RADSec globally and at the RADIUS server level in order for RADSec to be enabled for a RADIUS server.

Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Enable RADSec globally:

```
radius secure-flag
```
- Enable RADSec on the RADIUS server:

```
radius server host WORD<0-46> used-by {cli | eapol | endpoint-tracking
| snmp | web} secure-enable
```

Change the logging level for RADSec secure profile

About This Task

Use the following procedure to change the logging level for a RADSec secure profile.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Change the logging level of the RADIUS secure profile:

```
radius server host WORD<0-46> used-by cli secure-log-level debug
```

Variable Definitions

The following table defines parameters for the **radius server host WORD<0-46> used-by cli secure-log-level debug** command.

Variable	Value
<i>WORD<0-46></i>	Specifies the IPv4 address or the IPv6 address.

Display Log Information for Secure RADIUS Instance

About This Task

Use the following procedure to display log information for secure instance of RADIUS.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Display log information for a secure instance of RADIUS:

```
show radius secure-server log <0-9>.
```

Variable Definitions

The following table defines parameters for the **show radius secure-server** command.

Variable	Value
<i>log<0-9></i>	Specifies the log for a secure RADIUS instance.

RADIUS configuration using Enterprise Device Manager

You can configure Remote Access Dial-In User Services (RADIUS) to assist in securing networks against unauthorized access, and allow communication servers and clients to authenticate the identity of users through a central database.

The database within the RADIUS server stores client information, user information, password, and access privileges, including the use of shared secret.

RADIUS supports IPv4 and IPv6 addresses with no difference in functionality or configuration in all but the following case. When adding a RADIUS server in Enterprise Device Manager (EDM) or modifying a RADIUS configuration in EDM, you must specify if the address type is an IPv4 or an IPv6 address.

RADIUS is a fully open and standard protocol, defined by RFCs (Authentication: RFC2865, accounting RFC2866). With the switch, you use RADIUS authentication to secure access to the device (console/Telnet/SSH), and RADIUS accounting to track the management sessions for Command Line Interface (CLI) only.

RADIUS authentication allows the remote server to authenticate logons. RADIUS accounting logs all of the activity of each remote user in a session on the centralized RADIUS accounting server.

Enable RADIUS Authentication

About This Task

Enable RADIUS authentication globally to allow all features and functions of RADIUS to operate with the RADIUS server.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **RADIUS**.
3. Select the **RADIUS Global** tab.
4. Select **Enable**.
5. In the **MaxNumberServer** field, type a value for the maximum number of servers.
6. In the **AccessPriorityAttrValue** field, type an access policy value (by default, this value is 192).
7. Configure the rest of the parameters in the RADIUS global tab.
8. Select **Apply**.

RADIUS Global Field Descriptions

Use the data in the following table to use the **RADIUS Global** tab.

Name	Description
Enable	Enables the RADIUS authentication feature globally.
MaxNumberServer	Specifies the maximum number of servers to be used, between 1 and 10, inclusive.
AccessPriorityAttrValue	Specific to RADIUS authentication. Specifies the vendor-specific attribute value of the access-priority attribute to match the type value set in the dictionary file on the RADIUS server. The valid values are 192 through 240. The default is 192.
AcctEnable	Enables RADIUS accounting.
AcctAttrValue	Specific to RADIUS accounting. Specifies the vendor-specific attribute value of the CLI-command attribute to match the type value set in the dictionary file on the RADIUS server. This value must be different from the access-priority attribute value configured for authentication. The valid values are 192 through 240. The default value is 193.
AcctIncludeCli	Specifies whether you want CLI commands included in RADIUS accounting requests.
ClearStat	Clears RADIUS statistics from the device.

Name	Description
McastAttributeValue	Specifies the value of the Mcast attribute. The valid values are 0 through 255. The default value is 90.
AuthInfoAttrValue	Specifies the value of the authentication information attribute. The valid values are 0 through 255. The default value is 91.
CommandAccessAttrValue	Specifies the value of the command access attribute. The valid values are 192 through 240. The default value is 194.
CliCommandAttrValue	Specifies the value of the CLI command attribute. The valid values are 192 through 240. The default value is 195.
AuthInvalidServerAddress	Displays the number of access responses from unknown or invalid RADIUS servers.
CliCmdCount	Gives the value for the CLI command count. Specify an integer from 1 to 40. The default is 40.
CliProfEnable	Enables RADIUS CLI profiling.
SupportedVendorIds	Shows the vendor IDs that the software supports for RADIUS.
RadiusReachability	Specifies the mode for RADIUS reachability. Status-server mode provides a standard-compliant method for RADIUS reachability. Use-radius mode requires the configuration of dummy packets that are sent to RADIUS servers. The default is use-radius mode.
SecureEnable	Enable RADIUS Security (RADSec).
UserName	Specifies the username for RADIUS server reachability. The default is extremenetworks.
Password	Specifies the password for RADIUS server reachability. The default is extremenetworks.
Confirm Password	Confirms the password for RADIUS server reachability.
Unreachable Timer	Specifies, in seconds, the interval between checks when radius server is unreachable. The default is 60 seconds.
Keep Alive Timer	Specifies, in seconds, the interval between checks when radius server is reachable. The default is 180 seconds.

Enable RADIUS Accounting

Before You Begin

- You must set up a RADIUS server and add it to the configuration file of the device before you can enable RADIUS accounting on the device. Otherwise, the system displays an error message.

About This Task

Enable RADIUS accounting to log all of the activity of each remote user in a session on the centralized RADIUS accounting server.

Procedure

- In the navigation pane, expand **Configuration > Security > Control Path**.
- Click **RADIUS**.
- In the **RADIUS Global** tab, select the **AcctEnable** check box.

4. In the **AcctAttrValue** field, type an access policy value (by default, this value is 193).
5. Click **Apply**.

RADIUS Global Field Descriptions

Use the data in the following table to use the **RADIUS Global** tab.

Name	Description
Enable	Enables the RADIUS authentication feature globally.
MaxNumberServer	Specifies the maximum number of servers to be used, between 1 and 10, inclusive.
AccessPriorityAttrValue	Specific to RADIUS authentication. Specifies the vendor-specific attribute value of the access-priority attribute to match the type value set in the dictionary file on the RADIUS server. The valid values are 192 through 240. The default is 192.
AcctEnable	Enables RADIUS accounting.
AcctAttrValue	Specific to RADIUS accounting. Specifies the vendor-specific attribute value of the CLI-command attribute to match the type value set in the dictionary file on the RADIUS server. This value must be different from the access-priority attribute value configured for authentication. The valid values are 192 through 240. The default value is 193.
AcctIncludeCli	Specifies whether you want CLI commands included in RADIUS accounting requests.
ClearStat	Clears RADIUS statistics from the device.
McastAttributeValue	Specifies the value of the Mcast attribute. The valid values are 0 through 255. The default value is 90.
AuthInfoAttrValue	Specifies the value of the authentication information attribute. The valid values are 0 through 255. The default value is 91.
CommandAccessAttrValue	Specifies the value of the command access attribute. The valid values are 192 through 240. The default value is 194.
CliCommandAttrValue	Specifies the value of the CLI command attribute. The valid values are 192 through 240. The default value is 195.
AuthInvalidServerAddress	Displays the number of access responses from unknown or invalid RADIUS servers.
CliCmdCount	Gives the value for the CLI command count. Specify an integer from 1 to 40. The default is 40.
CliProfEnable	Enables RADIUS CLI profiling.
SupportedVendorIds	Shows the vendor IDs that the software supports for RADIUS.
RadiusReachability	Specifies the mode for RADIUS reachability. Status-server mode provides a standard-compliant method for RADIUS reachability. Use-radius mode requires the configuration of dummy packets that are sent to RADIUS servers. The default is use-radius mode.
SecureEnable	Enable RADIUS Security (RADSec).
UserName	Specifies the username for RADIUS server reachability. The default is extremenetworks.

Name	Description
Password	Specifies the password for RADIUS server reachability. The default is extremenetworks.
Confirm Password	Confirms the password for RADIUS server reachability.
Unreachable Timer	Specifies, in seconds, the interval between checks when radius server is unreachable. The default is 60 seconds.
Keep Alive Timer	Specifies, in seconds, the interval between checks when radius server is reachable. The default is 180 seconds.

Disable RADIUS Accounting

Before You Begin

- You cannot globally disable RADIUS accounting unless a server entry exists.

About This Task

Disabling RADIUS accounting removes the accounting function from the RADIUS server.

Procedure

- In the navigation pane, expand **Configuration > Security > Control Path**.
- Click **RADIUS**.
- In the **RADIUS Global** tab, disable RADIUS accounting by clearing the **AcctEnable** check box.
- Click **Apply**.

Enable RADIUS Accounting Interim Request

About This Task

Enable the RADIUS accounting interim request feature to create a log whenever more than the specified number of CLI commands are executed.

Procedure

- In the navigation pane, expand **Configuration > Security > Control Path**.
- Click **RADIUS**.
- In the **RADIUS Global** tab, type the number of CLI commands in the **CliCmdCount** field.
- Click **Apply**.

RADIUS Global Field Descriptions

Use the data in the following table to use the **RADIUS Global** tab.

Name	Description
Enable	Enables the RADIUS authentication feature globally.
MaxNumberServer	Specifies the maximum number of servers to be used, between 1 and 10, inclusive.

Name	Description
AccessPriorityAttrValue	Specific to RADIUS authentication. Specifies the vendor-specific attribute value of the access-priority attribute to match the type value set in the dictionary file on the RADIUS server. The valid values are 192 through 240. The default is 192.
AcctEnable	Enables RADIUS accounting.
AcctAttriValue	Specific to RADIUS accounting. Specifies the vendor-specific attribute value of the CLI-command attribute to match the type value set in the dictionary file on the RADIUS server. This value must be different from the access-priority attribute value configured for authentication. The valid values are 192 through 240. The default value is 193.
AcctIncludeCli	Specifies whether you want CLI commands included in RADIUS accounting requests.
ClearStat	Clears RADIUS statistics from the device.
McastAttributeValue	Specifies the value of the Mcast attribute. The valid values are 0 through 255. The default value is 90.
AuthInfoAttrValue	Specifies the value of the authentication information attribute. The valid values are 0 through 255. The default value is 91.
CommandAccessAttrValue	Specifies the value of the command access attribute. The valid values are 192 through 240. The default value is 194.
CliCommandAttrValue	Specifies the value of the CLI command attribute. The valid values are 192 through 240. The default value is 195.
AuthInvalidServerAddress	Displays the number of access responses from unknown or invalid RADIUS servers.
CliCmdCount	Gives the value for the CLI command count. Specify an integer from 1 to 40. The default is 40.
CliProfEnable	Enables RADIUS CLI profiling.
SupportedVendorIds	Shows the vendor IDs that the software supports for RADIUS.
RadiusReachability	Specifies the mode for RADIUS reachability. Status-server mode provides a standard-compliant method for RADIUS reachability. Use-radius mode requires the configuration of dummy packets that are sent to RADIUS servers. The default is use-radius mode.
SecureEnable	Enable RADIUS Security (RADSec).
UserName	Specifies the username for RADIUS server reachability. The default is extremenetworks.
Password	Specifies the password for RADIUS server reachability. The default is extremenetworks.
Confirm Password	Confirms the password for RADIUS server reachability.
Unreachable Timer	Specifies, in seconds, the interval between checks when radius server is unreachable. The default is 60 seconds.
Keep Alive Timer	Specifies, in seconds, the interval between checks when radius server is reachable. The default is 180 seconds.

Add a RADIUS Server

About This Task

Add a RADIUS server to allow RADIUS service on the switch.

Remote Dial-In User Services (RADIUS) supports both IPv4 and IPv6 addresses, with no differences in functionality or configuration in all but the following case. When adding a RADIUS server or updating a RADIUS server in Enterprise Device Manager (EDM) you must specify if the address type is an IPv4 or an IPv6 address.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **RADIUS**.
3. Select the **RADIUS Servers** tab.
4. Select **Insert**.
5. Configure the server as required.
6. Select **Insert**.

RADIUS Servers Field Descriptions

Use the data in the following table to use the **RADIUS Servers** tab.

Name	Description
AddressType	Specifies either an IPv4 or an IPv6 address. RADIUS supports IPv4 and IPv6 addresses.
Address	Specifies the IP address of the RADIUS server. RADIUS supports IPv4 and IPv6 addresses.
UsedBy	Configures how the server functions: <ul style="list-style-type: none"> • cli—configure the server for CLI authentication. • eapol—configure the server for EAPoL authentication. • endpointTracking—configure the server for Endpoint Tracking authentication. • snmp—configure the server for SNMP accounting. • web—configure the server for HTTP(s) authentication. The default is cli.
Priority	Specifies the priority of each server, or the order of servers to send authentication. The default is 10.
TimeOut	Specifies the time interval in seconds before the client retransmits the packet. The default is 8.
Enable	Enables or disables authentication on the server. The default is true.
MaxRetries	Specifies the maximum number of retransmissions allowed. The default is 1.
UdpPort	Specifies the UDP port that the client uses to send requests to the server. The default value is 1812. The UDP port value set for the client must match the UDP value set for the RADIUS server.

Name	Description
SecretKey	Specifies the RADIUS server secret key, which is the password used by the client to be validated by the server.
AcctEnable	Enables or disable RADIUS accounting. The default is true.
AcctUdpPort	Specifies the UDP port of the RADIUS accounting server. The default value is 1813. The UDP port value configured for the client must match the UDP value configured for the RADIUS server.
SecureEnable	Enable RADIUS Security (RADSec).
SecureMode	Specifies the RADSec security mode. Possible values are: <ul style="list-style-type: none"> tls - Transport Layer Security (TLS) encryption over Transmission Control Protocol (TCP) dtls - Datagram Transport Layer Security (DTLS) encryption over User Datagram Protocol (UDP) The default is tls.
SecureProfile	Specifies the name of the secure profile.
SecureLogLevel	Specifies the log severity level. Possible values are : <ul style="list-style-type: none"> critical error warning info debug
SourceIpAddr	Specifies the IP address to use as the source address in RADIUS packets. To use this option, you must set the global RADIUS SourceIpFlag to true. RADIUS supports IPv4 and IPv6 addresses.

Showing RADIUS Server Statistics

About This Task

Use the server statistics feature to display the number of input and output packets and the number of input and output bytes. Statistics from console ports are available to assist with debugging.

Procedure

1. In the navigation pane, expand the **Configuration > Security > Control Path** folders.
2. Click **RADIUS**.
3. Click the **RADIUS Servers Stats** tab.

RADIUS Server Stats Field Descriptions

Use the data in the following table to use the **RADIUS Server Stats** tab.

Name	Description
AddressType	Specifies the type of IP address. RADIUS supports IPv4 addresses only.
Address	Shows the IP address of the RADIUS server.

Name	Description
Used by	Identifies the client.
AccessRequests	Shows the number of access-response packets sent to the server; does not include retransmissions.
AccessAccepts	Shows the number of access-accept packets, valid or invalid, received from the server.
AccessRejects	Shows the number of access-reject packets, valid or invalid, received from the server.
BadResponses	Shows the number of invalid access-response packets received from the server.
PendingRequests	Shows the access-request packets sent to the server that have not yet received a response or that have timed out.
ClientRetries	Shows the number of authentication retransmissions to the server.
AcctOnRequests	Shows the number of accounting on requests sent to the server.
AcctOffRequests	Shows the number of accounting off requests sent to the server.
AcctStartRequests	Shows the number of accounting start requests sent to the server.
AcctStopRequests	Shows the number of accounting stop requests sent to the server.
AcctInterimRequests	Number of Accounting Interim requests sent to the server. Important: The AcctInterimRequests counter increments only if you select AcctIncludeCli from the RADIUS Global tab.
AcctBadResponses	Shows the number of Invalid responses discarded from the server.
AcctPendingRequests	Shows the number of requests waiting to be sent to the server.
AcctClientRetries	Shows the number of retries made to this server.
RoundTripTime	Shows the time difference between the instance when a RADIUS request is sent and the corresponding response is received.
AccessChallenges	Shows the number of RADIUS access-challenges packets sent to this server. This does not include retransmission.
NasIpAddress	Shows the RADIUS client NAS Identifier for this server.

Reauthenticate the RADIUS SNMP Server Session

About This Task

Specify the number of challenges that you want the RADIUS SNMP server to send to authenticate a given session.

Procedure

1. In the navigation pane, expand **Configuration** > **Security** > **Control Path**.
2. Click **RADIUS**.
3. Click the **RADIUS SNMP** tab.

The system displays RADIUS SNMP tab.

4. Select the **Enable** check box.
5. In the **ReauthenticateTimer** field, enter a value to specify the interval between RADIUS SNMP server reauthentications.

The timer for reauthentication of the RADIUS SNMP server session is enabled.

Important

To end the RADIUS SNMP server session, enter a value for the AbortSessionTimer, and then select Enable.

6. Select the **AcctEnable** check box if desired.
7. Select **Apply**.

RADIUS SNMP field descriptions

Use the data in the following table to use the **RADIUS SNMP** tab.

Name	Description
Enable	Enables or disables timer authentication on the server. The default is true.
AbortSessionTimer	Specifies the allowable time, in seconds, before aborting the RADIUS SNMP server session (30 to 65535). The default is 180.
ReAuthenticateTimer	Specifies the time, in seconds, between reauthentications of the RADIUS SNMP server (30 to 65535). The default is 180.
AcctEnable	Enables or disables the RADIUS SNMP session timer.
UserName	Specifies the user name for the RADIUS SNMP accounting.

Configure RADIUS SNMP

About This Task

Configure RADIUS SNMP parameters for authentication and session times.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **RADIUS**.
3. Select the **RADIUS SNMP** tab.
4. Select the **Enable** check box to enable RADIUS SNMP.
5. In the **AbortSessionTimer** field, enter the period after which the session expires in seconds.
6. In the **ReAuthenticateTimer** field, enter the period of time the system waits before reauthenticating in seconds.
7. Select the **AcctEnable** check box to enable RADIUS accounting for SNMP.
8. In the **UserName** field, type the RADIUS SNMP user name.
9. Click **Apply**.

RADIUS SNMP field descriptions

Use the data in the following table to use the **RADIUS SNMP** tab.

Name	Description
Enable	Enables or disables timer authentication on the server. The default is true.
AbortSessionTimer	Specifies the allowable time, in seconds, before aborting the RADIUS SNMP server session (30 to 65535). The default is 180.
ReAuthenticateTimer	Specifies the time, in seconds, between reauthentications of the RADIUS SNMP server (30 to 65535). The default is 180.
AcctEnable	Enables or disables the RADIUS SNMP session timer.
UserName	Specifies the user name for the RADIUS SNMP accounting.

Modify a RADIUS Configuration

About This Task

Use this procedure to modify an existing RADIUS configuration or single function such as retransmissions and RADIUS accounting.

RADIUS supports IPv4 and IPv6 addresses with no difference in functionality or configuration in all except the following case. When modifying a RADIUS configuration in Enterprise Device Manager (EDM), you must specify if the address type is an IPv4 or an IPv6 address.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **RADIUS**.
3. Click the **RADIUS Servers** tab.
4. In the row and field to modify, type the information or use the lists to make a selection. Access the lists by double-clicking in a field.
5. When you are done with modifying the RADIUS configuration, click **Apply**.

RADIUS Servers Field Descriptions

Use the data in the following table to use the **RADIUS Servers** tab.

Name	Description
AddressType	Specifies either an IPv4 or an IPv6 address. RADIUS supports IPv4 and IPv6 addresses.
Address	Specifies the IP address of the RADIUS server. RADIUS supports IPv4 and IPv6 addresses.

Name	Description
UsedBy	Configures how the server functions: <ul style="list-style-type: none"> • cli—configure the server for CLI authentication. • eapol—configure the server for EAPoL authentication. • endpointTracking—configure the server for Endpoint Tracking authentication. • snmp—configure the server for SNMP accounting. • web—configure the server for HTTP(s) authentication. The default is cli .
Priority	Specifies the priority of each server, or the order of servers to send authentication. The default is 10.
TimeOut	Specifies the time interval in seconds before the client retransmits the packet. The default is 8.
Enable	Enables or disables authentication on the server. The default is true.
MaxRetries	Specifies the maximum number of retransmissions allowed. The default is 1.
UdpPort	Specifies the UDP port that the client uses to send requests to the server. The default value is 1812. The UDP port value set for the client must match the UDP value set for the RADIUS server.
SecretKey	Specifies the RADIUS server secret key, which is the password used by the client to be validated by the server.
AcctEnable	Enables or disable RADIUS accounting. The default is true.
AcctUdpPort	Specifies the UDP port of the RADIUS accounting server. The default value is 1813. The UDP port value configured for the client must match the UDP value configured for the RADIUS server.
SecureEnable	Enable RADIUS Security (RADSec).
SecureMode	Specifies the RADSec security mode. Possible values are: <ul style="list-style-type: none"> • tls - Transport Layer Security (TLS) encryption over Transmission Control Protocol (TCP) • dtls - Datagram Transport Layer Security (DTLS) encryption over User Datagram Protocol (UDP) The default is tls .
SecureProfile	Specifies the name of the secure profile.
SecureLogLevel	Specifies the log severity level. Possible values are : <ul style="list-style-type: none"> • critical • error • warning • info • debug
SourceIpAddr	Specifies the IP address to use as the source address in RADIUS packets. To use this option, you must set the global RADIUS SourceIpFlag to true. RADIUS supports IPv4 and IPv6 addresses.

Delete a RADIUS Configuration

About This Task

Delete an existing RADIUS configuration.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **RADIUS**.
3. Click the **RADIUS Servers** tab.
4. Identify the configuration to delete by clicking anywhere in the row.
5. Click **Delete**.

Configure RADIUS Server Reachability

About This Task

Use this procedure to configure the RADIUS server reachability settings.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **RADIUS**.
3. Click the **RADIUS Global** tab.
4. In **RadiusReachability**, select either **useStatusServerPackets** or **useDummyRadiusRequests**.
5. In the **UserName** field, type the reachability user name.
6. In the **Password** field, type the reachability password.
7. In the **Confirm Password** field, retype the reachability password.
8. In the **Unreachable Timer** field, type the interval in seconds between checks when the RADIUS server is unreachable.
9. In the **KeepAlive Timer** field, type the interval in seconds between checks when the RADIUS server is reachable.
10. Click the **Apply**.

RADIUS Global Field Descriptions

Use the data in the following table to use the **RADIUS Global** tab.

Name	Description
Enable	Enables the RADIUS authentication feature globally.
MaxNumberServer	Specifies the maximum number of servers to be used, between 1 and 10, inclusive.
AccessPriorityAttrValue	Specific to RADIUS authentication. Specifies the vendor-specific attribute value of the access-priority attribute to match the type value set in the dictionary file on the RADIUS server. The valid values are 192 through 240. The default is 192.
AcctEnable	Enables RADIUS accounting.

Name	Description
AcctAttrValue	Specific to RADIUS accounting. Specifies the vendor-specific attribute value of the CLI-command attribute to match the type value set in the dictionary file on the RADIUS server. This value must be different from the access-priority attribute value configured for authentication. The valid values are 192 through 240. The default value is 193.
AcctIncludeCli	Specifies whether you want CLI commands included in RADIUS accounting requests.
ClearStat	Clears RADIUS statistics from the device.
McastAttributeValue	Specifies the value of the Mcast attribute. The valid values are 0 through 255. The default value is 90.
AuthInfoAttrValue	Specifies the value of the authentication information attribute. The valid values are 0 through 255. The default value is 91.
CommandAccessAttrValue	Specifies the value of the command access attribute. The valid values are 192 through 240. The default value is 194.
CliCommandAttrValue	Specifies the value of the CLI command attribute. The valid values are 192 through 240. The default value is 195.
AuthInvalidServerAddress	Displays the number of access responses from unknown or invalid RADIUS servers.
CliCmdCount	Gives the value for the CLI command count. Specify an integer from 1 to 40. The default is 40.
CliProfEnable	Enables RADIUS CLI profiling.
SupportedVendorIds	Shows the vendor IDs that the software supports for RADIUS.
RadiusReachability	Specifies the mode for RADIUS reachability. Status-server mode provides a standard-compliant method for RADIUS reachability. Use-radius mode requires the configuration of dummy packets that are sent to RADIUS servers. The default is use-radius mode.
SecureEnable	Enable RADIUS Security (RADSec).
UserName	Specifies the username for RADIUS server reachability. The default is extremenetworks.
Password	Specifies the password for RADIUS server reachability. The default is extremenetworks.
Confirm Password	Confirms the password for RADIUS server reachability.
Unreachable Timer	Specifies, in seconds, the interval between checks when radius server is unreachable. The default is 60 seconds.
Keep Alive Timer	Specifies, in seconds, the interval between checks when radius server is reachable. The default is 180 seconds.

Configure a RADIUS Dynamic-server Client

About This Task

Use this procedure to configure a client to allow processing of dynamic session changes.

Before You Begin

You must enable EAPOL globally and at the port level.

You must enable RADIUS dynamic extensions commands processing at the port level.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **RADIUS CoA**.
3. Click **Global**.
4. Click **Insert**.
5. In the **Address** field type a client address.
6. (Optional) In the **UdpPort** field, type a value for client port.
7. (Optional) In the **Secret** field, type a value for the secret key.
8. Select the **Enable** checkbox to enable dynamic session processing for the client.
9. Click **Insert**.

Global field descriptions

Use the data in the following table to use the **Global** tab.

Name	Description
AddressType	Specifies the type of address contained in the corresponding instance of a RADIUS Dynamic Authorization Client configured in this entry.
Address	Specifies the internet address of a RADIUS Dynamic Authorization Client configured in this entry.
UdpPort	Specifies the UDP port number the server/NAS listens on for requests from the RADIUS Dynamic Authorization Client configured in this entry.
Secret	Specifies the secret key shared between the RADIUS Dynamic Authorization Client and Server. Note that when this object is retrieved, it's value will always be a zero-length octet string.
Enable	Enable processing of dynamic session changes.

Displaying RADIUS CoA Disconnect Statistics

About This Task

Use this procedure to display RADIUS CoA Disconnect statistics.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Control Path**.
2. Click **RADIUS CoA**.
3. Click the **Disconnect Stats** tab.

Disconnect Stats Field Descriptions

Use the data in the following table to use the **Disconnect Stats** tab.

Name	Description
DisconRequests	Specifies the number of RADIUS disconnect requests received from this Dynamic Authorization Client. This also includes the RADIUS disconnect requests that have a Service-Type attribute with a value of Authorize Only.
DisconAuthOnlyRequests	Specifies the number of RADIUS disconnect requests that include a Service-Type attribute with a value of Authorize Only received from this Dynamic Authorization Client.
DupDisconRequests	Specifies the number of duplicate RADIUS Disconnect-Request packets received from this Dynamic Authorization Client.
DisconAcks	Specifies the number of RADIUS Disconnect-ACK packets sent to this Dynamic Authorization Client.
DisconNaks	Specifies the number of RADIUS Disconnect-NAK packets sent to this Dynamic Authorization Client. This includes the RADIUS Disconnect-NAK packets sent with a Service-Type attribute with a value of Authorize Only and the RADIUS Disconnect-NAK packets sent because no session context was found.
DisconNakAuthOnlyRequests	Specifies the number of RADIUS Disconnect-NAK packets that include a Service-Type attribute with a value of Authorize Only sent to this Dynamic Authorization Client.
DisconNakSessNoContext	Specifies the number of RADIUS Disconnect-NAK packets sent to this Dynamic Authorization Client because no session context was found.
DisconUserSessRemoved	Specifies the number of user sessions removed for the disconnect requests received from this Dynamic Authorization Client. Depending on site-specific policies, a single disconnect request can remove multiple user sessions. In cases where this Dynamic Authorization Server has no knowledge of the number of user sessions that are affected by a single request, each such disconnect request counts as a single affected user session only.
MalformedDisconRequests	Specifies the number of malformed RADIUS Disconnect-Request packets received from this Dynamic Authorization Client. Bad authenticators and unknown types are not included as malformed disconnect requests
DisconBadAuthenticators	Specifies the number of RADIUS Disconnect-Request packets that contain an invalid Authenticator field received from this Dynamic Authorization Client.

Name	Description
DisconPacketsDropped	Specifies the number of incoming disconnect requests from this Dynamic Authorization Client silently discarded by the server application for some reason other than malformed packets, bad authenticators, or unknown types.
UnknownTypes	Specifies the number of incoming requests that have an invalid ID type.

Displaying RADIUS CoA Reauthenticate Statistics

About This Task

Use this procedure to display RADIUS CoA Reauthenticate statistics.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Control Path**.
2. Click **RADIUS CoA**.
3. Click the **Reauthenticate Stats** tab.

Reauthenticate Stats Field Descriptions

Use the data in the following table to use the **Reauthenticate Stats** tab.

Name	Description
Requests	Specifies the number of RADIUS Reauthentication-Requests received from this Dynamic Authorization Client. This also includes the Reauthentication requests that have a Service-Type attribute with a value of Authorize Only.
AuthOnlyRequests	Specifies the number of RADIUS Reauthentication-Requests that include a Service-Type attribute with value Authorize Only received from this Dynamic Authorization Client.
DupRequests	Specifies the number of duplicate RADIUS Reauthentication-Request packets received from this Dynamic Authorization Client.
Acks	Specifies the number of incoming Reauthentication packets from this Dynamic Authorization Client silently discarded by the server application for some reason other than malformed, bad authenticators, or unknown types.
Nacks	Specifies the number of RADIUS Reauthentication-NAK packets sent to this Dynamic Authorization Client. This includes the RADIUS Reauthentication-NAK packets sent with a Service-Type attribute value of Authorize Only, and the RADIUS Reauthentication-NAK packets sent because no session context was found.

Name	Description
NacksAuthOnlyRequests	Specifies the number of RADIUS Reauthentication-NAK packets that include a Service-Type attribute with a value of Authorize Only sent to this Dynamic Authorization Client.
NacksNoSess	Specifies the number of RADIUS Reauthentication-NAK packets sent to this Dynamic Authorization Client because no session context was found.
SessReauthenticated	Specifies the number of user sessions reauthenticated for the Reauthentication-Requests received from this Dynamic Authorization Client. Depending on site-specific policies, a single Reauthentication-Request can change the authorization of multiple user sessions. In cases where the Dynamic Authorization Server has no knowledge of the number of user sessions that are affected by a single request, each CoA-Request counts as a single affected user session.
Malformed	Specifies the number of malformed RADIUS Reauthentication-Request packets received from the Dynamic Authorization Client. Bad authenticators and unknown types are not included as malformed Reauthentication-Requests.
Dropped	Specifies the number of incoming Reauthentication packets from the Dynamic Authorization Client silently discarded by the server application for some reason other than malformed, bad authenticators, or unknown types.
BadAuths	Specifies the number of RADIUS Reauthentication-Request packets that contained an invalid Authenticator field received from the Dynamic Authorization Client.
UnknownTypes	Specifies the number of incoming requests that have an invalid ID type.

Displaying RADIUS CoA Statistics

About This Task

Use this procedure to display information about RADIUS CoA statistics.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Control Path**.
2. Click **RADIUS CoA**.
3. Click the **CoA Stats** tab.

CoA Stats Field Descriptions

Use the data in the following table to use the **CoA Stats** tab.

Name	Description
AddressType	Specifies the RADIUS Dynamic Authorization Client IP address type.
Address	Specifies the RADIUS Dynamic Authorization Client IP address.
DisconRequests	Specifies the number of RADIUS Disconnect-Requests received from this Dynamic Authorization Client. This also includes the Disconnect requests that have a Service-Type attribute with a value of Authorize Only.
DisconAuthOnlyRequests	Specifies the number of RADIUS Disconnect-Requests that include a Service-Type attribute with value Authorize Only received from this Dynamic Authorization Client.
DupDisconRequests	Specifies the number of duplicate RADIUS Disconnect-Request packets received from this Dynamic Authorization Client.
DisconAcks	Specifies the number of RADIUS Disconnect-ACK packets sent to this Dynamic Authorization Client.
DisconNaks	Specifies the number of RADIUS Disconnect-ACK packets sent to this Dynamic Authorization Client. This includes the RADIUS Disconnect-ACK packets sent with a Service-Type attribute value of Authorize Only, and the RADIUS Disconnect-ACK packets sent because no session context was found.
DisconNakAuthOnlyRequests	Specifies the number of RADIUS Disconnect-NAK packets that include a Service-Type attribute with a value of Authorize Only sent to this Dynamic Authorization Client.
DisconNakSessNoContext	Specifies the number of RADIUS Disconnect-NAK packets sent to this Dynamic Authorization Client because no session context was found.
DisconUserSessRemoved	Specifies the number of user sessions removed for the Disconnect-Requests received from this Dynamic Authorization Client. Depending on site-specific policies, a single Disconnect-Request can change the authorization of multiple user sessions. In cases where the Dynamic Authorization Server has no knowledge of the number of user sessions that are affected by a single request, each Disconnect-Request counts as a single affected user session.

Name	Description
MalformedDisconRequests	Specifies the number of malformed RADIUS Disconnect-Request packets received from the Dynamic Authorization Client. Bad authenticators and unknown types are not included as malformed Disconnect-Requests.
UnknownTypes	Specifies the number of incoming requests that have an invalid ID type.

RADSec Configuration Using EDM

This section contains procedures for configuring RADSec with Enterprise Device Manager (EDM).

Configure a RADIUS Secure Profile

Configure a RADIUS Security (RADSec) profile to specify certificate information used by RADSec to develop trust between peers. You can also specify a password used for RADSec encryption.

About This Task

All the files (certificates and keys) must be in .pem format and copy it to flash /intflash directory.

A new profile directory is created for each new profile in the flash/intflash/.radsec/profile/radsec directory.

Profile configuration file "profile_info.cfg" is available in /intflash/.radsec/profile directory.

You can configure a maximum of 10 RADsec profiles.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **RADIUS**.
3. Select the **Secure Certificate Profile**
4. Select **Insert**.
5. For **Name**, enter the name for the profile.
6. For **RootCert**, enter the full path for the profile root certificate.
7. For **Cert**, enter the full path for the profile certificate.
8. For **Key**, enter the full path for the profile private key.
9. For **Password**, enter the full path to decrypt the profile private key.
10. For **RootCertDestFile**, enter the file name to use when installing the root certificate.
11. For **CertDestFile**, enter the file name to use when installing the certificate.
12. For **KeyDestFile**, enter the file name to use when installing the key.
13. Select **Insert**.

Secure Certificate Profile Field Descriptions

Use the data in the following table to use the **Secure Certificate Profile** tab.

Name	Description
Name	Specifies the profile name.
RootCert	Specifies the full path of the profile root certificate.
Cert	Specifies the full path of the profile certificate.
Key	Specifies the full path of the profile private key.
Password	Specifies the password used to decrypt the profile private key.
RootCertDestFile	Specifies the file name to use when installing the root certificate.
CertDestFile	Specifies the file name to use when installing the certificate.
KeyDestFile	Specifies the file name to use when installing the key.

RADIUS Attributes

[Vendor Specific Attributes on page 2376](#)
[IETF Attributes on page 2382](#)

The following topics list RADIUS attributes for EAP.

Vendor Specific Attributes

RADIUS Vendor Specific Frame Format

The following figure shows the frame format for RADIUS vendor specific attributes (VSA).

Figure 202: RADIUS vendor-specific frame format

FA-VLAN-ISID

On EAP-enabled Flex-UNI ports, the context for the authenticating MAC is the association using the FA-VLAN-ISID attribute. This attribute provides one VLAN:ISID binding.

- defined under vendor IDs 562 and 1584 and uses the value 171
- I-SID values are 0-15999999
- VLAN values are 0 - 4096 to create untagged S-UNIs in MHSA mode and MAC-BasedS-UNIs in MHMV mode
- RADIUS server provides up to 94 bindings
- for MHMV with multiple bindings, only the last binding is created

FA-Client-Type

This attribute is used in packets transmitted to the RADIUS server to inform that the current authenticated MAC is associated to a FA Client of type x. This attribute is defined under Nortel vendor id (562) and uses the value 182.

Only one FA Client per port is supported.

The following values are defined for FA Client type:

- 0: FA Element Not Found
- 1: FA Element Type Other
- 2: FA Server
- 3: FA Proxy
- 4: FA Server No Authentication
- 5: FA Proxy No Authentication
- 6: FA Client Wireless AP Type 1 [clients direct network attachment]
- 7: FA Client Wireless AP Type 2 [clients tunneled to controller]
- 8: FA Client Switch
- 9: FA Client Router
- 10: FA Client IP Phone
- 11: FA Client Camera
- 12: FA Client IP Video
- 13: FA Client Security Device
- 14: FA Client Virtual Switch
- 15: FA Client Server Endpoint
- 16: FA Client ONA SDN mode
- 17: FA Client ONA SPBOIP mode
- 63: FA Client Unknown

Any integer value provided by the FA is sent to the RADIUS server without any check from the EAP application.

Extreme-Dynamic-MHSA

On EAP-enabled Flex UNI ports, this attribute changes the current interface EAPoL operating mode from MHMV to MHSA.

- defined under Extreme Networks vendor ID 1916 and uses the value 250
- parsed only on ports with Flex-UNI enabled
- value contained in this attribute must be 1

Extreme-Dynamic-ACL

On EAP-enabled ports, this attribute assigns a dynamic ACL for an EAP-enabled port. The dynamic behavior of the ACL depends on the EAP port state (MHMV or MHSA).

- defined under Extreme Networks vendor ID 1916 and uses the value 251

For more information, see [RADIUS Dynamic User-Based Policies](#) on page 681.

Examples

The following examples provide the RADIUS configuration for the corresponding CLI filter configuration. This example is for MAC 0a:0a:0a:0a:0a:0a on port 1/1 and EAP is in MHMV mode.

```
filter acl 1 type inPort
filter acl port 1 1/1

filter acl ace 1 1 name RadiusGuest-Rule01
filter acl ace ethernet 1 1 src-mac eq 0a:0a:0a:0a:0a:0a
filter acl ace ethernet 1 1 ether-type eq 0x800
filter acl ace ip 1 1 ip-protocol-type eq 17
filter acl ace protocol 1 1 dst-port eq 53
filter acl ace 1 1 action permit
filter acl ace 1 1 enable

filter acl ace 1 2 name RadiusGuest-Rule02
filter acl ace ethernet 1 2 src-mac eq 0a:0a:0a:0a:0a:0a
filter acl ace ethernet 1 2 ether-type eq 0x800
filter acl ace ip 1 2 dst-ip mask 192.0.2.1 24
filter acl ace 1 2 action permit
filter acl ace 1 2 enable

filter acl ace 1 3 name RadiusGuest-Rule03
filter acl ace ethernet 1 3 src-mac eq 0a:0a:0a:0a:0a:0a
filter acl ace 1 3 action deny
filter acl ace 1 3 enable
```

The RADIUS VSA does not specify the MAC or the port number because they are already known at the EAP level.

```
Extreme-Dynamic-ACL = "CLIENT RadiusGuest",
Extreme-Dynamic-ACL += "acl inPort",
Extreme-Dynamic-ACL += "ace 1 sec ethernet ether-type eq 0x800 & ip ip-protocol-type eq
17 & protocol dst-port eq 53 action permit",
Extreme-Dynamic-ACL += "ace 2 sec ethernet ether-type eq 0x800 & ip dst-ip mask 192.0.2.1
24 action permit",
Extreme-Dynamic-ACL += "ace 3 sec action deny"
```

Extreme-Dynamic-Config

This attribute configures port and VLAN based attributes.

- Name: Extreme-Dyn-Config
- Value: 252
- Type: String
- Vendor: Extreme
- Extreme Vendor ID is 1916

The following features can be configured using Extreme-Dynamic-Config RADIUS VSA.

DAI

This setting enables Dynamic ARP Inspection (DAI) on the VLAN received from the RADIUS server. For a Flex-UNI port, DAI enables on the platform VLAN associated with the I-SID received from the RADIUS server.

DAI also enables on the default VLAN of the port to prepare for IP Source Guard (IPSG), which requires DAI and DHCP Snooping enabled on all VLANs. If the RADIUS server does not return a VLAN of I-SID, DAI enables on the default VLAN. For Flex-UNI ports, DAI enables on the platform VLAN associated with the untagged I-SID.

DHCP Snooping

This setting enables DHCP Snooping on the VLAN received from the RADIUS server. For a Flex-UNI port, DHCP Snooping enables on the platform VLAN associated with the I-SID received from the RADIUS server.

DHCP Snooping also enables on the default VLAN of that port to prepare for IP Source Guard (IPSG), which requires DAI and DHCP Snooping enabled on all VLANs. If the RADIUS server does not return a VLAN of I-SID, DHCP Snooping enables on the default VLAN. For Flex-UNI ports, DHCP Snooping enables for the platform VLAN associated with the untagged I-SID.

IGMP Snooping

This setting enables IGMP Snooping on the VLAN received from the RADIUS server. For a Flex-UNI port, IGMP Snooping enables on the platform VLAN associated with the I-SID received from the RADIUS server.

IPSG

This setting enables IP Source Guard (IPSG) on the port where the client resides.

In order to apply IPSG, DHCP Snooping and DAI must be configured on the RADIUS server. DHCP Snooping and DAI must be enabled on all VLANs.

The following is an example of a log message that displays if a setting is not configured correctly:

```
GlobalRouter EAP WARNING Cannot apply Radius IP Source Guard attribute on port 3/15 without DHCP Snooping and DAI attributes.
```

WOL

This setting enables EAP traffic-control (Wake On LAN) on the port where the client resides.

SLPP Guard

This setting enables Simple Loop Prevention Protocol (SLPP) Guard on the port where the client resides.

BPDU

This setting enables Bridge Protocol Data Unit (BPDU) Guard on the port where the client resides.

AN-ADVERTISEMENTS:100Half or AN-ADVERTISEMENTS:100H

AN-ADVERTISEMENTS:100Half or AN-ADVERTISEMENTS:100H settings configure Custom Auto-Negotiation Advertisements (CANA) speed and duplex to the following supported values:

- 10Half
- 100Full
- 100Half

- 100Full
- 1000Full

Examples

The following example enables DHCP Snooping and Dynamic ARP Inspection (DAI) on VLAN 100 and IP Source Guard on authentication port:

```
Auth-Type := Local
User-Password == "000000000001"
Service-Type = Administrative-User
Tunnel-Type = VLAN
Tunnel-Medium-Type = IEEE-802
Tunnel-Private-Group-Id = 100
Extreme-Dynamic-Config = "DHCP Snooping"
Extreme-Dynamic-Config += "DAI"
Extreme-Dynamic-Config += "IPSG"
```

The following example enables DHCP Snooping and DAI on platform VLAN associated with I-SID 10000 and IP Source Guard on authentication port:

```
Auth-Type := Local
User-Password == "000000000002"
Service-Type = Administrative-User
Fabric-Attach-ISID = "0:10000"
Extreme-Dynamic-Config = "DHCP Snooping"
Extreme-Dynamic-Config += "DAI"
Extreme-Dynamic-Config += "IPSG"
```

The following example enables IGMP Snooping on VLAN 100:

```
Auth-Type := Local
User-Password == "000000000003"
Service-Type = Administrative-User
Tunnel-Type = VLAN
Tunnel-Medium-Type = IEEE-802
Tunnel-Private-Group-Id = 100
Extreme-Dynamic-Config = "IGMP Snooping"
```

The following example enables IGMP Snooping platform VLAN associated with I-SID 10000:

```
Auth-Type := Local
User-Password == "000000000004"
Service-Type = Administrative-User
Fabric-Attach-ISID = "0:10000"
Extreme-Dynamic-Config = "IGMP Snooping"
```

The following example enable EAP traffic-control on authentication port:

```
Auth-Type := Local
User-Password == "000000000005"
Service-Type = Administrative-User
Extreme-Dynamic-Config = "WOL"
```

The following example enable BPDU Guard on authentication port:

```
Auth-Type := Local
User-Password == "000000000006"
Service-Type = Administrative-User
Extreme-Dynamic-Config = "BPDU"
```

The following example enable SLPP Guard on authentication port:

```
Auth-Type := Local
User-Password == "000000000007"
Service-Type = Administrative-User
Extreme-Dynamic-Config = "SLPPGUARD"
```

The following example configure the Custom Auto-Negotiation Advertisements (CANA) to 100Half on authentication port:

```
Auth-Type := Local
User-Password == "000000000008"
Service-Type = Administrative-User
Extreme-Dynamic-Config = "AN-ADVERTISEMENTS:100H"
```

EAP-Port-Priority

Important

Configure these attributes only if you require dynamic port priority.

Port priority (vendor-specific) attributes:

- Vendor ID: value 562 (Nortel)

Note

Vendor ID 1916 (Extreme) does not support port priority.

- Attribute Number: value 1, Port Priority
- Attribute Value: value 0 (zero) to 6 (this value indicates the port priority value assigned to the specified user)

The following list provides the switch Port Priority frame format:

- vendor specific type = 26
- length = 12
- vendor-id = 562
- string = vendor type = 1 + vendor length = 6 + attribute specific = priority

The following figure shows an example of the port priority frame format.

26	12	562	01	06	(0..6)
----	----	-----	----	----	--------

Figure 203: Port priority frame format

IETF Attributes

VLAN RADIUS Attributes

To control the tagging for traffic egressing a port, configure the preferred tagging option and one of the following attributes on the RADIUS server:

- EGRESS-VLAN-ID
- EGRESS-VLAN-NAME

VLAN attributes are defined by RFC 4675.

EGRESS-VLAN-ID

Functionality is combined with other RADIUS attributes and EAPoL configurations to create untagged S-UNIs.

This attribute supports the following combinations:

- untagged EGRESS-VLAN-ID + VLAN:ISID -> VLAN from S-UNI becomes untagged
- untagged EGRESS-VLAN-ID + vid[NEW_RADIUS_VID] + autolsidOffset -> create S-UNI for I-SID (VLAN+autolsidOffset)

Examples

From the RADIUS attributes, for untagged VLAN 15. The VLAN from S-UNI becomes untagged:

```
Egress-VLANID = "838860815" (untagged vlan 15)
Fabric-Attach-ISID += "15:23513"
```

The following example results in the value 0:1015 for creating an untagged S-UNI.

From the RADIUS attributes, for untagged VLAN 15 and RADIUS-assigned VLAN. Creates S-UNI for I-SID (VLAN+autolsidOffset):

```
Egress-VLANID = "838860815"
Tunnel-Private-Group-Id = "15"
```

From the EAP configuration:

```
eapol auto-isid-offset 1000
eapol auto-isid-offset enable
```

Considerations

Consider the following when using this attribute:

- Any combinations with EGRESS-VLAN-ID for a tagged VLAN are ignored.
- When EGRESS-VLAN-ID and VLAN:ISID binding attributes are used, the VLAN must have the same value.
- The RADIUS server can provide more than one VLAN:ISID binding but one must match the VLAN used in EGRESS-VLAN-ID to create an untagged S-UNI.

- Only one EGRESS-VLAN-ID attribute is used. If more than one is found in the packet, only the first one is used.
- If the untagged S-UNI is derived from EGRESS-VLAN-ID + VLAN-ID + VLAN attribute + auto-isid-offset, the packet must not contain any S-UNI bindings.

EGRESS-VLAN-NAME

Functionality is combined with other RADIUS attributes and EAPoL configurations to create untagged S-UNIs.

This attribute supports the following combinations:

- EGRESS-VLAN-ID + VLAN:I-SID
- EGRESS-VLAN-ID + VLAN + autolsidOffset

This attribute includes the following information:

- Egress-VLAN-Name = "1VLAN_NAME" for tagged VLAN
- Egress-VLAN-Name = "2VLAN_NAME" for untagged VLAN
- VLAN_NAME is the name of the VLAN on the switch

Example

The following example creates an untagged Switched UNI with I-SID 1000. VLAN 10 is named "Dummy_VLAN".

```
b0adaa41b830 Cleartext-Password := "b0adaa41b830"
                Service-Type = Framed-User,
                Framed-Protocol = PPP,
                Auth-Type := Accept,
                Fabric-Attach-ISID = "10:1000",
                Egress-VLAN-name = "2Dummy_VLAN"
```

RADIUS Tunnel Attributes

The switch uses the RADIUS tunnel attributes to place a port into a particular VLAN to support dynamic VLAN switching based on authentication. The server must send these attributes together in the same RADIUS packet. If one attribute is missing, the switch ignores the others.

The RADIUS server indicates the desired VLAN by including the tunnel attribute within the Access-Accept message. RADIUS uses the following tunnel attributes for VLAN membership:

- RAD_ATTR_TUNNEL_TYPE(64)
 - Tunnel-Type: value 13, Tunnel-Type-VLAN
- RAD_ATTR_TUNNEL_MEDIUM_TYPE(65)
 - Tunnel-Medium-Type: value 6, Tunnel-Medium-Type-802
- RAD_ATTR_TUNNEL_PRI_GROUP_ID
 - Tunnel-Private-Group-ID: ASCII value 1-4094 (this value identifies the specified VLAN)

Tunnel attributes are defined by RFC 2868.

**Important**

Configure these attributes only if you require Dynamic VLAN membership.

The VLAN ID is 12 bits, uses a value from <1–4094>, and is encoded as a string.

In addition, you can configure the RADIUS server to send a vendor-specific attribute (VSA) to configure port priority. You can assign the switch Supplicant port a QoS value from 0 to 6.

For more information, see [EAP-Port-Priority](#) on page 2381.

Representational State Transfer Configuration Protocol (RESTCONF)

[Representational State Transfer Configuration Protocol \(RESTCONF\) Fundamentals on page 2385](#)

[RESTCONF configuration using CLI on page 2387](#)

[RESTCONF Configuration using EDM on page 2392](#)

[Use Representational State Transfer Configuration Protocol \(RESTCONF\) to Configure a Switch on page 2393](#)

[RESTCONF Operational Behavior Examples on page 2395](#)

Table 177: Representational State Transfer Configuration Protocol (RESTCONF) product support

Feature	Product	Release introduced
Representational State Transfer Configuration Protocol (RESTCONF)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5

Representational State Transfer Configuration Protocol (RESTCONF) Fundamentals

Representational State Transfer Configuration Protocol (RESTCONF) is a next generation northbound interface that provides an additional way to configure and monitor the switch. RESTCONF is an HTTP-based protocol that provides a programmatic interface to access data defined in a YANG model using the datastore concepts defined in NETCONF. RESTCONF uses a client-server model. The server acts as an entry point to a datastore, a conceptual place to store and access information. Clients use HTTP or HTTPS to interface with the server to configure and monitor devices.

RESTCONF Client and Server

A typical RESTCONF interaction consists of an HTTP/HTTPS request sent by a RESTCONF client and an HTTP/HTTPS response sent by the server. The HTTP/HTTPS request and response contain a required set of expected HTTP headers and can also contain a request or response message body. The message body is encoded in JSON.

An HTTP request consists of the HTTP method (such as GET or POST) identifier, resource identifier, HTTP protocol version, HTTP headers, and HTTP body. The HTTP resource identifier is the string that identifies a service or resource that the server makes available to the client. The RESTCONF request

contains the Universal Resource Identifier or URI which starts with `/rest/restconf/data/` or `/rest/restconf/operations/`.

YANG Model

YANG is the data modeling language used for modeling configuration and state data for manipulation by using remote procedure calls (RPCs). The RESTCONF interface is generated with YANG Data Model. The YANG model is based on Open config model, which is a non vendor specific model that captures the key components found in multiple vendor solutions. RESTCONF is described by the Internet Engineering Task Force (IETF) in RFC 8040.

RESTCONF Authentication

RESTCONF uses the CLI user account and supports both local and remote authentication. Local authentication uses the local CLI user account while remote authentication can use either a RADIUS or TACACS+ server.

You can only use a CLI account with the RWA access level.

With RADIUS or TACACS+ enabled, if the remote server is not available, authentication falls back to local authentication and uses the local CLI user on the switch.

When the RESTCONF client posts for authentication, the HTTP server validates the login username and password if you have not enabled CLI remote authentication. If the remote server is not reachable, the HTTP server uses the local user for login validation.

For HTTPS access to the RESTCONF server, you must enable TLS and install a certificate.

RESTCONF APIs

You can access the RESTCONF API documentation on your switch using the following URL:

`http(s)://<IP>:<tcp-port>/apps/restconfdoc/`

Replace `<IP>` with the management IP address of your switch and `<tcp-port>` with the TCP port configured for RESTCONF. For example, `http://192.0.2.16:8080/apps/restconfdoc/`.

The on-switch URL works only if you enable the RESTCONF feature on the switch.

You can also access the RESTCONF API documentation online through the Developer Center (<https://www.extremenetworks.com/support/documentation-api/>).

Server Support

The RESTCONF server in the network operating system (NOS) supports the following actions:

HTTP Action	VOSS Instrumentation
GET	Corresponds to SHOW
POST	Corresponds to SET for creation

HTTP Action	VOSS Instrumentation
PATCH	Corresponds to SET for modification
DELETE	Corresponds to SET for deletion

The following table details modules supported by RESTCONF:

Modules	
OpenConfig	Extreme Network Service
OpenConfig	Relay Agent (DHCP support)
OpenConfig	Interfaces Port: POE, port attributes, such as auto-sense, default-vlan-id, flex-uni, qos, untag-port-default-vlan
OpenConfig	Interfaces LAG: attributes, such as flex-uni
OpenConfig	Platform: ports, CPU, fans, power supply, optical devices - GET operations only
OpenConfig	Network Instance: VLAN interface - VRF association, CVLAN I-SID, IS-IS redistribute direct, IPVPN, I-SID, and IP DHCP relay forward path)
OpenConfig	STP: STP global information and port interface bpduguard state, RSTP global and port level information, MSTP global, MST instance level state - GET operations only
OpenConfig	System (aaa)
OpenConfig	LLDP
OpenConfig	VLAN

The RESTCONF feature is disabled by default. The RESTCONF server uses the same management IP address as the other applications and TCP port. The default TCP port that RESTCONF server listens to is port 8080. The TCP port delivers the message to the HTTP server for RESTCONF.

RESTCONF configuration using CLI

Enable the RESTCONF Server

About This Task

Use the following procedure to enable the RESTCONF server.

Before You Begin

Run the **show application restconf conflict-ifname** command to see if any conflict in interface names exist. To enable RESTCONF, the interface names (VLAN name, MLT name, and Port interface name) must be unique.

Run the **show application restconf invalid-name mlt** and **show application restconf invalid-name vlan** commands to see if any MLT or VLAN names contain special

characters. To enable RESTCONF, VLAN and MLT names cannot contain special characters other than underscore (_) and en dash (-).

Procedure

1. Enter Application Configuration mode:

```
enable
```

```
configure terminal
```

```
application
```

2. Enable the RESTCONF server:

```
restconf enable
```

Note

If the interface names (VLAN, MLT, and Port) are not unique, or if VLAN or MLT names contain prohibited special characters, an error occurs indicating that you cannot enable RESTCONF. You must change the interface names before you enable RESTCONF.

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CTRL/Z.
Switch:1(config)#application
Switch:1(config-app)#restconf enable
```

Configure HTTPS Access to the RESTCONF Server

About This Task

By default, the RESTCONF server uses HTTP. If you need to use HTTPS, generate a certificate file and transfer the certificate file to the `/intflash` directory on the switch.

For more information on generating certificate files, see [Manage an SSL Certificate](#) on page 2570.

Before You Begin

Ensure that you have the certificate file in the `/intflash` directory on the switch.

Procedure

1. Enter Application Configuration mode:

```
enable
```

```
configure terminal
```

```
application
```

2. If RESTCONF is enabled, disable RESTCONF:

```
no restconf enable
```

3. Install the certificate file for the RESTCONF server:

```
restconf install-cert-file WORD<1-128>
```

4. Enable HTTPS:

```
restconf tls
```
5. Enable RESTCONF:

```
restconf enable
```

Example

```
Switch:1>enable
Switch:1# configure terminal
Enter configuration commands, one per line. End with CTRL/Z.
Switch:1(config)#application
Switch:1(config-app)#no restconf enable
Switch:1(config-app)#restconf install-cert-file /intflash/.cert/restconf-cert.pem
Switch:1(config-app)#restconf tls
Switch:1(config-app)#restconf enable
```

Variable Definitions

The following table defines parameters for the **restconf** command.

Variable	Value
<i>enable</i>	Enables the RESTCONF Server.
<i>install-cert-file WORD<1-128></i>	Installs the certificate file for the RESTCONF server.
<i>tcp-port <1-49151></i>	Set RESTCONF Server TCP port number.
<i>tls</i>	Enables TLS for the RESTCONF server. The default is disabled.
<i>trap-notification</i>	Enables trap notification.

Modifying the RESTCONF Server Settings

About This Task

Use this procedure to modify the RESTCONF server settings.

Note

These steps are considered optional and RESTCONF can operate with the default configuration of these values.

Procedure

1. Enter Application Configuration mode:

```
enable

configure terminal

application
```
2. Disable trap notification when the RESTCONF server is not available:

```
no restconf trap-notification
```

3. Modify the TCP port number for the RESTCONF server:
 - a. Disable RESTCONF: `no restconf enable`
 - b. Change the value of the TCP port: `restconf tcp-port <1-49151>`
 - c. Enable RESTCONF: `restconf enable`
4. Disable TLS for the RESTCONF server:
 - a. Disable RESTCONF: `no restconf enable`
 - b. Disable TLS: `no restconf tls`
 - c. Enable RESTCONF: `restconf enable`

Variable Definitions

Use the data in the following table to modify the RESTCONF server settings.

Variable	Value
<code>enable</code>	Enables or disables the RESTCONF server. The default is disabled.
<code>tcp-port <1-49151></code>	Specifies the TCP port to use for the RESTCONF server. The default is 8080.
<code>trap-notification</code>	Enables or disables trap notification when the RESTCONF server is not available. The default is enabled.

Showing the RESTCONF Configuration Information

About This Task

Use this procedure to show the RESTCONF configuration information and operation status.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Show the RESTCONF configuration:

```
show application restconf
```

Example

```
Switch:1>show application restconf
=====
                                RESTCONF Info
=====
Admin State           : true
TCP Port              : 8080
Certificate File Status : install
TLS Enable            : false
Trap Notification     : true
Oper State            : up
Web Server Version    : 1.0.1.11
RESTCONF Server Version : 1.0.1.39
=====
```

Show Conflicting Interface Name Information

About This Task

To enable RESTCONF, the interface name (VLAN name, MLT name, and Port interface name) must be unique. Use this procedure to display conflicting interface name information.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Show the RESTCONF conflicting interface name information:

```
show application restconf conflict-ifname
```

Example

```
Switch:1>show application restconf conflict-ifname
-----
Conflicting Interface IfName - Port, VLAN Name and MLT Name
-----
Mlt 1 name is same as Vlan 1001 name - "Interface-1"
Mlt 2 name is same as Vlan 1002 name - "VLAN-1002"
Vlan 1003 name is Mlt 1 Default Name - "MLT-1"
-----
Total Conflict Count: 3
```

What to Do Next

If a conflict exists, change the conflicting interface name to a unique name.

Show Special Characters in VLAN or MLT Names

About This Task

To enable RESTCONF, VLAN and MLT names cannot contain special characters other than underscore (_) and en dash (-). Use this procedure to display VLAN or MLT names that contain prohibited special characters.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Show the RESTCONF VLAN or MLT names that contain prohibited special characters:

```
show application restconf invalid-name vlan

show application restconf invalid-name mlt
```

Example

```
Switch:1>show application restconf invalid-name mlt
-----
Invalid MLT names - Only "-" and "_" special characters are allowed
-----
Mlt 3 name has special characters - "gigi#g"
Mlt 4 name has special characters - "my%mlt"
Mlt 5 name has special characters - "isa.text"
-----
Total Invalid Names Count: 3
```

What to Do Next

If any of the names contain prohibited special characters, change the names to remove the special characters.

RESTCONF Configuration using EDM

This section contains procedures for configuring RESTCONF with Enterprise Device Manager (EDM).

Configuring the RESTCONF Server**About This Task**

To configure the server, you must enable RESTCONF. RESTCONF is disabled by default.

After RESTCONF is enabled, you must disable RESTCONF to modify some of the RESTCONF parameters.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability**.
2. Click **RESTCONF**.
3. Click the **RESTCONF** tab.
4. Select the **GlobalEnable** check box to enable the RESTCONFserver.
5. Configure optional parameters as required.
6. Click **Apply**.

RESTCONF Field Descriptions

Use the data in the following table to use the RESTCONF tab.

Name	Description
GlobalEnable	Enables or disables the RESTCONF server. The default is disabled (cleared).
TcpPort	Specifies the TCP port to use for the RESTCONF server. The default is 8080. The RESTCONF status must be disabled before you can modify this field.
TlsEnable	Enables or disables TLS/SSL if you require HTTPS access to the RESTCONF server. The default is disabled. The RESTCONF status must be disabled before you can modify this field.
CertificateFilename	If HTTPS access is required, specifies the file name and path of the TLS/SSL certificate. The certificate file must be in the <code>/intflash</code> directory on the switch.
CertificateAction	Installs or uninstalls the TLS/SSL certificate file. It also shows the current status of the certificate installation.

Name	Description
NotificationEnable	Enables or disables trap notification when the RESTCONF server is not available. The default is enabled.
OperStatus	Shows the operational status of the RESTCONF server.
WebServerVersion	Shows the RESTCONF web server version that is running on the server.
RestConfServerVersion	Shows the RESTCONF server version that is running on the server.

Use Representational State Transfer Configuration Protocol (RESTCONF) to Configure a Switch

The documentation does not include information about how to use RESTCONF clients. This example documents some common tasks using Python.

For additional details, see [Extreme API with Python](#).

Before You Begin

Configure the RESTCONF server on the switch.

Procedure

1. Import classes, define variables, and prepare the session object:

```
#!/usr/bin/env python
import sys
import json
import requests
from requests import Request, Session
from requests.auth import HTTPBasicAuth
from requests.packages.urllib3.exceptions import InsecureRequestWarning
requests.packages.urllib3.disable_warnings(InsecureRequestWarning)
#####
Host      = '192.0.2.1'
TcpPort   = '8080'
UserName  = 'rwa'
Password  = 'rwa'
LoginUrl  = 'https://%s:%s/auth/token' % (Host, TcpPort)
QueryUrl  = 'https://%s:%s/rest/restconf/data/' % (Host, TcpPort)
vlan      = 123
#####
session   = Session()
session.verify = False
session.timeout = 5

session.headers.update({
    'Accept':          'application/json',
    'Accept-Encoding': 'gzip, deflate, br',
    'Connection':      'keep-alive',
    'Cache-Control':   'no-cache',
    'Pragma':           'no-cache', })
```

- Learn the authentication token:

**Note**

The token expires after 24 hours.

```
body = '{"username": "%s", "password" : "%s" }' % (UserName,PassWord)

response = session.put( LoginUrl, body )

if response.status_code != 200:
    print "ERROR: Login failed"
    sys.exit(1)
else:
    session.headers.update({
        'X-Auth-Token': response.headers['X-Auth-Token']
    })
    print "INFO: login passed"
```

- Query all VLANs:

```
response = session.get( QueryUrl + 'openconfig-vlan:vlan' )
if response.status_code != 200:
    print 'ERROR: can't fetch VLANs'
```

- Query specific VLANs:

```
response = session.get( QueryUrl + 'openconfig-vlan:vlan/vlan=%s' % vlan )

if response.status_code != 200:
    print 'INFO: VLAN %s doesn't exists' % vlan
else:
    print 'INFO: VLAN %s exists' % vlan
```

- Access data:

```
inbound_data = json.loads( response.text )

for vlan in inbound_data['openconfig-vlan:vlan']['vlan']:
    print 'VLAN: %s [%s]' % ( vlan['state']['name'], vlan['vlan-id'] )
```

- Present data:

```
inbound_data = json.loads( response.text )

for dataVlan in inbound_data[ dataObject ]['vlan']:
    print ''
    print 'VLAN: ' + dataVlan['state']['name'] + '[' + dataVlan['vlan-id'] + ']'
    interfaces = ' '
    if 'members' in dataVlan :
        for interface in dataVlan['members']['member ']:
            interfaces = interfaces + interface['interface-ref']['state']['interface']
    + ','

    print interfaces
```

- Add a VLAN:

```
dataObject = 'openconfig-vlan:vlan'

data = { "openconfig-vlan:vlan": [
    { "config":
        { "name": "Test-VLAN",
          "extreme-mod-oc-vlan:stg-id": 1,
          "vlan-id": vlan
        }
    }
]
```

```

    }

    response = session.post( QueryUrl + dataObject, json=data )

    if response.status_code != 201:
        print "ERROR: add VLAN %s failed" % vlan
    else:
        print "INFO: VLAN %s added " % vlan

```

8. Update a VLAN:

```

dataObject = 'openconfig-vlan:vlans/vlan=%s/config' % vlan

data = { "openconfig-vlan:config":
        { "name": "New-VLAN-Name" }
        }

response = session.patch( QueryUrl + dataObject )

if response.status_code != 204:
    print "ERROR: update VLAN %s fails" % vlan
else:
    print "INFO: VLAN %s updated" % vlan

```

9. Delete a VLAN:

```

dataObject = 'openconfig-vlan:vlans/vlan=%s' % vlan

response = session.delete( QueryUrl + dataObject )

if response.status_code != 204:
    print "ERROR: delete VLAN %s fails" % vlan
else:
    print "INFO: VLAN %s deleted" % vlan

```

RESTCONF Operational Behavior Examples

This section provides an example of RESTCONF operational behavior.

In the following example, RESTCONF sends a request that involves multiple commands where one command operation fails and other command operations proceed.

Example:

```

POST http://{{vossip}}:8080/rest/restconf/data/extreme-network-service:network-services
{
  "extreme-network-service:network-services": [
    {
      "network-service": {
        "id": "990099",
        "type": "elanTransparent",
        "name": "isid-990099",
        "interfaces": {
          "interface": [
            {
              "name": "1/8"
            }
          ]
        }
      }
    }
  ]
}

```

```

"ietf-restconf:errors": {
  "error": [
    {
      "error-message": "Unable to push data - Manual configuration not allowed on Auto-
Sense port",
      "error-tag": "operation-failed",
      "error-type": "protocol"
    }
  ]
}
}

```

The following sample output displays the configured I-SID and the created ELAN-transparent based service. The port does not display because the command operation failed.

```

Switch:1(config)#i-sid name 990099 isid-990099
Switch:1(config)#i-sid 990099 elan-transparent
Switch:1(elan-tp:990099)#port 1/8

Switch:1>show i-sid
*****

RIP fundamentals

Use the information in these sections to help you understand the Routing Information Protocol (RIP). For more information about the Border Gateway Protocol (BGP), see [BGP](#) on page 345.

Routing Information Protocol

In routed environments, routers communicate with one another to track available routes. Routers can dynamically learn about available routes using the RIP. The switch software implements standard RIP to exchange IP route information with other routers.

RIP uses broadcast User Datagram Protocol (UDP) data packets to exchange routing information. Each router advertises routing information by sending a routing information update every 30 seconds (one interval). If RIP does not receive information about a network for 180 seconds, the metric associated with the network rises to infinity (U); that is, the metric resets to 16, which means the network becomes

unreachable. If RIP does not receive information about a network for 120 seconds, it removes the network from the routing table.

RIP is a distance vector protocol. The vector is the network number and next hop, and the distance is the cost associated with the network number. RIP identifies network reachability based on cost, and cost is defined as hop count. One hop is the distance from one router to the next. This cost or hop count is the metric (see the following figure).

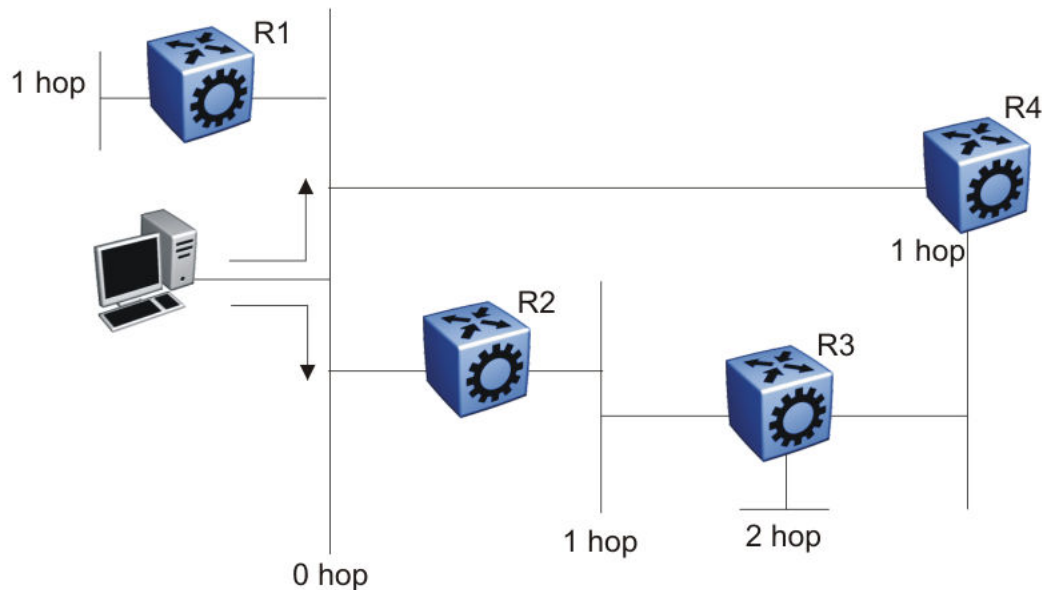

Figure 204: Hop count or metric in RIP

RIP version 1 (RIPv1) advertises default class addresses without subnet masking. RIP version 2 (RIPv2) advertises class addresses explicitly, based on the subnet mask.

The switch supports RIPv2, which supports variable length subnet masks (VLSM) and triggered router updates. RIPv2 sends mask information. If RIP does not receive information about a network for 90 seconds, the metric associated with the network rises to infinity (U); that is, the metric resets to 16, which means the network becomes unreachable. If RIP does not receive information about a network for 180 seconds (six update intervals), it removes the network from the routing table. You can change the default timers by configuring the RIP interface timeout timer and the holddown timer.

A directly connected network has a metric of zero. An unreachable network has a metric of 16. Therefore, the highest metric between two networks can be 15 hops or 15 routers.

RIP and route redistribution

Redistribution imports routes from one protocol to another. Redistribution sends route updates for a protocol-based route through another protocol. For example, if RIP routes exist in a router and they must travel through a BGP network, configure redistribution of RIP routes through BGP. Redistribution sends RIP routes to a router that uses BGP.

You can redistribute routes

- on an interface basis

- on a global basis between protocols on a single VRF instance (intraVRF)
- between the same or different protocols on different VRF instances (interVRF)

To configure interface-based redistribution, configure a route policy, and then apply it to the interface. Configure the match parameter to the protocol from which to learn routes.

You can redistribute routes on a global basis, rather than for every interface. The switch adds support for global RIP redistribution. Use the **ip rip redistribute** command to accomplish the (intraVRF) redistribution of routes through RIP, so that RIP redistribution occurs globally on all RIP-enabled interfaces. This redistribution does not require a route policy, but you can use one for more control.

If you configure redistribution globally and on an interface, redistribution through the route policy takes precedence.

You can redistribute routes from a protocol in one VRF to RIP in another VRF. You can use a route policy for redistribution control. If you enable route redistribution between VRF instances, ensure that IP addresses do not overlap.

RIPng fundamentals

Routing Information Protocol next generation (RIPng) allows routers to exchange information for computing routes through an IPv6-based network. You should implement RIPng only on routers. IPv6 provides neighbor router information required by RIPng protocol to function as intended. A RIPng router is assumed to have interfaces in several networks and the protocol relies primarily on the metric of each network to compute routes using the distance vector algorithm.

RIP identifies network reachability based on cost, and cost is defined as hop count. One hop is the distance from one router to the next. This cost, or hop count, is the metric.

RIPng-enabled routers use UDP port 521 (the RIPng port) to exchange routing information. RIPng responds to a request by sending a message to the port from which the request originates. Specific queries can be sent from ports other than the RIPng port, but they must be directed to the RIPng port on the target machine.

Each router advertises routing information by sending an update every 30 seconds (one interval). If RIPng does not receive information about a network for 180 seconds, the metric associated with the network rises to infinity (U); that is, the metric resets to 16, which means the network becomes unreachable. If RIP does not receive information about a network for 120 seconds, it removes the network from the routing table.

Note

These time interval values are default values which are configurable by the user.

Each router that implements RIPng contains a routing table. This table contains one entry for every destination that is reachable throughout the system operating RIPng. At a minimum, each routing table entry contains the following information:

- The IPv6 prefix of the destination.
- A metric that represents the total cost of getting a datagram from the router to that destination. The metric is the sum of the costs of traversing the networks to arrive at the destination.

- The IPv6 address of the next router in the path to the destination (the next hop). The next-hop IPv6 address is a linklocal address.
- The VLAN or brouter port on which the RIPng routes were learned.
- The age of the RIPng route.

RIPng protocol implementation is specified in IETF document RFC 2080.

RIPng messages and packet format

RIPng-enabled routers use UDP port 521 (the RIPng port) to send and receive datagrams.

The following figure shows the RIPng packet format:

Figure 205: RIPng packet format

A RIPng packet header consists of the following components:

- **command:** Specifies the purpose of the message.
- **version:** The version of RIPng.

Originate Default route

Generally you use a default route when it is not convenient to list every possible network in RIPng updates, and one or more routers in the system are able to handle traffic to networks that RIPng does not explicitly list.

RIPng is enabled with the default route only option. When you enable default route only on an interface, it suppresses all other routes in the update sent for the interface, and advertises only the default route.

Timers

RIPng states four different timer intervals for protocol operation:

- **Update timer:** The RIPng process sends a complete routing table to each neighboring router every 30 seconds. To prevent collisions on broadcast networks, the process adds an offset value to the timer.
- **Timeout time interval:** This is a 180 second time interval associated with every route. If the time interval expires, the metric for this route updates to the value of infinity (16) and the route is no longer valid. However, the routing table retains the value for another 120 seconds.
- **Garbage collection time interval:** After the timeout time interval expires and the route becomes invalid, it remains in the routing table until the garbage collection time interval expires. The garbage collection time interval is 120 seconds. Until the garbage collection time interval expires all updates sent by this router include the invalid route. When the garbage collection timer expires, the process removes the route from the routing table.
- **Triggered update time interval:** The triggered update time interval is set to a random value between 1 and 5 seconds after a triggered update is sent. A single update is sent even if multiple triggered updates occur before the timer expires.

Configuration of timers or time intervals is supported only at the CLI/SNMP/EDM level. Configuration of timers or time intervals is not supported at the interface/port level.

RIP configuration using CLI

Use Routing Information Protocol (RIP) to perform dynamic routing within an autonomous system. This section describes how you use the command line interface (CLI) to configure and manage RIP.

Configuring RIP globally

Configure RIP parameters on the switch so you can control RIP behavior on the system.

Before You Begin

- You configure RIP on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip rip**. The VRF must have an RP Trigger of RIP. Not all parameters are configurable on non0 VRFs.

About This Task

All router interfaces that use RIP use the RIP global parameters. Both brouter ports and VLAN virtual routing interfaces use the same RIP global parameters.

You can configure RIP on interfaces while RIP is globally disabled. This way, you can configure all interfaces before you enable RIP for the switch.

Procedure

1. Enter RIP Router Configuration mode:

```
enable

configure terminal

router rip
```

2. Define the default-import-metric for the switch:
`default-metric <0-15>`
3. (Optional) Configure one or more timer values:
`timers basic timeout <15-259200> [holddown <0-360>] [update <1-360>]`
4. Enable RIP on an IP network:
`network {A.B.C.D}`
5. Exit to Global Configuration mode:
`exit`
6. After the configuration is complete, enable RIP globally:
`router rip enable`
- 7.
8. Check that your configuration is correct:
`show ip rip [vrf WORD<1-16>] [vrfids WORD<0-512>]`

Example

Define the default-import-metric as 1, the timeout interval as 180, the holddown time as 120, and the update time as 30. Enable RIP on an IP network, and ensure your configuration is correct.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1#router rip
Switch:1(config-rip)#default-metric 1
Switch:1(config-rip)#timers basic timeout 180 holddown 120 update 30
Switch:1(config-rip)#network 192.0.2.11
Switch:1(config-rip)#exit
Switch:1(config)#router rip enable
Switch:1(config)#show ip rip
=====
                        RIP Global - GlobalRouter
=====
Default Import Metric : 1
      HoldDown Time   : 120
          Queries    : 0
              Rip     : Enabled
      Route Changes   : 0
      Timeout Interval : 180
          Update Time  : 30
```

Variable definitions

The following table defines parameters for the RIP commands.

Variable	Value
<code>default-metric <0-15></code>	Configures the value of default import metric to import a route into a RIP domain. To announce OSPF internal routes into RIP domain, if the policy does not specify a metric value, the default is used. For OSPF external routes, the external cost is used. The default is 8.
<code>domain <0-39321></code>	Specifies the RIP domain from 0-39321. The default is 0.

Variable	Value
<code>holddown <0-360></code>	Configures the RIP hold-down timer value, the length of time (in seconds) that RIP continues to advertise a network after it determines that the network is unreachable. The default is 120.
<code>network {A.B.C.D}</code>	Enables RIP on an IP network.
<code>timeout <15-259200></code>	Configures the RIP timeout interval. The default is 180.
<code>update <1-360></code>	Configures the RIP update timer. The update time is the time interval, in seconds, between RIP updates. The default is 30.

The following table defines parameters for the **show ip rip** command.

Variable	Value
<code>vrf WORD<1-16></code>	Specifies a VRF by name.
<code>vrfids WORD<0-512></code>	Specifies a range of VRF IDs.

Configuring RIP on an interface

Configure RIP on Ethernet ports and VLANs so that they can participate in RIP routing.

Before You Begin

- Assign an IP address to the port or VLAN.
- Configure RIP and enable it globally.
- Configure in and out policies.

About This Task

RIP does not operate on a port or VLAN until you enable it both globally and on the port or VLAN.

To configure RIP on a VRF instance for a port or VLAN, you configure RIP on the port or VLAN, and then associate the port or VLAN with the VRF.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Define the cost:

```
ip rip cost <1-15>
```

3. Specify an in policy for filtering inbound RIP packets:
`ip rip in-policy WORD<0-64>`
4. Specify an out policy for filtering outbound RIP packets:
`ip rip out-policy WORD<0-64>`
5. Enable RIP:
`ip rip enable`
6. Specify the send mode:
`ip rip send version <notsend|rip1|rip1comp|rip2>`
7. Specify the receive mode:
`ip rip receive version <rip1|rip2|rip1orrip2>`
8. Change other RIP parameters from their default values as required.

Example

The following configuration example shows how to configure the switch (labeled R1) to operate only in RIP version 2 mode.

Figure 206: Configuration example-RIPv2 only

Enable RIPv2 send mode on VLAN 2:

```
Switch:1(config-if)# ip rip send version rip2
```

Enable RIPv2 receive mode on VLAN 2:

```
Switch:1(config-if)# ip rip receive version rip2
```

Repeat these commands on VLAN 3 and the port interfaces.

Variable definitions

The following table defines parameters for the **ip rip** command.

Variable	Value
<i>advertise-when-down enable</i>	Enables or disables AdvertiseWhenDown. If enabled, RIP advertises the network on this interface as up, even if the port is down. The default is disabled. If you configure a port with no link and enable advertise-when-down, it does not advertise the route until the port is active. RIP advertises the route even when the link is down. To disable advertising based on link status, you must disable this parameter.
<i>auto-aggregation enable</i>	Enables or disables automatic route aggregation on the port. If enabled, the switch automatically aggregates routes to their natural mask when an interface in a different class network advertises them. The default is disable.
<i>cost <1-15></i>	Configures the RIP cost for this port (link).
<i>default-listen enable</i>	Enables DefaultListen. The switch accepts the default route learned through RIP on this interface. The default is disabled.
<i>default-supply enable</i>	Enables DefaultSupply. If enabled, this interface must advertise a default route. The default is false. RIP advertises the default route only if it exists in the routing table.
<i>enable</i>	Enables RIP routing on the port.
<i>holddown <0-360></i>	Configures the RIP holddown timer value, the length of time (in seconds) that RIP continues to advertise a network after it determines that the network is unreachable. The default is 120.
<i>in-policy WORD<0-64></i>	Configures the policy name for inbound filtering on this RIP interface. This policy determines whether to learn a route on this interface and specifies the parameters of the route when RIP adds it to the routing table.
<i>listen enable</i>	Specifies that the routing switch learns RIP routes through this interface. If enabled, the switch listens for a default route without listening for all routes. The default is enable.
<i>out-policy WORD<0-64></i>	Configures the policy name for outbound filtering on this RIP interface. This policy determines whether to advertise a route from the routing table on this interface. This policy also specifies the parameters of the advertisement. <i>WORD<0-64></i> is a string of length 0-64 characters.
<i>poison enable</i>	Enables Poison Reverse. If you disable Poison Reverse (<i>no poison enable</i>), Split Horizon is enabled. By default, Split Horizon is enabled. If you enable Split Horizon, the interface does not advertise IP routes learned from an immediate neighbor back to the neighbor. If you enable Poison Reverse, the RIP updates sent to a neighbor from which a route is learned are poisoned with a metric of 16. Therefore, the receiver neighbor ignores this route because the metric 16 indicates infinite hops in the network. These mechanisms prevent routing loops.

Variable	Value
<code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<code>receive version <rip1 rip2 rip1orrip2></code>	Indicates which RIP update version to accept on this interface. The default is rip1orrip2.
<code>send version <notsend rip1 rip1comp rip2></code>	Indicates which RIP update version the router sends from this interface. ripVersion1 implies sending RIP updates that comply with RFC1058. rip1comp implies broadcasting RIP2 updates using RFC1058 route subassumption rules. The default is rip1Compatible.
<code>supply enable</code>	Specifies that the switch advertises RIP routes through the port. The default is enable.
<code>timeout <15-259200></code>	Configures the RIP timeout interval in seconds. The default is 180.
<code>triggered enable</code>	Enables automatic triggered updates for RIP.

Configuring route redistribution to RIP

Configure a redistribute entry to announce certain routes into the RIP domain, including static routes, direct routes, RIP, Open Shortest Path First (OSPF), IS-IS, or Border Gateway Protocol (BGP). Optionally, use a route policy to control the redistribution of routes.

Before You Begin

- Enable RIP globally.
- Configure a route policy.

Procedure

1. Enter RIP Router Configuration mode:

```
enable
configure terminal
```

```
router rip
```

2. Create the redistribution instance:

```
redistribute <bgp|direct|isis|ospf|rip|static> [vrf-src WORD<1-16>]
```

3. Apply a route policy, if required:

```
redistribute <bgp|direct|isis|ospf|rip|static> route-map WORD<0-64>
[vrf-src WORD<1-16>]
```

4. Configure other parameters.

5. Enable the redistribution:

```
redistribute <bgp|direct|isis|ospf|rip|static> enable [vrf-src
WORD<1-16>]
```

6. Ensure that the configuration is correct:

```
show ip rip redistribute [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

7. Exit to Global Configuration mode:

```
exit
```

8. Apply the redistribution:

```
ip rip apply redistribute <bgp|direct|isis|ospf|rip|static> [vrf
WORD<1-16>] [vrf-src WORD<1-16>]
```

Example

Create the redistribution instance, apply a route policy, enable the redistribution, and apply the redistribution.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router rip
Switch:1(config-rip)#redistribute rip
Switch:1(config-rip)#redistribute rip route-map test1
Switch:1(config-rip)#redistribute rip enable
Switch:1(config-rip)#exit
Switch:1(config)#ip rip apply redistribute rip
```

Variable definitions

The following table defines parameters for the **redistribute** command.

Variable	Value
<i>metric</i> <0-65535>	Configures the metric to apply to redistributed routes.
<i>route-map</i> WORD<0-64>	Configures the route policy to apply to redistributed routes.
[<i>vrf-src</i> WORD<1-16>]	Specifies the optional source VRF instance. You can use this variable with the other command variables.
WORD<0-32>	Specifies the type of routes to redistribute (the protocol source). Valid options are bgp, isis, direct, rip, ospf, or static.

The following table defines parameters for the **show ip rip redistribute** command.

Variable	Value
<i>vrf</i> WORD<1-16>	Specifies the VRF instance.
<i>vrfids</i> WORD<1-512>	Specifies a range of VRF IDs.

The following table defines parameters for the **ip rip apply redistribute** command.

Variable	Value
<i>vrf</i> WORD<1-16>	Specifies the VRF instance.
<i>vrf-src</i> WORD<1-16>	Specifies the source VRF instance. You do not need to configure this parameter for redistribution within the same VRF.
< <i>bgp direct isis ospf rip static</i> >	Specifies the type of routes to redistribute (the protocol source). Valid options are bgp, isis, direct, rip, ospf, or static.

Configuring interVRF route redistribution for RIP

Configure a redistribute entry to announce certain routes into the RIP domain, including static routes, direct routes, RIP, OSPF, IS-IS, or BGP. Use a route policy to control the redistribution of routes.

Before You Begin

- Enable RIP globally.
- Configure a route policy.
- Configure the VRFs.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
router vrf WORD<1-16>
```

2. Create the redistribution instance:

```
ip rip redistribute <bgp|direct|isis|ospf|rip|static>
```

3. Apply a route policy, if required:

```
ip rip redistribute <bgp|direct|isis|ospf|rip|static> route-map  
WORD<0-64> [vrf-src WORD<1-16>]
```

4. Configure other parameters.

5. Enable the redistribution:

```
ip rip redistribute <bgp|direct|isis|ospf|rip|static> enable [vrf-src  
WORD<1-16>]
```

6. Ensure that the configuration is correct:

```
show ip rip redistribute [vrf WORD<1-16>] [vrfids WORD<1-512>]
```

7. Exit to Global Configuration mode:

```
exit
```

8. Apply the redistribution:

```
ip rip apply redistribute <bgp|direct|isis|ospf|rip|static> [vrf  
WORD<1-16>] [vrf-src WORD<1-16>]
```

Example

Create the redistribution instance, apply a route policy, enable the redistribution, and apply the redistribution.

```
Switch:1>enable  
Switch:1#configure terminal  
Switch:1#router vrf red  
Switch:1(router-vrf)#ip rip redistribute ospf  
Switch:1(router-vrf)#ip rip redistribute ospf route-map test1  
Switch:1(router-vrf)#ip rip redistribute ospf enable  
Switch:1(router-vrf)#exit  
Switch:1(config)#ip rip apply redistribute ospf
```

Variable definitions

The following table defines parameters for the **ip rip redistribute** `<bgp|isis|ospf|static|direct|rip>` command.

Variable	Value
<code><bgp direct isis ospf rip static></code>	Specifies the type of routes to redistribute (the protocol source). Valid options are bgp, isis, direct, rip, ospf, or static.
<code>vrf-src WORD<1-16></code>	Specifies the source VRF instance. You do not need to configure this parameter for redistribution within the same VRF.
<code>metric <0-65535></code>	Configures the metric to apply to redistributed routes.
<code>route-map WORD<0-64></code>	Configures the route policy to apply to redistributed routes.

The following table defines parameters for the **show ip rip redistribute** command.

Variable	Value
<code>vrf WORD<1-16></code>	Specifies the VRF instance.
<code>vrfids WORD<1-512></code>	Specifies a range of VRF IDs.

The following table defines parameters for the **ip rip apply redistribute** command.

Variable	Value
<code>vrf WORD<1-16></code>	Specifies the VRF instance.
<code>vrf-src WORD<1-16></code>	Specifies the source VRF instance. You do not need to configure this parameter for redistribution within the same VRF.
<code><bgp direct isis ospf rip static></code>	Specifies the type of routes to redistribute (the protocol source). Valid options are bgp, isis, direct, rip, ospf, or static.

Forcing a RIP Update for a Port or VLAN

Force RIP to update the routing table so that the port or VLAN uses the latest routing information.

About This Task

If you perform this procedure, you also update the tables for all VRFs associated with the port or VLAN.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable the triggered-update flag:

```
ip rip triggered enable
```

**Note**

You can enable this flag in either the GigabitEthernet or VLAN Interface Configuration mode. However, you can update the RIP routes in the GigabitEthernet Interface Configuration mode only.

3. Update the routing table:

```
action triggerRipUpdate
```

Example

Update the routing table:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 1
Switch:1(config-if)#ip rip triggered enable
```

Viewing the RIP redistribution configuration information

Displays the RIP redistribution configuration information.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. View the RIP redistribution configuration information:

```
show ip rip redistribute [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

Example

View the RIP redistribution configuration information:

```
Switch(config-ospf)#show ip rip redistribute
```

```
=====
RIP Redistribute List - GlobalRouter
=====
```

SRC-VRF	SRC	MET	ENABLE	RPOLICY
GlobalRouter	ISIS	0	FALSE	

Variable definitions

The following table defines parameters for the **show ip rip redistribute** command or the **show ipv6 rip redistribute** command.

Variable	Value
<code>vrf WORD<1-16></code>	Specifies a VRF by name.
<code>vrfids WORD<0-512></code>	Specifies a range of VRF IDs.

RIPng Configuration using CLI

Use the procedures in this section to configure RIPng using CLI.

Configuring RIPng globally

Configure RIPng parameters on the router so you can control RIPng behavior on the system.

Before You Begin

You can configure RIPng only on a global router. You cannot configure RIPng on a VRF instance.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Enable RIPng globally:

```
router rip ipv6-enable
```

Configuring RIPng on an interface

Configure RIPng on Ethernet ports and VLANs so that they can participate in RIPng routing.

About This Task

RIPng does not operate on a port or VLAN until you enable it both globally and on the port or VLAN.

Before You Begin

- Assign an IP address to the port or VLAN.
- Configure RIPng and enable it globally.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Create a RIPng interface:

```
ipv6 rip
```

3. Enable the RIPng interface:

```
ipv6 rip enable
```

4. Verify the operational status of the RIPng interface:

```
show ipv6 rip interface
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface vlan 22
Switch:1(config-if)#ipv6 rip
Switch:1(config-if)#ipv6 rip enable
Switch:1(config-if)#show ipv6 rip interface
```

```
Total RIPng interfaces: 2
```

```
=====
                        RIPng Interface - GlobalRouter

IFINDX          COST    POISON          SEND          ADMIN          OPER
                  STATUS    DEFAULT        STATUS        STATUS
-----
257 (2/2 ) 2         disable        disable        enable         enable
2070 (22 ) 5         disable        disable        enable         disable

2 out of 2 Total Num of RIPng interfaces displayed
```

Variable Definitions

The following table defines parameters for the **ipv6 rip** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. This variable applies only to VLAN interfaces, not ports.
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Configuring RIPng custom values

Configure custom values for RIPng parameters to replace default values.

Before You Begin

- Configure RIPng and enable it globally.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable RIPng poison:

```
ipv6 rip poison enable
```

3. Specify the RIPng cost:

```
ipv6 rip cost <1-15 Cost>
```

4. Access router RIPng configuration mode:

```
router rip
```

5. Specify the RIPng holddown timer value:

```
ipv6 timers basic holddown <0-360>
```

6. Specify the RIPng timeout timer value:
`ipv6 timers basic timeout <15-259200>`
7. Specify the RIPng update timer value:
`ipv6 timers basic update <1-360>`
8. Specify the default route metric value:
`ipv6 default-information metric <1-15>`
9. Enable default information globally:
`ipv6 default-information enable`
10. Ensure the configuration is correct:
`show ipv6 rip`

Example

Configure custom values for RIPng.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router rip
Switch:1(config-rip)#ipv6 default-information metric 1
Switch:1(config-rip)#ipv6 default-information enable
Switch:1(config-rip)#ipv6 timers basic update 30
Switch:1(config-rip)#ipv6 timers basic timeout 180
Switch:1(config-rip)#ipv6 timers basic holddown 120
Switch:1(config-rip)#router rip ipv6-enable
Switch:1(config)#show ipv6 rip
```

```
=====
                        RIPng Global - GlobalRouter
=====
                        Rip : Enabled
                        HoldDown Time : 120
                        Timeout Interval : 180
                        Update Time : 30
                        Default Info Metric : 1
                        Default Info State : Enabled
                        Default Import Metric : 1
```

Variable definitions

Use the data in the following table to use the **ipv6 rip poison**, **ipv6 default-information** and **ipv6 timers basic** commands.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. This variable applies only to VLAN interfaces, not ports.
port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
poison enable	Enables Poison Reverse. If you disable Poison Reverse (no poison enable), Split Horizon is enabled. By default, Split Horizon is enabled. If you enable Split Horizon, the interface does not advertise IP routes learned from an immediate neighbor back to the neighbor. If you enable Poison Reverse, the RIP updates sent to a neighbor from which a route is learned are poisoned with a metric of 16. Therefore, the receiver neighbor ignores this route because the metric 16 indicates infinite hops in the network. These mechanisms prevent routing loops.
<1-15 Cost>	Configures the RIPng cost for this port (link).
holddown <0-360>	Configures the RIPng holddown timer value, the length of time (in seconds) that RIPng continues to advertise a network after it determines that the network is unreachable. The default is 120.
timeout <15-259200>	Configures the RIPng timeout interval. The default is 180.
update <1-360>	Configure the RIPng update timer. The update time is the time interval between RIPng updates.
default-information <1-15>	Configure the default route metric value.

Configuring RIPng route distribution

Configure a redistribute entry to announce certain routes into the RIPng domain, including static routes, direct routes, Open Shortest Path First (OSPFv3), IS-IS, or Border Gateway Protocol (BGP+).

Before You Begin

- Enable RIPng globally.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Access router RIP configuration mode:

```
router rip
```
3. Enable the redistribution:

```
ipv6 redistribute {direct|isis|static|ospf|bgp} enable
```
4. Ensure the configuration is correct:

```
show ipv6 rip redistribute
```

Example

Enable the redistribution instance.

```
Switch:1#enable
Switch:1#configure terminal
Switch:1(config)#router rip
Switch:1(config-rip)#ipv6 redistribute bgp enable
Switch:1(config-rip)#ipv6 redistribute direct enable
Switch:1(config-rip)#ipv6 redistribute isis enable
Switch:1(config-rip)#ipv6 redistribute ospf enable
Switch:1(config-rip)#ipv6 redistribute static enable
Switch:1(config-rip)#show ipv6 rip redistribute
```

```
=====
                        RIPng Redistribute List
=====
```

```

direct          : enabled
static          : enabled
ospf            : enabled
bgp             : enabled
isis            : enabled
=====
```

Variable definitions

Use the data in the following table to use the **ipv6 redistribute** command.

Variable	Value
<bgp direct isis ospf static>	Specifies the type of routes to redistribute (the protocol source). Valid options are bgp, isis, direct, ospf, or static.

RIP configuration using EDM

Use Routing Information Protocol (RIP) to perform dynamic routing within an autonomous system. This section describes how you use Enterprise Device Manager (EDM) to configure and manage RIP.

Configuring RIP globally

Configure RIP global parameters on the switch so you can control RIP behavior on the system.

Before You Begin

- Change the VRF instance as required to configure RIP on a specific VRF instance. The VRF must have an RP trigger of RIP. Not all parameters are configurable on non-default VRFs.

About This Task

All router interfaces that use RIP use the RIP global parameters. Both brouter ports and VLAN virtual routing interfaces use the same RIP global parameters.

You can configure RIP on interfaces while RIP is globally disabled. This way, you can configure all interfaces before you enable RIP for the switch.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **RIP**.
3. Click the **Globals** tab.
4. Select the **enable** option button.
5. Configure other global RIP parameters as required.
6. Click **Apply**.

Globals field descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
Operation	Enables or disables RIP on all interfaces. The default is disabled.
UpdateTime	Specifies the time interval between RIP updates for all interfaces. The default is 30 seconds, and the range is 0–360.
RouteChanges	Specifies the number of route changes RIP made to the IP route database. RouteChanges does not include the refresh of a route age.
Queries	Specifies the number of responses sent to RIP queries received from other systems.
HoldDownTime	Configures the length of time that RIP continues to advertise a network after the network is unreachable. The range is 0–360 seconds. The default is 120 seconds.
TimeOutInterval	Configures the RIP timeout interval. The range is 15–259200 seconds. The default is 180 seconds.
DefImportMetric	Configures the default import metric used to import a route into a RIP domain. To announce OSPF internal routes into a RIP domain, if the policy does not specify a metric, you must use the default import metric. OSPF external routes use the external cost. The range is 0–15 and the default is 8.

Viewing RIP status

View RIP status.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **RIP**.
3. Click the **Status** tab.

Status field description

The following table defines parameters for the **RIP Status** tab.

Name	Description
Address	Specifies the IP address of the router interface.
RcvBadPackets	Specifies the number of RIP response packets received by the RIP process which were subsequently discarded; for example, version 0 packet, or an unknown command type.
RcvBadRoutes	Specifies the number of routes, in valid RIP packets, that are ignored; for example, unknown address family, or invalid metric.
SentUpdates	Specifies the number of triggered RIP updates sent on this interface, that do not include full updates sent containing new information.

Configuring RIP interface compatibility

Configure RIP parameters on an interface so you can control RIP behavior on the interface. You can specify the RIP version to use on interfaces that you configure to send (supply) or receive (listen to) RIP updates.

Before You Begin

- Configure a routing interface (either a router port or a virtual routing interface).
- Assign an IP address to the interface.
- Enable RIP globally.
- Change the VRF instance as required to configure RIP on a specific VRF instance. The VRF must have an RP trigger of RIP. Not all parameters are configurable on non-default VRFs.

About This Task

On an interface, RIP does not operate until you enable it globally and on the interface.

Although visible, the switch does not support the AuthType and AuthKey parameters.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **RIP**.
3. Click the **Interface** tab.
4. Double-click the **Send** value to edit it, and then select the RIP version datagrams the router sends.
5. Double-click the **Receive** value to edit it, and then select the RIP version datagrams for which the router listens.
6. Click **Apply**.

Interface Field Descriptions

Use the data in the following table to use the **Interface** tab.

Name	Description
Address	Specifies the IP address of the router interface.
Domain	Specifies the value inserted into the routing domain parameter of all RIP packets sent on this interface.
AuthType	Specifies the type of authentication to use on this interface.
AuthKey	Specifies the authentication key whenever AuthType is not noAuthentication.
Send	Specifies the update version the router sends on this interface: <ul style="list-style-type: none"> • DoNotSend—no RIP updates sent on this interface • ripVersion1—RIP updates compliant with RFC1058 • rip1Compatible—broadcast RIPv2 updates using RFC1058 route subassumption rules • ripVersion2—multicast RIPv2 updates The default is rip1compatible.
Receive	Indicates which versions of RIP updates to accept: <ul style="list-style-type: none"> • rip1 • rip2 • rip1OrRip2 The default is rip1OrRip2. Rip2 and rip1OrRip2 imply receipt of multicast packets.

Job Aid

Choose one of three options for receiving RIP updates:

- rip1OrRip2—accepts RIPv1 or RIPv2 updates
- rip1—accepts RIPv1 updates only
- rip2—accepts RIPv2 updates only

The following table describes the four RIP send modes that the switch supports. You can configure RIP send modes on all router interfaces.

Table 180: RIP send modes

Send mode	Description	Result
rip1Compatible	Broadcasts RIPv2 updates using RFC1058 route consumption rules. This is the default mode.	<ul style="list-style-type: none"> Destination MAC is a broadcast, ff-ff-ff-ff-ff Destination IP is a broadcast for the network (for example, 192.0.2.255) RIP update is formed as a RIP-2 update, including network mask RIP version = 2
ripVersion1	Broadcasts RIP updates that are compliant with RFC1058	<ul style="list-style-type: none"> Destination MAC is a broadcast, ff-ff-ff-ff-ff Destination IP is a broadcast for the network (for example, 198.0.2.255) RIP update is formed as a RIP-1 update, no network mask included RIP version = 1
ripVersion2	Broadcasts multicast RIPv2 updates	<ul style="list-style-type: none"> Destination MAC is a multicast, 01-00-5e-00-00-09 Destination IP is the RIP-2 multicast address, 224.0.0.9 RIP update is formed as a RIP-2 update including network mask RIP version = 2
doNotSend	Does not send RIP updates on the interface	None

Configuring RIP on an interface

Configure RIP parameters to control and optimize RIP routing for the interface.

Before You Begin

- Change the VRF instance as required to configure RIP on a specific VRF instance. The VRF must have an RP trigger of RIP. Not all parameters are configurable on non-default VRFs.

Procedure

- In the navigation pane, expand **Configuration > IP**.
- Click **RIP**.
- Click the **Interface Advance** tab.
- Double-click a RIP parameter to edit it, as required.
- Click **Apply**.

Interface Advance field descriptions

Use the data in the following table to use the RIP **Interface Advance** tab.

Name	Description
Address	Shows the address of the entry in the IP RIP interface table.
Interface	Indicates the index of the RIP interface.
Enable	Shows if the RIP interface is enabled or disabled.
Supply	Enables (true) or disables (false) the ability to send RIP updates on this interface.
Listen	Configures whether the switch learns routes on this interface.
Poison	Configures whether to advertise RIP routes learned from a neighbor back to the neighbor. If disabled, the interface invokes Split Horizon and does not advertise IP routes learned from an immediate neighbor back to the neighbor. If enabled, RIP poisons the RIP updates, sent to the neighbor from which a route is learned, with a metric of 16. Therefore, the receiver neighbor ignores this route because the metric 16 indicates infinite hops in the network.
DefaultSupply	Enables (true) or disables (false) an advertisement of a default route on this interface. This command takes effect only if a default route exists in the routing table.
DefaultListen	Enables (true) or disables (false) the switch to accept the default route learned through RIP on this interface. The default is disabled. Enable DefaultListen to add a default route to the route table if another route advertises it.
TriggeredUpdate	Enables (true) or disables (false) the switch to send RIP updates from this interface.
AutoAggregate	Enables (true) or disables (false) automatic route aggregation on this interface. If enabled, the switch automatically aggregates routes to their natural mask when an interface advertises them. The default is disabled.
InPolicy	Determines if RIP can learn routes on this interface. This variable also specifies the parameters of the route when RIP adds it to the routing table.
OutPolicy	Determines if RIP advertises a route from the routing table on this interface. This policy also specifies the parameters of the advertisement.
Cost	Indicates the RIP cost for this interface. The range is 1-15. The default is 1.

Job aid

The following table indicates the relationship between switch action and the RIP supply and listen settings.

Table 181: RIP supply and listen settings and switch action

RIP supply settings		RIP listen settings		Switch action
Supply	Default supply	Listen	Default listen	
Disabled (false)	Disabled (false)			Sends no RIP updates.
Enabled (true)	Disabled (false)			Sends RIP updates except the default.
Disabled (false)	Disabled (false)			Sends only the default (default route must exist in routing table).
Enabled (true)	Enabled (true)			Sends RIP updates including the default route (if it exists).
		Disabled (false)	Disabled (false)	Does not listen to RIP updates.
		Enabled (true)	Disabled (false)	Listens to all RIP updates except the default.
		Disabled (false)	Enabled (true)	Listens only to the default.
		Enabled (true)	Enabled (true)	Listens to RIP updates including the default route (if it exists).

Configuring RIP on a port

Configure RIP on a port so that the port can participate in RIP routing.

Before You Begin

- Assign an IP address to the port.
- Configure RIP and enable it globally.

Both brouter ports and VLAN virtual routing interfaces use the same RIP global parameters.

- Enable RIP on the interface.

About This Task

On an interface, RIP does not operate until you enable it globally and on the interface.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Click **IP**.
4. Click the **RIP** tab.

5. Configure the RIP parameters as required.
6. Click **Apply**.

RIP field descriptions

Use the data in the following table to use the **RIP** tab.

Name	Description
Enable	Enables or disables RIP on the port.
Supply	Specifies that the routing switch advertises RIP routes through the interface. The default is enable.
Listen	Specifies that the routing switch learns RIP routes through this interface. The default is enable.
Poison	If disabled, the interface invokes Split Horizon and does not advertise IP routes learned from an immediate neighbor back to the neighbor. If enabled, the RIP update sent to a neighbor from which a route is learned is poisoned with a metric of 16. In this manner, the route entry is not passed to the neighbor, because 16 is infinity in terms of hops on a network. The default is disable.
DefaultSupply	Enables or disables DefaultSupply. Enable DefaultSupply if a default route exists in the routing table. The default is false. RIP advertises the default route only if it exists in the routing table.
DefaultListen	Enables or disables DefaultListen. Enable DefaultListen if this interface must learn a default route after another router that connects to the interface advertises it. The default is false (disabled). Enable DefaultListen to add a default route to the route table if another router advertises it.
TriggeredUpdateEnable	Enables or disables triggered RIP updates. The default is false (disabled).
AutoAggregateEnable	Enables or disables RIP automatic aggregation. RIPv2 automatically aggregates routes to their natural mask. You can enable automatic aggregation only in RIPv2 mode or RIPv1 compatibility mode. The default is false.
AdvertiseWhenDown	Enables or disables AdvertiseWhenDown. If true, RIP advertises the network on this interface as up, even if the port is down. The default is false. If you configure a port with no link and enable AdvertiseWhenDown, the port does not advertise the route until the port is active. RIP advertises the route even when the link is down. To disable advertising based on link-states, disable AdvertiseWhenDown.
InPolicy	Determines whether the RIP can learn a route on this interface. This variable also specifies the parameters of the route when RIP adds it to the routing table.
OutPolicy	Determines if this interface advertises a route from the routing table on this interface. This policy also specifies the parameters of the advertisement.
Cost	Indicates the RIP cost for this interface. The default is 1, and the range is 1–15.

Name	Description
HolddownTime	Configures the length of time that RIP continues to advertise a network after determining it is unreachable. The range is 0–360 seconds. The default is 120 seconds
TimeOutInterval	Configures the RIP timeout interval in seconds. The range is 15–259200 seconds. The default is 180 seconds.

Configuring RIP on a VLAN

Configure RIP on a VLAN so that the VLAN acts as a routed VLAN (a virtual router).

Before You Begin

- Configure the VLAN.
- Assign an IP address to the VLAN.
- Enable RIP globally.
- Enable RIP on the interface.
- Change the VRF instance as required to configure RIP on a specific VRF instance. The VRF must have an RP trigger of RIP. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select a VLAN.
5. Click **IP**.
6. Click the **RIP** tab.
7. Configure the VLAN RIP parameters as required.
8. Click **Apply**.

RIP field descriptions

Use the data in the following table to use the **RIP** tab.

Name	Description
Enable	Enables or disables RIP on the VLAN.
Supply	Specifies that the routing switch advertises RIP routes through the interface. The default is enable.
Listen	Specifies that the routing switch learns RIP routes through this interface. The default is enable.
Poison	If disabled, the interface invokes Split Horizon and does not advertise IP routes learned from an immediate neighbor back to the neighbor. If enabled, the RIP update sent to a neighbor from which a route is learned is poisoned with a metric of 16. In this manner, the route entry is not passed to the neighbor, because 16 is infinity in terms of hops on a network. The default is disable.

Name	Description
DefaultSupply	Enables or disables DefaultSupply. Enable DefaultSupply if a default route exists in the routing table. The default is false. RIP advertises the default route only if it exists in the routing table.
DefaultListen	Enables or disables DefaultListen. Enable DefaultListen if this interface must learn a default route after another router that connects to the interface advertises it. The default is false (disabled). Enable DefaultListen to add a default route to the route table if another router advertises it.
TriggeredUpdateEnable	Enables or disables triggered RIP updates. The default is false (disabled).
AutoAggregateEnable	Enables or disables RIP automatic aggregation. RIPv2 automatically aggregates routes to their natural mask. You can enable automatic aggregation only in RIPv2 mode or RIPv1 compatibility mode. The default is false.
AdvertiseWhenDown	Enables or disables AdvertiseWhenDown. If true, RIP advertises the network on this interface as up, even if the interface is down. The default is false. If you configure a VLAN with no link and enable AdvertiseWhenDown, the VLAN does not advertise the route until the VLAN is active. RIP advertises the route even when the link is down. To disable advertising based on link-states, disable AdvertiseWhenDown.
InPolicy	Determines whether the RIP can learn a route on this interface. This variable also specifies the parameters of the route when RIP adds it to the routing table.
OutPolicy	Determines if this interface advertises a route from the routing table. This policy also specifies the parameters of the advertisement.
Cost	Indicates the RIP cost for this interface. The default is 1, and the range is 1–15.
HolddownTime	Configures the length of time that RIP continues to advertise a network after determining it is unreachable. The range is 0–360 seconds. The default is 120 seconds
TimeOutInterval	Configures the RIP timeout interval in seconds. The range is 15–259200 seconds. The default is 180 seconds.

Configuring route redistribution to RIP

Configure a redistribute entry to announce routes of a certain source protocol type into the RIP domain, for example, static, RIP, or direct. Use a route policy to control the redistribution of routes.

Before You Begin

- Enable RIP globally.
- Configure a route policy.
- Change the VRF instance as required to configure RIP on a specific VRF instance. The VRF must have an RP trigger of RIP. Not all parameters are configurable on non-default VRFs.

About This Task

Important

Changing the RIP redistribute context is a process-oriented operation that can affect system performance and network reachability while you perform the procedures. As a best practice, change default preferences for a RIP redistribute context, you must do so before you enable the protocols.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **RIP**.
3. Click the **Redistribute** tab.
4. Click **Insert**.
5. Configure the source of the routes to redistribute.
6. Select **enable**.
7. Select the route policy to apply to redistributed routes.
8. Configure a metric value.
9. Click **Insert**.

Redistribute field descriptions

Use the data in the following table to use the **Redistribute** tab.

Name	Description
DstVrfId	Specifies the destination VRF instance. You cannot configure this variable.
Protocol	Specifies the dynamic routing protocol that receives the external routing information.
SrcVrfId	Specifies the source VRF instance. You cannot configure this variable.
RouteSource	Specifies the route source protocol for the redistribution entry.
Enable	Enables (or disables) a RIP redistribute entry for a specified source type.
RoutePolicy	Configures the route policy (by name) that redistributes external routes from a specified source into an RIP domain. Click the ellipsis (...) button and choose from the list in the Route Policy dialog box.
Metric	Configures the RIP route redistribution metric for basic redistribution. The value can be in the range 0–65535. A value of 0 indicates to use the original cost of the route.

RIPng Configuration using EDM

Use the procedures in this section to configure RIPng using EDM.

Configuring RIPng globally

Configure RIPng global parameters on the switch so you can control RIPng behavior on the system.

About This Task

All router interfaces that use RIPng use the RIPng global parameters. Both brouter ports and VLAN virtual routing interfaces use the same RIPng global parameters.

You can configure RIPng on interfaces while RIPng is globally disabled. This way, you can configure all interfaces before you enable RIPng for the switch

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 RIPng**.
3. Click the **Globals** tab.
4. Select the **enable** option button.
5. Configure other global RIPng parameters as required.
6. Click **Apply**.

Globals field descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
AdminState	Enables or disables RIPng globally. The default is disabled.
UpdateTime	Specifies the time interval between RIPng updates for all interfaces. The default is 30 seconds, and the range is 1-360.
GlobalHoldDownTime	Configures the length of time that RIPng continues to advertise a network after the network is unreachable. The range is 0-360 seconds. The default is 120 seconds.
GlobalTimeOutInterval	Configures the RIPng timeout interval. The range is 15-259200 seconds. The default is 180 seconds.
DefaultInfoMetric	RIPng default-information metric.
DefaultInfoState	Default-information enable or disable at the global level
DefaultImportMetric	Specifies the RIPng default import metric.

Configuring an IPv6 RIPng interface

Configure RIPng parameters on an interface so you can control RIPng behavior on the interface.

About This Task

RIPng does not operate on an interface until you enable it globally and on the interface.

You can also configure an IPv6 RIPng interface for a brouter port by selecting **Device Physical View** , selecting a port, and following the **Edit** > **Port** > **IPv6** navigation path. You can configure an IPv6 RIPng interface for a VLAN through the **VLAN** > **VLANs** > **Basic** > **IPv6** navigation path. This procedure uses the main IPv6 RIPng navigation path where you can create both types of interfaces.

Before You Begin

- Configure a routing interface (either a brouter port or a virtual routing interface).
- Assign an IP address to the interface.
- Enable RIPng globally.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 RIPng**.
3. Click the **Interfaces** tab.
4. Click **Insert**.
5. In the **IfIndex** box, type a value to identify the IPv6 interface.
6. In the **RipAdminStatus** option box, select **enable**.
7. Configure other parameters as required.
8. Click **Insert**.

Interfaces field descriptions

Use the data in the following table to use the **Interfaces** tab.

Name	Description
IfIndex	RIPng interface index.
RipAdminStatus	Enable or disable RIPng on an interface.
DefaultInfoState	Enable or disable default information at the interface level.
Cost	Specifies the RIPng metric cost.
Poison	Enable or disable poison reverse on an RIPng interface.
RipOperStatus	Enable or disable the RIPng operational state on an interface.

Configuring an IPv6 RIPng VLAN interface

Configure RIPng parameters on a VLAN interface so you can control RIPng behavior on the interface.

About This Task

RIPng does not operate on an interface until you enable it globally and on the interface.

You can also configure an IPv6 RIPng interface for a brouter port by selecting **Device Physical View**, selecting a port, and following the **Edit > Port > IPv6** navigation path.

Before You Begin

- Configure a routing interface (either a brouter port or a virtual routing interface).
- Assign an IP address to the interface.
- Enable RIPng globally.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > VLAN**.

2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select a row, and click **IPv6**.
5. Click **Insert**.
6. Configure other parameters, as required.
7. Click **Insert**.
8. Click **Apply**.

IPv6 Interfaces VLAN Field Descriptions

Use the data in the following table to use the **IPv6 Interfaces** tab.

Name	Description
Interface	Specifies the port or VLAN.
Identifier	Shows the IPv6 address interface identifiers. This value is a binary string of up to 8 octets in network byte-order.
IdentifierLength	Shows the length of the identifier, in bits.
Descr	Specifies a description of the interface. The network management system also configures this string.
VlanId	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. This value corresponds to the lower 12 bits of the IEEE 802.1Q VLAN tag.
Type	Shows the interface type.
ReasmMaxSize(MTU)	Specifies the maximum size of the MTU of this IPv6 interface. This value must be the same for all the IP addresses defined on this interface. The default value is 1500.
PhysAddress	Specifies the media-dependent physical address. For Ethernet, this is a MAC address.
AdminStatus	Specifies if IPv6 is active on this interface. The default is false (disabled).
OperStatus	Specifies the current operational status of the interface.
ReachableTime	Specifies the time, in milliseconds, that a neighbor is considered reachable after receiving a reachability confirmation. The default is 30000.
RetransmitTimer	Specifies the time, in milliseconds, between retransmissions of neighbor solicitation messages to a neighbor when resolving the address, or when probing the reachability of a neighbor. The default is 1000.
CurHopLimit	Specifies the current hop limit field sent in router advertisements from this interface. The value must be the current diameter of the Internet. A value of zero indicates that the advertisement does not specify a value for CurHopLimit. The default is 64.
MulticastAdminStatus	The option to select MulticastAdminStatus is disabled. You cannot configure the administrative status for multicast in this context.

Name	Description
MacOffset	Requests a particular MAC for an IPv6 VLAN. You can specify a MAC offset when you configure IPv6 on a VLAN, or the system can assign a MAC address from within the available range. Different hardware platforms support different MAC offset ranges.
ForwardingEnabled	Indicates whether IPv6 forwarding is enabled. The default is enabled.
RSMLTEnable	Shows whether RSMLT is enabled on the interface. The default value is disabled (false).

Configuring an IPv6 RIPng brouter port interface

Configure RIPng parameters on an interface so you can control RIPng behavior on the interface.

About This Task

RIPng does not operate on an interface until you enable it globally and on the interface.

Before You Begin

- Configure a routing interface (either a brouter port or a virtual routing interface).
- Assign an IP address to the interface.
- Enable RIPng globally and on the interface.

Procedure

1. In the Device Physical View, select a port.
2. In the navigation pane, expand the **Configuration >EditPort** folders.
3. Click **IPv6**.
4. Click the **RIPng** tab.
5. In the **RipAdminStatus** option box, select **enable**.
6. Configure other parameters as required.
7. Click **Apply**.

RIPng Field Descriptions

Use the data in the following table to use the **RIPng** tab.

Name	Description
RipAdminStatus	Enable or disable RIPng on an interface.
DefaultInfoState	Enable or disable default information at the interface level. The default is disable.
Cost	Specifies the RIPng metric cost. The default is 1.
Poison	Enable or disable poison reverse on an RIPng interface. The default is disable.
RipOperStatus	Shows the RIPng operational state on an interface.

Graphing IPv6 RIPng statistics

Use the following procedure to graph RIPng statistics for monitoring RIPng behavior on the interface.

About This Task

RIPng does not operate on an interface until you enable it globally and on the interface.

Before You Begin

- Configure a routing interface (either a brouter port or a virtual routing interface).
- Assign an IP address to the interface.
- Enable RIPng globally and on the interface.

Procedure

1. In the navigation pane, expand the **Configuration >Ipv6** folders.
2. Click the **IPv6 RIPng**.
3. Click the **Stats** tab.
4. Select an interface row.
5. Click **Graph**.
6. Click **Apply**.

Configuring route redistribution to RIPng

Configure a redistribute entry to announce routes of a certain source protocol type into the RIPng domain, for example, static, RIP, or direct. Use a route policy to control the redistribution of routes.

Before You Begin

- Enable RIP globally.
- Configure a route policy.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 RIPng**.
3. Click the **Redistribute** tab.
4. Double-click the value in the **Enable** column that corresponds with the source protocol type you want to enable or disable.
5. Select **enable** or **disable** from the list.
6. Click **Apply**.

Redistribute field descriptions

Use the data in the following table to use the **Redistribute** tab.

Name	Description
DstVrfiled	Specifies the destination VRF ID used in the redistribution.
Protocol	Specifies the dynamic routing protocol that receives the external routing information.

Name	Description
SrcVrfId	Specifies the source VRF ID used in the redistribution.
RouteSource	Specifies the route source protocol for the redistribution entry.
Enable	Enables (or disables) a RIPng redistribute entry for a specified source type.

Viewing stats for RIPng interfaces

View statistics for RIPng interfaces.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 RIPng**.
3. Click the **Stats** tab.

Stats field descriptions

Use the data in the following table to use the **Stats** tab.

Name	Description
IfIndex	Shows the unique value to identify an IPv6 interface.
RcvBadPackets	The number of RIPng response packets received by the RIP process that were subsequently discarded for any reason (examples: a version 0 packet or an unknown command type).
RcvBadRoutes	The number of routes, in valid RIPng packets, that were ignored for any reason (examples: unknown address family or invalid metric).
SentUpdates	The number of triggered RIPng updates actually sent on this interface.
RcvUpdates	The number of triggered RIPng updates actually received on this interface. This explicitly does not include full updates received containing new information.

Remote Monitoring

Table 182: Remote Monitoring product support

Feature	Product	Release introduced
Remote Monitoring 1 (RMON1) for Layer 1 and Layer 2	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
Remote Monitoring 2 (RMON2) for network and application layer protocols	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5

Remote Monitoring

Remote Monitoring (RMON) is a management information base (MIB) or a group of management objects that you use to obtain or configure values using the Simple Network Management Protocol (SNMP). Use CLI, or EDM, to globally enable RMON on the system. After you globally enable RMON, you enable monitoring for individual devices on a port-by-port basis.

RMON1 is the original version of the protocol, which collects information for OSI Layer 1 and Layer 2 in Ethernet networks. RMON1 provides traffic statistics at the MAC layer, and provides statistics on Ethernet segments for packets and bytes received and transmitted.

You can use RMON1 to:

- Configure alarms for user-defined events.
- Collect Ethernet statistics.
- Log events.
- Send traps for events.

Within EDM, you can configure RMON1 alarms that relate to specific events or variables. You can also specify events associated with alarms to trap or log-and-trap. In turn, the system traps or logs tripped alarms.

You can view all RMON1 information using CLI or EDM. Alternatively, you can use any management application that supports SNMP traps to view RMON1 trap information.

This section describes RMON1 alarms, RMON1 history, RMON1 events, and RMON1 statistics.

RMON1 alarms

You can configure alarms to alert you if the value of a variable goes out of range. You can define RMON1 alarms on any MIB variable that resolves to an integer value. You cannot use string variables (such as system description) as alarm variables.

You can use RMON1 alarm to monitor anything that has a MIB OID associated with it and a valid instance.

All alarms share the following characteristics:

- A defined upper and lower threshold value.
- A corresponding rising and falling event.
- An alarm interval or polling period.

After you activate alarms, you can:

- View the activity in a log and/or a trap.
- Create a script directing the system to sound an audible alert at a console.
- Create a script directing the system to send an e-mail.
- Create a script directing the system to call a pager.

The system polls the alarm variable and the system compares the result against upper and lower limit values you select when you create the alarm. If the system reaches or crosses the alarm variable during the polling period, the alarm fires and generates an event that you can view in the event log or the trap log. You can configure the alarm to either create a log, or have the alarm send a Simple Network Management Protocol (SNMP) trap to a Network Management System (NMS). You can view the activity in a log or a trap log, or you can create a script to cause a console to beep, send an e-mail, or call a pager.

The upper limit of the alarm is the rising value, and the lower limit is the falling value. RMON1 periodically samples data based upon the alarm interval. During the first interval that the data passes above the rising value, the alarm fires as a rising event. During the first interval that the data drops below the falling value, the alarm fires as a falling event.

The following figure shows how alarms fire:

Figure 207: How alarms fire

The alarm fires during the first interval that the sample goes out of range. No additional events generate for that threshold until the system crosses the opposite threshold. Therefore, you must carefully define the rising and falling threshold values for alarms. Incorrect thresholds cause an alarm to fire at every alarm interval, or never at all.

You can define one threshold value to an expected, baseline value, and then define the opposite threshold as the out-of-bounds limit. Because of sample averaging, the value is equal to ± 1 baseline unit. For example, assume you define an alarm with octets leaving a port as the variable. The intent of the alarm is to notify you if excessive traffic occurs on that port. You enable spanning tree, and then 52 octets transmit from the port every 2 seconds, which is equivalent to baseline traffic of 260 octets every 10 seconds. This alarm notifies you if you define the lower limit of exiting octets at 260 and you define the upper limit at 320 (or at any value greater than $260 + 52 = 312$).

The rising alarm fires the first time outbound traffic, other than spanning tree Bridge Protocol Data Units (BPDUs), occurs. The falling alarm fires after outbound traffic, other than spanning tree, ceases. This process provides the time intervals of any nonbaseline outbound traffic.

If you define the alarm with a falling threshold of less than 260 and the alarm polling interval is at 10 seconds, for example, 250, then the rising alarm can fire only once, as shown in the following example. The falling alarm (the opposite threshold) must fire for the rising alarm to fire a second time. The falling alarm cannot fire unless the port becomes inactive or you disable spanning tree, which causes the value for outbound octets to drop to zero, because the baseline traffic is always greater than the value of the falling threshold. By definition, the failure of the falling alarm to fire prevents the rising alarm from firing a second time.

The following figure shows an example of the alarm threshold:

Figure 208: Alarm example, threshold less than 260

When you create an alarm, you select a variable from the variable list and a port, or another system component to which it connects. Some variables require port IDs, card IDs, or other indexes, for example, spanning tree group IDs. You then select a rising and a falling threshold value. The rising and falling values compare to the actual value of the variable that you choose. If the variable falls outside of the rising or falling value range, an alarm triggers, and the system logs an event or trap.

When you create an alarm, you also select a sample type, which can be either absolute or delta. Define absolute alarms for alarms based on the cumulative value of the alarm variable. An example of an absolute alarm value is card operating status. Because this value is not cumulative, but instead represents states, such as card up (value 1) and card down (value 2), you configure the value as the absolute value. Therefore, you can create an alarm with a rising value of 2 and a falling value of 1 to alert you whether the card is up or down.

Configure most alarm variables related to Ethernet traffic as a delta value. Define delta alarms for alarms based on the difference in the value of the alarm variable between the start of the polling period and the end of the polling period.

Note

If you create an alarm that monitors a variable that does not exist, you will receive an error message and the creation will fail. Also, if the variable you are monitoring is no longer valid at the time of sampling, the switch removes the alarm automatically. For example, if you create an alarm that monitors some information about a VLAN, and that VLAN is later removed, then the switch silently removes the associated alarm at the next sampling interval.

RMON1 history

The RMON1 history group records periodic statistical samples from a network. A sample is a history and the system gathers the sample in time intervals referred to as buckets.

You can use RMON1 history for the MAC layer in the network. You cannot use RMON1 history for application and network layer protocols.

You enable and create histories to establish a time-dependent method to gather RMON1 statistics on a port. The following are the default values for history:

- Buckets are gathered at 30-minute intervals.
- The number of buckets gathered is 50.

You can configure both the time interval and the number of buckets. However, after the system reaches the last bucket, the system dumps bucket 1 and recycles the bucket to hold a new bucket of statistics. Then the system dumps bucket 2, and so forth.

RMON1 events

RMON1 events and alarms work together to notify you when values in your network go out of a specified range. After a value passes the specified range, the alarm fires. The event specifies how the system records the activity.

You can use RMON1 events to monitor anything that has a MIB OID associated with it and a valid instance.

An event specifies whether a trap, a log, or both a trap and a log generates to view alarm activity.

You must create an event before associating it with an alarm, otherwise an error occurs. Also, you cannot delete an event as long as there are alarms associated with it. If you try to do so, an error message displays.

RMON1 statistics

You can use EDM to gather and graph statistics in a variety of formats, or you can save the statistics to a file and export the statistics to a third-party presentation or graphing application.

RMON1 scaling limits

The following tables shows the scaling limits for RMON1 elements.

Note

When the log table reaches the maximum 500 log limit, the oldest third of the logs per event is removed to make room for new events. For all other elements, a message displays when you reach the maximum limit and no other element can be added.

Alarms	100
Events	100
History (entries in the history control table with 2000 buckets shared between them)	20
Logs	500
Statistics (entries in stats table)	100

RMON 2

Remote Monitoring (RMON) is a management information base (MIB) or a group of management objects that you use to obtain or configure values using the Simple Network Management Protocol (SNMP).

Use CLI or EDM to globally enable RMON on the system.

After you globally enable RMON, you enable monitoring for individual devices on a port-by-port basis.

RMON1 is the original version of the protocol, which collects information for OSI Layer 1 and Layer 2 in Ethernet networks. RMON1 provides traffic statistics at the MAC layer, and provides statistics on Ethernet segments for packets and bytes received and transmitted.

RMON2 monitors and counts network layer and application layer protocol packets on configured network hosts, either VLAN or port interfaces, that you enable for monitoring. RMON2 monitors Segmented Management Instances at the mgmt configuration level for out-of-band (OOB), circuitless IP (CLIP), and VLAN interfaces.

Note

RMON2 counters on Segmented Management Instance interfaces are cleared only when a Segmented Management Instance interface is newly enabled, or when RMON2 is newly enabled on a previously enabled Segmented Management Instance interface.

The following figure shows which form of RMON monitors which layers in the OSI model:

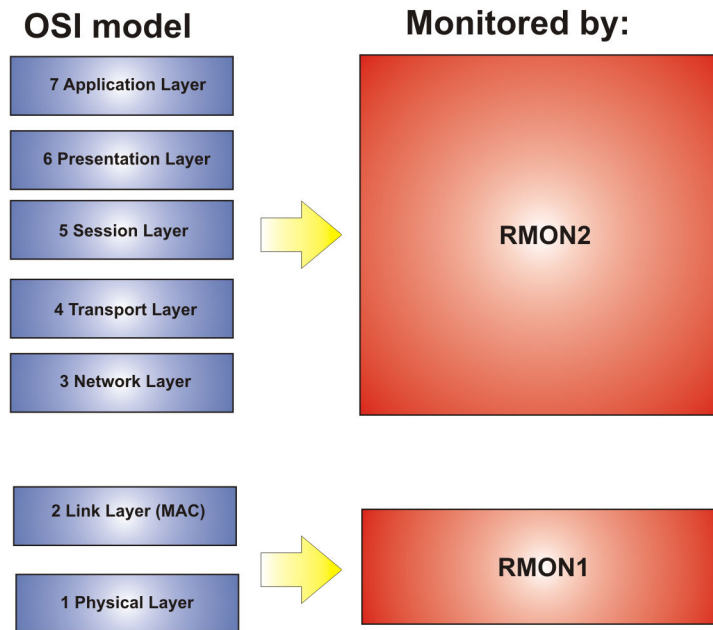

Figure 209: OSI model and RMON

The RMON2 feature is a management information base (MIB) or a group of management objects that you use to obtain or configure values using the Simple Network Management Protocol (SNMP). The switch supports a partial implementation of RMON2. The RMON2 feature adds the following MIBs: protocol directory, protocol distribution, address map, network-layer host and application layer host for the traffic passing through the (Control Processor) CP for these MIB tables.

The system only collects statistics for IP packets that pass through the CP. RMON2 does not monitor packets on other interfaces processed on the switch that do not pass through the CP. However, RMON2 monitors packets for applications listed in the RMON2 MIB, whether or not the application is enabled or supported on the switch.

After you globally enable RMON2, enable monitoring for individual devices. Identify the network hosts for the system to monitor with a manual configuration on the interfaces you want to monitor.

The RMON2 feature monitors a list of predefined protocols. The system begins to collect protocol statistics immediately after you enable RMON.

The RMON2 feature collects statistics on:

- Protocols predefined by the system.
- Address mapping between physical and network address on particular network hosts that you configure for monitoring.
- Network host statistics for particular hosts on a network layer protocol (IP) that you configure for monitoring.
- Application host statistics for a particular host on an application layer protocol that you configure for monitoring.

RMON2 MIBs

This section describes the following MIBs, on which RMON2 can collect statistics: protocol directory, protocol distribution, address map, network-layer host, and application layer host.

Protocol Directory MIB

The protocol directory is a master directory that lists all of the protocols RMON2 can monitor. The protocols include network layer, transport layer, and application layer protocols, under the OSI model. The system only monitors statistics for the predefined protocols. You cannot delete or add additional protocols to this table. The protocol directory MIB is enabled by default for the predefined protocols.

The predefined protocols include:

- Internet Protocol (IP)
- Secure Shell version 2 (SSHv2)
- Transmission Control Protocol (TCP)
- User Datagram Protocol (UDP)
- File Transfer Protocol (FTP)
- Hypertext Transfer Protocol (HTTP)
- Telnet
- Trivial File Transfer Protocol (TFTP)
- Simple Network Management Protocol (SNMP)

Protocol distribution MIB

The protocol distribution MIB collects traffic statistics that each protocol generates by local area network (LAN) segment. The switch acts as the probe and the system collects protocol statistics for the entire switch as part of the group for all of the protocols predefined in the protocol directory table. The protocol distribution control table is part of this group. The protocol distribution control table is predefined with an entry for the management IP for the switch to represent the network segment where the system collects the statistics.

No CLI or EDM support exists to add or delete entries in this table.

Address map MIB

The address map MIB maps the network layer IP to the MAC layer address.

The system populates the address map control table MIB with an entry for each host interface that you enable for monitoring on the switch.

Network layer host MIB

The network layer host MIB monitors the Layer 3 traffic statistics for each host. The network layer host MIB monitors traffic packets in and out of hosts based on the network layer address. The network layer host controls the network and application layer host tables.

The system populates an entry for the management IP of the switch to represent the network segment where the system collects the statistics. You have to enable each host interface that you want to monitor on the switch.

The system only collects statistics for this group from packets that go to the CP.

Application layer host MIB

The application layer host MIB monitors traffic statistics by application protocol for each host.

The system populates an entry for the management IP of the switch to represent the network segment where the system collects the statistics. You have to enable each host interface that you want to monitor on the switch.

The system only collects statistics for this group from packets that go to the CP.

RMON2 Considerations

The following considerations apply to RMON2:

- You must enable RMON globally before you enable RMON2 monitoring for a Segmented Management Instance interface.
- You must configure an IPv4 address for the Segmented Management Instance management interface before you enable RMON2 monitoring.
- You can enable RMON on a maximum of 30 IP interfaces on a host.
- You cannot directly configure RMON for a VOSS VLAN that is an underlying management VLAN. In this case, RMON must be configured at the mgmt vlan configuration level.
- RMON2 is not available if DHCP Client is configured on a Management Instance. DHCP Client is not available if RMON2 is configured on a Management Instance.
- You cannot delete the IPv4 manual address from a Segmented Management Instance management interface that is RMON enabled. If the only IPv4 address is deleted outside of the normal configuration process, RMON is administratively disabled on the Segmented Management Instance management interface.

RMON Configuration Using CLI

This section contains procedures to configure RMON using Command Line Interface (CLI).

For information about RMON statistics, see the following sections:

- [Displaying RMON Statistics for Specific Ports](#) on page 2449
- [View RMON Statistics](#) on page 2449

Configuring RMON

Enable RMON1 and RMON2 globally, and configure RMON1 alarms, events, history, statistics, and whether port utilization is calculated in half or full duplex. By default, RMON1 and RMON2 are disabled globally.

For RMON1, you enable RMON globally, and then you can use RMON1 alarm, history, events, and statistics for the MAC layer in the network. You cannot use RMON1 history or statistics for application and network layer protocols.

For RMON2, you enable RMON globally, and then you enable RMON on the host interfaces you want to monitor.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable RMON1 and RMON2 globally:

```
rmon
```
3. Configure an RMON1 alarm:

```
rmon alarm <1-65535> WORD <1-1536> <1-3600> {absolute|delta} [falling-  
threshold <-2147483647-2147483647> event <1-65535>] [owner WORD<1-  
127>] [rising-threshold <-2147483647-2147483647> event <1-65535>]
```
4. Configure an RMON1 event:

```
rmon event <1-65535> [community WORD<1-127>] [description WORD<0-127>]  
[log] [owner WORD<1-127>] [trap] [trap_dest [{A.B.C.D}]] [trap_src  
[{A.B.C.D}]]
```
5. Configure RMON1 history:

```
rmon history <1-65535> {slot/port [/sub-port] [-slot/port [/sub-port]  
[,...]} [buckets <1-65535>] [interval <1-3600>] [owner WORD<1-127>]
```
6. Configure RMON1 statistics:

```
rmon stats <1-65535> {slot/port [/sub-port] [-slot/port [/sub-port]  
[,...]} [owner <1-127>]
```
7. Configure whether the system calculates port utilization in half or full duplex:

```
rmon util-method [half|full]
```

Example

Configure RMON globally, an RMON1 alarm, and RMON1 event:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#rmon
Switch:1(config)#rmon event 60534 community public description "Rising Event" log trap
Switch:1(config)#rmon alarm 4 rcCliNumAccessViolations.0 10 absolute rising-threshold 2
event 60000
```

Variable Definitions

Use the data in this table to use the **rmon** command.

Variable	Value
<pre>alarm <1-65535> WORD <1-1536> <1-3600> {absolute delta} [falling-threshold <-2147483647-2147483647> event <1-65535>] [owner WORD<1-127>] [rising- threshold <- 2147483647-2147483647> event <1-65535>]</pre>	<p>Creates an alarm interface.</p> <ul style="list-style-type: none"> • <i><1-65535></i>— Specifies the interface index number from 1 to 65535. Each entry defines a diagnostics sample at a particular interval for an object on the device. The default is 1. • <i>WORD <1-1536></i>— Specifies the variable name or OID. The entry is case sensitive and can have a string length of 1 to 1536. • <i>{absolute delta}</i> — Specifies the sample type. • <i>rising-threshold <-2147483648-2147483647></i> <i>[<event:1-65535>]</i> — Specifies the rising threshold from -2147483648 to 2147483647, which is a threshold for the sampled statistic. After the current sampled value is greater than or equal to this threshold, and the value at the last sampling interval was less than this threshold, the system generates a single event. The system also generates a single event if the first sample after this entry that becomes valid is greater than or equal to the rising alarm, or the rising or falling alarm. After the system generates a rising event, the system does not generate another such event until the sampled value falls below this threshold and reaches the alarm falling threshold. You cannot modify this object if the associated alarm status is equal to valid. <p><i><1-65535></i>— Specifies the rising event index, which the system uses after the system crosses a rising threshold. The event entry identified by a particular value of this index is the same as identified by the same value of the event index object. If no corresponding entry exists in the event table, no association exists. In particular, if this value is zero, the system does not generate an associated event, as zero is not a valid event index. You cannot modify this object if the associated alarm status is equal to valid.</p> <ul style="list-style-type: none"> • <i>falling-threshold <-2147483648-2147483647></i> <i>[<event:1-65535>]</i> — Specifies the falling threshold from -2147483648 to 2147483647, which specifies a threshold for the sampled statistic. If the current sampled value is less than or equal to this threshold, and the value at the last sampling interval was greater than this threshold, the system generates a single event. The system also generates a single event if the first sample after this entry that becomes valid is less than or equal to this threshold and the associated alarm startup alarm is equal to falling alarm or rising or falling alarm. After the system generates a falling event, the system does not generate another such event until the sampled value rises above this threshold, and reaches the alarm rising threshold. You cannot modify this object if the associated alarm status is equal to valid.

Variable	Value
	<p><code><1-65535></code> - Specifies the index of the event entry that the system uses after a falling threshold is crossed. The event entry identified by a particular value of this index is the same as identified by the same value of the event index object. If no corresponding entry in the event table exists, no association exists. In particular, if this value is zero, the system does not generate an event, as zero is not a valid event index. You cannot modify this object if the associated alarm status is equal to valid. The default is 60535.</p> <ul style="list-style-type: none"> <code>owner WORD<1-127></code> - Specifies the name of the owner, with a string length 1 to 127. <p>Use the default operator to reset the RMON alarms to their default configuration: <code>default rmon alarm <65535></code></p> <p>Note: When configuring from CLI, the default owner is cli; when configuring with SNMP, the default owner is snmp. The default command only sets the owner to default. No other parameters can be changed after you create the alarm.</p> <p>Use the no operator to disable RMON alarms: <code>no rmon alarm [<1-65535>]</code></p>
<p><code>event <1-65535> [community WORD<1-127>] [description WORD<0-127>] [log] [owner WORD<1-127>] [trap]</code></p>	<p>Create an event.</p> <ul style="list-style-type: none"> <code><1-65535></code> - Specifies the event index number. Each entry defines one event that the system generates after the appropriate conditions occur. The default is 1. <code>log</code> - Specifies if this event stores a log when the event is triggered by the alarm. <code>trap</code> - Specifies if this event sends a trap when the event is triggered by the alarm. The trap will be sent to all the snmp-server hosts configured in the snmp table. <code>description WORD<0-127></code> - Specifies the event description, with a string length of 0 to 127. <code>owner WORD<1-127></code> - Specifies the name of the owner, with a string length of 1 to 127. <code>community WORD<1-127></code> - Specifies the SNMP community where you can send SNMP traps, with a string length 1 to 127. <p>You can set the community, but the trap is not filtered out. The trap is sent to all configured snmp-server hosts, regardless of the value of this field.</p> <p>Use the no operator to delete a RMON event: <code>no rmon event [<1-65535>] [log]</code></p>

Variable	Value
<pre>history <1-65535> {slot/port [/sub-port] [-slot/port[/ sub-port] [, ...]} [buckets <1- 65535>] [interval <1-3600>] [owner WORD<1-127>]</pre>	<p>Configures RMON history.</p> <ul style="list-style-type: none"> • <i><1-65535></i> – Specifies the history index number that uniquely identifies an entry in the history control table. Each entry defines a set of samples at a particular interval for an interface on the default. The default value is 1. • <i>{slot/port [/sub-port] [-slot/port[/sub-port] [, ...]}</i> – Specifies the single port interface. Identifies the source for which the system collects and places historical data in a media-specific table on behalf of this history control entry. The source is an interface on this device. The statistics in this group reflect all packets on the local network segment that attaches to the identified interface. • <i>buckets <1-65535></i>– Specifies the requested number of discrete time intervals where the system saves data in the part of the media-specific table associated with this history control entry. The default value is 50. • <i>interval <1-3600></i>– Specifies the time interval in seconds over which the system samples the data for each bucket in the part of the media-specific table associated with this history control entry. Because the counters in a bucket can overflow at their maximum value with no indication, you must take into account the possibility of overflow in all the associated counters. Consider the minimum time in which a counter can overflow on a particular media type, and then set the history control interval to a value less than this interval, which is typically most important for the octets counter in a media-specific table. The default value is 1800. • <i>owner WORD<1-127></i>– Specifies the name of the owner.

Variable	Value
<code>stats <1-65535> {slot/port [/sub-port] [-slot/port [/sub-port] [, ...]} owner WORD<1-127></code>	<p>Configures RMON statistics.</p> <ul style="list-style-type: none"> <code><1-65535></code>— Specifies the control Ether statistics entry index number. <code>{slot/port [/sub-port] [-slot/port [/sub-port] [, ...]}</code>— Specifies the single port interface. <code>owner WORD<1-127></code>— Specifies the name of the owner. <p>Use the no operator to delete a RMON Ether stats control interface: <code>no rmon stats [<1-65535>]</code></p>
<code>util-method [half full]</code>	<p>Configures whether port utilization is calculated in half or full duplex to calculate port usage.</p> <ul style="list-style-type: none"> <code>half</code>—Configures the string to half duplex. <code>full</code>—Configures the string to full duplex. <p>After you select <code>half</code> for half duplex, RMON uses InOctets and the speed of the port to calculate port usage (this is the standard RMON RFC 1271 convention). After you select <code>full</code> for full duplex, RMON uses InOctets and OutOctets, and 2X the speed of the port to calculate port usage. If you select <code>full</code>, but the port operates in half-duplex mode, the calculation defaults to the RFC1271 convention. The default is <code>half</code>.</p>

Enable Remote Monitoring on an Interface

Use the following procedure to enable Remote Monitoring (RMON) on an interface.

Before You Begin

- Enable RMON globally.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable RMON on a particular VLAN:

```
vlan rmon <1-4059>
```

3. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port [/sub-port] [-slot/port [/sub-port] [, ...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format `slot/port/sub-port`.

4. Enable RMON on a particular port:

```
rmon
```

Examples

Enable RMON on VLAN 2:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#vlan rmon 2
```

Enable RMON on port 3/8:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitethernet 3/8
Switch:1(config-if)#rmon
```

Variable Definitions

Use the data in this table to use the **vlan rmon** command.

Variable	Value
<1-4059>	Specifies the VLAN ID on which to configure RMON.

Enable RMON2 on a Segmented Management Instance Interface

Before You Begin

You must enable RMON globally before you enable RMON2 monitoring for a Segmented Management Instance interface.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enter the configuration mode for the Management Instance:

```
mgmt <clip | oob | vlan>
```
3. Enable RMON2 on the Segmented Management Interface:

```
(mgmt:oob) rmon
```

View RMON Information

View RMON1 and RMON2 information on the switch. You can view information about RMON1 alarms, events, history, logs, and statistics. You can also view RMON2 information about application host statistics, control tables, network host statistics, and protocol distribution statistics.

Procedure

1. View RMON1 information:

```
show rmon {alarm|event|history|log|stats}
```

2. View RMON2 information:

```
show rmon {address-map|application-host-stats WORD<1-64>|application
protocols|ctl-table|protocol-dist-stats|network-host-stats}
```

Example

View RMON event, log, and statistics information:

```
Switch:1(config)#show rmon event

=====
                        Rmon Event
=====

INDEX DESCRIPTION      TYPE      COMMUNITY OWNER      LAST_TIME_SENT
-----
60534 Rising Event    log-and-trap public    192.0.2.155 none
60535 Falling Event  log-and-trap public    192.0.2.155 8 day(s), 19:14:32

Switch:1(config)#show rmon log

=====
                        Rmon Log
=====

INDEX  TIME              DESCRIPTION
-----
60535. 1 8 day(s), 19:14:45  1.3.6.1.4.1.2272.1.19.14.0 (absValue = 0, Falling
Threshold = 2, interval = 10)[alarmIndex.1][trap]
"Falling Event"
60535. 2 8 day(s), 19:14:45  1.3.6.1.4.1.2272.1.19.14.0 (absValue = 0, Falling
Threshold = 1, interval = 10)[alarmIndex.2][trap]
"Falling Event"

Switch:1(config)#show rmon stats

=====
                        Rmon Ether Stats
=====

INDEX PORT  OWNER
-----
1     1/10  monitor
```

*Variable Definitions*The following table defines parameters for the **show rmon** command.

Variable	Value
<i>address-map</i>	Displays the RMON2 address map. This RMON2 parameter expands RMON capacity to display information on network, transport, and application layers.
<i>alarm</i>	Displays the RMON1 alarm table.

Variable	Value
<i>application-host-stats WORD<1-64></i>	Displays RMON2 application host statistics from one of the following protocols: TCP, UDP, FTP, Telnet HTTP, SSHv2, TFTP, SNMP, HTTPS. This RMON2 parameter expands RMON capacity to display network, transport, and application layers. Note: RMON2 counts application packets received on any platform on which the application is not enabled or supported, before dropping them.
<i>ctl-table</i>	Displays the RMON2 control tables. This RMON2 parameter expands RMON capacity to display network, transport, and application layers.
<i>event</i>	Displays the RMON1 event table.
<i>history</i>	Displays the RMON1 history table. This RMON1 parameter displays and is limited to link layer information, including as MAC information.
<i>log</i>	Displays the RMON1 log table.
<i>network-host-stats</i>	Displays RMON2 network-host statistics. This RMON2 parameter expands RMON capacity to display network, transport, and application layers.
<i>protocol-dist-stats</i>	Displays RMON2 protocol distribution statistics. This RMON2 parameter expands RMON capacity to display network, transport, and application layers.
<i>stats</i>	Displays the RMON1 statistics table. This RMON1 parameter displays and is limited to link layer information, including as MAC information.

Displaying RMON Address Maps

View the maps of network layer address to physical address to interface.

The probe adds entries based on the source MAC and network addresses in packets without MAC-level errors.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View RMON address maps:

```
show rmon address-map
```

Example

```
Switch:1# show rmon address-map
=====
                        Rmon Address Map Table
=====
PROTOIDX  HOSTADDR      SOURCE  PHYADDR      LASTCHANGE
-----
1         192.0.2.11    2060    b0:ad:aa:42:a5:03  10/09/15 17:30:41
```

View RMON Statistics

About This Task

View RMON statistics to manage network performance.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View RMON statistics:

```
show rmon stats
```

Example

```
Switch:1#show rmon stats
```

```
=====
                                     Rmon Ether Stats
=====
INDEX  PORT    OWNER
-----
1      1/10    monitor
```

Displaying RMON Statistics for Specific Ports

Display individual RMON statistics for specific ports to manage network performance.

Note

Slot and port information can differ depending on hardware platform.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. View statistics for specific ports:

```
show interfaces GigabitEthernet statistics rmon {slot/port[/sub-port]
[-slot/port[/sub-port]][,...]}
```

Example

View RMON statistics:

```
Switch:1>enable
Switch:1#show interfaces gigabitEthernet statistics rmon 1/13
```

```
=====
                                     Port Stats Rmon
=====
PORT  OCTETS   PKTS   MULTI  BROAD  CRC   UNDER  OVER  FRAG  COLLI
NUM   NUM      NUM    CAST   CAST   ALIGN SIZE  SIZE  MENT  SION
-----
1/13  1943     21     8      13     0     0       0     0     0
```

Variable Definitions

Use the data in the following table to use the **show interfaces GigabitEthernet statistics rmon** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

View RMON Application Host Statistics

View application host statistics to see traffic statistics by application protocol for each host.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View RMON application host statistics:

```
show rmon application-host-stats WORD<1-64>
```

Example

```
Switch:1# show rmon application-host-stats ?
WORD<1-64> Select one of these application protocols
             {TCP|UDP|FTP|TELNET|HTTP|RLOGIN|SSH|TFTP|SNMP|HTTPS}
Switch:1# show rmon application-host-stats FTP

=====
                        Rmon Application Host Stats
=====
HOSTADDR      INPKT      OUTPKT      INOCT      OUTOCT      CREATETIME
-----
192.0.2.10    0           0           0           0           10/09/15 17:29:54
```

Note

Protocol support can vary across platforms.

Variable Definitions

The following table defines parameters for the **show rmon application-host-stats** command.

Variable	Value
<code>WORD<1-64></code>	Specifies one of the following application protocols: TCP, UDP, FTP, TELNET, HTTP, SSH, TFTP, SNMP, HTTPS. Note: RMON2 counts application packets received on any platform on which the application is not enabled or supported, before dropping them.

View RMON Control Tables

View RMON control tables to see the data source for both network layer and application layer host statistics.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View RMON control tables:

```
show rmon ctl-table
```

Example

```
Switch:1# show rmon ctl-table
```

```

Note
Protocol support can vary across platforms.

Displaying RMON Network Host Statistics

View network host statistics to see Layer 3 traffic statistics for each host. The network layer host MIB monitors traffic packets in and out of hosts based on the network layer address.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View RMON network host statistics:
`show rmon network-host-stats`

View RMON Protocol Distribution Statistics

View protocol distribution statistics to see traffic statistics that each protocol generates by local area network (LAN) segment.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View RMON protocol distribution statistics:
`show rmon protocol-dist-stats`

Example

```
Switch:1# show rmon protocol-dist-stats

=====
Rmon Protocol Dist Stats
=====
PROTOCOL  PKTS      OCTETS
-----
IP         0          0
TCP        0          0
UDP        0          0
FTP        0          0
SSH        0          0
TELNET     0          0
HTTP       0          0
RLOGIN     0          0
TFTP       0          0
SNMP       0          0
HTTPS      0          0
```

Note
Protocol support can vary across platforms.

Displaying RMON Status

View the current RMON status on the switch.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View RMON status:

```
show rmon
```

Example

```
Switch:1# show rmon

RMON Info :
Status      : enable
```

View the RMON2 Configuration State of Management Interfaces

About This Task**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. View information about the RMON2 configuration state:

```
show mgmt rmon
```

Example

```
Switch:1>show mgmt rmon
=====
Mgmt Rmon Information
=====
INST  DESCR  RMON-ADMIN-ENABLE  RMON-OPER-ENABLE  RMON-IP-ADDR
-----
1  Mgmt-oob1  disable  disable  0.0.0.0
3  Mgmt-clip  enable  enable  192.0.2.72
4  Mgmt-vlan  enable  enable  198.51.100.72
```

RMON Configuration Using EDM

This section contains procedures to configure RMON using Enterprise Device Manager (EDM).

For information about RMON statistics, see the following sections:

- [Enabling RMON Statistics](#) on page 2464
- [Viewing RMON Statistics](#) on page 2465

Enabling RMON Globally

About This Task

You must globally enable RMON before you can use RMON2 functions. If you attempt to enable an RMON2 function before the global flag is disabled, EDM informs you that the flag is disabled and prompts you to enable the flag. You can configure RMON1 while RMON is globally disabled.

If you want to use nondefault RMON parameter values, you can configure them before you enable RMON, or as you configure the RMON functions.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Options**.
3. Click the **Options** tab.
4. Select the **Enable** check box.
5. In the **UtilizationMethod** option, select a utilization method.
6. Click **Apply**.

Options Field Descriptions

Use the data in the following table to use the **Options** tab.

Name	Description
Enable	Enables RMON. If you select the Enable check box, the RMON agent starts immediately. To disable RMON, clear the Enable check box and click Apply to save the new setting to NVRAM, and then restart the device. The default is disabled.
UtilizationMethod	Controls whether RMON uses a half-duplex or full-duplex formula to calculate port usage. After you select halfDuplex, RMON uses InOctets and the speed of the port to calculate port usage (this is the standard RMON RFC1271 convention). After you select fullDuplex, RMON uses InOctets and OutOctets and 2X the speed of the port to calculate port usage. If you select fullDuplex, but the port operates in half-duplex mode, the calculation defaults to the RFC1271 convention. The default is halfDuplex.

Enabling RMON on a Port or VLAN

Use the following procedure to enable RMON on an interface.

Before You Begin

- Enable RMON globally.

Procedure

1. Enable RMON on a VLAN:
 - a. In the navigation pane, expand the **Configuration > VLAN** folders.
 - b. Click **VLANs**.
 - c. Click the **Advanced** tab.
 - d. In the row for the VLAN, double-click the **RmonEnable** field, and then select **enable**.
 - e. Click **Apply**.
2. Enable RMON on a port:
 - a. In the Device Physical View, select a port.
 - b. In the navigation pane, expand the **Configuration > Edit > Port** folders.
 - c. Click **General**.
 - d. Click the **Interface** tab.

- e. For the **RmonEnable** field, select **enable**.
- f. Click **Apply**.

Enabling RMON1 History

About This Task

Use RMON1 to establish a history for a port and configure the bucket interval. For example, to gather RMON statistics over the weekend, you must have enough buckets to cover two days. Configure the history to gather one bucket every hour, and cover a 48-hour period. After you configure the history characteristics, you cannot modify them; you must delete the history and create another one.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Control**.
3. In the **History** tab, click **Insert**.
4. In the **Port** box, click the ellipsis (...) button.
5. Select a port.
6. Click **OK**.
7. In the **Buckets Requested** box, type the number of discrete time intervals to save data.
8. In the **Interval** box, type the interval in seconds.
9. In the **Owner** box, type the owner information.
10. Click **Insert**.

History Field Descriptions

Use the data in the following table to use the **History** tab.

Name	Description
Index	Specifies an index that uniquely identifies an entry in the historyControl table. Each entry defines a set of samples at a particular interval for an interface on the device. Index value ranges from 1–65535. The default value is 1.
Port	Identifies the source for which the system collects and places historical data in a media-specific table on behalf of this historyControlEntry. The source is an interface on this device. To identify a particular interface, the object identifies the instance of the ifIndex object, defined in (4,6), for the desired interface. For example, if an entry receives data from interface 1, the object is ifIndex 1. The statistics in this group reflect all packets on the local network segment attached to the identified interface. You cannot modify this object if the associated historyControlStatus object is equal to valid(1).

Name	Description
BucketsRequested	Specifies the requested number of discrete time intervals over which the system save data in the part of the media-specific table associated with this historyControlEntry. After this object is created or modified, the probe configures historyControlBucketsGranted as closely to this object as possible for the particular probe implementation and available resources. Values range from 1–65535. The default value is 50.
BucketsGranted	Specifies the number of discrete sampling intervals over which the system save data in the part of the media-specific table associated with this historyControlEntry. After the associated BucketsRequested object is created or modified, the probe sets this object as closely to the requested value as possible for the particular probe implementation and available resources. The probe must not lower this value except as a result of a modification to the associated BucketsRequested object. Occasionally, the actual number of buckets associated with this entry is less than the value of this object. In this case, at the end of each sampling interval, the system adds a new bucket to the media-specific table. After the number of buckets reaches the value of this object and the system is going to add a new bucket to the media-specific table, the agent deletes the oldest bucket associated with this entry so the system can added the new bucket. After the value of this object changes to a value less than the current value, entries are deleted from the media-specific table associated with this entry. The agent deletes the oldest of these entries so that their number remains less than or equal to the new value of this object. After the value of this object changes to a value greater than the current value, the system allows the number of associated media-specific entries to grow.
Interval	Specifies the interval in seconds over which the system samples data for each bucket in the part of the media-specific table associated with this historyControlEntry. You can set this interval between 1–3600 seconds (1 hour). Because the counters in a bucket can overflow at their maximum value with no indication, you must take into account the possibility of overflow in all of the associated counters. Consider the minimum time in which a counter can overflow on a particular media type, and then set the historyControlInterval object to a value less than this interval, which is typically most important for the octets counter in a media-specific table. For example, on an Ethernet network, the etherHistoryOctets counter can overflow in approximately 1 hour at the maximum utilization. You cannot modify this object if the associated historyControlStatus object is equal to valid. The default value is 1800.
Owner	Specifies the entity that configured this entry and uses the assigned resources.

Disabling RMON1 History

About This Task

Disable RMON1 history on a port if you do not want to record a statistical sample from that port.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Control**.
3. In the **History** tab, select the row that contains the port ID to delete.
4. Click **Delete**.

Viewing RMON1 History Statistics

View RMON1 history statistics when you want to see a statistical sample from the switch. You can create a graph of the statistics in a bar, pie, chart, or line format.

Procedure

1. In the Device Physical View, select a port.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Port**.
4. Click the **RMON History** tab.
5. Select the statistics you want to graph.
6. Click the button for the type of graph you require (bar, pie, chart, or line).

RMON History Field Descriptions

Use the data in the following table to use the **RMON History** tab.

Parameter	Description
SampleIndex	Identifies the particular sample this entry represents among all samples associated with the same history control entry. This index starts at one and increases by one as each new sample is taken.
Utilization	Specifies the best estimate of the mean physical layer network utilization on this interface during the sampling interval, in hundredths of a percent.
Octets	Specifies the total number of octets of data (including those in bad packets) received on the network (excluding framing bits but including FCS octets)
Pkts	Specifies the number of packets (including bad packets) received during this sampling interval.
BroadcastPkts	Specifies the number of good packets received during this sampling interval that were directed to the broadcast address.
MulticastPkts	Specifies the number of good packets received during this sampling interval that the system directs to a multicast address. This number does not include packets addressed to the broadcast address.
DropEvents	Specifies the total number of events in which the probe dropped packets due to lack of resources during this sampling interval. This number is not necessarily the number of packets dropped; it is only the number of times the system detects this condition.

Parameter	Description
CRCAAlignErrors	The number of packets the system receives during this sampling interval that had a length (excluding framing bits but including FCS octets) from 64–1518 octets, inclusive, but had either a bad Frame Check Sequence (FCS) with an integral number of octets (FCS Error) or a bad FCS with a nonintegral number of octets (Alignment Error).
UndersizePkts	Specifies the number of packets the system receives during this sampling interval that were less than 64 octets (excluding framing bits but including FCS octets), and were otherwise well formed.
OversizePkts	Specifies the number of packets the system receives during this sampling interval that were longer than 1518 octets (excluding framing bits but including FCS octets), but were otherwise well formed.
Fragments	Specifies the total number of packets received during this sampling interval that were less than 64 octets in length (excluding framing bits but including FCS octets) and had either a bad Frame Check Sequence (FCS) with an integral number of octets (FCS Error) or a bad FCS with a nonintegral number of octets (Alignment Error). It is entirely normal for Fragments to increment because it counts both runs (which are normal occurrences due to collisions) and noise hits.
Collisions	Specifies the best estimate of the total number of collisions on this Ethernet segment during this sampling interval. The value returned depends on the location of the RMON probe. Section 8.2.1.3 (10BASE-5) and section 10.3.1.3 (10BASE-2) of IEEE standard 802.3 states that a station must detect a collision in the receive mode if three or more stations transmit simultaneously. A repeater port must detect a collision when two or more stations transmit simultaneously. Thus, a probe placed on a repeater port can record more collisions than a probe connected to a station on the same segment. Probe location plays a small role when 10BASE-T. 14.2.1.4 (10BASE-T) of IEEE standard 802.3 defines a collision as the simultaneous presence of signals on the DO and RD circuits (transmitting and receiving at the same time). A 10BASE-T station can detect only collisions when it transmits. Thus, probes placed on a station and a repeater can report the same number of collisions. An RMON probe inside a repeater can ideally report collisions between the repeater and one or more other hosts (transmit collisions as defined by IEEE 802.3k) plus receiver collisions observed on any coax segments to which the repeater is connected.

Creating an RMON1 Alarm

After you enable RMON1 globally, you also create a default rising and falling event. The default for the events is log-and-trap, which means that you receive notification through a trap as well as through a log entry.

Before You Begin

- You must globally enable RMON.

Procedure

- In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
- Click **Alarms**.

3. Click the **Alarms** tab.
4. Click **Insert**.
5. In the **Variable** option, select a variable for the alarm.
If you select some variables, the system will prompt you for a port (or other object) on which you want to set an alarm.
6. In the **SampleType** option, select a sample type.
7. In the **Interval** box, type a sample interval in seconds.
8. In the **Index** box, type an index number.
9. In the **RisingThreshold** box, type a rising threshold value.
10. In the **RisingEventIndex** box, type a rising threshold event index.
11. In the **FallingThreshold** box, type a falling threshold value.
12. In the **FallingEventIndex** box, type a falling threshold event index.
13. In the **Owner** box, type the owner of the alarm.
14. Click **Insert**.

Alarms Field Descriptions

Use the data in the following table to use the **Alarms** tab.

Name	Description
Index	Uniquely identifies an entry in the alarm table. Each entry defines a diagnostic sample at a particular interval for an object on the device. The default is 1.
Interval	Specifies the interval, in seconds, over which the data is sampled and compared with the rising and falling thresholds. deltaValue sampling—Configures the interval short enough that the sampled variable is unlikely to increase or decrease by more than $2^{31}-1$ during a single sampling interval.

Name	Description
Variable	<p>Specifies the object identifier of the particular variable to be sampled. Only variables that resolve to an ASN.1 primitive type of INTEGER (INTEGER, Counter, Gauge, or TimeTicks) can be sampled.</p> <p>Alarm variables exist in three formats, depending on the type:</p> <ul style="list-style-type: none"> • A chassis, power supply, or fan-related alarm ends in x where the x index is hard-coded. No further information is required. • A card, spanning tree group (STG), or EtherStat alarm ends with a dot (.). You must enter a card number, STG ID, IP address, or EtherStat information. • A port alarm ends with no dot or index and requires that you use the port shortcut menu. An example of a port alarm is ifInOctets (interface incoming octet count). <p>Because the system articulates SNMP access control entirely in terms of the contents of MIB views, no access control mechanism exists to restrict the value of this object to identify only those objects that exist in a particular MIB view. Because no acceptable means of restricting the read access that is obtained through the alarm mechanism exists, the probe must grant only write access to this object in those views that have read access to all objects on the probe.</p> <p>After you configure a variable, if the supplied variable name is not available in the selected MIB view, the system returns a badValue error. After the variable name of an established alarmEntry is no longer available in the selected MIB view, the probe changes the status of this alarmEntry to invalid. You cannot modify this object if the associated alarmStatus object is equal to valid.</p>
SampleType	<p>Specifies the method of sampling the selected variable and calculating the value to be compared against the thresholds. If the value of this object is absoluteValue, the value of the system compares the selected variable directly with the thresholds at the end of the sampling interval. If the value of this object is deltaValue, the system subtracts the value of the selected variable at the last sample from the current value, and the system compares the difference with the thresholds. You cannot modify this object if the associated alarmStatus object is equal to valid. The default is deltaValue.</p>
Value	<p>Specifies the value of the statistic during the last sampling period. For example, if the sample type is deltaValue, this value is the difference between the samples at the beginning and end of the period. If the sample type is absoluteValue, this value is the sampled value at the end of the period. This system compares the value with the rising and falling thresholds. The value during the current sampling period is not made available until the period is completed and remains available until the next period is complete.</p>
StartupAlarm	<p>Specifies the alarm that is sent after this entry is first set to valid. If the first sample after this entry becomes valid is greater than or equal to the risingThreshold and alarmStartupAlarm is equal to the risingAlarm or the risingOrFallingAlarm, then the system generates a single rising alarm. If the first sample after this entry becomes valid is less than or equal to the fallingThreshold and alarmStartupAlarm is equal to the fallingAlarm or the risingOrFallingAlarm, then the system generates a single falling alarm. You cannot modify this object if the associated alarmStatus object is equal to valid.</p>

Name	Description
RisingThreshold	Specifies a threshold for the sampled statistic. After the current sampled value is greater than or equal to this threshold, and the value at the last sampling interval was less than this threshold, the system generates a single event. The system also generates a single event if the first sample after this entry becomes valid is greater than or equal to this threshold and the associated alarmStartupAlarm is equal to risingAlarm or risingOrFallingAlarm. After a rising event is generated, another such event is not generated until the sampled value falls below this threshold and reaches the alarmFallingThreshold. You cannot modify this object if the associated alarmStatus object is equal to valid.
RisingEventIndex	Specifies the index of the eventEntry that is used after a rising threshold is crossed. The eventEntry identified by a particular value of this index is the same as identified by the same value of the eventIndex object. If no corresponding entry exists in the eventTable, no association exists. In particular, if this value is zero, the system generates no associated event, as zero is not a valid event index. You cannot modify this object if the associated alarmStatus object is equal to valid. Note: You must create the event prior to associating it to an alarm.
FallingThreshold	Specifies a threshold for the sampled statistic. If the current sampled value is less than or equal to this threshold, and the value at the last sampling interval was greater than this threshold, the system generates a single event. The system also generates a single event if the first sample after this entry becomes valid is less than or equal to this threshold and the associated alarmStartupAlarm is equal to fallingAlarm or risingOrFallingAlarm. After the system generates a falling event, the system does not generate another similar event until the sampled value rises above this threshold and reaches the alarmRisingThreshold. You cannot modify this object if the associated alarmStatus object is equal to valid.
FallingEventIndex	Specifies the index of the eventEntry that the system uses after a falling threshold is crossed. The eventEntry identified by a particular value of this index is the same as identified by the same value of the eventIndex object. If there is no corresponding entry in the eventTable, no association exists. In particular, if this value is zero, the system generates no associated event, as zero is not a valid event index. You cannot modify this object if the associated alarmStatus object is equal to valid. Note: You must create the event prior to associating it to an alarm.
Owner	Specifies the entity that configured this entry and is therefore using the resources assigned to it.
Status	Specifies the status of this alarm entry.

Viewing RMON1 Alarms

View the RMON1 alarm information to see alarm activity.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Alarms**.
3. Click the **Alarm** tab.

Deleting an RMON1 Alarm

Delete an RMON1 alarm if you no longer display it in the log.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Alarms**.
3. Select the alarm you must delete.
4. Click **Delete**.

Creating an RMON1 Event

Create a custom rising and falling RMON1 event to specify if alarm information is sent to a trap, a log, or both.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Alarms**.
3. Click the **Events** tab.
4. Click **Insert**.
5. In the **Description** box, type an event name.
6. In the **Type** option, select an event type.

The default configuration is log-and-trap. To save memory, configure the event type to log. To reduce traffic from the system, configure the event type to snmp-log.

If you select snmp-trap or log, you must configure trap receivers.

7. In the **Community** box, type an SNMP community.
8. In the **Owner** box, type the owner of this event.
9. Click **Insert**.

Events Field Descriptions

Use the data in the following table to use the **Events** tab.

Name	Description
Index	Uniquely identifies an entry in the event table. Each entry defines one event that the system generates after the appropriate conditions occur. The default is 1.
Description	Specifies a comment that describes this event entry.

Name	Description
Type	Specifies the type of notification that the probe makes about this event. In the case of a log, the system makes an entry in the log table for each event. In the case of SNMP traps, the system sends an SNMP trap to one or more management stations.
Community	Specifies the SNMP community where you can send SNMP traps.
LastTimeSent	Specifies the value of sysUpTime at the time this event entry last generated an event. If this entry has not generated events, this value is zero.
Owner	Specifies the entity that configured this entry and is therefore using the assigned resources. If this object contains a string starting with monitor and has associated entries in the log table, all connected management stations retrieve those log entries, as they have significance to all management stations connected to this device.

Viewing RMON1 Events

View RMON1 events to see how many events occurred.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Alarms**.
3. Click the **Events** tab.

Events Field Descriptions

Use the data in the following table to use the **Events** tab.

Name	Description
Index	Uniquely identifies an entry in the event table. Each entry defines one event that the system generates after the appropriate conditions occur. The default is 1.
Description	Specifies a comment that describes this event entry.
Type	Specifies the type of notification that the probe makes about this event. In the case of a log, the system makes an entry in the log table for each event. In the case of SNMP traps, the system sends an SNMP trap to one or more management stations.
Community	Specifies the SNMP community where you can send SNMP traps.
LastTimeSent	Specifies the value of sysUpTime at the time this event entry last generated an event. If this entry has not generated events, this value is zero.
Owner	Specifies the entity that configured this entry and is therefore using the assigned resources. If this object contains a string starting with monitor and has associated entries in the log table, all connected management stations retrieve those log entries, as they have significance to all management stations connected to this device.

Deleting an Event

Delete an event after you no longer require the alarm information.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Alarms**.
3. Click the **Events** tab.
4. Select the event you must delete.
5. Click **Delete**.

Viewing the RMON Log

About This Task

View the trap log to see which activity occurred.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Alarms**.
3. Click the **Log** tab.

Log Field Descriptions

Use the data in the following table to use the **Log** tab.

Name	Description
EventIndex	Specifies an index that uniquely identifies an entry in the event table. Each entry defines one event that is generated under appropriate conditions.
Index	Specifies an index that uniquely identifies an entry in the log table generated by the same event entries.
Time	Specifies the creation time for this log entry.
Description	Specifies an implementation dependent description of the event that activated this log entry.

Enabling RMON Statistics

About This Task

Enable Ethernet statistics collection for RMON.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Control**.
3. Click the **Ethernet Statistics** tab.
4. Click **Insert**.
5. Next to the **Port** box, click the ellipsis (...) button.

6. Select a port.
7. Click **OK**.
8. In the **Owner** box, type the name of the owner entity.
9. Click **OK**.
10. Click **Insert**.

Ethernet Statistics Field Descriptions

Use the data in the following table to use the **Ethernet Statistics** tab.

Name	Description
Index	Uniquely identifies an entry in the Ethernet Statistics table. The default is 1.
Port	Identifies the source of the data that this etherStats entry is configured to analyze.
Owner	Specifies the entity that configured this entry and therefore uses the assigned resources.

Viewing RMON Statistics

Before You Begin

- You must enable RMON statistics collection.

About This Task

Use the following procedure to view RMON statistics for each port.

Procedure

1. In the Device Physical View, select a port.
2. In the navigation pane, expand the **Configuration** > **Graph** folders.
3. Click **Port**.
4. Click the **RMON** tab.
5. Select the statistics you want to graph.
6. Select a graph type:
 - bar
 - pie
 - chart
 - line

RMON Field Descriptions

The following table describes fields on the **RMON** tab.

Name	Description
Octets	<p>Specifies the number of octets of data (including those in bad packets) received on the network (excluding framing bits but including FCS octets).</p> <p>You can use this object as a reasonable estimate of Ethernet utilization. If additional precision is desired, sample the Pkts and Octets objects before and after a common interval. The differences in the sampled values are Pkts and Octets, and the number of seconds in the interval is Interval. These values are used to calculate the Utilization as follows:</p> $\text{Pkts} * (9.6+6.4) + (\text{Octets} * .8)$ <p>Utilization = Interval * 10,000</p> <p>The result of this equation is the value Utilization, which is the percent utilization of the Ethernet segment on a scale of 0 to 100 percent.</p>
Pkts	Specifies the number of packets (including bad packets, broadcast packets, and multicast packets) received.
BroadcastPkts	Specifies the number of good packets received that were directed to the broadcast address. This number does not include multicast packets.
MulticastPkts	Specifies the number of good packets received that were directed to a multicast address. This number does not include packets directed to the broadcast address.
CRCAAlignErrors	Specifies the number of packets received that had a length (excluding framing bits, but including FCS octets) between 64 and 1518 octets, inclusive, but had either a bad Frame Check Sequence (FCS) with an integral number of octets (FCS Error) or a bad FCS with a nonintegral number of octets (Alignment Error).
UndersizePkts	Specifies the number of packets received that were less than 64 octets long (excluding framing bits, but including FCS octets) and were otherwise well formed.
OversizePkts	Specifies the number of packets received that were longer than 1518 octets (excluding framing bits, but including FCS octets) and were otherwise well formed.

Name	Description
Fragments	<p>Specifies the number of packets received that were less than 64 octets in length (excluding framing bits but including FCS octets) and had either a bad Frame Check Sequence (FCS) with an integral number of octets (FCS Error) or a bad FCS with a nonintegral number of octets (Alignment Error).</p> <p>It is entirely normal for Fragments to increment because it counts both runs (which are normal occurrences due to collisions) and noise hits.</p>
Collisions	<p>Specifies the best estimate of the number of collisions on this Ethernet segment. The value returned depends on the location of the RMON probe. Section 8.2.1.3 (10BASE-5) and section 10.3.1.3 (10BASE-2) of IEEE standard 802.3 states that a station must detect a collision in the receive mode if three or more stations are transmitting simultaneously. A repeater port must detect a collision when two or more stations transmit simultaneously. Thus, a probe placed on a repeater port can record more collisions than a probe connected to a station on the same segment. Probe location plays a much smaller role when considering 10BASE-T. 14.2.1.4 (10BASE-T) of IEEE standard 802.3 defines a collision as the simultaneous presence of signals on the DO and RD circuits (transmitting and receiving at the same time). A 10BASE-T station can only detect collisions when it is transmitting. Thus, probes placed on a station and a repeater reports the same number of collisions.</p> <p>An RMON probe inside a repeater reports collisions between the repeater and one or more other hosts (transmit collisions as defined by IEEE 802.3k) plus receiver collisions observed on any coax segments to which the repeater is connected.</p>

View the Protocol Directory

View the protocol directory to see the list of protocols that RMON2 can monitor. You cannot change the list of protocols.

About This Task

The protocol directory MIB is enabled by default for the predefined protocols.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Protocol Directory**.
3. Click the **Protocol Directories** tab.

Protocol Directories Field Descriptions

The following table defines parameters for the **Protocol Directories** tab.

Name	Description
Index	Shows a unique identifier for the entry in the table.
Protocol	<p>Shows the protocols RMON2 can monitor:</p> <ul style="list-style-type: none"> • Internet Protocol (IP) • Secure Shell version 2 (SSHv2) • Transmission Control Protocol (TCP) • User Datagram Protocol (UDP) • File Transfer Protocol (FTP) • Hypertext Transfer Protocol (HTTP) • Telnet • Trivial File Transfer Protocol (TFTP) • Simple Networking Management Protocol (SNMP) <p>Note: RMON2 counts application packets received on any platform on which the application is not enabled or supported, before dropping them.</p>
AddressMapConfig	<p>Describes and configures the probe support for the network layer and application layer host tables for this protocol. The value can be one of the following:</p> <ul style="list-style-type: none"> • notSupported • supportedOff • supportedOn <p>If the value is supportedOn, the probe adds entries to the Address Map tab that maps the network layer address to the MAC layer address.</p>
HostConfig	<p>Describes and configures the probe support for the network layer and application layer host tables for this protocol. The value can be one of the following:</p> <ul style="list-style-type: none"> • notSupported • supportedOff • supportedOn <p>If the value is supportedOn, the probe adds entries to the Host Control tab to collect statistics for network layer and application layer hosts.</p>
MatrixConfig	<p>Describes and configures the probe support for the network layer and application layer host tables for this protocol. The value can be one of the following:</p> <ul style="list-style-type: none"> • notSupported • supportedOff • supportedOn
Owner	Shows the entity that configured this entry.

Viewing the Data Source for Protocol Distribution Statistics

View the Distribution Control tab to see the network segment data source on which the protocol distribution statistics are measured. The management IP mentioned as a data source represents the IP that the SNMP agent uses to access the switch.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Protocol Distribution**.
3. Click the **Distribution Control** tab.

Distribution Control Field Descriptions

Use the data in the following table to use the **Distribution Control** tab.

Name	Description
Index	Shows a unique identifier for the entry in the table.
DataSource	Specifies the source of data for this protocol distribution.
DroppedFrames	Shows the total number of frames that the probe receives and drops but does not include in the StatsDropEvents value. This event can occur if the probe is out of resources and sheds the load from this collection. This value does not include packets that were not counted because they had MAC-layer errors.
CreateTime	Shows the value of the sysUpTime when the entry was last activated.
Owner	Shows the entity that configured this entry.

Viewing Protocol Distribution Statistics

View protocol distribution statistics to see traffic statistics that each protocol generates by local area network (LAN) segment.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Protocol Distribution**.
3. Click the **Distribution Stats** tab.

Distribution Stats Field Descriptions

Use the data in the following table to use the **Distribution Stats** tab.

Name	Description
LocalIndex	Identifies the protocol distribution an entry is part of, as well as the particular protocol that it represents.
Pkts	Shows the number of packets without errors received for this protocol type. This value is the number of link-layer packets so a single, fragmented network-layer packet can increment the counter several times.
Octets	Shows the number of octets in packets received for this protocol type since it was added to the table. This value does not include octets in packets that contained errors. This value counts octets in the entire packet that contained the protocol, not just the particular protocol frames.

Viewing the Host Interfaces Enabled for Monitoring

View the entries in the address map control tab to see which host interfaces are enabled for monitoring on the switch. Each entry in this table enables the discovery of addresses on a new interface.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Address Map**.
3. Click the **Address Map Control** tab.

Address Map Control Field Descriptions

Use the data in the following table to use the **Address Map Control** tab.

Name	Description
Index	Shows a unique identifier for the entry in the table.
DataSource	Shows the source of data for the entry.
DroppedFrames	Shows the total number of frames that the probe receives and drops but does not include in the StatsDropEvents value. This event can occur if the probe is out of resources and sheds the load from this collection. This value does not include packets that were not counted because they had MAC-layer errors.
Owner	Shows the entity that configured this entry.

Viewing Address Mappings

View the mappings of network layer address to physical address to interface.

About This Task

The probe adds entries on this tab based on the source MAC and network addresses in packets without MAC-level errors.

The probe populates this table for all protocols on the **Protocol Directories** tab with a value of **AddressMapConfig** equal to **supportedOn**.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Address Map**.
3. Click the **Address Map** tab.

Address Map Field Descriptions

Use the data in the following table to use the **Address Map** tab.

Name	Description
LocalIndex	Shows a unique identifier for the entry in the table.
HostAddress	Shows the network address for this entry. The format of the value depends on the protocol portion of the local index.
Source	Shows the interface or port on which the network address was most recently seen.
PhysicalAddress	Shows the physical address on which the network address was most recently seen.
LastChange	Shows the value of the sysUpTime when the entry was created or last changed. If this value changes frequently, it can indicate duplicate address problems.

Viewing the Data Source for Host Statistics

View the Host Control tab to see the data source for both network layer and application layer host statistics.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Network Layer Host**.
3. Click the **Host Control** tab.

Host Control Field Descriptions

Use the data in the following table to use the **Host Control** tab.

Name	Description
Index	Shows a unique identifier for the entry in the table.
DataSource	Shows the source of data for the associated host table. The statistics in this group reflect all packets on the local network segment that attaches to the identified interface.
NHDropFrames	Shows the total number of frames that the probe receives and drops but does not include in the StatsDropEvents value. This event can occur if the probe is out of resources and sheds the load from this collection. This value does not include packets that were not counted because they had MAC-layer errors.
AHDropFrames	Shows the total number of frames that the probe receives and drops but does not include in the StatsDropEvents value. This event can occur if the probe is out of resources and sheds the load from this collection. This value does not include packets that were not counted because they had MAC-layer errors.
Owner	Shows the entity that configured this entry.

Viewing Network Host Statistics

View network host statistics to see Layer 3 traffic statistics for each host. The network layer host MIB monitors traffic packets in and out of hosts based on the network layer address.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Network Layer Host**.
3. Click the **Network Host Stats** tab.

Network Host Stats Field Descriptions

Use the data in the following table to use the **Network Host Stats** tab.

Name	Description
LocalIndex	Shows a unique identifier for the entry in the table.
HostAddress	Shows the host address for this entry.
InPkts	Shows the number of packets without errors transmitted to this address. This value is the number of link-layer packets so a single, fragmented network-layer packet can increment the counter several times.

Name	Description
OutPkts	Shows the number of packets without errors transmitted by this address. This value is the number of link-layer packets so a single, fragmented network-layer packet can increment the counter several times.
InOctets	Shows the number of octets transmitted to this address, excluding octets in packets that contained errors. This value counts octets in the entire packet that contained the protocol, not just the particular protocol frames.
OutOctets	Shows the number of octets transmitted by this address, excluding octets in packets that contained errors. This value counts octets in the entire packet that contained the protocol, not just the particular protocol frames.
CreateTime	Shows the value of the sysUpTime when the entry was last activated.

Viewing Application Host Statistics

View application host statistics to see traffic statistics by application protocol for each host.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Application Layer Host**.
3. Click the **Application Host Stats** tab.

Application Host Stats Field Descriptions

Use the data in the following table to use the **Application Host Stats** tab.

Name	Description
Index	Shows a unique identifier for the entry in the table.
HostAddress	Identifies the network layer address of this entry.
LocalIndex	Identifies the network layer protocol of the address.
InPkts	Shows the number of packets for this protocol type, without errors, transmitted to this address. This value is the number of link-layer packets so a single, fragmented network-layer packet can increment the counter several times.
OutPkts	Shows the number of packets for this protocol type, without errors, transmitted by this address. This value is the number of link-layer packets so a single, fragmented network-layer packet can increment the counter several times.

Name	Description
InOctets	Shows the number of octets transmitted to this address, excluding octets in packets that contained errors. This value counts octets in the entire packet that contained the protocol, not just the particular protocol frames.
OutOctets	Shows the number of octets transmitted by this address, excluding octets in packets that contained errors. This value counts octets in the entire packet that contained the protocol, not just the particular protocol frames.
CreateTime	Shows the value of the sysUpTime when the entry was last activated.

RMON Alarm Variables

RMON alarm variables are divided into three categories. Each category has subcategories.

The following table lists the alarm variable categories and provides a brief variable description.

Table 183: RMON alarm variables

Category	Subcategory	Variable	Definition
Security		rcCliNumAccessViolations.0	The number of CLI access violations detected by the system.
		rcWebNumAccessBlocks.0	The number of accesses the web server blocked.
		snmpInBadCommunityNames.0	The total number of SNMP messages delivered to the SNMP protocol entity that represented an SNMP operation not allowed by the SNMP community named in the message.
Errors	Interface	ifInDiscards	The number of inbound packets discarded even though no errors were detected to prevent the packets being deliverable to a higher-layer protocol. One possible reason for discarding a packet is to free buffer space.

Table 183: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		ifInErrors	For packet-oriented interfaces, the number of inbound packets that contained errors preventing them from being deliverable to a higher-layer protocol. For character-oriented or fixed-length interfaces, the number of inbound transmission units that contained errors, preventing them from being deliverable to a higher-layer protocol.
		ifOutDiscards	The number of outbound packets discarded even though no errors were detected to prevent the packets being transmitted. One possible reason for discarding such a packet is to free buffer space.
		ifOutErrors	For packet-oriented interfaces, the number of outbound packets that were not transmitted because of errors. For character-oriented or fixed-length interfaces, the number of outbound transmission units that were not transmitted because of errors.
	Ethernet	dot3StatsAlignmentErrors	A count of frames received on a particular interface that are not an integral number of octets in length and do not pass the Frame Check Sequence (FCS) check. The count represented by an instance of this object increments when the alignmentError status is returned by the MAC service to the LLC (or other MAC user). Received frames for which multiple error conditions exist are, according to the conventions of IEEE 802.3 Layer Management, counted exclusively according to the error status presented to the LLC.

Table 183: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		dot3StatsFCSErrors	A count of frames received on a particular interface that are an integral number of octets in length but do not pass the FCS check. The count represented by an instance of this object increments when the frameCheckError status is returned by the MAC service to the LLC (or other MAC user). Received frames for which multiple error conditions occur are, according to the conventions of IEEE 802.3 Layer Management, counted exclusively according to the error status presented to the LLC.
		dot3StatsSingleCollisionFrames	A count of successfully transmitted frames on a particular interface where transmission is inhibited by exactly one collision. A frame that is counted by an instance of this object is also counted by the corresponding instance of either the ifOutUcastPkts object, the ifOutMulticastPkts object, or the ifOutBroadcastPkts object, and is not counted by the corresponding instance of the dot3StatsMultipleCollisionFrames object.
		dot3StatsMultipleCollisionFrames	A count of successfully transmitted frames on a particular interface where transmission is inhibited by more than one collision. A frame that is counted by an instance of this object is also counted by the corresponding instance of either the ifOutUcastPkts, ifOutMulticastPkts, or ifOutBroadcastPkts object, and is not counted by the corresponding instance of the dot3StatsSingleCollisionFrames object.

Table 183: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		dot3StatsSQETestErrors	A count of times that the SQE TEST ERROR message is generated by the PLS sublayer for a particular interface. The SQE TEST ERROR message is defined in section 7.2.2.2.4 of ANSI/IEEE 802.3-1985 and its generation is described in section 7.2.4.6 of the same document.
		dot3StatsDeferredTransmissions	A count of frames for which the first transmission attempt on a particular interface is delayed because the medium is busy. The count represented by an instance of this object does not include frames involved in collisions.
		dot3StatsLateCollisions	The number of times that a collision is detected on a particular interface later than 512 bit-times into the transmission of a packet; 512 bit-times corresponds to 51.2 microseconds on a 10 Mb/s system. A (late) collision included in a count represented by an instance of this object is also considered as a (generic) collision for purposes of other collision-related statistics.
		dot3StatsExcessiveCollisions	A count of frames where the transmission on a particular interface fails due to excessive collisions.

Table 183: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		dot3StatsInternalMacTransmitErrors	<p>A count of frames where the transmission on a particular interface fails due to an internal MAC sublayer transmit error. A frame is only counted by an instance of this object if it is not counted by the corresponding instance of either the dot3StatsLateCollisions object, the dot3StatsExcessiveCollisions object, or the dot3StatsCarrierSenseErrors object.</p> <p>The precise meaning of the count represented by an instance of this object is implementation specific. In particular, an instance of this object can represent a count of transmission errors on a particular interface that are not otherwise counted.</p>
		dot3StatsCarrierSenseErrors	<p>The number of times the carrier sense condition was lost or never asserted when the switch attempted to transmit a frame on a particular interface. The count represented by an instance of this object increments at most once for each transmission attempt, even if the carrier sense condition fluctuates during a transmission attempt.</p>
		dot3StatsFrameTooLongs	<p>A count of frames received on a particular interface that exceeds the maximum permitted frame size. The count represented by an instance of this object increments when the frameTooLong status is returned by the MAC service to the LLC (or other MAC user). Received frames for which multiple error conditions obtained are, according to the conventions of IEEE 802.3 Layer Management, counted exclusively according to the error status presented to the LLC.</p>

Table 183: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		dot3StatsInternalMacReceiveErrors	<p>A count of frames where the transmission on a particular interface fails due to an internal MAC sublayer transmit error. A frame is counted by an instance of this object only if it is not counted by the corresponding instance of either the dot3StatsLateCollisions object, the dot3StatsExcessiveCollisions object, or the dot3StatsCarrierSenseErrors object.</p> <p>The precise meaning of the count represented by an instance of this object is implementation-specific. In particular, an instance of this object can represent a count of transmission errors on a particular interface that are not otherwise counted.</p>
	IP	ipInHdrErrors.0	The number of input datagrams discarded due to errors in the datagram IP headers, including bad checksums, version number mismatch, other format errors, time-to-live exceeded, and errors discovered in processing IP options.
		ipInDiscards.0	The number of discarded input IP datagrams where no problems were encountered to prevent continued processing. An example of why they were discarded can be lack of buffer space. This counter does not include any datagrams discarded while awaiting reassembly.
		ipOutDiscards.0	The number of output IP datagrams where no problems were encountered to prevent transmission to the destination, but that were discarded (for example, for lack of buffer space). This counter includes datagrams counted in ipForwDatagrams if packets meet this (discretionary) discard criterion.

Table 183: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		ipFragFails.0	The number of IP datagrams discarded because they needed to be fragmented at this entity but were not, for example, because the Don't Fragment flag was set.
		ipReasmFails.0	The number of failures detected by the IP reassembly algorithm (for whatever reason: timed out, errors, and so forth). This is not necessarily a count of discarded IP fragments because some algorithms (notably the algorithm in RFC 815) can lose track of the number of fragments by combining them as they are received.
		icmpInParmProbs.0	The number of ICMP In parameter problem messages received.
		icmpOutParmProbs.0	The number of ICMP Out parameter problem messages received.
	MLT	rcStatMltEtherAlignmentErrors	The number of frames received on an MLT that are not an integral number of octets in length, but do not pass the FCS check.
		rcStatMltEtherFCSErrors	The number of frames received on an MLT that are an integral number of octets in length, but do not pass the FCS check.
		rcStatMltEtherSingleCollFrames	The number of successfully transmitted frames on a particular MLT where transmission is inhibited by exactly one collision.
		rcStatMltEtherMultipleCollFrames	The number of successfully transmitted frames on a particular MLT where transmission is inhibited by more than one collision.
		rcStatMltEtherSQETestError	A count of times that the SQE TEST ERROR message is generated by the PLS sublayer for a particular MLT.

Table 183: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		rcStatMltEtherDeferredTransmiss	A count of frames where the first transmission attempt on a particular MLT is delayed because the medium is busy. The count represented by an instance of this object.
		rcStatMltEtherLateCollisions	The number of times that a late collision is detected on a particular MLT later than 512 bit-times into the transmission of a packet; 512-bit-times corresponds to 51.2-microseconds on a 10 Mb/s system.
		rcStatMltEtherExcessiveCollis	The number of times that excessive collisions are detected on a particular MLT later than 512 bit-times into the transmission of a packet; 512 bit-times corresponds to 51.2 microseconds on a 10-Mb/s system.
		rcStatMltEtherMacTransmitError	A count of frames where the transmission on a particular MLT fails due to an internal MAC sublayer transmit error. A frame is only counted by an instance of this object if it is not counted by the corresponding instance of either the LateCollisions object, the ExcessiveCollisions object, or the CarrierSenseErrors object.
		rcStatMltEtherCarrierSenseError	The number of times the carrier sense condition was lost or never asserted when attempting to transmit a frame on a particular MLT. The count represented by an instance of this object increments at most once for each transmission attempt, even if the carrier sense condition fluctuates during a transmission attempt.

Table 183: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		rcStatMltEtherFrameTooLong	A count of frames received on a particular MLT that exceeds the maximum permitted frame size. The count represented by an instance of this object increments when the frameTooLong status is returned by the MAC service to the LLC (or other MAC user).
		rcStatMltEtherMacReceiveError	A count of frames for which reception on a particular MLT fails due to an internal MAC sublayer receive error. A frame is only counted by an instance of this object if it is not counted by the corresponding instance of either the FrameTooLongs object, the AlignmentErrors object, or the FCSErrors object.
	Other	rcTblArNoSpace	The number of entries not added to the address translation table due to lack of space.
		snmplnAsnParseErrs.0	The total number of ASN.1 or BER errors encountered by the SNMP protocol entity when it decodes received SNMP messages.
		rcStgPortInBadBpdus	The number of bad BPDUs received by this port.
		dot1dTpPortInDiscards	Count of valid frames received that were discarded (that is, filtered) by the forwarding process.
Traffic	Interface	ifInOctets	The total number of octets received on the interface, including framing characters.
		ifInMulticastPkts	The number of packets, delivered by this sublayer to a higher sublayer, that are addressed to a multicast address at this sublayer. For a MAC layer protocol, this number includes both Group and Functional addresses.
		ifInBroadcastPkts	The number of packets, delivered by this sublayer to a higher (sub) layer, that are addressed to a broadcast address at this sublayer.

Table 183: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		ifInUnkownProtos	For packet-oriented interfaces, the number of packets received through the interface that are discarded because of an unknown or unsupported protocol. For character-oriented or fixed-length interfaces that support protocol multiplexing, the number of transmission units received through the interface that are discarded because of an unknown or unsupported protocol. For any interface that does not support protocol multiplexing, this counter is always 0.
		ifOutOctets	The total number of octets transmitted from the interface, including framing characters.
		ifOutMulticastPkts	The total number of packets that higher-level protocols requested be transmitted, and that are addressed to a multicast address at this sublayer, including those that are discarded or not sent. For a MAC layer protocol, this includes both Group and Functional addresses.
		ifoutBroadcastPkts	The total number of packets that higher level protocols requested transmitted, and that were addressed to a broadcast address at this sublayer, including those discarded or not sent.
		ifLastChange	The value of sysUpTime at the time the interface entered its current operational state. If the current state was entered prior to the last reinitialization of the local network management subsystem, this object contains a value of zero.

Table 183: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
	RmonEther Stats	etherStatsOctets	The total number of octets of data (including those in bad packets) received on the network (excluding framing bits but including FCS octets). Use this object as a reasonable estimate of Ethernet utilization. For greater precision, sample the etherStatsPkts and etherStatsOctets objects before and after a common interval.
		etherStatsPkts	The total number of packets (including bad packets, broadcast packets, and multicast packets) received.
		etherStatsBroadcastPkts	The total number of good packets received that are directed to the broadcast address. This number does not include multicast packets.
		etherStatsMulticastPkts	The total number of good packets received that are directed to a multicast address. This number does not include packets directed to the broadcast address.
		etherStatsCRCAAlignErrors	The total number of packets received that had a length (excluding framing bits, but including FCS octets) of 64 to 1518 octets, inclusive, but had either a bad Frame Check Sequence (FCS) with an integral number of octets (FCS Error) or a bad FCS with a nonintegral number of octets (Alignment Error).
		etherStatsUndersizePkts	The total number of packets received that are less than 64 octets long (excluding framing bits, but including FCS octets) and were otherwise well formed.
		etherStatsOversizePkts	The total number of packets received that are longer than 1518 octets (excluding framing bits, but including FCS octets) and were otherwise well formed.

Table 183: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		etherStatsFragments	The total number of packets received that are less than 64 octets in length (excluding framing bits but including FCS octets) and had either a bad Frame Check Sequence (FCS) with an integral number of octets (FCS Error) or a bad FCS with a nonintegral number of octets (Alignment Error). It is entirely normal for etherStatsFragments to increment because it counts both runts (which are normal occurrences due to collisions) and noise hits.
		etherStatsCollisions	The best estimate of the total number of collisions on this Ethernet segment.
	IP	ipInReceives.0	All incoming IP packets.
		ipInAddrErrors.0	The number of bad IP destination addresses.
		ipForwDatagrams.0	IP packets forwarded.
		ipInUnknownProtos.0	Number of unsupported IP protocols.
		ipInDelivers.0	The number of IP In packets delivered.
		ipOutRequests.0	The total number of IP datagrams that local IP user protocols supplied to IP in request for transmission.
		ipOutNoRoutes.0	The number of IP datagrams discarded because no route was found to transmit to the destination.
		ipFragOKs.0	The number of IP datagrams successfully fragmented.
		ipFragCreates.0	The number of IP datagram fragments generated as a result of fragmentation.
		ipReasmReqds.0	The number of requests to reassemble fragments.
		ipReasmOKs.0	The number of fragments reassembled successfully.
	ICMP	icmpInSrcQuenchs.0	The number of ICMP Source Quench messages received.

Table 183: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		icmpInRedirects.0	The number of ICMP redirect messages.
		icmpInEchos.0	The number of ICMP Echo requests messages received.
		icmpInEchosReps.0	The number of ICMP Echo reply messages received.
		icmpInTimeStamps.0	The number of ICMP timestamp request messages received.
		icmpInTimeStampsReps.0	The number of ICMP timestamp reply messages received.
		icmpInAddrMasks.0	The number of ICMP mask request messages reviewed.
		icmpInAddrMasksReps.0	The number of ICMP mask reply messages reviewed.
		icmpInDestUnreachs.0	The number of ICMP destinations unreachable messages received.
		icmpInTimeExcds.0	The number of ICMP Time Exceeded messages received.
		icmpOutSrcQuenchs.0	The number of ICMP Source Quench messages sent.
		icmpOutRedirects.0	The number of ICMP redirect messages sent.
		icmpOutEchos.0	The number of ICMP Echo request messages sent.
		icmpOutEchosReps.0	The number of ICMP Echo reply messages sent.
		icmpOutTimeStamps.0	The number of ICMP Timestamp request messages sent.
		icmpOutTimeStampsReps.0	The number of ICMP Timestamp reply messages sent.
		icmpOutAddrMasks.0	The number of ICMP Address mask messages sent.
		icmpOutAddrMasksReps.0	The number of ICMP Address mask reply messages sent.
		icmpOutDestUnreachs.0	The number of ICMP destination unreachable messages sent.
		icmpOutTimeExcds.0	The number of ICMP time exceeded messages sent.
	Snmp	snmpInPkts.0	The total number of messages delivered to the SNMP entity from the transport service.

Table 183: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		snmpOutPkts.0	The total number of SNMP messages passed from the SNMP protocol entity to the transport service.
		snmplnBadVersions.0	The total number of SNMP messages delivered to the SNMP protocol entity that were intended for an unsupported SNMP version.
		snmplnBadCommunityUses.0	The total number of SNMP messages delivered to the SNMP protocol entity that represented an SNMP operation that was not allowed by the SNMP community named in the message.
		snmplnTooBigs.0	The total number of SNMP PDUs delivered to the SNMP protocol entity and for which the value of the error-status field is tooBig.
		snmplnNoSuchNames.0	The total number of SNMP PDUs delivered to the SNMP protocol entity and for which the value of the error-status field is noSuchName.
		snmplnBadValues. 0	The total number of SNMP PDUs received that were generated by the SNMP protocol entity and for which the value of the error-status field is badValue.
		snmplnReadOnlys.0	The total number of valid SNMP PDUs delivered to the SNMP protocol entity and for which the value of the error-status field is readOnly. It is a protocol error to generate an SNMP PDU that contains the value readOnly in the error-status field; as such, this object is provided as a means of detecting incorrect implementations of the SNMP.
		snmplnGenErrs.0	The total number of SNMP PDUs delivered to the SNMP protocol entity and for which the value of the error-status field is genErr.

Table 183: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		snmpInTotalReqVars.0	The total number of MIB objects retrieved successfully by the SNMP protocol entity as the result of receiving valid SNMP Get-Request and Get-Next PDUs.
		snmpInTotalSetVars.0	The total number of MIB objects altered successfully by the SNMP protocol entity as the result of receiving valid SNMP Set-Request PDUs.
		snmpInGetRequests.0	The total number of SNMP Get-Request PDUs accepted and processed by the SNMP protocol entity.
		snmpInGetNexts.0	The total number of SNMP Get-Next PDUs accepted and processed by the SNMP protocol entity.
		snmpInSetRequests.0	The total number of SNMP Set-Request PDUs accepted and processed by the SNMP protocol entity.
		snmpInGetResponses.0	The total number of SNMP Get-Response PDUs accepted and processed by the SNMP protocol entity.
		snmpInTraps.0	The total number of SNMP Trap PDUs accepted and processed by the SNMP protocol entity.
		snmpOutTooBigs.0	The total number of SNMP PDUs generated by the SNMP protocol entity and for which the value of the error-status field is tooBig.
		snmpOutNoSuchNames.0	The total number of SNMP PDUs generated by the SNMP protocol entity and for which the value of the error-status field is noSuchName.
		snmpOutBadValues.0	The total number of SNMP PDUs sent that were generated by the SNMP protocol entity and for which the value of the error-status field is badValue.
		snmpOutGenErrs.0	The total number of SNMP PDUs generated by the SNMP protocol entity and for which the value of the error-status field is genErr.

Table 183: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		snmpOutGetRequests.0	The total number of SNMP Get-Request PDUs generated by the SNMP protocol entity.
		snmpOutGetNexts.0	The total number of SNMP Get-Next PDUs generated by the SNMP protocol entity.
		snmpOutSetRequests.0	The total number of SNMP Set-Request PDUs generated by the SNMP protocol entity.
		snmpOutGetResponses.0	The total number of SNMP Get-Response PDUs generated by the SNMP protocol entity.
		snmpOutTraps.0	The total number of SNMP Trap PDUs generated by the SNMP protocol entity.
	Bridge	rcStgTimeSinceTopologyChange	The time (in hundredths of a second) since the last topology change was detected by the bridge entity.
		rcStgTopChanges	The total number of topology changes detected by this bridge since the management entity was last reset or initialized.
		rcStgMaxAge	The maximum age of Spanning Tree Protocol information learned from the network on any port before it is discarded, in hundredths of a second. This is the actual value that this bridge is currently using.
		rcStgPortForwardTransitions	The number of times this port transitioned from the Learning state to the Forwarding state.
		rcStgPortInConfigBpdus	The number of Config BPDUs received by this port.
		rcStgPortInTcnBpdus	The number of Topology Change Notification BPDUs received by this port.
		rcStgPortOutConfigBpdus	The number of Config BPDUs transmitted by this port.
		rcStgPortOutTcnBpdus	The number of Topology Change Notification BPDUs transmitted by this port.

Table 183: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		dot1dTpPortInFrames	The number of frames received by this port from its segment. A frame received on the interface corresponding to this port is counted by this object only if it is for a protocol being processed by the local bridging function, including bridge management frames.
		dot1dTpPortOutFrames	The number of frames transmitted by this port to its segment. A frame transmitted on the interface corresponding to this port is counted by this object if and only if it is for a protocol processed by the local bridging function, including bridge management frames.
		dot1dTpLearnedEntryDiscards.0	The total number of Forwarding Database entries learned but discarded due to a lack of space to store them in the Forwarding Database. If this counter increases, it indicates that the forwarding database is regularly becoming full (a condition that has negative performance effects on the subnetwork). If this counter has a significant value but does not increase, it indicates that the problem occurred but is not persistent.
	Utilization	rcSysBufferUtil.0	Buffer utilization as a percentage of the total amount of buffer space in the system. A high value indicates congestion.
		rcSysNVRamUsed.0	Nonvolatile RAM (NVRAM) in use in kilobytes.
		rcSysLastChange.0	Last management-initiated configuration change since sysUpTime.
		rcSysLastVlanChange.0	Last management-initiated VLAN configuration change since sysUpTime.
	MLT	rcStatMltIfExtnIfInMulticastPkts	The total number of multicast packets delivered to this MLT interface.

Table 183: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		rcStatMltIfExtnIfInBroadcastPkts	The total number of broadcast packets delivered to this MLT Interface.
		rcStatMltIfExtnIfOutMulticastPkts	The total number of MLT interface multicast packets delivered to this MLT interface.
		rcStatMltIfExtnIfOutBroadcastPkts	The total number of MLT interface broadcast packets delivered to this MLT interface.
		rcStatMltIfExtnIfHCInOctets	The total number of octets received on this MLT interface including framing characters detected by the high-count (64-bit) register.
		rcStatMltIfExtnIfHCInUcastPkts	The number of packets delivered by this MLT interface to a higher MLT that were not addressed to a multicast or broadcast address as detected by the high-count (64-bit) register.
		rcStatMltIfExtnIfHCInMulticastPkt	The total number of multicast packets delivered to this MLT interface detected by the high-count (64-bit) register.
		rcStatMltIfExtnIfHCInBroadcastPkt	The total number of broadcast packets delivered to this MLT interface detected by the high-count (64-bit) register.
		rcStatMltIfExtnIfHCOctets	The total number of octets transmitted from the MLT interface, including framing characters.
		rcStatMltIfExtnIfHCOutUcastPkts	The number of packets transmitted by this MLT interface to a higher MLT that were not addressed to a multicast or broadcast address as detected by the high-count (64-bit) register.

Table 183: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		rcStatMltIfExtnIfHCOutMulticast	The total number of packets that higher-level protocols requested be transmitted, and that were addressed to a multicast address at this sublayer, including those that were discarded or not sent registered by the high-count (64-bit) register.
		rcStatMltIfExtnIfHCOutBroadcast	The total number of packets that higher-level protocols requested be transmitted, and that were addressed to a broadcast address at this sublayer, including those that were discarded or not sent registered by the high-count (64-bit) register.

**Note**

In addition to these elements that are offered in a graphical way by EDM, you can manually set any valid OID in the variable field to be monitored by an alarm. For these cases, the name of the variable cannot be translated automatically in OID, the exact OID must be set as a sequence of numbers.

	5520 Series	VOSS 8.2.5

Route Filtering and IP Policies

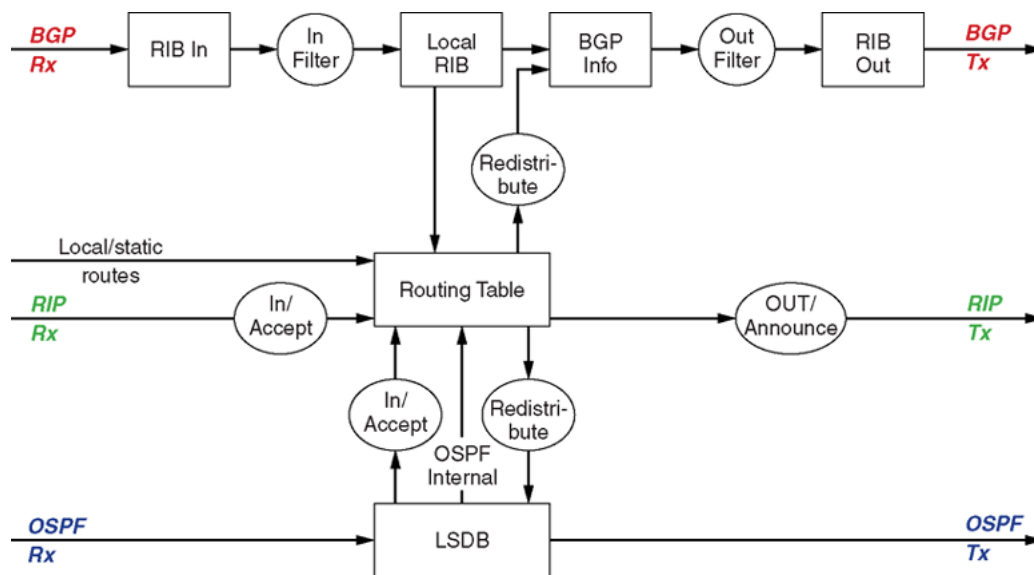

When the switch routes IP traffic, you can apply a number of filters to manage, accept, redistribute, and announce policies for unicast routing table information. Filters apply differently to different unicast routing protocols.

Note

IPv6 ingress QoS ACL/Filters and IPv6 Egress Security and QoS ACL/Filters are not supported. For information on the maximum number of IPv6 ingress port/vlan security ACL/filters supported on the switch, see [Fabric Engine Release Notes](#).

The following figure shows how filters apply to BGP, RIP, and OSPF protocols.

11041fa

Figure 210: Route filtering for BGP, RIP, and OSPF routing protocols

The following figure shows how filters apply to the IS-IS protocol for Fabric Connect Layer 3 VSNs or IP Shortcuts.

Figure 211: Route filtering for the IS-IS routing protocol

Accept Policies

Accept policies are applied to incoming traffic to determine whether to add the route to the routing table. Accept policies are applied differently to protocols, as follows:

- RIP and BGP—filters apply to all incoming route information.

- OSPF—filters apply only to external route information. Internal routing information is not filtered because otherwise, other routers in the OSPF domain can have inconsistent databases that can affect the router view of the network topology.
- IS-IS —filters apply to all incoming route information.

In a network with multiple routing protocols, you can prefer specific routes from RIP instead of from OSPF. The network prefix is a commonly used match criterion for accept policies.

Redistribution Filters

Redistribution filters notify changes in the route table to the routing protocol (within the device). With redistribution filters, providing you do not breach the protocol rules, you can choose not to advertise everything that is in the protocol database, or you can summarize or suppress route information. By default, no external routes are leaked to protocols that are not configured.

Announce Policies

Announce policies are applied to outgoing advertisements to neighbors or peers in the protocol domain to determine whether to announce specific route information. Out filtering applies to RIP updates and BGP NLRI updates.

In contrast, announce policies are not applied to IS-IS or OSPF information because routing information must always be consistent across the domain. To restrict the flow of external route information in the IS-IS or OSPF protocol database, apply redistribution filters instead of announce policies.

Route Filtering Stages

The following figure shows the three distinct filter stages that are applied to IP traffic.

These stages are:

- Filter stage 1 is the accept policy or in filter that applies to incoming traffic to detect changes in the dynamic (protocol-learned) routing information, which are then submitted to the routing table.
- Filter stage 2 is the redistribution filter that applies to the entries in the routing table to the protocol during the leaking process.
- Filter stage 3 is the announce policy or out filter that applies to outgoing traffic within a protocol domain.

Figure 212: Route filtering stages

The following figure shows the logical process for route filtering on the switch.

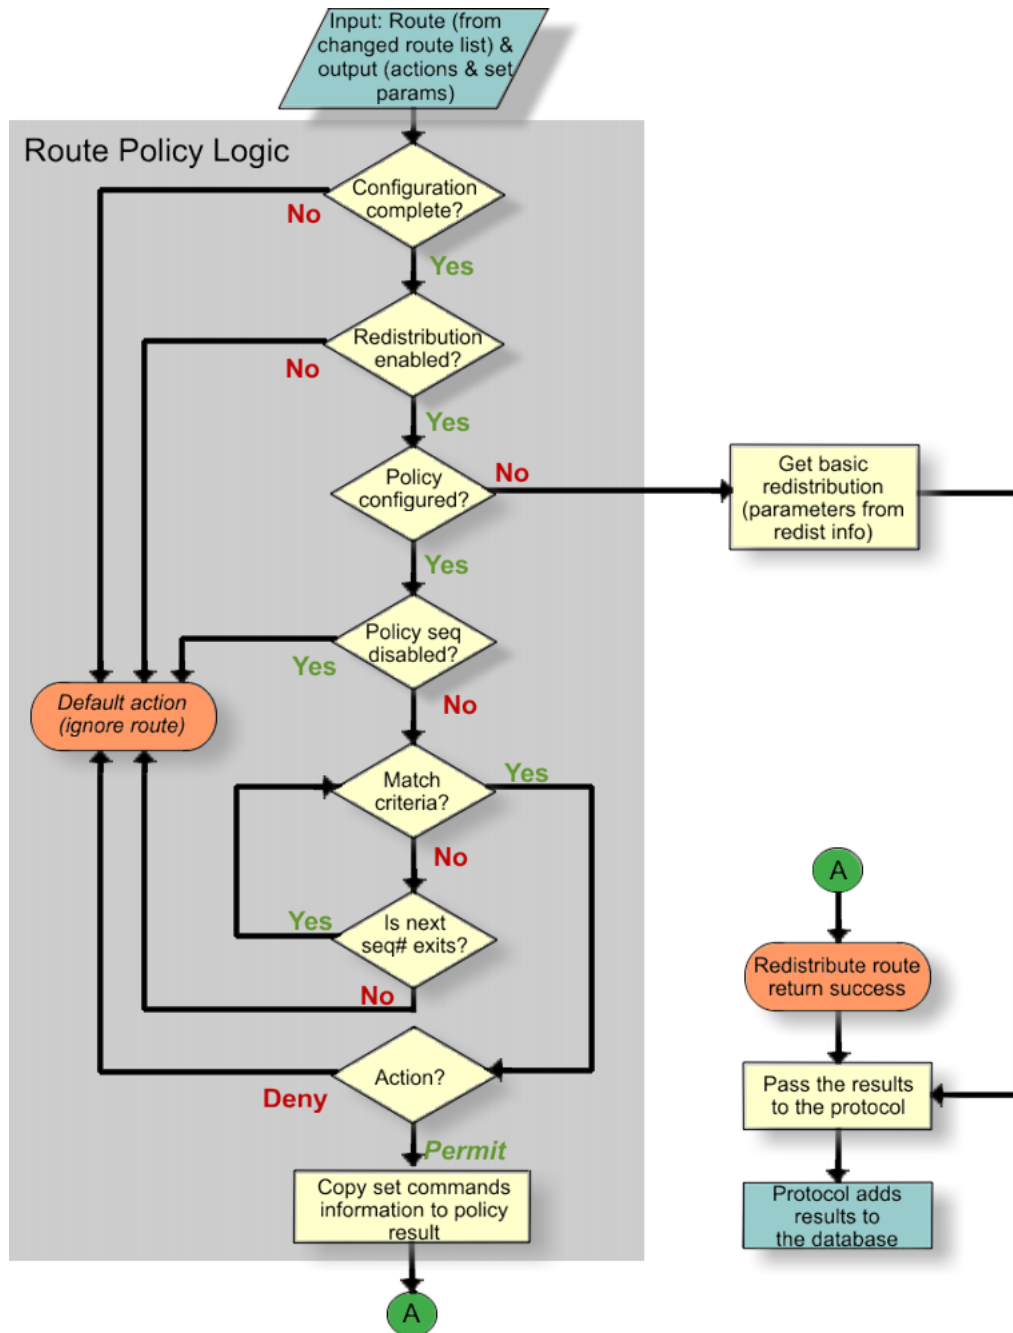

Figure 213: Route filtering logic

Prefix list

In the switch software, you can create one or more IP prefix lists and apply these lists to IP route policy.

Route Policy Definition

You can define an IP route policy and its attributes globally, and then apply them individually to interfaces and protocols. You can also form a unified database of route policies that the RIP or OSPF protocol can use for type of filtering purpose. A name or ID identifies a policy.

Under a policy you can have several sequence numbers. If you do not configure a field in a policy, the system displays the field as 0 in CLI show command output. This value indicates that the device ignores the field in the match criteria. Use the clear option to remove existing configurations for the field.

Each policy sequence number contains a set of fields. Only a subset of those fields is used when the policy is applied in a certain context. For example, if a policy has a configured set-preference field, it is used only when the policy is applied for accept purposes. This field is ignored when the policy is applied for announce or redistribute purposes.

You can only apply one policy for each purpose (RIP Announce, for example) on a given RIP interface. In this case, all sequence numbers under the policy apply to that filter. A sequence number also acts as an implicit preference; a lower sequence number is preferred.

The following tables display the accept, announce, and redistribute policies for RIP, OSPF, IS-IS and BGP. The tables also display which matching criteria apply for a certain routing policy. In these tables, 1 denotes advertise router, 2 denotes RIP gateway, and 3 denotes that external type 1 and external type 2 are the only options.

Note

The route policies treat permit and deny rules differently for inbound and outbound traffic.

- For an in-policy (RIP, BGP) or an accept policy (OSPF) using a route-map, if a particular route is not explicitly denied in the accept policy or in-policy with the route-map, then the route is implicitly allowed.
- For an out-policy (RIP, BGP) or a redistribute policy (RIP, OSPF, BGP) using a route-map, even if a particular route is not explicitly allowed in the redistribution policy or out-policy with the route-map, then the route is implicitly denied.
- In order to permit or deny only explicit routes, configure a policy with additional sequences, where, the last sequence permits all routes that are not explicitly permitted or denied.

Note

IPv4 and IPv6 route-maps cannot be configured on the same match statement.

IP policy configuration using the CLI

Configure IP policies to form a unified database of route policies that Routing Information Protocol (RIP) or Open Shortest Path First (OSPF) can use for filtering tasks.

A policy is identified by a name or an ID. Under a given policy you can have several sequence numbers, each of which is equal to one policy in the old convention. Each policy sequence number contains a set of fields. Only a subset of those fields is used when the policy is applied in a certain context. For example, if a policy has a configured set-preference field, use only when the policy is applied for accept purposes. This field is ignored when the policy is applied for announce and redistribute purposes.

You can apply one policy for one purpose, for example, RIP announce on a RIP interface. All sequence numbers under the given policy apply to that filter. A sequence number also acts as an implicit preference; a lower sequence number is preferred.

Configuring prefix lists

Configure a prefix list to allow or deny specific route updates. A prefix list policy specifies route prefixes to match. After a match occurs, the system uses the route.

The prefix list contains a set of contiguous or noncontiguous routes. Reference prefix lists by name from within a routing policy.

About This Task

Important

When you configure a prefix list for a route policy, add the prefix as a.b.c.d/32. You must enter the full 32-bit mask to exact a full match of a specific IP address.

You configure prefix lists on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure a prefix list:

```
ip prefix-list WORD<1-64> {A.B.C.D/X} [ge <0-32>] [id <1-2147483647>]
[le <0-32>]
```

3. (Optional) Rename an existing prefix list:

```
ip prefix-list WORD<1-64> name WORD<1-64>
```

4. Display the prefix list:

```
show ip prefix-list [prefix {A.B.C.D}] [vrf WORD<1-16>] [vrfids
WORD<0-512>] [WORD <1-64>]
```

Example

Configure a prefix-list. Display the prefix list.

```
Switch> enable
Switch# configure terminal
Switch(config)# ip prefix-list LIST1 192.0.2.1/255.255.255.0
Switch(config)# show ip prefix-list LIST1
```

```
=====
Prefix List - GlobalRouter
```

```

=====
                PREFIX                MASKLEN FROM TO
-----
List 1      LIST1:
           192.0.1.2.1      24      24      24
1 Total Prefix List entries configured
-----
Name Appendix for Lists Converted from Old Config:
@A=conv addr list, @N=conv net list, @NR=conv net list modified as range

```

Variable definitions

The following table defines parameters for the **ip prefix-list** command.

Variable	Value
{A.B.C.D/X}	Specifies the IP address and the mask in one of the following formats: <ul style="list-style-type: none"> a.b.c.d/x a.b.c.d/x.x.x.x default
ge <0-32>	Specifies the minimum length to match. Lower bound and higher bound mask lengths together can define a range of networks.
id <1-2147483647>	Specifies the Prefix list ID.
le <0-32>	Specifies the maximum length to match. Lower bound and higher bound mask lengths together can define a range of networks.
name WORD<1-64>	Renames the specified prefix list. The name length is 1-64 characters.
WORD<1-64>	Specifies the name for a new prefix list.

Use the data in the following table to use the **show ip prefix-list** command.

Variable	Value
{A.B.C.D}	Specifies the prefix to include in the command output.
vrf WORD<1-16>	Specifies the name of the VRF.
vrfids WORD<0-512>	Specifies the ID of the VRF and is an integer in the range of 0-512.
WORD<1-64>	Specifies a prefix list, by name, to use for the command output.

The following table defines parameters for the **show ip prefix-list** command output.

Variable	Value
PREFIX	Indicates the member of a specific prefix list.
MASKLEN	Indicates the prefix mask length in bits.
FROM	Indicates the prefix mask starting point in bits.
TO	Indicates the prefix mask endpoint in bits.

Configure IP Route Policies

Configure a route policy so that the device can control routes that certain packets can take. For example, you can use a route policy to deny certain Border Gateway Protocol (BGP) routes.

The route policy defines the matching criteria and the actions taken if the policy matches.

About This Task

After you create and enable the policy, you can apply it to an interface. You can apply one policy for one purpose, for example, RIP Announce, on a given RIP interface. In this case, all sequence numbers under the given policy apply to that filter.

Create and enable the policy for IS-IS accept policies for Fabric Connect for Layer 3 Virtual Services Networks (VSNs) and IP Shortcuts, then apply the IS-IS accept policy filters.

Note

After you configure route-map in Global Configuration mode or VRF Router Configuration mode, the device enters Route-Map Configuration mode, where you configure the action the policy takes, and define other fields the policy enforces.

Note

The route policies treat permit and deny rules differently for inbound and outbound traffic.

- For an in-policy (RIP, BGP) or an accept policy (OSPF) using a route-map, if a particular route is not explicitly denied in the accept policy or in-policy with the route-map, then the route is implicitly allowed.
- For an out-policy (RIP, BGP) or a redistribute policy (RIP, OSPF, BGP) using a route-map, even if a particular route is not explicitly allowed in the redistribution policy or out-policy with the route-map, then the route is implicitly denied.
- In order to permit or deny only explicit routes, configure a policy with additional sequences, where, the last sequence permits all routes that are not explicitly permitted or denied.

Note

You cannot configure IPv4 and IPv6 route-maps on the same match statement.

Procedure

1. Enter Route-Map Configuration mode:

```
enable
```

```
configure terminal
```

```
route-map WORD<1-64> <1-65535>
```

2. At the route-map prompt, define the match criteria for the policy:

```
match {as-path WORD<0-256> | community WORD<0-256> | community-exact
enable | extcommunity WORD<0-1027> | interface WORD<0-259> | local-
preference <0-2147483647> | metric <0-65535> | metric-type-isis <any|
internal|external> | network WORD<0-259> | next-hop WORD<0-259> |
protocol WORD<0-60> | route-source WORD<0-259> | route-type <any|
local|internal|external|external-1|external-2> | tag WORD<0-256> | vrf
WORD<1-16> | vrfids WORD<0-512> }
```

3. Define the action the policy takes:

- a. Allow the route:

```
permit
```

OR

- b. Ignore the route:

```
no permit
```

4. Define the set criteria for the policy:

```
set {as-path WORD<0-256> | as-path-mode <tag|prepend> | automatic-tag
enable | community WORD<0-256> | community-mode <additive|none|
unchanged> | injectlist WORD<0-1027> | ip-preference <0-255> | local-
preference <0-2147483647> | mask <A.B.C.D> | metric <0-65535> |
metric-type <type1|type2> | metric-type-internal <0-1> | metric-type-
isis <none|internal|external> | metric-type-live-metric | next-hop
WORD<0-256> | nssa-pbit enable | origin <igp|egp|incomplete> | origin-
egp-as <0-65535> | tag WORD<0-256> | weight <0-65535> }
```

5. Display current information about the IP route policy:

```
show route-map [WORD<1-64>] [<1-65535>] [vrf WORD<1-16>] [vrfids
WORD<0-512>]
```

Example

Enter Route-Map Configuration mode. At the route-map prompt, define the fields the policy enforces. Define the action the policy takes. Display current information about the IP route policy.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#route-map RedisStatic 1
Switch:1(route-map)# match metric 0
Switch:1(route-map)# permit
Switch:1(route-map)# show route-map RedisStatic

PRMT DIS

Variable Definitions

Use the data in the following table to use the **match** command.

Variable	Value
<i>as-path</i> WORD<0-256>	Configures the device to match the as-path attribute of the Border Gateway Protocol (BGP) routes against the contents of the specified AS-lists. This field is used only for BGP routes and ignored for all other route types. WORD <0-256> specifies the list IDs of up to four AS-lists, separated by a comma. Use the no operator to disable match as-path: no match as-path WORD<0-256>
<i>community</i> WORD<0-256>	Configures the device to match the community attribute of the BGP routes against the contents of the specified community lists. This field is used only for BGP routes and ignored for all other route types. WORD <0-256> specifies the list IDs of up to four defined community lists, separated by a comma. Use the no operator to disable match community: no match community WORD<0-256>
<i>community-exact</i> enable	When disabled, configures the device so match community-exact results in a match when the community attribute of the BGP routes match an entry of a community-list specified in match-community. When enabled, configures the device so match-community-exact results in a match when the community attribute of the BGP routes matches all of the entries of all the community lists specified in match-community. enable enables match community-exact. Use the no operator to disable match community-exact: no match community-exact enable
<i>extcommunity</i> WORD <0-1027>	Configures the device to match the extended community. WORD<0-1027> specifies an integer value from 1-1027 that represents the community list ID you want to create or modify.
<i>interface</i> WORD <0-259>	If configured, configures the device to match the IP address of the interface by which the RIP route was learned against the contents of the specified prefix list. This field is used only for RIP routes and ignored for all other route types. WORD <0-259> specifies the name of up to four defined prefix lists, separated by a comma. Use the no operator to disable match-interface: no match interface WORD <0-259>
<i>local-preference</i> <0-2147483647>	Configures the device to match the local preference, applicable to all protocols. <0-2147483647> specifies the preference value.

Variable	Value
<code>metric <0-65535></code>	Configures the device to match the metric of the incoming advertisement or existing route against the specified value. If 0, this field is ignored. <code><0-65535></code> specifies the metric value. The default is 0.
<code>network WORD <0-259></code>	Configures the device to match the destination network against the contents of the specified prefix lists. <code>WORD <0-259></code> specifies the name of up to four defined prefix lists, separated by a comma. Use the no operator to disable match network: <code>no match network WORD <0-259></code>
<code>next-hop WORD<0-259></code>	Configures the device to match the next-hop IP address of the route against the contents of the specified prefix list. This field applies only to nonlocal routes. <code>WORD <0-259></code> specifies the name of up to four defined prefix lists, separated by a comma. Use the no operator to disable match next hop: <code>no match next-hop WORD<0-259></code>
<code>protocol WORD<0-60></code>	Configures the device to match the protocol through which the route is learned. <code>WORD <0-60></code> is xxx, where xxx is local, ospf, ebgp, ibgp,isis, rip, static, or a combination separated by . Use the no operator to disable match protocol: <code>no match protocol WORD<0-60></code>
<code>route-source WORD<0-259></code>	Configures the system to match the next-hop IP address for RIP routes and advertising router IDs for OSPF routes against the contents of the specified prefix list. This option is ignored for all other route types. <code>WORD <0-259></code> specifies the name of up to four defined prefix lists, separated by a comma. Use the no operator to disable match route source: <code>no match route-source WORD<0-259></code>
<code>route-type {any local internal external external-1 external-2}</code>	Configures a specific route type to match (applies only to OSPF routes). <code>any local internal external external-1 external-2</code> specifies OSPF routes of the specified type only (External-1 or External-2). Another value is ignored.
<code>tag WORD<0-256></code>	Specifies a list of tags used during the match criteria process. Contains one or more tag values. <code>WORD<0-256></code> is a value from 0-256.
<code>[vrf WORD<1-16>] [vrfs WORD<0-512>]</code>	Configures a specific VRF to match (applies only to RIP routes).

Use the data in the following table to use the **set** command.

Variable	Value
<code>as-path WORD<0-256></code>	Configures the device to add the AS number of the AS-list to the BGP routes that match this policy. <code>WORD<0-256></code> specifies the list ID of up to four defined AS-lists separated by a comma. Use the no operator to delete the AS number: <code>no set as-path WORD<0-256></code>
<code>as-path-mode <tag prepend></code>	Configures the AS path mode. Prepend is the default configuration. The device prepends the AS number of the AS-list specified in <code>set-as-path</code> to the old <code>as-path</code> attribute of the BGP routes that match this policy. Note: Prepend is not applicable to an internal BGP (iBGP) peer with outbound route policy. For more information about iBGP, see BGP on page 345.
<code>automatic-tag enable</code>	Configures the tag automatically. Used for BGP routes only. Use the no operator to disable the tag: <code>no set automatic-tag enable</code>
<code>community WORD<0-256></code>	Configures the device to add the community number of the community list to the BGP routes that match this policy. <code>WORD <0-256></code> specifies the list ID of up to four defined community lists separated by a comma. Use the no operator to delete the community number: <code>no set community WORD<0-256></code>
<code>community-mode <additive none unchanged></code>	Configures the community mode. <code>additive</code> —the device prepends the community number of the community list specified in <code>set-community</code> to the old community path attribute of the BGP routes that match this policy. <code>none</code> —the device removes the community path attribute of the BGP routes that match this policy to the specified value.
<code>injectlist WORD<0-1027></code>	Configures the device to replace the destination network of the route that matches this policy with the contents of the specified prefix list. <code>WORD<0-1027></code> specifies one prefix list by name. Use the no operator to disable <code>set injectlist</code> : <code>no set injectlist</code>
<code>ip-preference <0-255></code>	Configures the preference. This applies to accept policies only. <code><0-255></code> is the range you can assign to the routes.
<code>local-preference <0-65535></code>	Configures the device to match the local preference, applicable to all protocols. <code><0-65535></code> specifies the preference value.

Variable	Value
<code>mask <A.B.C.D></code>	Configures the mask of the route that matches this policy. This applies only to RIP accept policies. <i>A.B.C.D</i> is a valid contiguous IP mask. Use the no operator to disable set mask: <code>no set mask</code>
<code>metric <0-65535></code>	Configures the metric value for the route while announcing a redistribution. The default is 0. If the default is configured, the original cost of the route is advertised into OSPF for RIP, the original cost of the route or default-import-metric is used (applies to IS-IS routes also).
<code>metric-type {type1 type2}</code>	Configures the metric type for the routes to announce into the OSPF domain that matches this policy. The default is type 2. This field is applicable only for OSPF announce policies.
<code>metric-type-internal <0-1></code>	Configures the MED value for routes advertised to ebgp nbrs to the IGP metric value. <code><0-1></code> specifies the metric type internal.
<code>metric-type-isis <none internal external></code>	Configures the metric type for IS-IS routes. The default is none. This field is applicable only for IS_IS policies.
<code>metric-type-live-metric</code>	Configures the metric type for BGP routes. The default is disabled. This field is applicable only for BGP policies.
<code>next-hop WORD <1-256></code>	Specifies the IP address of the next-hop router. Both IPv4 and IPv6 addresses are supported. Use the no operator to disable set next-hop: <code>no set next-hop</code>
<code>nssa-pbit enable</code>	Configures the not so stubby area (NSSA) translation P bit. Applicable to OSPF announce policies only. Use the no operator to disable set nssa-pbit: <code>no set nssa-pbit enable</code>
<code>origin {igp egp incomplete}</code>	Configures the device to change the origin path attribute of the BGP routes that match this policy to the specified value.
<code>origin-egp-as <0-65535></code>	Indicates the remote autonomous system number. Applicable to BGP only.
<code>tag <0-65535></code>	Configures the tag of the destination routing protocol. If not specified, the device forwards the tag value in the source routing protocol. A value of 0 indicates that this parameter is not configured. Note: This parameter is not supported on all hardware platforms.
<code>weight <0-65535></code>	Configures the weight value for the routing table. For BGP, this value overrides the weight configured through NetworkTableEntry, FilterListWeight, or NeighborWeight. Used for BGP only. A value of 0 indicates that this parameter is not configured.

Use the data in the following table to use the **name** command.

Variable	Value
<code>WORD<1-64></code>	Renames a policy and changes the name field for all sequence numbers under the given policy.

Configure a Policy to Accept External Routes from a Router

Perform this procedure to configure a policy to accept external routes from a specified advertising router.

Note

The route policies treat permit and deny rules differently for inbound and outbound traffic.

- For an in-policy (RIP, BGP) or an accept policy (OSPF) using a route-map, if a particular route is not explicitly denied in the accept policy or in-policy with the route-map, then the route is implicitly allowed.
- For an out-policy (RIP, BGP) or a redistribute policy (RIP, OSPF, BGP) using a route-map, even if a particular route is not explicitly allowed in the redistribution policy or out-policy with the route-map, then the route is implicitly denied.
- In order to permit or deny only explicit routes, configure a policy with additional sequences, where, the last sequence permits all routes that are not explicitly permitted or denied.

Procedure

1. Enter OSPF Router Configuration mode:

```
enable

configure terminal

router ospf
```
2. Create a policy to accept external routes from a specified advertising route:

```
accept adv-rtr <A.B.C.D>
```
3. Exit to the Privileged EXEC mode.

```
exit
```
4. Apply the OSPF accept policy change:

```
ip ospf apply accept adv-rtr <A.B.C.D>
```
5. Confirm your configuration:

```
show ip ospf accept
```

Example

Log on to the OSPF Router Configuration mode:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router ospf
```

Create a policy to accept external routes from a specified advertising route:

```
Switch:1(config-ospf)#accept adv-rtr 192.0.2.122
```

Enable an OSPF accept entry for a specified advertising route:

```
Switch:1(config-ospf)#accept adv-rtr 192.0.2.122 enable
```

Exit to the Privileged EXEC mode:

```
Switch:1(config-ospf)#exit
Switch:1(config)#exit
```

Apply the OSPF accept policy change and confirm your configuration:

```
Switch:1#ip ospf apply accept adv-rtr 192.0.2.122
Switch:1#show ip ospf accept
=====
                        Ospf Accept - GlobalRouter
=====
ADV_RTR          MET_TYPE  ENABLE  POLICY
-----
192.0.2.122     -          FALSE
```

Variable definitions

Use the data in the following table to use the **accept adv-rtr** command.

Variable	Value
<A.B.C.D>	Specifies the IP address.
<i>enable</i>	Enables an OSPF accept entry for a specified advertising router. Use the no operator to disable an OSPF accept entry: <code>no accept adv-rtr <A.B.C.D> enable</code>
<i>metric-type {type1 type2 }</i>	Indicates the OSPF external type. This parameter describes which types of OSPF external routes match this entry. <i>type1</i> means match all external routes. <i>type1</i> means match external type 1 only. <i>type2</i> means match external type 2 only. Use the no operator to disable metric-type: <code>no ip ospf accept adv-rtr <A.B.C.D> metric-type</code>
<i>route-map WORD<0-64></i>	Specifies the name of the route policy to use for filtering external routes advertised by the specified advertising router before accepting into the routing table.

Apply OSPF Accept Policy Changes

Apply OSPF accept policy changes to enable the configuration changes in the policy to take effect in an OSPF Accept context (and to prevent the device from attempting to apply the changes one by one after each configuration change).

About This Task

Important

Changing OSPF Accept contexts is a process-oriented operation that can affect system performance and network accessibility while you perform the procedures. If you want to change the default preferences for an OSPF Accept or a prefix-list configuration (as opposed to the default preference), do so before enabling the protocols.

Note

The route policies treat permit and deny rules differently for inbound and outbound traffic.

- For an in-policy (RIP, BGP) or an accept policy (OSPF) using a route-map, if a particular route is not explicitly denied in the accept policy or in-policy with the route-map, then the route is implicitly allowed.
- For an out-policy (RIP, BGP) or a redistribute policy (RIP, OSPF, BGP) using a route-map, even if a particular route is not explicitly allowed in the redistribution policy or out-policy with the route-map, then the route is implicitly denied.
- In order to permit or deny only explicit routes, configure a policy with additional sequences, where, the last sequence permits all routes that are not explicitly permitted or denied.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Apply an OSPF accept policy change:
ip ospf apply accept [vrf WORD<1-16>]
3. Display information about the configured OSPF entries:
show ip ospf accept [vrf WORD<1-16>] [vrfids WORD<0-512>]

Example

Apply the OSPF accept policy and confirm the configuration:

```
Switch:1>enable
Switch:1#ip ospf apply accept
Switch:1#show ip ospf accept
=====
                        Ospf Accept - GlobalRouter
=====
ADV_RTR      MET_TYPE ENABLE POLICY
-----
192.0.2.11   type1    true  test1
```

Variable Definitions

Use the data in the following table to use the `ip ospf apply accept adv-rtr` command.

Variable	Value
<code>adv-rtr</code>	Commits entered changes. Issue this command after you modify a policy configuration that affects an OSPF accept policy.
<code>vrf WORD<1-16></code>	Specifies the name of the VRF.

Configure Inter-VRF Redistribution Policies

Configure redistribution entries to allow a protocol to announce routes of a certain source type, for example, static, RIP, or direct.

Before You Begin

- Ensure the routing protocols are globally enabled.
- You must configure the route policy, if required.
- Ensure the VRFs exist.
- You must create the route policy and prefix list under the source VRF context.

Note

The route policies treat permit and deny rules differently for inbound and outbound traffic.

- For an in-policy (RIP, BGP) or an accept policy (OSPF) using a route-map, if a particular route is not explicitly denied in the accept policy or in-policy with the route-map, then the route is implicitly allowed.
- For an out-policy (RIP, BGP) or a redistribute policy (RIP, OSPF, BGP) using a route-map, even if a particular route is not explicitly allowed in the redistribution policy or out-policy with the route-map, then the route is implicitly denied.
- In order to permit or deny only explicit routes, configure a policy with additional sequences, where, the last sequence permits all routes that are not explicitly permitted or denied.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
router vrf WORD<1-16>
```

2. Create the redistribution instance:

```
ip <bgp|ospf|rip> redistribute <bgp|direct|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|ospfv3|rip|static|dvr>
```

3. Apply a route policy if required:

```
ip <bgp|ospf|rip> redistribute <bgp|direct|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|ospfv3|rip|static|dvr> route-map <WORD 0-64> [vrf-src <WORD 1-16>]
```

4. Use the following variable definitions table to configure other parameters as required.

5. Enable the redistribution:

```
ip <bgp|ospf|rip> redistribute <bgp|direct|ipv6-direct|ipv6-isis|ipv6-
static|isis|ospf|ospfv3|rip|static|dvr> enable [vrf-src <WORD 1-16>]
```

6. Ensure that the configuration is correct:

```
show ip <bgp|ospf|rip> redistribute [vrf WORD<1-16>] [vrfids
WORD<0-512>]
```

For RIPng, use `show ipv6 rip redistribute`.

7. Apply the redistribution:

```
ip <bgp|ospf|rip> apply redistribute <bgp|direct|ipv6-direct|ipv6-
isis|ipv6-static|isis|ospf|ospfv3|rip|static|dvr> [vrf WORD<1-16>]
[vrf-src WORD<1-16>]
```

Example

```
Switch:1>enable
Switch:1#config terminal
```

Log on to the VRF Router Configuration mode:

```
Switch:1(config)#router vrf test
```

Create the redistribution instance:

```
Switch:1(router-vrf)#ip rip redistribute ospf
```

Enable the redistribution

```
Switch:1(router-vrf)#ip rip redistribute ospf enable
```

Ensure that the configuration is correct:

```
Switch:1(router-vrf)#show ip rip redistribute
```

Exit to Global Configuration mode:

```
Switch:1(router-vrf)#exit
```

Apply the redistribution:

```
Switch:1(config)#ip rip apply redistribute ospf
```

Variable definitions

Use the data in the following table to use the redistribution commands.

Variable	Value
<code><bgp direct isis ospf rip static dvr></code>	Specifies the type of routes to redistribute—the protocol source.
<code>vrf WORD<1-16></code>	Specifies the VRF instance.
<code>vrfids WORD<0-512></code>	Specifies a list of VRF IDs.
<code>vrf-src WORD<1-16></code>	Specifies the source VRF instance. This parameter is not required for redistribution within the same VRF.

Use the data in the following table to use the `ip <bgp|ospf|rip> redistribute <bgp|direct|isis|ospf|rip|static|dvr>` command.

Variable	Value
<code>apply [vrf-src WORD<1-16>]</code>	Applies the redistribution configuration.
<code>enable [vrf-src WORD<1-16>]</code>	Enables the OSPF route redistribution instance.
<code>metric <metric-value> [vrf-src WORD<1-16>]</code>	Configures the metric to apply to redistributed routes.
<code>metric-type <type1 type2> [vrf-src WORD<1-16>]</code>	Specifies a type 1 or a type 2 metric. For metric type 1, the cost of the external routes is equal to the sum of all internal costs and the external cost. For metric type 2, the cost of the external routes is equal to the external cost alone.
<code>route-map <WORD 0-64> [vrf-src WORD<1-16>]</code>	Configures the route policy to apply to redistributed routes.
<code>subnets <allow suppress> [vrf-src WORD<1-16>]</code>	Allows or suppresses external subnet route advertisements when routes are redistributed into an OSPF domain.

IP Policy Configuration using Enterprise Device Manager

You can form a unified database of route policies that the protocols (RIP, OSPF or Border Gateway Protocol [BGP]) can use for any type of filtering task.

For information about configuring a prefix list, see [Configuring a prefix list](#) on page 2515. For more information about community list, see [Configure a Community Access List](#) on page 447. For more information about AS path list, see [Configure an AS Path List](#) on page 447.

A name or an ID identifies a policy. Under a policy you can have several sequence numbers, each of which is equal to one policy in the old convention. If a field in a policy is not configured, the system displays it as 0 or any when the system displays it in Enterprise Device Manager (EDM). This means that the field is ignored in the match criteria. You can use the clear option to remove existing configurations for any field.

Each policy sequence number contains a set of fields. Only a subset of those fields is used when the policy is applied in a certain context. For example, if a policy has a set-preference field set, it is used only when the policy is applied for accept purposes. This field is ignored when the policy is applied for announce and redistribute purposes.

You can apply only one policy for one purpose (for example, RIP Announce on a given RIP interface). In that example, all sequence numbers under the given policy are applicable for that filter. A sequence number also acts as an implicit preference: a lower sequence number is preferred.

Configuring a prefix list

Configure a prefix list to allow or deny specific route updates. A prefix list policy specifies route prefixes to match. After a match occurs, the system uses the route.

The prefix list contains a set of contiguous or non-contiguous routes. Reference prefix lists by name from within a routing policy.

Before You Begin

- Change the VRF instance as required to configure a prefix list on a specific VRF instance.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **Policy**.
3. Click the **Prefix List** tab.
4. Click **Insert**.
5. In the **Id** box, type an ID for the prefix list.
6. In the **Prefix** box, type an IP address for the route.
7. In the **PrefixMaskLength** box, type the length of the prefix mask.
8. Configure the remaining parameters as required.
9. Click **Insert**.

Prefix List field descriptions

Use the data in the following table to use the **Prefix List** tab.

Name	Description
Id	Configures the list identifier.
Prefix	Configures the IP address of the route.
PrefixMaskLen	Configures the specified length of the prefix mask. You must enter the full 32-bit mask to exact a full match of a specific IP address, for example, if you create a policy to match on the next hop.
Name	Names a specified prefix list during the creation process or renames the specified prefix list. The name length can use from 1 to 64 characters.
MaskLenFrom	Configures the lower bound of the mask length. The default is the mask length. Lower bound and higher bound mask lengths together can define a range of networks.
MaskLenUpto	Configures the higher bound mask length. The default is the mask length. Lower bound and higher bound mask lengths together can define a range of networks.

Configure a Route Policy

Configure a route policy so that all protocols use them for In, Out, and Redistribute purposes.

Procedure

1. In the navigation pane, expand: **Configuration > IP**.
2. Select **Policy**.
3. Select the **Route Policy** tab.
4. Select **Insert**.

5. Enter the appropriate information for your configuration in the Insert Route Policy dialog box.
6. Select **Insert**.

Route Policy Field Descriptions

Use the data in the following table to use the **Route Policy** tab.

Name	Description
Id	Specifies the ID of an entry in the Prefix list table.
SequenceNumber	Specifies a policy within a route policy group.
Name	Specifies the name of the policy. This command changes the name field for all sequence numbers under the given policy.
Enable	Indicates whether this policy sequence number is enabled or disabled. If disabled, the policy sequence number is ignored. The default is disabled.
Mode	Specifies the action to take when a policy is selected for a specific route. Select permit (allow the route) or deny (ignore the route). The default is permit.
MatchProtocol	Selects the appropriate protocol. If configured, matches the protocol through which the route is learned. This field is used only for RIP Announce purposes. The default is to enable all match protocols.
MatchNetwork	Specifies if the system matches the destination network against the contents of the specified prefix list.
MatchIpRouteSource	Specifies if the system matches the next-hop IP address for RIP routes and advertising router IDs for OSPF routes against the contents of the specified prefix list. This option is ignored for all other route types. Select the ellipsis and choose from the list in the Match Route Source dialog box. You can select up to four entries. To clear an entry, use the ALT key. You can also change this field in the Route Policy tab of the Policy dialog box.
MatchIpRouteDest	Specifies if the system matches the next-hop IP address for RIP routes and advertising router IDs for OSPF routes against the contents of the specified prefix list. This option is ignored for all other route types.
MatchNextHop	Specifies if the system matches the next-hop IP address of the route against the contents of the specified prefix list. This field applies only to nonlocal routes. Select the ellipsis and choose from the list in the Match Next Hop dialog box. You can select up to four entries. To clear an entry, use the ALT key.
MatchInterface	Specifies if the system matches the IP address of the interface by which the RIP route was learned against the contents of the specified prefix list. This field is used only for RIP routes and ignored for all other type of route. Select the ellipsis and choose from the list in the Match Interface dialog box. You can select up to four entries. To clear an entry, use the ALT key.

Name	Description
MatchRouteType	Configures a specific route type to match (applies only to OSPF routes). Externaltypel and Externaltypel2 specify the OSPF routes of the specified type only. OSPF internal refers to intra- and inter-area routes. The default is any.
MatchMetric	Specifies if the system matches the metric of the incoming advertisement or existing route against the specified value (1 to 65535). If 0, this field is ignored. The default is 0.
MatchMetricTypelisis	Specifies the match metric type field in the incoming ISIS routes in accept policy.
MatchAsPath	Configures if the system matches the BGP autonomus system path. Applicable to BGP only. This overrides the BGP neighbor filter list information.
MatchCommunity	Filters incoming and outgoing updates based on a Community List. Applicable to BGP only. The default is disable.
MatchCommunityExact	Indicates if the match must be exact (that is, all of the communities specified in the path must match). Applicable to BGP only. The default is disabled.
MatchTag	Specifies a list of tags used during the match criteria process. Applicable to BGP only. It contains one or more tag values.
MatchVrf	Identifies the source VRFs that leaks routes to the local VRF (applies only to RIP routes).
MatchLocalPref	Specifies the local preference value to be matched.
NssaPbit	Configures or resets the P bit in specified type 7 link state advertisements (LSA). By default, the Pbit is always configured in case the user configures the Pbit to a disable state for a particular route policy other than all type 7. LSAs associated with that route policy have the Pbit cleared. With this intact, not so stubby area (NSSA) area border router (ABR) does not perform translation of these LSAs to type 5. The default is enable.
SetRoutePreference	Configures a value from 0 to 255. The default value is 0. If the default is configured, the global preference value is used. When configured to a value greater than zero, specifies the route preference value assigned to the routes that matches the policy. This feature applies to accept policies only.
SetMetricTypeInternal	Identifies the MED value for routes advertised to BGP numbers to the Interior Gateway Protocol (IGP) metric value. The value must be 0 or 1. The default is 0.
SetMetricTypelisis	Sets the metric type IS-IS.
SetMetric	Configures the system to use the metric value for the route while announcing or redistributing. The default-import-metric is 0. If the default is configured, the original cost of the route is advertised into OSPF; for RIP, the original cost of the route or the default value is used (applies to IS-IS routes also). The default is 0.

Name	Description
SetMetricType	Configures the metric type for the routes to announce into the OSPF routing protocol that matches this policy. Applicable to OSPF protocol only. The default is type 2. This field is applicable only for OSPF announce policies. The default is type2.
SetNextHop	Configures the IP address of the next-hop router. Applicable to BGP only. The default is 0.0.0.0.
SetInjectNetList	Configures the destination network of the route that matches this policy with the contents of the specified prefix list. Select the ellipsis and choose from the list in the Set Inject NetList dialog box.
SetMask	Configures the mask of the route that matches this policy. This applies only to RIP accept policies.
SetAsPath	Indicates the AS path value to use whether the SetAsPathMode field is Tag or Prepend. Applicable to BGP only. Note: Prepend is not applicable to an internal BGP (iBGP) peer with outbound route policy.
SetAsPathMode	Configures if the system converts the tag of a route into an AS path. Applicable to BGP protocol only. The mode is either Tag or Prepend tag. The value is applicable only while redistributing routes to BGP. The default is prepend. Note: Prepend is not applicable to an iBGP peer with outbound route policy.
SetAutomaticTag	Enables the automatic tag feature. Applicable to BGP protocol only. The default is disable.
SetCommunityNumber	Configures the community number for BGP advertisements. This value can be a number (1 to 42949672000) or no-export or no-advertise.
SetCommunityMode	Configures the community mode for the BGP protocol. This value can be either append, none, or unchanged. The default is unchanged. <ul style="list-style-type: none"> • Unchanged—keeps the community attribute in the route path as it is. • None—removes the community in the route path additive. • Append—adds the community number specified in SetCommunityNumber to the community list attribute.
SetExtCommunity	Configures a BGP community. The values are 0 to 256.

Name	Description
SetExtCommunityMode	Configures the extended-community mode. The value can be append, unchanged, or overwrite. The default value is unchanged. <ul style="list-style-type: none"> append — creates another community string. unchanged — keeps the community attribute as it is. overwrite — changes the current value.
SetOrigin	Configures the origin for the BGP protocol to IGP, EGP, incomplete, or unchanged. If not configured, the system uses the route origin from the IP routing table (protocol). The default is unchanged.
SetLocalPref	Configures the local preference for the BGP protocol only. The system uses this value during the route decision process for the BGP protocol. The default is 0.
SetOriginEgpAs	Indicates the remote autonomous system number for the BGP protocol. The default is 0.
SetWeight	Configures the weight value for the routing table for the BGP protocol. This field must be used with the match as-path condition. For BGP, this value overrides the weight configured through the NetworkTableEntry, FilterListWeight, or NeighborWeight. The default is 0.
SetTag	Configures the list of tags used during the match criteria process for the BGP protocol. The default is 0.
Ipv6SetNextHop	Specifies the address of the IPv6 next hop router.

Apply a Route Policy

Apply route policies to define route behavior.

About This Task

Important

Changing route policies or prefix lists that affect OSPF accept or redistribute is a process-oriented operation that can affect system performance and network reachability while you perform the procedures. Therefore, if you want to change a prefix list or a routing protocol, you configure all route policies and prefix lists before enabling the protocols.

Procedure

1. In the navigation pane, expand: **Configuration > IP**.
2. Select **Policy**
3. Select the **Applying Policy** tab.
4. Select the type of policy to apply.
5. Select **Apply**.

Applying Policy Field Descriptions

Use the data in the following table to use the **Applying Policy** tab.

Name	Description
RoutePolicyApply	Specifies that configuration changes in the policy take effect in an OSPF route policy context. This prevents the system from attempting to apply the changes one by one after each configuration change. The default is enabled.
RedistributeApply	Specifies that configuration changes in the policy take effect for an OSPF Redistribute context. This prevents the system from attempting to apply the changes one-by-one after each configuration change. The default is enabled.
OspfInFilterApply	Specifies that configuration changes in a route policy or a prefix list take effect in an OSPF Accept context. This prevents the system from attempting to apply the changes one by one after each configuration change. The default is enabled. Note: This field does not apply on all hardware platforms. If you do not see this command in EDM, the feature is not supported on your hardware.

Configure an OSPF Accept Policy

Perform the following procedure to create or configure an OSPF accept policy.

Procedure

1. In the navigation pane, expand: **Configuration > IP**.
2. Select **Policy**.
3. Select the **OSPF Accept** tab.
4. Select **Insert**.
5. Configure the parameters as required.
6. Select **Insert**.

OSPF Accept field descriptions

Use the data in the following table to use the **OSPF Accept** tab.

Name	Description
AdvertisingRtr	Specifies the routing ID of the advertising router.
Enable	Enables or disables the advertising router. You can also enable or disable advertising in the OSPF Accept tab of the Policy dialog box by clicking in the field and selecting enable or disable from the menu. The default is disable.

Name	Description
MetricType	<p>Specifies the OSPF external type. This parameter describes which types of OSPF ASE routes match this entry.</p> <ul style="list-style-type: none"> Any means match either ASE type 1 or 2 Type1 means match any external type 1 Type2 means match any external type 2 <p>You can also select your entry in the OSPF Accept tab of the Policy dialog box by clicking in the field and selecting any, type1, or type2 from the menu. The default is any.</p>
PolicyName	<p>Specifies the name of the OSPF in filter policy. Click the ellipsis button and choose from the list in the Policy Name dialog box. To clear an entry, use the ALT key.</p>

Configuring inbound/outbound filtering policies on a RIP interface

About This Task

Configure inbound filtering on a RIP interface to determine whether to learn a route on a specified interface and to specify the parameters of the route when it is added to the routing table. Configure outbound filtering on a RIP interface to determine whether to advertise a route from the routing table on a specified interface and to specify the parameters of the advertisement.

The port on which the multimedia filter is enabled becomes a DIFFSERV access port.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **Policy**.
3. Click the **RIP In/Out Policy** tab.
4. In the desired row, double-click the **InPolicy** or **OutPolicy** column.
5. Select a preconfigured In/Out policy and click **OK**.

RIP In/Out Policy field descriptions

Use the data in the following table to use the **RIP In/Out Policy** tab.

Name	Description
Address	Specifies the IP address of the RIP interface.
Interface	Specifies the internal index of the RIP interface.
InPolicy	Specifies the policy name used for inbound filtering on this RIP interface. This policy determines whether to learn a route on this interface and specifies the parameters of the route when it is added to the routing table.
OutPolicy	Specifies the policy name used for outbound filtering on this RIP interface. This policy determines whether to advertise a route from the routing table on this interface and specifies the parameters of the advertisement.

Deleting inbound/outbound filtering policies on a RIP interface

About This Task

Delete a RIP In/Out policy when you no longer want to learn a route on a specified interface or advertise a route from the routing table on a specified interface.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **Policy**.
3. Click the **RIP In/Out Policy** tab.
4. In the desired row, double-click the **InPolicy** or **OutPolicy** column for the policy you want to delete.
5. In the **InPolicy** or **OutPolicy** dialog box, press **CTRL** and then, click the policy you want to delete.
6. Click **OK**.
The policy is deleted and you are returned to the RIP In/Out Policy tab.
7. Click **Apply**.

Table 189: RSMLT for IPv4 product support

Feature	Product	Release introduced
IPv4 RSMLT	5320 Series	Not Supported
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5

Table 190: RSMLT for IPv6 product support

Feature	Product	Release introduced
IPv6 RSMLT	5320 Series	Not Supported
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5

RSMLT

In many cases, core network convergence time depends on the length of time a routing protocol requires to successfully converge. Depending on the specific routing protocol, this convergence time can cause network interruptions that range from seconds to minutes.

Routed Split MultiLink Trunking (RSMLT) permits rapid failover for core topologies by providing an active-active router concept to core SMLT networks.

RSMLT scenarios include SMLT triangles, squares, and SMLT full-mesh topologies, with routing enabled on the core VLANs.

Routing protocols include the following:

- IP Unicast Static Routes
- RIP1
- RIP2

- OSPF
- BGP

In the event of core router failures, RSMLT manages packet forwarding, thus eliminating dropped packets during the routing protocol convergence.

IPv6 RSMLT

Routed Split Multi-Link Trunking (RSMLT) is an enhancement to SMLT that enables the exchange of Layer 3 information between peer nodes in a switch cluster. RSMLT provides two main advantages over SMLT:

- provides backup for the peer after the peer goes down
- routes traffic on behalf of the peer to prevent Virtual Inter-Switch Trunk (vIST) overload

IPv6 RSMLT enables the subsecond failover for IPv6 forwarding.

The overall model for IPv6 RSMLT is essentially identical to that of IPv4 RSMLT. In short, RSMLT peers exchange their IPv6 configuration and track their states by using vIST messages. An RSMLT node always performs IPv6 forwarding on the IPv6 packets destined to the MAC addresses of the peer. If an RSMLT node detects that the RSMLT peer is down, the node forwards IPv6 traffic destined to the IPv6 addresses of the peer.

With RSMLT enabled, an SMLT switch performs IP forwarding on behalf of the SMLT peer, which prevents IP traffic from being sent over the vIST.

IPv6 RSMLT supports the full set of topologies and features supported by IPv4 RSMLT, including SMLT triangles, squares, and SMLT full-mesh topologies, with routing enabled on the core VLANs.

Because you configure RSMLT on a VLAN, not at the IP layer, the configuration applies to both IPv4 and IPv6. You cannot enable or disable RSMLT on a VLAN for IPv6 but not IPv4; or for IPv4 but not IPv6.

With IPv6, you must configure the RSMLT peers to use the same set of IPv6 prefixes.

Supported routing protocols include the following:

- IPv6 static routes
- OSPFv3

Note

IPv6 RSMLT is not virtualized, therefore it is not possible to enable IPv6 and RSMLT together on a VLAN which is associated with a VRF.

The system will display the configuration errors if you attempt to perform the following:

- Create an IPv6 interface on a VLAN which is associated with a VRF and RSMLT is enabled on the VLAN.
- Enable RSMLT on an IPv6 enabled VLAN which is associated with a VRF.

IPv6 differences

The following list identifies ways in which the IPv6 implementation of RSMLT differs from the IPv4 implementation of RSMLT.

- After the switch begins to forward traffic on behalf of the peer, duplicate address detection (DAD) is not executed for the IPv6 address of the peer. The implementation assumes that the peer IPv6 address is already known to be unique.
- An RSMLT switch installs a neighbor entry for the peer IPv6 address immediately after the peer disappearance is detected, possibly while a route for the peer still exists. This action can result in packets destined to the peer IPv6 address being delivered to the CP for a short period of time.
- You cannot configure a vIST with IPv6 peer address
- In a dual-stack VLAN, adding or deleting IPv4 or IPv6 does not affect the RSMLT functionality of one another. If you add IPv4 or IPv6 to an existing IPv6 or IPv4 RSMLT VLAN, the RSMLT state for the protocol you add second will be the same as the previous RSMLT state.

SMLT and RSMLT Operation in Layer 3 Environments

Figure 214 on page 2527 shows a typical redundant network example with user aggregation, core, and server access layers. To minimize the creation of many IP subnets, one VLAN (VLAN 1, IP subnet A) spans all wiring closets.

SMLT provides the loop-free topology and forwards all links for VLAN 1, IP subnet A.

The aggregation layer switches are configured with routing enabled and provide active-active default gateway functionality through RSMLT.

After you enable RSMLT on a VLAN (on both aggregation devices), the cluster devices simply inform each other (over vIST messaging) of their physical IP and MAC on that VLAN. Thereafter, the two cluster devices take mutual ownership of their IP addresses on that VLAN. This action means each cluster device routes IP traffic that is directed to the physical MAC of the IP or the physical MAC of the peer IP on that VLAN, and when one of them is down the other cluster device:

- Replies to ARP requests for both the IP and the peer IP on that VLAN
- Replies to pings to the IP and the peer IP on that VLAN

In this case, routers R1 and R2 forward traffic for IP subnet A. RSMLT provides both router failover and link failover. For example, if the Split MultiLink Trunk link between R2 and R4 is broken, the traffic fails over to R1 as well.

For IP subnet A, VRRP with a backup master can provide the same functionality as RSMLT, as long as no additional router is connected to IP subnet A.

RSMLT provides superior router redundancy in core networks (IP subnet B), where OSPF is used for the routing protocol. Routers R1 and R2 provide router backup for each other, not only for the edge IP subnet A, but also for the core IP subnet B. Similarly routers R3 and R4 provide router redundancy for IP subnet C and also for core IP subnet B.

Router R1 Failure

The following figure shows SMLT and RSMLT in Layer 3 environments.

Figure 214: SMLT and RSMLT in Layer 3 environments

R3 and R4 both use R1 as their next hop to reach IP subnet A. Even though R4 sends the packets to R2, they are routed directly at R2 into subnet A. R3 sends its packets to R1 and they are also sent directly into subnet A. After R1 fails, all packets are directed to R2, with SMLT. R2 still routes for R2 and R1. After OSPF convergence, the routing tables in R3 and R4 change their next hop to R2 to reach IP subnet A. You can configure the hold-up timer (that is, for the amount of time R2 routes for R1 in a failure) for a time period greater than the routing protocol convergence, you can configure it as indefinite (that is, the members of the pair always route for each other).

Use an indefinite hold-up timer value for applications that use RSMLT at the edge instead of VRRP.

Router R1 Recovery

When R1 restarts after a failure, it does not route traffic for R2, nor does it provide backup for R2, until the hold-down timer expires. Similar to VRRP, the hold-down timer value must be greater than the time the routing protocol requires to converge its tables.

During the hold-down interval, R1 routes traffic if the destination MAC of the packet is its own routable VLAN MAC. R1 bridges incoming traffic to R2 if the destination MAC of the packet is the routable VLAN MAC of R2. A temporary default route (one having a route preference equal to 4) that points to R2 is installed on R1. R1 uses this temporary route to forward traffic to R2 that it cannot route itself because of the incomplete routing table; the default route is not saved in the configuration file.

After the hold-down timer expires, the temporary default route that points to R2 is deleted; from this moment on, in addition to routing packets destined to itself, R1 starts routing packets for R2, as well.

RSMLT Network Design and Configuration

Because RSMLT is based on SMLT, all SMLT configuration rules apply. In addition, RSMLT is enabled on the SMLT aggregation switches for each VLAN. The VLAN must be a member of SMLT links and vIST's L2VSN. For more information about how to configure SMLT in a Layer 2 environment, see [MultiLink Trunking and Split MultiLink Trunking](#) on page 1988.

The VLAN also must be routable (IP address configured) and you must configure an Interior Gateway Protocol (IGP) such as OSPF on all four routers, although it is independent of RSMLT. All routing protocols, even static routes, work with RSMLT.

The RSMLT pair switches provide backup for each other. As long as one of the two routers of an vIST pair is active, traffic forwarding is available for both next hops R1/R2 and R3/R4.

RSMLT Edge Support

The switch stores the peer MAC and IP address pair in its local configuration file and restores the configuration if the peer does not restore after a simultaneous restart of both RSMLT-peer switches.

The RSMLT edge support feature adds an enhancement whereby the peer MAC (for the IP on the VLAN) is committed to the config.cfg file after you use the **save config** command. If you power off both devices, and then power up only one of them, that single device can still take ownership of its peer IP on that VLAN even if it has not seen that peer switch since it started. This enhancement is necessary if you configure the peer (the device which is still down) IP as the default gateway in end stations.

If you enable RSMLT edge support, you must also ensure that the hold-up timer for RSMLT on those edge VLANs equals infinity (9999). This timer value ensures that if one cluster device fails, the remaining cluster device maintains ownership of the failed peer IP indefinitely.

The edge VLAN can be tagged over SMLT links, single attached links, or more SMLT links.

Important

If you clear the peer information the device can stop forwarding for the peer.

RSMLT implementation does not use a virtual IP address but instead uses physical IP addresses for redundancy. At the same time, you can deploy RSMLT in either routed configurations, or edge

configurations, where you previously used VRRP (and back-up master). Previously, if a power outage occurred or a shutdown of both switches within a dual core vIST pair, only one device came back up. Clients using the powered-off device IP/MAC as the default gateway lost connectivity to the network. In such a scenario, even with RSMLT enabled on the device, it cannot act as a backup for the peer as it was unaware of the peer IP or MAC address.

After both the dual core vIST switches come back, the vIST is operational. If an RSMLT peer-enabled message is received from the peer, normal RSMLT operation occurs.

If the peer has either an IP or MAC change, you must save the configuration for the RSMLT edge support to operate correctly. However, if the vIST peer up message is not received (for example, if you do not enable RSMLT properly), and you enable the RSMLT edge support flag, the RSMLT hold-down timer starts and permits routing protocols to converge; during this time user operation can be affected. After the hold-down timer expires, saved peer information is picked up and the device starts to act as backup for the peer by adding the previously saved MAC and ARP records.

The hold-up timer starts and after this timer expires the previously added MAC and ARP records are deleted and the device stops acting as backup for the peer, as the peer is not running proper RSMLT for the VLAN. The RSMLT is a parameter for each VLAN, and therefore all affects are on an individual VLAN basis, not necessarily a global device. Edge support mode uses the local values of the hold-down timer (default value of 60 seconds) and hold-up timer (default value of 180 seconds).

RSMLT Configuration using CLI

Use the procedures in this section to configure RSMLT using CLI.

Configure RSMLT on a VLAN

Configure RSMLT on a VLAN to exchange Layer 3 information between peer nodes in a switch cluster. This configuration applies to both IPv4 and IPv6.

Before You Begin

- An IP routing protocol is enabled on VLAN Layer 3 interfaces.
- VLANs with Layer 3 interfaces participate in Split MultiLink Trunking (SMLT).

About This Task

The VLAN can be either IPv4 or IPv6, or both. RSMLT configuration on a VLAN simultaneously affects both IPv4 and IPv6. By default, RSMLT is disabled on a VLAN.

Procedure

1. Enter VLAN Interface Configuration mode:

```
enable  
  
configure terminal  
  
interface vlan <1-4059>
```
2. Configure the holddown timer:

```
ip rsmlt holddown-timer <0-3600>
```

3. Configure the holdup timer:

```
ip rsmlt holdup-timer <0-9999>
```
4. Enable RSMLT on the VLAN:

```
ip rsmlt
```

Example

Configure and enable RSMLT on a VLAN:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 100
Switch:1(config-if)#ip rsmlt holddown-timer 100
Switch:1(config-if)#ip rsmlt holdup-timer 200
Switch:1(config-if)#ip rsmlt
```

Variable Definitions

The following table defines parameters for the **ip rsmlt** command.

Variable	Value
<i>holddown-timer</i> <0-3600>	Defines how long the recovering or restarting system remains in a non-Layer 3 forwarding mode for the peer router MAC address. The default is 60. Configure this value to be longer than the anticipated routing protocol convergence. If you disable RSMLT on a VLAN, non default values for this variable do not save across restarts.
<i>holdup-timer</i> <0-3600 9999>	Defines how long the RSMLT system maintains forwarding for its peer. The value is a range from 0 to 3600 seconds or 9999. 9999 means infinity. The default is 1800. If you disable RSMLT on a VLAN, non default values for this variable do not save across restarts.

The following table defines parameters for the **interface** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.

Enable RSMLT Edge Support

Enable RSMLT Edge support to store the RSMLT peer MAC and IP address-pair in the local configuration file and restore the configuration if the peer does not restore after a simultaneous restart of both RSMLT peer systems.

If enabled, peer MAC and IP information for all RSMLT-enabled VLANs is saved after you next use the **save config** command.

About This Task

RSMLT Edge support configuration applies to both IPv4 and IPv6. You do not configure IPv4 and IPv6 separately.

The RSMLT Edge support default is disabled.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable RSMLT Edge support:

```
ip rsmlt edge-support
```

Example

If you have enabled RSMLT Edge Support, disable the feature as follows:

```
Switch:1(config)#no ip rsmlt edge-support
```

View RSMLT Information

Show RSMLT information to view data about all RSMLT interfaces. The output of the command includes IPv6 information for the local and peer nodes.

About This Task

If you use the **show ip rsmlt** command after you delete an RSMLT, the RSMLT still shows in the command output until you restart the switch.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Show RSMLT information about the interface:

```
show ip rsmlt [local|peer] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```
3. View the status of the switch to act as a peer forwarder:

```
show ip rsmlt edge-support
```

Examples

```
Switch:1>show ip rsmlt
```

```

RSMLT Peer Info:
      rsmlt-peer-forwarding : disable

```

Variable definitions

Use the data in the following table to use the **show ip rsmlt** command.

Variable	Value
<i>local</i>	Shows local RSMLT information.
<i>peer</i>	Shows RSMLT information for the peer.
<i>vrf WORD<1-16></i>	Shows information for a specific VRF name.
<i>vrfids WORD<0-512></i>	Shows information for a specific VRF ID.

RSMLT Configuration using EDM

Use the procedures in this section to configure RSMLT using EDM.

Configuring RSMLT on a VLAN

Configure RSMLT on a VLAN to exchange Layer 3 information between peer nodes in a switch cluster. This configuration applies to both IPv4 and IPv6.

Before You Begin

- Enable an IP routing protocol on VLAN Layer 3 interfaces.
- Ensure VLANs with Layer 3 interfaces participate in Split MultiLink Trunking (SMLT).

About This Task

The VLAN can be either IPv4 or IPv6, or both. RSMLT configuration on a VLAN simultaneously affects both IPv4 and IPv6.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select a VLAN.
5. Click **IP**.
6. Click the **RSMLT** tab.
7. Select **Enable**.
8. In the **HoldDownTimer** field, type a hold-down timer value.
9. In the **HoldUpTimer** field, type a holdup timer value.
10. Click **Apply**.

RSMLT Field Descriptions

Use the data in the following table to use the **RSMLT** tab.

Name	Description
Enable	Enables RSMLT. The default is disabled.
HoldDownTimer	Defines how long the recovering or restarting system remains in a non-Layer 3 forwarding mode for the peer router MAC address. The range of this value is from 0 to 3600 seconds. The default is 60. If you disable RSMLT on a VLAN, non default values for this field do not save across restarts.
HoldUpTimer	Defines how long the RSMLT system maintains forwarding for its peer. The value is a range from 0 to 3600 seconds or 9999. 9999 means infinity. The default is 1800. If you disable RSMLT on a VLAN, non default values for this field do not save across restarts.

Enabling RSMLT Edge support

Enable RSMLT Edge support to store the RSMLT peer MAC and IP address-pair in the local configuration file and restore the configuration if the peer does not restore after a simultaneous restart of both RSMLT peer systems.

The default is disabled.

About This Task

RSMLT Edge support configuration applies to both IPv4 and IPv6.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **RSMLT**.
3. Click the **Globals** tab.
4. Select **EdgeSupportEnable**.
5. Click **Apply**.

View and Edit IPv4 RSMLT Local Information

About This Task

Perform the following procedure to view and edit RSMLT local VLAN information.

Procedure

1. In the navigation pane, expand **ConfigurationIP**.
2. Select **RSMLT**.
3. Select the **Local** tab.
4. Configure the parameters as required.

5. Select **Apply**.

Local field descriptions

Use the data in the following table to use the **Local** tab.

Name	Description
IfIndex	IP interface identification.
VlanId	Specifies the VLAN ID of the chosen VLAN.
IpAddr	Specifies the IP address on the RSMLT VLAN.
MacAddr	Specifies the MAC address of the selected VLAN.
Enable	Displays the RSMLT operating status as enabled or disabled.
OperStatus	Displays the RSMLT operating status as either up or down. The default is down.
HoldDownTimer	Defines how long the recovering/restarting system remains in a non-Layer 3 forwarding mode for the peer router MAC address. The range of this value is from 0 to 3600 seconds. The default is 60.
HoldUpTimer	Defines how long the RSMLT system maintains forwarding for its peer. The value is a range from 0 to 3600 seconds or 9999. 9999 means infinity. The default is 1800.
SmltId	Specifies the ID range for the SMLT. A valid range is 1 to 512.
VrfId	Identifies the VRF.
VrfName	Indicates the VRF name.

Modify the IPv6 RSMLT Local Information

Edit the existing RSMLT configuration for the local node in the cluster.

Procedure

1. In the navigation pane, expand **ConfigurationIPv6**.
2. Select **RSMLT**.
3. Select the **Local** tab.
4. Select a cell to change the value.
5. Select **Apply**.

Local field descriptions

Use the data in the following table to use the **Local** tab.

Name	Description
IfIndex	Shows the route SMLT operation index.
Ipv6Addr	Configures the IPv6 address of the RSMLT interface.
Ipv6PrefixLength	Configures the IPv6 prefix length.

Name	Description
Enable	Enables or disables RSMLT. The default is disabled.
HoldDownTimer	Defines how long the recovering/rebooting switch remains in a non-Layer 3 forwarding mode for the peer router MAC address. The default is 60.
HoldUpTimer	Defines how long the RSMLT switch maintains forwarding for its peer. The value is a range from 0 to 3600 seconds or 9999. 9999 means infinity. The default is 1800.
OperStatus	Displays the RSMLT operating status as either up or down.
SmltId	Specifies the ID range for the SMLT.
VlanId	Configures the VLAN ID.
MacAddr	Configures the MAC address of the VLAN.
VrfId	Indicates the virtual router ID to which the local RSMLT instance belongs.
VrfName	Indicates the virtual router name to which the local RSMLT instance belongs.

Modify IPv6 RSMLT Peer Information

Edit the existing configuration for the RSMLT peer node in the cluster.

Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Select **RSMLT**.
3. Select the **Peer** tab.
4. Select a cell to change the value.
5. Select **Apply**.

Peer Field Descriptions

Use the data in the following table to use the **Peer** tab.

Name	Description
IfIndex	Shows the route SMLT operation index.
Ipv6Addr	Configures the IPv6 address of the RSMLT interface.
Ipv6PrefixLength	Configures the IPv6 prefix length.
AdminStatus	Shows the administrative status of RSMLT on the peer.

Name	Description
HoldDownTimer	Defines how long the recovering/rebooting switch remains in a non-Layer 3 forwarding mode for the peer router MAC address. The default is 0.
HoldDownTimeRemaining	Indicates the time remaining in the HoldDownTimer.
HoldUpTimer	Defines how long the RSMLT switch maintains forwarding for its peer. The value is a range from 0 to 3600 seconds or 9999. 9999 means infinity. The default is 0.
HoldUpTimeRemaining	Indicates the time remaining in the HoldUpTimer.
OperStatus	Displays the RSMLT operating status as either up or down.
SmltId	Specifies the ID range for the SMLT.
VlanId	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
MacAddr	Configures the MAC address of the VLAN.
VrfId	Indicates the virtual router ID to which the peer belongs.
VrfName	Indicates the virtual router name to which the peer belongs.

View IPv4 RSMLT Peer Information

About This Task

Perform this procedure to view and edit RSMLT peer information.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **RSMLT**.
3. Select the **Peer** tab.

Peer field descriptions

The following table defines parameters for the **Peer** tab.

Name	Description
IfIndex	IP interface identification.
VlanId	Specifies the VLAN ID of the chosen VLAN.
IpAddr	Specifies the IP address on the RSMLT VLAN.
MacAddr	Specifies the MAC address of the selected VLAN.
Enable	Displays the RSMLT operating status as enabled or disabled.
OperStatus	Displays the RSMLT operating status as either up or down. The default is down.
HoldDownTimer	Defines how long the recovering/restarting system remains in a non-Layer 3 forwarding mode for the peer router MAC address. The range of this value is from 0 to 3600 seconds. The default is 0.
HoldUpTimer	Defines how long the RSMLT system maintains forwarding for its peer. The value is a range from 0 to 3600 seconds or 9999. 9999 means infinity. The default is 0.
HoldDownTimeRemaining	Displays the time remaining of the HoldDownTimer. The default is 0.
HoldUpTimeRemaining	Displays the time remaining of the HoldUpTimer. The default is 0.
SmtId	Specifies the ID range for the Split MultiLink Trunk. A valid range is 1 to 32.
VrfId	Identifies the VRF.
VrfName	Indicates the VRF name.

View IPv6 RSMLT Edge Peers

View the RSMLT peers for which the switch acts as a peer forwarder.

Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Select **RSMLT**.
3. Select the **Edge Peers** tab.

Edge Peers field descriptions

Use the data in the following table to use the **Edge Peers** tab.

Name	Description
PeerVlanId	Specifies the ID of the VLAN associated with this entry.
PeerIpv6Address	Specifies the IPv6 address of the peer RSMLT interface.
PeerIpv6PrefixLength	Specifies the peer IPv6 address prefix.
PeerMacAddress	Specifies the peer MAC address.

View IPv4 RSMLT Edge Support Information

About This Task

View RSMLT edge support information to verify the RSMLT peer MAC/IP address-pair in its local configuration file and restore the configuration if the peer does not restore it after a simultaneous restart of both RSMLT-peer systems.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **RSMLT**.
3. Select the **Edge Peers** tab.

Edge Peers field descriptions

Use the data in the following table to use the **Edge Peers** tab fields.

Name	Description
VlanId	Specifies the VLAN ID of the chosen VLAN.
PeerIpAddress	Specifies the peer IP address.
PeerMacAddress	Specifies the peer MAC address.
PeerVrfId	Identifies the Peer VRF.
PeerVrfName	Specifies the Peer VRF name.

Secure Shell Fundamentals

Methods of remote access such as Telnet or FTP generate unencrypted traffic. Anyone that can see the network traffic can see all data, including passwords and user names. Secure Shell (SSH) is a client and server protocol that specifies the way to conduct secure communications over a network. Secure Shell can replace Telnet and other remote login utilities. Secure File Transfer Protocol (SFTP) can replace FTP with an encrypted alternative.

Note

If both SSH and SFTP are concurrently active, you have the ability to disable SFTP while allowing SSH to remain active. For more information, see [Disabling SFTP without disabling SSH](#) on page 2571.

The switch software supports Secure CoPy protocol (SCP), which is a secure file transfer protocol. Use SCP to securely transfer files between a local host and a remote host. SCP is in off state by default, but you can turn it on when you enable SSH using the **boot config flags** command in the global config mode. The switch supports SCP only as an SCP server, which means that clients can send files to the switch or can request files from the switch. Secure CoPy (SCP) can replace FTP with an encrypted alternative.

Secure Shell supports a variety of the different public and private key encryption schemes available. Using the public key of the host server, the client and server negotiate to generate a session key known only to the client and the server. This one-time key encrypts all traffic between the client and the server. The switch supports Secure Shell version 2 (SSHv2).

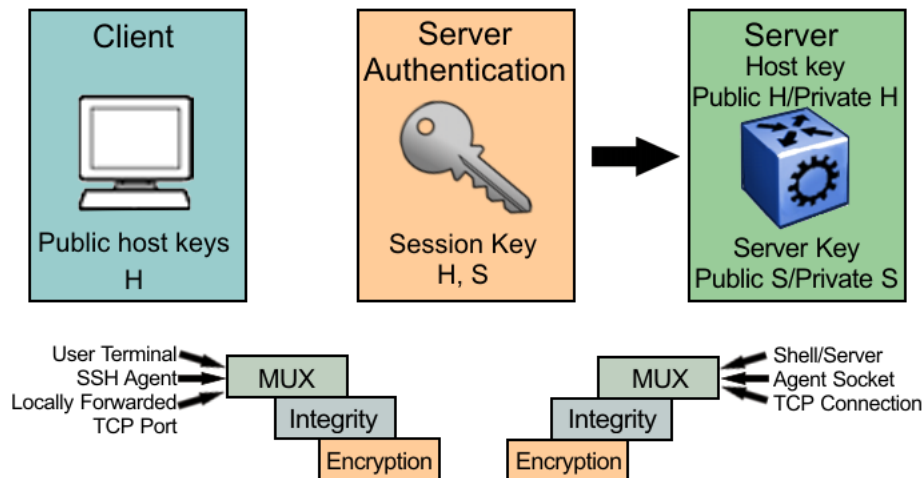

Figure 215: Overview of the SSHv2 protocol

By using a combination of host, server, and session keys, the SSHv2 protocol can provide strong authentication and secure communication over an insecure network, offering protection from the following security risks:

- IP spoofing
- IP source routing
- Domain name server (DNS) spoofing

- Man-in-the-middle/TCP hijacking attacks
- Eavesdropping and password sniffing

Even if network security is compromised, traffic cannot be played back or decrypted, and the connection cannot be hijacked.

The SSH secure channel of communication does not provide protection against break-in attempts or denial-of-service (DoS) attacks.

With the SSHv2 server in the switch, you can use an SSHv2 client to make a secure connection to the switch and work with commercially available SSHv2 clients. For more information about supported clients, see [Third-Party SSH and SCP Client Software](#) on page 2549. The switch also supports outbound connections to remote SSHv2 servers to provide complete inbound and outbound secure access.

Outbound Connections

The SSHv2 client supports SSHv2 DSA public key authentication and password authentication.

Note

For certain switches in enhanced secure mode, all sensitive files are protected. You cannot access any sensitive files using Telnet, SSH, FTP, SFTP, TFTP, and SCP connections. For more information, see [Sensitive File Protection](#) on page 2891.

Note

You must enable SSH globally before you can generate SSH DSA user keys.

The SSHv2 client is a secure replacement for outbound Telnet. Password authentication is the easiest way to use the SSHv2 client feature.

Instead of password authentication, you can use DSA public key authentication between the SSHv2 client and an SSHv2 server. Before you can perform a public key authentication, you must generate the key pair files and distribute the key files to all the SSHv2 server systems. Because passphrase encrypts and further protects the key files, you must provide a passphrase to decrypt the key files as part of the DSA authentication.

Note

SSH RSA and DSA public and private keys are copied from `/intflash/shared` to `/intflash/.ssh`.

To attempt public key authentication, the SSHv2 client looks for the associated DSA key pair files in the `/intflash/.ssh` directory. If no DSA key pair files are found, the SSHv2 client automatically prompts you for password authentication. If the SSHv2 client succeeds with the authentication, then a

new secured SSHv2 session is established to the remote SSHv2 server. For more information, see [.DSA Authentication Access Level and File Name](#) on page 2551.

Important

If you configure the DSA user key with a passphrase but you do not supply the correct passphrase when you try to make the SSHv2 connection, then the system defaults back to the password authentication. If the SSHv2 client succeeds with the authentication, then a new secured SSHv2 session is established to the remote SSHv2 server.

SSH Version 2

SSH version 2 (SSHv2) protocol is a complete rewrite of the SSHv1 protocol. In SSHv2 the functions are divided among three layers:

- SSH Transport Layer (SSH-TRANS)

The SSH Transport Layer manages the server authentication and provides the initial connection between the client and the server. After the connection is established, the Transport Layer provides a secure, full-duplex connection between the client and server.

- SSH Authentication Protocol (SSH-AUTH)

The SSH Authentication Protocol runs on top of the SSH Transport Layer and authenticates the client-side user to the server. SSH-AUTH defines three authentication methods: public key, host-based, and password. SSH-AUTH provides a single authenticated tunnel for the SSH connection protocol.

- SSH Connection Protocol (SSH-CONN)

The SSH Connection Protocol runs on top of the SSH Transport Layer and user authentication protocols. SSH-CONN provides interactive logon sessions, remote execution of commands, forwarded TCP/IP connections, and forwarded X11 connections. These services are multiplexed into the single encrypted tunnel provided by the SSH transport layer.

The following figure shows the three layers of the SSHv2 protocol.

Figure 216: Separate SSH version 2 protocols

The modular approach of SSHv2 improves on the security, performance, and portability of the SSHv1 protocol.

Important

The SSHv1 and SSHv2 protocols are not compatible. The switch does not support SSHv1.

Security Features

The SSHv2 protocol supports the following security features:

- **Authentication.** This feature determines, in a reliable way, the SSHv2 client. During the log on process, the SSHv2 client is queried for a digital proof of identity.

Supported authentications with the switch as a server for SSHv2, are: RSA, DSA, and passwords. Supported authentications with the switch as a client for SSHv2, are: DSA and passwords. The switch does not support RSA when the switch acts as a client.

When the switch acts as an SSH server, by default the switch allows a maximum of only four sessions, although it can accommodate up to eight sessions at a time. However, only one SSH public key encryption per access level is allowed at a time. For instance, if multiple SSH public key encryption clients need to connect to the server with the same access level, such as rwa, then the clients must connect to the server one-by-one as the switch only supports one public key per access level.

- Encryption. The SSHv2 server uses encryption algorithms to scramble data and render it unintelligible except to the receiver.

Supported encryption and ciphers are: 3DES, AES128-cbc, AES192-cbc, AES256-cbc, AES128-ctr, AES192-ctr, AES256-ctr, MD5, secure hash algorithm 1 (SHA-1) and SHA-2.

- Integrity. This feature guarantees that the data transmits from the sender to the receiver without alterations. If a third party captures and modifies the traffic, the SSHv2 server detects this alteration.

Note

SCP is supported for RWA users only. RW or R level will not work and the switch logs a message on the device.

SSHv2 Considerations using EDM

You must use CLI to initially configure SSHv2. You can use Enterprise Device Manager (EDM) to change the SSHv2 configuration parameters. CLI is the user interface for SSHv2 configuration and use the console port to configure the SSHv2 parameters. Depending on the hardware platform, the console port displays as console or 10101.

Important

Do not enable SSHv2 secure mode using Configuration and Orchestration Manager (COM). If you enable SSHv2 secure mode, then the system disables Simple Network Management Protocol (SNMP). This locks you out of a COM session. Enable SSH secure mode using CLI or EDM.

SSHv2 secure mode is different from enhanced secure mode and hsecure. SSHv2 secure mode disables unsecure management protocols on the device such as FTP, rlogin, SNMP, Telnet, and TFTP. SSHv2 secure mode is enabled through the **ssh secure** command.

When you enable SSHv2 secure mode, the system disables FTP, remote login (rlogin), SNMPv1, SNMPv2, SNMPv3, Telnet and TFTP. After SSHv2 secure mode is enabled, you can choose to enable individual non-secure protocols. However, after you save the configuration and restart the system, the non-secure protocol is again disabled, even though it is shown as enabled in the configuration file. After you enable SSHv2 secure mode, you cannot enable non-secure protocols by disabling SSHv2 secure mode.

You can disable block-snmp after you enable SSHv2 secure mode, and you can connect again using COM.

User ID log of an SSH session established by SCP client

The switch logs the user ID of an SSH session initiated by the SCP client. If an SCP client establishes an SSH session, the system displays the message in the following format:

```
CP1 [08/06/15 09:43:42.230:UTC] 0x000d8602 00000000 GlobalRouter SSH INFO SSH user
authentication succeeded for user rwa on host 10.68.231.194
CP1 [08/06/15 09:43:42.232:UTC] 0x000d8602 00000000 GlobalRouter SSH INFO SSH SCP session
start by user rwa on host 10.68.231.194
CP1 [08/06/15 09:43:44.020:UTC] 0x000d8602 00000000 GlobalRouter SSH INFO SCP session
closed by user rwa on host 10.68.231.194
CP1 [08/06/15 09:43:44.021:UTC] 0x000d8602 00000000 GlobalRouter SSH INFO SSH session
closed by user rwa on host 10.68.231.194
```

In the preceding example log output, rwa is the user name.

User ID log of an SSH session established by SFTP

The switch logs the user ID of an SSH session initiated by SFTP. If SFTP establishes an SSH session, the system displays the message in the following format:

```
CP1 [08/06/15 09:45:32.903:UTC] 0x000d8602 00000000 GlobalRouter SSH INFO SSH user
authentication succeeded for user rwa on host 10.68.231.194
CP1 [08/06/15 09:45:32.905:UTC] 0x000d8602 00000000 GlobalRouter SSH INFO SFTP session
start: user rwa on host 10.68.231.194
CP1 [08/06/15 09:45:46.775:UTC] 0x000d8602 00000000 GlobalRouter SSH INFO SFTP session
closed by user rwa on host 10.68.231.194
CP1 [08/06/15 09:45:46.776:UTC] 0x000d8602 00000000 GlobalRouter SSH INFO SSH SFTP
session end: user rwa on host 10.68.231.194
CP1 [08/06/15 09:45:46.776:UTC] 0x000d8602 00000000 GlobalRouter SSH INFO SSH session
closed by server for user rwa on host 10.68.231.194
```

In the preceding example log output, rwa is the user name.

User Key Files

Generating keys requires that you have free space on the flash. A typical configuration requires less than 2 kbyte of free space. Before you generate a key, verify that you have sufficient space on the flash, using the **dir** command. If the flash is full when you attempt to generate a key, the system displays an error message and the key is not generated. You must delete some unused files and regenerate the key.

If you remove only the public keys, enabling the SSH does not create new public keys.

SSHv2 password authentication uses the same login and password authentication mechanism as Telnet. The SSHv2 client also supports DSA public key authentication compatible with the switch SSHv2 server and Linux SSHv2 server for SSHv2.

If the switch is the client, use the following table to locate the DSA user key files for DSA authentication for user access level `rwa`.

Note

For certain switches in enhanced secure mode, all sensitive files are protected. The home directory for enhanced secure mode is `/intflash/shared`. You cannot access any sensitive files using Telnet, SSH, FTP, SFTP, TFTP, and SCP connections. For more information, see [Sensitive File Protection](#) on page 2891.

Table 192: DSA user key files

SSH server	SSH client side	SSH server side
switch with enhanced secure mode disabled	Private and public keys by access level: <ul style="list-style-type: none"> • <code>rwa—/intflash/.ssh/id_dsa_rwa</code> (private key), <code>/intflash/.ssh/id_dsa_rwa.pub</code> (public key) • <code>rw—/intflash/.ssh/id_dsa_rw</code> (private key), <code>/intflash/.ssh/id_dsa_rw.pub</code> (public key) • <code>ro—/intflash/.ssh/id_dsa_ro</code> (private key), <code>/intflash/.ssh/id_dsa_ro.pub</code> (public key) • <code>rw1—/intflash/.ssh/id_dsa_rw1</code> (private key), <code>/intflash/.ssh/id_dsa_rw1.pub</code> (public key) • <code>rw2—/intflash/.ssh/id_dsa_rw2</code> (private key), <code>/intflash/.ssh/id_dsa_rw2.pub</code> (public key) • <code>rw3—/intflash/.ssh/id_dsa_rw3</code> (private key), <code>/intflash/.ssh/id_dsa_rw3.pub</code> (public key) 	Public keys on the server side based on access level: <ul style="list-style-type: none"> • <code>rwa—/intflash/.ssh/dsa_key_rwa</code> (public key) • <code>rw—/intflash/.ssh/dsa_key_rw</code> (public key) • <code>ro—/intflash/.ssh/dsa_key_ro</code> (public key) • <code>rw1—/intflash/.ssh/dsa_key_rw1</code> (public key) • <code>rw2—/intflash/.ssh/dsa_key_rw2</code> (public key) • <code>rw3—/intflash/.ssh/dsa_key_rw3</code> (public key)
switch with enhanced secure mode enabled	Private and public keys by access role level: <ul style="list-style-type: none"> • <code>administrator—/intflash/shared/id_dsa_admin</code> (private key), <code>/intflash/shared/id_dsa_admin.pub</code> (public key) • <code>operator—/intflash/shared/id_dsa_operator</code> (private key), <code>/intflash/shared/id_dsa_operator.pub</code> (public key) • <code>security—/intflash/shared/id_dsa_security</code> (private key), <code>/intflash/shared/id_dsa_security.pub</code> (public key) • <code>auditor—/intflash/shared/id_dsa_auditor</code> (private key), <code>/intflash/shared/id_dsa_auditor.pub</code> (public key) 	Public keys on the server side based on access level: <ul style="list-style-type: none"> • <code>administrator—/intflash/shared/dsa_key_admin</code> (public key) • <code>operator—/intflash/shared/dsa_key_operator</code> (public key) • <code>security—/intflash/shared/dsa_key_security</code> (public key) • <code>privilege—/intflash/shared/dsa_key_priv</code> (public key) • <code>auditor—/intflash/shared/dsa_key_auditor</code> (public key)

Table 192: DSA user key files (continued)

SSH server	SSH client side	SSH server side
	intflash/shared/ id_dsa_auditor.pub (public key) <ul style="list-style-type: none"> • privilege —/intflash/shared/ id_dsa_priv (private key), / intflash/shared/id_dsa_priv.pub (public key) 	
Linux with Open SSH	~/.ssh/id_dsa (private key) file permission 400 ~/.ssh/id_dsa.pub (public key) file permission 644	~/.ssh/authorized_keys (public key) file
ERS 8600/8800		/flash/.ssh/dsa_key_rwa (public key)

When you attempt to make an SSH connection from the switch, the SSHv2 client looks in its own internal flash for the public key pair files. If the key files exist, the SSHv2 client prompts you for the passphrase to decrypt the key files. If the passphrase is correct, the SSHv2 client initiates the DSA key authentication to the remote SSHv2 server. The SSHv2 client looks for the login user access level public key file on the SSHv2 server to process and validate the public key authentication. If the DSA authentication is successful, then the SSHv2 session is established.

If no matching user key pair files exist on the client side when initiating the SSHv2 session, or if the DSA authentication fails, you are automatically prompted for a password to attempt password authentication.

If the remote SSHv2 server is a Linux system, the server looks for the login user public key file `~/.ssh/authorized_keys` by default for DSA authentication. For a Linux SSHv2 client, the user DSA key pair files are located in the user home directory as `~/.ssh/id_dsa` and `~/.ssh/id_dsa.pub`.

Block SNMP

The boot flag setting for block-snmpp (**boot config flags block-snmpp**) and the runtime configuration of SSH secure (**ssh secure**) each modify the block-snmpp boot flag. If you enable SSH secure mode, the system automatically sets the block-snmpp boot flag to true; the change takes effect immediately. After enabling SSH in secure mode, you can manually change the block-snmpp flag to false to allow both SSH and SNMP access.

Important

The block flag setting for block-snmpp blocks Simple Network Management Protocol (SNMP)v1, SNMPv2, and SNMPv3.

SCP command

Use short file names with the Secure CoPy (SCP) command. The entire SCP command, including all options, user names, and file names must not exceed 80 characters. The switch supports incoming SCP connections but does not support outgoing connections using an SCP client.

Third-Party SSH and SCP Client Software

Tested Software

The following table describes the third-party SSH and SCP client software that has been tested but is not included with the switch software.

Table 193: Tested software

SSH Client	Secure Shell (SSH)	Secure Copy (SCP)
Tera Term Pro with TTSSH extension MS Windows	<ul style="list-style-type: none"> • Supports SSHv2. • Authentication: <ul style="list-style-type: none"> - RSA is supported when the switch acts as a server. The switch does not support RSA as a client. - DSA - Password • Provides a keygen tool. • It creates both RSA and DSA keys. 	<ul style="list-style-type: none"> • Client distribution does not include SCP client.
Secure Shell Client Windows 2000	<ul style="list-style-type: none"> • Supports SSHv2 client. • Authentication <ul style="list-style-type: none"> ◦ DSA ◦ Password • Provides a keygen tool. • It creates a DSA key in SSHv2 format. • The switch generates a log message stating that a DSA key has been generated. 	<ul style="list-style-type: none"> • Client distribution includes an SCP client that is not compatible with switch.

Table 193: Tested software (continued)

SSH Client	Secure Shell (SSH)	Secure Copy (SCP)
OpenSSH Unix Solaris 2.5 / 2.6	<ul style="list-style-type: none"> • Supports SSHv2 clients. • Authentication: <ul style="list-style-type: none"> - RSA is supported when the switch acts as a server. The switch does not support RSA as a client. - DSA - Password • Provides a keygen tool. • It creates both RSA and DSA keys. 	<ul style="list-style-type: none"> • Client distribution includes an SCP client that is supported on switch.
WinSCP	N/A	This SCP client is unsupported on the switch.

Switch As Client

The switch acting as the SSHv2 client generates a DSA public and private server key pair. The public part of the key for DSA is stored in the following location:

```
/intflash/.ssh/dsa_key_rwa
```

**Note**

For certain switches in enhanced secure mode, all sensitive files are protected. The home directory for protected files is `/intflash/shared`. You cannot access any sensitive files using Telnet, SSH, FTP, SFTP, TFTP, and SCP connections. For more information, see [Sensitive File Protection](#) on page 2891.

The public part of the key must be copied to the SSH server and be named according to the naming requirement of the server.

Consult [DSA Authentication Access Level and File Name](#) on page 2551 for proper naming convention.

If a DSA key pair does not exist, you can generate the DSA key pair using the **ssh dsa-user-key [WORD<1-15>] [size <1024-1024>]** command.

You need to copy the DSA public key to the SSHv2 server that you connect to using the switch as a client. RSA is not supported when using the switch as a client, but you can use RSA when the switch is acting as the server.

**Note**

SSH RSA and DSA public and private keys are copied from `/intflash/shared` to `/intflash/.ssh`.

Switch As Server

After you install one of the SSHv2 clients you must generate a client and server key using the RSA or DSA algorithms.

To authenticate an SSHv2 client using DSA, the administrator must copy the public part of the client DSA key to `/intflash/.ssh` directory on the switch that acts as the SSHv2 server. The file that is copied over to the SSHv2 server must be named according to [DSA Authentication Access Level and File Name](#) on page 2551.

DSA Authentication Access Level and File Name

The following table lists the access levels and file names that you must use to store the SSHv2 client authentication information using DSA onto the switch that acts as the SSHv2 server.

For certain switches in enhanced secure mode, all sensitive files are protected. The home directory for enhanced secure mode is `/intflash/shared`. You cannot access any sensitive files using Telnet, SSH, FTP, SFTP, TFTP, and SCP connections. For more information, see [Sensitive File Protection](#) on page 2891.

Table 194: DSA authentication access levels and file names

Client key format or WSM	Access level	File name
Client key in non IETF and IETF format with enhanced secure mode disabled Note: The switch supports IETF and non-IETF for DSA.	RWA	/intflash/.ssh/dsa_key_rwa
	RW	/intflash/.ssh/dsa_key_rw
	RO	/intflash/.ssh/dsa_key_ro
	L3	/intflash/.ssh/dsa_key_rwl3
	L2	/intflash/.ssh/dsa_key_rwl2
	L1	/intflash/.ssh/dsa_key_rwl1
Client key in enhanced secure mode	administrator	/intflash/shared/dsa_key_admin
	operator	/intflash/shared/dsa_key_operator
	security	/intflash/shared/dsa_key_security
	privilege	/intflash/shared/dsa_key_priv
	auditor	/intflash/shared/dsa_key_auditor

The switch generates an RSA public and private server key pair. The public part of the key for RSA is stored in `/intflash/.ssh/ssh_key_rsa_pub.key`. If an RSA key pair does not exist, then the switch automatically generates one when you enable the SSH server. To authenticate a client using RSA, the administrator must copy the public part of the client RSA key to the switch.

For a certain switches in enhanced secure mode, sensitive files are protected. You cannot copy public or private keys directly to `/intflash/.ssh`. You must import the DSA/RSA private and public key from `/intflash/shared`. For more information, see [Import DSA and RSA Private or Public Keys](#) on page 2556.

RSA Authentication Access Level and File Name

For certain switches in enhanced secure mode, all sensitive files are protected. The home directory for enhanced secure mode is `/intflash/shared`. You cannot access any sensitive files using Telnet, SSH, FTP, SFTP, TFTP, and SCP connections. For more information, see [Sensitive File Protection](#) on page 2891.

The following table lists the access levels and file names you can use for storing the SSH client authentication information using RSA.

Table 195: RSA authentication access levels and file names

Client key format or WSM	Access level	File name
Client key in IETF format with enhanced secure mode disabled.	RWA	/flash/.ssh/rsa_key_rwa
	RW	/flash/.ssh/rsa_key_rw
	RO	/flash/.ssh/rsa_key_ro
	L3	/flash/.ssh/rsa_key_rwl3
	L2	/flash/.ssh/rsa_key_rwl2
	L1	/flash/.ssh/rsa_key_rwl1
Client key with enhanced secure mode enabled	administrator	/intflash/shared/rsa_key_admin
	operator	/intflash/shared/rsa_key_operator
	security	/intflash/shared/rsa_key_security
	privilege	/intflash/shared/rsa_key_priv
	auditor	/intflash/shared/rsa_key_auditor

SSH rekeying

SSH rekeying is an SSHv2 feature that allows the SSH server or client to force a key exchange between server and client, while changing the encryption and integrity keys. After you enable SSH rekeying, key exchanges occur after a pre-determined time interval or after the data transmitted in the session reaches the data-limit threshold. The default time-interval is 1 hour and the default data-limit is 1 GB. You can configure these values using the **ssh rekey** command.

SSH rekey is optional. You can enable SSH rekey only when SSH is enabled globally. Most SSH clients and servers do not provide a rekey mechanism, do not enable SSH rekey in such cases. Active sessions shut down if the rekey fails.

Note

You cannot enable SSH rekey selectively for either SSH client or server, it is enabled both on the SSH client and server together.

Configure Secure Shell using CLI

Use Secure Shell version 2 (SSHv2) to enable secure communications support over a network for authentication, encryption, and network Integrity.

Before You Begin

- Disable the `sshd` daemon. All SSHv2 commands, except `enable`, require that you disable the `sshd` daemon.
- Set the user access level to `read/write/all` community strings.
- Disable all nonsecure access services. As a best practice, disable the following services: Trivial File Transfer Protocol (TFTP), File Transfer Protocol (FTP), and Telnet. For more information about disabling access services, see [Enable Remote Access Services](#) on page 141.
- Use the console port to configure the SSHv2 parameters. Depending on your hardware platform, the console port displays as `console` or `10101`.

Enabling the SSHv2 server

Enable the SSHv2 server to provide secure communications for accessing the switch. The switch does not support SSHv1.

Before You Begin

To enable SSH, ensure to enable RSA or DSA authentication, or both using command `ssh rsa-auth` or `ssh dsa-auth`.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable the SSH server:

```
boot config flags sshd
```

3. Save the configuration file:

```
save config
```

Example

Enable the SSHv2 server:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#boot config flags sshd
Switch:1(config)#save config
```

Changing the SSH server authentication mode

Use this procedure to change the SSH server authentication mode from the default of password-authentication to keyboard-interactive.

About This Task

If you enable keyboard-interactive authentication mode, the server uses that mode over other authentication methods, except for public-key authentication, if the SSH client supports it.

If you enable keyboard-interactive authentication mode, the server generates the password prompts to display to the client rather than the client generating the prompts automatically like with password authentication.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Enable keyboard-interactive authentication:

```
ssh keyboard-interactive-auth
```

Configure SSH Authentication Type

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure the authentication type to use:

```
ssh authentication-type {[aead-aes-128-gcm-ssh] [aead-aes-256-gcm-ssh]
[hmac-sha1] [hmac-sha2-256]}
```

Variable Definitions

The following table defines parameters for the **ssh authentication-type** command.

Variable	Value
<code>[aead-aes-128-gcm-ssh] [aead-aes-256-gcm-ssh] [hmac-sha1] [hmac-sha2-256]</code>	Specifies the authentication type. Select from one of the following: <ul style="list-style-type: none"> • aead-aes-128-gcm-ssh • aead-aes-256-gcm-ssh • hmac-sha1 • hmac-sha2-256

Enable DSA Authentication

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Enable DSA authentication:

```
ssh dsa-auth
```

Generate the DSA Host Key

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Generate a new DSA host key:
`ssh dsa-host-key [<1024-1024>]`

Variable Definitions

The following table defines parameters for the **ssh dsa-host-key** command.

Variable	Value
<1024-1024>	The DSA host key size is 1024.

Generate a DSA User Key

Before You Begin

You must enable SSH globally before you can generate DSA user keys.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Create the DSA user key:
`ssh dsa-user-key WORD<1-15> [size <1024-1024>]`

Variable Definitions

The following table defines parameters for the **ssh dsa-user-key** command.

Variable	Value
<i>WORD</i> <1-15>	<p>Specifies the user access level. You must enable SSH globally before you can generate SSH DSA user keys.</p> <p>If enhanced secure mode is disabled, the valid user access levels for the switch are:</p> <ul style="list-style-type: none"> • rwa — Specifies read-write-all. • rw — Specifies read-write. • ro — Specifies read-only. • rw1 — Specifies read-write for Layer 1. • rw2 — Specifies read-write for Layer 2. • rw3 — Specifies read-write for Layer 3. <p>If you enable enhanced secure mode, the switch uses role-based authentication. You associate each username with a specific role and the appropriate authorization rights to commands based on that role.</p> <p>If enhanced secure mode is enabled, the valid user access levels for the switch are:</p> <ul style="list-style-type: none"> • admin—Specifies a user role with access to all of the configurations, show commands, and the ability to view the log file and security commands. The administrator role is the highest level of user roles. • operator—Specifies a user role with access to all of the configurations for packet forwarding on Layer 2 and Layer 3, and has access to show commands to view the configuration, but cannot view the audit logs and cannot access security and password commands. • auditor—Specifies a user role that can view log files and view all configurations, except password configuration. • security—Specifies a user role with access only to security settings and the ability to view the configurations. • priv—Specifies a user role with access to all of the commands that the administrator has access to, and is referred to as an emergency-admin. However, the user with the privilege role must be authenticated within the switch locally. RADIUS and TACACS+ authentication is not accessible. A user role at the privilege level must login to the switch through the console port only.
<i>size</i> <1024-1024>	Specifies the size of the DSA user key.

Import DSA and RSA Private or Public Keys

About This Task

Use this task to import SSH RSA and DSA public and private keys.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enter the following command to install the DSA or RSA public or private key:

```
ssh install-user-key WORD<1-15> {rwa | rw | ro | rwl1 | rwl2 | rwl3 |  
admin | operator | auditor | security | priv} WORD<1-15> {public |  
private} WORD<1-15> {dsa | rsa}
```

Examples

```
Switch:1(config)#ssh install-user-key admin public dsa

```

Variable Definitions

the following table defines parameters for the **ssh install-user-key** command.

Variable	Value
<pre>WORD<1-15>{ rwa rw ro rwl1 rwl2 rwl3, enhanced-secured mode : admin operator auditor security priv }</pre>	<p>Specifies the user access level. You must enable SSH globally before you can generate SSH DSA user keys. If enhanced secure mode is disabled, the valid user access levels for the switch are:</p> <ul style="list-style-type: none"> • rwa — Specifies read-write-all. • rw — Specifies read-write. • ro — Specifies read-only. • rwl1 — Specifies read-write for Layer 1. • rwl2 — Specifies read-write for Layer 2. • rwl3 — Specifies read-write for Layer 3. <p>If you enable enhanced secure mode, the switch uses role-based authentication. You associate each username with a specific role and the appropriate authorization rights to commands based on that role. If enhanced secure mode is enabled, the valid user access levels for the switch are:</p> <ul style="list-style-type: none"> • admin—Specifies a user role with access to all of the configurations, show commands, and the ability to view the log file and security commands. The administrator role is the highest level of user roles. • operator—Specifies a user role with access to all of the configurations for packet forwarding on Layer 2 and Layer 3, and has access to show commands to view the configuration, but cannot view the audit logs and cannot access security and password commands. • auditor—Specifies a user role that can view log files and view all configurations, except password configuration. • security—Specifies a user role with access only to security settings and the ability to view the configurations. • priv—Specifies a user role with access to all of the commands that the administrator has access to, and is referred to as an emergency-admin. However, the user with the privilege role must be authenticated within the switch locally. RADIUS and TACACS+ authentication is not accessible. A user role at the privilege level

Variable	Value
	must login to the switch through the console port only.
<i>WORD</i> <1-15>{ <i>public</i> <i>private</i> }	Specifies the public key or the private key type to copy from /intflash/shared to /intflash/.ssh.
<i>WORD</i> <1-15>{ <i>dsa</i> <i>rsa</i> }	Specifies the DSA or RSA signature algorithm for the public key or the private key to copy.

Configure Encryption Type

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the type of encryption to use:

```
ssh encryption-type {[3des-cbc] [aead-aes-128-gcm-ssh ] [aead-aes-256-gcm-ssh] [aes128-cbc] [aes128-ctr] [aes192-cbc] [aes192-ctr] [aes256-cbc] [aes256-ctr] [blowfish-cbc] [rijndael128-cbc] [rijndael192-cbc]}
```

Variable Definitions

The following table defines parameters for the **ssh encryption-type** command.

Variable	Value
<i>[3des-cbc] [aead-aes-128-gcm-ssh] [aead-aes-256-gcm-ssh] [aes128-cbc] [aes128-ctr] [aes192-cbc] [aes192-ctr] [aes256-cbc] [aes256-ctr] [blowfish-cbc] [rijndael128-cbc] [rijndael192-cbc]</i>	Configures the encryption-type. Select an encryption-type from one of the following: <ul style="list-style-type: none"> • 3des-cbc • aead-aes-128-gcm-ssh • aead-aes-256-gcm-ssh • aes128-cbc • aes128-ctr • aes192-cbc • aes192-ctr • aes256-cbc • aes256-ctr • blowfish-cbc • rijndael128-cbc • rijndael192-cbc

Configure the Key-Exchange Method

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure the key-exchange to use:

```
ssh key-exchange-method {[diffie-hellman-group14-sha1] [diffie-hellman-group-exchange-sha256]}
```

Variable Definitions

The following table defines parameters for the **ssh key-exchange-method** command.

Variable	Value
<code>[diffie-hellman-group14-sha1] [diffie-hellman-group-exchange-sha256]</code>	Configures the key-exchange method. Select a key-exchange method from one of the following: <ul style="list-style-type: none"> • diffie-hellman-group14-sha1 • diffie-hellman-group-exchange-sha256

Configure the Maximum Number of SSH Sessions

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure the maximum number of SSH sessions:

```
ssh max-sessions <0-8>
```

Variable Definitions

The following table defines parameters for the **ssh max-sessions** command.

Variable	Value
<code><0-8></code>	Specifies the maximum number of SSH sessions allowed. A value from 0 to 8. Default is 4.

Enable SSH Password Authentication

Enable password authentication. The default is enabled.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable password authentication:

```
ssh pass-auth
```

Configure the SSH Connection Port

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure the SSH connection port:

```
ssh port <22,1024..49151>
```

Variable Definitions

The following table defines parameters for the **ssh port** command.

Variable	Value
<22,1024-49151>	Specifies the TCP port number. The default is 22. Important: You cannot configure TCP port 6000 as the SSH connection port.

Enable RSA Authentication

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable the RSA authentication:

```
ssh rsa-auth
```

Generate an RSA Host Key

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Generate a new RSA host key:

```
ssh rsa-host-key [<1024-2048>]
```

Variable Definitions

The following table defines parameters for the **ssh rsa-host-key** command.

Variable	Value
<1024-2048>	Specify an optional key size from 1024 to 2048. The default is 2048.

Generate an RSA User Key

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Generate a new RSA user key.
`ssh rsa-user-key WORD<1-15> [size <1024-2048>]`

Variable Definitions

The following table defines parameters for the **ssh rsa-user-key** command.

Variable	Value
<i>WORD</i> <1-15>	<p>Specifies the user access level.</p> <p>If enhanced secure mode is disabled, the valid user access levels for the switch are:</p> <ul style="list-style-type: none"> • rwa — Specifies read-write-all • rw — Specifies read-write • ro — Specifies read-only • rw1 — Specifies read-write for Layer 1 • rw2 — Specifies read-write for Layer 2 • rw3 — Specifies read-write for Layer 3 <p>If you enable enhanced secure mode, the switch uses role-based authentication. You associate each username with a specific role and the appropriate authorization rights to commands based on that role.</p> <p>If enhanced secure mode is enabled, the value user access levels for the switch are:</p> <ul style="list-style-type: none"> • admin—Specifies a user role with access to all of the configurations, show commands, and the ability to view the log file and security commands. The administrator role is the highest level of user roles. • operator—Specifies a user role with access to all of the configurations for packet forwarding on Layer 2 and Layer 3, and has access to show commands to view the configuration, but cannot view the audit logs and cannot access security and password commands. • auditor—Specifies a user role that can view log files and view all configurations, except password configuration. • security—Specifies a user role with access only to security settings and the ability to view the configurations • priv—Specifies a user role with access to all of the commands that the administrator has access to, and is referred to as an emergency-admin. However, the user with the privilege role must be authenticated within the switch locally. RADIUS and TACACS+ authentication is not accessible. A user role at the privilege level must login to the switch through the console port only.
<i>size</i> <1024-1024>	Specifies the size of the RSA user key.

Enable SSH Secure Mode

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```

2. Enable SSH secure mode:

```
ssh secure
```

Configure the SSH version

Configure Secure Shell version 2 (SSHv2). The switch does not support SSHv1.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the SSH version:

```
ssh version <v2only>
```

Configure the SSH Authentication Timeout

Configure the timeout for SSH connection authentication.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the authentication timeout:

```
ssh timeout <1-120>
```

Variable Definitions

The following table defines parameters for the **ssh timeout** command.

Variable	Value
<1-120>	Specifies the SSH connection authentication timeout in seconds. Default is 60 seconds.

Resetting the SSH

About This Task

Perform this task to terminate all SSH sessions and restart SSH server.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Reset the SSH.

```
ssh reset
```

Configure X.509 V3 Authentication

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable X.509 V3 authentication:

```
ssh x509v3-auth enable
```

3. Configure X.509 V3 revocation:

```
ssh x509v3-auth revocation-check-method {none | oosp}
```

4. Configure X.509 V3 username:

```
ssh x509v3-auth username {overwrite | strip-domain | use-domain  
WORD<1-254>}
```

5. Configure X.509 V3 CA trustpoint name:

```
ssh x509v3-auth ca-name WORD<1-45>
```

6. Configure the X.509 V3 digital certificate subject name to use as the identity certificate:

```
ssh x509v3-auth cert-subject-name WORD<1-45>
```

Example

Display the certificate authority details:

```
Switch:1(config)#show certificate ca

```

Variable Definitions

The following table defines parameters for the **ssh x509v3-auth** command.

Variable	Value
<code><none oscp></code>	<p>Specifies the X.509 V3 authentication revocation check method. The default is OCSP.</p> <ul style="list-style-type: none"> none - Specifies no revocation check method. oscp - Specifies Online Certificate Status Protocol (OSCP) as revocation check method.
<code>overwrite strip-domain use-domain WORD<1-254></code>	<p>Specifies the X.509 V3 username configuration. The default is disabled.</p> <ul style="list-style-type: none"> overwrite - Specifies the switch to send the principal name and domain name from the certificate to the RADIUS server for authorization. strip-domain - Specifies the switch to send the principal name from the certificate without the domain name to the RADIUS server for authorization. use-domain WORD<1-254> - Specifies the switch to send the principal name from the certificate, with the domain name you entered to the RADIUS server for authorization.
<code>ca-name WORD<1-45></code>	Specifies the X.509 V3 CA trustpoint name.
<code>cert-subject-nameWORD<1-45></code>	Specifies the digital certificate subject name to be used as the identity certificate.

Verify and Display SSH Configuration Information

Verify that SSH services are enabled on the switch and display SSH configuration information to ensure that the SSH parameters are properly configured.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Verify that SSH services are enabled and view the SSH configuration:

```
show ssh <global|session>
```

Example

Display global system SSH information:

```
Switch:1(config)#show ssh global

Variable Definitions

The following table defines parameters for the **show ssh** command.

Variable	Value
<i>global</i>	Display global system SSH information.
<i>session</i>	Display the current session SSH information.

Connect to a Remote Host using the SSH Client

Make an SSH connection to a remote host.

Before You Begin

Enable the SSH server on the remote host.

About This Task

The command format, for the CLI SSH client command, is similar to Telnet with two additional parameters: `-l login` and an optional `-p port` parameter.

On IPv6 networks, the switch supports SSH server only. The switch does not support outbound SSH client over IPv6. On IPv4 networks, the switch supports both SSH server and SSH client.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Connect to a remote host:

```
ssh WORD<1-256> -l WORD<1-32> [-p <1-32768>]
```

Example

Connect to the remote host:

```
Switch:1>enable
Switch:1#ssh 192.0.2.1 -l rwa
```

Variable Definitions

The following table defines parameters for the **ssh** command.

Variable	Value
<code>WORD<1-32></code>	Specifies the user login name of the remote SSH server.
<code>-p <1-32768></code>	Specifies the port number to connect to the remote SSH server. The default is 22.

Generate User Key Files

Configure the SSH parameters to generate DSA user key files.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable SSH server.
3. Create the DSA user key file:

```
ssh dsa-user-key [WORD<1-15>][size <1024-1024>]
```

4. Enter the encryption password to protect the key file.
5. Copy the user public key file to the remote SSH servers.

**Note**

For certain switches in enhanced secure mode, the public key is copied from `/intflash/.ssh` to `/intflash/shared` after key pair generation to be available in enhanced secure mode.

6. If you are generating the compatible keys on a Linux system, use the following steps:
 - a. Create the DSA user key file:

```
ssh-keygen -t dsa
```
 - b. Copy the user public key to the remote SSH servers.

**Note**

The DSA pair key files can be generated on the Linux system and used by the SSH client on the switch.

Example

Create the DSA user key file with the user access level set to read-write-all and size of the DSA user key set to 1024 bits:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ssh dsa-user-key rwa size 1024
```

Variable Definitions

The following table defines parameters for the **ssh dsa-user-key** command.

Variable	Value
<i>WORD</i> <1-15>	<p>Specifies the user access level. If enhanced secure mode is disabled, the valid user access levels for the switch are:</p> <ul style="list-style-type: none"> • <i>rwa</i>—Specifies read-write-all. • <i>rw</i>—Specifies read-write. • <i>ro</i>—Specifies read-only • <i>rw13</i>—Specifies read-write for Layer 3. • <i>rw12</i>—Specifies rread-write for Layer 2. • <i>rw11</i>—Specifies read-write for Layer 1. <p>If you enable enhanced secure mode, the switch uses role-based authentication. You associate each username with a specific role and the appropriate authorization rights to commands based on that role.</p> <p>If enhanced secure mode is enabled, the valid user access levels for the switch are:</p> <ul style="list-style-type: none"> • <i>admin</i>—Specifies a user role with access to all of the configurations, show commands, and the ability to view the log file and security commands. The administrator role is the highest level of user roles. • <i>operator</i>—Specifies a user role with access to all of the configurations for packet forwarding on Layer 2 and Layer 3, and has access to show commands to view the configuration, but cannot view the audit logs and cannot access security and password commands. • <i>auditor</i>—Specifies a user role that can view log files and view all configurations, except password configuration. • <i>security</i>—Specifies a user role with access only to security settings and the ability to view the configurations. • <i>priv</i>—Specifies a user role with access to all of the commands that the administrator has access to, and is referred to as an emergency-admin. However, the user with the privilege role must be authenticated within the switch locally. RADIUS and TACACS+ authentication is not accessible. A user role at the privilege level must login to the switch through the console port only.
<i>size</i> <1024-1024>	Specifies the size of the DSA user key. The default is 1024 bits.

Manage an SSL Certificate

Note

For certain switches in enhanced secure mode, all sensitive files are protected. You cannot access any sensitive files using Telnet, SSH, FTP, SFTP, TFTP, and SCP connections. For more information, see [Sensitive File Protection](#) on page 2891.

The TLS server selects a certificate authority (CA)-signed certificate if the certificate is already installed in the Digital Certificate module.

If the server certificates are not available, the TLS server generates a new self-signed certificate at startup and uses that by default. You can choose to use an online or an offline CA-signed certificate, which takes precedence over the self-signed certificate.

For more information about SSL certificate manipulation, see [Certificate Order Priority](#) on page 2593.

About This Task

If a certificate is already present, you must confirm that it can be deleted before a new one is created.

After you create a certificate, the system logs one of the following INFO alarms:

- New default Server Certificate and Key are generated and installed
- Current Server Certificate and Key are installed

The default certificate key length for a certificate generated on the switch is 2,048 bits.

Note

The **ssl certificate [validity-period-in-days <30-3650>]** command in this procedure does not require a system reboot.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Create and install a new self-signed certificate:

```
ssl certificate [validity-period-in-days <30-3650>]
```
3. Delete a certificate:

```
no ssl certificate
```

Note

The certificate loaded in memory remains valid until you use the **ssl reset** command or reboot the system.

Variable Definitions

The following table defines parameters for the **ssl certificate** command.

Variable	Value
<code>validity-period-in-days <30-3650></code>	Specifies an expiration time for the certificate. The default is 365 days.

Disabling SFTP without disabling SSH

Disable SFTP while allowing SSH to remain active.

Before You Begin

Enhanced secure mode must be enabled. For information about enabling enhanced secure mode, see [Enabling enhanced secure mode](#) on page 2905.

Procedure

1. Enter Global Configuration mode:
enable

configure terminal
2. Enable the SSHv2 server:
no ssh sftp enable
3. Save the configuration file:
save config

Enabling SSH rekey

Before You Begin

Enable SSH globally.

Procedure

1. Enter Global Configuration mode:
enable

configure terminal
2. Enter the following command:
ssh rekey enable

Example

```
Switch:1>enable
Switch:1#configure terminal
```

Enable SSH rekeying globally:

```
Switch:1(config)#ssh rekey enable
```

Variable Definitions

The following table defines parameters for the **ssh rekey** command.

Variable	Value
<i>enable</i>	Enables SSH rekey globally.

Configuring SSH rekey data-limit

Use the following procedure to configure the limit for data transmission during the session.

Procedure

1. Enter Global Configuration mode:
enable

configure terminal

2. Enter the following command:

```
ssh rekey data-limit <1-6>
```

Example

```
Switch:1>enable
Switch:1#configure terminal
```

Configure the SSH rekey data-limit to 2 GB:

```
Switch:1(config)#ssh rekey data-limit 2
```

Variable Definitions

The following table defines parameters for the **ssh rekey data-limit** command.

Variable	Value
<1-6>	Sets the SSH rekey data limit in GB, range is 1-6.

Configuring SSH rekey time-interval

Use the following procedure to configure a time interval, after which the key exchange takes place.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enter the following command:

```
ssh rekey time-interval <1-6>
```

Example

```
Switch:1> enable
Switch:1# configure terminal
```

Configure the SSH rekey time-interval to 3 hours:

```
Switch:1(config)# ssh rekey time-interval 3
```

Variable Definitions

The following table defines parameters for the **ssh rekey time-interval** command.

Variable	Value
<1-6>	Sets the time-interval for SSH rekeying in hours, the range is 1 to 6.

Display SSH Rekey Information

Use the following procedure to display the SSH rekey information.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. Enter the following command:
`show ssh rekey`

Example

```
Switch:1> enable
Switch:1#show ssh rekey
    Rekey Status      : TRUE
    Rekey data limit  : 1 GB
    Rekey time interval : 1 hours
```

Enabling or Disabling the SSH Client

About This Task

You can disable the SSH client functionality on the switch. By default, the SSH client functionality is enabled.

**Note**

In order to enable the SSH client functionality, SSH must be enabled globally.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Disable the SSH client functionality:
`no ssh client <enable>`
3. Use one of the following commands to enable the SSH client functionality:
 - `ssh client <enable>`
 - `default ssh client <enable>`

**Note**

You must enable SSH globally before the SSH client functionality can be re-enabled.

Example

Display the general SSH settings::

```
Switch:1(config)# show ssh global
Total Active Sessions : 0
    version            : v2only
    port               : 22
    max-sessions       : 4
    timeout            : 60
    action rsa-host key : rsa-hostkeysize 2048
    action dsa-host key : dsa-hostkeysize 1024
```

```

rsa-auth          : true
dsa-auth          : true
pass-auth        : true
keyboard-interactive-auth : false
sftp enable      : true
enable           : true
client enable    : true

```

Disable SSH client functionality:

```
Switch:1(config)# no ssh client
```

```
Switch:1(config)# show ssh global
```

```

Total Active Sessions : 0
  version              : v2only
  port                 : 22
  max-sessions         : 4

```

Downgrading or Upgrading from Releases that Support Different Key Sizes

Use this procedure if you need to downgrade or upgrade from a release that supports different key sizes.

Different releases can support different DSA host key, RSA host key, and DSA user key sizes. If you need to upgrade or downgrade to an earlier release that does not support the same key size, you must delete all of the keys from the .ssh directory and generate new keys for SSH. If you do not do this, key sizes that are no longer supported will no longer function.

You only need to perform this procedure if you have previously generated DSA host, RSA host, or DSA user keys with a release that supports different key sizes.

Procedure

1. Use the following command to disable SSH:

```
no ssh
```
2. From the config terminal go to the .ssh directory using the command:

```
cd /intflash/.ssh
```
3. After you upgrade or downgrade, delete the following keys from the .ssh directory.

```

ssh_dss.key
ssh_rsa.key
moc_sshc_dsa_file
moc_sshc_rsa_file
id_dsa_rwa
id_dsa_rwa.pub
id_rsa_rwa
id_rsa_rwa.pub

```

```
noc_sshc_dsa_file_fed
noc_sshc_rsa_file_fed
known_hosts
ssh_ecdsa.key
dsa_key <access level like rwa/rw/ro/admin/security/privilege/operator/auditor>,
example: dsa_key_rwa
rsa_key <access level like rwa/rw/ro/admin/security/privilege/operator/auditor>,
example: rsa_key_rwa
```

4. Generate a new DSA host key:
`ssh dsa-host-key [<1024-1024>]`
5. Generate a new SSH DSA user key:
`ssh dsa-user-key WORD<1-15> [size <1024-1024>]`
6. Generate a new RSA host key:
`ssh rsa-host-key [<1024-2048>]`

Secure Shell configuration using Enterprise Device Manager

Use Secure Shell version 2 (SSHv2) to enable secure communications support over a network for authentication, encryption, and network Integrity.

On IPv6 networks, the switch supports SSHv2 server only. The switch does not support outbound SSHv2 client over IPv6. On IPv4, the switch supports both SSHv2 server and SSHv2 client.

For more information, see [Change Secure Shell Parameters](#) on page 2576.

Change Secure Shell Parameters

You can use Enterprise Device Manager to change the SSHv2 configuration parameters. However, as a best practice, use the CLI to perform the initial configuration of SSHv2. The switch does not support SSHv1.

Before You Begin

- The user access level is read/write/all community strings.
- You must disable the SSH service before you configure the SSH service parameters. If the SSHv2 service is enabled, the system displays all fields dimmed until the SSH service is disabled.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **SSH**.
3. Select the **SSH** tab.
4. In the **Enable** field, select the type of SSH service you want to enable.
5. In the **Version** field, select a version.
6. In the **Port** field, type a port.
7. In the **MaxSession** field, type the maximum number of sessions allowed.
8. In the **Timeout** field, type the timeout.
9. From the **KeyAction** field, choose a key action.
10. In the **RsaKeySize** field, type the RSA key size.
11. In the **DSAKeySize** field, type the DSA key size.

12. Select the **RsaAuth** check box for RSA authentication.
13. Select the **DsaAuth** check box for DSA authentication.
14. Select the **PassAuth** check box for password authentication.
15. In the **AuthType** section, select the authentication types you want.
16. In the **Encryption Type** section, select the authentication types you want.
17. In the **KeyExchangeMethod** section, select the authentication types you want.
18. Select **Apply**.

SSH Field Descriptions

Use the data in the following table to use the **SSH** tab.

Name	Description
Enable	<p>Enables, disables, or securely enables SSHv2. The options are:</p> <ul style="list-style-type: none"> • false • true • secure <p>Select false to disable SSHv2 services. Select true to enable SSHv2 services. Select secure to enable SSH and disable access services (SNMP, FTP, TFTP, and Telnet). The default is false.</p> <p>Important: Do not enable SSHv2 secure mode using Enterprise Device Manager. Enabling secure mode disables SNMP. This locks you out of the Enterprise Device Manager session. Enable SSHv2 secure mode using CLI.</p>
Version	<p>Configures the SSH version. The options are:</p> <ul style="list-style-type: none"> • v2only <p>The default is v2only.</p>
Port	<p>Configures the SSHv2 connection port number. <code><22 or 1024-49151></code> is the port range of SSHv2.</p> <p>Important: You cannot configure the TCP port 6000 as SSHv2 connection port.</p>
MaxSession	<p>Configures the maximum number of SSHv2 sessions allowed. The value can be from 0 to 8. The default is 4.</p>
Timeout	<p>Configures the SSHv2 authentication connection timeout in seconds. The default is 60 seconds.</p>
KeyAction	<p>Configures the SSHv2 key action. The options are:</p> <ul style="list-style-type: none"> • none • generateDsa • generateRsa • deleteDsa • deleteRsa
RsaKeySize	<p>Configures SSHv2 RSA key size. The value can be from 1024 to 2048. The default is 2048.</p>

Name	Description
DsaKeySize	Configures the SSHv2 DSA key size. The value can be from 512 to 1024. The default is 1024.
RsaAuth	Enables or disables SSHv2 RSA authentication. The default is enabled.
DsaAuth	Enables or disables SSHv2 DSA authentication. The default is enabled.
PassAuth	Enables or disables SSHv2 RSA password authentication. The default is enabled.
RekeyEnable	Enables SSH rekey globally. The default is disabled.
RekeyTimeInterval	Configures a time interval, after which the key exchange takes place. The default is 1 hour.
RekeyDataLimit	Configures the limit for data transmission during the session. The default is 1 GB.
SftpEnable	Enables or disables SFTP. You can use this check box to disable SFTP without affecting the SSH status. The default is enabled.
KeyboardInteractiveAuth	Changes the SSH server authentication mode from the default of password authentication to keyboard interactive.
ClientEnable	Enables SSH client functionality on the switch. By default, the SSH client functionality is enabled. To enable the SSH client functionality, SSH must be enabled globally.
X509AuthEnable	Enables SSH x509 authentication. The default is enabled.
X509AuthRevocationCheckMethod	Specifies the X.509 V3 authentication revocation check method. The default is OCSP. <ul style="list-style-type: none"> • none - Specifies no revocation check method. • oscp - Specifies Online Certificate Status Protocol (OCSP) as revocation check method.
X509AuthUserNameOverwrite	Enables the switch to send the principal name and domain name from the certificate to the RADIUS server for authorization. The default is disabled.
X509AuthUserNameStripDomain	Enables the switch to send the principal name from the certificate without the domain name to the RADIUS server for authorization. The default is disabled.
X509AuthUserNameUseDomain	Enables the switch to send the principal name from the certificate, with the domain name you entered to the RADIUS server for authorization.
X509AuthCertificateSubjectName	Specifies the digital certificate subject name used as identity certificate.
X509AuthCertificateCAName	Specifies the digital certificate CA trustpoint name to use.
AuthType	Specifies the authentication type. Select from one of the following: <ul style="list-style-type: none"> • hmacSha1 • hmacSha2256 • aeadAes128GcmSsh • aeadAes256GcmSsh By default, all authentication types are selected.

Name	Description
EncryptionType	Configures the encryption-type. Select an encryption-type from one of the following: <ul style="list-style-type: none">• aes128Cbc• aes256Cbc• threeDesCbc• aeadAes128GcmSsh• aeadAes256GcmSsh• aes128Ctr• rijndael128Cbc• aes256Ctr• aes192Ctr• aes192Cbc• rijndael192Cbc• blowfishCbc
KeyExchangeMethod	Configures the key-exchange type. Select from one of the following: <ul style="list-style-type: none">• diffieHellmanGroupExchangeSha256• diffieHellmanGroup14Sha1• diffieHellmanGroup1Sha1

Security

[Security Fundamentals](#) on page 2580

[Security Configuration using CLI](#) on page 2595

[Security Configuration using EDM](#) on page 2641

Security Fundamentals

This section provides conceptual content to help you configure and customize the security services on the switch.

Security overview

Security is a critical attribute of networking devices. Security features are split into two main areas:

- Control path—protects the access to the device from a management perspective.
- Data path—protects the network from malicious users by controlling access authorization to the network resources (such as servers and stations). This protection is primarily accomplished by using filters or access lists.

You can protect the control path using the following mechanism:

- logon and passwords
- access policies to specify the network and address that can use a service or daemon
- secure protocols, such as Secure Shell (SSH), Secure Copy (SCP), and the Simple Network Management Protocol version 3 (SNMPv3)
- the Message Digest 5 Algorithm (MD5) to protect routing updates, Open Shortest Path First (OSPF), and Border Gateway Protocol (BGP)

You can protect the data path using the following mechanism

- Media Access Control (MAC) address filtering
- Layer 3 filtering, such as Internet Protocol (IP) and User Datagram Protocol (UDP)/Transmission Control Protocol (TCP) filtering
- routing policies to prevent users from accessing restricted areas of the network
- mechanisms to prevent denial-of-service (DOS) attacks

Security Modes

The switch support three security modes:

- Enhanced secure
- Hsecure
- SSH secure

Enable SSH secure mode to allow only SSH to be used and disable all other protocols which include Telnet, FTP, SNMP, TFTP, HTTP, and HTTPS. Enabling this mode disables Telnet, FTP, SNMP, TFTP, HTTP, and HTTPS by setting the boot flags for these protocols to off. You can over-ride the configuration and enable required protocols individually for run-time use. The administrator must enable required protocols individually for run-time use again following a reboot even if you save the configuration. This is because the SSH secure mode enable takes precedence at the time of reboot and the other protocols will be disabled even though the configuration file has them set to enabled.

Note

Disabling SSH secure mode will not automatically enable the OA&M protocols that were disabled. The boot flags for the required protocols will have to be individually set to enabled.

The following table lists the differences between enhanced secure mode and hsecure mode.

Table 196: Enhanced secure mode versus hsecure mode

Feature	Enhanced secure	Hsecure
Authentication	Role-based: <ul style="list-style-type: none"> • admin • privilege • operator • security • auditor 	Access-level based: <ul style="list-style-type: none"> • rwa • rw • ro • l3 • l2 • l1
Password length	Minimum of 8 characters with the exception of the Admin, which requires a minimum of 15 characters	10 characters, minimum
Password rules	1 or 2 upper case, lower case, numeric and special characters	Minimum of 2 upper case, 2 lower case, 2 numeric and 2 special characters
Password expiration	Per-user minimum change interval is enforced, which is programmed by the Administrator	Global expiration, configured by the Admin
Password-unique	Previous passwords and common passwords between users are prevented	The same
Password renewal	Automatic password renewal is enforced	The same
Audit logs	Audit logs are encrypted, and authorized users are able to view, modify, and delete.	Standard operation
SNMPv3	Password rules apply to SNMPv3 Auth&Priv. SNMPv3 is required (V1/V2 disabled)	SNMPv1 and SNMPv2 can be enabled.

Table 196: Enhanced secure mode versus hsecure mode (continued)

Feature	Enhanced secure	Hsecure
EDM	Site Admin to enable or disable	Disabled
Telnet and FTP	Site Admin to enable or disable	The same
DOS attack Prevention	Not available	Prevents DOS attacks by filtering IP addresses and IP address ranges.

For information on Enhanced secure mode and SSH, see [Enhanced Secure Mode](#) on page 2887.

hsecure Mode

The switch supports a flag called high secure (hsecure). hsecure introduces the following behaviors for passwords:

- 10-character enforcement
- aging time
- limitation of failed logon attempts
- protection mechanism to filter certain IP addresses

After you enable the hsecure flag, the software enforces the 10-character rule for all passwords. This password must contain a minimum of two uppercase characters, two lowercase characters, two numbers, and two special characters.

After you enable hsecure, the system requires you to save the configuration file and reboot the system for hsecure to take effect. If the existing password does not meet the minimum requirements for hsecure, the system prompts you to change the password during the first login.

The default username is rwa and the default password is rwa. In hsecure, the system prompts you to change these during first login because they do not meet the minimum requirements for hsecure.

When you enable hsecure, the system disables Simple Network Management Protocol (SNMP) v1, SNMPv2 and SNMPv3. If you want to use SNMP, you must re-enable SNMP, using the command **no boot config flag block-snmp**.

Aging Enforcement

After you enable the hsecure flag, you can configure a duration after which you must change your password. You configure the duration by using the aging parameter.

For SNMP and File Transfer Protocol (FTP), after a password expires, access is denied. Before you access the system, you must change a community string to a new string consisting of more than eight characters.

Important

Consider the following after you enable the hsecure flag:

- You cannot enable the web server for Enterprise Device Manager (EDM) access.
- You cannot enable the Secure Shell (SSH) password authentication.

Filtering Mechanism

Incorrect IP source addresses as network or broadcast addresses are filtered at the virtual router interface. Source addresses 192.168.168.0 and 192.168.168.255 are discarded.

This change is valid for all IP subnets, not only for /24.

You can filter addresses only if you enable the hsecure mode.

CLI Passwords

The switch ships with default passwords assigned for access to Command Line Interface (CLI) through a console or management session. If you have read/write/all access authority, and you are using SNMPv3, you can change passwords that are in an encrypted format. If you are using Enterprise Device Manager (EDM), you can also specify the number of available Telnet sessions.

Important

The default passwords are documented and well known. Change the default passwords and community strings immediately after you first log on.

After a factory default or if your switch has no primary or backup configuration files, a password change is required to access the CLI. The system provides three attempts to change the password, if unsuccessful you are taken back to the login prompt but are not locked out. You cannot reuse a password and your password cannot be empty. A password change is required irrespective of security mode, console, SSH, or Telnet access.

If you enable enhanced secure mode with the **boot config flags enhancedsecure-mode** command, you enable different access levels, along with stronger password complexity, length, and minimum change intervals. For more information on system access fundamentals and configuration, see [System Access](#) on page 2881.

Port Lock feature

You can use the Port Lock feature to administratively lock a port or ports to prevent other users from changing port parameters or modifying port action. You cannot modify locked ports until the ports are first unlocked.

Access Policies for Services

You can control access to the switch by creating an access policy. An access policy specifies the hosts or networks that can access the device through various services, such as Telnet, SNMP, Trivial File Transfer Protocol (TFTP), File Transfer Protocol (FTP), and Hypertext Transfer Protocol (HTTP). You can enable or disable access services by setting flags from CLI.

You can define network stations that can explicitly access the switch or stations that cannot access it. For each service you can also specify the level of access, such as read-only or read-write-all.

Important

A third-party security scan shows the switch service ports open and in the listen state. No connections are accepted on these ports unless you enable the particular daemon. The switch does not dynamically start and stop the daemons at runtime and needs to keep them running from system startup.

For more information about configuring access policies, see [Access Policies for Services](#) on page 2885.

User-based policy support

You can set up a user-based policy (UBP) system by using Enterprise Policy Manager (EPM), a RADIUS server.

EPM is an application designed to manage the traffic prioritization and network access security for business applications. It provides centralized control of advanced packet classification and the ability to priority mark, police, meter, or block traffic.

EPM 5.0 supports UBPs, which allow security administrators to establish and enforce roles and conditions for each user for all access ports in the network. The UBP feature in EPM works in conjunction with Extensible Access Protocol (EAP) technology to enhance the security of the network. Users log on to the networks and are authenticated as the network connection is established.

The UBP feature works as an extension to the Roles feature in EPM. In a UBP environment, role objects are linked directly to specific users (as RADIUS attributes), as opposed to being linked simply to device interfaces. The role object then links the users to specific policies that control the user's access to the network.

When the RADIUS server successfully authenticates a user, the device sends an EAP session start event to the EPM policy server. The policy server then sends user-based policy configuration information for the new user roles to the interface, based on the role attribute that was assigned to that user on the RADIUS server.

Denial-of-Service Attack Prevention

Table 197: Denial-of-service attack prevention product support

Feature	Product	Release introduced
Directed Broadcast	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
High Secure mode (hsecure boot configuration flag)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5

Hsecure

The switch supports a configurable flag, called high secure (hsecure). High secure mode introduces a protection mechanism to filter certain IP addresses, and two restrictions on passwords: 10-character enforcement and aging time.

If the device starts in hsecure mode with default factory settings, and no previously configured password, the system will prompt you to change the password. The new password must follow the rules mandated by high secure mode. After you enable hsecure and restart the system, if you have an invalid-length password you must change the password.

If you enable hsecure for the first time and the password file does not exist, then the device creates a normal default username (rwa) and password (rwa). In this case, the password does not meet the minimum requirements for hsecure and as a result the system prompts you to change the password.

The following information describes hsecure mode operations:

- When you enable the hsecure flag, after a certain duration you are asked to change your password. If not configured, the aging parameter defaults to 90 days.
- For SNMP and FTP, access is denied when a password expires. You must change the community strings to a new string made up of more than eight characters before accessing the system.
- You cannot enable the web server at any time.
- You cannot enable the SSH password-authentication feature at any time.

Hsecure is disabled by default. When you enable hsecure, the desired behavior applies to all ports.

For more information, see [Preventing certain types of DOS attacks](#) on page 2601.

Prioritization of Control Traffic

The switch uses a sophisticated prioritization scheme to schedule control packets on physical ports. This scheme involves two levels with both hardware and software queues to guarantee proper handling of control packets regardless of the switch load. In turn, this scheme guarantees the stability of the network. Prioritization also guarantees that applications that use many broadcasts are handled with lower priority.

You cannot view, configure, or modify control-traffic queues.

Directed Broadcast Suppression

You can enable or disable forwarding for directed broadcast traffic on an IP-interface basis. A directed broadcast is a frame sent to the subnet broadcast address on a remote IP subnet. By disabling or suppressing directed broadcasts on an interface, you cause all frames sent to the subnet broadcast address for a local router interface to be dropped. Directed broadcast suppression protects hosts from possible DoS attacks.

To prevent the flooding of other networks with DoS attacks, such as the Smurf attack, the switch is protected by directed broadcast suppression. This feature is enabled by default. As a best practice, do not disable it.

For more information, see [Configuring directed broadcast](#) on page 2600.

ARP Request Threshold

The Address Resolution Protocol (ARP) request threshold defines the maximum number of outstanding unresolved ARP requests. The default value for this function is 500 ARP requests. To avoid excessive amounts of subnet scanning that a virus can cause, as a best practice, change the ARP request threshold to a value between 100 and 50. This configuration protects the CPU from causing excessive ARP requests, protects the network, and lessens the spread of the virus to other PCs. The following list provides further ARP threshold values:

- Default: 500
- Severe conditions: 50
- Continuous scanning conditions: 100
- Moderate: 200
- Relaxed: 500

For more information about how to configure the ARP threshold, see [Address Resolution Protocol](#) on page 257.

Multicast Learning Limitation

The Multicast Learning Limitation feature protects the CPU from multicast data packet bursts generated by malicious applications. If more than a certain number of multicast streams enter the CPU through a port during a sampling interval, the port is shut down until the user or administrator takes the appropriate action.

For more information, see [IP Multicast](#) on page 1139.

Authentication for Privileged EXEC Command Mode

Table 198: Authentication for Privileged EXEC Mode product support

Feature	Product	Release introduced
Authentication for Privileged EXEC CLI Command Mode	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.4

For enhanced security, you can enable user authentication to enter Privileged EXEC command mode. Use the **sys priv-exec-password** command to enable password authentication.

After you enable password authentication for Privileged EXEC command mode, the system prompts you to enter a password to access Privileged EXEC command mode from User EXEC command mode. You must enter the same password that you used to log on to the switch.

Considerations

- The same username and password used to Telnet or SSH to the switch is used to access Privileged EXEC command mode when authentication is enabled.
- RADIUS and TACACS+ protocols are supported. If RADIUS and TACACS+ servers are not reachable, access to Privileged EXEC command mode is denied. You must open a new session and type the same username and password used to Telnet or SSH to the switch.

- No timeout exists for the password used to log on to the Privileged EXEC command mode.
- No limit to the number of retries if you enter an incorrect password.

Configuration Considerations

Use the information in this section to understand the limitations of some security functions, such as BSAC RADIUS servers and Layer 2 protocols before you attempt to configure security.

Attribute Format for a Third-party RADIUS Server

If you use a third-party RADIUS server and need to modify the dictionary files, you must add a vendor-specific attribute (attribute #26) and use 1584 as vendor code for all the devices and then send back access-priority vendor-assigned attribute number 192 with a decimal value of 1 to 6, depending upon whether you want read only to read-write-all.

Authentication for Privileged EXEC Command Mode

Authentication for Privileged EXEC command mode supports RADIUS and TACACS+ protocols. If RADIUS and TACACS+ servers are not reachable, access to Privileged EXEC command mode is denied. You must open a new session and type the same username and password used to Telnet or SSH to the switch.

RADIUS on Management Ports

The management port supports the RADIUS protocol. When RADIUS packets are sent out of the management port, the SRC-IP address is properly entered in the RADIUS header.

For more information about the supported RADIUS servers, see the documentation of the RADIUS server.

RADIUS Server SNMP Accounting

An SNMP query sent by an unreachable RADIUS server configured as used-by snmp and with accounting enabled, can cause a timeout. A timeout can occur if the device that receives the SNMP query attempts to send accounting packets to the unreachable server. You can mitigate the timeout issue by configuring lower retry and timeout values on the RADIUS server. Alternatively, you can configure a higher timeout value for SNMP.

Single Profile Enhancement for BSAC RADIUS Servers

Before enabling Remote Access Dial-In User Services (RADIUS) accounting on the device, you must configure at least one RADIUS server.

The switch software supports Microsoft Radius Servers (NPS Windows 2008, Windows 2003 IAS Server), BaySecure Access Control (BSAC), Merit Network servers and Linux based servers. To use these servers, you must first obtain the software for the server. You must also make changes to one or more configuration files for these servers.

Single Profile is a feature that is specific to BSAC RADIUS servers. In a BSAC RADIUS server, when you create a client profile, you can specify all the returnable attributes. When you use the same profile for different products, you specify all the returnable attributes in the single profile.

SNMP Cloned User Considerations

If the user from which you are cloning has authentication, you can choose for the new user to either have the same authentication protocol as the user from which it was cloned, or no authentication. If you choose authentication for the new user, you must provide a password for that user. If you want a new user to have authentication, you must indicate that at the time you create the new user. You can assign a privacy protocol only to a user that has authentication.

If the user from which you are cloning has no authentication, then the new user has no authentication.

Source IP Configuration

Note

The following Source IP configuration considerations are only applicable on hardware platforms running VOSS Release 8.2 and later.

The Source IP is the Internet Protocol address of the device sending the IP data packet. For devices running VOSS Release 8.2 and later, the system limits the Source IP to a maximum of three interfaces; the management Out-of-Band (OOB) management interface, the VLAN management interface, or the Circuitless IP (CLIP) management interface. The system uses separate routing tables for each Segmented Management Instance interface, plus a default main table. Since multiple routing tables are in use, each management interface can have overlapping or identical static routes without interfering with each other. The main table has a super-set of all routes where the weight of the static route can tie-break routes to the same destination going through different segmented management interfaces. By default, the following weights are used and the default route priority is management CLIP, then management VLAN, then management OOB:

- mgmt CLIP - 100
- mgmt VLAN - 200
- mgmt OOB - 300

You can route packets through a different management interface than the default configuration, but you must add a specific static route or change the default weight of the management interface.

For example, if the default route uses mgmt CLIP and you want to use the mgmt OOB interface as the source IP to reach a RADIUS server, you must perform one of the following options:

- Configure a specific source IP static route for the mgmt OOB interface:

```
mgmt oob
ip route 192.0.2.0/24 next-hop 198.51.100.1
```

OR

- Configure the default mgmt OOB route weight lower than the default mgmt CLIP route weight:

```
mgmt oob
no ip route 0.0.0.0/24 next-hop 198.51.100.1
ip route 0.0.0.0/24 next-hop 198.51.100.1 weight 50
```

Note

If you change the default route weight, the management interface with the lowest weight value becomes the default route for all segmented management interface traffic.

For VOSS Release 8.1.5 and earlier, there was a potential for thousands of different Source IP management interfaces for applications initiating an outbound connection without a Source IP specified. To avoid Source IP fluctuations for many management interfaces with frequent route updates, you could specify the Source IP for applications where the source IP identifies the client. Configuring a Source IP for specific management applications is deprecated in VOSS Release 8.2 and later.

Note

This applies only to client mgmt applications initiating an outgoing connection, where the source IP address is not specified. If an application is running in server mode, the source IP address of the reply packet is configured to the destination IP address of the original request for TCP connections.

Interoperability configuration

The switch is compatible with RADIUS servers.

Unicast Reverse Path Forwarding (uRPF)

Table 199: Unicast Reverse Path Forwarding product support

Feature	Product	Release introduced
Unicast Reverse Path Forwarding (URPF) checking (IPv4)	5320 Series	Fabric Engine 8.6 5320-48P-8XE and 5320-48T-8XE only
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
Unicast Reverse Path Forwarding (URPF) checking (IPv6)	5320 Series	Fabric Engine 8.6 5320-48P-8XE and 5320-48T-8XE only
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5

The Unicast Reverse Path Forwarding (uRPF) feature prevents packet forwarding for incoming unicast IP packets that have incorrect or forged (spoofed) IP addresses. The uRPF feature checks that the traffic received on an interface comes from a valid IP address, thereby preventing address spoofing. On a reverse path check, if the source IP address of the received packet at the interface is not reachable using the FIB, the system drops the packet as the packet may have originated from a misconfigured or a malicious source.

You can configure uRPF for each IP interface or VLAN. When uRPF is enabled on an interface, the switch checks all routing packets that come through that interface. It ensures that the system displays the source address and source interface in the routing table, and that it matches the interface, on which the packet was received.

You can use one of two modes for uRPF:

- **Strict mode:** In strict mode, uRPF checks whether the source IP address of the incoming packet exists in the FIB. If the incoming interface is not the best reverse path, the packet check fails and

uRPF drops the packet. If the routing engine finds the source IP entry, uRPF further checks if the source IP interface matches the incoming interface of the packet. If they match, the system forwards the packet as usual, otherwise, the system discards the packet.

Note

The number of packets dropped due to uRPF check on the ingress interface gets incremented along with other general dropped statistics under the `IN-DISCARD` column in the output of the command `show interfaces gigabitEthernet error <collision|verbose> {slot/port[-slot/port] [,...]}`.

- Loose mode: In loose mode, uRPF checks whether the source IP address of the incoming packet exists in the FIB. The packet is dropped only if the source address is not reachable via any interface on that router.

uRPF can be enabled independently for IPv4 and IPv6. However, on a given interface, if uRPF is enabled for both IPv4 and IPv6, the `urpf-mode` can be either `strict-mode` or `loose-mode` for both IPv4 and IPv6. That means we cannot have IPv4 `urpf-mode` configured differently than that of IPv6.

Note

When you enable uRPF mode the MTU values for both IPv4 and IPv6 packets on the same VLAN are matched. Different Layer 3 MTU sizes on the same VLAN are not allowed in uRPF mode.

Note

uRPF check cannot detect spoofed source IP address if the source IP address belongs to a known subnet.

Digital Certificate/PKI

Table 200: Digital Certificate/PKI product support

Feature	Product	Release introduced
Digital Certificate/PKI	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
Subject alternative name	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
Certificate fingerprint validation	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.3
Multiple CA Trustpoints and multiple Certificate Identities	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.5
	5520 Series	VOSS 8.3.100

This section provides information on the digital certificate framework and offline certificate management.

A digital certificate is an electronic document that identifies the subject, proves the ownership of a public key, and is digitally signed by a certificate authority (CA) that certifies the validity of the information in the certificate. A digital certificate is valid for a specific time period.

The switch uses Public Key Infrastructure (PKI) support to obtain and use digital certificates for secure communication in the network.

To be certified, a switch performs the following tasks:

- Generate a certificate signing request.
- Verify that a present certificate has not been revoked.
- Validate the certificate.
- Renew the certificate before it expires.
- Remove the certificate, if required.

Subject

An administrator configures the subject parameters, such as common name, organization name, organization unit, locality, state, country, and subject name for requesting the identity certificate.

Subject Name

You can configure up to 10 distinguished subject names.

Subject Alternative Name

A subject alternative name associates host name values, such as an e-mail address, an IP address, or a Fully qualified domain name (FQDN) with a security certificate. You can protect these additional host names with a single certificate.

Challenge Password

A password is required for Simple Certificate Enrollment Protocol (SCEP) operations, such as the enrollment and renewal of identity certificates. This password is given offline by the CA during end entity registration. The administrator provides this password during enroll and renew operations.

UsePost

There are different types of CAs such as EJBCA, Win2012, and others. The *usePost* parameter enables you to choose the style of HTTP request. The value for the *usePost* parameter can be **True** or **False**.

For example, if Win2012 SCEP does not support the POST mode of HTTP request, configure the *usePost* as False for Win2012 and configure *usePost* as True for EJBCA.

Root CA Certificate

The Root CA certificate obtained offline from a CA must be installed for SCEP operations. This Root CA certificate is transferred to the device during the certificate installation. SCEP operations cannot be performed if the offline Root CA certificate is not installed and if error messages are logged.

Key Generation

The supported key type is RSA with RSA key of size 2048. There can be only one active key-pair associated with the trustpoint CA and digital certificate. A new key-pair cannot be generated if there is a key-pair already associated with the active digital certificate. The system logs the error message if such new key generation is attempted. In such a case, the certificate must be revoked before a new key-pair is generated.

Trustpoint CA

Use trustpoints to manage and track CAs and certificates. A trustpoint is a representation of a CA or of an identity pair. A trustpoint contains the identity of the CA, CA-specific configuration parameters, and an association with one generated key. The switch can enroll with a trustpoint to obtain an identity certificate. Trustpoint is configured after the RSA key pair is generated and the CA identity and other configuration parameters are available. You can configure up to eight CA trustpoints by providing the CA name.

You can configure a SHA-256 fingerprint to authenticate a received CA certificate that matches the configured common name. The switch first checks for an installed, offline root certificate and validates against it. If no root certificate is present, the switch checks the SHA-256 fingerprint in the received CA certificate. The SHA-256 fingerprint does not authenticate the root certificate.

Certificate Enrollment

Certificate enrollment involves generating a certificate signing request (CSR). Before certificate enrollment, the trustpoint CA must be configured and the user configuration parameters should be available. The key usage extension parameter is required as an input; it indicates the purpose of the key contained in the certificate, that the key can be used for encipherment, digital signature, certificate signing and so on.

The certificate enrollment is not allowed if there is an active certificate already available. If new certificate enrollment is required, the existing active certificate must be revoked first. The system logs the enrollment success or failure responses.

Certificate Renewal

The administrator must renew the certificate before it expires. A trap is configured for a pre-defined period before the expiry date of the certificate, and the system logs the certificate renewal due warning message. A certificate renewal request is not performed if an active certificate is not available. The system replaces the existing certificate with the newly obtained certificate on successful renewal. The system logs the renewal success or failure responses.

Certificate Revocation or Removal

The certificate can be revoked or withdrawn from the specific device for a specific reason at any time. A certificate revocation request is not performed if an active certificate is not available. The system releases the existing certificate on successful revocation. The system logs the revocation success or failure responses.

During boot up, the system checks whether an active installed certificate is available. If a valid certificate is not available, the system logs the warning message.

Offline Certificate Management

Offline certificate management supports switches that cannot communicate with the Certificate Authority to obtain the identity certificate or certificates online by certificate enrollment operation.

The certificate signing request (CSR) is used to obtain the offline identity certificate. Configure the subject and RSA key-pair to obtain the offline identity certificate. You can generate and store up to 10 RSA keys identified by the key name label. To obtain multiple offline certificates, you must specify a distinguished subject-name and key-name.

You must install the Root CA certificate and all the intermediate CA certificates of the certificate chain in the device before installing the offline identity or device certificate. All the intermediate and Root CA certificates are stored in the certificate store and are used for CA certificate chain validation. The CA certificate chain validation is performed starting from the issuing CA certificate to the Root CA certificate during the installation of offline identity certificate. The offline identity certificate is installed only if the CA certificate chain validation, subject, and key match.

Storage

No digital certificate configuration is visible if you use the **show running-config** command. Instead, use the commands appropriate for displaying digital certificate information. For more information, see [View the Certificate Details](#) on page 2624.

Certificate Order Priority

Table 201: Certificate order priority product support

Feature	Product	Release introduced
Certificate order priority	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5

Use the following information to understand the certificate order priority when the Transport Layer Security (TLS) server and switch connect.

Note

For certain switches in enhanced secure mode, all sensitive files are protected. You cannot access any sensitive files using Telnet, SSH, FTP, SFTP, TFTP, and SCP connections. For more information, see [Sensitive File Protection](#) on page 2891.

The TLS server selects a certificate authority (CA)-signed certificate if the certificate is already installed in the Digital Certificate module.

If the server certificates are not available, the TLS server generates a new self-signed certificate at startup and uses that by default. You can choose to use an online or an offline CA-signed certificate, which takes precedence over the self-signed certificate.

SSL-Based Self-Signed Certificate

Some early releases use the default certificate available in the `/intflash/.ssh` folder, which is the open SSL-based self-signed certificate that is named `host.cert`.

To use the Mocana stack-based self-signed certificate, delete the open SSL self-signed certificate prior to upgrading your software release. The Mocana certificate offers better and stronger encryption than open SSL-based certificates.

If you do not delete the `host.cert` file in the `/intflash/.ssh` folder used in earlier releases, you must generate a self-signed certificate automatically during upgrade or post upgrade using the command **`config ssl certificate`**.

If you have a subscribed CA-signed certificate renamed as `host.cert` in folder `/intflash/.ssh` in a previous release, it cannot be reused.

To use your subscribed CA-signed certificate, upgrade with the Mocana-based self-signed certificate, and then use the digital certificates feature to install a CA-signed certificate through the online or offline method.

You cannot obtain a CA-signed certificate and rename the certificate as `host.cert`. You must use the online or offline method to obtain a certificate.

SAN Entries in Default TLS Certificates

The default TLS certificates add `hostname.domainname` and management IP address as subject alternative name (SAN) entries:

- If you configure both `hostname` and `domain-name`, the self-signed certificate uses `hostname.domain-name` for both common name (CN) and SAN DNS.
- If you configure `domain-name` but not `hostname`, the self-signed certificate uses `*.domain-name` for both CN and SAN DNS.
- If you configure `hostname` but not `domain-name`, the self-signed certificate uses `hostname.extremenetworks.com` for both CN and SAN DNS.
- If you do not configure either `hostname` or `domain-name`, the self-signed certificate uses `*.extremenetworks.com` for both CN and SAN DNS.
- All management IP addresses are added as SAN IP entries.

If you use default self-signed certificates generated in a release that did not include SAN entries in the certificate, generate the certificate again to avoid certificate errors in Web browsers that require these entries.

Note

As a best practice, use custom Public Key Infrastructure (PKI) certificates rather than the default self-signed certificates.

Two-Factor Authentication for SSH

Table 202: Two-Factor Authentication for SSH product support

Feature	Product	Release introduced
Two-Factor Authentication for SSH	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5

Use the following information to understand the Two-Factor Authentication feature.

Two-Factor Authentication uses smart card technology for remote device management. Two-Factor Authentication requires enhanced secure mode with Secure Shell (SSH) and X.509 V3 authorization enabled on the switch. You must provide the digital certificates to enable the identity management for the SSH client and SSH server. Two-Factor Authentication requires the following items:

- a VSP Operating System Software (VOSS) switch
- a switch
- a computer with Secure CRT 8.3.2 or 8.3.3 as the SSH client
- a smart card reader
- a Common Access Card (CAC) or Personal Identity Verification (PIV) card for each configured user

You can also use a Windows Server 2008, or newer, configured with a Remote Access Dial-In User Services (RADIUS) server and Active Directory.

Digital certificates in the X.509 V3 format provide identity management. A chain of signatures by a trusted certificate authority (CA) and its intermediate certificate CAs binds a given public signing key to a given digital identity. For user authentication, the SSH client sends the user certificate stored on the CAC or PIV card to the SSH server for verification. The SSH server validates the incoming user certificate using Public Key Infrastructure (PKI) trust-store.

After the switch validates the SSH certificate, the system parses for a username to forward to the RADIUS server for authorization. The switch prompts you to enter a password for the username. If the RADIUS server is unreachable or not configured, the authorization occurs locally on the switch for the username and password.

Two-Factor Authentication on the switch uses SSH and the X.509 V3 certificates stored on the smart card. X.509 V3 digital certificates are documented in RFC5280.

Smart Card Authentication Process

The process for PIV or CAC card authentication is as follows:

1. The PIV Authentication or the Card Authentication certificate is read from the PIV Card Application.
2. The relying system validates the PIV Authentication certificate from the PIV Card Application using standards-compliant PKI path validation to ensure that the certificate is valid and from a trusted source.
3. The cardholder is prompted to submit a PIN to activate the card.
4. The relying system issues a challenge string to the card and requests an asymmetric operation in response.
5. The card responds to the previously issued challenge by signing using the PIV Authentication private key.
6. The relying system verifies that the response from the card is expected for the issued challenge.
7. A unique identifier from the PIV Authentication certificate is extracted and passed as input to the access control decision.

Security Configuration using CLI

Configure security information used on the control and data paths to protect the network from uncontrolled access to network resources.

For more information about how to configure passwords and access policies, see [System access configuration using CLI](#) on page 2892.

Enable hsecure

The hsecure flag is disabled by default. When you enable it, the software enforces the 10 character rule for all passwords.

About This Task

When you upgrade from a previous release, if the password does not have at least 10 characters, you receive a prompt to change your password to the mandatory 10-character length.

If you enable hsecure for the first time and the password file does not exist, then the device creates a normal default username (rwa) and password (rwa). In this case, the password does not meet the minimum requirements for hsecure and as a result the system prompts you to change the password.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Enable or disable hsecure mode:
`boot config flags hsecure`

The system displays the following warning messages:

```
Warning: For security purposes, all unsecure services - TFTP, FTP, Rlogin, Telnet,
SNMP are disabled. Individually enable the required services.
Warning: Please save boot configuration and reboot the switch for this to take effect.
```

Note

Warning message text can vary across hardware models.

3. Save the configuration and restart the device for the change to take effect.

Example

Enable hsecure mode. Save the configuration. Restart the switch.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#boot config flags hsecure
Warning: For security purposes, all unsecure services - TFTP, FTP, Rlogin, Telnet, SNMP
are disabled. Individually enable the required services. Warning: Please save boot
configuration and reboot the switch for this to take effect.
Switch:1(config)#save config
Switch:1(config)#reset
Are you sure you want to reset the switch (y/n)?y
```

Change an Invalid-Length Password

Before You Begin

Important

When you enable hsecure, passwords must contain a minimum of 10 characters or numbers. The password must contain a minimum of: two uppercase characters, two lowercase characters, two numbers, and two special characters.

About This Task

After you enable hsecure mode and restart the system, change your password if you have an invalid-length password.

Procedure

1. At the CLI prompt, log on to the system.
2. Enter the password.

If you have an invalid-length password, the system displays the following message:

```
Your password is valid but less than mandatory 10 characters.  
Please change the password to continue.
```

3. When prompted, enter the new password.
4. When prompted, re-enter the new password.

Example

Log on to the switch:

```
Login: rwa
```

Enter the password:

```
Password: ***  
Your password is valid but less than mandatory 10 characters. Please change the password  
to continue.
```

Enter the new password:

```
Enter the new password: *****
```

Re-enter the new password:

```
Re-enter the new password: *****  
Password successfully changed.
```

Configure New Passwords

Configure new passwords for each access level, or change the logon or password for the different access levels of the switch. After you receive the switch, use default passwords to initially access CLI. If you use Simple Network Management Protocol version 3 (SNMPv3), you can change encrypted passwords.

Before You Begin

- You must use an account with read-write-all privileges to change passwords. For security, the switch saves passwords to a hidden file.

About This Task

If you enable the hsecure flag, after the aging time expires, the system prompts you to change your password. If you do not configure the aging time, the default is 90 days.

Procedure

- Enter Global Configuration mode:
enable

configure terminal
- Change a password:
cli password WORD<1-20> {layer1|layer2|layer3|read-only|read-write|read-write-all}
- Enter the old password.
- Enter the new password.
- Enter the new password a second time.
- Configure password options:
password access-level WORD<2-8>

password aging-time day <1-365>

password default-lockout-retries <1-255>

password default-lockout-time <60-65000>

password lockout WORD<0-46> [time <60-65000>]

password min-passwd-len <10-20>

password password-history <3-32>

Example

```
Switch:1>enable  
Switch:1#configure terminal
```

Change a password:

```
Switch:1(config)# password smith read-write-all
```

Enter the old password:

```
Switch:1(config)#*****
```

Enter the new password:

```
Switch:1(config)#*****
```

Enter the new password a second time:

```
Switch:1(config)#*****
```

Set password to an access level of read-write-all and the expiration period for the password to 60 days:

```
Switch:1(config)#access-level rwa aging-time 60
```

Variable Definitions

The following table defines parameters for the **cli password** command.

Variable	Value
<i>layer1</i> <i>layer2</i> <i>layer3</i> <i>read-only</i> <i>read-write</i> <i>read-write-all</i>	Changes the password for the specific access level.
<i>WORD</i> <1-20>	Specifies the user logon name.

The following table defines parameters for the **password** command.

Variable	Value
<i>access level WORD</i> <2-8>	Permits or blocks this access level. The available access level values are as follows: <ul style="list-style-type: none"> • l1 • l2 • l3 • ro • rw • rwa
<i>aging-time day</i> <1-365>	Configures the expiration period for passwords in days, from 1-365. The default is 90 days.
<i>default-lockout-retries</i> <1-255>	Configures the default number of login attempts. The default is 3.
<i>default-lockout-time</i> <60-65000>	Changes the default lockout time after three invalid attempts. Configures the lockout time, in seconds, and is in the 60-65000 range. The default is 60 seconds. To configure this option to the default value, use the default operator with the command.
<i>lockout WORD</i> <0-46> <i>time</i> <60-65000>	Configures the host lockout time. <ul style="list-style-type: none"> • <i>WORD</i><0-46> is the host IP address in the format a.b.c.d. • <60-65000> is the lockout-out time, in seconds, in the 60-65000 range. The default is 60 seconds.

Variable	Value
<code>min-passwd-len <10-20></code>	Configures the minimum length for passwords in high-secure mode. The default is 10 characters. To configure this option to the default value, use the default operator with the command.
<code>password-history <3-32></code>	Specifies the number of previous passwords the switch stores. You cannot reuse a password that is stored in the password history. The default is 3. To configure this option to the default value, use the default operator with the command.

Configuring directed broadcast

A directed broadcast is a frame sent to the subnet broadcast address on a remote IP subnet. When you disable (or suppress) directed broadcasts on an interface, all frames sent to the subnet broadcast address for a local router interface are dropped. Disabling directed broadcasts protects hosts from possible denial-of-service (DOS) attacks. By default, this feature is enabled on the device.

Procedure

1. Enter VLAN Interface Configuration mode:

```
enable

configure terminal

interface vlan <1-4059>
```
2. Configure the switch to forward directed broadcasts for a VLAN:

```
ip directed-broadcast enable
```

Example

Enable directed broadcast on a VLAN:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 2
Switch:1(config-if)#ip directed-broadcast enable
```

Display VLAN IDs with directed broadcast enabled:

```
Switch:1>show ip directed-broadcast vlan

                                Vlan Directed-Broadcast
=====
  VLAN ID  DIRECTED-BROADCAST
-----
      2           true
```

Variable Definitions

The following table defines parameters for the **ip directed-broadcast** command.

Variable	Value
<i>enable</i>	Enables the device to forward directed broadcast frames to the specified VLAN. The default setting for this feature is enabled.

Preventing certain types of DOS attacks

Protect the switch against IP packets with illegal IP addresses such as loopback addresses or a source IP address of ones, or Class D or Class E addresses from being routed. The switch supports high-secure configurable flag.

About This Task

Important

After you enable this flag, the desired behavior (not routing source packets with an IP address of 255.255.255.255) applies to all ports that belong to the same port.

Important

The setting to enable hsecure only takes effect for packets going to the CP; not to datapath traffic.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable high-secure mode:

```
high-secure [port {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]] enable
```

Example

```
Switch:1> enable  
Switch:1# configure terminal  
Switch:1(config)# interface GigabitEthernet 1/16  
Switch:1(config-if)# high-secure enable
```

Variable Definitions

The following table defines parameters for the **high-secure** command.

Variable	Value
<code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Specifies the port on which you want to enable high-secure mode. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<code>enable</code>	Enables the high-secure feature that blocks packets with illegal IP addresses. This flag is disabled by default. Use the no operator to remove this configuration. To configure this option to the default value, use the default operator with the command.

Configuring port lock

Configure port lock to administratively lock a port or ports to prevent other users from changing port parameters or modifying port action. You cannot modify a locked port until you unlock the port.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable port lock globally:

```
portlock enable
```

3. Enter GigabitEthernet Interface Configuration mode:

```
interface gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

4. Lock a port:

```
lock [port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]]
enable
```

Example

```
Switch:1> enable
Switch:1# configure terminal
```

Log on to GigabitEthernet Interface Configuration mode:

```
Switch:1(config)# interface GigabitEthernet 1/1
```

Lock port 1/1:

```
Switch:1(config-if)# lock port 1/1 enable
```

Unlock port 1/1:

```
Switch:1(config-if)# no lock port 1/1 enable
```

Variable Definitions

The following table defines parameters for the **interface gigabitethernet** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

The following table defines parameters for the **lock port** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Specifies the port you want to lock. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. The default is disabled.

Unicast Reverse Path Forwarding configuration using CLI

This section provides CLI procedures for Unicast Reverse Path Forwarding configuration.

Enable urpf-mode Boot Flag

To configure Unicast Reverse Path Forwarding on a port or VLAN, you are required to enable the urpf-mode boot flag. If you try to configure uRPF on an interface, that is, enable or change the urpf operating mode with the urpf-mode boot flag disabled, a consistency check error message is displayed: Unicast Reverse Path Forwarding configuration is not supported when urpf-mode boot flag is disabled.

About This Task

Use the following procedure to enable the urpf-mode boot flag. By default, urpf-mode is disabled.

Procedure

1. Enter Global Configuration mode:

```
enable
configure terminal
```
2. Enable the urpf-mode boot flag:

```
boot config flags urpf-mode
```

3. When you get the following prompt to reboot the switch, enter `y` to reboot.

```
The new setting requires a reboot to take effect!
```

```
The configuration will be saved and rebooted.
```

```
Are you sure you want to re-boot the switch (y/n)?
```

**Note**

If you enter `n`, the following message is displayed: Warning: Please save the configuration and reboot the switch for this configuration to take effect.

4. Check the status of the urpf-mode boot flag:

```
show boot config flags
```

Example

Enable the urpf-mode boot flag:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# boot config flags urpf-mode
The new setting requires a reboot to take effect!
The configuration will be saved and rebooted.
Are you sure you want to re-boot the switch (y/n)? y
```

View the status of the urpf-boot flag:

**Note**

Flag support can vary across hardware models.

```
Switch:1#show boot config flags
flags advanced-feature-bandwidth-reservation low
flags block-snmp false
flags debug-config false
flags debugmode false
flags dvr-leaf-mode false
flags enhancedsecure-mode false
flags factorydefaults false
flags flow-control-mode true
flags ftpd true
flags hsecure false
flags ipv6-egress-filter true
flags ipv6-mode false
flags logging true
flags macsec false
flags nni-mstp false
flags reboot true
flags spanning-tree-mode mstp
flags spbm-config-mode true
flags spbm-node-scaling true
flags sshd true
flags syslog-rfc5424-format true
flags telnetd true
flags tftpd true
flags trace-logging false
flags urpf-mode true
```

```
flags verify-config true
flags vrf-scaling true
```

Configuring unicast reverse path forwarding on a port

About This Task

You can use the Unicast Reverse Path Forwarding (uRPF) feature to reduce the problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network. When you enable uRPF, the switch performs a check to determine if the source IP address of the packet is verifiable. If the address is not verifiable, the system drops the packet.

uRPF runs in two modes:

- strict mode
- loose mode (exist-only mode)

Before You Begin

- You must enable the urpf-mode boot flag. See [Enable urpf-mode Boot Flag](#) on page 2603.

Note

When you try to configure uRPF on an interface, that is, enable or change the urpf operating mode with the urpf-mode boot flag disabled, a consistency check error message is displayed: `Unicast Reverse Path Forwarding configuration is not supported when urpf-mode boot flag is disabled.`

- You must log on to the GigabitEthernet Interface Configuration mode in CLI.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format `slot/port/sub-port`.

2. Set or change the urpf operating mode on a port:

For IPv4, enter: `ip rvs-path-chk mode {strict|exist-only}`

For IPv6, enter: `ipv6 rvs-path-chk mode {strict|exist-only}`

3. Verify the configuration on the port:

For IPv4, enter: `show ip interface gigabitethernet`

For IPv6, enter: `show ipv6 interface gigabitethernet`

Example

Example for IPv4:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface GigabitEthernet 1/10
```

Check whether the source IP address of the incoming packet exists in the FIB table:

```
Switch:1(config-if)# ip rvs-path-chk mode strict
```

Verify the configuration on the port:

```
Switch:1(config-if)# show ip interface gigabitethernet
```

```
=====

Variable Definitions

The following table defines parameters for the `ip rvs-path-chk mode` and `ipv6 rvs-path-chk mode` commands.

Variable	Value
mode{strict exist-only}	Specifies the mode for Unicast Reverse Path Forwarding (uRPF). In strict mode, uRPF checks whether the source IP address of the incoming packet exists in the FIB. If the incoming interface is not the best reverse path, the packet check fails and uRPF drops the packet. In exist-only mode, uRPF checks whether the source IP address of the incoming packet exists in the FIB. The packet is dropped only if the source address is not reachable via any interface on that router.

Configuring unicast reverse path forwarding on a VLAN

About This Task

Use the Unicast Reverse Path Forwarding (uRPF) feature to reduce the problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network. When you enable uRPF, the switch performs a check to determine if the source IP address of the packet is verifiable. If the address is not verifiable, the system drops the packet.

uRPF runs in two modes:

- strict mode
- loose mode (exist-only mode)

Before You Begin

- You must enable the `urpf-mode boot` flag.

Note

When you try to configure uRPF on an interface, that is, enable or change the `urpf` operating mode with the `urpf-mode boot` flag disabled, a consistency check error message is displayed: `Unicast Reverse Path Forwarding configuration is not supported when urpf-mode boot flag is disabled.`

- You must log on to the VLAN Interface Configuration mode in CLI.

Important

You must assign a valid IP address to the selected port.

Procedure

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

- Set or change the urpf operating mode on a VLAN:

For IPv4, enter: `ip rvs-path-chk mode {strict|exist-only}`

For IPv6, enter: `ipv6 rvs-path-chk mode {strict|exist-only}`

- Verify the configuration on the VLAN:

For IPv4, enter: `show interfaces vlan ip`

For IPv6, enter: `show ipv6 interface vlan`

Example

Example for IPv4:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface vlan 2
```

Check whether the source IP address of the incoming packet exists in the FIB table:

```
Switch:1(config-if)# ip rvs-path-chk mode exist-only
```

Verify the configuration on the VLAN:

```
Switch:1(config-if)# show interfaces vlan ip
```

```

Variable Definitions

The following table defines parameters for the **ip rvs-path-chk mode** and **ipv6 rvs-path-chk mode** commands.

Variable	Value
mode{strict exist-only}	Specifies the mode for Unicast Reverse Path Forwarding (uRPF). In strict mode, uRPF checks whether the source IP address of the incoming packet exists in the FIB. If the incoming interface is not the best reverse path, the packet check fails and uRPF drops the packet. In exist-only mode, uRPF checks whether the source IP address of the incoming packet exists in the FIB. The packet is dropped only if the source address is not reachable via any interface on that router.

Viewing unicast reverse path forwarding configuration on a port

About This Task

Use the following procedure to view the status of the uRPF configuration on a port.

Before You Begin

- You must enable the urpf-mode boot flag.

Note

When you try to configure uRPF on an interface, that is, enable or change the urpf operating mode with the urpf-mode boot flag disabled, a consistency check error message is displayed: Unicast Reverse Path Forwarding configuration is not supported when urpf-mode boot flag is disabled.

- You must log on to the GigabitEthernet Interface Configuration mode in CLI.
- You must configure unicast reverse path forwarding on a port.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Verify the configuration on the port:

For IPv4, enter: `show ip interface gigabitethernet`

For IPv6, enter: `show ipv6 interface gigabitethernet`

Example

Example for IPv4:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface GigabitEthernet 1/10
```

Verify the configuration on the port:

```
Switch:1(config-if)# show ip interface gigabitethernet

Viewing unicast reverse path forwarding configuration on a VLAN

About This Task

Use the following procedure to view the status of the uRPF configuration on a VLAN.

Before You Begin

- You must enable the urpf-mode boot flag.

Note

When you try to configure uRPF on an interface, that is, enable or change the urpf operating mode with the urpf-mode boot flag disabled, a consistency check error message is displayed: Unicast Reverse Path Forwarding configuration is not supported when urpf-mode boot flag is disabled.

- You must log on to the VLAN Interface Configuration mode in CLI.

Important

You must assign a valid IP address to the selected port.

- You must configure unicast reverse path forwarding on a VLAN.

Procedure

- Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

- Verify the configuration on the VLAN:

For IPv4, enter: `show interfaces vlan ip`

For IPv6, enter: `show ipv6 interface vlan`

Example

Example for IPv4:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface vlan 2
```

Verify the configuration on the VLAN:

```
Switch:1(config-if)# show interfaces vlan ip
```

```

Configuring Digital Certificates using CLI

The following section provides procedures to configure digital certificates using CLI.

Configure Device Subject Parameters

About This Task

Use this procedure to configure the device subject parameters to identify the device, such as the name, Email ID, company, department, location, and subject name.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure the subject parameters of the device:

```
certificate subject {[common-name WORD<0-64>] [country WORD<2-2>] [e-
mail WORD<0-254>] [locality WORD<0-128>] [organization WORD<0-64>]
[province WORD<0-128>] [subject-name WORD<1-45>] [unit WORD<0-64>]}
```
3. Verify the subject names configured on the switch:

```
show certificate subject
```

Example

Configuring subject parameters:

```

Switch:1>enable
Switch:1#configure terminal
Switch:1(config)# certificate subject common-name 822-pki e-mail
client1@extemenetworks.com unit Engineering
organization ExtremeNetworks locality Salem province Massachusetts country US subject-
name 822

```

View the configuration.

```

Switch:1>show certificate subject
Subject Name      : 822
Common Name       : 822-pki
Email Address     : client1@extemenetworks.com
Organizational Unit : Engineering
Organization      : ExtremeNetworks
Locality          : Salem

```

```

Province           : Massachusetts
Country            : US

Subject Name       : 823
Common Name        : 823-pki
Email Address      : client1@extemenetworks.com
Organizational Unit : Engineering
Organization       : ExtremeNetworks
Locality           : Salem
Province          : Massachusetts
Country            : US

Subject Name       : Global
Common Name        : 821
Email Address      : client1@extemenetworks.com
Organizational Unit : Engineering
Organization       : ExtremeNetworks
Locality           : Salem
Province          : Massachusetts
Country            : US

```

Variable Definitions

The following table defines parameters for the **certificate subject** command.

Variable	Value
<i>common-name</i> <i>WORD<0-64></i>	Specifies the name of the subject sending the Certificate Signing Request to the Certificate Authority.
<i>country</i> <i>WORD<2-2></i>	Specifies the country of the subject sending the Certificate Signing Request to the Certificate Authority.
<i>e-mail</i> <i>WORD<0-254></i>	Specifies the Email address of the subject sending the Certificate Signing Request to the Certificate Authority.
<i>locality</i> <i>WORD<0-128></i>	Specifies the locality of the subject sending the Certificate Signing Request to the Certificate Authority.
<i>organization</i> <i>WORD<0-64></i>	Specifies the organization of the subject sending the Certificate Signing Request to the Certificate Authority.
<i>province</i> <i>WORD<0-128></i>	Specifies the state or province of the subject sending the Certificate Signing Request to the Certificate Authority.
<i>subject-name</i> <i>WORD<1-45></i>	Specifies the Subject Identity Label to be used in local digital certificate request. You can configure up to 10 subject DN identities. If a subject name is not specified, the default subject name is Global.
<i>unit</i> <i>WORD<0-64></i>	Specifies the organizational unit of the subject sending the Certificate Signing Request to the Certificate Authority.

Configure Subject Alternative Names

About This Task

Use this procedure to protect additional host names with a single certificate.

Note

The switch supports 100 subject alternative names.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure a subject alternative name for the entity:

```
certificate subject-alternative-name {[dns WORD<1-255>] [e-mail  
WORD<1-255>] [ip> WORD<1-255>] [subject-name WORD<1-45>]}
```

Note

Note

You can configure up to 10 distinct subject names. The default subject name is Global.

3. View the subject alternative names configured on the switch:

```
show certificate subject-alternative-name
```

Examples

Configure a subject alternative name subject name 822:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#certificate subject-alternative-name subject-name 822 dns
822.extremenetworks.com
Switch:1(config)#certificate subject-alternative-name subject-name 822 e-mail
name@company.com
Switch:1(config)#certificate subject-alternative-name subject-name 822 ip 192.0.2.22
```

View the configuration:

```
Switch:1>show certificate subject-alternative-name
=====
=====
                                SAN Table

```

Variable Definitions

The following table defines parameters for the **certificate subject-alternative-name** command.

Variable	Value
<i>dns</i> WORD<1-255>	Specifies the DNS subject alternative name.
<i>e-mail</i> WORD<1-255>	Specifies the e-mail subject alternative name.
<i>ip</i> WORD<1-255>	Specifies the IP subject alternative name.
<i>subject-name</i> WORD<1-45>	Specifies the Subject Identity Label to be used in local digital certificate request. You can configure up to 10 subject DN identities. If the subject-name is not specified, the default subject name is Global.

Generate the Key Pair

About This Task

Use the following procedure to generate the private and public key pair for the specific cryptography type. By default, the switch generates a 2,048 RSA key when the system starts. You can use this procedure to generate a new RSA key or to generate multiple RSA keys identified by a key-name. You can generate up to 10 RSA keys.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Generate the key pair:

```
certificate generate-keypair {[type rsa size 2048] | [key-name
WORD<1-45>]}
```

Example

Generating the key pair identified by a key-name:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#certificate generate-keypair key-name pki_key
Switch:1(config)#1 2021-06-22T11:33:53.036Z 5520-24X-VOSS CP1 - 0x003a864c - 00000000
```

```
GlobalRouter DIGITALCERT INFO Digicert Key-pair generation is in progress
Switch:1(config):#1 2021-06-22T11:33:53.052Z 5520-24X-VOSS CP1 - 0x003a8604 - 00000000
GlobalRouter
DIGITALCERT INFO Generation of RSA key-pair for digital certificate is successful

Variable Definition

The following table defines parameters for the **generate-keypair** command.

Variable	Value
<i>type rsa</i>	Specifies type of cryptography algorithm used to generate the key-pair. The switch uses only <i>rsa</i> as the cryptography algorithm type.
<i>size 2048</i>	Specifies the size or modulus of key-pair to be generated. The switch only supports 2048.
<i>key-name WORD<1-45></i>	Specifies the key label for RSA 2048 key to be generated. You can configure up to 10 RSA keys by specifying the key-name label. The default key-name label is <i>rsa_2048</i> .

Configure a Trustpoint CA

About This Task

Use this procedure to configure the certificate authority and perform related actions. You can configure up to eight CA trustpoints.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the trustpoint and associate it with the generated key pair:

```
certificate ca WORD<1-45> {[subject-name WORD<1-45>] [common-name WORD<0-64>] [key-name WORD<0-45>] [ca-url WORD<0-1000>] [use-post <true|false>]}
```

3. Configure an SHA-256 fingerprint to authenticate the received CA certificate:

```
certificate ca WORD<1-45> sha256-fingerprint WORD<64-64>
```

4. Configure the appropriate action:

- Configure trustpoint, authenticate the trustpoint CA by getting the certificate of the CA, and store the CA certificate locally:

```
certificate ca WORD<1-45> action caauth
```

- Generate certificate signing request to obtain identity certificate from configured trustpoint CA, get the digital certificate, and store it locally, associating with the trustpoint CA:

```
certificate ca WORD<1-45> action enroll [validity-days <7-1185>]
```

- Get the Certificate Revocation List from the CDP and store into a file:

```
certificate ca WORD<1-45> action get-crl
```

- Install the subject certificate obtained from the given trustpoint CA:

```
certificate ca WORD<1-45> action install
```

- Configure trustpoint and perform no other operation:

```
certificate ca WORD<1-45> action noop
```

- Release the locally stored certificate associated with the trustpoint CA post revocation:

```
certificate ca WORD<1-45> action remove
```

- Generate certificate renew request for given trustpoint CA, get the new digital certificate, and store it locally by replacing the old certificate with the new one:

```
certificate ca WORD<1-45> action renew [validity-days <7-1185>]
```

5. Install the Root Certificate Authority certificate obtained offline:

```
certificate ca WORD<1-45> install-file {root-ca-filename WORD<1-80>}
```

6. Set the HTTP request type to support the type of CA:

```
certificate ca WORD<1-45> use-post <false | true>
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#certificate ca ej common-name CaA2 key-name pki_key subject-name 822
Switch:1(config)#certificate ca ej action enroll
Switch:1(config)#CP1 [07/21/16 12:22:11.992:CEST] 0x003a8604 00000000 GlobalRouter

Variable Definitions

The following table defines parameters for the **certificate ca** command.

Variable	Value
<code>action caauth</code>	Authenticates the trustpoint CA by getting the certificate of the CA and stores the CA certificate locally.
<code>action enroll</code> <code>[validity-days <7-1185>]</code>	Generates certificate signing request to obtain identity certificate from configured trustpoint CA, gets the digital certificate, and stores it locally, associating with the trustpoint CA. The validity-days specifies the number of days for which the certificate will remain valid. The default value is 365 days.
<code>action get-crl</code>	Gets the Certificate Revocation List from the CDP and stores into a file.
<code>action install</code>	Installs the subject certificate obtained from the given trustpoint CA.
<code>action noop</code>	Specifies that no operation should be performed after configuring trustpoint.
<code>action remove</code>	Releases the locally stored certificate associated with the trustpoint CA post revocation.
<code>action renew</code> <code>[challenge-password</code> <code>WORD<0-128>]</code>	Specifies the password. This password is provided offline by the CA during the end entity registration.
<code>action renew</code> <code>[validity-days <7-1185>]</code>	Generates certificate renewal request for given trustpoint CA, gets the digital certificate, and stores it locally by replacing the old certificate with the new one. The validity-days specifies the number of days for which the certificate will remain valid. The default value is 365 days.
<code>ca WORD<1-45></code>	Specifies the name of the CA. You can configure up to 8 CA trustpoints by specifying the CA name. It should be alphanumeric and case-sensitive. The maximum length should be 45 characters.
<code>ca-url WORD<0-1000></code>	Specifies the trusted CA url.
<code>common-name</code> <code>WORD<0-64></code>	Specifies the name of the owner of the device or user.
<code>key-name WORD<0-45></code>	Specifies the key pair generated by the command that was first associated with the CA trustpoint.
<code>install-file root-ca-filename</code> <code>WORD<1-80></code>	Installs the Root CA file obtained offline from the CA.
<code>sha256-fingerprint</code> <code>WORD<64-64></code>	Specifies an encrypted fingerprint of the expected certificate to match.
<code>subject-name</code> <code>WORD<1-45></code>	Specifies the configured Subject Identity label. The default is Global.
<code>use-post <false true></code>	Specify the HTTP request style. The default value is True. For example, True for EJBCA and False for Win2012 CA.

*Install the Certificate***About This Task**

Use this procedure to install the following:

- certificate authority (CA) certificate
- root CA certificates
- subject certificates
- Certificate Revocation List (CRL) file obtained offline from the CA

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Install the offline CA certificate:

```
certificate install-file offline-ca-filename WORD<1-80>
```

3. Install the CRL offline file:

```
certificate install-file offline-crl-filename WORD<1-80>
```

4. Install the root CA offline certificate:

```
certificate install-file offline-root-ca-filename WORD<1-80>
```

5. Install the subject offline certificate:

```
certificate install-file offline-subject-filename WORD<1-80> [relaxed]
[key-name WORD<1-45>] [subject-name WORD<1-45>]
```

**Note**

To obtain the offline subject certificate, you must first generate a certificate signing request (CSR).

6. (Optional) Install the subject offline certificate with PKCS12-format:

```
certificate install-file offline-subject-filename WORD<1-80> relaxed
pkcs12-password WORD<1-128>
```

Example

View the installed offline subject certificate:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1#certificate install-file offline-subject-filename 823pki.crt subject-name 823 key-
name pki

Variable Definitions

The following table defines parameters for the **certificate install-file** command.

Variable	Definition
<i>offline-ca-filename</i> WORD<1-80>	Specifies the certificate authority (CA) file name obtained from the CA.
<i>offline-crl-filename</i> WORD<1-80>	Specifies the CRL file obtained from the CA.
<i>offline-root-ca-filename</i> WORD<1-80>	Specifies the root CA file name obtained from the CA.
<i>offline-subject-filename</i> WORD<1-80>	Specifies the subject certificate file name obtained from the CA.
<i>relaxed</i> [<i>pkcs12-password</i> WORD<1-128>]	Uses the relaxed mode for offline subject certificate installation for less restrictive consistency checks. You can also install a PKCS12 format certificate and secret key in relaxed mode. WORD<1-128> is the password to extract the PKCS12 container. If you do not include this parameter, the supported format is Distinguished Encoding Rules (DER).
<i>key-name</i> WORD<1-45>	Refers to the key name of the generated key-pair.
<i>subject-name</i> WORD<1-45>	Refers to the subject identity name.

Generate the Certificate Signing Request

About This Task

Use this procedure to generate a certificate signing request (CSR) and store it into a file. This CSR is required to obtain the offline subject certificate. The generated file is located in the `/intflash/shared/certs` folder.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Generate certificate signing request:

```
certificate generate-csr [relaxed]
```
3. (Optional) Configure the subject-name and the key name:

```
certificate generate-csr subject-name WORD<1-45> key-name WORD<1-45>
```

Example

Display the generated CSR.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#certificate generate-crs subject-name 823 key-name pki
Switch:1(config)#1 2021-02-02T13:57:39.716z Switch CP1 - 0x003a8635 - 0000000
GlobalRouter DIGITALCERTIFICATE INFO Generate CSR for Digital Certificate successful!
```

*Display Configured Key Pairs***About This Task****Procedure**

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Display the names and public keys of all the key-pairs:

```
show certificate key-name [WORD<1-64>]
```

Example

The following output example displays the names and public keys of all the key-pairs.

```
Switch:1(config)#show certificate key-name

Key Name: pki_key

View the Certificate Details

About This Task

Use this procedure for the following tasks:

- Displaying the digital certificate for given certificate type or list all the certificate details from the local store for given certificate type.
- Displaying the CA details for a given trustpoint CA name or listing all the CA details from the local store if the CA name is not specified.
- Displaying the configured key details for given key name.
- Displaying the configured subject details.

Procedure

1. To enter User EXEC mode, log on to the switch.

2. Display the digital certificate for given certificate type:

```
show certificate cert-type [default-tls-certificate] | [intermediate-
ca-cert WORD<1-80>] | [offline-ca-cert] | [offline-subject-cert] |
[online-ca-cert] | [online-subject-cert] | [root-ca-cert WORD<1-80>]
```

3. Display the certificate authority details:

```
show certificate ca WORD<1-45>
```

4. Display the name and public key of all the key-pairs:

```
show certificate key-name
```

5. Display the details of the configured subject:

```
show certificate subject
```

Example

Display the Root CA certificate:

```
Switch:1>show certificate cert-type root-ca-cert

Variable Definitions

The following table defines parameters for the **show certificate** command.

Variable	Value
cert-type default-tls-certificate	Displays the default TLS certificate (self-signed).
cert-type online-ca-cert	Specifies Certificate Authority's Certificate obtained online from Certificate Authority.
cert-type online-subject-cert	Specifies subject certificate obtained online from Certificate Authority.
cert-type offline-ca-cert	Specifies Certificate Authority's certificate obtained offline from Certificate Authority.
cert-type offline-subject-cert	Specifies subject certificate obtained offline from Certificate Authority.
cert-type intermediate-ca-cert [WORD<1-80>]	Specifies the intermediate certificate obtained offline from Certificate Authority.
cert-type root-ca-cert [WORD<1-80>]	Specifies root certificate obtained offline from Root Certificate Authority.
ca [WORD<1-45>]	Specifies name of the Certificate Authority. If the name is not specified, the command displays the CA details of all configured CA.

*Configure a Web Server Certificate***About This Task**

Use this task to configure a web server certificate.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure the Certificate Authority for the installed digital certificate:

```
web-server certificate ca-name <1-45>
```
3. Configure the subject identity label to be used

```
web-server certificate cert-subject-name <1-45>
```

Example

Display the web server certificate information:

```
Switch:1(config)#web-server certificate cert-subject-name 823
Switch:1(config)#1 2021--2--2T14:35:38.865z Switch CP1 - 0x003z8604 - 0000000
GlobalRouter DIGITALCERT INFO Digital Certificate Module: Configuration Saved
1 2021--2--2T14:35:38.865z Switch CP1 Switch CP1 - 0x00040601 - 0000000 Global Router
WEB INFO HTTPS: Using the CA Signed Server Cert
```

Variable Definitions

Use the data in the following table to use the **web-server certificate** command

Variable	Value
<i>ca-name</i> WORD<1-45>	Specifies the name of the Certificate Authority.
<i>ca-subject-label</i> WORD<1-45>	Specifies the name of the local certificate used.

*Configure Certificate Authority Trustpoint for Syslog***Before You Begin**

Configure and install the digital certificate.

About This Task

Use this procedure to configure the certificate authority for the syslog.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure the Certificate Authority trustpoint:

```
syslog certificate ca-common-name WORD<1-45>
```

Variable Definitions

The following table defines parameters for the **syslog certificate** command.

Variable	Value
<code>ca-common-name WORD<1-45></code>	Specifies the Certificate Authority common name.

Digital certificate configuration examples

This section shows how to obtain an online CA signed certificate, remove the expired certificate, renew the certificate, and install an offline subject certificate.

Obtain an Online CA-signed Subject Certificate

Use the following procedure as an example to obtain an online CA signed subject certificate that the application can use.

About This Task

In the following commands, the variable `WORD<1-45>` refers to the name of the certificate authority and the variable `WORD<1-80>` refers to the certificate filename.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the subject:

```
certificate subject common-name 822-pki
certificate subject e-mail 822@extremenetworks.com
certificate subject unit Engineering
certificate subject organization ExtremeNetworks
certificate subject locality Salem
certificate subject country US
certificate subject province Massachusetts
certificate subject subject-name 822

certificate subject common-name 823-pki
certificate subject e-mail 823@extremenetworks.com
certificate subject unit Engineering
certificate subject organization ExtremeNetworks
certificate subject locality Salem
certificate subject country US
certificate subject province Massachusetts
certificate subject subject-name 823
```

Note

The values mentioned are for example only.

3. Generate the key pair:

```
certificate generate-keypair {[type rsa size 2048] | [key-name WORD<1-45>]}
```

- Configure the certificate authority (CA):

```
certificate ca ej common-name subca5
certificate ca ej key-name rsa_2048
certificate ca ej ca-url http://192.51.100.9:8080/ejbca/publicweb/apply/scep/test/
pkiclient.exe
certificate ca ej use-post true
```

Note

The values mentioned are for example.

- Use SCP to upload the Root CA certificate to: `/intflash/shared/certs`.
- Install the Root CA certificate:

```
certificate ca WORD<1-45> install-file root-ca-filename WORD<1-80>
```

- Authenticate the CA:

```
certificate ca WORD<1-45> action caauth
```

- Enroll the subject certificate by the CA:

```
certificate ca WORD<1-45> action enroll
```

- Install the certificate:

```
certificate ca WORD<1-45> action install
```

- (Optional) If the certificate expires, remove the enrolled subject certificate:

```
certificate ca WORD<1-45> action remove
```

- (Optional) To obtain the new certificate before the old certificate expires, enter the following command to renew the certificate:

```
certificate ca WORD<1-45> action renew
```

The Certificate Authority generates a new certificate for the subject.

Install an Offline CA Certificate

Use the following procedure as an example to install an offline CA certificate.

About This Task

In the following commands, the variable `WORD<1-80>` refers to the certificate filename.

Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

- Configure the subject:

```
certificate subject common-name 822-pki
certificate subject e-mail client1@extemenetworks.com
certificate subject unit Engineering
certificate subject organization ExtremeNetworks
certificate subject locality Salem
certificate subject province Massachusetts
```

```
certificate subject country US
certificate subject subject-name 822
```

**Note**

The values mentioned are for example only.

3. Generate the certificate signing request to support multiple subject identities on the switch:

```
certificate generate-csr subject-name WORD< 1-45> key-name WORD<1-64>
```

```
#certificate generate-csr subject-name 823 key-name mimi
Switch:1(config)#1 2021-02-02T13:57:39.716Z 5520-24X-VOSS CP1 - 0x003a8635 - 00000000
GlobalRouter DIGITALCERT
INFO Generate CSR For Digital Certificate successful!
```

4. Use the generated CSR file to enroll the certificate on the server.
5. Use SCP to upload the enrolled certificate along with Root certificate and all intermediary certificates to:

```
/intflash/shared/certs/
```

6. Install the Root CA certificate:

```
certificate install-file offline-root-ca-filename WORD<1-80>
```

**Note**

If the subject certificate issuer is directly the Root, then Step 7 and 8 are optional. If the subject is issued by Intermediate CA, then Step 7 and 8 are mandatory, also in the certificate chain between Root and Subject, all the Intermediates must be installed using these steps.

7. Copy and paste the Intermediate CA certificate to:

```
/intflash/shared/certs/
```

8. Install the intermediate CA:

```
certificate install-file offline-ca-filename WORD<1-80>
```

9. Install the offline subject filename:

```
certificate install-file offline-subject-filename WORD<1-80>
```

```
#certificate install-file offline-subject-filename sd

Error: File Name Not Found in /intflash/shared/certs/ or /intflash/.cert/.offlineCert/
#certificate install-file offline-subject-filename 823mimi.crt subject-name 823 key-

Configuring X.509 V3 certificates for SSH Two Factor Authentication

Use the following procedure as an example to configure the SSH server on the VOSS switch, and the SSH client Secure CRT for two factor authentication using X.509 V3 certificates.

Before You Begin

The following certificates must be loaded on the SSH server and SSH client:

- For the Secure CRT (SSH client):
 - subject certificate from the PIV card.
- For the VOSS switch (SSH server):
 - CAC-server.pem - the subject certificate
 - ca.cert.pem - the root CA certificate
 - Self-signedTrustAnchorCertificate.cer - the root CA certificate that signed the intermediate certificate
 - RSA2048IssuingCACertificate.cer - the intermediate certificate signed by the previous root CA that signed the subject certificate.

About This Task

Use the following steps as an example to configure the SSH server on the VOSS switch, the RADIUS Windows server, and the SSH client Secure CRT.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Ensure the switch is running in Enhanced Secure Mode:

```
Switch:1(config)#show boot config flags
flags enhancedsecure-mode true
```

Note

This shows a partial output of only the relevant entry.

3. Ensure the switch clock is synchronized:

```
Switch:1#show clock
System Clock time : Fri Oct 12 19:36:36 2018 UTC
```

4. Provision PKI with certificates.

For information about provisioning PKI with certificates, see the following sections:

- [Obtain an Online CA-signed Subject Certificate](#) on page 2633
- [Install an Offline CA Certificate](#) on page 2634

X.509 Authentication Username Option Example

Use the following procedure as an example to configure username authentication options using X.509 V3 certificates.

Procedure

1. Enable X.509 V3 authentication username override:

```
Switch:1(config)# ssh x509v3-auth username overwrite
```

The switch disregards the username sent by the SSH client and uses the principal name from the client's certificate for authentication. If RADIUS authentication is configured, the username is sent after you type the RADIUS password. For example, if you configure the SSH client with the username "John" and enable x509v3-auth username overwrite on the device, the switch sends the principal name 1403824387@mil to the RADIUS server for authorization.

```

64 5c 85 78 10 93 ee
Cert: 8066aec3484d3740d7d99ec2f5ed1983365bb1
```

2. Enable X.509 V3 authentication username strip:

```
Switch:1(config)#ssh x509v3-auth username strip-domain
```

If x509v3-auth username strip-domain is configured, the switch sends the principal name without the domain to the RADIUS for authorization. The username is sent after you type the RADIUS password. For example: If you select principal name 1403824387@mil, the switch sends the principal name 1403824387 without the domain to the RADIUS server for authorization.

```
Test CAC John Smith
Issuer: CN=DOD JITC ID CA-49, OU=PKI, OU=DoD, O=U.S. Government, C=US
NotBefore: 12/19/2017 7:00 PM

Serial: 019ab3
SubjectAltName: Other Name:Principal Name=1403824387@mil, Other
Name:2.16.840.1.101.3.6.6=04 19 d4 f8 10 da 08 26 6c 10 e7 22 e5 83 68 5a 04 0e 44 82
64 5c 85 78 10 93 ee
Cert: 8066aec3484d3740d7d99ec2f5ed1983365bb129
```

3. Enable X.509 V3 authentication username use-domain:

```
Switch:1(config)ssh x509v3-auth username use-domain extreme.com
```

If you select the username as the principal name, the switch sends the principal name from the certificate with the domain configured on the switch to the RADIUS for authorization. The username is sent after typing the RADIUS password. For example: If you configure use-domain "extreme.com" on the switch and you configure the username to be the principal name 1403824387@mil, the switch sends the username 1403824387@extreme.com to the RADIUS server for authorization.

```

4. RADIUS server is not configured:

If the Radius server is not configured, the authorization fallbacks locally on the switch, for the username. You must configure the usernames on the switch. You are prompted for the password. For example: If you select the principal name 1403824387@mil, the switch authorizes locally the username as 1403824387@mil or 1403824387 if strip domain is enabled. You are prompted for the password.

Configure TCP Keepalive and TCP Timestamp

About This Task

TCP Keepalive configures the system TCP keepalive interval, probes, and time.

TCP Timestamp option (RFC 1323) allows TCP to determine the order in which the packets are sent. The TCP Timestamp provides protection against Wrapped Sequence numbers. However, it is possible to calculate the system uptime when the Timestamp option is enabled. The analysis of timestamp behaviour can provide information on the system identity, which poses security threats and can cause a potential attack.

The TCP Timestamp option is enabled by default. You can disable the timestamp to avoid any security risks.

Note

The configuration will be applied only to the new TCP connections and the existing connections are not affected. You must perform a **config save** and **reboot** to apply the new configuration to all TCP connections.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure the TCP keepalive interval:

```
sys control tcp-keepalive-interval <1-3600>
```
3. Configure the TCP keepalive probes:

```
sys control tcp-keepalive-probes <1-50>
```

4. Configure the TCP keepalive time:

```
sys control tcp-keepalive-time <5-65535>
```
5. Enable the TCP Timestamp:

```
sys control tcp-timestamp
```
6. Disable the TCP Timestamp:

```
no sys control tcp-timestamp
```
7. View the status of TCP Timestamp:

```
show sys control
```

Examples

Configure the TCP keepalive to interval 60 seconds, with 15 probes, and 120 seconds time:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#sys control tcp-keepalive-interval 60
Switch:1(config)#sys control tcp-keepalive-probes 15
Switch:1(config)#sys control tcp-keepalive-time 120
```

Disable TCP Timestamp:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#no sys control tcp-timestamp
```

Warning: Existing TCP connections won't be affected.
A config save and reboot is required to apply this configuration for all TCP connections

Display the status of the TCP Timestamp:

```
Switch:1>show sys control
```

```
=====
                        System Control Settings
=====
      tcp-timestamp : disable
      tcp-keepalive-time : 120
      tcp-keepalive-interval : 60
      tcp-keepalive-probes : 15
      mac-move-protection : on
```

Variable Definitions

The following table defines parameters for the **sys control** command.

Variable	Value
<i>tcp-keepalive-interval</i> <1-3600>	Configure the TCP keepalive interval in seconds. The default is 10.
<i>tcp-keepalive-probes</i> <1-50>	Configure the TCP keepalive probes. The default is 5.

Variable	Value
<code>tcp-keepalive-time <5-65535></code>	Configure the TCP keepalive time in seconds. The default is 60.
<code>tcp-timestamp</code>	<p>Enable or disable tcp-timestamp.</p> <p>Note: The timestamp is enabled by default. The system displays the following warning message when a new configuration is applied: Warning: Existing TCP connections won't be affected. A config save and reboot is required to apply this configuration for all TCP connections.</p>

Enable Authentication for Privileged EXEC Command Mode using CLI

With authentication enabled, you must enter a username and password to access Privileged EXEC command mode from User-EXEC command mode. The username and password is the same username and password you used to Telnet or SSH to the switch.

Note

When you enable authentication for the Privileged EXEC CLI command mode, the changes do not affect any existing CLI sessions. For the changes to take effect, you must first log out from your current CLI session and log back in on a new session.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Enable authentication for Privileged EXEC CLI command mode:
`sys priv-exec-password`
3. Verify the configuration:
`show sys priv-exec-password`

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

Switch:1(config)#sys priv-exec-password
```

Enable MAC Move Protection on vIST

About This Task

Perform this procedure to enable MAC move protection on virtual interswitch trunk (vIST).

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable MAC move protection:

```
sys control virtual-ist mac-move-protection
```
3. Confirm the configuration:

```
show sys control
```

Examples

Enable MAC move protection on vIST:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#sys control virtual-ist mac-move-protection
Switch:1>show sys control
```

```
=====
                        System Control Settings
=====
      tcp-timestamp : disable
      tcp-keepalive-time : 120
tcp-keepalive-interval : 60
      tcp-keepalive-probes : 15
      mac-move-protection : on
```

Variable Definitions

The following table defines parameters for the **sys control virtual-ist** command.

Variable	Value
<i>mac-move-protection</i>	Enable MAC move protection on vIST. The default value is disabled.

Security Configuration using EDM

Configure security information used on the control and data paths to protect the network from uncontrolled access to network resources.

For more information about how to configure passwords and access policies, see [System access configuration using EDM](#) on page 2917.

Enable Port Lock**About This Task**

Use the port lock feature to administratively lock a port or ports to prevent other users from changing port parameters or modifying port action. You cannot modify locked ports until you first unlock the port.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **Port Lock** tab.
4. To enable port lock, select the **Enable** check box.
5. Click **Apply**.

Port Lock field descriptions

Use the data in the following table to use the **Port Lock** tab.

Name	Description
Enable	Activates the port lock feature. Clear this check box to unlock ports. The default is disabled.
LockedPorts	Lists the locked ports. Click the ellipsis (...) button to select the ports you want to lock or unlock.

Lock a Port

Before You Begin

- You must enable port lock before you lock or unlock a port.

About This Task

Use the port lock feature to administratively lock a port or ports to prevent other users from changing port parameters or modifying port action. You cannot modify locked ports until you first unlock the port.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **Port Lock** tab.
4. In the **LockedPorts** box, click the ellipsis (...) button.
5. Click the desired port or ports.
6. Click **Ok**.
7. In the **Port Lock** tab, click **Apply**.

Port Lock field descriptions

Use the data in the following table to use the **Port Lock** tab.

Name	Description
Enable	Activates the port lock feature. Clear this check box to unlock ports. The default is disabled.
LockedPorts	Lists the locked ports. Click the ellipsis (...) button to select the ports you want to lock or unlock.

Change Passwords

About This Task

Configure new passwords for each access level, or change the logon or password for the different access levels of the system to prevent unauthorized access. After you receive the switch, use default passwords to initially access CLI. If you use Simple Network Management Protocol version 3 (SNMPv3), you can change passwords in encrypted format.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **CLI** tab.
4. Specify the username and password for the appropriate access level.
5. Click **Apply**.

CLI Field Descriptions

The following table defines parameters for the **CLI** tab.

Name	Description
RWAUserName	Specifies the user name for the read-write-all CLI account.
RWAPassword	Specifies the password for the read-write-all CLI account.
RWEnable	Activates the read-write access. The default is enabled.
RWUserName	Specifies the user name for the read-write CLI account.
RWPassword	Specifies the password for the read-write CLI account.
RWL3Enable	Activates the read-write Layer 3 access. The default is enabled.
RWL3UserName	Specifies the user name for the Layer 3 read-write CLI account.
RWL3Password	Specifies the password for the Layer 3 read-write CLI account.
RWL2Enable	Activates the read-write Layer 2 access. The default is enabled.
RWL2UserName	Specifies the user name for the Layer 2 read-write CLI account.
RWL2Password	Specifies the password for the Layer 2 read-write CLI account.
RWL1Enable	Activates the read-write Layer 1 access. The default is enabled.
RWL1UserName	Specifies the user name for the Layer 1 read-write CLI account.
RWL1Password	Specifies the password for the Layer 1 read-write CLI account.
ROEnable	Activates the read-only CLI account. The default is enabled.
ROUserName	Specifies the user name for the read-only CLI account.

Name	Description
ROPassword	Specifies the password for the read-only CLI account.
MaxTelnetSessions	Specifies the maximum number of concurrent Telnet sessions in a range from 0–8. The default is 8.
Timeout	Specifies the number of seconds of inactivity for a Telnet before the system initiates automatic timeout and disconnect, expressed in a range from 30–65535. The default is 900 seconds.
NumAccessViolations	Indicates the number of CLI access violations detected by the system. This variable is a read-only field.
CustomBannerText	Specifies the text message that is displayed to users on the CLI before authentication. The message can be company information, such as company name and contact, or a warning message for the users of CLI. With character limitation from 1-1800, the text box displays 79 characters per line.
CustomBannerEnable	Specifies whether custom logon banner is enabled or disabled. The default is enabled.

Configure Directed Broadcast on a VLAN

Configure directed broadcast on a VLAN to enable or disable directed broadcast traffic forwarding for an IP interface.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANs**.
3. Select the **Basic** tab.
4. Select a VLAN.
5. Click **IP**.
6. Click the **Direct Broadcast** tab.
7. Select **DirectBroadcastEnable**.

Important

Configure multiple VLANs or IPs in the same subnet but in different systems simultaneously.

8. Click **Apply**.

Direct Broadcast field descriptions

Use the data in the following table to use the **Direct Broadcast** tab.

Name	Description
DirectBroadcastEnable	Specifies that an Isolated Routing Port (IRP) can forward directed broadcast traffic. A directed broadcast is a frame sent to the subnet broadcast address on a remote IP subnet. By disabling or suppressing directed broadcast on an interface, all frames sent to the subnet broadcast address for a local router interface are dropped. Disabling this function protects a host from possible denial of service (DoS) attacks. With the feature enabled, the Control Processor (CP) does not receive a copy of the directed broadcast. As a result, the system does not respond to a subnet broadcast ping sent from a remote subnet. The default is disabled.

Unicast Reverse Path Forwarding configuration using EDM

This section provides EDM procedures for Unicast Reverse Path Forwarding configuration.

*Configure Reverse Path Checking on a Port***Before You Begin**

- The system supports reverse path checking only on ports that have a valid IP address.

About This Task

Configure reverse path checking on a port to determine if a packet IP address is verifiable. Use reverse path checking to reduce the problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network. After you enable reverse path checking, the switch performs a reverse path check to determine if the packet IP address is verifiable. If the address is not verifiable, the system discards the packet.

Reverse path checking operates in one of two modes:

- exist-only mode
- strict mode

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Click **IP**.
4. Click the **Reverse Path Checking** tab.
5. Select the **Enable** check box to enable reverse path checking.
6. Select **exist-only** or **strict**.
7. Click **Apply**.

Reverse Path Checking field descriptions

Use the data in the following table to use the **Reverse Path Checking** tab.

Name	Description
Enable	Enables reverse path checking on the selected port. The default is disabled.
Mode	Specifies the mode for reverse path checking. The modes are <ul style="list-style-type: none"> • exist-only—reverse path checking checks whether the incoming packet source IP address exists in the routing table. If reverse path checking finds the source IP entry, the packet is forwarded; otherwise the packet is discarded. • strict—reverse path checking checks whether the incoming packet source IP address exists in routing table. If reverse path checking does not find the source IP entry, the packet is dropped; otherwise, reverse path checking further checks if the source IP interface matches the incoming interface of the packet. If they match, the packet is forwarded; otherwise the packet is discarded. The default is exist-only.

*Configure Reverse Path Checking on an IPv6 Port***Before You Begin**

- The system supports reverse path checking only on ports that have a valid IP address.

About This Task

Configure reverse path checking on a port to determine if a packet IP address is verifiable. Use reverse path checking to reduce the problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network. After you enable reverse path checking, the switch performs a reverse path check to determine if the packet IP address is verifiable. If the address is not verifiable, the system discards the packet.

Reverse path checking operates in one of two modes:

- exist-only mode
- strict mode

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Click **IPv6**.
4. Click the **Reverse Path Checking** tab.
5. Select the **ReversePathCheckEnable** check box to enable reverse path checking.
6. Select **exist-only** or **strict**.
7. Click **Apply**.

Reverse Path Checking field descriptions

Use the data in the following table to use the **Reverse Path Checking** tab.

Name	Description
ReversePathCheckEnable	Enables reverse path checking on the selected port. The default is disabled.
ReversePathCheckMode	<p>Specifies the mode for reverse path checking. The modes are</p> <ul style="list-style-type: none"> • exist-only—reverse path checking checks whether the incoming packet source IP address exists in the routing table. If reverse path checking finds the source IP entry, the packet is forwarded; otherwise the packet is discarded. • strict—reverse path checking checks whether the incoming packet source IP address exists in routing table. If reverse path checking does not find the source IP entry, the packet is dropped; otherwise, reverse path checking further checks if the source IP interface matches the incoming interface of the packet. If they match, the packet is forwarded; otherwise the packet is discarded. <p>The default is exist-only.</p>

Configure Reverse Path Checking on a VLAN

Before You Begin

- Before you can configure reverse path checking on a VLAN, you must assign a valid IP address to the selected VLAN.

About This Task

Configure reverse path checking on a VLAN to determine if a packet IP address is verifiable. Use reverse path checking to reduce the problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network. After you enable reverse path checking, the switch performs a reverse path check to determine if the packet IP address is verifiable. If the address is not verifiable, the system discards the packet.

Reverse path checking operates in one of two modes:

- exist-only mode
- strict mode

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the VLAN on which you want to configure reverse path checking.
4. In the toolbar, click **IP**.
5. Click the **Reverse Path Checking** tab.
6. Select the **Enable** box to enable reverse path checking.
7. Select **exist-only** or **strict**.
8. Click **Apply**.

Reverse Path Checking field descriptions

Use the data in the following table to use the **Reverse Path Checking** tab.

Name	Description
Enable	Enables reverse path checking on the selected VLAN.
Mode	<p>Specifies the mode for reverse path checking. The modes are</p> <ul style="list-style-type: none"> • exist-only—reverse path checking checks whether the incoming packet source IP address exists in the routing table. If reverse path checking finds the source IP entry, the packet is forwarded; otherwise, the packet is discarded. • strict—reverse path checking checks whether the incoming packet source IP address exists in routing table. If reverse path checking does not find the source IP entry, then the packet is dropped. Otherwise, reverse path checking further checks if the source IP interface matches the incoming interface of the packet. If they match, then the packet is forwarded. Otherwise, the packet is discarded. <p>The default is exist-only.</p>

*Configure Reverse Path Checking on an IPv6 VLAN***Before You Begin**

- Before you can configure reverse path checking on a VLAN, you must assign a valid IP address to the selected VLAN.

About This Task

Configure reverse path checking on a VLAN to determine if a packet IP address is verifiable. Use reverse path checking to reduce the problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network. After you enable reverse path checking, the switch performs a reverse path check to determine if the packet IP address is verifiable. If the address is not verifiable, the system discards the packet.

Reverse path checking operates in one of two modes:

- exist-only mode
- strict mode

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Click the VLAN on which you want to configure reverse path checking.
5. Click **IPv6**.
6. Click the **Reverse Path Checking** tab.
7. Select the **ReversePathCheckEnable** box to enable reverse path checking.
8. Select **exist-only** or **strict**.

- Click **Apply**.

Reverse Path Checking field descriptions

Use the data in the following table to use the **Reverse Path Checking** tab.

Name	Description
ReversePathCheckEnable	Enables reverse path checking on the selected VLAN.
ReversePathCheckMode	<p>Specifies the mode for reverse path checking. The modes are</p> <ul style="list-style-type: none"> • exist-only—reverse path checking checks whether the incoming packet source IP address exists in the routing table. If reverse path checking finds the source IP entry, the packet is forwarded; otherwise, the packet is discarded. • strict—reverse path checking checks whether the incoming packet source IP address exists in routing table. If reverse path checking does not find the source IP entry, then the packet is dropped. Otherwise, reverse path checking further checks if the source IP interface matches the incoming interface of the packet. If they match, then the packet is forwarded. Otherwise, the packet is discarded. <p>The default is exist-only.</p>

Digital certificate configuration using EDM

The following section provides procedures to configure digital certificates using EDM.

Configure Device Subject Parameters

Use this procedure to configure the device subject parameters to identify the device. The parameters include name, Email ID, company, department, and location of the subject.

Procedure

- In the navigation pane, expand **Configuration > Security > Control Path**.
- Select **Certificate**.
- Select the **Global Subject** tab.
- In the **CommonName** field, type the name of the subject.
- Complete the remaining optional configuration to customize the policy.
- Select **Apply**.

Subject field descriptions

Use the data in the following table to use the **Subject** tab.

Name	Description
CommonName	Specifies the name of the subject sending the Certificate Signing Request to the Certificate Authority.
EmailAddress	Specifies the Email address of the subject sending the Certificate Signing Request to the Certificate Authority.
OrganizationalUnit	Specifies the organizational unit of the subject sending the Certificate Signing Request to the Certificate Authority.
Organization	Specifies the organization of the subject sending the Certificate Signing Request to the Certificate Authority.
Locality	Specifies the locality of the subject sending the Certificate Signing Request to the Certificate Authority.
Province	Specifies the province of the subject sending the Certificate Signing Request to the Certificate Authority.
Country	Specifies the country of the subject sending the Certificate Signing Request to the Certificate Authority.
InstallFile	Installs the specific certificate file type obtained offline from the Certificate Authority.
InstallFileName	Specifies the certificate file name to install.
UninstallFile	Uninstalls the specific certificate file type obtained offline from the Certificate Authority.
UninstallFileName	Specifies the certificate file name to uninstall.
GenerateCsr	Generates the certificate signing request to obtain the offline subject certificate.

Configure Device Subject Entries Parameters

Use this procedure to configure the device subject parameters to identify the device. The parameters include name, Email ID, company, department, and location of the subject.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **Certificate**.
3. Select the **Subject Entries** tab.
4. Select **Insert**.
5. In the **Name** field, type the name of the subject.
6. Complete the remaining optional configuration to customize the policy.
7. Select **Insert**.

Subject Entries Field Descriptions

Use the data in the following table to use the **Subject Entries** tab.

Name	Description
Name	Specifies the user defined name referring to the subject.
CommonName	Specifies the name of the subject sending the Certificate Signing Request to the Certificate Authority.
EmailAddress	Specifies the Email address of the subject sending the Certificate Signing Request to the Certificate Authority.
OrganizationalUnit	Specifies the organizational unit of the subject sending the Certificate Signing Request to the Certificate Authority.
Organization	Specifies the organization of the subject sending the Certificate Signing Request to the Certificate Authority.
Locality	Specifies the locality of the subject sending the Certificate Signing Request to the Certificate Authority.
Province	Specifies the province of the subject sending the Certificate Signing Request to the Certificate Authority.
Country	Specifies the country of the subject sending the Certificate Signing Request to the Certificate Authority.
InstallFile	Installs the specific certificate file type obtained offline from the Certificate Authority.
InstallFileName	Specifies the certificate file name to install.
UninstallFile	Uninstalls the specific certificate file type obtained offline from the Certificate Authority.
UninstallFileName	Specifies the certificate file name to uninstall.
GenerateCsr	Generates the certificate signing request to obtain the offline subject certificate.
RelaxedMode	Specifies relaxed mode for offline subject certificate installation for less restrictive consistency checks.
Pkcs1Password	Specifies the password to extract the PKCS12 container when in relaxed mode.
KeyName	Specifies the key name of the generated key-pair.

Generate the Key Pair

Use the following procedure to generate the private and public key pair for the specific cryptography type.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **Certificate**.
3. Select the **Key-Pair** tab.
4. Select **Insert**.
5. In the **Type** field, select the cryptography type.
6. In the **Size** field, type the size of the key.
7. Select **Insert**.

Certificate key-pair field description

Use the data in the following table to use the **Certificate > Key-Pair** tab.

Name	Description
Type	Specifies the cryptography algorithm used to generate the key-pair. Only RSA is supported.
Size	Specifies the size of the key-pair to be generated. Only 2048 is supported.
Name	Specifies the name of the key-pair generated for the subject. This name is auto-generated as the combination of key-type and key-size.

Configure the Certificate Authority

Use this procedure to configure the certificate authority (CA) and perform related actions. You can configure only one CA in a device at a time.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **Certificate**.
3. Select the **CA** tab.
4. Select **Insert**.
5. In the **Name** field, type a user-defined name of the CA.
6. In the **CommonName** field, type the common name of the CA.
7. In the **KeyName** field, type the name of the associated key pair.
8. Complete the remaining optional configuration to customize the policy.
9. Select **Insert**.
10. (Optional) Select **Retry Action** if the trustpoint CA certificate authentication fails or takes time for authentication. This can be done only when the selected Action is **caauth**.

CA field descriptions

Use the data in the following table to use the **CA** tab.

Name	Description
Name	Specifies the user-defined name referring to the Certificate Authority issuing the Digital Certificate.
CommonName	Specifies the Common Name of the Certificate Authority issuing the Digital Certificate.
KeyName	Specifies the name of the associated key pair.
CaUrl	Specifies the URL of the Certificate Authority issuing the Digital Certificate.
Action	Specifies the action the Certificate Authority can take: <ul style="list-style-type: none"> • noop – no operation • caauth – CA authentication • enroll – certificate enrolment request • renew – certificate renew request • remove – remove the subject certificate obtained online from the CA • install – install the subject certificate obtained online from the CA • getCrl – retrieve the Certificate Revocation List (CRL) from the CRL Distribution Point (CDP).
ActionChallengePassword	Specifies the challenge password required to perform the SCEP operation.
LastActionStatus	Specifies the status of the last action: <ul style="list-style-type: none"> • none - No action is performed yet • success - Execution of the action triggered is completed successfully • failed - Execution of the action triggered has failed • inProgress - Execution of the action triggered is in progress
LastActionFailureReason	Specifies the reason of failure for the last action performed by the Certificate Authority.
InstallRootCaFileName	Specifies the certificate file obtained offline from the Root Certificate Authority.
SubjectCertificateValidityDays	Specifies the number of days for which subject certificate will remain valid. The default value is 365 days.
UsePost	Specifies the HTTP request type: URL or POST. TRUE for EJBCA and FALSE for Win2012 CA
Sha256Fingerprint	Specifies an encrypted fingerprint of the expected certificate to match.

Name	Description
SubjectName	Specifies the Subject Name of the subject sending the Certificate Signing Request to the Certificate Authority.
UsedFor	Specifies the name of the application the certificate uses. The default is enabled if there is only 1 CA trustpoint configured.

View the Certificate Details

Use this procedure to:

- display the configured key details for given key name.
- display the digital certificate for the given certificate index or list all the certificate details from the local store if the certificate index is not specified.
- display the CA details for given trustpoint CA name or list all the CA details from the local store if the CA name is not specified.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **Certificate**.
3. Select the **Certificate** tab.

Certificate Field Descriptions

Use the data in the following table to use the **Certificate** tab.

Name	Description
Type	Specifies the certificate type.
VersionNumber	Specifies the version number of the certificate for the subject as issued by the Certificate Authority.
SerialNumber	Specifies the serial number of the certificate for the subject as issued by the Certificate Authority.
IssuerName	Specifies the name of the issuer of the certificate for the subject as issued by the Certificate Authority.
ValidStartPeriod	Specifies the start date of the validation period of the certificate for the subject as issued by the Certificate Authority.
ValidEndPeriod	Specifies the last date of the validation period of the certificate for the subject as issued by the Certificate Authority.
CertificateSignatureAlgorithm	Specifies the algorithm used for the signature of the issuer on the certificate for the subject as issued by the Certificate Authority.

Name	Description
CertificateSignature	Specifies the signature of the issuer on the certificate for the subject as issued by the Certificate Authority.
Subject	Specifies the details of the subject on its certificate as issued by Certificate Authority.
SubjectPublicKeyAlgorithm	Specifies the algorithm used to generate the public key of the subject for the certificate issued by the Certificate Authority.
SubjectPublicKey	Specifies the public key of the subject used for the Certificate Signing Request.
HasBasicConstraint	Specifies whether the certificate contains any basic certificate constraint or not.
HasKeyUsage	Specifies whether the certificate contains basic key usage constraint or not.
IsCa	Specifies whether the certificate is a ca certificate or not.
KeyUsage	Specifies the purpose of the key used in the certificate. It is represented in the form of bits as follows: <ul style="list-style-type: none"> • bit 0 - digitalSignature • bit 1 - nonRepudiation • bit 2 - keyEncipherment • bit 3 - dataEncipherment • bit 4 - keyAgreement • bit 5 - keyCertSign • bit 6 - cRLSign • bit 7 - encipherOnly • bit 8 - decipherOnly
Status	Specifies the status of the certificate.
Installed	Specifies whether the certificate is installed or not.
CdpUrl	Specifies the CDP URL present in the Digital Certificate Extensions field.
OcspUrl	Specifies the OCSP URL present in the Digital Certificate AIA field.
ExtendedKeyUsage	Indicates the purpose for which the key is used in addition to or in place of the basic purposes indicated in the key-usage field of the certificate.
RevocationStatus	Specifies the revocation status of the certificate.

View the Certificate Store

Use the following procedure to view the online, offline and root certificates in the local store.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.

2. Click **Certificate**.
3. Click the **Certificate Store** tab.

Certificate Store field descriptions

Use the data in the following table to use the **Certificate Store** tab.

Name	Description
CommonName	Specifies the Common Name of the Certificate Authority issuing the Digital Certificate.
Type	Specifies the certificate type.
VersionNumber	Specifies the version number of the certificate for the subject as issued by the Certificate Authority.
SerialNumber	Specifies the serial number of the certificate for the subject as issued by the Certificate Authority.
IssuerName	Specifies the name of the issuer of the certificate for the subject as issued by the Certificate Authority.
ValidStartPeriod	Specifies the start date of the validation period of the certificate for the subject as issued by the Certificate Authority.
ValidEndPeriod	Specifies the last date of the validation period of the certificate for the subject as issued by the Certificate Authority.
CertificateSignatureAlgorithm	Specifies the algorithm used for the signature of the issuer on the certificate for the subject as issued by the Certificate Authority.
CertificateSignature	Specifies the signature of the issuer on the certificate for the subject as issued by the Certificate Authority.
Subject	Specifies the details of the subject on its certificate as issued by Certificate Authority.
SubjectPublicKeyAlgorithm	Specifies the algorithm used to generate the subject's public key for the certificate issued by the Certificate Authority.
SubjectPublicKey	Specifies the public key of the subject used for Certificate Signing Request.
HasBasicConstraint	Specifies whether certificate contains basic certificate constraint.
HasKeyUsage	Specifies whether certificate contains basic key usage constraint.
IsCa	Specifies if the certificate is a CA certificate or not.

Name	Description
KeyUsage	Specifies the purpose of the key used in the certificate. It is represented in the form of bits as follows: <ul style="list-style-type: none"> • bit 0 - digitalSignature • bit 1 - nonRepudiation • bit 2 - keyEncipherment • bit 3 - dataEncipherment • bit 4 - keyAgreement • bit 5 - keyCertSign • bit 6 - cRLSign • bit 7 - encipherOnly • bit 8 - decipherOnly
Status	Specifies the status of the certificate.
Installed	Specifies whether the certificate is installed or not.
CdpUrl	Specifies the CDP URL present in the Digital Certificate Extensions field.
OscpUrl	Specifies the OCSP URL present in the Digital Certificate AIA field.
ExtendedKeyUsage	Indicates the purpose for which the key is used in addition to or in place of the basic purposes indicated in the key-usage field of the certificate.
CaFileName	Specifies the certificate file obtained offline from the Root Certificate Authority.

Configure TCP Keepalive and TCP Timestamp

About This Task

TCP Keepalive configures the system TCP keepalive interval, probes, and time.

TCP Timestamp option (RFC 1323) allows TCP to determine the order in which the packets are sent. The TCP Timestamp provides protection against Wrapped Sequence numbers. However, it is possible to calculate the system uptime when the Timestamp option is enabled. The analysis of timestamp behaviour can provide information on the system identity, which poses security threats and can cause a potential attack.

The TCP Timestamp option is enabled by default. You can disable the timestamp to avoid any security risks.

Note

The configuration will be applied only to the new TCP connections and the existing connections are not affected. You must save the configuration and reboot the switch to apply the new configuration to all TCP connections.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.

2. Select **Chassis**.
3. Select the **System Control** tab.
4. Configure the TCP timestamp by performing one of the following actions:
 - a. Select **TcpTimestamp** to enable the TCP timestamp.
 - b. Clear **TcpTimestamp** to disable the TCP timestamp.
5. In **KeepaliveTime**, enter a number in seconds.
6. In **KeepaliveInterval**, enter a number in seconds.
7. In **KeepaliveProbes**, enter a number of probes.
8. Select **Apply**.

System Control Field Descriptions

Use the data in the following table to use the **System Control** tab.

Name	Description
TcpTimestampEnable	Enables or disables the TCP timestamp. The timestamp is enabled by default. The system displays the following warning message after you apply a new configuration: <code>Warning: Existing TCP connections won't be affected. A config save and reboot is required to apply this configuration for all TCP connections.</code>
KeepaliveTime	Specify the TCP keepalive time in seconds. The default is 60.
KeepaliveInterval	Specify the TCP keepalive interval in seconds. The default is 10.
KeepaliveProbes	Specify the TCP keepalive probes. The default is 5.
PrivExecPasswordEnable	Enables authentication to access Privileged EXEC CLI command mode. Authentication is disabled by default.

Enable Authentication for Privileged EXEC Command Mode

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Chassis**.
3. Select the **System Control** tab.
4. Select **PrivExecPasswordEnable**.

sFlow

Table 203: sFlow product support

Feature	Product	Release introduced
sFlow	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
sFlow collector reachability on user-created VRFs	5320 Series	Not Supported
	5420 Series	Not Supported
	5520 Series	Not Supported

sFlow Fundamentals

sFlow monitors traffic in a data network. Use sFlow to monitor routers and switches in the network, and capture traffic statistics about those devices. sFlow uses sampling to provide scalability for network-wide monitoring, and therefore applies to high speed networks. The switch sends the sampled data as a User Datagram Protocol (UDP) packet to the specified host and port.

Note

sFlow and Application Telemetry send mirrored packets from a common source to a common destination. sFlow sends samples directly to the destination, while Application Telemetry sends mirrored packets through a GRE tunnel, to the same destination. For more information, see [Common Elements Between sFlow and Application Telemetry](#) on page 291.

sFlow consists of the following:

- sFlow agent—Performs two types of sampling:
 - Flow samples: Flow sampling randomly samples an average of 1 out of n packets for each operation.
 - Counter samples: Counter sampling periodically polls and exports counters for a configured interface. This type of sampling uses a counter to determine if the packet is sampled. Each

packet that an interface receives, and that a filter does not drop, reduces the counter by one. After the counter reaches zero, the sFlow agent takes a sample.

**Note**

Only generic interface counters and Ethernet interface counters are supported.

- sFlow datagrams—Supports both flow samples and counter samples. Datagrams can be sent from the front panel port or an out-of-band (OOB) port. Each datagram provides information about the sFlow version, the originating IP address of the device, a sequence number, the number of samples it contains, and one or more flow and/or counter samples.
- sFlow collector—Located on a central server and runs software that analyzes and reports on network traffic. Two sFlow collectors can be configured to be reachable over a management network or Shortest Path Bridging (SPB). The preferred network is SPB.

Limitations

- Application-specific integrated circuit (ASIC) or Software Development Kit (SDK) limitation—To avoid wobbling, the counter interval for sFlow is 20 seconds. Minor wobbling can still occur even after configuring the counter interval due to the interaction between the sFlow agent counter export schedule and the frequency with which the switch ASIC SDK copies and caches counters from the ASIC.
- sFlow supports a maximum of two collectors.
- UDP datagram size and the collector buffer are restricted to 1400 bytes. sFlow sends datagrams to the collector when the buffer reaches the 1400-byte capacity or after a timeout of one second is triggered. The collector buffer size cannot be modified.
- The switch supports IPv4 collector IP addresses.
- VLAN counters/statistics are not supported.
- sFlow can be enabled only on the front panel ports.
- You cannot configure the sampling limit. The sampling limit applies system-wide rather than on a per port basis. Sampling rates differ depending on the hardware platform so any sampled packets beyond the limit are dropped. For more information about feature support, see [Fabric Engine Release Notes](#).
- The switch supports only ingress sampling. The switch does not support egress sampling.
- The switch does not support enabling sFlow on a link aggregation group (LAG) interface. However, you can enable sFlow on the member interfaces of a LAG.
- The sFlow collector can be reachable through the Management VRF, the Global Routing Table (GRT) or if your switch supports doing so, through a user created VRF (virtual routing and forwarding). If the sFlow collector is hosted in either the GRT or a user created VRF, SPB reachability only supports using Layer 2 VSN or IP shortcuts to access the collector. Layer 3 VSNs are not supported in accessing the collector when it is hosted in the GRT or a User created VRF.
- For Segmented Management Instance interfaces, sFlow is only supported on Segmented Management Instance OOB and on circuitless IP (CLIP) in GRT.

Configuration considerations

- If the sFlow collector has two network interface controller (NIC) cards, to avoid dropped sFlow datagrams that are a result of reverse path checks, you can add a route to the agent-ip address for the NIC card on which the sFlow datagrams are received.
- First preference is always given to either the GRT or management VRF to where the sFlow agent IP address is configured. For example, if you configure the sFlow agent IP address as part of GRT, the GRT route to the collector is given preference over the management VRF. If the management network hosts a collector with a collector IP address that is reachable over SPB as a result of redistributing direct routes on a peer Backbone Edge Bridge (BEB) or in situations where the GRT has a default route (0.0.0.0) and the collector route is in the local management VRF, first preference is given to the VRF where you have configured the sFlow agent IP address.
- For Segmented Management Instance interfaces, preference for sFlow collector reachability checks is determined by agent-ip configuration. If you configure the sFlow agent IP address to Segmented Management Instance OOB, preference for route lookup is given to the management VRF. If no route is found, lookup occurs in GRT.

If you do not configure the agent-ip address to Segmented Management Instance OOB, preference for route lookup is given to GRT. If no route is found, lookup occurs in the management VRF.

After you configure the sFlow agent on the network device that you want to monitor, the system collects flow samples or counter samples, and exports these traffic statistics as sFlow datagrams to the sFlow collector on a server or appliance.

For example, after the buffers reach capacity or a timeout is triggered, an sFlow datagram, which is a UDP packet, sends the measurement information to the sFlow collector buffers. The UDP payload contains the sFlow datagram.

The following figure shows the sFlow agent on various routers and switches with sFlow datagrams being sent to the sFlow collector.

Table 204: sFlow legend

Number	Description
1	sFlow collector
2	sFlow datagrams
3	sFlow agents

As a general rule, drop action occurs after sampling completes. However, in situations related to Layer 1 errors such as, MTU exceeded packets, the drop action occurs before sampling begins. For errors such as, frame too long, packets are dropped due to the size of the frame being greater than the interface MTU. In this situation, the packets are dropped before sampling begins so only counter polling occurs. To enable trace, use **line-card 1 trace level 232 <0-4>**.

Important

The defined sampling rate, an average of 1 out of n packets/operations does not provide a 100% accurate result, but it does provide a result with quantifiable accuracy.

sFlow Configuration Using CLI

Use sFlow to capture traffic statistics to monitor traffic in a data network. This section provides procedures to view and configure sFlow using CLI.

Configuring the agent-ip and Enabling sFlow Globally

Configure the sFlow agent IPv4 address, and then enable sFlow before the system can monitor and capture traffic statistics to send to an sFlow collector. By default, sFlow is globally disabled.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Enable the agent IPv4 address:
`sflow agent-ip {A.B.C.D}`
3. Enable sFlow:
`sflow enable`
4. Verify the global configuration:
`show sflow`

Example

Globally enable sFlow, and then verify the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#sflow agent-ip 192.0.2.27
INFO: Please be aware that sFlow agent IP address is only supported in MGMT or GRT VRF.
Switch:1(config)#sflow enable
Switch:1(config)#show sflow
=====
                        sFlow Global Configuration
=====
Global State           : Enabled
Agent IP               : 192.0.2.27
```

What to Do Next

After you configure the agent-ip and globally enable sFlow, proceed to configuring the sFlow collector.

Variable Definitions

Use the data in the following table to use the **sflow agent-ip** command.

Variable	Definition
{A.B.C.D. }	Specifies the agent-ip address (IPv4). Note: For Segmented Management Instance interfaces, you must configure the agent-ip address to the IP address of the Segmented Management Instance interface on which datagrams egress.

Configuring an sFlow Collector

Configure an sFlow collector to determine the device to which the sFlow agent sends sFlow datagrams. You can configure up to two collectors for each interface slot in the chassis.

Before You Begin

- You must globally enable sFlow.

About This Task

The sFlow datagrams that the agent sends to the collector are not encrypted. Use a VLAN to create a secure measurement network to route sFlow datagrams.

To further protect the sFlow collector, configure it to accept only sFlow datagrams, or to check sequence numbers and verify source addresses.

Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Configure the collector information:

```
sflow collector <1-2> address {A.B.C.D} [Owner WORD <1-20>] [port <1-65535>] [timeout <1-65535>]
```
- Verify the collector configuration:

```
show sflow collector <1-2>
```

Example

Configure collector ID, and then verify the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#sflow collector 1 address 192.0.2.26 owner sflow1 port 6343 timeout 497
Switch:1(config)#sflow collector 2 address 192.0.2.27 owner sflow2 port 6343 timeout 531
Switch:1(config)#show sflow collector
=====
```

sFlow Collector Configuration Info					
Id	Owner	Collector-IP	Port	Timeout (secs)	Reachable via
1	sflow1	192.0.2.26	6343	497	192.0.2.15
2	sflow2	192.0.2.27	6343	531	192.0.2.16

All 2 out of 2 Total Num of sflow collector entries displayed

What to Do Next

After you configure the sFlow collector, configure the packet sampling rate to enable sFlow on a port or ports.

Variable Definitions

Use the data in the following table to use the **sflow collector** command.

Variable	Value
<code>collector <1-2></code>	Specifies the id to export sFlow datagrams to the collector id. Use the no operator to remove an sflow collector id and a collector name. no <code>sflow collector <1-2> owner WORD<1-20></code> To configure the default value, enter <code>default sflow collector <1-2></code>
<code>address {A.B.C.D. }</code>	Specifies the collector IP address. Use the no operator to remove an sflow collector address. no <code>sflow collector <1-2> address {A.B.C.D}</code>
<code>owner WORD<1-20></code>	Specifies the sFlow collector name.
<code>port <1-65535></code>	Specifies the destination UDP port. The default port is 6343. To configure the default value, enter <code>default sflow collector <1-2> port</code>
<code>timeout <1-65535></code>	Specifies the time remaining (in seconds) before the collector is released. The default timeout is 0, which means the timeout is not used and the collector sends data forever. To configure the default value, enter <code>default sflow collector <1-2> timeout</code>
<code>vrf WORD<1-16></code>	Specifies the name of the VRF used to reach the collector. Note: This parameter is not supported on all hardware platforms.

Configuring the Packet Sampling Rate

Configure the packet sampling rate at port level to determine how many packets the system counts before it takes a sample. Configuring the sampling rate enables sFlow on the port.

Before You Begin

- You must globally enable sFlow.

About This Task

If you configure a conservative sampling rate to prevent overloading the sFlow agent, the result will reflect high values that do not reflect typical traffic levels.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the collector id:

```
sflow collector <1-2>
```

3. Configure the sampling rate:

```
sflow sampling-rate <1024-1000000>
```

4. Verify the configuration:

```
show sflow interface {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Example

Configure sampling rates for ports 2/1, 2/2, 2/3, and 2/4.

```
Switch:1(config-if)#interface gigabitethernet 2/1,2/2
Switch:1(config-if)#sflow collector 1
Switch:1(config-if)#sflow sampling-rate 10000
Switch:1(config-if)#interface gigabitethernet 2/3
Switch:1(config-if)#sflow collector 2
Switch:1(config-if)#sflow sampling-rate 8192
Switch:1(config-if)#interface gigabitethernet 2/4
Switch:1(config-if)#sflow collector 2
Switch:1(config-if)#sflow sampling-rate 12001
Switch:1(config-if)#show sflow interface enabled
```

sFlow Port Configuration Info

Port	Packet-Sample-Rate	Max-Header-Size	Counter-interval (in secs)	Collector-list
2/1	10000	128	0	1
2/2	10000	128	0	1
2/3	8192	128	0	2
2/4	12001	128	0	2

All 4 out of 4 Total Num of sflow port entries displayed

Variable Definitions

Use the data in the following table to use the **sflow sampling-rate** and **show sflow interface** commands.

Variable	Value
<1024-1000000>	Configures the packet sampling rate on a port. The default value is 0 (disabled). To configure the default value, enter <code>default sflow sampling-rate</code> .
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Configuring sFlow Maximum Header Size

Configure the maximum header size on a single port or multiple ports.

Before You Begin

- You must globally enable sFlow.

Procedure

- Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

- Configure the maximum-header size:

```
sflow max-header-size <64-256>
```

- Verify the configuration:

```
show sflow interface {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Example

For ports 1/1 to 1/10, configure the maximum header size, and then verify the configuration.

```
Switch:1(config-if)#interface gigabitethernet 1/1-1/10
Switch:1(config-if)#sflow max-header-size 255
Switch:1(config-if)#show sflow interface 1/1-1/10
```

```
=====
sFlow Port Configuration Info
```

Port	Packet-Sample-Rate	Max-Header-Size	Counter-interval (in secs)	Collector-list
1/1	0	255	525	1,2
1/2	0	255	525	1,2
1/3	0	255	525	1,2
1/4	0	255	525	1,2
1/5	0	255	525	1,2
1/6	0	255	525	1,2
1/7	0	255	525	1,2
1/8	0	255	525	1,2
1/9	0	255	525	1,2
1/10	0	255	525	1,2

Variable Definitions

Use the data in the following table to use the **max-header-size** command.

Variable	Value
<64-256>	Identifies the maximum number of bytes to be copied from the sampled packet. Default 128 bytes.

Configuring the Counter Sampling Interval

Configure the counter sampling interval values at port level to determine how often the sFlow agent polls and exports counters for a configured interface.

Before You Begin

- You must globally enable sFlow.

Procedure

- Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

- Configure the counter sampling interval:

```
sflow counter-interval <1-3600>
```

- Verify the configuration:

```
show sflow interface {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

Example

Verify all slots use the default polling-interval configuration.

```
Switch:1(config-if)#sflow counter-interval 525
Switch:1(config-if)#show sflow interface 1/1-1/10
```

```

Variable Definitions

Use the data in the following table to use the **sflow counter-interval** and **show sflow interface** commands.

Variable	Value
<1-3600>	Specifies the polling interval for a slot. Default value is 0 (disabled).
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Viewing sFlow Statistics

Display statistics for sFlow datagrams.

Before You Begin

- You must globally enable sFlow.

Procedure

- To enter User EXEC mode, log on to the switch.
- View sFlow statistics:

```
show sflow statistics [collector <1-2>]
```

Example

```
Switch:1>show sflow statistics

=====
sFlow Statistics Info
=====
Collector-id          sFlow-Datagrams

sFlow Configuration Using EDM

Use sFlow to capture traffic statistics to monitor traffic in a data network. This section provides procedures to view and configure sFlow using EDM.

Enabling sFlow and Configuring the Agent IP Address

Use this procedure to enable sFlow and configure the sFlow agent IP address so the system can send packets to an sFlow collector.

About This Task

Application Telemetry and sFlow both use the **sFlow Globals** tab.

Before You Begin

You must enable sFlow before you enable Application Telemetry.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **Sflow**.
3. Click the **Globals** tab.
4. Check **AdminEnable** to enable sFlow.
5. In the **AgentAddress** field, enter the agent IPv4 address.
6. Click **Apply**.

What to Do Next

After you configure the agent IP address and globally enable sFlow, proceed to configuring the sFlow collector.

Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
AdminEnable	Shows whether sFlow is enabled. By default, the check box is not enabled.
AgentAddressType	Specifies the collector IP address type. Only IPv4 collector addresses are supported.
AgentAddress	Specifies the agent IP address of an interface that exists in the local management VRF or GRT. Note: For Segmented Management Instance interfaces, you must configure AgentAddress to the IP address of the Segmented Management Instance interface on which datagrams egress.

Configuring an sFlow Collector

Use this procedure to configure the device used as either an sFlow Collector or an Application Telemetry Analytics Engine. This device is where the agent sends sFlow datagrams and Application Telemetry packets for analysis.

sFlow supports up to two collectors for each interface slot in the chassis. However, Application Telemetry supports Collector 1 only.

Note

- You can configure two Collectors, but Application Telemetry uses Collector 1 only. You must configure Collector 1 before you enable Application Telemetry.
- Before you change or remove Collector 1, you must disable Application Telemetry.
- By default, Application Telemetry is globally disabled.

About This Task

Tip

You can configure the **Collector** tab to select only the columns you are interested in seeing. By default, the system does not display **AddressType** option. To make the **AddressType** column visible, click the down arrow on one of the menu headings, navigate to **Columns**, and select the **AddressType** check box.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **Sflow**.
3. Click the **Collector** tab.
4. Configure the fields for Collector 1.
5. Click **Apply**.

What to Do Next

After you configure the sFlow collector, configure the packet sampling rate to enable sFlow on a port or ports.

Collector Field Descriptions

Use the data in the following table to use the **Collector** tab.

Name	Description
Index	Shows collector 1 and collector 2. The switch exports sFlow and Application Telemetry traffic to the collector.
Owner	Specifies the sFlow collector name. The string length is 1 to 20 characters.
Timeout	Specifies the time remaining (in seconds) before the collector is released and stops sampling. The default timeout is 0, which means the timeout is not used and the switch sends data forever.
Address	Specifies the collector IP address. If the default address is set to 0.0.0.0, no traffic is sent.
Port	Specifies the destination port. The default port is 6343.

Name	Description
IsReachable	Shows whether the sFlow collector is reachable.
NextHop	If the collector is reachable, shows the name or address of the next hop through which the collector is reachable.

Configure the Packet Samples and Counter Samples

Configure the packet sampling rate to determine how many packets the system counts before it takes a sample and configure the counter sampling interval to determine how often the sFlow agent polls and exports counters for a configured interface. You can also configure the maximum header size on a single port or multiple ports.

Configuring the sampling rate enables sFlow on the port.

Before You Begin

- You must globally enable sFlow.

About This Task

Tip

You can configure the **Interfaces** tab to select only the columns you are interested in seeing. By default, the system does not display **Instances** option. To make the **Instances** column visible, click the down arrow on one of the menu headings, navigate to **Columns**, and select the **Instances** check box.

Procedure

- In the navigation pane, expand **Configuration > Serviceability**.
- Select **Sflow**.
- Select the **Interfaces** tab.
- In the **DataSource** column, navigate to the slot and port where you want to configure sFlow, and configure the following:
 - PacketSamplingRate—Double-click the field, and enter a sampling rate value.
 - MaximumHeaderSize—Double-click the field, and enter a maximum header size value.
 - Interval—Double-click the field, and enter the counter sampling interval value in seconds.
- Select **Apply**.

Interfaces Field Descriptions

Use the data in the following table to use the **Interfaces** tab.

Name	Description
DataSource	Shows the slot and port for which traffic statistics are collected. The field name is different on different hardware platforms.
Instance	Shows the number of sFlow samplers associated with a specific datasource. Note: You must select this field for it to display on the Interfaces tab.
Collectors	Shows the collectors that have been configured for the sFlow agent to send sFlow datagrams. Two collectors are supported. The field name is different on different hardware platforms.
PacketSamplingRate	Specifies the packet sampling rate to determine how many packets the system counts before it take a sample. The default is 0.
MaximumHeaderSize	Specifies the maximum header size on a single port or multiple ports. The default is 128 bytes.
Interval	Specifies the counter sampling interval to determine how often the sFlow agent polls and exports counters for a configured interface. The default is 0.

Displaying sFlow Statistics

Use the following procedure to display (true) sFlow statistics. Statistics for sFlow are cleared (false), by default.

About This Task

Tip

You can configure the **Stats** tab to select only the columns you are interested in seeing. The system displays all the options, by default. To hide a column, click the down arrow on one of the menu headings, navigate to **Columns**, and select the check box for the column you want to hide.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **sFlow**.
3. Click the **Stats** tab.
4. In the **ClearStats** column, double-click the field, and select true or false from the list.
5. Click **Apply**.

Stats Field Descriptions

Use the data in the following table to use the **Statistics** tab.

Name	Description
Index	Shows sFlow collector ID 1 and 2
DatagramCount	Shows the number of datagrams that have been sent to the collector.
ClearStats	Shows whether the sFlow statistics are displayed (true) or cleared (false). The default is false.

Simple Network Management Protocol (SNMP)

Table 205: Simple Network Management Protocol product support

Feature	Product	Release introduced
Simple Network Management Protocol (SNMP) v1/2/3 (IPv4)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
SNMP (IPv6)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5

You can use the Simple Network Management Protocol (SNMP) to remotely collect management data and configure devices.

An SNMP agent is a software process that monitors the UDP port 161 for SNMP messages. Each SNMP message sent to the agent contains a list of management objects to retrieve or modify.

SNMPv3

The SNMP version 3 (v3) is the third version of the Internet Standard Management Framework and is derived from and builds upon both the original Internet Standard Management Framework SNMP version 1 (v1) and the second Internet Standard Management Framework SNMP version 2 (v2).

The SNMPv3 is not a stand-alone replacement for SNMPv1 or SNMPv2. The SNMPv3 defines security capabilities you must use in conjunction with SNMPv2 (preferred) or SNMPv1. The following figure shows how SNMPv3 specifies a user-based security model (USM) that uses a payload of either an SNMPv1 or an SNMPv2 Protocol Data Unit (PDU).

Figure 217: SNMPv3 USM

SNMPv3 is an SNMP framework that supplements SNMPv2 by supporting the following:

- New SNMP message formats
- Security for messages
- Access control
- Remote configuration of SNMP parameters

The recipient of a message can use authentication within the USM to verify the message sender and to detect if the message is altered. According to RFC2574, if you use authentication, the USM checks the entire message for integrity.

An SNMP entity is an implementation of this architecture. Each SNMP entity consists of an SNMP engine and one or more associated applications.

SNMP Engine

An SNMP engine provides services for sending and receiving messages, authenticating and encrypting messages, and controlling access to managed objects. A one-to-one association exists between an SNMP engine and the SNMP entity, which contains the SNMP engine.

EngineID

Within an administrative domain, an EngineID is the unique identifier of an SNMP engine. Because there is a one-to-one association between SNMP engines and SNMP entities, the ID also uniquely and unambiguously identifies the SNMP entity within that administrative domain. The system generates an EngineID during the startup process. The SNMP engine contains a:

- [Dispatcher](#) on page 2678.
- [Message Processing Subsystem](#) on page 2678.
- [Security Subsystem](#) on page 2678.
- [Access Control Subsystem](#) on page 2679.

Automatic discovery of a Remote EngineID is performed so that Inform messages are populated properly and not rejected by the SNMP Manager. This automatic discovery is performed by the switch using a request to the Manager for a response that contains the EngineID. The switch then uses this Remote EngineID value to populate all subsequent Inform messages.

Dispatcher

The dispatcher is part of an SNMP engine. You can use the dispatcher for concurrent support of multiple versions of SNMP messages in the SNMP engine through the following ways:

- To send and receive SNMP messages to and from the network.
- To determine the SNMP message version and interact with the corresponding message processing model.
- To provide an abstract interface to SNMP applications for delivery of a PDU to an application.
- To provide an abstract interface for SNMP applications to send a PDU to a remote SNMP entity.

Message Processing Subsystem

The message processing subsystem prepares messages for sending and extracts data from received messages. The subsystem can contain multiple message processing models.

Security Subsystem

The security subsystem provides the following features:

- Authentication
- Privacy
- Security

Authentication

You can use authentication within the SNMPv3 to verify the message sender and whether the message is altered. If you use authentication, the integrity of the message is verified. The supported SNMPv3 authentication protocols are HMAC-MD5 and HMAC-SHA-96. By default, the switch uses HMAC-SHA1-96 with 160-bit key length.

Privacy

SNMPv3 is an encryption protocol for privacy. Only the data portion of a message is encrypted; the header and the security parameters are not. The privacy protocol that SNMPv3 supports is CBC-DES Symmetric Encryption Protocol and Advanced Encryption Standard (AES).

Security

The SNMPv3 security protects against:

- Modification of information—protects against altering information in transit.
- Masquerade—protects against an unauthorized entity assuming the identity of an authorized entity.

- Message stream modification—protects against delaying or replaying messages.
- Disclosure—protects against eavesdropping.

The SNMPv3 security also offers:

- Discovery procedure—finds the EngineID of an SNMP entity for a given transport address or transport endpoint address.
- Time synchronization procedure—facilitates authenticated communication between entities

The SNMPv3 does not protect against the following:

- Denial-of-service—prevention of exchanges between manager and agent.
- Traffic analysis—general pattern of traffic between managers and agents.

Access Control Subsystem

SNMPv3 provides a group option for access policies.

The access policy feature in the switch determines the access level for the users connecting to the device with different services like File Transfer Protocol (FTP), Trivial FTP (TFTP), and Telnet. The system access policy feature is based on the user access levels and network address. This feature covers services, such as TFTP, HTTP, SSH, and SNMP. However, with the SNMPv3 engine, the community names do not map to an access level. The View-based Access Control Model (VACM) determines the access privileges.

Use the configuration feature to specify groups for the SNMP access policy. You can use the access policy services to cover SNMP. Because the access restriction is based on groups defined through the VACM, the synchronization is made using the SNMPv3 VACM configuration. The administrator uses this feature to create SNMP users (USM community) and associate them to groups. You can configure the access policy for each group and network.

The following are feature specifications for the group options:

- After you enable SNMP service, this policy covers all users associated with the groups configured under the access policy. The access privileges are based on access allow or deny. If you select allow, the VACM configuration determines the management information base (MIB)-views for access.
- The SNMP service is disabled by default for all access policies.
- The access level configured under **access-policy policy <id>** does not affect SNMP service. The VACM configuration determines the SNMP access rights.

User-Based Security Model

In a USM system, the security model uses a defined set of user identities for any authorized user on a particular SNMP engine. A user with authority on one SNMP engine must also have authorization on all SNMP engines with which the original SNMP engine communicates.

The USM provides the following levels of communication:

- NoAuthNoPriv—communication without authentication and privacy.
- AuthNoPriv—communication with authentication and without privacy.

- AuthPriv—communication with authentication and privacy.

The following figure shows the relationship between USM and VACM.

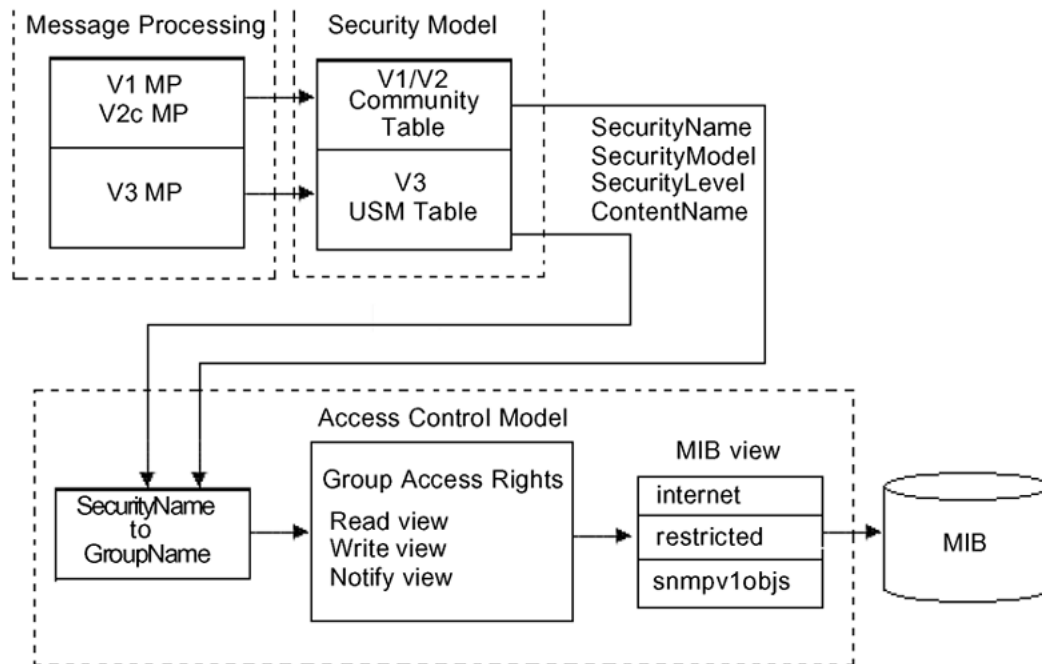

Figure 218: USM association with VACM

View-Based Access Control

View-based Access Control Model (VACM) provides group access, group security levels, and context based on a predefined subset of MIB objects. These MIB objects define a set of managed objects and instances.

VACM is the standard access control mechanism for SNMPv3, and it provides:

- Authorization service to control access to MIB objects at the PDU level.
- Alternative access control subsystems.

The access is based on principal, security level, MIB context, object instance, and type of access requested (read or write). You can use the VACM MIB to define the policy and control remote management.

SNMPv3 Encryption

A user-based security port for SNMPv3 is defined as a security subsystem within an SNMP engine. The switch USM uses HMAC-MD5-96 and HMAC-SHA-96 as the authentication protocols, and CBC-DES as the privacy protocol. Use USM to use other protocols instead of, or concurrently with, these protocols. CFB128-AES-128, an AES-based Symmetric Encryption Protocol, is an alternative privacy protocol for the USM.

The AES standard is the current encryption standard, Federal Information Processing Standard 140-2 (FIPS 140-2), intended to be used by the U.S. Government organizations to protect sensitive information. The AES standard is also becoming a global standard for commercial software and hardware that uses encryption or other security features.

The AES-Based Symmetric Encryption Protocol

This symmetric encryption protocol provides support for data confidentiality. The system encrypts the designated portion of the SNMP message and includes it as part of the transmitted message.

The USM specifies that the scoped PDU is the portion of the message that requires encryption. An SNMP engine that can legitimately originate messages on behalf of the appropriate user shares a secret value, in combination with a timeliness value and a 64-bit integer, used to create the (localized) encryption/decryption key and the initialization vector.

The AES Encryption Key and Initialization Vector

The AES encryption key uses the first 128 bits of the localized key. The 128-bit Initialization Vector (IV) is the combination of the authoritative SNMP engine 32-bit `snmpEngineBoot`, the SNMP engine 32-bit `snmpEngineTime`, and a local 64-bit integer. The system initializes the 64-bit integer to a pseudo-random value at startup time.

Data Encryption

The switch handles data encryption in the following manner:

1. The system treats data as a sequence of octets.
2. The system divides the plaintext into 128-bit blocks.

The first input block is the IV, and the forward cipher operation is applied to the IV to produce the first output block.

3. The system produces the first cipher text block by executing an exclusive-OR function on the first plaintext block with the first output block.
4. The system uses the cipher text block as the input block for the subsequent forward cipher operation.
5. The system repeats the forward cipher operation with the successive input blocks until it produces a cipher text segment from every plaintext segment.
6. The system produces the last cipher text block by executing an exclusive-OR function on the last plaintext segment of r bits (r is less than or equal to 128) with the segment of the r most significant bits of the last output block.

Data Decryption

The switch handles data decryption in the following manner:

1. In CFB decryption, the IV is the first input block, the system uses the first cipher text for the second input block, the second cipher text for the third input block, and this continues until the system runs out of blocks to decrypt.
2. The system applies the forward cipher function to each input block to produce the output blocks.

3. The system passes the output blocks through an exclusive-OR function with the corresponding cipher text blocks to recover the plaintext blocks.
4. The system sends the last cipher text block (whose size r is less than or equal to 128) through an exclusive-OR function with the segment of the r most significant bits of the last output block to recover the last plaintext block of r bits.

Trap Notifications

You configure traps by creating SNMP trap notifications, creating a target address to which you want to send the notifications, and specifying target parameters. For more information about how to configure trap notifications, see [Logs and Traps](#) on page 1900.

SNMP Community Strings

For security reasons for SNMPv1 and SNMPv2, the SNMP agent validates each request from an SNMP manager before responding to the request by verifying that the manager belongs to a valid SNMP community. An SNMP community is a logical relationship between an SNMP agent and one or more SNMP managers (the manager software implements the protocols used to exchange data with SNMP agents). You define communities locally at the agent level.

The agent establishes one community for each combination of authentication and access control characteristics that you choose. You assign each community a unique name (community string), and all members of a community have the same access privileges, either read-only or read-write:

- Read-only: members can view configuration and performance information.
- Read-write: members can view configuration and performance information, and change the configuration.

By defining a community, an agent limits access to its MIB to a selected set of management stations. By using more than one community, the agent can provide different levels of MIB access to different management stations.

SNMP community strings are used when a user logs on to the device over SNMP, for example, using an SNMP-based management software. You set the SNMP community strings using CLI . If you have read/write/all access authority, you can modify the SNMP community strings for access to the device through Enterprise Device Manager (EDM).

You are provided with community strings for SNMPv1 and SNMPv2. If you want to use SNMPv3 only, you must disable SNMPv1 and SNMPv2 access by deleting the default community string entries and create the SNMPv3 user and group. [SNMPv3](#).

Note

If you enable enhanced secure mode, the switch does not support the default SNMPv1 and default SNMPv2 community strings, and default SNMPv3 user name. The individual in the administrator access level role can configure a non-default value for the community strings, and the switch can continue to support SNMPv1 and SNMPv2. The individual in the administrator access level role can also configure a non-default value for the SNMPv3 user name and the switch can continue to support SNMPv3.

If you disable enhanced secure mode, the SNMPv1 and SNMPv2 support for community strings remains the same, and the default SNMPv3 user name remains the same. Enhanced secure mode is disabled by default.

For more information on enhanced secure mode, see [Enhanced Secure Mode](#) on page 2887.

The following table lists the default community strings for SNMPv1 and SNMPv2.

VRF	Default community string	Access
GlobalRouter VRF	public	Read access
	private	Write access
ManagementRouter VRF	public:512	Read access
	private:512	Write access

Community strings are encrypted using the AES encryption algorithm. The system does not display community strings on the device and are not stored in the configuration file.

Caution Security risk

For security reasons, as a best practice, set the community strings to values other than the factory defaults.

The switch handles community string encryption in the following manner:

- When the device starts up, community strings are restored from the hidden file.
- When the SNMP community strings are modified, the modifications are updated to the hidden file.
- Stale snmp-server community entries for different VRFs that the system displays it after reboot with no VRFs . On an node with any valid config file saved with more than the default vrf0 , snmp_community entries for that VRF are created and maintained in a separate txt file, snmp_comm.txt, on every boot. The node reads this file and updates the snmp communities available on the node. As a result for a boot with config having no VRFs, you may still see snmp_community entries for VRFs other than the globalRouter vrf0.

Hsecure with SNMP

If you enable hsecure, the system disables SNMPv1, SNMPv2 and SNMPv3. If you want to use SNMP, you must use the command **no boot config flag block-snmp** to re-enable SNMP.

SNMPv3 support for VRF

Use Virtual Router Forwarding (VRF) to offer networking capabilities and traffic isolation to customers that operate over the same node (switch). Each virtual router emulates the behavior of a dedicated hardware router and is treated by the network as a separate physical router. You can use VRF Lite to perform the functions of many routers using a single router running VRF Lite. This substantially reduces the cost associated with providing routing and traffic isolation for multiple clients.

SNMPv3 Remote Engine ID Discovery

The following sections contain information about SNMPv3 remote engine ID discovery.

Traps and Informs

SNMPv3 supports two types of notifications, traps and informs.

Traps are unacknowledged notifications sent by agents to managers. Traps are generated by the agent, and the authoritative SNMP engine for a trap packet is the sending SNMP agent. Because the generator of the message and the authoritative engine are the same, there is no need for the SNMPv3 discovery process.

Informs are acknowledged notifications. An agent sends an inform notification and waits for acknowledgement. If the agent does not receive the acknowledgement within the configured timeout period, it resends the inform notification. The agent continues to resend the inform notification until a reply is received or until the maximum retry value is reached. For information about configuring an inform timeout period or configuring a maximum retry value, see [Configure SNMP settings](#) on page 2686.

Remote Engine ID Discovery

Inform packets must contain the management (remote) SNMP engine ID. The agent generates informs, but the authoritative SNMP engine is the manager. To generate valid inform packets and avoid manual configuration of the manager SNMP engine ID, the agent must discover the SNMP engine ID of the manager.

The agent discovers the management SNMP Engine ID by sending a probe message to the manager. The manager response to the probe message is a report message that contains the SNMP engine ID of the authoritative SNMP engine. The agent stores the SNMP engine ID received from the manager in the engine table, and sends inform packets using the manager SNMP engine ID. If the manager SNMP engine ID changes, the discovery process updates the manager SNMP engine ID value in the engine table.

Note

Remote engine ID discovery cannot use SNMP config files created in releases prior to VOSS 8.1. Config files must be saved in Release VOSS 8.1 or higher in order to be compatible with remote engine ID discovery.

SNMP configuration using CLI

Configure the SNMP engine to provide services to send and receive messages, authenticate and encrypt messages, and control access to managed objects. A one-to-one association exists between an SNMP engine and the SNMP entity.

- To perform the procedures in this section, you must log on to the Global Configuration mode in CLI. For more information about how to use CLI, see [CLI Procedures](#) on page 215.

This task flow shows you the sequence of procedures you perform to configure basic elements of SNMP when using CLI.

Figure 219: SNMP configuration procedures

Configure SNMP settings

Configure Simple Network Management Protocol (SNMP) to define or modify the SNMP settings, and specify the security level for SNMP communications.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Enable the generation of authentication traps:
`snmp-server authentication-trap enable`
3. Configure the contact information for the system:
`snmp-server contact WORD<0-255>`
4. Create an SNMPv1 server host:
`snmp-server host WORD<1-256> [port <1-65535>] v1 WORD<1-32> [filter WORD<1-32>]`
5. Create an SNMPv2 server host:
`snmp-server host WORD<1-256> [port <1-65535>] v2c WORD<1-32> [inform] [timeout <1-2147483647>] [retries <0-255>] [mms <0-2147483647>] [filter WORD<1-32>]`
6. Create an SNMPv3 server host:
`snmp-server host WORD<1-256> [port <1-65535>] v3 {noAuthNoPriv|authNoPriv|authPriv WORD<1-32> [inform] [timeout <1-2147483647>] [retries <0-255>]} [filter WORD<1-32>]`
7. Configure the system location:
`snmp-server location WORD<0-255>`
8. Enable login-success traps:
`snmp-server login-success-trap enable`
9. Configure the system name:
`snmp-server name WORD<0-255>`
10. Create a new entry in the notify filter table:
`snmp-server notify-filter WORD<1-32> WORD<1-32>`

Example

Enable the generation of SNMP traps. Configure the contact information for the system. Configure hosts to receive SNMP notifications:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#snmp-server authentication-trap enable
Switch:1(config)#snmp-server contact xxxx@company.com
Switch:1(config)#snmp-server host 192.0.2.16 port 1 v1 SNMPv1 filter SNMPfilterv1
```

Variable Definitions

The following table defines parameters for the `snmp-server` command.

Variable	Value
<code>authentication-trap</code> { <i>enable</i> }	Enables generation of SNMP server authentication traps.
<code>contact</code> <i>WORD</i> <0-255>	Changes the sysContact information for the switch. <i>WORD</i> <0-255> is an ASCII string from 0-255 characters (for example, a phone extension or email address).
<code>host</code> <i>WORD</i> <1-256> [<i>port</i> <1-65535>] { <i>v1</i> <i>WORD</i> <1-32> <i>v2c</i> <i>WORD</i> <1-32> [<i>inform</i>] [<i>timeout</i> <1-2147483647>] [<i>retries</i> <0-255>] [<i>mms</i> <0-2147483647>]} <i>v3</i> { <i>noAuthPriv</i> <i>authNoPriv</i> <i>authPriv</i> } <i>WORD</i> <1-32> [<i>inform</i> [<i>timeout</i> <1-2147483647>] [<i>retries</i> <0-255>]]} [<i>filter</i> <i>WORD</i> <1-32>]	Configures hosts to receive SNMP notifications. <ul style="list-style-type: none"> <i>host</i> <i>WORD</i><1-256> specifies the IPv4 or IPv6 host address <i>port</i> <1-65535> specifies the port number <i>v1</i> <i>WORD</i><1-32> specifies the SNMPv1 security name <i>v2c</i> <i>WORD</i><1-32> specifies the SNMPv2 security name <i>inform</i> specifies the notify type <i>timeout</i> <1-2147483647> specifies the timeout value <i>retries</i> <0-255> specifies the number of retries <i>mms</i> <1-2147483647> specifies the maximum message size <i>v3</i> specifies SNMPv3 <i>noAuthPriv</i> <i>authNoPriv</i> <i>authPriv</i> specifies the security level <i>WORD</i><1-32> specifies the user name <i>filter</i> specifies a filter profile name
<code>location</code> <i>WORD</i> <0-255>	Configures the sysLocation information for the system. < <i>WORD</i> 0-255> is an ASCII string from 0-255 characters.
<code>login-success-trap</code> { <i>enable</i> }	Enables generation of SNMP server login-success traps.
<code>name</code> <i>WORD</i> <0-255>	Configures the sysName information for the system. < <i>WORD</i> 0-255> is an ASCII string from 0-255 characters.
<code>notify-filter</code> <i>WORD</i> <1-32> <i>WORD</i> <1-32>	Creates a new entry in the notify filter table. The first <i>WORD</i> <1-32> specifies the filter profile name, and the second <i>WORD</i> <1-32> specifies the subtree object identifier (OID).

Creating a user

Create a new user in the USM table to authorize a user on a particular SNMP engine.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create a user on a remote system:

```
snmp-server user engine-id WORD<16-97> WORD<1-32> {md5 | sha } [aes | des ]
```

3. Enter and confirm your password.

4. Create a user on the local system:

```
snmp-server user WORD<1-32> [notify-view WORD<0-32>] [read-view
WORD<0-32>] [write-view WORD<0-32>] {md5 | sha} [aes | des ]
```

5. Enter and confirm your password.

6. Add the user to a group:

```
snmp-server user WORD<1-32> group WORD<1-32> {md5 | sha} [aes | des ]
```

7. Enter and confirm your password.

8. Verify the configuration:

```
show snmp-server user
```

Example

Create a user named test1 on a remote system with MD5:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#snmp-server user engine-id 0x80:00:08:E0:03:10:CD:AE:6B:D0:00 test1 md5
aes
Enter the authentication protocol password : *****
Re-enter the authentication protocol password : *****
Enter the privacy protocol password : *****
Re-enter the privacy protocol password : *****

WARNING: For best security practices avoid the use
of repeated patterns in passwords.

Switch:1(config)#show snmp-server user
*****
Engine ID = 0x80:00:08:E0:03:10:CD:AE:6B:D0:00

=====
USM Configuration

Variable Definitions

The following table defines parameters for the `snmp-server user` command.

Variable	Value
<code>{aes des}</code>	Specifies a privacy protocol. If no value is entered, no authentication capability exists. The choices are aes or des. Important: You must set authentication before you can set the privacy option.
<code>engine-id WORD<16-97></code>	Assigns an SNMPv3 engine ID. Use the no operator to remove this configuration.
<code>group WORD<1-32></code>	Specifies the group access name.
<code>{md5 sha}</code>	Specifies an authentication protocol. If no value is entered, no authentication capability exists. The protocol choices are: MD5 and SHA.
<code>notify-view WORD<0-32></code>	Specifies the view name in the range of 0 to 32 characters. The first instance is a noAuth view. The second instance is an auth view and the last instance is an authPriv view.
<code>read-view WORD<0-32></code>	Specifies the view name in the range of 0 to 32 characters. The first instance is a noAuth view. The second instance is an auth view and the last instance is an authPriv view.
<code>write-view WORD<0-32></code>	Specifies the view name in the range of 0 to 32 characters. The first instance is a noAuth view. The second instance is an auth view and the last instance is an authPriv view.
<code>user WORD<1-32></code>	Creates the new entry with this security name. The name is used as an index to the table. The range is 1-32 characters. Use the no operator to remove this configuration.

Creating a new user group

Create a new user group to logically group users who require the same level of access. Create new access for a group in the View-based Access Control Model (VACM) table to provide access to managed objects.

Note

There are several default groups (public and private) created that you can use. To see the list of default groups and their associated security names (secnames), enter **show snmp-server group**. If you use one of these groups, there is no need to create a new group.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create a new user group:

```
snmp-server group WORD <1-32> WORD<1-32> {auth-no-priv|auth-priv|no-
auth-no-priv} [notify-view WORD<1-32>] [read-view WORD<1-32>] [write-
view WORD<1-32>]
```

Example

This example uses the following variable names:

- The new group name is *lan6grp*.
- The context of the group is "", which represents the Global Router (VRF 0).
- The security level is *no-auth-no-priv*.
- The access view name is *v1v2only* for all three views: **notify-view**, **read-view**, and **write-view**.

```
Switch:1>enable
Switch:1#configure terminal
```

Create a new user group:

```
Switch:1(config)#snmp-server group lan6grp "" no-auth-no-priv notify-view v1v2only read-
view v1v2only write-view v1v2only
```

Variable Definitions

The following table defines parameters for the `snmp-server group` command.

Variable	Value
<i>auth-no-priv</i>	Assigns the minimum level of security required to gain the access rights allowed by this conceptual row. If the <i>auth-no-priv</i> parameter is included, it creates one entry for SNMPv3 access.
<i>auth-priv</i>	Assigns the minimum level of security required to gain the access rights allowed by this conceptual row. If the <i>auth-priv</i> parameter is included, it creates one entry for SNMPv3 access.
<i>group WORD<1-32></i> <i>WORD<1-32></i>	The first <i>WORD<1-32></i> specifies the group name for data access. The range is 1-32 characters. Use the no operator to remove this configuration. The second <i>WORD<1-32></i> specifies the context name. The range is 1-32 characters. If you use a particular group name value but with different context names, you create multiple entries for different contexts for the same group. You can omit the context name and use the default. If the context name value ends in the wildcard character (*), the resulting entries match a context name that begins with that context. For example, a context name value of <i>foo*</i> matches contexts starting with <i>foo</i> , such as <i>foo6</i> and <i>foofofum</i> . Use the no operator to remove this configuration.
<i>no-auth-no-priv</i>	Assigns the minimum level of security required to gain the access rights allowed by this conceptual row. If the <i>no-auth-no-priv</i> parameter is included, it creates 3 entries, one for SNMPv1 access, one for SNMPv2c access, and one for SNMPv3 access.
<i>notify-view WORD<1-32></i>	Specifies the view name in the range of 0-32 characters.

Variable	Value
<code>read-view WORD<1-32></code>	Specifies the view name in the range of 0-32 characters.
<code>write-view WORD<1-32></code>	Specifies the view name in the range of 0-32 characters.

Creating a new entry for the MIB in the view table

Create a new entry in the MIB view table. The default Layer 2 MIB view cannot modify SNMP settings. However, a new MIB view created with Layer 2 permission can modify SNMP settings.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Create a new entry:

```
snmp-server view WORD<1-32> WORD<1-32>
```

Example

```
Switch:1>enable
Switch:1#configure terminal
```

Create MIB views:

```
Switch:1(config)#snmp-server view 2 1.3.8.7.1.4
```

Variable Definitions

The following table defines parameters for the `snmp-server view` command.

Variable	Value
The first <code>WORD<1-32></code>	Specifies the prefix that defines the set of MIB objects accessible by this SNMP entity. The range is 1-32 characters.
The second <code>WORD<1-32></code>	Specifies a new entry with this group name. The range is 1-32 characters.

Creating a community

Create a community to use in forming a relationship between an SNMP agent and one or more SNMP managers. You require SNMP community strings to access the system using an SNMP-based management software.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```

2. Create a community:

```
snmp-server community WORD<1-32> [group WORD<1-32>] [index WORD<1-32>]
[secname WORD<1-32>]
```

**Important**

- The **group** parameter is only required if you created a new user group using the procedure in [Creating a new user group](#). If you use any of the default groups, the **secname** automatically links the community to its associated group so there is no need specify the group in this command.
- If you do create a new group, use the **snmp-server community** command to create an SNMP community with a new security name and link it to the new group you created. There is no separate command to create a security name (secname). You use the **snmp-server community** command. The security name is the key to link the community name to a group.
- You cannot use the @ character or the string :: when you create community strings.

Example

In the following example, the community name is *anewcommunity*, the index is *third*, and the secname is *readview*. There is no group specified because this is a default public/read only group.

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

```
Switch:1(config)#snmp-server community anewcommunity index third secname
readview
```

Variable Definitions

The following table defines parameters for the `snmp-server community` command.

Variable	Value
<i>community</i> <i>WORD<1-32></i>	Specifies a community string. The range is 1-32 characters.
<i>group</i> <i>WORD<1-32></i>	Specifies the group name. The range is 1-32 characters.
<i>index</i> <i>WORD<1-32></i>	Specifies the unique index value of a row in this table. The range is 1-32 characters.
<i>secname</i> <i>WORD<1-32></i>	Maps the community string to the security name in the VACM Group Member Table. The range is 1-32 characters.

Add a User to a Group

Add a user to a group to logically group users who require the same level of access.

Procedure

1. Enter Global Configuration mode:
enable

configure terminal
2. Create a new user group:
snmp-server user *WORD<1-32>* group *WORD<1-32>* {md5 | sha} [aes | des]
3. Enter and confirm your password.
4. Verify the configuration:
show snmp-server group

Example

Add a user to a group to logically group users who require the same level of access:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#snmp-server user test4 group grouptest4 md5 aes
Enter the authentication protocol password : *****
Re-enter the authentication protocol password : *****
Enter the privacy protocol password : *****
Re-enter the privacy protocol password : *****

WARNING: For best security practices avoid the use
of repeated patterns in passwords.

Switch:1(config)#show snmp-server group

Variable Definitions

The following table defines parameters for the `snmp-server user` command.

Variable	Value
<code>{aes des}</code>	Specifies a privacy protocol. If no value is entered, no authentication capability exists. The choices are aes or des. Important: You must set authentication before you can set the privacy option.
<code>engine-id WORD<16-97></code>	Assigns an SNMPv3 engine ID. Use the no operator to remove this configuration.
<code>group WORD<1-32></code>	Specifies the group access name.
<code>{md5 sha}</code>	Specifies an authentication protocol. If no value is entered, no authentication capability exists. The protocol choices are: MD5 and SHA.
<code>notify-view WORD<0-32></code>	Specifies the view name in the range of 0 to 32 characters. The first instance is a noAuth view. The second instance is an auth view and the last instance is an authPriv view.
<code>read-view WORD<0-32></code>	Specifies the view name in the range of 0 to 32 characters. The first instance is a noAuth view. The second instance is an auth view and the last instance is an authPriv view.
<code>write-view WORD<0-32></code>	Specifies the view name in the range of 0 to 32 characters. The first instance is a noAuth view. The second instance is an auth view and the last instance is an authPriv view.
<code>user WORD<1-32></code>	Creates the new entry with this security name. The name is used as an index to the table. The range is 1-32 characters. Use the no operator to remove this configuration.

Blocking SNMP

Disable SNMP by using the SNMP block flag. By default, SNMP access is enabled.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Disable SNMP:

```
boot config flags block-snmp
```

Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

Disable SNMP:

```
Switch:1(config)#boot config flags block-snmp
```

Variable Definitions

The following table defines parameters for the `boot config flags` command.

Variable	Value
<code>block-snmp</code>	Configures the block SNMP flag as active. Use the no operator to remove this configuration. The default is off. To set this option to the default value, use the default operator with the command.

View SNMP System Information

View SNMP system information to view trap and authentication profiles.

For a comprehensive set of SNMP-related `show` commands, see [Fabric Engine CLI Commands Reference](#).

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View SNMP system information:

```
show snmp-server
```

Example

```
Switch:1>show snmp-server
```

```

      contact : http://www.extremenetworks.com/contact/
      location :
        name : Switch-BEB
AuthenticationTrap : false
LoginSuccessTrap : false
```

SNMP configuration using Enterprise Device Manager

Configure SNMP to provide services to send and receive messages, authenticate and encrypt messages, and control access to managed objects with Enterprise Device Manager (EDM).

The following task flow shows you the sequence of procedures you perform to configure basic elements of SNMP using EDM.

Figure 220: SNMP configuration using Enterprise Device Manager procedures

Create a User

About This Task

Create a new user in the USM table to authorize a user on a particular SNMP engine.

Note

In EDM, to create new SNMPv3 users you must use the **CloneFromUser** option. However, you cannot clone the default user, named initial. As a result, you must first use CLI to configure at least one user, and then you can use EDM to create subsequent users with the **CloneFromUser** option.

Procedure

1. In the navigation pane, expand **Configuration > Edit > SnmpV3**.
2. Click **USM Table**.
3. Click **Insert**.
4. In the **EngineID** box, use the default Engine ID provided or type an administratively-unique identifier to an SNMP engine.
5. In the **User Name** box, type a name.
6. From the **CloneFromUser** list, select a security name from which the new entry copies authentication data and private data, if required.
7. From the **Auth Protocol** list, select an authentication protocol.
8. In the **Cloned User's Auth Password** box, type the authentication password of the cloned user.
9. In the **New User's Auth Password** box, type an authentication password for the new user.
10. From the **Priv Protocol** list, select a privacy protocol.
11. In the **Cloned User's Priv Password** box, type the privacy password of the cloned user.
12. In the **New User's Priv Password** box, type a privacy password for the new user.
13. Click **Insert**.

Caution

Security risk

To ensure security, change the GroupAccess table default view after you set up a new user in the USM table. This prevents unauthorized people from accessing the system using the default user logon. Also, change the Community table defaults, because the community name is used as a community string in SNMPv1/v2 PDU.

USM Table field descriptions

Use the data in the following table to use the **USM Table** tab and the **Insert USM Table** dialog box. The system displays some fields only on the Insert USM Table dialog box.

Name	Description
EngineID	Specifies an administratively-unique identifier to an SNMP engine.
UserName	Creates the new entry with this security name. The name is used as an index to the table. The range is 1-32 characters.
SecurityName	Identifies the name on whose behalf SNMP messages are generated.

Name	Description
Clone From User	Specifies the security name from which the new entry must copy privacy and authentication parameters. The range is 1–32 characters. The system displays this option only in the Insert USM Table dialog box.
Auth Protocol (Optional)	Assigns an authentication protocol (or no authentication) from a list. If you select an authentication protocol, you must enter an old AuthPass and a new AuthPass.
Cloned User's Auth Password	Specifies the current authentication password of the cloned user. The system displays this option only in the Insert USM Table dialog box.
New User's Auth Password	Specifies the authentication password of the new user. The system displays this option only in the Insert USM Table dialog box.
Priv Protocol (Optional)	Assigns a privacy protocol (or no privacy) from a list. If you select a privacy protocol, you must enter an old PrivPass and a new PrivPass.
Cloned User's Priv Password	Specifies the current privacy password of the cloned user. The system displays this option only in the Insert USM Table dialog box.
New User's Priv Password	Specifies the privacy password of the new user. The system displays this option only in the Insert USM Table dialog box.

Create a New Group Membership

About This Task

Create a new group membership to logically group users who require the same level of access.

Note

There are several default groups (public and private) created that you can use. To see the list of default groups and their associated security names (secnames), enter **show snmp-server group**. If you use one of these groups, there is no need to create a new group.

Procedure

1. In the navigation pane, expand **Configuration > Edit > SnmpV3**.
2. Click **VACM Table**.
3. Click the **Group Membership** tab.
4. Click **Insert**.
5. From the **SecurityModel** options, select a security model.
6. In the **SecurityName** box, type a security name.
7. In the **GroupName** box, type a group name.
8. Click **Insert**.

Group Membership field descriptions

Use the data in the following table to use the **Group Membership** tab.

Name	Description
SecurityModel	Specifies the security model to use with this group membership.
SecurityName	Specifies the security name assigned to this entry in the View-based Access Control Model (VACM) table. The range is 1–32 characters.
GroupName	Specifies the name assigned to this group in the VACM table. The range is 1–32 characters.

Create Access for a Group

About This Task

Create access for a group in the View-based Access Control Model (VACM) table to provide access to managed objects.

Procedure

1. In the navigation pane, expand **Configuration > Edit > SnmpV3**.
2. Click **VACM Table**.
3. Click the **Group Access Right** tab.
4. Click **Insert**.
5. In the **GroupName** box, type a VACM group name.
6. In the **ContextPrefix** box, select a VRF instance. This is an optional step.
7. From the **SecurityModel** options, select a model.
8. From the **SecurityLevel** options, select a security level.
9. In the **ContextMatch** option, select a value to match the context name. This value is **exact** by default.
10. (Optional) In the **ReadViewName** box, type the name of the MIB view that forms the basis of authorization when reading objects. This is an optional step.
11. (Optional) In the **WriteViewName** box, type the name of the MIB view that forms the basis of authorization when writing objects. This is an optional step.
12. (Optional) In the **NotifyViewName** box, type MIB view that forms the basis of authorization for notifications. This is an optional step.
13. Click **Insert**.

Group Access Right field descriptions

Use the data in the following table to use the **Group Access Right** tab.

Name	Description
GroupName	Specifies the name of the new group in the VACM table. The range is 1–32 characters.
ContextPrefix	Specifies if the contextName must match the value of the instance of this object exactly or partially. The range is an SnmpAdminString, 1–32 characters.

Name	Description
SecurityModel	Specifies the authentication checking to communicate to the switch. The security models are: <ul style="list-style-type: none"> • SNMPv1 • SNMPv2 • USM
SecurityLevel	Specifies the minimum level of security required to gain the access rights allowed. The security levels are: <ul style="list-style-type: none"> • noAuthNoPriv • authNoPriv • authpriv
ContextMatch	Specifies if the prefix and the context name must match. If the value is exact, all rows where the contextName exactly matches vacmAccessContextPrefix are selected. If you do not select exact, all rows where the contextName with starting octets that exactly match vacmAccessContextPrefix are selected.
ReadViewName	Identifies the MIB view of the SNMP context to which this conceptual row authorizes read access. The default is the empty string.
WriteViewName	Identifies the MIB view of the SNMP context to which this conceptual row authorizes write access. The default is the empty string.
NotifyViewName	Identifies the MIB view of the SNMP context to which this conceptual row authorizes access for notifications. The default is the empty string.

Create Access Policies for SNMP Groups

About This Task

Create an access policy to determine the access level for the users who connect to the switch with different services like File Transfer Protocol (FTP), Trivial FTP (TFTP), and Telnet.

You only need to create access policies for SNMP groups if you have the access policy feature enabled.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **Access Policies**.
3. Select the **Access Policies-SNMP Groups** tab.
4. Select **Insert**.
5. Enter an **ID**.
6. In the **Name** box, type a name.
7. From the **Model** options, select a security model.
8. Select **Insert**.

Access Policies – SNMP Groups field descriptions

The following table defines parameters for the **Access Policies-SNMP Groups** tab.

Name	Description
Id	Specifies the ID of the group policy.
Name	Specifies the name assigned to the group policy. The range is 1–32 characters.
Model	Specifies the security model {SNMPv1 SNMPv2c USM}.

Assign MIB View Access for an Object

About This Task

Create a new entry in the MIB View table.

You cannot modify SNMP settings with the default Layer 2 MIB view. However, you can modify SNMP settings with a new MIB view created with Layer 2 permissions.

Procedure

1. In the navigation pane, expand **Configuration > Edit > SnmpV3**.
2. Click **VACM Table**.
3. In the **VACM Table** tab, click the **MIB View** tab.
4. Click **Insert**.
5. In the **ViewName** box, type a view name.
6. In the **Subtree** box, type a subtree.
7. In the **Mask** box, type a mask.
8. From the **Type** options, select whether access to the MIB object is granted.
9. Click **Insert**.

MIB View field descriptions

Use the data in the following table to use the **MIB View** tab.

Name	Description
ViewName	Creates a new entry with this group name. The range is 1–32 characters.
Subtree	Specifies a valid object identifier that defines the set of MIB objects accessible by this SNMP entity, for example, 1.3.6.1.1.5.
Mask (optional)	Specifies a bit mask with vacmViewTreeFamilySubtree to determine whether an OID falls under a view subtree.
Type	Determines whether access to a MIB object is granted (included) or denied (excluded). The default is included.

Create a Community

About This Task

Create a community to use in forming a relationship between an SNMP agent and one or more SNMP managers. You require SNMP community strings for access to the switch using an SNMP-based management software.

Procedure

1. In the navigation pane, expand **Configuration > Edit > SnmpV3**.
2. Click **Community Table**.
3. Click **Insert**.
4. In the **Index** box, type an index.
5. In the **Name** box, type a name that is a community string.
6. In the **SecurityName** box, type a security name.
7. In the **ContextName** box, type the context name.
8. Click **Insert**.

Community Table field descriptions

Use the data in the following table to use the **Community Table** tab.

Name	Description
Index	Specifies the unique index value of a row in this table. The range is 1–32 characters.
Name	Specifies the community string for which a row in this table represents a configuration.
SecurityName	Specifies the security name in the VACM group member table to which the community string is mapped. The range is 1–32 characters.
ContextEngineID	Indicates the location of the context in which management information is accessed when using the community string specified in Name .
ContextName	Specifies the context in which management information is accessed when you use the specified community string.

View All Contexts for an SNMP Entity

About This Task

View contexts to see the contents of the context table in the View-based Access Control Model (VACM). This table provides information to SNMP command generator applications so that they can properly configure the VACM access table to control access to all contexts at the SNMP entity.

Procedure

1. In the navigation pane, expand **Configuration > Edit > SnmpV3**.
2. Click **VACM Table**.
3. In the **VACM Table** tab, click the **Contexts** tab.

Contexts field descriptions

Use the data in the following table to use the **Contexts** tab.

Variable	Value
ContextName	Shows the name identifying a particular context at a particular SNMP entity. The empty contextName (zero length) represents the default context.

Showing SNMP Statistics

About This Task

Display SNMP statistics to monitor the number of specific error messages, such as the number of messages that were delivered to SNMP but were not allowed.

Procedure

1. In the navigation pane, expand the **Configuration > Security > Control Path** folders.
2. Click **General**.
3. Click the **SNMP** tab.

SNMP Field Descriptions

Use the data in the following table to display SNMP statistics.

Name	Description
OutTooBigs	Shows the number of SNMP PDUs that the SNMP protocol entity generated and for which the value of the error-status field is tooBig.
OutNoSuchNames	Shows the number of SNMP PDUs that the SNMP protocol entity generated and for which the value of the error-status is noSuchName.
OutBadValues	Shows the number of SNMP PDUs that SNMP protocol entity generated and for which the value of the error-status field is badValue.
OutGenErrors	Shows the number of SNMP PDUs that the SNMP protocol entity generated and for which the value of the error-status field is genErr.
InBadVersions	Shows the number of SNMP messages that were delivered to the SNMP protocol entity and were for an unsupported SNMP version.
InBadCommunityNames	Shows the number of SNMP messages delivered to the SNMP protocol entity that used an SNMP community name not known to the entity.
InBadCommunityUsers	Shows the number of SNMP messages delivered to the SNMP protocol entity that represented an SNMP operation not allowed by the SNMP community named in the message.
InASNParseErrs	Shows the number of ASN.1 or BER errors encountered by the SNMP protocol entity when decoding received SNMP messages.

Name	Description
InTooBigs	Shows the number of SNMP PDUs that were delivered to the SNMP protocol entity and for which the value of the error-status field is tooBig.
InNoSuchNames	Shows the number of SNMP PDUs that were delivered to the SNMP protocol entity and for which the value of the error-status field is noSuchName.
InBadValues	Shows the number of SNMP PDUs that were delivered to the SNMP protocol entity and for which the value of the error-status field is badValue.
InReadOnlys	Shows the number of valid SNMP PDUs delivered to the SNMP protocol entity and for which the value of the error-status field is "read-only". It is a protocol error to generate an SNMP PDU that contains the value "read-only" in the error-status field; this object is provided as a means of detecting incorrect implementations of the SNMP.
InGenErrors	Shows the number of SNMP PDUs delivered to the SNMP protocol entity and for which the value of the error-status field is "genErr."

Spanning Tree Configuration

[Spanning Tree Fundamentals](#) on page 2705

[Spanning Tree Configuration Using CLI](#) on page 2712

[Spanning Tree Configuration Using EDM](#) on page 2733

Spanning Tree Fundamentals

Table 206: Spanning Tree Protocol product support

Feature	Product	Release introduced
Spanning Tree Protocol (STP): <ul style="list-style-type: none">• Multiple STP (MSTP)• Rapid STP (RSTP)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5

The switch supports Rapid Spanning Tree Protocol (RSTP) and Multiple Spanning Tree Protocol (MSTP).

Spanning Tree

Spanning Tree protocols detect and eliminate logical loops in a bridged or switched network. If multiple paths exist, the spanning Tree algorithm configures the network so that a bridge or device uses the root bridge path based on hop counts. Although link speed is taken into account, the path is based on the root bridge rather than on an optimized path. If that path fails, the protocol automatically reconfigures the network and makes another path active, thereby sustaining network operations. The switch supports RSTP and MSTP but can downgrade a port automatically if it receives an STP Bridge Protocol Data Unit (BPDU) from a switch that runs STP.

Note

Spanning Tree is disabled on all Switched UNI (S-UNI) ports. The ports will move into forwarding state as soon as the physical port or VLACP or LACP comes up on the port. If the platform VLAN is associated to the S-UNI Service Instance Identifier (I-SID), then the S-UNI ports added to the platform VLAN will become the member of MSTP instances associated with the platform VLAN. To enable SLPP on the S-UNI ports, the platform VLAN must be associated with the S-UNI I-SID.

Spanning Tree Groups

Spanning Tree Groups (STGs) represent logical topologies. A topology is created based on bridge configuration values such as root bridge priority. In the case of multiple STGs, you can map a VLAN to the most appropriate logical topology in the physical network.

The switch supports Spanning Tree modes RSTP and MSTP. The default Spanning Tree mode is MSTP. The default STG is 0. In RSTP mode, all VLANs run in the default STG. In MSTP mode, you can create additional STGs by using the VLAN create command. The switch supports up to 64 STGs.

Although STP and MSTP are variations of the same Spanning Tree protocol, they communicate information differently. A switch in MSTP mode cannot recognize the Spanning Tree groups running on a chassis configured with STP. MSTP Spanning Tree groups are not the same as STP Spanning Tree groups. Using a switch in MSTP mode with a chassis in STP mode can create a loop in the network.

The root bridge for Rapid Spanning Tree Protocol (RSTP) and Multiple Spanning Tree Protocol (MSTP) is determined by comparing attributes of each bridge in the network.

The protocol considers bridge priority first. If more than one bridge has the same priority, then the protocol must consider the bridge ID. The bridge with the lowest ID becomes the root bridge. For MSTP, this bridge is called the Common and Internal Spanning Tree (CIST) Root because it is the root of the entire physical network.

In MSTP mode, you can create additional Spanning Tree instances, by using the VLAN command. These instances, known as Multiple Spanning Tree Instances (MSTIs), can assign different priorities to switches. The MSTIs have different link costs or port priorities and as a result create separate logical topologies.

MSTP also allows the creation of MSTP regions. A region is a collection of switches sharing the same view of physical and logical topologies. For switches to belong to the same region, the following attributes must match:

- MSTP configuration ID selector
- MSTP configuration name
- MSTP configuration revision number
- VLAN instance mapping

Links connecting sections are called boundary ports. In a region, the boundary switch that contains the boundary port providing the shortest external path cost to the CIST Root is the CIST Regional Root.

STGs and VLANs

When you map VLANs to STGs, be aware that all links on the bridge belong to all STGs. Because each Spanning Tree group can differ in its decision to make a link forwarding or blocking, you must ensure that the ports you add to a VLAN are in the expected state.

Untagged ports can only belong to one VLAN and therefore can only belong to one STG. Tagged ports can belong to multiple VLANs and therefore to multiple STGs.

BPDU handling on S-UNI port/MLT

The switch handles Bridge Protocol Data Units (BPDUs) according to whether or not you configure a platform VLAN.

- When you configure a platform VLAN:
 - BPDUs are forwarded to the CPU by default.
 - For both the ingress and egress ports, BPDUs are not flooded in the S-UNI I-SID associated with the platform VLAN.

Note

If the platform VLAN is configured for the S-UNI port, you cannot enable BPDU forwarding.

- When you DO NOT configure a platform VLAN:
 - BPDUs received on untagged-traffic ports are dropped by default.
 - To flood BPDUs in its I-SID, enable BPDU forwarding under S-UNI I-SID using the command **untagged-traffic port <port no> bpdu enable**.

BPDU Guard

Table 207: Bridge Protocol Data Unit (BPDU) Guard product support

Feature	Product	Release introduced
Bridge Protocol Data Unit (BPDU) Guard	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5

The switch supports Bridge Protocol Data Unit (BPDU) Guard for STGs, RSTP, and MSTP.

Overview

Spanning Tree eliminates loops in a network. A bridge that participates in spanning tree uses BPDUs to exchange information with other bridges. The bridges select a single bridge as the root bridge based on the BPDU information exchange. The bridge with the lowest priority becomes the root bridge. If all bridges share the same priority, the bridge with the lowest bridge ID becomes the root bridge. This process is the root selection process.

After you add a new bridge to the network, or remove an existing bridge, the bridges repeat the root selection process, and then select a new root bridge.

To ensure the correct operation of Spanning Tree in the network, BPDU Guard protects the stability of the Root Bridge by dropping stray, unexpected, or unwanted BPDU packets entering a port, and immediately shutting down those ports for a specified time period. BPDU Guard is normally enabled on access ports connecting to end user devices such as servers that are not expected to operate Spanning Tree.

Use BPDU Guard to achieve the following results:

- Block the root selection process after an edge device, such as a laptop that uses Linux with STP enabled, is added to the network. Blocking the root selection process prevents unknown devices from influencing the spanning tree topology.
- Block BPDU flooding of the switch from an unknown device.

Operation

You can enable or disable BPDU Guard on an individual port basis, regardless of the spanning tree state. Each port uses a timer to determine port-state recovery.

After you enable BPDU Guard on a port and the port receives a BPDU, the following actions occur:

1. The guard disables the port.
2. The switch generates an SNMP trap and alarm, and the following log message:

```
BPDU Guard - Port <slot/port> is being shutdown by BPDU Guard, timeout <time_seconds>
```

3. The port timer begins.
4. The port remains in the disabled state until the timer expires.

If you disable BPDU Guard before the timer expires, the timer stops and the port remains in the disabled state. You must manually enable the port.

BPDU Guard is enabled at the interface level. You can configure the BPDU Guard timer for each port, for 10 to 65535 seconds. If you set the port timer to zero, it will not expire.

Rapid Spanning Tree Protocol and Multiple Spanning Tree Protocol

The Rapid Spanning Tree Protocol (RSTP or IEEE 802.1w) reduces the recovery time after a network breakdown. It also maintains backward compatibility with IEEE 802.1d (the spanning tree implementation prior to RSTP). In certain configurations, the recovery time of RSTP can be reduced to less than 1 second. RSTP also reduces the amount of flooding in the network by enhancing the way Topology Change Notification (TCN) packets are generated.

With Multiple Spanning Tree Protocol (MSTP or IEEE 802.1s), you can configure multiple instances or Spanning Tree groups on the same device. Each instance or Spanning Tree group can include one or more VLANs.

By using RSTP and MSTP, the switch achieves the following:

- reduces convergence time after a topology change (from 30 seconds to less than 1 or 2 seconds)
- eliminates unnecessary flushing of the MAC database and the flooding of traffic to the network
- creates backward compatibility with classic 802.1d switches
- creates support for 64 instances of spanning tree in MSTP mode

The following sections relate to RSTP and MSTP:

- [RSTP interoperability with STP](#) on page 2709
- [Differences in port roles for STP and RSTP](#) on page 2709
- [Port roles: root forwarding role](#) on page 2710

- [Port roles: designated forwarding role](#) on page 2710
- [Port roles: alternate blocking role](#) on page 2710
- [Edge port](#) on page 2710
- [Path cost values](#) on page 2711
- [RSTP negotiation process](#) on page 2711

RSTP interoperability with STP

RSTP provides a parameter called ForceVersion to provide backward compatibility with standard STP. A user can configure a port in either STP-compatible mode or RSTP mode:

- An STP-compatible port transmits and receives only STP Bridge Protocol Data Units (BPDUs). An RSTP BPDUs that the port receives in this mode is discarded.
- An RSTP-compatible port transmits and receives only RSTP BPDUs. If an RSTP port receives an STP BPDUs, it becomes an STP port. User intervention is required to change this port back to RSTP mode. This process is called Port Protocol Migration.

Note

You must configure protocol migration to true on all spanning-tree enabled interfaces when you change the spanning tree version from STP-compatible to MSTP for those interfaces to work in the proper mode.

Before implement MSTP or RSTP you must be aware of the following:

- The default mode is MSTP. A special boot configuration flag identifies the mode.
- You can lose your configuration if you change the spanning tree mode from MSTP to RSTP and the configuration file contains VLANs configured with MSTI greater than 0. RSTP only supports VLANs configured with the default instance 0.
- For best interoperability results, contact your vendor representative.

Differences in port roles for STP and RSTP

RSTP is an enhanced version of STP. These two protocols have almost the same parameters.

The following table lists the differences in port roles for STP and RSTP. STP supports two port roles, while RSTP supports four port roles.

Table 208: Differences in port roles for STP and RSTP

Port Role	STP	RSTP	Description
Root	Yes	Yes	This port receives a better BPDUs than its own and has the best path to reach the Root. The root port is in Forwarding state. The root port and designated ports can be in the Discarding state before they go to root forwarding.
Designated	Yes	Yes	This port has the best BPDUs on the segment. The designated port is in the Forwarding state.

Table 208: Differences in port roles for STP and RSTP (continued)

Port Role	STP	RSTP	Description
Alternate	No	Yes	This port receives a better BPDU than its own BPDU, and a root port exists within the same device. The alternate port is in the Discarding state.
Backup	No	Yes	This port receives a better BPDU than its own BPDU, and this BPDU is from another port within the same device. The backup port is in the Discarding state.

Port roles: root forwarding role

MSTP and RSTP root forwarding roles are as follows:

- The port that receives the best path BPDU on a device is the root port, and is referred to as a Root Forwarding (RF) port. This is the port that is the closest to the root bridge in terms of path cost.
- The spanning tree algorithm elects a single root bridge in a bridged network. With MSTP, a root bridge is selected for the Common and Internal Spanning Tree (CIST). A root bridge is selected for the region, and a root bridge is selected for each spanning tree instance.
- The root bridge is the only bridge in a network that does not have root ports; all ports on a root bridge are Designated Forwarding (DF).
- Only one path towards a root bridge can exist on a given segment; otherwise, loops can occur.

Port roles: designated forwarding role

MSTP and RSTP designated forwarding roles are as follows:

- All bridges connected on a segment monitor the BPDUs of all other bridges. The bridge that sends the best BPDU is the root bridge for the segment.
- The corresponding port on the bridge is referred to as a Designated Forwarding Port.

Port roles: alternate blocking role

MSTP and RSTP alternate blocking roles are as follows:

- A blocked port is defined as not being the designated or root port. An alternate port provides an alternate path to the root and can replace the root port if it fails.
- An alternate blocked port is a port that is blocked because it received better path cost BPDUs from another bridge.

Port roles: backup blocking role

MSTP and RSTP backup blocking roles are as follows:

- A backup port receives the more useful BPDUs from the bridge on which the port exists.

Edge port

RSTP uses a parameter called the edge port. After a port connects to a nonswitch device, such as a PC or a workstation, it must be configured as an edge port. An active edge port enters the forwarding state without delay. An edge port becomes a nonedge port if it receives a BPDU.

Path cost values

RSTP and MSTP path cost values support a wide range of link speeds. The following table lists the path cost values.

Table 209: Path cost values

Link speed	Value
Less than or equal to 100 Kbps	200 000 000
1 Mbps	20 000 000
10 Mbps	2 000 000
100 Mbps	200 000
1 Gbps	20 000
10 Gbps	2000
100 Gbps	200
1 Tbps	20
10 Tbps	2

RSTP negotiation process

The following section describes the negotiation process between switches that takes place before PCs can exchange data (see the following figure).

**Figure 221: RSTP negotiation process**

After turning on, all ports assume the role of designated ports. All ports are in the discarding state except edge ports. Edge ports go directly into the forwarding state without delay.

Unit A port 1 and Unit B port 1 exchange BPDUs. Unit A knows that it is the root and that Unit A port 1 is the designated port. Unit B learns that Unit A has higher priority. Unit B port 1 becomes the root port. Both Unit A port 1 and Unit B port 1 are still in the discarding state.

Unit A starts the negotiation process by sending a BPDU with the proposal bit set.

Unit B receives the proposal BPDU and configures its nonedge ports to discarding state. This operation occurs during the synchronization process.

Unit B sends a BPDU to Unit A with the agreement bit set.

Unit A configures port 1 to the forwarding state, and Unit B configures port 1 to the forwarding state. PC 1 and PC 2 can now communicate. The negotiation process now moves on to Unit B port 3 and its partner port. PC 3 cannot exchange data with either PC 1 or PC 2 until the negotiation process between Unit B and Unit C finishes.

The RSTP convergence time depends on how quickly the switches can exchange BPDUs during the negotiation process, and on the number of switches in the network.

Spanning Tree Configuration Using CLI

Important

The switch supports up to 64 STGs on a device, however, SPBM uses STG 63 and MSTI 62 for internal use. STG 63 or MSTI 62 cannot be used by other VLANs or MSTIs.

Configuring Spanning Tree

Configure the STP mode to configure the spanning tree mode on the device.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Configure the STP mode:
`boot config flags spanning-tree-mode {rstp|mstp}`

Example

Configure the STP mode:

```
Switch:1(config)#boot config flags spanning-tree-mode mstp
Warning: Please save the configuration and reboot the switch
         for this to take effect.
Warning: Please carefully save your configuration files before
         starting configuring the switch in RSTP or MSTP mode.
```

Variable Definitions

Use the data in the following table to use the **boot config flags spanning-tree-mode** command.

Variable	Value
<i>rstp mstp</i>	Specifies the Spanning Tree modes: Rapid Spanning Tree Protocol (RSTP) or Multiple Spanning Tree Protocol (MSTP).

Configure BPDU Guard

Configure BPDU Guard to block the root selection process or to prevent BPDU flooding from unknown devices.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable BPDU Guard for the port:

```
spanning-tree bpduguard enable
```

3. (Optional) Configure the timer for port-state recovery:

```
spanning-tree bpduguard timeout <0, 10-65535>
```

4. (Optional) Enable BPDU Guard on an additional port or group of ports:

```
spanning-tree bpduguard port {slot/port[/sub-port] [-slot/port[/subport]]
[,...]} enable
```

5. (Optional) Configure the timer for port-state recovery for an additional port or group of ports:

```
spanning-tree bpduguard port {slot/port[/sub-port] [-slot/port[/subport]]
[,...]} timeout <0-65535>
```

6. Verify the configuration:

```
show spanning-tree bpduguard [GigabitEthernet {slot/port[/sub-port] [-slot/port[/subport]]
[,...]}] [{slot/port[/sub-port] [-slot/port[/subport]]
[,...]}]
```

Example

Enable BPDU Guard on port 1/8, and specify a timer value of 200 seconds. Verify the configuration.

```
Switch:1>enable
Switch:1#configure terminal
```

```

Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 1/8
Switch:1(config-if)#spanning-tree bpduguard enable
Switch:1(config-if)#spanning-tree bpduguard timeout 200
Switch:1(config-if)#show spanning-tree bpduguard 1/8

=====
                                Bpdu Guard
=====
Port          PORT          PORT          TIMER  BPDUGUARD  BPDUGUARD
NUM MLTID  ADMIN_STATE  OPER_STATE  TIMEOUT  COUNT  ADMIN_STATE  ORIGIN
-----
1/8          Up           Up           200      0       Enabled      CONFIG
    
```

Variable Definitions

Use the data in the following table to use the **spanning-tree bpduguard** commands.

Variable	Value
<i>enable</i>	Enables BPDU Guard on the port. The default is disabled.
<i>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<i>timeout <0, 10-65535></i>	Specifies the value to use for port-state recovery. After a BPDU guard disables a port, the port remains in the disabled state until this timer expires. You can configure a value from 10 to 65535. The default is 120 seconds. If you configure the value to 0, the expiry is infinity.

Use the data in the following table to use the **show spanning-tree bpduguard** command.

Variable	Value
<i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Configuring Rapid Spanning Tree Protocol

Configure Rapid Spanning Tree Protocol (RSTP) to reduce the recovery time after a network breakdown.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure RSTP:

```
spanning-tree rstp [forward-time <400-3000>] [group-stp enable]
[hello-time <100-1000>] [max-age <600-4000>] [pathcost-type <bits16|
bits32>] [priority <0-61440>] [tx-holdcount <1-10>] [version <rstp|
stp-compatible>]
```

Example

Configure RSTP:

```
Switch:1(config)# spanning-tree rstp forward-time 1000 hello-time 200 max-age 4000
pathcost-type bits16 priority 4096 tx-holdcount 10 version rstp group-stp enable
```

*Variable Definitions*Use the data in the following table to use the **spanning-tree rstp** command.

Variable	Value
<i>forward-time <400-3000></i>	Configures the RSTP forward delay for the bridge in hundredths of a second.
<i>group-stp enable</i>	Enables or disables RSTP for a specific STG. Enter the no form of the command to disable RSTP for the STG (<code>no spanning-tree rstp group-stp enable</code>).
<i>hello-time <100-1000></i>	Assigns the RSTP hello time delay for the bridge in hundredths of a second.
<i>max-age <600-4000></i>	Assigns the RSTP maximum age time for the bridge in hundredths of a second.
<i>pathcost-type {bits16 bits32}</i>	Assigns the RSTP default pathcost version. The default is 32 bits.
<i>priority <0-61440></i>	Assigns the RSTP bridge priority.
<i>tx-holdcount <1-10></i>	Assigns the RSTP transmit hold count from 1 to 10. The default value is 6.
<i>version {rstp/stp-compatible}</i>	Sets the version to RSTP or STP compatible.

Configuring Rapid Spanning Tree Protocol for a port

Configure RSTP to reduce the recovery time after a network breakdown.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure RSTP:

```
spanning-tree rstp cost <1-200000000> edge-port <false|true> p2p
<auto|force-false|force-true> priority <0-240> protocol-migration
<false|true> stp enable
```

Example

Configure RSTP:

```
Switch:1(config-if)# spanning-tree rstp cost 100 edge-port true p2p auto
priority 32 protocol-migration true stp enable
```

Variable Definitions

Use the data in the following table to use the **spanning-tree rstp** command.

Variable	Value
<code>cost <1-200000000></code>	Specifies the contribution of this port to the path cost.
<code>edge-port <false true></code>	Configures the edge-port value for the port. A value of true indicates that this port is an edge-port, and a value of false indicates that this port is a nonedge-port.
<code>p2p <auto force-false force-true></code>	Specifies the point-to-point status of the LAN segment attached to this port. A value of force-true indicates that this port is treated as if it connects to a point-to-point link. A value of force-false indicates that this port is treated as having a shared media connection. A value of auto indicates that this port is considered to have a point-to-point link if it is an aggregator and all of its members are aggregatable, or if the MAC entity is configured for full-duplex operation, either through autonegotiation or by management means.
<code>priority <0-240></code>	Assigns the RSTP bridge priority in a range of 0-240. The value has to increment in steps of 16.

Variable	Value
<code>protocol-migration <false true></code>	If you chose true, the option initiates protocol migration for a port. If you chose false, the option terminates protocol migration for a port. An RSTP-compatible port transmits and receives only RSTP BPDUs. If an RSTP port receives an STP BPDU, it becomes an STP port. User intervention is required to change this port back to RSTP mode. This process is called Port Protocol Migration.
<code>stp enable</code>	Configures STP for the port.

Configuring the Rapid Spanning Tree Protocol version

Perform this procedure to specify the RSTP mode.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure Rapid Spanning Tree Protocol version:

```
spanning-tree rstp version {rstp|stp-compatible}
```

Example

Configure Rapid Spanning Tree Protocol version:

```
Switch:1(config)# spanning-tree rstp version rstp
```

Variable Definitions

Use the data in the following table to use the **spanning-tree rstp version** command.

Variable	Value
<code>rstp version {rstp stp-compatible}</code>	Sets the version to RSTP or to STP compatible. The default is RSTP.

Viewing the global RSTP configuration information

View the global RSTP configuration information to display the Rapid Spanning Tree Protocol (RSTP) configuration details.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View global RSTP configuration information:

```
show spanning-tree rstp config
```

Example

View global RSTP configuration information:

```
Switch:1> show spanning-tree rstp config
```

```

Variable Definitions

Use the data in the following table to use optional parameters with the **show spanning-tree rstp port config** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Viewing the RSTP Status for a Port

View the RSTP status for a port to display the RSTP-related status information for a selected port.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View the RSTP status for a port:

```
show spanning-tree rstp port status {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
```

Note

If your platform supports channelization for 40 Gbps ports and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Example

View the RSTP status for a port:

```
Switch:1> show spanning-tree rstp port status 1/2
```

```

=====

```

Variable Definitions

Use the data in the following table to use optional parameters with the **show spanning-tree rstp port status** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Viewing RSTP information for a selected port

View the RSTP information for a selected port to display the RSTP-related configuration information for the selected port.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. View the RSTP information for a selected port:

```
show spanning-tree rstp port statistics [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]
```

Example

View the RSTP information for a selected port:

```
Switch:1# show spanning-tree rstp port statistics 1/4
```

```

=====
                        RSTP Port Statistics
=====

Tx Config BPDU Count      : 0
Tx TCN BPDU Count         : 0
Invalid RST BPDUs Rx Count : 0
Invalid Config BPDU Rx Count : 0
Invalid TCN BPDU Rx Count : 0
Protocol Migration Count   : 0
=====

```

Variable definitions

Use the data in the following table to use optional parameters with the `show spanning-tree rstp port statistics` command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Viewing the RSTP role

View the RSTP role to display the RSTP information.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View the RSTP role:

```
show spanning-tree rstp port role [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]
```

Example

View the RSTP role:

```
Switch:1> show spanning-tree rstp port role 1/3
```

```

=====
                        RSTP Port Roles and States
=====
Port-Index  Port-Role   Port-State   PortSTPStatus  PortOperStatus
-----
1/3         Designated  Forwarding   Enabled         Enabled

```

Variable definitions

Use the data in the following table to use optional parameters with the `show spanning-tree rstp port role` command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Viewing spanning tree configuration

Perform this procedure to view configuration and status information for spanning tree in your network.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View spanning tree configuration information:

```
show spanning-tree config
```
3. View spanning tree status information:

```
show spanning-tree status
```

Example

View spanning tree configuration information:

```
Switch:1> show spanning-tree config
```

```

```

Configuring Multiple Spanning Tree Protocol

Use the following procedure to configure the Multiple Spanning Tree Protocol.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure MSTP:

```
spanning-tree mstp
```

Example

Configure Multiple Spanning Tree Protocol to configure the MSTP configuration version.

```
Switch:1(config)# spanning-tree mstp forward-time 500 max-age 3000 max-hop 200 pathcost-type bits32 priority 8192 tx-holdcount 10 version mstp
```

Variable Definitions

Use the data in the following table to use the **spanning-tree mstp** command.

Variable	Value
<i>forward-time</i> <400-3000>	Configures the MSTP forward delay for the bridge from 400 to 3000 hundredths of a second.
<i>max-age</i> <600-4000>	Assigns the MSTP maximum age time for the bridge from 600 to 4000 one hundredths of a second.
<i>max-hop</i> <100-4000>	Assigns the MSTP bridge maximum hop count. The range is 100 to 4000 one hundredths of a second. The original MIB erroneously designated the value in hundredths of a second, when it should have been in hops. The replacement MIB kept the range at 100-4000 to remain backwards compatible. To convert this value to hops, divide by 100 so 100-4000 equals 1-40 hops.
<i>msti</i> <1-63> <i>priority</i> <0-65535>	Assigns the MSTP MSTI instance parameter.
<i>pathcost-type</i> { <i>bits16</i> <i>bits32</i> }	Assigns the MSTP default pathcost type to either 16 bits or 32 bits. The default is 32 bits.
<i>priority</i> <0-61440>	Assigns the MSTP bridge priority in a range of 0 to 61440 in steps of 4096.
<i>region</i> [<i>config-id-sel</i> <0-255>] [<i>region-name</i> <WORD 1-32>] [<i>region-version</i> <0-65535>]	Assigns the MSTP region commands: <ul style="list-style-type: none"> • <i>config-id-sel</i>—Assigns the MSTP region configuration ID number. The range is 0 to 255. • <i>region-name</i>—Assigns the MSTP region name. The character string can be a range of 1 to 32 characters • <i>region-version</i>—Assigns the MSTP region version. The range is 0 to 65535.

Variable	Value
<code>tx-holdcount <1-10></code>	Assigns the MSTP transmit hold count. The range is 1 to 10. The default value is 3.
<code>version {mstp rstp stp-compatible}</code>	Assigns the bridge version. Although STP and MSTP are variations of the same spanning tree protocol, they communicate information differently. A switch in MSTI mode cannot recognize the spanning tree groups running on a chassis configured with STP. MSTP spanning tree groups are not the same as STP spanning tree groups. Using a switch in MSTP mode with another chassis in STP mode can create a loop in the network. You must configure protocol migration to true on all spanning-tree enabled interfaces when you change the spanning tree version from STP-compatible to MSTP for those interfaces to work in the proper mode.

Configuring MSTP MSTI options

Use the following procedure to configure MSTP multiple spanning tree instance (MSTI) options.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure MSTP MSTI:

```
spanning-tree mstp msti <1-63> priority <0-65535>
```

Example

Configure MSTP MSTI:

```
Switch:1(config)# spanning-tree mstp msti 62 priority 4096
```

Variable Definitions

Use the data in the following table to use the **spanning-tree mstp msti <1-63> priority <0-65535>** command.

Variable	Value
<1-63>	Specifies the instance ID.
<0-65535>	Specifies the priority value. Enter values in increments of 4096: <ul style="list-style-type: none"> • 4096 • 8192 • 12288 • 16384 • 20480 • 24576 • 28672 • 32768 • 36864 • 40960 • 45056 • 49152 • 53248 • 57344 • 61440

Configuring Ethernet MSTP

Configure Ethernet MSTP on a port to enable this feature.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port]} [-slot/port[/sub-port]]
[,...]
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure Ethernet MSTP:

```
spanning-tree mstp [cost <1-200000000>] [edge-port <false|true>]
[force-port-state enable] [hello-time <100-1000>] [msti <1-63>] [p2p
{auto|force-false|force-true}] [port {slot/port[/sub-port]}] [priority
<0-240>] [protocol-migration <false|true>]
```

Example

Configure Ethernet MSTP:

```
Switch:1(config)# spanning-tree mstp cost 1 edge-port true force-port-
state enable hello-time 100 p2p auto priority 2 protocol-migration true
```

Variable Definitions

Use the data in the following table to use the **spanning-tree mstp** command.

Variable	Value
<i>cost</i> <1-200000000>	Configures the path cost for a port. Valid values are 1 to 200000000
<i>edge-port</i> <false true>	Enables or disables the port as an edge port.
<i>force-port-state enable</i>	Enables STP.
<i>hello-time</i> <100-1000>	Configures the hello-time for a port.
<i>msti</i> <1-63>	Configures the port MSTP MSTI.
<i>p2p</i> {auto force-false force-true}	Enables or disables point-to-point for a port.
{slot/port[/sub-port]}	Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<i>priority</i> <0-240>	Configures priority for the port.
<i>protocol-migration</i> {false true}	If you chose true, the option initiates protocol migration for a port. If you chose false, the option terminates protocol migration for a port. An MSTP-compatible port transmits and receives only RSTP BPDUs. If an MSTP port receives an STP BPDU, it becomes an STP port. User intervention is required to change this port back to MSTP mode. This process is called Port Protocol Migration. You must configure protocol migration to true on all spanning-tree enabled interfaces when you change the spanning tree version from STP-compatible to MSTP for those interfaces to work in the proper mode.

Configuring Ethernet MSTP MSTI

Use the following procedure to configure the Ethernet MSTP MSTI parameters on a port.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure Ethernet MSTP MSTI:

```
spanning-tree mstp msti <1-63> [cost <1-200000000>] [force-port-state
enable] [port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]
[priority <0-240>]
```

Example

Configure Ethernet MSTP MSTI:

```
Switch(config-if)# spanning-tree mstp msti 62 priority 32
```

Variable Definitions

Use the data in the following table to use the **spanning-tree mstp msti <1-63>** command.

Variable	Value
<1-63>	Specifies the instance ID.
<i>cost <1-200000000></i>	Configures the path cost for the port
<i>force-port-state enable</i>	Enables MSTI learning for the port.
<i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<i>priority <0-240></i>	Configures the priority for the port. Enter the priority value (0-240) as increments of 16.

Viewing MSTP configurations

View the MSTP configurations to display the MSTP-related bridge-level VLAN and region information.

Procedure

1. To enter User EXEC mode, log on to the switch.

- View the MSTP configurations:

```
show spanning-tree mstp config
```

Example

View the MSTP configurations:

```
Switch:1> show spanning-tree mstp config
```

```

Configuring tc-receive-alarm-threshold

About This Task

You can establish a threshold rate for receiving TC/TCN packets by configuring values for count and interval. If the threshold rate is exceeded, you receive a warning message. Use the following procedure to configure values for **tc-receive-alarm-threshold count** and **tc-receive-alarm-threshold interval**.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure a value for count:

```
spanning-tree tc-receive-alarm-threshold count <1-1000>
```
3. Configure a value for interval:

```
spanning-tree tc-receive-alarm-threshold interval <1-15>
```

Example

Configure count and interval values:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#spanning-tree tc-receive-alarm-threshold count 3
Switch:1(config)#spanning-tree tc-receive-alarm-threshold interval 2
```

Display the alarm threshold configuration:

```
Switch:1#show spanning-tree tc-receive-alarm-threshold
```

```
=====
                        Spanning Tree TC/TCN Rx Alarm Threshold Configuration
=====
Interval           : 2 minutes
Count              : 3
```

Variable definitions

Use the data in the following table to use the **tc-receive-alarm-threshold** command.

Variable	Value
count <1-1000>	Specifies the number of packets used to establish the threshold rate. The default is 2.
interval <1-15>	Specifies the time interval (in minutes) used to establish the threshold rate. The default is 1.

Displaying the tc-receive-alarm-threshold configuration

About This Task

You can configure a threshold rate for receiving TC/TCN packets. If the threshold is exceeded, you receive a warning message. Use the following procedure to display the tc-receive-alarm-threshold configuration.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the tc-receive-alarm-threshold configuration:

```
show spanning-tree tc-receive-alarm-threshold
```

Example

```
Switch:1(config)#show spanning-tree tc-receive-alarm-threshold
```

```
=====
                        Spanning Tree TC/TCN Rx Alarm Threshold Configuration
=====
Interval                : 1 minutes
Count                   : 2
```

Spanning Tree Configuration Using EDM

This section describes how to create, manage, and monitor spanning tree groups (STG). It also describes how to configure the Rapid Spanning Tree Protocol (RSTP) and the Multiple Spanning Tree Protocol (MSTP) using Enterprise Device Manager (EDM).

Important

The switch supports up to 64 STGs in a device, however, SPBM uses STG 63 and MSTI 62 for internal use. STG 63 or MTSI 62 cannot be used by other VLANs or MSTIs.

Configuring the Spanning Tree mode

Configure the Spanning Tree mode to change the mode to MSTP or RSTP mode.

Important

After you change the mode, restart the system for the changes to take effect.

Procedure

1. In the navigation pane, expand the **Configuration > VLAN > Spanning Tree** folders.
2. Click **Globals**.
3. Select the required spanning tree mode.
4. Click **Apply**.

The system notifies you that the setting takes effect after you save the configuration and restart the server.

Globals field descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
SpanningTreeAdminMode	Configures the spanning tree mode as either RSTP or MSTP. The default is MSTP.
SpanningTreeOperMode	Specifies the current mode of the spanning tree.

Restarting the switch

Restart the switch so that changes to the bootconfig parameters (or other parameters) take effect. For example, you must restart the device to enable a change to the Spanning Tree mode.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Edit**.
2. Click **Chassis**.
3. In the System tab, locate the **ActionGroup1** box.
4. Select **saveRuntimeConfig**.
5. Click **Apply**.
6. In the **ActionGroup4** box, select **softReset**.
7. Click **Apply**.

Configure BPDU Guard

Configure BPDU Guard to block the root selection process or to prevent BPDU flooding from unknown devices.

About This Task

To configure multiple ports simultaneously, select more than one port in the Device Physical View tab. The system displays **BPDU Guard** tab as a table-based tab.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand the following folders: **Configuration > Edit > Port**.
3. Click **General**.
4. Click the **Interface** tab.

5. Select **BpduGuardAdminEnabled** to enable BPDU Guard for the port.
6. (Optional) Type a value in **BpduGuardTimeout** to configure the timer for port-state recovery
7. Click **Apply**.

Interface Field Descriptions

Use the data in the following table to use the **Interface** tab.

Name	Description
Index	Displays the index of the port, written in the slot/port[/sub-port] format.
Name	Configures the name of the port.
Descr	Displays the description of the port. A textual string containing information about the interface.
Type	Displays the type of connector plugged in the port.
Mtu	Displays the Maximum Transmission Unit (MTU) for the port. The size of the largest datagram which can be sent or received on the interface, specified in octets. For interfaces that are used for transmitting network datagrams, this is the size of the largest network datagram that can be sent on the interface.
PhysAddress	Displays the physical address of the port. The address of the interface at the protocol layer immediately `below' the network layer in the protocol stack. For interfaces which do not have such an address, for example, a serial line, this object should contain an octet string of zero length.
VendorDescr	Displays the vendor of the connector plugged in the port.
DisplayFormat	Identifies the slot and port numbers (slot/port). If the port is channelized, the format also includes the sub-port in the format slot/port/sub-port
AdminStatus	Configures the port as enabled (up) or disabled (down) or testing. The testing state indicates that no operational packets can be passed.
OperStatus	Displays the current status of the port. The status includes enabled (up) or disabled (down) or testing. The testing state indicates that no operational packets can be passed.
LicenseControlStatus	Shows the port license status.
Note: Exception: only supported on 5320 Series.	
ShutdownReason	Indicates the reason for a port state change.
LastChange	Displays the timestamp of the last change.

Name	Description
LinkTrap	Enable or disable link trapping.
AutoNegotiate	Enables or disables Auto-Negotiation for this port. The default Auto-Negotiation behavior depends on the switch model and transceiver type.
AutoNegAd	Specifies the port speed and duplex abilities to advertise during link negotiation. Supported speeds and duplex modes vary, depending on your hardware. The abilities specified in this object are only used when auto-negotiation is enabled on the port. If all bits in this object are disabled, and auto-negotiation is enabled on the port, then the physical link process on the port will be disabled (if hardware supports this ability). Any change to this configuration restarts the auto-negotiation process, which has the same effect as physically unplugging and reattaching the cable attached to the port. If you select default , all capabilities supported by the hardware are advertised.
AdminDuplex	Configures the administrative duplex setting for the port.
OperDuplex	Indicates the operational duplex setting for the port.
AdminSpeed	Configures the administrative speed for the port.
OperSpeed	Indicates the operational speed for the port.
QoSLevel	Selects the Quality of Service (QoS) level for this port. The default is level1.
DiffServ	Enables the Differentiated Service feature for this port. The default is disabled.
Layer3Trust	Configures if the system should trust Layer 3 packets coming from access links or core links only. The default is core.
Layer2Override8021p	Specifies whether Layer 2 802.1p override is enabled (selected) or disabled (cleared) on the port. The default is disabled (clear).
MltId	Shows the MLT ID associated with this port. The default is 0.
Locked	Shows if the port is locked. The default is unlocked.
UnknownMacDiscard	Discards packets that have an unknown source MAC address, and prevents other ports from sending packets with that same MAC address as the destination MAC address. The default is disabled.
DirectBroadcastEnable	Specifies if this interface forwards direct broadcast traffic.

Name	Description
OperRouting	Shows the routing status of the port.
HighSecureEnable	Enables or disables the high secure feature for this port.
RmonEnable	Enables or disables Remote Monitoring (RMON) on the interface. The default is disabled.
FlexUniEnable	Enables Flex UNI on the port. The default is disabled.
EgressRateLimitState	Enables or disables egress port-based shaping to bind the maximum rate at which traffic leaves the port. The default is disabled.
EgressRateLimit	Specifies the egress rate limit in Kbps. Different hardware platforms support different egress rate limits, depending on the port with the highest speed available on the platform. You cannot configure the egress shaper rate to exceed the port capability. If you configure this value to 0, shaping is disabled on the port.
TxFlowControl	Configures if the port sends pause frames. By default, an interface does not send pause frames. You must also enable the flow control feature globally before an interface can send pause frames.
TxFlowControlOperState	Shows the operational state of flow control.
BpduGuardTimerCount	Shows the time, starting at 0, since the port became disabled. When the BpduGuardTimerCount reaches the BpduGuardTimeout value, the port is enabled. Displays in 1/100 seconds.
BpduGuardTimeout	Specifies the value to use for port-state recovery. After a BPDU guard disables a port, the port remains in the disabled state until this timer expires. You can configure a value of 0 or to 65535. The default is 120 seconds. If you configure the value to 0, the expiry is infinity.
BpduGuardAdminEnabled	Enables BPDU Guard on the port. The default is disabled.
ForwardErrorCorrection	Configures one of the following options for Forward Error Correction (FEC) on the port: <ul style="list-style-type: none"> • CL 91 • CL 108 • CL 74 • disable • auto <p>The disable option disables this configuration on the port.</p>

Name	Description
ForwardErrorCorrectionApplicability	Displays whether FEC is applicable on the interface.
OperAutoNegotiate	Shows the operational state of Auto-Negotiation.
OperForwardErrorCorrection	Shows the negotiated operational FEC clause. If the value is off, the port supports FEC and is up but not configured for FEC. If the value is notApplicable, the port does not support FEC. If the value is unknown, the port supports FEC but is down.
Action	Performs one of the following actions on the port <ul style="list-style-type: none"> • none - none of the following actions • flushMacFdb - flush the MAC forwarding table • flushArp - flush the ARP table • flushIp - flush the IP route table • flushAll - flush all tables • triggerRipUpdate – manually triggers a RIP update The default is none.
Result	Displays the result of the selected action. The default is none.
AutoSense	Enables or disables Auto-sense on the specific port. The default value is disabled for existing configurations but enabled for new Zero Touch Fabric Configuration deployments.
AutoSenseKeepAutoConfig	Retains the Auto-sense configuration if you disable Auto-sense on the port. The dynamic configuration becomes a manual configuration and is visible in the show running-config output.
CustomAutoNegAdOrigin	Specifies the origin of Custom Auto Negotiation Advertisements (CANA) configuration on the port. The supported values are: <ul style="list-style-type: none"> • config - Set by the user. • radius - Set by the Remote Authentication Dial-In User Service (RADIUS) attribute.
BpduGuardOrigin	Specifies the origin of BPDU Guard configuration on the port. The supported values are: <ul style="list-style-type: none"> • config - Set by the user. • radius - Set by the Remote Authentication Dial-In User Service (RADIUS) attribute.
AutoSenseState	Displays the Auto-sense port state.

Name	Description
LinkDebounce	Specifies the extended debounce timer on the port. The range is 0 to 300000 milliseconds. The value 0 milliseconds disables debounce time. The default value is 1000.
AutoSenseDatalsid	Specifies the Auto-sense data I-SID per port. The range is 0 to 15999999.

Configuring RSTP global parameters

Perform this procedure to configure the RSTP global parameters.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN > Spanning Tree**.
2. Click **RSTP**.
3. Configure the parameters as required.
4. Click **Apply**.

Globals field descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
PathCostDefault	Specifies the version of the spanning tree default path costs that are used by this bridge. A value of 8021d1998 indicates the use of the 16-bit default path costs from IEEE Std. 802.1d-1998. A value of stp8021t2001 indicates the use of the 32-bit default path costs from IEEE Std. 802.1t.
TxHoldCount	Specifies the value used by the port transmit state machine to limit the maximum transmission rate. The default is 3.
Version	Specifies the version of STP that the bridge currently runs. The value stpCompatible indicates that the Spanning Tree Protocol as specified in IEEE 802.1d is in use; rstp indicates that the Rapid Spanning Tree Protocol as specified in IEEE 802.1w is in use.
EnableStp	Indicates whether the spanning tree protocol is active in this STG. The default is enabled.
Priority	Specifies the RSTP bridge priority.
BridgeMaxAge	Specifies the value that all bridges use for MaxAge while this bridge acts as the root.
BridgeHelloTime	The value that all bridges use for HelloTime while this bridge acts as the root.
BridgeForwardDelay	Specifies the value that all bridges use for forward delay while this bridge acts as the root.

Name	Description
DesignatedRoot	Specifies the unique bridge identifier of the bridge recorded as the root in the configuration BPDUs transmitted by the designated bridge for the segment to which the port is attached.
RootCost	Specifies the cost of the path to the root from this bridge.
RootPort	Specifies the port number of the port which offers the lowest cost path from this bridge to the root bridge.
MaxAge	Specifies the maximum age of Spanning Tree Protocol information in hundredths of a second learned from the network on any port before the port is discarded.
HelloTime	Specifies the amount of time in hundredths of a second between the transmission of configuration bridge PDUs by this node on any port while it is the root of the spanning tree (or trying to become the root).
ForwardDelay	Specifies a time value, measured in hundredths of a second, controls how fast a port changes its spanning state after moving towards the forwarding state. The value determines how long the port stays in each of the listening and learning states, which precede the forwarding state. This value is also used after a topology change is detected, and is underway, to age all dynamic entries in the forwarding database.
RstpUpCount	Specifies the number of times the RSTP module is enabled. A trap is generated on the occurrence of this event.
RstpDownCount	Specifies the number of times the RSTP module is disabled. A trap is generated on the occurrence of this event.
NewRootIdCount	Specifies the number of times this bridge detects a root identifier change. A trap is generated on the occurrence of this event.
TimeSinceTopology Change	Specifies the time (in hundredths of a second) since the TcWhile Timer for any port in this bridge was nonzero for Common Spanning Tree.
TopChanges	Specifies the number of times that there was at least one nonzero TcWhile Timer on this bridge for Common Spanning Tree.

Configuring RSTP ports

Configure RSTP to reduce the recovery time after a network breakdown.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN > Spanning Tree**.
2. Click **RSTP**.
3. Click the **RSTP Ports** tab.
4. Use the fields in the **RSTP Ports** tab to configure the RSTP ports.
5. Click **Apply**.

RSTP Ports field descriptions

Use the data in the following table to use the **RSTP Ports** tab.

Name	Description
Port	Specifies a unique value, greater than zero, indicating the port number.
Priority	Specifies the value of the priority field.
PathCost	Specifies the contribution of this port to the path cost of paths towards the root that includes this port.
ProtocolMigration	Specifies a port to transmit RSTP BPDUs if operating in RSTP mode. Any other operation on this object has no effect, and RSTP mode returns false if read.
AdminEdgePort	Specifies the administrative value of the Edge Port parameter. A value of true indicates that this port is an edge-port, and a value of false indicates that this port is a nonedge-port.
OperEdgePort	Specifies the operational value of the Edge Port parameter. The object is initialized to the value of AdminEdgePort and is configured to false on reception of a BPDU.
AdminPointToPoint	Specifies the administrative point-to-point status of the LAN segment attached to this port. A value of forceTrue indicates that this port is treated as if it is connected to a point-to-point link. A value of forceFalse indicates that this port is treated as having a shared media connection. A value of auto indicates that this port is considered to have a point-to-point link if it is an aggregator and all of its members are aggregatable, or if the MAC entity is configured for full-duplex operation, either through autonegotiation or by management means.

Name	Description
OperPointToPoint	Specifies the operational point-to-point status of the LAN segment attached to this port. It indicates whether a port is considered to have a point-to-point connection or not. The value is determined by management or by autodetection as described in the AdminPointToPoint object.
OperVersion	Indicates if the port is in MSTP mode, RSTP mode or STP-compatible mode. MSTP mode transmits MST BDUs, RSTP mode transmits RST BPDUs and STP-compatible transmits Config/TCN BPDUs.

Viewing RSTP port status

View the RSTP port status to ensure proper functioning of RSTP.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN > Spanning Tree**.
2. Click **RSTP**.
3. In the RSTP tab, click the **RSTP Status** tab.

RSTP Status field descriptions

Use the data in the following table to use the **RSTP Status** tab.

Name	Description
Port	Specifies a unique value, greater than zero, indicating the port number.
State	Specifies the current state of the port as defined by application of the Spanning Tree Protocol. This state controls what action a port takes on reception of a frame.
Role	Indicates the current port role assumed by this port.
OperVersion	Indicates whether the port is operationally in the RSTP- or STP-compatible mode; that is, whether the port transmits RSTP BPDUs or Config/TCN BPDUs.
EffectivePortState	Specifies the effective operational state of the port. This object is configured to true if the port is operationally up in the Interface Manager, and if Force Port State for this port and the specified port state is enabled. Otherwise, this object is configured to false.

Viewing RSTP Status Statistics

About This Task

You can view status statistics for Rapid Spanning Tree Protocol (RSTP).

Procedure

1. In the navigation pane, expand the **Configuration > VLAN > Spanning Tree** folders.
2. Click **RSTP**.
3. In the **RSTP Status** tab, select a port, and then click **Graph**.

RSTP Status Field Descriptions

The following table describes the **RSTP Status** fields.

Name	Description
RxRstBpduCount	Specifies the number of RSTP BPDUs this port received.
RxConfigBpduCount	Specifies the number of configuration BPDUs this port received.
RxTcnBpduCount	Specifies the number of TCN BPDUs this port received.
TxRstBpduCount	Specifies the number of RSTP BPDUs this port transmitted.
TxConfigBpduCount	Specifies the number of Config BPDUs this port transmitted.
TxTcnBpduCount	Specifies the number of TCN BPDUs this port transmitted.
InvalidRstBpduRxCount	Specifies the number of invalid RSTP BPDUs this port received. A trap is generated on the occurrence of this event.
InvalidConfigBpduRx Count	Specifies the number of invalid configuration BPDUs this port received. A trap is generated on the occurrence of this event.
InvalidTcnBpduRxCount	Specifies the number of invalid TCN BPDUs this port received. A trap is generated on the occurrence of this event.
ProtocolMigrationCount	Specifies the number of times this port migrated from one STP protocol version to another. The relevant protocols are STP-Compatible and RSTP. A trap is generated on the occurrence of this event.

Viewing Port Spanning Tree Statistics

View port spanning tree statistics to manage network performance.

Procedure

1. In the Device Physical View, select a port.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Port**.
4. Click the **Spanning Tree** tab.

Spanning Tree *Field Descriptions*

The following table describes parameters on the **Spanning Tree** tab.

Name	Description
InConfigBpdus	The number of Config BPDUs received.
InTcnBpdus	The number of Topology Change Notifications BPDUs received.
InBadBpdus	The number of unknown or malformed BPDUs received.
OutConfigBpdus	The number of Config BPDUs transmitted.
OutTcnBpdus	The number of Topology Change Notifications BPDUs transmitted.

Configuring MSTP global parameters

Configure the global MSTP parameters to determine how MSTP operates for the system. Interface-level parameters override global settings.

Before You Begin

- The system must be in MSTP mode.

Procedure

- In the navigation tree, expand the following folders: **Configuration > VLAN > Spanning Tree**.
- Click **MSTP**.
- Click the **Globals** tab.
- Configure MSTP as required.
- Click **Apply**.

Globals *field descriptions*

Use the data in the following table to use the **Globals** tab.

Name	Description
PathCostDefaultType	Specifies the version of the spanning tree default path costs to be used by this bridge. A value of 8021d1998 denotes the use of the 16-bit default path costs from IEEE 802.1d-1998. A value of stp8021t2001 denotes the use of the 32-bit default path costs from IEEE 802.1t.
TxHoldCount	Specifies the value used by the port transmit state to limit the maximum transmission rate. The default is 3.

Name	Description
MaxHopCount	<p>Assigns the MSTP bridge maximum hop count. The range is 100 to 4000 one hundredths of a second.</p> <p>The original MIB erroneously designated the value in hundredths of a second, when it should have been in hops. The replacement MIB kept the range at 100-4000 to remain backwards compatible. To convert this value to hops, divide by 100 so 100-4000 equals 1-40 hops.</p>
NoOfInstancesSupported	<p>Indicates the maximum number of spanning tree instances supported.</p>
MstpUpCount	<p>The number of times the MSTP module is enabled. A trap is generated on the occurrence of this event.</p>
MstpDownCount	<p>The number of times the MSTP module is disabled. A trap is generated on the occurrence of this event.</p>
ForceProtocolVersion	<p>Specifies the version of Spanning Tree Protocol that the bridge currently runs. stpCompatible indicates that the Spanning Tree Protocol as specified in IEEE 802.1d is in use; rstp indicates that the Rapid Spanning Tree Protocol as specified in IEEE 802.1w is in use; and mstp indicates that the multiple spanning tree protocol as specified in IEEE 802.1s is in use.</p> <p>Although STP and MSTP are variations of the same spanning tree protocol, they communicate information differently. A switch in MSTP mode cannot recognize the spanning tree groups running on a chassis configured with STP. MSTP spanning tree groups are not the same as STP spanning tree groups. Using a switch in MSTP mode with a chassis in STP mode can create a loop in the network.</p> <p>The default is MSTP.</p>
BrgAddress	<p>Specifies the MAC address used by this bridge if it must be referred to in a unique fashion. This should be the numerically smallest MAC address of all ports that belong to this bridge. If concatenated with MstCistBridgePriority or MstBridgePriority, a unique bridge identifier is formed, which is used in the STP.</p>
Root	<p>Specifies the bridge identifier of the root of the common spanning tree as determined by the STP by this node. This value is used as the CIST root identifier parameter in all configuration bridge PDUs originated by this node.</p>

Name	Description
RegionalRoot	Specifies the bridge identifier of the root of the multiple spanning tree region as determined by the STP as executed of this node. This value is used as the common and internal spanning tree (CIST) regional root identifier parameter in all configuration bridge PDUs originated by this node.
RootCost	Specifies the cost of the path to the CIST root from this bridge.
RegionalRootCost	Specifies the cost of the path to the CIST regional root from this bridge.
RootPort	Specifies the port number of the port which offers the lowest path cost from this bridge to the CIST root bridge.
BridgePriority	Specifies the value of the writable portion of the bridge identifier comprising the first two octets. The values you enter for bridge priority must be in steps of 4096. The default is 32768.
BridgeMaxAge	Specifies the value that all bridges use for MaxAge while this bridge acts as the root. The granularity of this timer is specified as 1 second. An agent can return a bad value error if you attempt to configure a value which is not a whole number of seconds. The default is 2000.
BridgeForwardDelay	Specifies the value that all bridges use for forward delay if this bridge acts as the root. Note that 802.1d specifies that the range for this parameter is related to the value of BridgeMaxAge. The granularity of this timer is specified as 1 second. An agent can return a bad value error if you attempt to configure a value which is not a whole number of seconds. The default is 1500.
HoldTime	Determines the interval length in hundredths of a second during which no more than two configuration bridge PDUs can be transmitted by this node.
MaxAge	Specifies the maximum age of Spanning Tree Protocol information learned from the network on any port before it is discarded. This is the value that this bridge currently uses.
ForwardDelay	Specifies the time value, measured in units of hundredths of a second, that controls how fast a port changes its spanning state after moving towards the forwarding state. This value determines how long the port stays in a particular state before moving to the next state.
TimeSinceTopology Change	Specifies the time (in hundredths of a second) since the TcWhile Timer for any port in this bridge was nonzero for Common Spanning Tree.

Name	Description
TopChanges	Specifies the number of times that there was at least one nonzero TcWhile Timer on this bridge for Common Spanning Tree.
NewRootBridgeCount	Specifies the number of times this bridge detects a root bridge change for Common Spanning Tree. A trap is generated on the occurrence of this event.
RegionName	Specifies the name for the region configuration. By default, the region name is equal to the bridge MAC Address.
RegionVersion	Specifies the version of the MST region.
ConfigIdSel	Specifies the configuration identifier format selector used by the bridge. This has a fixed value of 0 to indicate RegionName. RegionVersions are specified as in the standard.
ConfigDigest	Specifies the configured MD5 digest value for this region, which must be 16 octets long.
RegionConfigChange Count	Specifies the number of times a region configuration identifier change is detected. A trap is generated on the occurrence of this event.

Configuring CIST ports for MSTP

Configure Common and Internal Spanning Tree (CIST) ports to configure ports for MSTP.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN > Spanning Tree**.
2. Click **MSTP**.
3. Click the **CIST Port** tab.

Note

The MSTP, CIST Port tab contains information for each port that is common to all bridge and spanning tree instances.

4. Use the fields in the **CIST Port** box to configure the MSTP CIST port.
5. Click **Apply**.

CIST Port field descriptions

Use the data in the following table to use the **CIST Port** tab.

Name	Description
Port	Specifies the port number of the port for which this entry contains spanning tree information.
PathCost	Specifies the contribution of this port to the path cost of paths towards the CIST root that includes this port.
Priority	Specifies the four most significant bits of the port identifier of the spanning tree instance which are modified by setting the CistPortPriority value. The values that are configured for port priority must be in steps of 16. Although port priority values can range from 0 to 255, only the following values are used: 0, 16, 32, 48, 64, 80, 96, 112, 128, 144, 160, 176, 192, 208, 224, 240. The default is 128.
DesignatedRoot	Specifies the unique bridge identifier of the bridge recorded as the CIST root in the configuration BPDUs transmitted.
DesignatedCost	Specifies the path cost of the designated port of the segment that connects to this port.
DesignatedBridge	Specifies the unique bridge identifier of the bridge which that port considers to be the designated bridge for the ports segment.
DesignatedPort	Specifies the port identifier of the port on the designated bridge for this port segment.
RegionalRoot	Specifies the unique bridge identifier of the bridge recorded as the CIST regional root identifier in the configuration BPDUs transmitted.
RegionalPathCost	Specifies the contribution of this port to the path cost of paths towards the CIST regional root that include this port.
ProtocolMigration	Indicates the protocol migration state of this port. If you chose true, the option initiates protocol migration for a port. If you chose false, the option terminates protocol migration for a port. An MSTP-compatible port transmits and receives only RSTP BPDUs. If an MSTP port receives an STP BPDU, it becomes an STP port. User intervention is required to change this port back to MSTP mode. This process is called Port Protocol Migration. You must configure protocol migration to true on all spanning-tree enabled interfaces when you change the spanning tree version from STP-compatible to MSTP for those interfaces to work in the proper mode.

Name	Description
AdminEdgeStatus	Specifies the administrative value of the Edge Port parameter. A value of true indicates that this port is an edge-port, and a value of false indicates that this port is a nonedge-port.
OperEdgeStatus	Specifies the operational value of the Edge Port parameter. The object is initialized to the value of AdminEdgeStatus and is configured to false on reception of a BPDU.
AdminP2P	Specifies the administrative point-to-point status of the LAN segment attached to this port. A value of forceTrue indicates that this port is treated as if it connects to a point-to-point link. A value of forceFalse indicates that this port is treated as having a shared media connection. A value of auto indicates that this port is considered to have a point-to-point link if it is an aggregator and all of its members are aggregatable, or if the MAC entity is configured for full-duplex operation, either through autonegotiation or by management means.
OperP2P	Specifies the operational point-to-point status of the LAN segment attached to this port. It indicates whether a port is considered to have a point-to-point connection or not. The value is determined by management or by autodetection as described in the AdminP2P object.
HelloTime	Specifies the amount of time in hundredths of a second between the transmission of configuration bridge PDUs by this node on this port.
OperVersion	Indicates whether the port is operationally in the MSTP mode, the RSTP mode, or the STP-compatible mode; that is, whether the port transmits MST BPDUs, RST BPDUs, or Config/TCN BPDUs. Although STP and MSTP are variations of the same spanning tree protocol, they communicate information differently. A switch in MSTI mode cannot recognize the spanning tree groups running on a chassis configured with STP. MSTP spanning tree groups are not the same as STP spanning tree groups. Using a switch in MSTP mode with another chassis in STP mode can create a loop in the network.
EffectivePortState	Specifies the effective operational state of the port for CIST. This is true only if the port is operationally up at the interface and protocol levels for CIST. This is configured to false for all other conditions.
State	Specifies the current state of the port as defined by the common spanning tree protocol. It can be disabled, discarding, learning, or forwarding.

Name	Description
ForcePortState	Specifies the current state of the port. You can change the port to either Disabled or Enabled for the base spanning tree instance.
SelectedPortRole	Specifies the selected port role of the port for this spanning tree instance.
CurrentPortRole	Specifies the current port role of the port for this spanning tree instance.

Configuring MSTI bridges for MSTP

Perform this procedure to configure multiple spanning tree instance (MSTI) bridges for MSTP.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN > Spanning Tree**.
2. Click **MSTP**.
3. Click the **MSTI Bridges** tab.

Note

The systems generates MSTI bridge instances after you create a VLAN in MSTP mode.

4. Use the fields in the **MSTI Bridges** box to configure the MSTP bridge.
5. Click **Apply**.

MSTI Bridges field descriptions

Use the data in the following table to use the **MSTI Bridges** tab.

Name	Description
Instance	Specifies the spanning tree instance to which this information belongs.
RegionalRoot	Specifies the MSTI regional root identifier value for the instance. This value is used as the MSTI regional root identifier parameter in all configuration bridge PDUs originated by this node.
Priority	Specifies the writable portion of the MSTI bridge identifier comprising the first two octets. The values that are configured for bridge priority must be in steps of 4096. The default is 32768.
RootCost	Specifies the cost of the path to the MSTI regional root as seen by this bridge.
RootPort	Specifies the port number of the port that offers the lowest path cost from this bridge to the MSTI region root bridge.

Name	Description
TimeSinceTopologyChange	Specifies the time (in hundredths of a second) since the TcWhile Timer for any port in this bridge was nonzero for this spanning tree instance.
TopChanges	Specifies the number of times that there was at least one nonzero TcWhile Timer on this bridge for this spanning tree instance.
NewRootCount	Specifies the number of times this bridge detects a root bridge change for this spanning tree instance. A trap is generated on the occurrence of this event.
InstanceUpCount	Specifies the number of times a new spanning tree instance is created. A trap is generated on the occurrence of this event.
InstanceDownCount	Specifies the number of times a spanning tree instance is deleted. A trap is generated on the occurrence of this event.

Configuring MSTI ports for MSTP

Perform the following procedure to configure MSTI ports for MSTP.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN > Spanning Tree**.
2. Click **MSTP**.
3. Click the **MSTI Port** tab.

Note

Port members you select on the VLAN, the system displays **Basic** tab in the **MSTI Port** tab.

4. Use the fields in the **MSTI Port** box to configure the MSTP.
5. Click **Apply**.

MSTI Port field descriptions

Use the data in the following procedure to use the **MSTI Port** tab.

Name	Description
Port	Specifies the port number of the port for which this entry contains spanning tree information.
Instance	Specifies the spanning tree instance to which the information belongs.
PathCost	Specifies the contribution of this port to the path cost of paths towards the MSTI root that includes this port.

Name	Description
Priority	Specifies the four most significant bits of the port identifier for a given spanning tree instance can be modified independently for each spanning tree instance supported by the bridge. The values configured for port priority must be in steps of 16. The default is 128.
DesignatedRoot	Specifies the unique bridge identifier of the bridge recorded as the MSTI regional root in the configuration BPDUs transmitted.
DesignatedBridge	Specifies the unique bridge identifier of the bridge that this port considers to be the designated bridge for the port segment.
DesignatedPort	Specifies the port identifier of the port on the designated bridge for this port segment.
State	Specifies the current state of the port, as defined by the MSTP. A port which is in forwarding state in one instance can be in discarding (blocking) state in another instance.
ForcePortState	Specifies the current state of the port, that is changed to either disabled or enabled for the specific spanning tree instance.
DesignatedCost	Specifies the path cost of the designated port of the segment connected to this port.
CurrentPortRole	Specifies the current port role of the port for this spanning tree instance.
EffectivePortState	Specifies the effective operational state of the port for a specific instance. This is configured to true if the port is operationally up at the interface and protocol levels for the specific instance. This is configured to false at all other times.

Viewing VLAN and Spanning Tree CIST Statistics

About This Task

View CIST port statistics to manage network performance.

Procedure

1. In the navigation pane, expand the **Configuration > VLAN > Spanning Tree** folders.
2. Click **MSTP**.
3. Click the **CIST Port** tab.
4. Select a port, and then click **Graph**.

CIST Field Descriptions

The following table describes parameters on the **CIST** tab.

Name	Descriptions
ForwardTransitions	Specifies the number of times this port has transitioned to the forwarding state.
RxMstBpduCount	Specifies the number of MSTP BPDUs received on this port.
RxRstBpduCount	Specifies the number of RSTP BPDUs received on this port.
RxConfigBpduCount	Specifies the number of configuration BPDUs received on this port.
RxTcnBpduCount	Specifies the number of TCN BPDUs received on this port.
TxMstBpduCount	Specifies the number of MSTP BPDUs transmitted from this port.
TxRstBpduCount	Specifies the number of RSTP BPDUs transmitted from this port.
TxConfigBpduCount	Specifies the number of configuration BPDUs transmitted from this port.
TxTcnBpduCount	Specifies the number of TCN BPDUs transmitted from this port.
InvalidMstBpduRxCount	Specifies the number of Invalid MSTP BPDUs received on this port.
InvalidRstBpduRxCount	Specifies the number of Invalid RSTP BPDUs received on this port.
InvalidConfigBpduRxCount	Specifies the number of invalid configuration BPDUs received on this port.
InvalidTcnBpduRxCount	Specifies the number of invalid TCN BPDUs received on this port. The number of times this port has migrated from one STP protocol version to another. The relevant protocols are STP-compatible and RSTP/MSTP. A trap is generated on the occurrence of this event.
ProtocolMigrationCount	Specifies the number of times this port has migrated from one STP protocol version to another. The relevant protocols are STP-compatible and RSTP. A trap is generated on the occurrence of this event.

Viewing VLAN and Spanning Tree MSTI Statistics

About This Task

View multiple spanning tree instance (MSTI) port statistics to manage network performance.

Procedure

1. In the navigation pane, expand the **Configuration > VLAN > Spanning Tree** folders.
2. Click **MSTP**.
3. Click the **MSTI Port** tab.
4. Select a port, and then click **Graph**.

MSTI Field Descriptions

The following table describes parameters on the **MSTI** tab.

Name	Description
ForwardTransitions	Specifies the number of times this port has transitioned to the forwarding state for this specific instance.
ReceivedBPDUs	Specifies the number of BPDUs received by this port for this spanning tree instance.
TransmittedBPDUs	Specifies the number of BPDUs transmitted on this port for this spanning tree instance.
InvalidBPDUsRcvd	Specifies the number of invalid BPDUs received on this port for this spanning tree instance.

SPB-PIM Gateway configuration

Table 210: SPB-PIM Gateway product support

Feature	Product	Release introduced
SPB-PIM Gateway controller node	5320 Series	Not Supported
	5420 Series	Not Supported
	5520 Series	VOSS 8.2.5
SPB-PIM Gateway interface	5320 Series	Not Supported
	5420 Series	Not Supported
	5520 Series	VOSS 8.2.5

SPB-PIM Gateway configuration includes controller and gateway nodes, and Multicast Source Discovery Protocol (MSDP) configuration.

The following topics provide necessary concepts and procedures to configure SPB-PIM Gateway.

SPB-PIM Gateway fundamentals

This section provides conceptual content to help you configure and customize SPB-PIM Gateway (SPB-PIM GW) on the switch.

IP Multicast over Fabric Connect in Protocol Independent Multicast networks

IP Multicast over Fabric Connect provides simplicity in provisioning and deploying IP multicast bridging and routing. Also, due to the fact that only one control plane protocol (IS-IS) exists, convergence times in the event of a network failure, are typically sub second.

IP Multicast over Fabric Connect

IP Multicast over Fabric Connect introduces extensions to the SPBM IS-IS control plane to exchange IP multicast stream advertisement and membership information. IP Multicast over Fabric Connect uses

these extensions, along with the Internet Group Management Protocol (IGMP) Snooping and Querier functions at the edge of the SPBM cloud, to create sub-trees of the VSN SPB for each multicast group to transport IP multicast data.

With IP Multicast over Fabric Connect, the switch supports the following:

- Layer 2 Virtual Services Network with IGMP support on the access networks for optimized forwarding of IP multicast traffic in a bridged network (Layer 2 VSN with IP Multicast over Fabric Connect). Example application: Multicast in data centers.
- IP multicast routing support for IP Shortcuts using SPBM in the core and IGMP on the access (IP Shortcuts with IP Multicast over Fabric Connect). Example applications: Video surveillance, TV/Video/Ticker/Image distribution, VX-LAN.
- Layer 3 Virtual Services Network with VRF based routing support for IP Multicast over Fabric Connect in the core and IGMP on the access (Layer 3 VSN with IP Multicast over Fabric Connect). Example applications: Video surveillance, TV/Video/Ticker/Image Distribution, VXLAN, Multi-tenant IP multicast.

Important

Sources must be IGMP enabled to support discovery functions specific to the multicast applications in use.

IP Multicast over Fabric Connect restrictions

- IP Multicast over Fabric Connect cannot connect to an IP Multicast router outside the SPB network.
- You can only deploy IP Multicast over Fabric Connect in environments where there are no multicast routers between the edge of the SPB network and the IP Multicast hosts that connect to the network.
- An existing network which is Protocol Independent Multicast (PIM) based cannot participate in the SPB network either by connecting to SPB originated streams or by injecting PIM network streams into the SPB network.
- In certain environments it is not possible to deploy an SPB network all the way to the point where the SPB network directly connects to an IGMP edge.

You encounter these restrictions during the following typical deployment scenarios:

- **Scenario 1:** You deployed IP Multicast using PIM and want to expand the network by deploying SPB for the new portion of the network. You want multicast applications to work across the old and new portion of the network.
- **Scenario 2:** Multicast traffic is exchanged between independent network operators at the boundary between their networks. PIM is the multicast routing protocol. A network operator wants to upgrade or replace the existing network to an SPB network. The inter-domain multicast traffic exchanges with other networks should not be disrupted.

The following figure shows the traditional Multicast over Fabric Connect environment with no PIM routers.

Figure 222: IP Multicast over Fabric Connect streams

In the above figure, sources and receivers on the edges of the SPB network are IGMP hosts and sources of multicast data. Hence, the traditional Multicast over Fabric Connect host-to-host deployment works.

The following figure shows the traditional Multicast over Fabric Connect environment with PIM routers.

Figure 223: IP Multicast over Fabric Connect Streams

In the above figure, sources and receivers on the edges of the SPB network, which are IGMP or source hosts can communicate over the SPB network. Sources and receivers connected to PIM routers cannot participate in the SPB network.

SPB-PIM Gateway

Multicast over Fabric Connect cannot connect to a PIM router that is external to the SPB network. When a receiver joins the SPB network for a specific group, the receiver must receive multicast streams in the neighboring multicast domains (PIM network). Similarly, a receiver in the neighboring multicast domain (PIM network) must receive multicast streams from sources in the SPB network. SPB-PIM Gateway (SPB-PIM GW) provides multicast inter-domain communication between an SPB network and a PIM network. SPB-PIM GW accomplishes this inter-domain communication across a special gateway VLAN. The gateway VLAN communicates with the PIM network through a subset of the full protocol messaging required for RFC 4601 compliance of a PIM interface, and translates the PIM network requirements into SPB language and vice versa.

SPB-PIM GW provides the following functionality:

- One or more SPB domains can share streams with one or more PIM domains.
- SPB-PIM GW can connect two independent SPB domains. The independent SPB domains connected by SPB-PIM GW share a subset of multicast streams without a PIM network in between.

SPB-PIM GW is supported in the GRT and in VRFs.

Multicast over Fabric Connect with SPB-PIM GW

In a Multicast over Fabric Connect environment with SPB-PIM GW, the SPB network connects sources and receivers from one or more PIM networks. The multicast traffic is then delivered across the domain boundaries through a path that transports the multicast traffic.

Multicast over Fabric Connect with SPB-PIM GW functionality consists of SPB nodes, which act as SPB-PIM Controller nodes and SPB-PIM Gateway nodes. The SPB Controller uses the Multicast Source Discovery Protocol (MSDP) to discover foreign sources.

The following figure shows the Multicast over Fabric Connect environment with SPB-PIM GW.

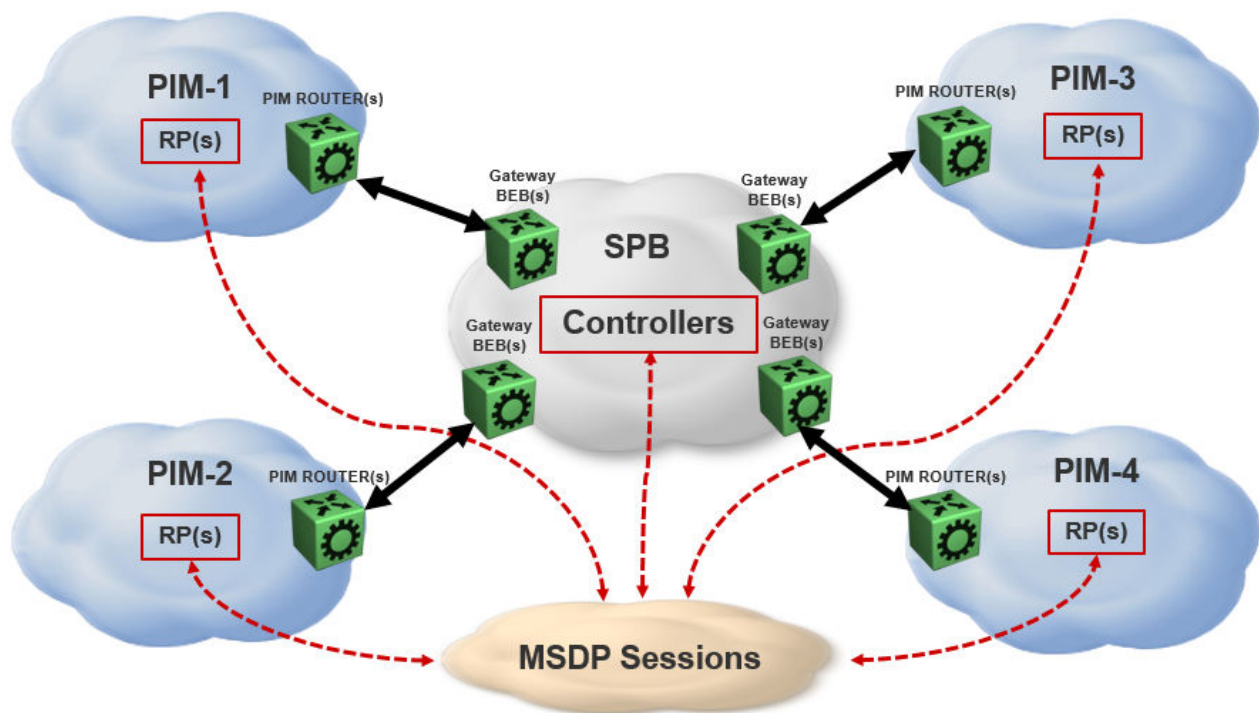

Figure 224: Multicast over Fabric Connect with SPB-PIM GW

SPB-PIM GW components

SPB-PIM GW has two functional components:

- SPB-PIM Gateway Controller Nodes (Controller), which are used for multicast source discovery.
- SPB-PIM Gateway Nodes (Gateway), on which the SPB-PIM Gateway interfaces reside.

Note

The Controller and Gateway can reside in a single node.

The following figure shows the SPB-PIM GW components.

Figure 225: SPB-PIM GW components

SPB-PIM Gateway Controller Node

SPB-PIM Gateway Controller Node (Controller) shares stream information between the local SPB domain and a foreign domain. The foreign domain is the PIM network Rendezvous point (RP) or another SPB domain Controller.

The Controller functionality is outlined below:

- The Controller discovers PIM sources for a specific multicast group and distributes them to the Gateways.

Note

PIM source discovery is either through MSDP or static configuration of foreign streams at the Controller.

- The Controller advertises local SPB originated streams through MSDP to another PIM domain or another SPB domain.
- The Controller references the Unicast IP route table to determine which Gateway has the best route to the PIM source. The Controller then assigns the stream to the selected Gateway.

The Controller Node has the following components:

- Source Discovery (MSDP and static configuration)
- Gateway Selection Controller

Source Discovery (MSDP and static configuration)

MSDP resides in the Controller BEB or Controller BCB and PIM network RP that wish to advertise multicast source information between domains.

You can implement SPB-PIM GW under the following scenarios:

- The multicast source resides in the Protocol Independent Sparse Module (PIM-SM) domain. The multicast source must be discovered by MSDP residing on the Gateway Controller in the SPB domain.
- The multicast source resides in the SPB domain. The multicast source must be advertised to the neighboring PIM domain through MSDP peers.

For more information on MSDP, see [MSDP overview](#) on page 2764.

Note

You can also configure multicast sources statically on the Controller. Static configuration is useful for SSM multicast group range streams in the foreign domain, which are not advertised by MSDP. Static configuration is also useful for when two SPB domains are connected through a PIM Gateway, and want to only advertise a subset of streams to each other, without enabling MSDP.

Gateway Selection Controller

The Gateway Selection Controller resides in the Controller BEB or Controller BCB node in the SPB network. The Gateway Selection Controller receives source information from MSDP or through static configuration. The source information consists of the following components:

- Sender IP address (S)
- Group IP address (G)
- VRF ID of the stream
- RP of the source (optional)

Gateway Selection Controller finds the best BEB (Gateway Node) in the SPB network through which the sender sends traffic to group G. The Gateway Selection Controller performs the following tasks:

- The Gateway Selection Controller uses Layer 3 reachability information to reach S, which is retrieved from the ISIS IP Shortcuts (IPSC) database.
- The VSN identifier (I-SID) is determined by using the VRF ID provided by MSDP.
- The Gateway Selection Controller uses the VRF ID and searches the IP shortcut database to determine which Gateway is closest to S.

Note

If multiple BEBs have a route to S, the BEB with the lowest Layer 3 metric is selected as the Gateway.

Note

If a Gateway link fails or the cost of the route changes, the selection process identifies the link failure as a route change and selects another best Gateway BEB.

The selected Gateway BEB for a stream must satisfy the following criteria:

- The selected Gateway BEB for a stream must announce a route to the source of the foreign stream through ISIS.

**Note**

Among all the routes to the source of the foreign stream announced by different BEBs through ISIS, the route announced by the selected Gateway has the longest prefix match and has the lowest external route metric.

- If multiple BEBs meet the Gateway selection criteria, a deterministic hash function of system ID, source IP address, and group IP address is used. The deterministic hash function is computed for each of the BEBs that meet the Gateway selection criteria. The BEB that generates the lowest hash value is selected as the Gateway for the stream.

The result of the Gateway selection process is saved in the Gateway assignment table. The Gateway assignment table consists of VSN identifier or I-SID, S, G, and the selected Gateway BEB. Having only one selected Gateway BEB ensures that traffic from source S is drawn into the SPB network by only one BEB, the selected Gateway BEB. The selection Controller then distributes the Gateway assignment table information to all the Gateway nodes.

SPB-PIM Gateway Node

The SPB-PIM Gateway Node (Gateway) has the following components:

- Gateway Selection Agent
- SPB-PIM Gateway interface

Gateway Selection Agent

The Gateway Selection Agent (Agent) resides in the Gateway BEB Node in the SPB network. The Gateway BEB has connections into the foreign network over SPB-PIM Gateway Interfaces. The Agent receives foreign network source information from the Controller BEB or the Controller BCB Node. The source information consists of the following components:

- Sender IP address (S)
- Group IP address (G)
- VSN identifier (I-SID)
- Gateway assigned to the stream

The Agent interacts with SPB-PIM Gateway interface and creates the multicast path. The Agent receives foreign source information from the Controller and creates a foreign source address (SA) cache after validating the reachability to S. The Agent interacts with the SPB-PIM Gateway interface to validate that the next-hop ip address toward the source is a valid PIM adjacency. The foreign SA cache includes the following components:

- Source IP address (information received from the Gateway Controller)
- Group IP address (information received from the Gateway Controller)
- Ingress port (The port through which S is accessible)
- Upstream IP address (The next-hop IP address, which is also the PIM neighbor across the SPB-PIM Gateway interface which is used to reach S as indicated by the unicast routing entry)
- Ingress VLAN ID

If multiple next-hops are available, then the first valid PIM neighbor next-hop is used for the upstream.

**Note**

If the Agent receives the same source information from multiple Controllers, then the Agent takes action only for the information received from the preferred Controller. The Controller with the lowest system ID is the preferred Controller.

SPB-PIM Gateway interface

The SPB-PIM Gateway interface provides inter-domain multicast services. The SPB-PIM Gateway interface connects senders and receivers of multicast streams across a PIM Domain and a SPB network boundary over a Gateway interface. The SPB-PIM Gateway interface provides the following functionality:

- PIM HELLO exchanges
- Issuing Joins and Leaves
- Process received Joins and Leaves
- Implements the Gateway assignment table by acting as the Ingress BEB for streams for which the SPB-PIM Gateway interface is the selected Gateway
- Enforces the Gateway assignment table and does not forward streams for which the SPB-PIM Gateway interface is not the selected Gateway
- Forwards local and remote SPB streams to satisfy stream requests from neighboring multicast domains
- SPB-PIM Gateway Interfaces supports both SM and SSM multicast group range joins and prunes. *G joins are only supported in SM group range.

The PIM Gateway interface resides in the SPB-PIM Gateway Node (Gateway). The SPB-PIM Gateway interface connects to a PIM router in a PIM network or to another Gateway BEB in an SPB network. Local hosts (IGMP member hosts and multicast data source hosts) are not supported on SPB-PIM Gateway interfaces, only PIM Routers or another SPB BEB with SPB-PIM Gateway interface configured. Multicast data from local source hosts and IGMP reports from local hosts are dropped. An SPB Node must be configured as a SPB-PIM Gateway Node if the SPB Node is connected to a foreign PIM network or a foreign SPB network. A single Gateway Node can have multiple SPB-PIM Gateway interfaces. The SPB-PIM Gateway interface can be a VLAN or a brouter port, can reside on an MLT and is fully virtualized. The SPB-PIM Gateway interface is a translation mechanism between the PIM protocol and SPB TLVs.

**Note**

- Only PIM protocol messages are communicated over the SPB-PIM Gateway interface
- Only SPB TLVs are communicated over Fabric Connect over SPB
- The SPB-PIM Gateway interface is the only component that handles the translation mechanism

The SPB-PIM Gateway interface communicates with the PIM router through the standard PIM protocol messaging HELLO, JOIN, and PRUNE. The SPB-PIM Gateway interface then forms a normal PIM adjacency with the PIM router or another SPB Gateway Node. The SPB-PIM Gateway Interface processes received SG joins and prunes, *G joins and prunes, and SG-RPT joins and prunes. The SPB-PIM Gateway interface transmits SG joins and prunes, but never *G joins. The SPB-PIM Gateway Interface does not have RP capabilities, and therefore has no need for group-to-RP mapping configurations. A *G

JOIN received on a SPB-PIM Gateway Interface is accepted if the destination IP is the IP address of the interface or of a neighbor on the interface if the neighbor is learned on another port in the interface. However, the RP address within the *G JOIN message is ignored by the SPB-PIM Gateway Interface.

MSDP overview

MSDP enables advertisement of multicast source information between different PIM-SM domains. This function of MSDP in SPB-PIM GW topologies is to advertise multicast source information between SPB domains and PIM domains. MSDP routers in a PIM-SM or SPB domain have a peering relationship with MSDP peers in another domain. The peering relationship is a TCP connection in which the control information is exchanged. The TCP connection between peers uses the underlying unicast routing system.

Source Active messages

In a PIM domain, MSDP enabled routers are RPs. MSDP routers form adjacencies through TCP port 639 to share multicast source information. This functionality is similar to the Border Gateway Protocol (BGP). When an MSDP router receives multicast source information, the routers use reachability information to perform Reverse Path Forwarding (RPF) checks. The reachability information is exchanged through BGP or any other unicast routing protocol.

When a RP router learns of a new (S,G), the RP router saves the (S,G) information and the RP address in the MSDP Source Active (SA) local cache. The RP router learns the new (S,G) through a directly connected source or PIM register message. The RP router then sends an SA update message which contains (S,G,RP) information to the MSDP peers. The MSDP peers broadcast the SA to RPs in their local domains and to their MSDP peers in other PIM-SM domains.

Note

A PIM domain is a set of routers in a single Autonomous System (AS), which uses the same RP for any given multicast group.

When an SPB-PIM Gateway Controller in the SPB domain learns of a new (S,G) in its own domain, the Controller saves the (S,G) information in the local SA cache. The Controller learns the new (S,G) through a directly connected source or Intermediate-System-to-Intermediate-System (IS-IS). The controller sends an SA update message to the MSDP peers in the PIM domain. SA uses the CLIP address configured on the controller as the RP address.

Note

Configure CLIP before you enable MSDP. Peer connections use the CLIP address as the local address.

Reverse Path Forwarding check

When an MSDP peer receives the SA from a peer, the MSDP performs an RPF check. The RPF check ensures that the SA received from the MSDP peer is the closest to the originating RP. An RPF check prevents SA loops.

Note

This RPF check is different from the multicast routing RPF check.

If the RPF checks pass, then the receiving MSDP enabled router saves the SA information in the SA foreign cache and makes it available to the local domain. Each MSDP peer floods the SA information away from the originating RP. The flooding process is called peer RPF flooding.

SA redistribution and filtering

Redistribution and filtering is used to control SA flooding. The MSDP redistribute policy is applied on the MSDP node that originates the SAs to control which SAs are advertised on all MSDP peers. An SA filter is applied to a specific MSDP peer in the inbound direction or outbound directions or both inbound and outbound direction on any MSDP router. Filtering is multicast group based.

When configuring MSDP redistribution, use prefix lists to create the route policies. When a route policy is created it must match the group prefix with the name of the prefix list created for the group address. If deny action is set for the lists in the route-policy, the policy blocks the matching groups from all the sources. If permit action is set for the lists in the route-policy, the policy accepts the matching groups from all the sources. MSDP redistribution does not refer to the redistribution of SPB domain sources to MSDP. MSDP redistribution refers to SAs which needs to be redistributed to other MSDP peers.

Note

MSDP redistribution is applied globally to all MSDP peers. SA filtering is used to filter SAs on a peer-to-peer level.

MSDP and SPB-PIM GW

The SPB-PIM GW functional component for MSDP resides in the SPB-PIM Gateway Controller node (Controller).

Overview

Controllers from an SPB network discover sources through MSDP sessions with RPs from a PIM network. Once the SA packed is received at the MSDP module of the Controller, the IP routing table is examined to determine which peer is the next hop towards the originating RP of the SA message. Once the SA RPF test passes, the SA packet is saved in the foreign cache and passed to the Controller.

The Controller nodes also distribute the sources from an SPB domain to a PIM domain through an MSDP session with RPs in the PIM network. Similar to RP, when a Controller in the SPB domain learns of a new (S,G), through a directly connected source or ISIS, the Controller saves the new (S,G) in its local SA cache. The Controller then transmits an SA update message for this source to its MSDP peers in the PIM domain. The Controller that sends the SA to the MSDP is viewed as the RP (circuitless IP interface is used).

MSDP as part of SPB-PIM GW

MSDP does not work with the traditional PIM implementation. MSDP communicates only with the Controller and should be configured as an IP endpoint.

MSDP configuration considerations:

- A circuitless IP interface (CLIP) is used in the context of global router or VRF, hence at least one CLIP in each VRF should be configured.
- MSDP should use a single CLIP address as the source for establishing all MSDP connections in the same VRF.
- For SPB sources, this CLIP is used as the RP in all SA messages advertised.

- MSDP source IP address should be one of the CLIP interfaces pre-configured on the global router or VRF.
- The originator-id should be configured before enabling MSDP.

**Note**

MSDP transmits encapsulated multicast data packets inside forwarded MSDP messages. If the received SA is an encapsulated SA, then the switch parses the TTL value of the encapsulated data and compares it against the configured value. If the configured value is less than or equal to the parsed value, then the switch forwards the encapsulated data along with the SA, otherwise the switch forwards the SA alone by stripping the encapsulate data. By default, MSDP forwards encapsulated data along with the SA message. MSDP does not forward the encapsulated data to the local receivers.

When MSDP generates SA messages for SPB sources, the local cache miss data cannot be encapsulated into the SA messages that are sent to the peers.

The switch supports forwarding SA messages with encapsulated data from sources to MSDP peers but not from MSDP peers to the receivers.

For more information on MSDP configuration, see [Multicast Source Discovery Protocol configuration](#) on page 2767.

Full mesh group

MSDP mesh groups are full mesh of MSDP peers and is a subset of MSDP speakers. MSDP mesh groups are used for SA flooding which is similar to the BGP route reflector concept. MSDP floods the SA to all the members of the mesh group when:

- The MSDP peers are fully meshed
- The MSDP enabled router learns a new SA from a non-member of its mesh group
- The SA passes the RPF check

The receiving routers accept the SA and forwards it only to any non-mesh Group MSDP peers.

The SPB-PIM Gateway is deployed in two models:

- Model 1: All multicast networks have peering agreements with one another. The full mesh MSDP is setup.
- Model 2 : An inter-domain multicast provider exists. All multicast networks setup MSDP peering with the provider.

The controllers relay SA messages between individual networks.

**Note**

Consider the following when you deploy SPB-PIM Gateway:

- Use mesh group of MSDP peers (PIM RP's and SPB-PIM Gateway Controller nodes) to avoid flooding and RPF failure.

**Note**

Since MSDP uses CLIP interface in its peering relation, the MSDP peer may not fall in any of the RFC rules and the MSDP SA messages will be rejected.

- Controllers from the same SPB network must not have MSDP sessions with each other, regardless of whether mesh groups are used or not.
- When using mesh groups, all Controllers within one SPB domain should peer with the same set of RPs and Controllers in adjacent domains, ie, one Controller should not peer with an RP that the other Controllers do not peer with.

Multicast Source Discovery Protocol configuration

This section provides procedures to configure Multicast Source Discovery Protocol (MSDP) using the Command Line Interface (CLI) and Enterprise Device Manager (EDM).

Basic MSPD configuration using the CLI

This section provides procedures to configure Basic MSDP using the command line interface (CLI).

Configuring the MSDP originator ID

Configure the originator ID to set the Rendezvous Point (RP) address inside the Source Active (SA) message. The RP address must be a pre-configured CLIP interface on the global router or a VRF. The RP address is also the local IP address in all peer relations.

**Note**

To delete the originator ID, you must first disable MSDP.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:
`enable`

`configure terminal`

Optional: `router vrf WORD<1-16>`
2. Configure the MSDP originator ID:
`ip msdp originator-id {A.B.C.D}`

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip msdp originator-id 2.0.2.2
```

Variable definitions

The following table defines parameters for the **ip msdp originator-id** command.

Variable	Value
{A.B.C.D}	Specifies the MSDP source IP address. The IP address must be one of the CLIP interfaces configured on the global router or a VRF.

Configuring MSDP on a VRF

Create an MSDP instance on a user defined VRF to allow further configuration to take place. This command does not exist in the Global Configuration mode because the MSDP instance for a default VRF is created by default.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

router vrf WORD<1-16>
```
2. Create the MSDP instance:

```
ip msdp
```

Enabling MSDP globally

Enable or disable MSDP globally on the device to allow further configuration to take place.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Enable MSDP globally on the switch:

```
ip msdp enable
```

Creating an MSDP peer

Create an MSDP peer to establish a peer relationship between the local MSDP enabled router and a peer in another domain.

**Important**

Do not enable more than 20 active peers.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
Optional: router vrf WORD<1-16>
```

2. Create an MSDP peer:

```
ip msdp peer {A.B.C.D}
```

3. Enable an MSDP peer:

```
ip msdp peer {A.B.C.D} enable
```

Note

MSDP peer is disabled by default.

4. (Optional) Specify the remote autonomous system (AS) number of the MSDP peer:

```
ip msdp peer {A.B.C.D} remote-as WORD<0-11>
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip msdp peer 21.0.0.2
Switch:1(config)#ip msdp peer 21.0.0.2 enable
Switch:1(config)#ip msdp peer remote-as 1
```

Variable definitions

The following table defines parameters for the **ip msdp peer** command.

Variable	Value
{A.B.C.D}	Specifies the MSDP peer IP address.
WORD<0-11>	Specifies the AS number of the MSDP peer, 0-65535 (2-Byte AS) 0-4294967295 (4-Byte AS).

MSDP Peer Configuration using the CLI

This section provides procedures to configure MSDP peer using the command line interface (CLI).

Configuring a peer description

Configure a peer description to add descriptive text to an MSDP peer for easy identification of a peer.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Configure the peer description:

```
ip msdp description {A.B.C.D} WORD<1-255>
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip msdp peer 21.0.0.2 primary
```

Variable definitions

The following table defines parameters for the **ip msdp description** command.

Variable	Value
<code>{A.B.C.D}</code>	Specifies the MSDP peer IP address.
<code>WORD<1-255></code>	Specifies a descriptive text to a MSDP peer in the range of 1-255 characters. To include spaces in the peer description, enclose the text string in quotation marks.

Securing control messages

Configure Message Digest (MD) 5 authentication to secure control messages on the TCP connection between MSDP peers.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Enable MD5 authentication:

```
ip msdp md5-authentication {A.B.C.D} [enable]
```

3. Specify the case sensitive password for MD5 authentication:

```
ip msdp password peer {A.B.C.D} WORD<1-80>
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip msdp md5-authentication 21.0.0.2 enable
Switch:1(config)#ip msdp password peer 21.0.0.2 helloworld
```

Variable definitions

The following table defines parameters for the **ip msdp** command.

Variable	Value
<i>{A.B.C.D}</i>	Specifies the MSDP peer IP address.
<i>WORD<1-80></i>	Specifies the MD5 authentication password.

Configuring the MSDP peer SA limit

Configure the SA limit to limit the number of SA messages from an MSDP peer that the router saves in the SA cache. The default value is 6,144 messages.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

Optional: router vrf WORD<1-16>
```
2. Configure the SA limit:

```
ip msdp sa-limit {A.B.C.D} <0-6144>
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip msdp sa-limit 21.0.0.2 6100
```

Variable definitions

The following table defines parameters for the **ip msdp sa-limit** command.

Variable	Value
<i>{A.B.C.D}</i>	Specifies the MSDP peer IP address.
<i><0-6144></i>	Specifies the maximum number of SA messages to keep in SA cache.

Limiting which packets the router sends

Configure the time-to-live (TTL) threshold to limit which multicast data packets the router encapsulated in SA Messages forwarded to an MSDP peer. The TTL limits the number of hops a packet can take before the router drops the packet. The router sends out SA Messages with encapsulated data only if

TTL equals or exceeds the value you configure. If the TTL is lower than the value you configure, the router drops the data packet and forwards the SA Message without the encapsulated data.

Note

MSDP transmits encapsulated multicast data packets inside forwarded MSDP messages. If the received SA is an encapsulated SA, then the switch parses the TTL value of the encapsulated data and compares it against the configured value. If the configured value is less than or equal to the parsed value, then the switch forwards the encapsulated data along with the SA, otherwise the switch forwards the SA alone by stripping the encapsulate data. By default, MSDP forwards encapsulated data along with the SA message. MSDP does not forward the encapsulated data to the local receivers.

When MSDP generates SA messages for SPB sources, the local cache miss data cannot be encapsulated into the SA messages that are sent to the peers.

The switch supports forwarding SA messages with encapsulated data from sources to MSDP peers but not from MSDP peers to the receivers.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Configure the MSDP peer TTL threshold:

```
ip msdp ttl-threshold {A.B.C.D} <1-255>
```

Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

```
Switch:1(config)#ip msdp ttl-threshold 21.0.0.2 10
```

Variable definitions

The following table defines parameters for the `ip msdp ttl-threshold` command.

Variable	Value
<code>{A.B.C.D}</code>	Specifies the MSDP peer IP address.
<code><1-255></code>	Specifies the TTL value. Default value is 1.

Configuring the MSDP peer keep alive messages

Configure keepalive messages to adjust the interval in seconds at which an MSDP peer sends keep alive messages (default is 60 seconds) and the interval at which the MSDP peer waits for keep alive messages from other peers before it declares them down (default is 75 seconds).

**Note**

In a peer relationship, the keep alive interval configured on one peer must be at least 1 second less than the hold time configured on the other side of the peer relationship. This is not applicable when the hold time is set to 0 seconds.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Configure the MSDP peer keep alive interval:

```
ip msdp keepalive {A.B.C.D} <0-21845> <0-65535>
```

Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

```
Switch:1(config)#ip msdp keepalive 21.0.0.2 70 71
```

Variable definitions

The following table defines parameters for the `ip msdp keepalive` command.

Variable	Value
<code>{A.B.C.D}</code>	Specifies the MSDP peer IP address.
<code><0-21845></code>	Specifies the keep alive interval in seconds. The default is 60 seconds.
<code><0-65535></code>	Specifies the hold time interval in seconds. The default is 75 seconds. Note: 0 seconds means the peer never expires. Values 1 and 2 are not allowed.

Configuring the MSDP peer connect-retry period

Configure the connect-retry period to specify the amount of time, in seconds, between connection attempts for peering sessions. The default is 30 seconds.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Configure the MSDP peer connect-retry period:

```
ip msdp connect-retry {A.B.C.D} <1-65535>
```

Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

```
Switch:1(config)#ip msdp connect-retry 21.0.0.2 40
```

Variable definitions

The following table defines parameters for the **ip msdp connect-retry** command.

Variable	Value
<code>{A.B.C.D}</code>	Specifies the MSDP peer IP address.
<code><1-65535></code>	Specifies the connect-retry interval in seconds. The default is 30 seconds.

Clearing the peer connection

Clear the peer connection to clear the TCP connection to the specified MSDP peer, and reset all MSDP message counters.

**Note**

This procedure does not clear the SA cache entries the router learns from the peer.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Clear the peer connection:

```
clear ip msdp peer {A.B.C.D} [vrf WORD<0-16>] [vrfids WORD<0-512>]
```

Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

```
Switch:1(config)#clear ip msdp peer 21.0.0.2
```

Variable definitions

The following table defines parameters for the **clear ip msdp peer** command.

Variable	Value
<i>{A.B.C.D}</i>	Specifies the MSDP peer IP address.
<i>vrf WORD<0-16></i>	Specifies the VRF name.
<i>vrfids WORD<0-512></i>	Specifies the VRF ID.

Deleting an MSDP peer

Use this procedure to delete an MSDP peer.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Clear the peer connection:
no ip msdp peer *{A.B.C.D}*

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#no ip msdp peer 21.0.0.2
```

MSDP Message Control using the CLI*Filtering PIM routes*

Filter SPB routes to filter which (S,G,RP) entries sent out to all MSDP peers. This procedure applies only to the rendezvous point (RP) that originates the MSDP SA messages and not the intermediate MSDP peers that forward the received SA messages.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:
enable

configure terminal

Optional: router vrf *WORD<1-16>*
2. Create the MSDP filter:
ip msdp redistribute
3. Create the route policy name:
ip msdp redistribute route-policy *WORD<1-64>*

4. Apply the redistribution filters:

```
ip msdp apply redistribute
```

Example

```
Switch:1>enable

Switch:1#configure terminal

Switch:1(config)#ip msdp redistribute

Switch:1(config)#ip msdp redistribute route-policy helloworld

Switch:1(config)#ip msdp apply redistribute
```

Variable definitions

The following table defines parameters for the **clear ip redistribute** command.

Variable	Value
<i>WORD</i> <1-64>	Specifies the route policy name.

Filtering SA messages

Filter SA messages to determine which SA messages to accept from a peer and which SA messages to send to a peer. By default, no inbound or outbound filter exists.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`
2. Create the inbound filter:

```
ip msdp sa-filter in {A.B.C.D}
```
3. Create the inbound filter route policy name:

```
ip msdp sa-filter in {A.B.C.D} route-policy WORD<1-64>
```
4. Create the outbound filter:

```
ip msdp sa-filter out {A.B.C.D}
```
5. Create the outbound filter route policy name:

```
ip msdp sa-filter out {A.B.C.D} route-policy WORD<1-64>
```

Example

```
Switch:1>enable

Switch:1#configure terminal

Switch:1(config)#ip msdp sa-filter in 21.0.0.2 route-policy helloworld
```

Variable definitions

The following table defines parameters for the **ip msdp sa-filter** command.

Variable	Value
<i>{A.B.C.D}</i>	Specifies the MSDP peer IP address.
<i>route-policy WORD<1-64></i>	Specifies the route policy name for an inbound or outbound filter.

Configuring MSDP mesh groups

Configure mesh groups to reduce SA flooding. A mesh group does not forward SA messages to other group members. The originator, which is also a mesh group member, forwards SA messages to all group members. Create MSDP mesh groups from a group of meshed MSDP speakers from a domain.

Note

The MSDP router does not belong to any mesh group by default.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Configure the MSDP mesh group:

```
ip msdp mesh-group WORD<1-64> {A.B.C.D}
```

Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

```
Switch:1(config)#ip msdp mesh-group helloworld 21.0.0.2
```

Variable definitions

The following table defines parameters for the **ip msdp mesh-group** command.

Variable	Value
<i>WORD<1-64></i>	Specifies the mesh group name.
<i>{A.B.C.D}</i>	Specifies the MSDP peer IP address.

Clearing the MSDP SA cache

Clear the SA cache to clear the SA entries the router learns from all peers or a specific peer.

**Note**

This procedure clears the foreign cache. This procedure does not clear the local cache.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Clear the SA cache for all peers:

```
clear ip msdp sa-cache [vrf WORD<0-16>] [vrfids WORD<0-512>]
```

3. Clear the SA cache for a specific peer:

```
clear ip msdp sa-cache peer {A.B.C.D} [vrf WORD<0-16>] [vrfids  
WORD<0-512>]
```

4. Clear the SA cache for a specific group range, source range, and RP.

```
clear ip msdp sa-cache [source prefix/len] [group prefix/len] [rp  
{A.B.C.D}] [vrf WORD<0-16>] [vrfids WORD<0-512>]
```

Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

```
Switch:1(config)#clear ip msdp sa-cache peer 21.0.0.2
```

Variable definitions

The following table defines parameters for the **clear ip msdp sa-cache** command.

Variable	Value
{A.B.C.D}	Specifies the MSDP peer IP address.
vrf WORD<0-16>	Specifies the VRF names.
vrfids WORD<0-512>	Specifies the VRF ID.

MSDP Verification using the CLI

This section provides procedures to verify MSDP using the command line interface (CLI).

Displaying the peer information

Use the following procedure to display the peer configuration and SA message information.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Display the peer information:

```
show ip msdp peer {A.B.C.D} [vrf WORD<0-16>] [vrfids WORD<0-512>]
```

Example

```
Switch:#enable
Switch:1#show ip msdp peer 2.2.2.2
=====
                        MSDP Peer - GlobalRouter
=====

Variable definitions

The following table defines parameters for the **show ip msdp peer** command.

Variable	Value
<i>{A.B.C.D}</i>	Specifies the MSDP peer IP address.
<i>vrf WORD<0-16></i>	Displays configuration info for a particular VRF.
<i>vrfids WORD<0-512></i>	Displays configuration info for a particular VRF ID.

Displaying the SA cache

Use the following procedure to display the (S,G) state learned from MSDP peers and the local (S,G) state. The local (S,G) is the SPB (S,G) sent to MSDP.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Display the SA cache:

```
show ip msdp sa-cache [local] [vrf WORD<0-16>] [vrfids WORD<0-512>]
[group {A.B.C.D}] [rp {A.B.C.D}] [source {A.B.C.D}]
```

```

Variable definitions

The following table defines parameters for the **show ip msdp show-all** command.

Variable	Value
<code>file WORD<1-99></code>	Specifies the file name to save the display output.
<code>vrf WORD<0-16></code>	Displays configuration information for a particular VRF.
<code>vrfids WORD<0-512></code>	Displays configuration information for a particular VRF ID.

Clearing IPv4 MSDP Statistics

Use the following procedure to clear all IPv4 Multicast Source Discovery Protocol (MSDP) statistics for all peers or a specific peer.

About This Task

The switch supports this command for local management VRF or global routing table (GRT). If you do not specify a VRF or VRF ID, the switch defaults to GRT.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Clear IPv4 MSDP statistics for all peers:

```
clear ip msdp statistics [vrf WORD<0-16>] [vrfids WORD<0-512>]
```
3. Clear IPv4 MSDP statistics for a specific peer:

```
clear ip msdp statistics {A.B.C.D.} [vrf WORD<0-16>] [vrfids WORD<0-512>]
```

Variable Definitions

Use the data in the following table to use the **clear ip msdp statistics** command.

Variable	Value
<code>vrf WORD<0-16></code>	Specifies a VRF instance by VRF name.
<code>vrfids WORD<0-512></code>	Specifies the ID of the VRF.
<code>{A.B.C.D.}</code>	Specifies the IPv4 MSDP address for a specific peer.

Basic MSDP configuration using the EDM

This section provides procedures to configure basic MSDP using the EDM.

Configuring the MSDP originator ID

Configure the originator ID to set the RP address inside the SA message. The RP address must be a pre-configured CLIP interface on the global router or a VRF. The RP address is also the local IP address in all peer relations.

**Note**

Originator ID cannot be deleted if MSDP is enabled.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Globals** tab.
4. In the **RPAddress** box, type the IP address to use as the originator ID.
5. Click **Apply**.

Global field descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
Enabled	Enables MSDP. If you clear this check box, you disable MSDP. The default setting is clear (disabled).
CacheLifetime	Configures the lifetime given to SA cache entries when created or refreshed.
NumSACacheEntries	Displays the total number of entries in the SA cache.
RPAddress	Specifies the IP address to use as the originator ID. If the address is not a system local address, the system rejects the configuration.
RouteMapName	Specifies the name of the optional route policy to create or modify. You do not need to create a route policy to use the redistribution filter. Note: To delete the route map name, clear the field and click Apply .
RedistributeFilterEnabled	Filters the (S,G,RP) entries provided by PIM to MSDP. The default is clear (disabled).
RedistruteFilterApply	Applies the changes made to the redistribute filter.
StatsClear	Clears MSDP statistics.

Enabling MSDP

Enable or disable MSDP globally on the switch to allow further configuration to take place.

Before You Begin

You must configure the originator ID before you enable MSDP.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Globals** tab.
4. Select the **Enabled** check box to enable MSDP.
5. Click **Apply**.

Global field descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
Enabled	Enables MSDP. If you clear this check box, you disable MSDP. The default setting is clear (disabled).
CacheLifetime	Configures the lifetime given to SA cache entries when created or refreshed.
NumSACacheEntries	Displays the total number of entries in the SA cache.
RPAddress	Specifies the IP address to use as the originator ID. If the address is not a system local address, the system rejects the configuration.
RouteMapName	Specifies the name of the optional route policy to create or modify. You do not need to create a route policy to use the redistribution filter. Note: To delete the route map name, clear the field and click Apply .
RedistributeFilterEnabled	Filters the (S,G,RP) entries provided by PIM to MSDP. The default is clear (disabled).
RedistruteFilterApply	Applies the changes made to the redistribute filter.
StatsClear	Clears MSDP statistics.

Creating an MSDP peer

Create an MSDP peer to establish a peer relationship between the local MSDP enabled router and a peer in another domain.

Important

Do not enable more than 20 active peers.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Peers** tab.
4. Click **Insert**.
5. In the **RemoteAddress** box, type the IP address of the peer.
6. Click **Insert**.

Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
RemoteAddress	Shows the IP address of the remote MSDP peer.
State	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
AdminEnabled	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
ClearPeer	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
ConnectRetryInterval	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
HoldTimeConfigured	The default value is 75 seconds.
KeepAliveConfigured	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.
DataTtl	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
InSAFilterEnabled	Activates the inbound SA filter for the peer.
InSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
OutSAFilterEnabled	Activates the outbound SA filter for the peer.

Name	Description
OutSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
Description	Specifies the text description, up to 255 characters, for the peer.
SALimit	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0-6144; the default value is 6144.
Md5AuthEnabled	Activates MD5 authentication on the TCP connection between peers. The default is false.
Md5AuthPassword	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
RemotePort	Shows the remote port for the TCP connection between the MSDP peers.
LocalPort	Shows the local port for the TCP connection between the MSDP peers.
OperEnabled	Shows the operational status of the peer.
RPFFailures	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAs	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAs	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSARequests	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSARequests	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
InSAResponses	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAResponses	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InControlMessages	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutControlMessages	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InDataPackets	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutDataPackets	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
FsmEstablishedTransitions	Shows the total number of times the BGP transitioned to the established state.
FsmEstablishedTime	Shows the time when the peer transitioned to the established state.
InMessageTime	Shows the time when the last MSDP message was received from the peer.
ConnectionAttempts	Shows the number of times the state machine has transitioned from inactive to connecting.
DiscontinuityTime	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.

Name	Description
AsNumber	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
TooShortMessages	Shows the number of short messages received from this peer.
InBadMessages	Shows the number of bad MSDP messages received from this peer.
InKeepAliveMessages	Shows the number of keepalive messages received from this peer.
OutKeepAliveMessages	Shows the number of keepalive messages transmitted to this peer.
SAsLearnedFromThisPeer	Shows the total number of SAs learned from this peer.
SAsAdvertisedToThisPeer	Shows the total number of SAs advertised from this peer.
UpOrDownTime	Shows the duration a peer has been up or down.
ConnAndStatsClearedTime	Shows the duration of connection and statistics cleared.

MSDP Peer Configuration using the EDM

This section provides procedures to configure MSDP peer using the EDM.

Securing control messages

Configure Message Digest (MD) 5 authentication to secure control messages on the TCP connection between MSDP peers.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Peers** tab.
4. In the row for the peer, double-click the **Md5AuthEnabled** field, and then select true.
5. In the row for the peer, double-click the **Md5AuthPassword** field, and then type a password.
6. Click **Apply**.

Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
RemoteAddress	Shows the IP address of the remote MSDP peer.
State	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
AdminEnabled	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
ClearPeer	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
ConnectRetryInterval	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
HoldTimeConfigured	The default value is 75 seconds.
KeepAliveConfigured	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.
DataTtl	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
InSAFilterEnabled	Activates the inbound SA filter for the peer.
InSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
OutSAFilterEnabled	Activates the outbound SA filter for the peer.
OutSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
Description	Specifies the text description, up to 255 characters, for the peer.

Name	Description
SALimit	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0-6144; the default value is 6144.
Md5AuthEnabled	Activates MD5 authentication on the TCP connection between peers. The default is false.
Md5AuthPassword	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
RemotePort	Shows the remote port for the TCP connection between the MSDP peers.
LocalPort	Shows the local port for the TCP connection between the MSDP peers.
OperEnabled	Shows the operational status of the peer.
RPFFailures	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAs	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAs	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSARquests	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSARquests	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAResponses	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAResponses	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InControlMessages	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
OutControlMessages	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InDataPackets	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutDataPackets	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
FsmEstablishedTransitions	Shows the total number of times the BGP transitioned to the established state.
FsmEstablishedTime	Shows the time when the peer transitioned to the established state.
InMessageTime	Shows the time when the last MSDP message was received from the peer.
ConnectionAttempts	Shows the number of times the state machine has transitioned from inactive to connecting.
DiscontinuityTime	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
AsNumber	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
TooShortMessages	Shows the number of short messages received from this peer.
InBadMessages	Shows the number of bad MSDP messages received from this peer.
InKeepAliveMessages	Shows the number of keepalive messages received from this peer.
OutKeepAliveMessages	Shows the number of keepalive messages transmitted to this peer.

Name	Description
SAsLearnedFromThisPeer	Shows the total number of SAs learned from this peer.
SAsAdvertisedToThisPeer	Shows the total number of SAs advertised from this peer.
UpOrDownTime	Shows the duration a peer has been up or down.
ConnAndStatsClearedTime	Shows the duration of connection and statistics cleared.

Configuring the MSDP peer SA limit

Configure the SA limit to limit the number of SA messages from an MSDP peer. The router saves the SA messages in the local cache.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Peers** tab.
4. In the row for the peer, double-click the **SALimit** field, and then type a value.
5. Click **Apply**.

Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
RemoteAddress	Shows the IP address of the remote MSDP peer.
State	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
AdminEnabled	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
ClearPeer	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
ConnectRetryInterval	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
HoldTimeConfigured	The default value is 75 seconds.
KeepAliveConfigured	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.

Name	Description
DataTtl	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
InSAFilterEnabled	Activates the inbound SA filter for the peer.
InSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
OutSAFilterEnabled	Activates the outbound SA filter for the peer.
OutSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
Description	Specifies the text description, up to 255 characters, for the peer.
SALimit	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0–6144; the default value is 6144.
Md5AuthEnabled	Activates MD5 authentication on the TCP connection between peers. The default is false.
Md5AuthPassword	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
RemotePort	Shows the remote port for the TCP connection between the MSDP peers.
LocalPort	Shows the local port for the TCP connection between the MSDP peers.
OperEnabled	Shows the operational status of the peer.
RPFFailures	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAs	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAs	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
InSARequests	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSARequests	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAResponses	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAResponses	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InControlMessages	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutControlMessages	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InDataPackets	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutDataPackets	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
FsmEstablishedTransitions	Shows the total number of times the BGP transitioned to the established state.
FsmEstablishedTime	Shows the time when the peer transitioned to the established state.
InMessageTime	Shows the time when the last MSDP message was received from the peer.
ConnectionAttempts	Shows the number of times the state machine has transitioned from inactive to connecting.

Name	Description
DiscontinuityTime	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
AsNumber	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
TooShortMessages	Shows the number of short messages received from this peer.
InBadMessages	Shows the number of bad MSDP messages received from this peer.
InKeepAliveMessages	Shows the number of keepalive messages received from this peer.
OutKeepAliveMessages	Shows the number of keepalive messages transmitted to this peer.
SAsLearnedFromThisPeer	Shows the total number of SAs learned from this peer.
SAsAdvertisedToThisPeer	Shows the total number of SAs advertised from this peer.
UpOrDownTime	Shows the duration a peer has been up or down.
ConnAndStatsClearedTime	Shows the duration of connection and statistics cleared.

Configuring a peer description

About This Task

Configure a peer description to add a descriptive text to an MSDP peer, for easy identification of a peer.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Peers** tab.
4. In the row for the peer, double-click the **Description** field, and then type a description for the peer.
5. Click **Apply**.

Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
RemoteAddress	Shows the IP address of the remote MSDP peer.
State	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
AdminEnabled	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
ClearPeer	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
ConnectRetryInterval	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
HoldTimeConfigured	The default value is 75 seconds.
KeepAliveConfigured	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.
DataTtl	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
InSAFilterEnabled	Activates the inbound SA filter for the peer.
InSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
OutSAFilterEnabled	Activates the outbound SA filter for the peer.
OutSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
Description	Specifies the text description, up to 255 characters, for the peer.

Name	Description
SALimit	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0-6144; the default value is 6144.
Md5AuthEnabled	Activates MD5 authentication on the TCP connection between peers. The default is false.
Md5AuthPassword	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
RemotePort	Shows the remote port for the TCP connection between the MSDP peers.
LocalPort	Shows the local port for the TCP connection between the MSDP peers.
OperEnabled	Shows the operational status of the peer.
RPFFailures	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAs	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAs	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSARequests	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSARequests	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAResponses	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAResponses	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InControlMessages	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
OutControlMessages	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InDataPackets	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutDataPackets	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
FsmEstablishedTransitions	Shows the total number of times the BGP transitioned to the established state.
FsmEstablishedTime	Shows the time when the peer transitioned to the established state.
InMessageTime	Shows the time when the last MSDP message was received from the peer.
ConnectionAttempts	Shows the number of times the state machine has transitioned from inactive to connecting.
DiscontinuityTime	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
AsNumber	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
TooShortMessages	Shows the number of short messages received from this peer.
InBadMessages	Shows the number of bad MSDP messages received from this peer.
InKeepAliveMessages	Shows the number of keepalive messages received from this peer.
OutKeepAliveMessages	Shows the number of keepalive messages transmitted to this peer.

Name	Description
SAsLearnedFromThisPeer	Shows the total number of SAs learned from this peer.
SAsAdvertisedToThisPeer	Shows the total number of SAs advertised from this peer.
UpOrDownTime	Shows the duration a peer has been up or down.
ConnAndStatsClearedTime	Shows the duration of connection and statistics cleared.

Configuring the MSDP peer time to live threshold

Configure the time-to-live (TTL) threshold to limit which multicast data packets the router encapsulated in SA Message forwarded to an MSDP peer. The TTL limits the number of hops a packet can take before the router drops the packet. The router sends out SA Messages with encapsulated data only if TTL equals or exceeds the value you configure. If the TTL is lower than the value you configure, the router drops the data packet and forwards the SA Message without the encapsulated data.

Note

MSDP transmits encapsulated multicast data packets inside forwarded MSDP messages. If the received SA is an encapsulated SA, then the switch parses the TTL value of the encapsulated data and compares it against the configured value. If the configured value is less than or equal to the parsed value, then the switch forwards the encapsulated data along with the SA, otherwise the switch forwards the SA alone by stripping the encapsulate data. By default, MSDP forwards encapsulated data along with the SA message. MSDP does not forward the encapsulated data to the local receivers.

When MSDP generates SA messages for SPB sources, the local cache miss data cannot be encapsulated into the SA messages that are sent to the peers.

The switch supports forwarding SA messages with encapsulated data from sources to MSDP peers but not from MSDP peers to the receivers.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Peers** tab.
4. In the row for the peer, double-click the **Md5AuthEnabled** field, and then select true.
5. In the row for the peer, double-click the **DataTtl** field, and then type a value.
6. Click **Apply**.

Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
RemoteAddress	Shows the IP address of the remote MSDP peer.
State	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
AdminEnabled	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
ClearPeer	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
ConnectRetryInterval	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
HoldTimeConfigured	The default value is 75 seconds.
KeepAliveConfigured	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.
DataTtl	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
InSAFilterEnabled	Activates the inbound SA filter for the peer.
InSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
OutSAFilterEnabled	Activates the outbound SA filter for the peer.
OutSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
Description	Specifies the text description, up to 255 characters, for the peer.

Name	Description
SALimit	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0-6144; the default value is 6144.
Md5AuthEnabled	Activates MD5 authentication on the TCP connection between peers. The default is false.
Md5AuthPassword	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
RemotePort	Shows the remote port for the TCP connection between the MSDP peers.
LocalPort	Shows the local port for the TCP connection between the MSDP peers.
OperEnabled	Shows the operational status of the peer.
RPFFailures	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAs	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAs	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSARequests	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSARequests	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAResponses	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAResponses	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InControlMessages	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
OutControlMessages	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InDataPackets	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutDataPackets	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
FsmEstablishedTransitions	Shows the total number of times the BGP transitioned to the established state.
FsmEstablishedTime	Shows the time when the peer transitioned to the established state.
InMessageTime	Shows the time when the last MSDP message was received from the peer.
ConnectionAttempts	Shows the number of times the state machine has transitioned from inactive to connecting.
DiscontinuityTime	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
AsNumber	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
TooShortMessages	Shows the number of short messages received from this peer.
InBadMessages	Shows the number of bad MSDP messages received from this peer.
InKeepAliveMessages	Shows the number of keepalive messages received from this peer.
OutKeepAliveMessages	Shows the number of keepalive messages transmitted to this peer.

Name	Description
SAsLearnedFromThisPeer	Shows the total number of SAs learned from this peer.
SAsAdvertisedToThisPeer	Shows the total number of SAs advertised from this peer.
UpOrDownTime	Shows the duration a peer has been up or down.
ConnAndStatsClearedTime	Shows the duration of connection and statistics cleared.

Configuring the MSDP peer keepalive messages

Configure keepalive messages to adjust the interval in seconds at which an MSDP peer sends keep alive messages (default is 60 seconds) and the interval at which the MSDP peer waits for keep alive messages from other peers before it declares them down (default is 75 seconds).

Note

In a peer relationship, the keep alive interval configured on one peer must be at least 1 second less than the hold time configured on the other side of the peer relationship. This is not applicable when the hold time is set to 0 seconds.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Peers** tab.
4. In the row for the peer, double-click the **KeepAliveConfigured** field, and then type the interval at which to send keepalive messages.
5. In the row for the peer, double-click the **HoldTimeConfigured** field, and then type the interval at which to wait for keepalive messages.
6. Click **Apply**.

Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
RemoteAddress	Shows the IP address of the remote MSDP peer.
State	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
AdminEnabled	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
ClearPeer	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).

Name	Description
ConnectRetryInterval	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
HoldTimeConfigured	The default value is 75 seconds.
KeepAliveConfigured	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.
DataTtl	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
InSAFilterEnabled	Activates the inbound SA filter for the peer.
InSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
OutSAFilterEnabled	Activates the outbound SA filter for the peer.
OutSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
Description	Specifies the text description, up to 255 characters, for the peer.
SALimit	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0–6144; the default value is 6144.
Md5AuthEnabled	Activates MD5 authentication on the TCP connection between peers. The default is false.
Md5AuthPassword	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
RemotePort	Shows the remote port for the TCP connection between the MSDP peers.
LocalPort	Shows the local port for the TCP connection between the MSDP peers.
OperEnabled	Shows the operational status of the peer.

Name	Description
RPFFailures	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAs	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAs	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSARquests	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSARquests	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAResponses	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAResponses	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InControlMessages	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutControlMessages	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InDataPackets	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutDataPackets	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
FsmEstablishedTransitions	Shows the total number of times the BGP transitioned to the established state.
FsmEstablishedTime	Shows the time when the peer transitioned to the established state.
InMessageTime	Shows the time when the last MSDP message was received from the peer.
ConnectionAttempts	Shows the number of times the state machine has transitioned from inactive to connecting.
DiscontinuityTime	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
AsNumber	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
TooShortMessages	Shows the number of short messages received from this peer.
InBadMessages	Shows the number of bad MSDP messages received from this peer.
InKeepAliveMessages	Shows the number of keepalive messages received from this peer.
OutKeepAliveMessages	Shows the number of keepalive messages transmitted to this peer.
SAsLearnedFromThisPeer	Shows the total number of SAs learned from this peer.
SAsAdvertisedToThisPeer	Shows the total number of SAs advertised from this peer.
UpOrDownTime	Shows the duration a peer has been up or down.
ConnAndStatsClearedTime	Shows the duration of connection and statistics cleared.

Configuring the MSDP peer connect-retry period

Configure the connect-retry period to specify the amount of time, in seconds, between connection attempts for peering sessions. The default is 30 seconds.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Peers** tab.
4. In the row for the peer, double-click the **ConnectRetryInterval** field, and then type the interval.
5. Click **Apply**.

Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
RemoteAddress	Shows the IP address of the remote MSDP peer.
State	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
AdminEnabled	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
ClearPeer	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
ConnectRetryInterval	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
HoldTimeConfigured	The default value is 75 seconds.
KeepAliveConfigured	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.
DataTtl	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
InSAFilterEnabled	Activates the inbound SA filter for the peer.
InSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
OutSAFilterEnabled	Activates the outbound SA filter for the peer.

Name	Description
OutSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
Description	Specifies the text description, up to 255 characters, for the peer.
SALimit	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0-6144; the default value is 6144.
Md5AuthEnabled	Activates MD5 authentication on the TCP connection between peers. The default is false.
Md5AuthPassword	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
RemotePort	Shows the remote port for the TCP connection between the MSDP peers.
LocalPort	Shows the local port for the TCP connection between the MSDP peers.
OperEnabled	Shows the operational status of the peer.
RPFFailures	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAs	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAs	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSARequests	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSARequests	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
InSAResponses	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAResponses	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InControlMessages	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutControlMessages	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InDataPackets	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutDataPackets	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
FsmEstablishedTransitions	Shows the total number of times the BGP transitioned to the established state.
FsmEstablishedTime	Shows the time when the peer transitioned to the established state.
InMessageTime	Shows the time when the last MSDP message was received from the peer.
ConnectionAttempts	Shows the number of times the state machine has transitioned from inactive to connecting.
DiscontinuityTime	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.

Name	Description
AsNumber	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
TooShortMessages	Shows the number of short messages received from this peer.
InBadMessages	Shows the number of bad MSDP messages received from this peer.
InKeepAliveMessages	Shows the number of keepalive messages received from this peer.
OutKeepAliveMessages	Shows the number of keepalive messages transmitted to this peer.
SAsLearnedFromThisPeer	Shows the total number of SAs learned from this peer.
SAsAdvertisedToThisPeer	Shows the total number of SAs advertised from this peer.
UpOrDownTime	Shows the duration a peer has been up or down.
ConnAndStatsClearedTime	Shows the duration of connection and statistics cleared.

Changing the MSDP peer status

Change the peer status to administratively enable or disable a configured peer. Disable the peer to stop the peering relationship.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Peers** tab.
4. In the row for the peer, double-click the **AdminEnabled** field, and then select true.
5. Click **Apply**.

Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
RemoteAddress	Shows the IP address of the remote MSDP peer.
State	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
AdminEnabled	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
ClearPeer	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
ConnectRetryInterval	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
HoldTimeConfigured	The default value is 75 seconds.
KeepAliveConfigured	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.
DataTtl	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
InSAFilterEnabled	Activates the inbound SA filter for the peer.
InSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
OutSAFilterEnabled	Activates the outbound SA filter for the peer.
OutSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
Description	Specifies the text description, up to 255 characters, for the peer.

Name	Description
SALimit	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0-6144; the default value is 6144.
Md5AuthEnabled	Activates MD5 authentication on the TCP connection between peers. The default is false.
Md5AuthPassword	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
RemotePort	Shows the remote port for the TCP connection between the MSDP peers.
LocalPort	Shows the local port for the TCP connection between the MSDP peers.
OperEnabled	Shows the operational status of the peer.
RPFFailures	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAs	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAs	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSARquests	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSARquests	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAResponses	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAResponses	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InControlMessages	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
OutControlMessages	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InDataPackets	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutDataPackets	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
FsmEstablishedTransitions	Shows the total number of times the BGP transitioned to the established state.
FsmEstablishedTime	Shows the time when the peer transitioned to the established state.
InMessageTime	Shows the time when the last MSDP message was received from the peer.
ConnectionAttempts	Shows the number of times the state machine has transitioned from inactive to connecting.
DiscontinuityTime	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
AsNumber	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
TooShortMessages	Shows the number of short messages received from this peer.
InBadMessages	Shows the number of bad MSDP messages received from this peer.
InKeepAliveMessages	Shows the number of keepalive messages received from this peer.
OutKeepAliveMessages	Shows the number of keepalive messages transmitted to this peer.

Name	Description
SAsLearnedFromThisPeer	Shows the total number of SAs learned from this peer.
SAsAdvertisedToThisPeer	Shows the total number of SAs advertised from this peer.
UpOrDownTime	Shows the duration a peer has been up or down.
ConnAndStatsClearedTime	Shows the duration of connection and statistics cleared.

Clearing the MSDP peer connection

Clear the TCP connection to the specified MSDP peer, and reset all MSDP message counters.

The default is disabled (false).

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Peers** tab.
4. In the row for the peer, double-click the **ClearPeer** field, and then select true.
5. Click **Apply**.

Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
RemoteAddress	Shows the IP address of the remote MSDP peer.
State	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
AdminEnabled	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
ClearPeer	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
ConnectRetryInterval	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
HoldTimeConfigured	The default value is 75 seconds.
KeepAliveConfigured	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.

Name	Description
DataTtl	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
InSAFilterEnabled	Activates the inbound SA filter for the peer.
InSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
OutSAFilterEnabled	Activates the outbound SA filter for the peer.
OutSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
Description	Specifies the text description, up to 255 characters, for the peer.
SALimit	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0–6144; the default value is 6144.
Md5AuthEnabled	Activates MD5 authentication on the TCP connection between peers. The default is false.
Md5AuthPassword	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
RemotePort	Shows the remote port for the TCP connection between the MSDP peers.
LocalPort	Shows the local port for the TCP connection between the MSDP peers.
OperEnabled	Shows the operational status of the peer.
RPFFailures	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAs	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAs	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
InSARRequests	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSARRequests	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAResponses	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAResponses	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InControlMessages	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutControlMessages	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InDataPackets	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutDataPackets	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
FsmEstablishedTransitions	Shows the total number of times the BGP transitioned to the established state.
FsmEstablishedTime	Shows the time when the peer transitioned to the established state.
InMessageTime	Shows the time when the last MSDP message was received from the peer.
ConnectionAttempts	Shows the number of times the state machine has transitioned from inactive to connecting.

Name	Description
DiscontinuityTime	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
AsNumber	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
TooShortMessages	Shows the number of short messages received from this peer.
InBadMessages	Shows the number of bad MSDP messages received from this peer.
InKeepAliveMessages	Shows the number of keepalive messages received from this peer.
OutKeepAliveMessages	Shows the number of keepalive messages transmitted to this peer.
SAsLearnedFromThisPeer	Shows the total number of SAs learned from this peer.
SAsAdvertisedToThisPeer	Shows the total number of SAs advertised from this peer.
UpOrDownTime	Shows the duration a peer has been up or down.
ConnAndStatsClearedTime	Shows the duration of connection and statistics cleared.

Deleting an MSDP peer

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Peers** tab.
4. Select a row from the peer to delete.
5. Click **Delete**.
6. Click **Yes**.

Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
RemoteAddress	Shows the IP address of the remote MSDP peer.
State	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
AdminEnabled	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
ClearPeer	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
ConnectRetryInterval	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
HoldTimeConfigured	The default value is 75 seconds.
KeepAliveConfigured	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.
DataTtl	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
InSAFilterEnabled	Activates the inbound SA filter for the peer.
InSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
OutSAFilterEnabled	Activates the outbound SA filter for the peer.
OutSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
Description	Specifies the text description, up to 255 characters, for the peer.

Name	Description
SALimit	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0-6144; the default value is 6144.
Md5AuthEnabled	Activates MD5 authentication on the TCP connection between peers. The default is false.
Md5AuthPassword	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
RemotePort	Shows the remote port for the TCP connection between the MSDP peers.
LocalPort	Shows the local port for the TCP connection between the MSDP peers.
OperEnabled	Shows the operational status of the peer.
RPFFailures	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAs	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAs	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSARequests	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSARequests	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAResponses	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAResponses	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InControlMessages	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
OutControlMessages	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InDataPackets	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutDataPackets	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
FsmEstablishedTransitions	Shows the total number of times the BGP transitioned to the established state.
FsmEstablishedTime	Shows the time when the peer transitioned to the established state.
InMessageTime	Shows the time when the last MSDP message was received from the peer.
ConnectionAttempts	Shows the number of times the state machine has transitioned from inactive to connecting.
DiscontinuityTime	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
AsNumber	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
TooShortMessages	Shows the number of short messages received from this peer.
InBadMessages	Shows the number of bad MSDP messages received from this peer.
InKeepAliveMessages	Shows the number of keepalive messages received from this peer.
OutKeepAliveMessages	Shows the number of keepalive messages transmitted to this peer.

Name	Description
SAsLearnedFromThisPeer	Shows the total number of SAs learned from this peer.
SAsAdvertisedToThisPeer	Shows the total number of SAs advertised from this peer.
UpOrDownTime	Shows the duration a peer has been up or down.
ConnAndStatsClearedTime	Shows the duration of connection and statistics cleared.

MSDP Message Control using the EDM

This section provides procedures to configure MSDP message control using the EDM.

Filtering PIM routes

Configure MSDP global filter for which the SA local cache are distributed to all MSDP peers. All SA local cache entries generate SA messages.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Globals** tab.
4. Select the **RedistributeFilterEnabled** check box.
5. Type the name of the route policy in the **RouteMapName** field.
6. Select the **RedistributeFilterApply** check box to apply the changes to the redistribute filter.

You do not need to apply the changes in the following situations:

- You create the redistribute filter without a route policy.
- You disable the redistribute filter.
- You remove a route policy from the redistribute filter.

7. Click **Apply**.

Global field descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
Enabled	Enables MSDP. If you clear this check box, you disable MSDP. The default setting is clear (disabled).
CacheLifetime	Configures the lifetime given to SA cache entries when created or refreshed.
NumSACacheEntries	Displays the total number of entries in the SA cache.
RPAddress	Specifies the IP address to use as the originator ID. If the address is not a system local address, the system rejects the configuration.

Name	Description
RouteMapName	Specifies the name of the optional route policy to create or modify. You do not need to create a route policy to use the redistribution filter. Note: To delete the route map name, clear the field and click Apply .
RedistributeFilterEnabled	Filters the (S,G,RP) entries provided by PIM to MSDP. The default is clear (disabled).
RedistruteFilterApply	Applies the changes made to the redistribute filter.
StatsClear	Clears MSDP statistics.

Filtering SA messages

Filter SA messages to determine which SA messages to accept from a peer and which SA messages to send to a peer. By default, no inbound or outbound filter exists.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Peers** tab.
4. In the row for the peer, double-click the **InSAFilterEnabled** field, and then select true.
5. In the row for the peer, double-click the **InSAFilterRouteMapName** field, and then type the route map name for the IN SA Filter of the peer.
6. In the row for the peer, double-click the **OutSAFilterEnabled** field, and then select true.
7. In the row for the peer, double-click the **OutSAFilterRouteMapName** field, and then type the route map name for the OUT SA Filter of the peer.
8. Click **Apply**.

Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
RemoteAddress	Shows the IP address of the remote MSDP peer.
State	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
AdminEnabled	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
ClearPeer	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).

Name	Description
ConnectRetryInterval	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
HoldTimeConfigured	The default value is 75 seconds.
KeepAliveConfigured	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.
DataTtl	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
InSAFilterEnabled	Activates the inbound SA filter for the peer.
InSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
OutSAFilterEnabled	Activates the outbound SA filter for the peer.
OutSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
Description	Specifies the text description, up to 255 characters, for the peer.
SALimit	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0–6144; the default value is 6144.
Md5AuthEnabled	Activates MD5 authentication on the TCP connection between peers. The default is false.
Md5AuthPassword	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
RemotePort	Shows the remote port for the TCP connection between the MSDP peers.
LocalPort	Shows the local port for the TCP connection between the MSDP peers.
OperEnabled	Shows the operational status of the peer.

Name	Description
RPFFailures	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAs	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAs	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSARquests	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSARquests	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAResponses	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAResponses	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InControlMessages	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutControlMessages	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InDataPackets	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutDataPackets	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
FsmEstablishedTransitions	Shows the total number of times the BGP transitioned to the established state.
FsmEstablishedTime	Shows the time when the peer transitioned to the established state.
InMessageTime	Shows the time when the last MSDP message was received from the peer.
ConnectionAttempts	Shows the number of times the state machine has transitioned from inactive to connecting.
DiscontinuityTime	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
AsNumber	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
TooShortMessages	Shows the number of short messages received from this peer.
InBadMessages	Shows the number of bad MSDP messages received from this peer.
InKeepAliveMessages	Shows the number of keepalive messages received from this peer.
OutKeepAliveMessages	Shows the number of keepalive messages transmitted to this peer.
SAsLearnedFromThisPeer	Shows the total number of SAs learned from this peer.
SAsAdvertisedToThisPeer	Shows the total number of SAs advertised from this peer.
UpOrDownTime	Shows the duration a peer has been up or down.
ConnAndStatsClearedTime	Shows the duration of connection and statistics cleared.

Configuring the MSDP mesh groups

Configure mesh groups to reduce SA flooding. A mesh group does not forward SA messages to other group members in the same mesh group. The originator, which is also a mesh group member, forwards SA messages to all group members. Create MSDP mesh groups from a group of meshed MSDP

speakers from a domain. Do not create MSDP peerings between Controllers within the same SPB domain.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Mesh Group** tab.
4. Click **Insert**.
5. In the **Name** field, type a name for the mesh group.
6. In the **PeerAddress** field, type the IP address of the peer to add the mesh group.
7. Click **Insert**.

Mesh Group field descriptions

Use the data in the following table to use the **Mesh Group** tab.

Name	Description
Name	Specifies the mesh group ID; the name of the mesh group from 1-64 characters.
PeerAddress	Specifies the IP address of the MSDP router that is the peer.

Clearing the MSDP SA cache

Clear the SA cache to clear the SA entries the router learns from all the peers or a specific peer.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **SA-Cache** tab.
4. Click **Clear SA-Cache**.

SA-Cache field descriptions

Use the data in the following table to use the **SA-Cache** tab.

Name	Description
GroupAddr	Shows the group IP address of the SA cache entry.
SourceAddr	Shows the source IP address of the SA cache entry.
OriginRP	Shows the RP address of the SA cache entry.
PeerLearnedFrom	Shows the peer from which this SA cache entry was accepted.
RPFPeer	Shows the peer from which an SA message corresponding to the cache entry is accepted.

Name	Description
InSAs	Discontinuities in the value of this counter can occur at reinitialization of the management system.
InDataPackets	Shows the number of MSDP encapsulated data packets received that are relevant to this cache entry.
UpTime	Shows the time since this entry was first placed in the SA cache.
ExpiryTime	Shows the time remaining before this entry expires from the SA cache.

MSDP Verification using the EDM

This section provides procedures to verify MSDP using the EDM.

Viewing peer information

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Peers** tab.

Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
RemoteAddress	Shows the IP address of the remote MSDP peer.
State	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
AdminEnabled	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
ClearPeer	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
ConnectRetryInterval	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
HoldTimeConfigured	The default value is 75 seconds.

Name	Description
KeepAliveConfigured	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.
DataTtl	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
InSAFilterEnabled	Activates the inbound SA filter for the peer.
InSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
OutSAFilterEnabled	Activates the outbound SA filter for the peer.
OutSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
Description	Specifies the text description, up to 255 characters, for the peer.
SALimit	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0–6144; the default value is 6144.
Md5AuthEnabled	Activates MD5 authentication on the TCP connection between peers. The default is false.
Md5AuthPassword	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
RemotePort	Shows the remote port for the TCP connection between the MSDP peers.
LocalPort	Shows the local port for the TCP connection between the MSDP peers.
OperEnabled	Shows the operational status of the peer.
RPFFailures	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
InSAs	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAs	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSARequests	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSARequests	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAResponses	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAResponses	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InControlMessages	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutControlMessages	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InDataPackets	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutDataPackets	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
FsmEstablishedTransitions	Shows the total number of times the BGP transitioned to the established state.
FsmEstablishedTime	Shows the time when the peer transitioned to the established state.

Name	Description
InMessageTime	Shows the time when the last MSDP message was received from the peer.
ConnectionAttempts	Shows the number of times the state machine has transitioned from inactive to connecting.
DiscontinuityTime	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
AsNumber	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
TooShortMessages	Shows the number of short messages received from this peer.
InBadMessages	Shows the number of bad MSDP messages received from this peer.
InKeepAliveMessages	Shows the number of keepalive messages received from this peer.
OutKeepAliveMessages	Shows the number of keepalive messages transmitted to this peer.
SAsLearnedFromThisPeer	Shows the total number of SAs learned from this peer.
SAsAdvertisedToThisPeer	Shows the total number of SAs advertised from this peer.
UpOrDownTime	Shows the duration a peer has been up or down.
ConnAndStatsClearedTime	Shows the duration of connection and statistics cleared.

Viewing the local SA cache

View the local SA cache to display the (S, G) state the router learns from local Protocol Independent Multicast - Sparse Mode (PIM-SM) entries.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **SA-Cache-Records** tab.

SA-Cache-Records field descriptions

Use the data in the following table to use the **SA-Cache-Records** tab.

Name	Description
TypeInformation	Shows the SA cache type. The SA cache type can be local or foreign cache.
GroupAddr	Shows the group IP address of the SA cache entry.
SourceAddr	Shows the source IP address of the SA cache entry.
OriginRP	Shows the RP address of the SA cache entry.
OriginatorAsNumber	Shows the AS number of the originator.
RouteType	Shows the type of route used for Reverse Path Forwarding checking. The value can be rip (1), ospf (2), static (3), bgp (4), isis(5) or none (6).

Viewing the foreign SA cache

View the foreign SA cache to display the (S, G) state the router learns from SA messages.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **SA-Cache-Records** tab.

SA-Cache-Records field descriptions

Use the data in the following table to use the **SA-Cache-Records** tab.

Name	Description
TypeInformation	Shows the SA cache type. The SA cache type can be local or foreign cache.
GroupAddr	Shows the group IP address of the SA cache entry.
SourceAddr	Shows the source IP address of the SA cache entry.
OriginRP	Shows the RP address of the SA cache entry.
OriginatorAsNumber	Shows the AS number of the originator.
RouteType	Shows the type of route used for Reverse Path Forwarding checking. The value can be rip (1), ospf (2), static (3), bgp (4), isis(5) or none (6).

Viewing the mesh group

Configure Message Digest (MD) 5 authentication to secure control messages on the TCP connection between MSDP peers.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Mesh Group** tab.

Mesh Group field descriptions

Use the data in the following table to use the **Mesh Group** tab.

Name	Description
Name	Specifies the mesh group ID; the name of the mesh group from 1-64 characters.
PeerAddress	Specifies the IP address of the MSDP router that is the peer.

Controller configuration

This section provides procedures to configure the Controller using Command Line Interface (CLI) and Enterprise Device Manager (EDM).

The Controller functionality is configured at the global (switch-wide) level.

Controller Configuration using the CLI

This section provides procedures to configure controller using the command line interface (CLI).

Enabling the Controller

Enable the Controller globally.

Procedure

1. Enter IS-IS Router Configuration mode:

```
enable
configure terminal
router isis
```
2. Enable the Controller globally:

```
spbm <1-100> multicast spb-pim-gw controller enable
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#spbm 1 multicast spb-pim-gw controller enable
```

Variable definitions

The following table defines parameters for the **spb** command.

Variable	Value
<1-100>	Specifies the isis spbm instance-id to create the spbm instance.
<i>controller enable</i>	Enables the SPB-PIM Gateway Controller.

Displaying the Controller admin status

Use the following procedure to display the admin status of the Controller.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the Controller Status:

```
show isis spbm
```

Example

Note

The SPB-PIM-GW column displays either Controller, Gateway, or Controller/Gateway if the Controller and or Gateway functionality is configured.

```
Switch:1>show isis spbm

Displaying the active Controller and Gateway Nodes

Use the following procedure to display the active Controllers and Gateways in the SPBM domain.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the SPB-PIM Gateway active Controller and Gateway Nodes:

```
show ip spb-pim-gw node [controller | gateway] [spb-node-as-mac]
```

Example

Display all node lists:

```
Switch:1>show ip spb-pim-gw node
=====
                               Spb-pim-gw Active Controller/Gateway
=====
HOST-NAME      Role
-----
BEB3-4037      Gateway
BEB5-4011      Controller

Total Number of Nodes = 2/2
=====
```

Display Controller node lists only:

```
Switch:1>show ip spb-pim-gw node controller
=====
                               Spb-pim-gw Active Controller/Gateway
=====
HOST-NAME      Role
-----
BEB5-4011      Controller

Total Number of Nodes = 1/2
=====
```

Display Gateway node lists only:

```
Switch:1>show ip spb-pim-gw node gateway
=====
                               Spb-pim-gw Active Controller/Gateway
=====
HOST-NAME      Role
-----
BEB3-4037      Gateway

Total Number of Nodes = 1/2
=====
```

Display all node lists with MAC address:

```
Switch:1>show ip spb-pim-gw node spb-node-as-mac
```

```

=====
                               Spb-pim-gw Active Controller/Gateway
=====
HOST-NAME      Role      Mac Address
-----
BEB3-4037      Gateway   00:37:00:37:00:37
BEB5-4011      Controller 00:11:00:11:00:11
Total Number of Nodes = 2/2
=====

```

Display Controller node lists with MAC address:

```

Switch:1>show ip spb-pim-gw node controller spb-node-as-mac

=====
                               Spb-pim-gw Active Controller/Gateway
=====
HOST-NAME      Role      Mac Address
-----
BEB5-4011      Controller 00:11:00:11:00:11
Total Number of Nodes = 1/2
=====

```

Display Gateway node lists with MAC address:

```

Switch:1>show ip spb-pim-gw node gateway spb-node-as-mac

=====
                               Spb-pim-gw Active Controller/Gateway
=====
HOST-NAME      Role      Mac Address
-----
BEB3-4037      Gateway   00:37:00:37:00:37
Total Number of Nodes = 1/2
=====

```

Configuring a static foreign source on the global router

Configure a static foreign source on the global router. Configuration is done at the Controller. Statically configure foreign sources, such as streams in a Source Specific Multicast (SSM) group range that are not advertised by the foreign network through MSDP. Non-SSM range group multicast address streams are advertised by MSDP and do not need to be statically configured.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure a static foreign source:

```
ip spb-pim-gw foreign-source {A.B.C.D} group {A.B.C.D}
```

Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

```
Switch:1(config)#ip spb-pim-gw foreign-source 10.0.0.1 group 240.0.0.1
```

Variable definitions

The following table defines parameters for the **ip spb-pim-gw** command.

Variable	Value
<i>foreign-source</i> {A.B.C.D}	Specifies the multicast foreign source IP address.
<i>group</i> {A.B.C.D}	Specifies the group IP address.

Configuring a static foreign source on a VRF

Configure a static foreign source on a VRF, configuration is done at the Controller.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
router vrf WORD<1-16>
```

2. Configure a static foreign source:

```
ip spb-pim-gw foreign-source {A.B.C.D} group {A.B.C.D}
```

Example

In the following example, vrf-10 is configured with vrf id 10.

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

```
Switch:1(config)#router vrf vrf-10
```

```
Switch:1(router-vrf)#ip spb-pim-gw foreign-source 10.0.0.1 group
240.0.0.1
```

Variable definitions

The following table defines parameters for the **ip spb-pim-gw** command.

Variable	Value
<i>foreign-source</i> {A.B.C.D}	Specifies the multicast foreign source IP address.
<i>group</i> {A.B.C.D}	Specifies the group IP address.

Displaying foreign sources

Use the following procedure to display the foreign sources learned from MSDP or statically configured at the Controller.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the foreign source information:

```
show ip spb-pim-gw foreign-source [all] [controller | gateway] [vrf
WORD<0-16>] [vrfids WORD<0-512>] [source {A.B.C.D}] [group {A.B.C.D}]
[static | msdp] [spb-node-as-mac]
```

Example

Note

The command **show ip spb-pim-gw**, which specifies the parameter *controller*, the OWNER column displays the RP address of the MSDP peer from which the foreign source was learned. If the *gateway* parameter is specified, then the OWNER column displays MSDP rather than the actual RP address.

```
Switch:1>show ip spb-pim-gw foreign-source controller
=====
==
SPB-PIM-GW Controller Foreign Source
=====
==
SOURCE      GROUP      SPB-PIM-GW      VRF          OWNER
-----
--
10.0.0.1    240.0.0.1  beb-1           GlobalRouter  47.17.0.1
10.0.0.2    240.0.0.2  beb-1           GlobalRouter  static
10.0.0.3    240.0.0.3  -               GlobalRouter  47.17.0.2
-----
--
```

Display the foreign sources from a specific VRF:

```
Switch:1>show ip spb-pim-gw foreign-source controller vrf green
=====
==
SPB-PIM-GW Controller Foreign Source
=====
==
SOURCE      GROUP      SPB-PIM-GW      VRF          OWNER
-----
--

10.0.0.2    240.0.0.2  beb-1           green        static
10.0.0.3    240.0.0.3  -               green        47.17.0.2
-----
--
```

Display all the foreign sources at the Controller with the Gateway in the SPB-PIM-GW shown as a mac address rather than a nickname:

```
Switch:1>show ip spb-pim-gw foreign-source controller vrf green spb-node-as-mac
=====
==
SPB-PIM-GW Controller Foreign Source
=====
==
SOURCE      GROUP      SPB-PIM-GW      VRF          OWNER
-----
```

```

-----
--
10.0.0.1 240.0.0.1 00:0b:eb:00:00:a1 green      47.17.0.1
10.0.0.2 240.0.0.2 00:0b:eb:00:00:a1 green      static
10.0.0.3 240.0.0.3 -                green      47.17.0.2
-----
--

```

Variable definitions

The following table defines parameters for the **show ip spb-pim-gw foreign source** command.

Variable	Value
<i>all</i>	Displays information for all the VRF IDs from the Controller and Gateway foreign source database.
<i>controller</i>	Displays information from the Controller foreign source database. Only displays information on nodes configured as Controller.
<i>gateway</i>	Displays information from the Gateway foreign source database. Only displays information on nodes configured as Gateway.
<i>vrf WORD<0-16></i>	Displays information from the Controller foreign source database for a specific VRF name.
<i>vrfids WORD<0-512></i>	Displays information from the Controller foreign source database for a range of VRF IDs. Note: Enter a single VRF ID or multiple VRF IDs separated by ',' or enter a range of VRF IDs 'x-y'.
<i>source {A.B.C.D}</i>	Displays information for the specific source IP address from the Controller foreign source database.
<i>group {A.B.C.D}</i>	Displays information for the specific multicast group IP address from the Controller foreign source database.
<i>static</i>	Displays information from the Controller foreign source database that is configured statically.
<i>msdp</i>	Displays information from the Controller foreign source database that is learned through MSDP.
<i>spb-node-as-mac</i>	Displays the MAC address for the assigned SPB-PIM Gateway.

Displaying Multicast over Fabric Connect sources

Use the following procedure to display all the SPB Multicast over Fabric Connect sources distributed to MSDP. This procedure is only valid on a Controller node.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the SPB source information:

```
show ip spb-pim-gw spbmc-source [vrf WORD<1-32>] [vrfids WORD<0-512>]
[source {A.B.C.D}] [group {A.B.C.D}] [originator WORD<1-32>] [spb-
node-as-mac]
```

Example

```
Switch:1>show ip spb-pim-gw spbmc-source
```

```
=====
SPB-PIM-GW SPB Source
=====
SOURCE          GROUP          VRF          ORIGINATOR
-----
10.0.0.1        240.0.0.1     GlobalRouter bcb-1
10.0.0.2        240.0.0.2     GlobalRouter bcb-2
10.0.0.3        240.0.0.3     GlobalRouter bcb-2
-----
--
```

Display the SPB Multicast over Fabric Connect from a specific VRF:

```
Switch:1>show ip spb-pim-gw spbmc-source vrf green
```

```
=====
SPB-PIM-GW Foreign Source
=====
SOURCE  GROUP    SPB-PIM-GW  VRF    OWNER    CONTROLLER
-----

-----
---
```

Variable definitions

The following table defines parameters for the **show ip spb-pim-gw spbmc-source** command.

Variable	Value
<code>vrf WORD<1-32></code>	Displays SPB originated sources for a specific VRF.
<code>vrfids WORD<0-512></code>	Displays SPB originated sources for a range of VRF IDs. Note: Enter a single VRF ID or multiple VRF IDs separated by ',' or enter a range of VRF IDs 'x-y'.
<code>source {A.B.C.D}</code>	Displays information for a specific source IP address from SPB originated sources database.
<code>group {A.B.C.D}</code>	Displays information for a specific multicast group IP address from SPB originated sources database.
<code>originator WORD<0-32></code>	Displays information for a specific originator host name from SPB originated sources database.
<code>spb-node-as-mac</code>	Displays the originator of SPB originated sources as a MAC address rather than a nickname.

Controller Configuration using the EDM

This section provides procedures to configure controller using the EDM.

Enabling the Controller

Enable the Controller globally.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **SPBM**.
3. In the row for the SPBM, double click the **McastSpbPimGwControllerEnable** field, and then select true.
4. Select **Apply**.

SPBM field descriptions

Use the data in the following table to use the **SPBM** tab.

Name	Description
McastSpbPimGwControllerEnable	Enables or disables the ISIS multicast SPM-PIM Gateway Controller node.
McastSpbPimGWGatewayEnable	Enables or disables the ISIS multicast SPM-PIM Gateway node.

Displaying the Controller and Gateway admin status

Use the following procedure to display the admin status of the Controller and Gateway.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **SPBM**.
3. Select the **SPBM** tab.

Displaying active Controller and Gateway nodes

Use the following procedure to display the active Controllers and Gateways in the SPBM domain.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **SPB-PIM-GW**.
3. Click the **Node** tab.

Node field descriptions

Use the data in the following table to use the **Node** tab.

Name	Description
MacAddress	Shows the MAC address of the active node.
HostName	Shows the host name of the active node.
RoleType	Shows the role of the active node: either gateway, controller, or both.

Configuring a static foreign source globally

Configure a static foreign source on the global router. Configuration is done at the Controller.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **SPB-PIM-GW**.
3. Click the **Controller-Foreign-Source** tab.
4. Click **Insert**.
5. In the **SourceAddress** box, type the multicast foreign source IP address.
6. In the **GroupAddress** box, type the group IP address.
7. Click **Insert**.

Controller-Foreign-Source field descriptions

Use the data in the following table to use the **Controller-Foreign-Source** tab.

Name	Description
SourceAddress	Specifies the source IP address from a foreign multicast domain.
GroupAddress	Specifies the multicast group IP address associated with the foreign source.
GatewaySysId	Displays the system ID of the node selected as the Gateway for this foreign source. GatewaySysId field will have a valid value if the Gateway is assigned to a source. If the Gateway is not assigned to a source the value is 0.
GatewayHostName	Displays the host name of the node selected as the Gateway for this foreign source. GatewayHostName field will have valid values if the Gateway is assigned to a source. If the Gateway is not assigned to a source the value is NULL.
Type	Displays the owner type for this source.
Owner	Displays the IP address of the MSDP peer if the foreign source is MSDP.

Configuring a static foreign source on a VRF

Configure a static foreign source on a VRF. Configuration is done at the Controller.

Procedure

1. In the navigation pane, expand **Configuration > VRF Context View**.
2. Click **Set VRF Context view**.
3. Select a row and click **Launch VRF Context view**.
4. Select a switch port in the **Device Physical View** tab.
5. In the navigation pane, expand **Configuration > IP**.
6. Click **SPB-PIM-GW**.
7. Click the **Controller-Foreign-Source** tab.
8. Click **Insert**.
9. In the **SourceAddress** box, type the multicast foreign source IP address.
10. In the **GroupAddress** box, type the group IP address.
11. Click **Insert**.

Controller-Foreign-Source field descriptions

Use the data in the following table to use the **Controller-Foreign-Source** tab.

Name	Description
SourceAddress	Specifies the source IP address from a foreign multicast domain.
GroupAddress	Specifies the multicast group IP address associated with the foreign source.
GatewaySysId	Displays the system ID of the node selected as the Gateway for this foreign source. GatewaySysId field will have a valid value if the Gateway is assigned to a source. If the Gateway is not assigned to a source the value is 0.
GatewayHostName	Displays the host name of the node selected as the Gateway for this foreign source. GatewayHostName field will have valid values if the Gateway is assigned to a source. If the Gateway is not assigned to a source the value is NULL.
Type	Displays the owner type for this source.
Owner	Displays the IP address of the MSDP peer if the foreign source is MSDP.

Displaying foreign sources

Use the following procedure to display the foreign sources learned from MSDP or statically configured at the Controller.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **SPB-PIM-GW**.
3. Click the **Controller-Foreign-Source** tab.

Controller-Foreign-Source field descriptions

Use the data in the following table to use the **Controller-Foreign-Source** tab.

Name	Description
SourceAddress	Specifies the source IP address from a foreign multicast domain.
GroupAddress	Specifies the multicast group IP address associated with the foreign source.
GatewaySysId	Displays the system ID of the node selected as the Gateway for this foreign source. GatewaySysId field will have a valid value if the Gateway is assigned to a source. If the Gateway is not assigned to a source the value is 0.

Name	Description
GatewayHostName	Displays the host name of the node selected as the Gateway for this foreign source. GatewayHostName field will have valid values if the Gateway is assigned to a source. If the Gateway is not assigned to a source the value is NULL.
Type	Displays the owner type for this source.
Owner	Displays the IP address of the MSDP peer if the foreign source is MSDP.

Displaying Multicast over Fabric Connect sources

Use the following procedure to display all the SPB Multicast over Fabric Connect sources distributed to MSDP.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **SPB-PIM-GW**.
3. Click the **spbm-source** tab.

Spbmc-Source field descriptions

Use the data in the following table to use the **Spbmc-Source** tab.

Name	Description
SourceAddress	Displays the source IP address from SPBM multicast domain.
GroupAddress	Displays the multicast group IP address associated with the SPBM source.
OriginatorSysId	Displays the system ID of the node from which the source originates.
OriginatorHostName	Displays the host name of the node from which the source originates.

Gateway configuration

This section provides procedures to configure the Gateway using Command Line Interface (CLI) and Enterprise Device Manager (EDM).

The Gateway functionality is configured at the global (switch-wide) level. SPB-PIM Gateway Interfaces are configured at the interface level. For more information on SPB-PIM Gateway Interfaces configuration, see [SPB-PIM Gateway interface configuration](#) on page 2856.

Gateway Configuration using the CLI

This section provides procedures to configure gateway using the command line interface (CLI).

Enabling the Gateway

Enable the Gateway at the global (switch-wide) level.

Procedure

1. Enter IS-IS Router Configuration mode:

```
enable

configure terminal

router isis
```
2. Enable the Gateway globally:

```
spbm <1-100> multicast spb-pim-gw gateway enable
```

Example

```
Switch:1>enable

Switch:1#configure terminal

Switch:1(config)#router isis

Switch:1(config-isis)#spbm 1 multicast spb-pim-gw gateway enable
```

Variable definitions

The following table defines parameters for the **spb** command.

Variable	Value
<1-100>	Specifies the isis spbm instance-id to create the spbm instance.
<i>gateway enable</i>	Enables the SPB-PIM Gateway.

Displaying the Gateway admin status

Use the following procedure to display the admin status of the Gateway.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the Gateway admin status:

```
show isis spbm
```

Example

```
Switch:1>show isis spbm

Displaying foreign sources information

Use the following procedure to display the Gateway foreign sources database. If executed on a Gateway node, it displays the foreign sources assigned to the Gateway by the Controller. Foreign sources are originally learned from MSDP or statically configured on the Controller.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the foreign sources information:

```
show ip spb-pim-gw foreign-source [all] [controller | gateway] [vrf
WORD<0-16>] [vrfids WORD<0-512>] [source {A.B.C.D}] [group {A.B.C.D}]
[from-controller <0x00:0x00:0x00:0x00:0x00:0x00> | preferred][static |
msdp] [spb-node-as-mac]
```

Example

```
Switch:1>show ip spb-pim-gw foreign-source gateway
=====
==
SPB-PIM-GW Gateway Foreign Source
=====
==
SOURCE      GROUP      SPB-PIM-GW      VRF      PORT  VLAN  CONTROLLER      OWNER
-----
--
10.0.0.1    240.0.0.1  beb-2           GlobalRouter 1/1    200   bcb-2           msdp
10.0.0.2    240.0.0.2  beb-2           GlobalRouter 1/1    200   bcb-2           static
10.0.0.3    240.0.0.3  beb-2           GlobalRouter -      -     bcb-2           msdp
-----
--
```

**Note**

The SPB-PIM-GW column displays the node that is selected as the Gateway for the particular source or group stream. The OWNER column displays either msdp or static depending on how the source was originally learned at the assigning Controller. The PORT and VLAN columns represent the port or VLAN toward the source.

Display the foreign sources from a specific VRF:

```
Switch:1>show ip spb-pim-gw foreign-source gateway vrf green
=====
==
SPB-PIM-GW Gateway Foreign Source
=====
==
SOURCE      GROUP      SPB-PIM-GW      VRF      PORT  VLAN  CONTROLLER      OWNER

```

Variable definitions

The following table defines parameters for the **show ip spb-pim-gw foreign source** command.

Variable	Value
<i>all</i>	Displays information for all the VRF IDs from the Controller and Gateway foreign source database.
<i>controller</i>	Displays information from the Controller foreign source database. Only displays information on nodes configured as Controller.
<i>gateway</i>	Displays information from the Gateway foreign source database. Only displays information on nodes configured as Gateway.
<i>vrf WORD<0-16></i>	Displays information from the Gateway foreign source database for a specific VRF name.
<i>vrfids WORD<0-512></i>	Displays information from the Gateway foreign source database for a range of VRF IDs. Note: Enter a single VRF ID or multiple VRF IDs separated by ',' or enter a range of VRF IDs 'x-y'.

Variable	Value
<i>source {A.B.C.D}</i>	Displays information for the specific source IP address from the Gateway foreign source database.
<i>group {A.B.C.D}</i>	Displays information for the specific multicast group IP address from the Gateway foreign source database.
<i>from-controller 0x00:0x00:0x00:0x00:0x00:0x00</i>	Displays information filtering on a specific Controllers assignments, where the Controller is specified as a mac address.
<i>from-controller preferred</i>	Displays information from Gateway source database filtering on a preferred Controller or chosen by the Gateway.
<i>static</i>	Displays information from the Gateway foreign source database that is configured statically at the assigning Controller.
<i>msdp</i>	Displays information from the Gateway foreign source database that is learned through MSDP.
<i>spb-node-as-mac</i>	Displays the MAC address for the assigned PIM-GW.

Gateway Configuration using the EDM

This section provides procedures to configure gateway using the EDM.

Enabling the Gateway globally

Use this procedure to enable the Gateway at the global (switch-wide) level.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **SPBM**.
3. In the row for the SPBM, double click the **McastSpbPimGwGatewayEnable** field, and then select true.
4. Select **Apply**.

SPBM field descriptions

Use the data in the following table to use the **SPBM** tab.

Name	Description
McastSpbPimGwControllerEnable	Enables or disables the ISIS multicast SPM-PIM Gateway Controller node.
McastSpbPimGWGatewayEnable	Enables or disables the ISIS multicast SPM-PIM Gateway node.

Displaying foreign sources

Use the following procedure to display the Gateway foreign source database. Foreign sources are originally learned from MSDP or statically configured on the Controller.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **SPB-PIM-GW**.
3. Click the **Gateway-Foreign-Source** tab.

Gateway-Foreign-Source field descriptions

Use the data in the following table to use the **Gateway-Foreign-Source** tab.

Name	Description
SourceAddress	Displays the foreign source IP address.
GroupAddress	Displays the multicast group IP address associated with the foreign source.
ControllerSysId	Displays the system ID of the controller node that sends this foreign source.
ControllerHostName	Displays the host name of the controller node that sends this foreign source.
GatewaySysId	Displays the system ID of the node selected as the gateway for this foreign source.
GatewayHostName	Displays the host name of the node selected as the gateway for this foreign source.
InVid	Displays the VLAN ID of the SPB-PIM Gateway interface through which the source of this source is reachable.
InPort	Displays the physical interface through which the source of this source is reachable.
OwnerType	Displays if the owner is MSDP or static.

SPB-PIM Gateway interface configuration

This section provides procedures to configure the SPB-PIM Gateway interface using the Command Line Interface (CLI) and Enterprise Device Manager (EDM).

The SPB-PIM Gateway interface is either a VLAN or a Brouter port interface. An SPB-PIM Gateway interface is configured separately from the global (switch-wide) Gateway functionality. The global Gateway configuration does not affect the administrative or the operational state of the SPB-PIM Gateway interfaces which function independently. However, the Gateway node functionality works in conjunction with the Gateway Interface functionality. Configure SPB-PIM Gateway on an interface that connects to a router in a foreign PIM or SPB multicast domain.

SPB-PIM Gateway Interface Configuration using the CLI

This section provides procedures to configure SPB-PIM gateway interface using the command line interface (CLI).

Enabling SPB-PIM Gateway on a VLAN

Enable SPB-PIM Gateway on a VLAN interface.

Procedure

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

2. Enable SPB-PIM Gateway on a VLAN:

```
ip spb-pim-gw enable
```

Note

SPB-PIM Gateway cannot be enabled under the following circumstances:

- If the IP interface does not exist on the VLAN. An IP Address must first be configured on the VLAN.
- If the **spbm_config_mode** boot flag is set to false.
- If the VLAN is configured with a circuitless IP.
- If the interface is a management VLAN.
- If **ip igmp snooping** is enabled.
- If the spb-multicast is enabled on the VLAN.
- If the VLAN has SMLT ports.
- If the VLAN has an i-sid configured.
- If the VLAN is a vIST VLAN.

Enabling SPB-PIM Gateway on a brouter port interface

Enable SPB-PIM Gateway on a brouter port.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable SPB-PIM Gateway on a brouter port:

```
ip spb-pim-gw enable
```

Note

SPB-PIM Gateway cannot be enabled under the following circumstances:

- If the IP interface is not configured using the **brouter** command
- If the IP interface does not exist on the brouter port
- If the **spbm_config_mode** boot flag is set to false
- If **ip igmp snooping** is enabled
- If the spb-multicast is enabled on the brouter port
- If the brouter port is part of an SMLT or vIST Vlan
- If the brouter port has an i-sid configured

Configuring the SPB-PIM Gateway VLAN optional parameters

Configure the SPB-PIM Gateway interface parameters on a VLAN.

Procedure

1. Enter VLAN Interface Configuration mode:

```
enable

configure terminal

interface vlan <1-4059>
```
2. Configure the SPB-PIM Gateway VLAN HELLO interval:

```
ip spb-pim-gw hello-interval <0-18724>
```
3. Configure the SPB-PIM Gateway VLAN JOIN PRUNE interval:

```
ip spb-pim-gw ip join-prune-interval <1-18724>
```

Variable definitions

The following table defines parameters for the **ip spb-pim-gw** command.

Variable	Value
<i>hello-interval<0-18724></i>	Specifies the HELLO interval in seconds. The default value is 30 seconds.
<i>join-prune-interval<1-18724></i>	Specifies the JOIN PRUNE interval in seconds. The default value is 60 seconds.

Configuring the SPB-PIM Gateway brouter port optional parameters

Configure the SPB-PIM Gateway interface parameters on a brouter port.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the SPB-PIM Gateway router port HELLO interval:

```
ip spb-pim-gw hello-interval <0-18724>
```

3. Configure the SPB-PIM Gateway router port JOIN PRUNE interval:

```
ip spb-pim-gw join-prune-interval <1-18724>
```

Variable definitions

The following table defines parameters for the **ip spb-pim-gw** command.

Variable	Value
<code>hello-interval<0-18724></code>	Specifies the HELLO interval in seconds. The default value is 30 seconds.
<code>join-prune-interval<1-18724></code>	Specifies the JOIN PRUNE interval in seconds. The default value is 60 seconds.

Displaying the SPB-PIM Gateway interface default values

Use the following procedure to display the default values used for the SPB-PIM Gateway interface HELLO and JOIN PRUNE intervals unless specifically configured on the individual interface.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the SPB-PIM Gateway interface default values:

```
show ip spb-pim-gw
```

Example

```
Switch:1>show ip spb-pim-gw
=====
                               Spb-pim-gw General Group
=====
Hello Interval                  : 30
Join-Prune Interval             : 60
```

Displaying the SPB-PIM Gateway router port information

Use the following procedure to display the SPB-PIM Gateway router port information. This procedure displays the administrative (configured) state of the interface as well as the operational state, and the HELLO and JOIN PRUNE intervals. An interface can be administratively ENABLED but operationally

DISABLED if, for example, mvpn is not enabled on the VRF, or **spbm <spbm-instance> multicast enable** is not configured.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the SPB-PIM Gateway interface information:

```
show ip spb-pim-gw interface [gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

Example

```
Switch:1#show ip spb-pim-gw interface gigabitethernet 1/2

=====
Port Ip Spb-pim-gw
=====
ORT-NUM  OPSTATE      ADMINSTATE  HELLOINT  JPINT
=====
1/2      Disabled     Enabled     30        60
=====
```

Variable definitions

The following table defines parameters for the **show ip spb-pim-gw interface** gigabit command.

Variable	Value
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
vrf WORD<1-16>	Displays SPB-PIM Gateway interface information for a specific VRF.
vrfids WORD<0-512>	Displays SPB-PIM Gateway interface information for a range of VRF IDs. Note: Enter a single VRF ID or multiple VRF IDs separated by ',' or enter a range of VRF IDs 'x-y'.

Displaying the SPB-PIM Gateway VLAN information

Use the following procedure to display the SPB-PIM Gateway VLAN interface information.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the SPB-PIM Gateway VLAN interface information:

```
show ip spb-pim-gw interface [vlan]
```

Example

```
Switch:1>show ip spb-pim-gw interface
=====
===
                               Spb-pim-gw Interface - GlobalRouter
=====
===

IF          ADDR          MASK          JPINT    HELLOINT  OPSTATE  ADMINSTATE
Vlan50     50.1.1.1      255.255.255.0  60      30        Disabled Enabled
Vlan123    123.1.1.1    255.255.255.0  60      30        Disabled Disabled
Vlan142    142.1.1.1    255.255.255.0  60      30        Enabled  Enabled
Vlan400    100.1.1.2    255.255.255.0  60      30        Disabled Disabled

Total spb-pim-gw Interfaces Displayed 4/4
```

Variable definitions

The following table defines parameters for the **show ip spb-pim-gw interface** command.

Variable	Value
vlan-id	The VLAN ID of an interface to display.

Displaying the SPB-PIM Gateway neighbor information

Use the following procedure to display the SPB-PIM Gateway interfaces neighbor information.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the SPB-PIM Gateway neighbor information:

```
show ip spb-pim-gw neighbor [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

Example

```
Switch:1>show ip spb-pim-gw neighbor
=====
                               Spb-pim-gw Neighbor - GlobalRouter
=====
=====
INTERFACE ADDRESS          UPTIME          EXPIRE
Vlan26     26.1.1.10      0 day(s), 00:11:36  0 day(s), 00:01:28

Total SPB-PIM-GW Neighbors Displayed = 1/1
=====
```

Variable definitions

The following table defines parameters for the **show ip spb-pim-gw neighbor** command.

Variable	Value
<code>vrf WORD<1-16></code>	Displays the SPB-PIM Gateway interface neighbor information for a specific VRF name.
<code>vrfids WORD<0-512></code>	Displays the SPB-PIM Gateway interface neighbor information for a range of VRF IDs. Note: Enter a single VRF ID or multiple VRF IDs separated by ',' or enter a range of VRF IDs 'x-y'.

Displaying the SPB-PIM Gateway multicast routes

Use the following procedure to display the SPB-PIM Gateway multicast routes. This procedure displays upstream (toward the foreign source) information and downstream (receiver) information on the SPB-PIM Gateway interfaces. This command does not display the following information:

- Upstream information for streams ingressing on spb-multicast interfaces
- Upstream information for streams ingressing from a remote SPB node
- Receivers in spb-multicast interfaces

Use the **show isis spbm ip-multicast-route** command to display information on all multicast streams and the multicast streams ingress interfaces and egress interfaces.

Use the **show ip spb-pim-gw mroute** command to display information only on SPB-PIM Gateway interfaces.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the SPB-PIM Gateway multicast routes:

```
show ip spb-pim-rw mroute [source {A.B.C.D}] [group {A.B.C.D}] [vrf
WORD<1-16>] [vrfids WORD<0-512>]
```

Example

Note

The **show ip spb-pim-gw mroute** command displays active upstream information and active downstream information per (*,g) and (s,g) per port, which includes *G Join or Prune pending state, SG join or prune pending state, and SG Rpt PRUNE or PRUNE pending state.. There can be upstream information for a specific SG and no downstream, and vice-versa, as the information in the command **show ip spb-pim-gw mroute** reflects only information known on the SPB-PIM Gateway interfaces. For example, there might be downstream receivers on a SPB-PIM Gateway Interface for a particular stream which is ingressing on an spb-multicast interface; thus, the upstream information will not be displayed using this command.

```
Switch:1>show ip spb-pim-gw mroute
=====
```

```

```

Variable definitions

The following table defines parameters for the **show ip spb-pim-gw mroute** command.

Variable	Value
<i>vrf WORD<1-16></i>	Displays the SPB-PIM Gateway mroute information for a specific VRF name.
<i>vrfids WORD<0-512></i>	Displays the SPB-PIM Gateway interface mroute information for a range of VRF IDs. Note: Enter a single VRF ID or multiple VRF IDs separated by ',' or enter a range of VRF IDs 'x-y'.

Variable	Value
<code>group {A.B.C.D}</code>	Displays mroute information specific to a group IP address.
<code>source {A.B.C.D}</code>	Displays mroute information specific to a source IP address.

Display the IP mroute Routes

Use the following procedure to display multicast routes ingressing on either SPB-PIM Gateway interfaces or SPB multicast interfaces.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the multicast routes:

```
show ip mroute mroute
```

Example

Note

The UPSTREAM_NBR field is populated only if the stream was learned across a spb-pim-gw interface, and the upstream neighbor is the PIM neighbor IP address toward the source. The PROT field equals spb-pim-gw when the stream’s source is learned on a VLAN configured for protocol spb-pim-gw. If the stream’s source is learned on a VLAN configured for spb-multicast, the PROT field equals spb.

```
Switch:1>show ip mroute route

=====
Mroute Route - GlobalRouter

```

Variable definitions

The following table defines parameters for the **show ip mroute route** command.

Variable	Value
<code>vrf WORD<1-32></code>	Displays the multicast mroute information for a specific VRF name.
<code>vrfids WORD<0-512></code>	Displays the multicast mroute information for a range of VRF IDs. Note: Enter a single VRF ID or multiple VRF IDs separated by ',' or enter a range of VRF IDs 'x-y'.

SPB-PIM Gateway Interface Configuration using the EDM

This section provides procedures to configure SPB-PIM gateway interface using the EDM.

Enabling SPB-PIM Gateway on a VLAN

Enable SPB-PIM Gateway on a VLAN interface.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANS**.
3. Click the **Advanced** tab.
4. In the row for the VLANs, double click the **SpbPimGatewayMulticast** field, and then select enable from the drop down menu.
5. Click **Apply**.

Enabling SPB-PIM Gateway on a Brouter port interface

Enable SPB-PIM Gateway on a Brouter port.

Procedure

1. In the Device Physical View tab, select the port you need to configure.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Click **IP**.
4. Click the **SPB-PIM-GW** tab.
5. Select the **Enable** check box to enable SPB-PIM Gateway on a Brouter port interface.
6. Click **Apply**.

SPB-PIM-GW field descriptions

Use the data in the following table to use the **SPB-PIM-GW** tab.

Name	Description
Enable	Enables SPB-PIM Gateway on the interface. The default is disabled.
OperState	Displays the current operational state of this SPB-PIM Gateway interface.
Address	Displays the primary IP address of this router on this SPB-PIM Gateway interface.
AddressMask	Displays the primary IP address mask of this router on this SPB-PIM Gateway interface.
HelloInterval	Configures the PIM HELLO transmission interval.
JoinPruneInterval	Configures the PIM JOIN PRUNE transmission interval.

Configuring SPB-PIM Gateway VLAN optional parameters

Configure the SPB-PIM Gateway interface parameters on a VLAN.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANS**.
3. Select a row from the VLAN and click the **IP** tab.
4. Click the **SPB-PIM-GW** tab.
5. In the **HelloInterval** field, type the hello transmission interval.
6. In the **JoinPruneInterval** field, type the join prune transmission interval.
7. Click **Apply**.

SPB-PIM-GW field descriptions

Use the data in the following table to use the **SPB-PIM-GW** tab.

Name	Description
OperState	Displays the current operational state of this SPB-PIM Gateway interface.
Address	Displays the primary IP address of this router on this SPB-PIM Gateway interface.
AddressMask	Displays the primary IP address mask of this router on this SPB-PIM Gateway interface.

Name	Description
HelloInterval	Configures the PIM HELLO transmission interval. This SPB-PIM Gateway VLAN level interval setting overrides the inherited global SPB-PIM Gateway HELLO interval setting. Setting the HELLO Interval to 0 causes the neighbors to never expire its neighborhood with this local SPB-PIM Gateway interface.
JoinPruneInterval	Configures the PIM JOIN PRUNE transmission interval. This SPB-PIM Gateway VLAN level interval setting overrides the inherited global level JOIN PRUNE transmission interval setting.

Configuring the SPB-PIM Gateway optional parameters

Perform this procedure to configure the optional parameters on existing SPB-PIM Gateway interfaces.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **SPB-PIM-GW**.
3. Click the **Interfaces** tab.
4. In the row for the interfaces, double-click the **HelloInterval** box, and then type the hello interval in seconds.
5. In the row for the interfaces, double-click the **JoinPruneInterval** box, and then type the join prune interval in seconds.

Interfaces field descriptions

Use the data in the following table to use the **Interfaces** tab.

Name	Description
IfIndex	Shows the interface index.
OperState	Shows the operational state of the interface.
AddressType	Shows the address type of the interface.
Address	Shows the address assigned to the interface.
AddressMask	Shows the address mask associated with the interface address.
HelloInterval	Configures the PIM HELLO transmission interval. The default is 30 seconds.
JoinPruneInterval	Configures the PIM JOIN PRUNE transmission interval. The default is 60 seconds.

Displaying the SPB-PIM Gateway interface default values

Use the following procedure to display the default values used for the SPB-PIM Gateway interface HELLO and JOIN PRUNE intervals unless specifically configured on the individual interface.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **SPB-PIM-GW**.
3. Click the **Globals** tab.

Globals field descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
HelloInterval	Displays the PIM HELLO transmission interval.
JoinPruneInterval	Displays the PIM JOIN PRUNE transmission interval.

Displaying the SPB-PIM Gateway router port information

Use the following procedure to display the SPB-PIM Gateway interface information.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **SPB-PIM-GW**.
3. Click the **Interfaces** tab.

Interfaces field descriptions

Use the data in the following table to use the **Interfaces** tab.

Name	Description
IfIndex	Displays the VLAN ID.
OperState	Displays the current operational state of this SPB-PIM Gateway interface.
AddressType	Displays the address type of this SPB-PIM Gateway interface.
Address	Displays the primary IP address of this router on this SPB-PIM Gateway interface.
AddressMask	Displays the primary IP address mask of this router on this SPB-PIM Gateway interface.
HelloInterval	Configures the PIM HELLO transmission interval. This SPB-PIM Gateway VLAN level interval setting overrides the inherited global SPB-PIM Gateway HELLO interval setting. Setting the HELLO Interval to 0 causes the neighbors to never expire its neighborhood with this local SPB-PIM Gateway interface.
JoinPruneInterval	Configures the PIM JOIN PRUNE transmission interval. This SPB-PIM Gateway VLAN level interval setting overrides the inherited global level JOIN PRUNE transmission interval setting.

Displaying the SPB-PIM Gateway VLAN information

Use the following procedure to display the SPB-PIM Gateway VLAN information.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANs**.
3. Select a row from the VLAN and click the **IP** tab.
4. Click the **SPB-PIM-GW** tab.

SPB-PIM-GW field descriptions

Use the data in the following table to use the **SPB-PIM-GW** tab.

Name	Description
OperState	Displays the current operational state of this SPB-PIM Gateway interface.
Address	Displays the primary IP address of this router on this SPB-PIM Gateway interface.
AddressMask	Displays the primary IP address mask of this router on this SPB-PIM Gateway interface.
HelloInterval	Configures the PIM HELLO transmission interval. This SPB-PIM Gateway VLAN level interval setting overrides the inherited global SPB-PIM Gateway HELLO interval setting. Setting the HELLO Interval to 0 causes the neighbors to never expire its neighborship with this local SPB-PIM Gateway interface.
JoinPruneInterval	Configures the PIM JOIN PRUNE transmission interval. This SPB-PIM Gateway VLAN level interval setting overrides the inherited global level JOIN PRUNE transmission interval setting.

*Displaying the SPB-PIM Gateway neighbor information***About This Task**

Use the following procedure to display the SPB-PIM Gateway neighbor information

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **SPB-PIM-GW**.
3. Click the **Neighbors** tab.

Neighbors field descriptions

Use the data in the following table to use the **Neighbors** tab.

Name	Description
IfIndex	Specifies the IfIndex for the interface which is used to reach this SPB-PIM Gateway neighbor.
AddressType	Specifies the address type of this SPB-PIM Gateway neighbor.
Address	Specifies the primary IP address of this router on this SPB-PIM Gateway neighbor.
UpTime	Specifies the time since this SPB-PIM Gateway neighbor last became a neighbor of the local router.
ExpiryTime	Specifies the minimum time remaining before this SPB-PIM Gateway neighbor times out.

Displaying the IP mroute routes

Use the following procedure to display multicast routes ingressing on either SPB-PIM Gateway interfaces or SPB multicast interfaces.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **Multicast**.
3. Click the **Routes** tab.

Routes field descriptions

Use the data in the following table to use the **Routes** tab.

Name	Description
Group	Displays the IP multicast group address for this entry that contains multicast routing information.
Source	Displays the network address that, when combined with the corresponding route SourceMask value, identifies the source that contains multicast routing information.
SourceMask	Displays the network mask that, when combined with the corresponding route Source value, identifies the multicast source.
UpstreamNeighbor	Shows the address of the upstream neighbor from which the IP datagrams from these sources are received. The address is 0.0.0.0 if the network is local.
Interface	Displays the interface, slot and portnumber, or VLAN ID where IP datagrams sent by these multicast sources to this multicast address are received.

Name	Description
ExpiryTime	Displays the amount of time that remains before this entry ages out. The value 0 indicates that the entry is not subject to aging.
Protocol	Displays the protocol as one of the following: <ul style="list-style-type: none"> • other(1): none of the following • local(2): manually configured • netmgmt(3): configured by a network management protocol • pimSparseMode(8): PIM-SMv2 • igmpOnly(10) • pimSsmMode(11) • spb (12) • spbpimgw(13)

SPB-PIM Gateway Interface Deployment Scenarios

This section provides information about different deployment scenarios for SPB-PIM gateway interface.

SPB-PIM Gateway Base Case Deployment Scenario

There are several different customer topology scenarios for the SPB-PIM Gateway (SPB-PIM GW) feature deployment . One of these scenarios, shown in [Figure 5](#), is fully described here, along with configuration details, and display information.

The deployment scenario described here has two domains:

- SPB domain
- PIM domain

The PIM network has 5 PIM routers:

- RP
- PIM-A1
- PIM-A2
- PIM-B
- PIM-C

The RP router is the PIM-SM rendezvous point. PIM router PIM-B has receiver host R2 attached to it and source S1 is connected to PIM router PIM-C.

The SPB domain has the following components:

- SPB-PIM Gateway Controller node
- Two Gateway nodes, BEB-A1 and BEB-A2
- BEB-A1 is connected to the PIM network through a SPB-PIM Gateway interface to the PIM router PIM-A1

- BEB-A2 is connected to the PIM network through a SPB-PIM Gateway interface to the PIM router PIM-A2

Note

PIM-A1 and PIM-A2 routers attached to the BEBs SPB-PIM Gateway interface have standard PIM configured on their side of the interface.

- The SPB cloud has a BEB-B to which the source S2 is connected
- The SPB cloud has a BEB-C to which a receiver R1 is connected

Note

You can place the controller anywhere in the SPB cloud. The controller can be in the boundary or the core. Anywhere there is a connection into the PIM network from the SPB network, there must be a Gateway node(s) and Gateway interface(s).

Figure 226: SPB-PIM Gateway base case configuration

The SPB-PIM Gateway nodes BEB-A1 and BEB-A2 from the SPB cloud are connected to the PIM network. The connection is established by SPB-PIM Gateway interface connections to PIM routers PIM-A1 and PIM-A2. A MSDP connection is established between the RP from the PIM domain and the SPB-PIM Gateway Controller from the SPB domain. A MSDP connection is established to exchange the multicast source information between the RP and the SPB Controller. Unicast routing or reachability is setup before establishing the MSDP connection between the RP and the Gateway controller. The Unicast setup is not shown in the above figure.

SPB-PIM Gateway base case configuration example

Before You Begin

- The Shortest Path Bridging (SPB) infrastructure must be configured and setup in the SPB domain (not shown in this example)
- Protocol Independent Multicast (PIM) infrastructure must be configured and setup in the PIM domain (not shown in this example)
- Unicast routing table must be setup in the PIM domain to ensure reachability of the Multicast Source Discovery Protocol (MSDP) peer and source S2 from the SPB network
- Unicast routing table must be setup in the SPB domain to ensure reachability of the MSDP peer and source S1 from the PIM network

Example

Node: Gateway controller

Configure ISIS and SPBM:

```
Switch:1#configure terminal
Switch:1(config)#spbm
Switch:1(config)#router isis
Switch:1(config-isis)#system-id 0026.0026.0026
Switch:1(config-isis)#manual-area 01.0202.0303.04
Switch:1(config-isis)#spbm 1
Switch:1(config-isis)#spbm 1 nick-name 0.00.26
Switch:1(config-isis)#spbm 1 b-vid 10,20 primary 10
Switch:1(config-isis)#vlan create 10 name bvlan1 type spbm-bvlan
Switch:1(config)#vlan create 20 name bvlan2 type spbm-bvlan
Switch:1(config)#router isis enable
```

NNI Configuration:

```
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config-if)#isis
Switch:1(config-if)#isis spbm 1
Switch:1(config-if)#isis enable
Switch:1(config-if)#no shutdown
```

- Enable IPSC to setup Unicast route table. This setup ensures reachability of Rendezvous Point (RP) in the PIM network
- Create a loopback interface 2.0.2.2 to enable IPSC and MSDP originator-id
- Enable Multicast over Fabric Connect
- Configure static route and direct route redistribution
- Apply the static route and direct route redistribution

Note

Static route is used to reach RP for the below sample configuration.

```
Switch:1(config)#interface loopback 1
Switch:1(config-if)#ip address 2.0.2.2/32
Switch:1(config)#router isis
Switch:1(config-isis)#ip-source-address 2.0.2.2
Switch:1(config-isis)#spbm 1 ip enable
Switch:1(config-isis)#spbm 1 multicast enable
Switch:1(config-isis)#
Switch:1(config-isis)#redistribute static
Switch:1(config-isis)#redistribute static enable
Switch:1(config-isis)#redistribute direct
Switch:1(config-isis)#redistribute direct enable
```

```
Switch:1(config-isis)#
Switch:1(config-isis)#end
Switch:1#isis apply redistribute static
Switch:1#isis apply redistribute direct
```

MSDP Configuration:

Create an instance for the MSDP session. This IP interface is used for establishing an MSDP session with an RP in the PIM network. The source IP address used for the MSDP session must not be the newly created IP interface. The originator-id specifically configured for MSDP is used as the source IP address to establish the MSDP session. The originator-id is also used by the RP in the source active (SA) messages sent to the MSDP peers. The CLIP configured earlier is used as the originator-id.

```
Switch:1#configure terminal
Switch:1(config)#vlan create 2100 type port-mstprstp 0
Switch:1(config)#vlan members add 2100 1/3 portmember
Switch:1(config)#interface vlan 2100
Switch:1(config-if)#ip address 21.0.0.1/24
Switch:1(config-if)#exit

Switch:1(config)#ip msdp originator-id 2.0.2.2
Switch:1(config)#ip msdp enable
Switch:1(config)#ip msdp peer 21.0.0.2
Switch:1(config)#ip msdp peer 21.0.0.2 enable
```

SPB-PIM Gateway Controller configuration:

Enable SPB-PIM Gateway Controller

```
Switch:1(config)#router isis
Switch:1(config-isis)#spbm 1 multicast spb-pim-gw controller enable
```

Node: BEB-A1 (SPB-PIM Gateway)

Configure ISIS and SPBM:

```
Switch:1#configure terminal
Switch:1(config)#spbm
Switch:1(config)#
Switch:1(config)#router isis
Switch:1(config-isis)#system-id 0015.0015.0015
Switch:1(config-isis)#manual-area 01.0202.0303.04
Switch:1(config-isis)#spbm 1
Switch:1(config-isis)#spbm 1 nick-name 0.00.15
Switch:1(config-isis)#spbm 1 b-vid 10,20 primary 10
Switch:1(config-isis)#
Switch:1(config-isis)#vlan create 10 name bvlan1 type spbm-bvlan
Switch:1(config)#vlan create 20 name bvlan2 type spbm-bvlan
Switch:1(config)#router isis enable
```

NNI Configuration:

```
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config-if)#isis
Switch:1(config-if)#isis spbm 1
```

```
Switch:1(config-if)#isis enable
Switch:1(config-if)#no shutdown
```

- Enable IP Shortcuts (IPSC) to setup Unicast route table. This setup ensures reachability of sources in the PIM network
- Create a loopback interface 1.0.1.1 to enable IPSC
- Enable Multicast over Fabric Connect
- Configure static route and direct route redistribution
- Apply the static route and direct route redistribution

Note

Static route is used to reach sources in the PIM network for the below sample configuration.

```
Switch:1(config)#interface loopback 1
Switch:1(config-if)#ip address 1.0.1.1/32
Switch:1(config-if)#router isis
Switch:1(config-isis)#ip-source-address 1.0.1.1
Switch:1(config-isis)#spbm 1 ip enable
Switch:1(config-isis)#spbm 1 multicast enable
Switch:1(config-isis)#
Switch:1(config-if)#router isis
Switch:1(config-isis)#redistribute static
Switch:1(config-isis)#redistribute static enable
Switch:1(config-isis)#redistribute direct
Switch:1(config-isis)#redistribute direct enable
Switch:1(config-isis)#
Switch:1(config-isis)#end
Switch:1#isis apply redistribute static
Switch:1#isis apply redistribute direct
```

SPB-PIM Gateway interface configuration:

- Create an IP interface
- Enable SPB-PIM Gateway on the IP interface

Note

For the sample configuration below, the SPB-PIM Gateway interface is on VLAN 2000 with IP address 20.0.0.1

```
Switch:1#configure terminal
Switch:1(config)#vlan create 2000 type port-mstprstp 0
Switch:1(config)#vlan members add 2000 1/1 portmember
Switch:1(config)#interface vlan 2000
Switch:1(config-if)#ip address 20.0.0.1/24
Switch:1(config-if)#ip spb-pim-gw enable
```

Enable SPB-PIM Gateway node functionality:

```
Switch:1(config-if)#router isis
Switch:1(config-isis)#spbm 1 multicast spb-pim-gw gateway enable
```

Similar configuration is done for the SPB-PIM Gateway node BEB-A2.

PIM Sparse Mode (PIM-SM) is enabled at the PIM routers PIM-A1 and PIM-A2 on the interfaces connecting SPB-PIM Gateway nodes BEB-A1 and BEB-A2. The SPB-PIM Gateway nodes BEB-A1 and BEB-A2 see the PIM routers PIM-A1 and PIM-A2 as PIM neighbors. The PIM routers PIM-A1 and PIM-A2 see the SPB-PIM Gateway nodes as PIM neighbors. The SPB-PIM Gateway nodes BEB-A1 and BEB-A2 have IP reachability to the PIM source S1 with PIM neighbors as the next hop.

The route to reach source S1 is distributed to the Gateway controller through IPSC. The Gateway controller uses this route information to select only one of the Gateways to which the source S1 will be assigned for a specific group. The Gateway node is the only node that can draw the source S1 stream into the SPB network on behalf of SPB receivers, by sending an SG Join across a Gateway Interface to the nexthop toward the source S1. This ensures that the data is not duplicated from multiple ingress interfaces from the PIM network. Other Gateway nodes that are not assigned as the Gateway to the source S1 will not establish multicast path.

When S1 from the PIM network sends traffic to G1, RP from the PIM network sends MSDP SA message for (S1,G1) to the Gateway Controller. If the Gateway Controller selects BEB-A1 as the Gateway for the foreign source S1 and group G1, the Gateway Controller assigns BEB-A1 to (S1,G1). The Gateway Controller then sends the Gateway assignment information to all the nodes. When BEB-A1 receives the assignment information, it sees that it is assigned as the Gateway to (S1,G1). The BEB-A1 then checks if the next hop to reach S1 is a valid PIM neighbor. If the next hop is a valid PIM neighbor, the BEB-A1 interacts with Multicast over Fabric Connect and advertises a sender TLV for the (S1,G1) into the SPB cloud. The BEB-A2 also receives the Gateway assignment information but silently saves the received Gateway assignment information since it is not the selected Gateway. If the interested receiver R1 is found at BEB-C, as part of Multicast over Fabric Connect processing, BEB-C sends receiver TLV for the group G1 to the advertising node, BEB-A1. Upon receiving this receiver TLV, BEB-A1 establishes the multicast stream through its Gateway interface which is upstream towards the PIM neighbor, by sending out a PIM SG Join message toward the source S1. This causes PIM-A1 node to forward multicast data from S1 to BEB-A1.

When the local source S2 (local to the SPB network) at BEB-B in the SPB network sends traffic to group G1, BEB-B advertises a sender TLV for (S1,G1). The controller sees this sender TLV and sends an MSDP SA message for (S2,G1) to the RP in the PIM network.

**Note**

The controller does not send SA messages for (S1,G1) to the PIM network since S1 is a foreign source.

When PIM network receiver R2 is interested in group G1, the PIM router PIM-B sends PIM a (*,G) Join message to the RP. RP in turn sends (S2,G1) Join towards the source S2. The unicast IP reachability to source S2 which is setup in the RP is used for sending (S2,G1) joins hop-by-hop towards the source. From the RP point of view, the next hop to reach the source S2 is one of the PIM routers PIM-A1 or PIM-A2 (depending on the unicast route table next hop address). For this example, the next hop is PIM-A1. The RP sends the (S2,G1) Join message towards the PIM-A1. PIM-A1 then sends an SG Join to BEB-A1. Upon receiving the Join for (S2,G1) from the PIM network, BEB-A1 sends a receiver TLV into the SPB network to the S2 advertising router BEB-B. When the BEB-B receives the receiver TLV, the BEB-B establishes the multicast stream from source S2 toward the receiver.

Source Specific Multicast

PIM-SSM does not use a Rendezvous Point to centralize the receivers and sources. A PIM-SSM router which has a receiver for a group multicast address in the SSM address range joins directly to a source for that group by sending an SG join toward the source, not a *G join toward the RP for the group. Because of this, MSDP is not required in order for the PIM Network to learn of an SSM range stream in the SPB network. However, in order for the SPB network to know where a PIM SSM source resides, it must statically configure S1,SSM-G1 at the controllers. In this way, a Gateway can be chosen for the stream, even in the absence of MSDP.

The following figure shows a non-MSDP SSM environment where stream PIM network source S1, for an SSM group, must be statically configured at the SPB Controllers:

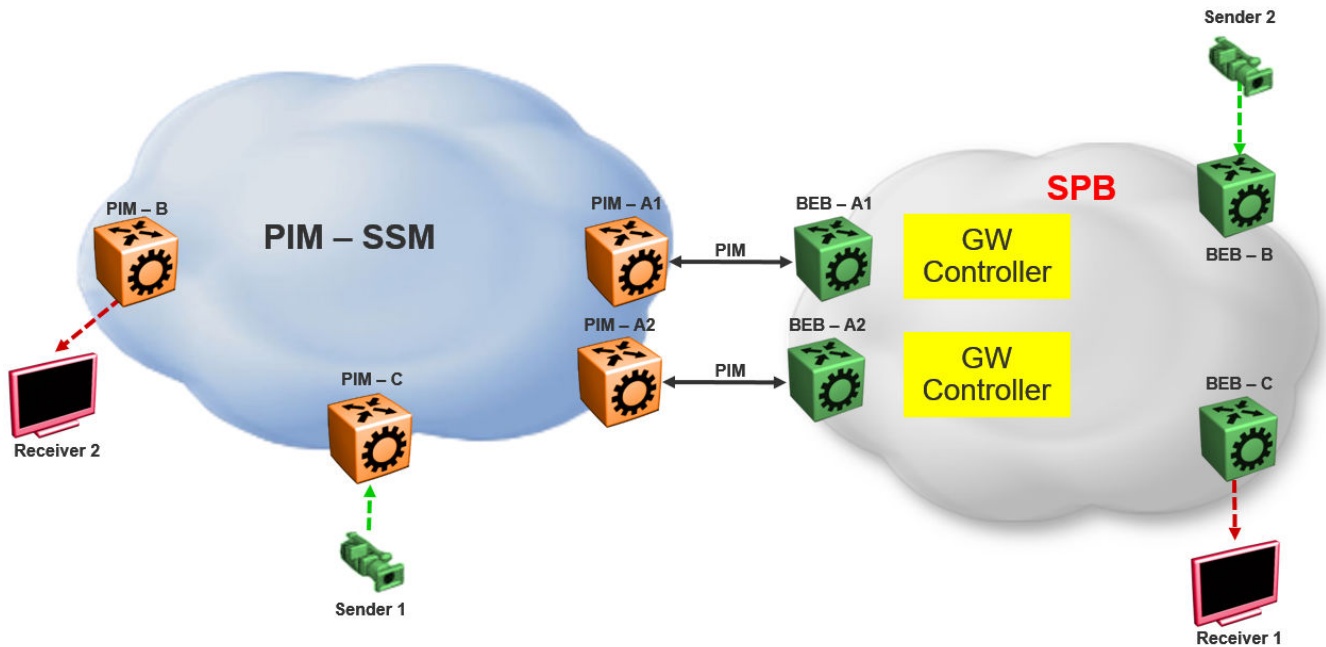

Figure 227: Static configuration of SSM groups in Controllers

Peer Mesh Group

The following figure shows the Peer Mesh Group configuration:

Note

Controllers within a single SPB network must never peer with each other, regardless of whether mesh groups exist. In addition, both Controllers must have the same peerings configured with other networks RPs.

Figure 228: Peer Mesh Group

MSDP Peer Mesh Group configuration example

Example

Configure MSDP:

If the MSDP speakers are fully meshed, the speakers can be configured into a mesh group in order to prevent excessive SA forwarding and RPF checks. To configure a mesh group, specify a name along with the MSDP peer. For example, on router RP1, configure a mesh group which includes RP2, RP3, and both Gateway controllers. On RP2, configure the same mesh group with members RP1, RP3, and both Gateway controllers. On RP3, configure the same mesh group with members RP1, RP2, and both Gateway controllers. On each Gateway controller, configure the same mesh group with members RP1, RP2, and RP3, but never with another Gateway controller in the same SPB domain.

```
Switch:1(config)#ip msdp originator-id 2.0.2.2
Switch:1(config)#ip msdp enable
Switch:1(config)#ip msdp peer 21.0.0.2 enable
Switch:1(config)#ip msdp mesh-group mgTest 21.0.0.2
```

Multi domain

The following figure shows a multi domain scenario, where two PIM domains and one SPB domain share multicast streams:

Figure 229: Multi domain configuration

SPB domain interconnect

The following figure shows the SPB domain interconnect configuration. In this scenario, two SPB domains are connected by PIM Gateway interfaces, and there is no traditional PIM Network involved. The Controllers from each SPB domain form MSDP adjacencies with the Controllers in the other domain (but not within the same domain) in order to share their multicast sources. The SPB-PIM Gateway nodes see the other SPB-PIM Gateway nodes as PIM neighbors on the SPB-PIM Gateway interfaces.

Figure 230: SPB domain interconnect

System Access

[System access fundamentals](#) on page 2881

[System access configuration using CLI](#) on page 2892

[System access configuration using EDM](#) on page 2917

The following sections describe how to access the switch, create users, and user passwords.

System access fundamentals

This section contains conceptual information about how to access the switch and create users and user passwords for access.

Logging On to the System

After the startup sequence is complete, the system opens the login prompt.

Note

With enhanced secure mode enabled, the person in the role-based authentication level of administrator configures the login and password values for the other role-based authentication levels. The administrator initially logs on to the switch using the default login of `admin` and the default password of `admin`. After the initial login, the switch prompts the administrator to create a new password.

The administrator then configures default logins and passwords for the other users based on the role-based authentication levels of the user. For more information on enhanced secure mode, see [System access security enhancements](#) on page 2904.

The following table shows the default values for login and password for the console and Telnet sessions.

Table 211: Access levels and default logon values

Access level	Description	Default logon	Default password
Read-only	Permits view only configuration and status information. This access level is equivalent to Simple Network Management Protocol (SNMP) read-only community access.	ro	ro
Layer 1 read-write	View most switch configuration and status information and change physical port settings.	l1	l1

Table 211: Access levels and default logon values (continued)

Access level	Description	Default logon	Default password
Layer 2 read-write	View and change configuration and status information for Layer 2 (bridging and switching) functions.	l2	l2
Layer 3 read-write	View and change configuration and status information for Layer 2 and Layer 3 (routing) functions.	l3	l3
Read-write	View and change configuration and status information across the switch. Read-write access does not allow you to change security and password settings. This access level is equivalent to SNMP read-write community access.	rw	rw
Read-write-all	Permits all the rights of read-write access and the ability to change security settings. This access level allows you to change the command line interface (CLI) and web-based management user names and passwords and the SNMP community strings.	rwa	rwa

You can enable or disable users with particular access levels, eliminating the need to maintain large numbers of access levels and passwords for each user.

The system denies access to a user with a disabled access level who attempts to log on. The system displays the following error message after a user attempts to log on with a blocked access level:

```
CPU1 [mm/dd/yy hh:mm:ss] 0x0019bfff GlobalRouter CLI WARNING Slot 1: Blocked unauthorized cli access
```

The system logs the following message to the log file:

```
User <user-name> tried to connect with blocked access level <access-level> from <src-ipaddress> via <login type>.
```

The system logs the following message for the console port:

```
User <user-name> tried to connect with blocked access level <access-level> from console port.
```

RADIUS authentication

Remote Authentication Dial-in User Service (RADIUS) authentication takes precedence over the local configuration. If you enable RADIUS authentication on the switch, the user can access the switch even if you block an access level on the switch.

Important

When you enable RADIUS on the switch and configure a RADIUS server to be used by CLI or EDM, the server authenticates the connection, whether it is FTP, HTTPS, SSH, or TELNET. However, in the event that the RADIUS server is unresponsive or is unreachable, the switch will fall back to the local authentication, so that you can access the switch using your local login credentials.

If you disable an access level, all running sessions, except FTP sessions, with that access level to the switch terminate.

Important

Only the RWA user can disable an access level on the switch. You cannot disable the RWA access level on the switch.

The system preserves these configurations across restarts.

hsecure mode boot configuration flag

The switch supports a configurable flag called high secure (hsecure). Use the hsecure flag to enable the following password features:

- 10 character enforcement
- aging time
- limitation of failed login attempts
- protection mechanism to filter designated IP addresses

If you activate the **hsecure** flag, the software enforces the 10-character rule for all passwords. The password must contain a minimum of two uppercase characters, two lowercase characters, two numbers, and two special characters.

If you enable hsecure for the first time and the password file does not exist, then the device creates a normal default username (rwa) and password (rwa). In this case, the password does not meet the minimum requirements for hsecure and as a result the system prompts you to change the password.

For more information about the hsecure flag, see [hsecure Mode](#) on page 2582.

Enhanced secure mode

If you enable enhanced secure mode, the system uses different authentication levels. Enhanced secure mode allows the system to:

- Provide role-based access levels
- Stronger password requirements
- Stronger rules on password length
- Stronger rules on password complexity
- Stronger rules on password change intervals

- Stronger rules on password reuse
- Stronger password maximum age use

For more information on enhanced secure mode, see [System access security enhancements](#) on page 2904.

Default Web-Server Behavior

The default switch configuration enforces the following restrictions for web-server access:

- The web-server password must be a minimum of 8 characters.
- Secure communications with the web server use Transport Layer Security (TLS) version 1.2 and above.
- The switch does not support the RC4 cipher. The switch supports the following ciphers:
 - TLS_RSA_WITH_AES_128_CBC_SHA
 - TLS_RSA_WITH_AES_256_CBC_SHA
 - TLS_RSA_WITH_AES_128_CBC_SHA256
 - TLS_RSA_WITH_AES_256_CBC_SHA256

For information about how to enable and configure the web server, see [Configure the Web Server](#) on page 218 or [Configure the Web Management Interface](#) on page 233. For information about supported browser versions, see [Supported Browsers](#) on page 225.

Managing the System using Different VRF Contexts

You can use the Enterprise Device Manager (EDM) to manage the system using different Virtual Router Forwarding (VRF) contexts.

- Using the GlobalRouter (VRF 0), you can manage the entire system. GlobalRouter is the default view at log in
- Using a VRF context other than the GlobalRouter (VRF 0), you have limited functionality to manage the system. For instance you can only manage the ports assigned to the specified VRF instance

Specify the VRF instance name on the EDM screen when you launch a VRF context view. You can use the context names (SNMPv3) and community strings (SNMPv1/v2) to assign different VRFs to manage selected components, such as ports and VLANs. For more information about context names and community strings, see [Simple Network Management Protocol \(SNMP\)](#) on page 2676.

CLI Passwords

The switch ships with default passwords configured for access to CLI through a console or Telnet session. If you possess read-write-all access authority, and you use SNMPv3, then you can change passwords in encrypted format. If you use Enterprise Device Manager (EDM), then you can also specify the number of allowed Telnet sessions.

Important

Be aware that the default passwords and community strings are documented and well known. Change the default passwords and community strings immediately after the first logon.

For security, if you fail to log on correctly in three consecutive instances, then the device locks for 60 seconds.

The switch stores passwords in encrypted format and not in the configuration file.

Subscriber or administrative interaction

As a network administrator, you can configure the RADIUS server for user authentication to override user access to commands. You must still provide access based on the existing access levels in the switch, but you can customize user access by allowing and denying specific commands.

You must configure the following three returnable attributes for each user:

- Access priority (single instance)—the access levels currently available on the switch (ro, l1, l2, l3, rw, rwa)
- Command access (single instance)—indicates whether the user has access to the commands on the RADIUS server
- CLI commands (multiple instances)—the list of commands that the user can or cannot use

Access Policies for Services

You can control access to the switch by creating an access policy. An access policy specifies the hosts or networks that can access the switch through various services, such as Telnet, Simple Network Management Protocol (SNMP), Hypertext Transfer Protocol (HTTP), and Secure Shell version 2 (SSHv2). You can enable or disable access services by configuring flags.

Use access policies for in-band management to secure access to the switch. When configuring an access policy, a lower precedence takes higher priority if you use multiple policies. For example, preference 120 has priority over preference 128.

You can define network stations that can access the switch or stations that cannot access the switch. For each service you can also specify the level of access, such as read-only or read-write-all.

When you configure access policies, you can perform either of the following actions:

- Globally enable the access policy feature, and then create and enable individual policies. Each policy takes effect immediately after you enable it.
- Create and enable individual access policies, and then globally enable the access policy feature to activate all the policies at the same time.

HTTP and SSH support IPv4 and IPv6 with no difference in configuration or functionality.

Web interface passwords

The switch includes a web-management interface, Enterprise Device Manager (EDM), that you can use to monitor and manage the device through a supported web browser from anywhere on the network. For more information on supported web browsers, see [Supported Browsers](#) on page 225.

A security mechanism protects EDM and requires you to log on to the device using a user name and password. The default user name is `admin` and the default password is `password`.

Important

For security reasons, EDM is disabled by default.

By default, the minimum password length for the web server is 8 characters but you can override this value. For more information about how to enable and configure the web server, see [Configure the Web Server](#) on page 218 or [Configure the Web Management Interface](#) on page 233.

Password encryption

The switch handles password encryption in the following manner:

- After the device starts, the system restores the web-server passwords and community strings from the hidden file.
- After you modify the web-server username and password or SNMP community strings, the system makes the modifications to the hidden file.

Multiple CLI Users for Each Role

Table 212: Multiple CLI Users product support

Feature	Product	Release introduced
Multiple CLI users per role	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5

You can create up to a maximum of 10 CLI users for each role, which includes:

- 3 default users (`rwa`, `rw`, and `ro`)—User Type = `default`
- 7 user defined users (`rwa` or `rw` or `ro`)—User Type = `userDefined`

Username for default users (`rwa`, `rw`, and `ro`) can be changed; however, usernames for user defined users cannot be changed.

Users require a username and password to connect to the switch. Users can log on through the local serial port, Telnet, SSH, or ftp. When a user is created, authentication is enabled, by default.

For security reasons, if a login attempt fails, the error feedback does not indicate if the failed login is due to an invalid user name or an invalid password. Response times for invalid user name and invalid user name/password pair are identical to prevent identification of which of the two failed.

Note

Multiple CLI users for each role does not apply in enhanced secure mode.

Enhanced Secure Mode

Table 213: Enhanced Secure Mode product support

Feature	Product	Release introduced
Enhanced Secure mode	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
Enhanced Secure mode for JITC and non-JITC sub-modes.	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
Enhanced Secure mode - sensitive file protection	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.5
	5520 Series	VOSS 8.5

Authentication Levels

After you enable enhanced secure mode with the **boot config flags enhancedsecure-mode** command, the switch supports role-based authentication levels. With enhanced secure mode enabled, the switch supports the following authentication access levels for local authentication, Remote Authentication Dial-In User Service (RADIUS), and Terminal Access Controller Access Control System Plus (TACACS+) authentication:

- Administrator
- Privilege
- Operator
- Auditor
- Security

Each username is associated with a certain role in the product and appropriate authorization rights for viewing and executing commands are available for that role.

With enhanced secure mode enabled, the person in the role-based authentication level of administrator configures the login and password values for the other role-based authentication levels. The administrator access level cannot be disabled on VOSS switches.

The administrator initially logs on to the switch using the default login of `admin` and the default password of `admin`. After the initial login, the switch prompts the administrator to create a new password.

The following displays an example of the initial login to the switch by the administrator after enhanced secure mode is enabled.

```

Login: admin
Password: ****
      This is an initial attempt using the default user name and password.
      Please change the user name and password to continue.
Enter the new name : rwa
Enter the New password : *****
Re-enter the New password : *****

```

```

Password changed successfully
Last Successful Login:Wed Oct 14 12:20:42 2015
Unsuccessful Login attempts from last login is: 0

```

The administrator then configures default logins and passwords for the other users based on the role-based authentication levels of the user.

Access Level and Login Details

Access level	Description	Login location
Administrator	The administrator access level permits all read-write access, and can change security settings. The administrator access level can configure CLI and web-based management user names, passwords, and the SNMP community strings. The administrator access level can also view audit logs.	SSH/Telnet (in band/mgmt)/ console
Privilege	The privilege access level has the same access permission as the administrator; however, the privilege access level cannot use RADIUS or TACACS+ authentication.	SSH/Telnet(in band/mgmt)/ console/
Operator	The operator access level can view most switch configurations and status information. The operator access level can change physical port settings at layer 2 and layer 3. The operator access level cannot access audit logs or security settings.	SSH/Telnet(in band/mgmt)/ console/
Auditor	The auditor access level can view configuration information, status information, and audit logs.	SSH/Telnet(in band/mgmt)/ console/
Security	The security access level can change security settings only. The security access level also has permission to view configuration and status information.	SSH/Telnet(in band/mgmt)/ console/

Password Requirements

After you enable enhanced secure mode on the switch, the password requirements are stronger. The individual in the administrator access level role configures and provides a temporary user name and password. After you log in for the first time with the temporary user name and temporary password, the system forces you to change the temporary password. After you change the temporary password, you cannot use the password again in subsequent sessions.

The following topics discuss the enhanced password requirements.

Password Complexity Rule

After you enable enhanced secure mode, the system checks each password change request to ensure the new password meets the password complexity required.

The default for the password complexity rule includes the following:

- Two uppercase characters, from the range: ABCDEFGHIJKLMNOPQRSTUVWXYZ
- Two lowercase characters, from the range: abcdefghijklmnopqrstuvwxyz
- Two numeric characters, from the range: 1234567890
- Two special characters, from the range: `~!@#\$%^&*()_+={[]|\:;'"<>.,?/

Password Length Rule

The system enforces a minimum password length of 15 characters after you enable enhanced secure mode.

If the password is not long enough, the system displays the following message:

```
Password change aborted. The new password does not meet the minimum complexity requirement. Please select another password that meets the change interval, length, complexity, no consecutive repeating characters or history requirements of the domain.
```

Password Change Interval Rule

The system enforces a minimum password change interval, which defines the minimum amount of time before you can change to a new password. By default, the minimum change interval is 24 hours between changing from one password to a new password. When you attempt to change your password, the system checks the timestamp for your password to determine if enough time has passed to enable you to change the password.

If you attempt to change the password and not enough time has passed, the system rejects the request, and the system informs you that the password was recently changed. Any password change outside of the enforced interval requires the Administrator to approve the change.

If you try to change the password before the change interval allows, the system displays the following message:

```
Password change aborted. The new password does not meet the minimum complexity requirement. Please select another password that meets the change interval, length, complexity, no consecutive repeating characters or history requirements of the domain.
```

Minimum Password Change

The system enforces a minimum password change requirement, which defines that 8 characters must differ within the same position from the old password.

If the new password does not have at least 8 characters changed within the same position from the old password, the system rejects the password and displays the following message:

```
The password change failed, less than eight characters were changed.
```

Password Reuse Rule

After you enable enhanced secure mode, the administrator access level can define the number of old passwords that cannot be reused. The password reuse rule ensures that recently used passwords are not reused immediately, which reduces the risk of someone unlawfully gaining access to the system. The default number of prohibited recently used passwords is 3, but you can define up to 99.

The system saves the password history and stores the history in an encrypted format, along with the user name and date of change. If a particular user attempts to change a password, the system checks the new password against the stored passwords the user has previously used. If the password is on the list of previously used passwords, the system rejects the password change, and displays the following message:

Old password not allowed.

Password Maximum Age Rule

The system enforces automatic password renewal and password lockout after the expiration period because long-term usage of the same password can cause the system to be vulnerable to hacking.

You can configure the password expiration period to a range of 1 to 365 days. The default password expiration period is 90 days.

Password Max-Session

The password max-sessions value indicates the maximum number of times a particular type of role-based user can log in to the switch through the SSH session at the same time. The max-sessions value applies only for SSH sessions, and only with enhanced secure mode enabled.

After the maximum session number is reached that particular type of user cannot login. For example, if the max-sessions for an auditor user is configured as 5, then the auditor user can log in to only five SSH sessions at the same time. The default is 3.

Password Pre-Notification Interval and Post-Notification Interval Rule

After enhanced secure mode is enabled, the switch enforces password expiry. To ensure a user does not lose access, the switch offers pre- and post-notification messages explaining when the password will expire.

The administrator can define pre- and post-notification intervals to between one to 99 days.

The system maintains the password with a time stamp for when the password expiration. When you log in, the system checks the password time stamp and the notification timer values. If the administrator configures the pre-notification to 30 days, when you log in, the system checks the time stamp and notification timer values, and if the password expiry is due in 30 days, the system displays the first notification.

The pre-notification intervals provide messages to warn users that their passwords will expire within a particular timeframe:

- interval 1—By default, interval 1 is 30 days.
- interval 2—By default, interval 2 is 7 days.
- interval 3—By default, interval 3 is 1 day.

The post-notification intervals provide notification to users that their passwords have expired within a particular timeframe:

- interval 1—By default, interval 1 is 1 day.
- interval 2—By default, interval 2 is 7 days.
- interval 3—By default, interval 3 is 30 days.

If you do not change the password before the expiry date, the system locks your account. When your account is locked, only the administrator can unlock the account. The administrator creates a temporary password, and then you can login with the temporary password. If the administrator password expires and the configured notification interval lapses, access to SSH/Telnet/FTP connections is denied. The administrator must connect to the console port using a serial connection to change the password.

Sensitive File Protection

For certain switches in enhanced secure mode, sensitive files and paths are protected. The home directory for enhanced secure mode is `/intflash/shared`. You cannot access sensitive files using Telnet, SSH, FTP, SFTP, TFTP, and SCP connections. You cannot access sensitive files using CLI commands. Files transferred on the switch through the default path are saved in `/intflash/shared`.

The following sensitive files and paths are protected in enhanced secure mode:

- `/intflash/.cert`
- `/intflash/.ike_psk.txt`
- `/intflash/ospf_key.txt`
- `/intflash/ospf_vrfif_key.txt`
- `/intflash/ospf_vrfvif_key.txt`
- `/intflash/ospf_vrfif_md5key.txt`
- `/intflash/ospf_vrfvif_md5key.txt`
- `/intflash/.ospf_md5key.txt`
- `/intflash/.isis_md5key.txt`
- `/intflash/.isis_sha2key.txt`
- `/intflash/.isis_simplekey.txt`
- `/intflash/.shadovfedmoc.txt`
- `/intflash/snmp_usm_moc.txt`
- `/intflash/snmp_usm_moc_fed.txt`
- `/intflash/snmp_comm_moc.txt`
- `/intflash/snmp_comm_moc_fed.txt`
- `/intflash/.radsec/profile`
- `/intflash/.ssh/ssh_rsa.key`
- `/intflash/.ssh/ssh_dss.key`
- `/intflash/.ssh/moc_sshc_rsa_file`
- `/intflash/.ssh/moc_sshc_dsa_file`
- `/intflash/.ssh/id_dsa_*`
- `/intflash/.ssh/id_rsa_*`
- `/intflash/server.pem`
- `/intflash/app/server.pem`
- `/intflash/app/restweb/certs/privkey.pem`
- `/intflash/app/restweb/certs/server.pem`
- `/intflash/app/restweb/certs/cert.pem`
- `/intflash/app/slamon/certs/trustcerts.txt`
- `/intflash/ovsdb/keys/privatekey.pem`
- `/intflash/ovsdb/keys/sc-cert.pem`
- `/intflash/.shadov.txt`
- `/intflash/.ntp_keys.txt`

Sensitive files cannot be accessed using the following CLI commands:

- **cd**
- **copy**
- **move**
- **move**
- **rename**
- **remove**
- **delete**
- **more**
- **edit**
- **dir**
- **mkdir**

Operational Considerations

- If you attempt to change the value of the `enhancedsecure-mode` flag when the system is running, you are prompted to continue or to cancel the action. If you decide to continue, all sensitive files are deleted. You must save the current configuration and then reset the switch for the change to take effect.
- When you upgrade the software from releases versions earlier than VOSS 8.5, even if the `enhancedsecure-mode` flag is changed, no sensitive files are deleted.

If you upgrade the software to VOSS 8.5, if the `enhancedsecure-mode` flag is changed, all sensitive files are deleted.

- If you enable the `boot config flags factorydefaults` configuration flag to return an existing switch to factory default configuration, in enhanced secure mode, all sensitive files are deleted.
- When the switch resets after you enable enhanced secure mode or you upgrade the switch software, all configuration files, such as the runtime, primary, and backup configuration files are copied to `/intflash/shared`. The system displays the following message:

```
GlobalRouter SW INFO The runtime config file /intflash/config.cfg is
copied to /intflash/shared/config.cfg due to changing ESM mode/upgrade
version.
```

When the switch resets after you disable enhanced secure mode or after you downgrade the switch software, the switch uses the same configuration files as it used before the switch reset, either from `/intflash/shared` or from `/intflash`.

System access configuration using CLI

The section provides procedures to manage system access through configurations such as usernames, passwords, and access policies.

Change the Default Username

You can change usernames for default users (rwa, rw, and ro) for the specified access level. You cannot change usernames for user-defined users.

Before You Begin

Only the rwa user can change the default username.

About This Task

Perform this procedure to change the default username for the specified access level.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Change the default username:

```
username WORD <1-20> level {l1|l2|l3|ro|rw|rwa}
```

The system displays the following message:

```
Do you want to change username for the default RO user ?
```

3. Type y.
4. Enter the old password.
5. Enter the new password.
6. Re-enter the new password.

Example

Change the default username:

```
Switch:1>enable
Switch:1#config t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#username EXUser ?
  level  Which access level
Switch:1(config)#username EXUser level ?
  l1  Change Layer 1 read write enable password
  l2  Change Layer 2 read write enable password
  l3  Change Layer 3 read write enable password
  ro  Change read only enable password
  rw  Change read write enable password
  rwa Change read write all enable password

Switch:1(config)#username EXUser level ro

Do you want to change username for the default RO user ? (y/n) ? y

Enter the old password : **
Enter the New password : *****
Re-enter the New password : *****
```

Variable Definitions

The following table defines parameters for the **username** command.

Table 214:

Variable	Value
<i>WORD</i> <1-20>	Specifies the user logon name.
<i>level</i> 11 12 13 <i>ro</i> <i>rw</i> <i>rwa</i>	Specifies the access level.

Enabling CLI access levels

Enable CLI access levels to control the configuration actions of various users.

About This Task

Important

Only the RWA user can disable an access level on the switch. You cannot disable the RWA access level on the switch.

The system preserves these configurations across restarts.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable an access level:

```
password access-level WORD<2-8>
```

Example

Block CLI access to Layer 1:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#no password access-level 11
```

Variable Definitions

The following table defines parameters for the **password access-level** command.

Variable	Value
<code>WORD<2-8></code>	<p>Permits or blocks this access level. The available access level values are as follows:</p> <ul style="list-style-type: none"> • l1 — Specifies Layer 1. • l2 — Specifies Layer 2. • l3 — Specifies Layer 3. • ro — Specifies read-only. • rw — Specifies read-write. • rwa — Specifies read-write-all. <p>To set this option to the default value, use the default operator with the command. By default, the system permits all access levels. To block an access level, use the no operator with the command.</p>

Changing passwords

Configure new passwords for each access level, or change the logon or password for the different access levels of the switch. After you receive the switch, use default passwords to initially access CLI. If you use Simple Network Management Protocol version 3 (SNMPv3), you can change encrypted passwords.

Before You Begin

- You must use an account with read-write-all privileges to change passwords. For security, the switch saves passwords to a hidden file.

About This Task

If you enable the hsecure flag, after the aging time expires, the system prompts you to change your password. If you do not configure the aging time, the default is 90 days.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Change a password:

```
cli password WORD<1-20> {layer1|layer2|layer3|read-only|read-write|
read-write-all}
```
3. Enter the old password.
4. Enter the new password.
5. Enter the new password a second time.

6. Configure password options:

```
password [access-level WORD<2-8>] [aging-time <1-365>] [default-
lockout-time <60-65000>] [lockout WORD<0-46> time <60-65000>] [min-
passwd-len <10-20>] [password-history <3-32>]
```

Example

Change a password, and then set the password to an access level of read-write-all and the expiration period for the password to 60 days:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#cli password smith read-write-all
Switch:1(config)#Enter the old password : winter
Switch:1(config)#Enter the New password : summer
Switch:1(config)#Re-enter the New password : summer
Switch:1(config)#password access-level rwa aging-time 60
```

Variable Definitions

The following table defines parameters for the **cli password** command.

Variable	Value
<i>layer1 layer2 layer3 read-only read-write read-write-all</i>	Changes the password for the specific access level.
<i>WORD<1-20></i>	Specifies the user logon name.

Use the data in the following table to use the **password** command.

Variable	Value
<i>access level WORD<2-8></i>	Permits or blocks this access level. The available access level values are as follows: <ul style="list-style-type: none"> • l1 • l2 • l3 • ro • rw • rwa
<i>aging-time <1-365></i>	Configures the expiration period for passwords in days, from 1-365. The default is 90 days.
<i>default-lockout-time <60-65000></i>	Changes the default lockout time after three invalid attempts. Configures the lockout time, in seconds, and is in the 60-65000 range. The default is 60 seconds. To configure this option to the default value, use the default operator with the command.

Variable	Value
<code>lockout WORD<0-46> time <60-65000></code>	Configures the host lockout time. <ul style="list-style-type: none"> <code>WORD<0-46></code> is the host IP address in the format a.b.c.d. <code><60-65000></code> is the lockout-out time, in seconds, in the 60-65000 range. The default is 60 seconds.
<code>min-passwd-len <10-20></code>	Configures the minimum length for passwords in high-secure mode. The default is 10 characters. To configure this option to the default value, use the default operator with the command.
<code>password-history <3-32></code>	Specifies the number of previous passwords the switch stores. You cannot reuse a password that is stored in the password history. The default is 3. To configure this option to the default value, use the default operator with the command.

Configure an Access Policy

About This Task

Configure an access policy to control access to the switch.

You can permit network stations to access the switch or forbid network stations to access the switch.

For each service, you can also specify the level of access; for example, read-only or read-write-all.

Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Create an access policy by assigning it a number:

```
access-policy <1-65535>
```
- Restrict the access to a specific level:

```
access-policy <1-65535> access-strict
```
- Configure access for an access policy:

```
access-policy <1-65535> accesslevel <ro|rwa|rw>
```
- Configure the access policy mode, network, and precedence:

```
access-policy <1-65535> [mode <allow|deny>] [precedence <1-128>]
[network <A.B.C.D> <A.B.C.D>]
```

If you configure the access policy mode to **deny**, the system checks the mode and service, and if they match the system denies the connection. With the access policy mode configured to **deny**, the system does not check **accesslevel** and **access-strict** information. If you configure the access policy mode to allow, the system continues to check the **accesslevel** and **access-strict** information.

6. (Optional) Configure access protocols for an access policy:

```
access-policy <1-65535> [ftp] [http] [ssh] [telnet] [tftp]
```
7. (Optional) Configure trusted username access for an access policy:

```
access-policy <1-65535> host WORD<0-46> [username WORD<0-30>]
```
8. (Optional) Configure SNMP parameters for an access policy:

```
access-policy <1-65535> [snmp-group WORD<1-32> <snmpv1|snmpv2c|usm>]
```

OR

```
access-policy <1-65535> [snmpv3]
```
9. Enable the access policy:

```
access-policy <1-65535> enable
```
10. Enable access policies globally:

```
access-policy
```

Example

Assuming no access policies exist, start with policy 3 and name the policy policy3. Add the read-write-all access level and the usm group group_example. Enable access strict, and finally, enable the policy.

```
Switch:1(config)#access-policy 3
Switch:1(config)#access-policy 3 name policy3
Switch:1(config)#access-policy 3 accesslevel rwa
Switch:1(config)#access-policy 3 snmp-group group_example usm
Switch:1(config)#access-policy 3 access-strict
Switch:1(config)#access-policy 3 enable
```

Variable Definitions

The following table defines parameters for the **access-policy** command.

Variable	Value
<i>access-strict</i>	Restrains access to criteria specified in the access policy. <ul style="list-style-type: none"> • true—The system accepts only the currently configured access level. • false—The system accepts access up to the configured level. Use the no operator to remove this configuration.
<i>accesslevel</i> <ro rwa rw>	Specifies the level of access if you configure the policy to allow access.
<i>enable</i>	Enables the access policy.
<i>ftp</i>	Activates or disables FTP for the specified policy. Because FTP derives its login and password from the CLI management filters, FTP works for read-write-all (rwa) and read-write (rw) access, but not for the read-only (ro) access. Use the no operator to remove this configuration.

Variable	Value
<i>host</i> <i>WORD</i> <0-46>	For remote login access, specifies the trusted host address as an IP address. The switch supports access-policies over IPv4 and IPv6 with no difference in functionality or configuration. Use the no operator to remove this configuration.
<i>http</i>	Activates the HTTP for this access policy. Use the no operator to remove this configuration.
<i>mode</i> < <i>allow</i> <i>deny</i> >	Specifies whether the designated network address is allowed access to the system through the specified access service. The default is <i>allow</i> . If you configure the access policy mode to <i>deny</i> , the system checks the mode and service, and if they match, the system denies the connection. With the access policy mode configured to <i>deny</i> , the system does not check <i>accesslevel</i> and <i>access-strict</i> information. If you configure the access policy mode to <i>allow</i> , the system continues to check the <i>accesslevel</i> and <i>access-strict</i> information.
<i>name</i> <i>WORD</i> <0-15>	Specifies the access policy name.
<i>network</i> < <i>A.B.C.D</i> > < <i>A.B.C.D</i> >	Specifies the IP address and subnet mask for IPv4, or the IP address and prefix for IPv6, that can access the system through the specified access service. The switch supports access-policies over IPv4 and IPv6 with no difference in functionality or configuration. Use the no operator to remove this configuration.
<i>precedence</i> <1-128>	Specifies a precedence value for a policy, expressed as a number from 1-128. The precedence value determines which policy the system uses if multiple policies apply. Lower numbers take higher precedence. The default value is 10.
<i>snmp-group</i> <i>WORD</i> <1-32> < <i>snmpv1</i> <i>snmpv2c</i> <i>usm</i> >	Adds an SNMP version 3 group under the access policy. <i>WORD</i> <1-32> is the SNMP version 3 group name consisting of 1-32 characters. < <i>snmpv1</i> <i>snmpv2c</i> <i>usm</i> > is the security model; either <i>snmpv1</i> , <i>snmpv2c</i> , or <i>usm</i> . Use the no operator to remove this configuration.
<i>snmpv3</i>	Activates SNMP version 3 for the access policy. Use the no operator to remove this configuration.
<i>ssh</i>	Activates SSH for the access policy. Use the no operator to remove this configuration.
<i>telnet</i>	Activates Telnet for the access policy. Use the no operator to remove this configuration.

Variable	Value
<code>tftp</code>	Activates the Trivial File Transfer Protocol (TFTP) for this access policy. Use the no operator to remove this configuration.
<code>username WORD<0-30></code>	Specifies the trusted host user name for remote login access.

Specifying a name for an access policy

Before You Begin

The policy must exist before you can name it.

About This Task

Assign a name to an existing access policy to uniquely identify the policy.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Assign a name to the access policy:

```
access-policy <1-65535> name WORD<0-15>
```

Example

Assign a name to an access policy:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#access-policy 10 name useraccounts
```

Variable Definitions

The following table defines parameters for the **access-policy** command.

Variable	Value
<code>name WORD<0-15></code>	Specifies a name expressed as a string from 0-15 characters.

Allowing a network access to the switch

About This Task

Specify the network to which you want to allow access.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Specify the network:

```
access-policy <1-65535> [mode <allow|deny>] [network <A.B.C.D> <A.B.C.D>]
```

Example

Specify the network to which you want to allow access:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#access-policy 5 mode allow network 192.192.192.0 24
```

Variable Definitions

The following table defines parameters for the **access-policy** command.

Variable	Value
<i>mode</i> <allow deny>	Specifies whether a designated network address is allowed or denied access through the specified access service. The default is allow.
<i>network</i> <A.B.C.D> <A.B.C.D>	Specifies the IPv4 address and subnet mask, or the IPv6 address and prefix-length, permitted or denied access through the specified access service.

Configuring access policies by MAC address**About This Task**

Configure access-policies by MAC address to allow or deny local MAC addresses on the network management port after an access policy is activated. If the source MAC does not match a configured entry, the default action is taken. For connections coming in from a different subnet, the source MAC of the last hop is used in decision making. Configuring access-policies by MAC address does not perform MAC or Forwarding Database (FDB) filtering on data ports.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Add the MAC address and configure the action for the policy:

```
access-policy by-mac <0x00:0x00:0x00:0x00:0x00:0x00> <allow|deny>
```
3. Specify the action for a MAC address that does not match the policy:

```
access-policy by-mac action <allow|deny>
```

Example

Add the MAC address:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#access-policy by-mac 00-C0-D0-86-BB-E7 allow
```

Variable Definitions

The following table defines parameters for the **access-policy by-mac** command.

Variable	Value
<0x00:0x00:0x00:0x00:0x00:0x00>	Adds a MAC address to the policy. Enter the MAC address in hexadecimal format.
<allow deny>	Specifies the action to take for the MAC address.

Creating multiple CLI users

You can create up to seven new CLI users on the switch, in addition to the three default CLI users. The username must be unique. If you enable the hsecure flag, password complexity rules apply to all users.

Before You Begin

You must use an account with read-write-all privileges to create new CLI users.

About This Task**Note**

When a new CLI user is created, the specified username and access level cannot be changed later.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Create a new CLI user:

```
username add {<WORD 1-20> level [ro|rw|rwa] enable}
```
3. Enter a password.
4. Enter the password a second time.

Example

Create a new CLI user:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#username add smith level rwa enable
Enter password : *****
```

```
Re-enter password : *****
Switch:1(config)#
```

Variable Definitions

The following table defines parameters for the **username** command.

Variable	Value
<code>add WORD<1-20></code>	Specifies the username to create.
<code>enable</code>	Enables the new CLI user.
<code>level <ro rw rwa></code>	Specifies the level assigned to the new CLI user: <ul style="list-style-type: none"> ro: Read-only level rw: Read-write level rwa: Read-write-all level

Deleting a username

About This Task

Use this task to delete a username. Default ro, rw, and rwa users cannot be deleted.

Before You Begin

You must use an account with read-write-all privileges to delete a user.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Delete the username:

```
no username <WORD 1-20>
```

Example

Delete a user:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#no username smith
The specified username will be deleted! Continue (y/n) ? Y
Switch:1(config)#show cli username smith
Username does not exist
```

Variable Definitions

The following table defines parameters for the **no username** command.

Variable	Value
<i>WORD</i> <1-20>	Specifies the username to delete.
<i>enable</i>	Disables the username.

Displaying CLI usernames and roles

About This Task

Use this task to display CLI usernames and roles.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display CLI usernames and roles:

```
show cli username
```

Example

```
Switch:1>show cli username

=====
UserName           AccessLevel   State        Type
=====
ro                  ro            enable       default
rw                  rw            enable       default
rwa                 rwa           NA           default
smith               rw            enable       userDefined
```

System access security enhancements

The section provides information on security enhancements after you enable enhanced secure mode.

Display the Boot Config Flags Status

Use the following procedure to display the boot config flags status.

If enhanced secure mode is enabled, the status displays whether the JITC or non-JITC sub-mode is enabled. If enhanced secure mode is disabled, the status displays as false.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. View the boot flags status:

```
show boot config flags
```

Example

In the following example, the status displays that enhanced secure mode is disabled.

Note

Flag support can vary across hardware models.

```
Switch:1#show boot config flags
flags advanced-feature-bandwidth-reservation low
flags block-snmp false
flags debug-config false
flags debugmode false
flags dvr-leaf-mode false
flags enhancedsecure-mode false
flags factorydefaults false
flags flow-control-mode true
flags ftpd true
flags hsecure false
flags ipv6-egress-filter true
flags ipv6-mode false
flags logging true
flags macsec false
flags nni-mstp false
flags reboot true
flags spanning-tree-mode mstp
flags spbm-config-mode true
flags spbm-node-scaling true
flags sshd true
flags syslog-rfc5424-format true
flags telnetd true
flags tftpd true
flags trace-logging false
flags urpf-mode true
flags verify-config true
flags vrf-scaling true
```

Enabling enhanced secure mode

Use the following procedure to enable enhanced secure mode. Enhanced secure mode is disabled by default.

About This Task

Note

When you migrate your switch from enhanced secure mode enabled to disabled, or from disabled to enabled, you must build a new configuration. Do not use a configuration created in either enhanced secure mode disabled or enabled, and expect it to transfer over to the new mode.

The configuration file cannot be guaranteed if you transfer between enhanced secure mode enabled to disabled, or from enhanced secure mode disabled to enabled.

After you enable the enhanced secure mode, the system provides role-based access levels, stronger password requirements, and stronger rules on password length, password complexity, password change intervals, password reuse, and password maximum age use. The enhanced secure mode boot flag supports two sub-modes namely JITC and non-JITC.

After you disable enhanced secure mode, the authentication, access-level, and password requirements work similarly to any of the existing commercial releases.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable enhanced secure mode:

```
boot config flags enhancedsecure-mode [jitc | non-jitc]
```

Note

As a best practice, enable the enhanced secure mode in the non-JITC sub-mode, because the JITC sub-mode is more restrictive and prevents the use of some CLI commands that are commonly used for troubleshooting.

3. (Optional) Disable enhanced secure mode:

```
no boot config flags enhancedsecure-mode
```

4. (Optional) Configure the enhanced secure mode to the default value:

```
default boot config flags enhancedsecure-mode
```

5. Save the configuration:

```
save config
```

Note

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

6. Restart the switch:

```
boot [config WORD<1-99>] [-y]
```

Note

If you enter the **boot** command with no arguments, you cause the switch to start using the current boot choices defined by the **boot config choice** command.

If you enter a boot command and the configuration filename without the directory, the device uses the configuration file from `/intflash/`.

Example

Enable the enhanced secure non-JITC sub-mode:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#boot config flags enhancedsecure-mode non-jitc
Switch:1(config)#save config
Switch:1(config)#exit
Switch:1(config)#boot config /intflash/config.cfg -y
```

Enable the enhanced secure JITC sub-mode:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#boot config flags enhancedsecure-mode jitc
Switch:1(config)#save config
Switch:1(config)#exit
Switch:1(config)#boot config /intflash/config.cfg -y
```

Variable definitions

Use the data in the following table to use the **boot config flags enhancedsecure-mode** command.

Variable	Value
<i>jitc</i>	Enables the JITC enhanced secure mode. The JITC mode is more restrictive and prevents the use of some CLI commands that are commonly used for troubleshooting.
<i>non-jitc</i>	Enables the non-JITC enhanced secure mode.

Create Accounts for Different Access Levels

Use the following procedure to create accounts for different access levels in enhanced secure mode. You must be the administrator to configure the different access levels.

Before You Begin

- You must enable enhanced secure mode in either the JITC or non-JITC sub-modes. As a best practice, use the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.

Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Create accounts on the switch for different access levels:

```
password create-user {auditor|operator|privilege|security} WORD<1-255>
```
- Save the configuration:

```
save config
```

Note

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

Example

Create an account at the auditor level for jsmith:

```
Switch:1>enable
Switch:1#configure terminal
```

```
Switch:1(config)#password create-user auditor jsmith
Switch:1(config)#save config
```

Variable definitions

Use the data in the following table to use the **password create-user** command.

Variable	Value
<i>{auditor operator privilege security}</i>	Specifies the access level for the user.
<i>WORD<1-255></i>	Specifies the user name.

Deleting Accounts in Enhanced Secure Mode

Use the following procedure to delete accounts in enhanced secure mode.

Before You Begin

- You must enable enhanced secure mode in either the JITC or non-JITC sub-modes. As a best practice, use the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.
- You must be an admin or privilege user to delete accounts.

Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Delete an account on the switch:

```
password delete-user username WORD<1-255>
```
- Save the configuration:

```
save config
```

Note

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

Example

Delete an account for jsmith:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#password delete-user user-name jsmith
Switch:1(config)#save config
```

Variable definitions

Use the data in the following table to use the **password delete-user** command.

Variable	Value
<code>user-name WORD<1-255></code>	Specifies the user name.

Configuring a password for a specific user

Configure a new password for a user if the password has expired or locked. Only the administrator can configure a password for a user.

Before You Begin

- You must enable enhanced secure mode in either the JITC or non-JITC sub-modes. As a best practice, use the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.

Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Create accounts on the switch for different access levels:

```
password set-password user-name WORD<1-255>
```
- Save the configuration:

```
save config
```

Note

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

Example

Configure a password for jsmith:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#password set-password user-name jsmith
Enter the New password : *****
Switch:1(config)#Password modified for user jsmith
Switch:1(config)#save config
```

Variable definitions

Use the data in the following table to use the **password set-password** command.

Variable	Value
<code>user-name WORD<1-255></code>	Specifies the user for which to configure the password.

Return the System to the Factory Defaults

To return the system to factory defaults, run the **boot config flags factorydefaults** command.

For more information about the factorydefaults boot flag, see [Boot Sequence](#) on page 123.

Configuring the Password Complexity Rule

About This Task

Use the following procedure to configure the password complexity rule.

The password complexity rule default is to use at least two uppercase, two lowercase, two numeric, and two special character to meet the password criteria.

Before You Begin

- You must enable enhanced secure mode in either the JITC or non-JITC sub-modes. As a best practice, use the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.

Procedure

- Enter Global Configuration mode:
`enable`
`configure terminal`
- Configure the password complexity rule:
`password password-rule <1-2> <1-2> <1-2> <1-2>`
- (Optional) Configure the password complexity rule to the default:
`default password password-rule`
- Save the configuration:
`save config`

Note

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

Example

Configure the password complexity rule to require two uppercase, two lowercase, two numeric and two special characters in each password:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#password password-rule 2 2 2 2
Switch:1(config)#save config
```

Variable definitions

Use the data in the following table to use the **password password-rule** command.

Variable	Value
<1-2> <1-2> <1-2> <1-2>	Configures the minimum password rule. The first variable defines the number of uppercase characters required. The second <1-2> variable defines the number of lowercase characters required. The third <1-2> variable defines the number of numeric characters required. The fourth <1-2> variable defines the number of special characters required. The default for each of these is 2.

Configuring the password length rule

About This Task

Configure the password length rule after you enable enhanced secure mode. By default, the minimum password length is 15.

Before You Begin

- You must enable enhanced secure mode in either the JITC or non-JITC sub-modes. As a best practice, use the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.

Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
- Configure the password length rule option:

```
password min-passwd-len <8-32>
```
- (Optional) Configure the password length rule to the default:

```
default password min-passwd-len
```
- Save the configuration:

```
save config
```

Note

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

Example

Configure the password length rule to 20:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#password min-passwd-len 20
Switch:1(config)#save config
```

Variable definitions

Use the data in the following table to use the **password min-passwd-len** command.

Variable	Value
<8-32>	Configures the minimum character length required. The default is 15.

Configuring the change interval rule

About This Task

Use the following procedure to configure the change interval rule. The system enforces a minimum password change interval, which defines the minimum amount of time before you can change to a new password. By default, the minimum change interval is 24 hours between changing from one password to a new password.

Before You Begin

- You must enable enhanced secure mode in either the JITC or non-JITC sub-modes. As a best practice, use the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.

Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
- Configure the change interval rule option:

```
password change-interval <1-999 hours>
```
- (Optional) Configures the change interval rule to the default:

```
default password change-interval
```
- Save the configuration:

```
save config
```

Note

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

Example

Configure the change interval rule to 72 hours:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#password change-interval 72
Switch:1(config)#save config
```

Variable definitions

Use the data in the following table to use the **password change-interval** command.

Variable	Value
<1-999>	Configures the minimum interval between consecutive password changes. The default is 24 hours.

Configuring the reuse rule

Use the following procedure to configure the password reuse rule. The default password reuse rule is 3.

Before You Begin

- You must enable enhanced secure mode in either the JITC or non-JITC sub-modes. As a best practice, use the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.

Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
- Configure the password reuse rule option:

```
password password-history <3-32>
```
- (Optional) Configure the password reuse rule to the default:

```
default password password-history
```
- Save the configuration:

```
save config
```

Note

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

Example

Configure the reuse rule to 30:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#password password-history 30
Switch:1(config)#save config
```

Variable definitions

Use the data in the following table to use the **password password-history** command.

Variable	Value
<3-32>	Configures the minimum number of previous passwords to remember. The default is 3.

Configuring the maximum number of sessions

Use the following procedure to configure the maximum number of sessions on the switch. The `max-sessions` value configures the number of times a particular role-based user can log in to the switch through the SSH session at the same time. The default `max-sessions` value is 3.

The `max-sessions` value applies only for SSH sessions, and only with enhanced secure mode enabled.

Before You Begin

- You must enable enhanced secure mode in either the JITC or non-JITC sub-modes. As a best practice, use the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.

Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
- Configure the maximum number of sessions:

```
password max-sessions <1-8> user-name WORD<1-255>
```
- (Optional) Configure the password reuse rule to the default:

```
default password max-sessions
```
- Save the configuration:

```
save config
```

Note

The `save config` command saves the configuration file with the filename configured as the primary configuration filename in `boot config`. Use the command `show boot config choice` to view the current primary and backup configuration filenames.

Example

Configure the reuse rule to 5:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#password max-sessions 5 user-name jsmith
Switch:1(config)#save config
```

Variable definitions

Use the data in the following table to use the `password max-sessions` command.

Variable	Value
<1-8>	Specifies the maximum number of sessions. The default is 3.
user-name WORD<1-255>	Specifies the user-name.

Configuring the maximum age rule

Use the following procedure to configure the maximum age rule.

If enhanced secure mode is enabled, the individual with the administrator access level role can configure the aging-time for each user. If you configure the aging time for each user, the aging time must be more than the global change interval value. The default is 90 days.

If you do not enable enhanced secure mode, the aging time is a global value for all users.

Before You Begin

- You must enable enhanced secure mode in either the JITC or non-JITC sub-modes. As a best practice, use the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.

Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Configure the maximum age rule option:

```
password aging-time day <1-365> [user WORD<1-255>]
```
- (Optional) Configure the maximum age rule to the default:

```
default password aging-time [user WORD<1-255>]
```
- Save the configuration:

```
save config
```

Note

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

Example

Configure the maximum age rule option to 100 days for user jsmith:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#password aging-time day 100 user jsmith
Switch:1(config)#save config
```

Variable definitions

Use the data in the following table to use the **password aging-time** command.

Variable	Value
<i>day</i> <1-365>	Configures the password aging time in days. The default is 90 days.
<i>user</i> WORD<1-255>	Specifies a particular user.

Configuring the Pre-notification and Post-notification Rule

Use the following procedure to configure the pre-notification and post-notification rule.

After enhanced secure mode is enabled, the switch enforces password expiry. To ensure a user does not lose access, the switch offers pre- and post-notification messages explaining when the password will expire.

The administrator can define pre- and post-notification intervals to between one to 99 days.

Before You Begin

- You must enable enhanced secure mode in either the JITC or non-JITC sub-modes. As a best practice, use the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.

About This Task

The pre-notification intervals provide messages to warn users that their passwords will expire within a particular timeframe:

The post-notification intervals provide notification to users that their passwords have expired within a particular timeframe:

- interval 1—By default, interval 1 is 1 day.
- interval 2—By default, interval 2 is 7 days.
- interval 3—By default, interval 3 is 30 days.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Configure the pre-notification rule option:
`password pre-expiry-notification-interval <1-99> <1-99> <1-99>`
3. Configure post-notification rule option:
`password post-expiry-notification-interval <1-99> <1-99> <1-99>`
4. Configure the pre-notification rule to the default:
`default password pre-expiry-notification-interval`
5. Configure the post-notification rule to the default:
`default password post-expiry-notification-interval`
6. Save the configuration:
`save config`

Note

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

Example

Configure the pre- and post-notification rules to the default:

```
Switch:1>enable
Switch:1#configure terminal
```

```
Switch:1(config)#default password pre-expiry-notification-interval
Switch:1(config)#default password post-expiry-notification-interval
Switch:1(config)#save config
```

Variable definitions

Use the data in the following table to use the **pre-expiry-notification-interval** command.

Variable	Value
<1-99> <1-99> <1-99>	Configure the pre-notification intervals to provide messages to warn the users that their passwords will expire within a particular timeframe. The first <1-99> variable specifies the first notification, the second <1-99> specifies the second notification, and the third <1-99> variable specifies the third interval. By default, the first interval is 30 days, the second interval is 7 days, and the third interval is 1 day.

Use the data in the following table to use the **post-expiry-notification-interval** command.

Variable	Value
<1-99> <1-99> <1-99>	Configure the post-notification intervals to provide notification to the users that their passwords have expired within a particular timeframe. The first <1-99> variable specifies the first notification, the second <1-99> specifies the second notification, and the third <1-99> variable specifies the third interval. By default, the first interval is 1 day, the second interval is 7 days, and the third interval is 30 days.

System access configuration using EDM

The section provides procedures you can use to manage system access by using Enterprise Device Manager (EDM). Procedures include configurations for usernames, passwords, and access policies.

Configuring CLI Access using EDM

Use the following procedures to perform CLI access configuration tasks such as:

- Enable access levels
- Change passwords
- Configure the logon banner

Enable Access Levels

About This Task

Enable access levels to control the configuration actions of various users.

Important

Only the RWA user can disable an access level on the switch. You cannot disable the RWA access level on the switch.

The system preserves these configurations across restarts.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **CLI** tab.
4. Select the enable check box for the required access level.
5. Click **Apply**.

*Change Passwords***About This Task**

Configure new passwords for each access level, or change the logon or password for the different access levels of the system to prevent unauthorized access. After you receive the switch, use default passwords to initially access CLI. If you use Simple Network Management Protocol version 3 (SNMPv3), you can change passwords in encrypted format.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **CLI** tab.
4. Specify the username and password for the appropriate access level.
5. Click **Apply**.

*Configure the Logon Banner***About This Task**

Configure the logon banner using EDM to display a warning message to users on the CLI before authentication.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **CLI** tab.
4. Enter the banner text in the **CustomBannerText** field.
5. Check the **CustomBannerEnable** check box.
6. Click **Apply**.

CLI Field Descriptions

The following table defines parameters for the **CLI** tab.

Name	Description
RWAUserName	Specifies the user name for the read-write-all CLI account.
RWAPassword	Specifies the password for the read-write-all CLI account.
RWEnable	Activates the read-write access. The default is enabled.
RWUserName	Specifies the user name for the read-write CLI account.

Name	Description
RWPassword	Specifies the password for the read-write CLI account.
RWL3Enable	Activates the read-write Layer 3 access. The default is enabled.
RWL3UserName	Specifies the user name for the Layer 3 read-write CLI account.
RWL3Password	Specifies the password for the Layer 3 read-write CLI account.
RWL2Enable	Activates the read-write Layer 2 access. The default is enabled.
RWL2UserName	Specifies the user name for the Layer 2 read-write CLI account.
RWL2Password	Specifies the password for the Layer 2 read-write CLI account.
RWL1Enable	Activates the read-write Layer 1 access. The default is enabled.
RWL1UserName	Specifies the user name for the Layer 1 read-write CLI account.
RWL1Password	Specifies the password for the Layer 1 read-write CLI account.
ROEnable	Activates the read-only CLI account. The default is enabled.
ROUserName	Specifies the user name for the read-only CLI account.
ROPassword	Specifies the password for the read-only CLI account.
MaxTelnetSessions	Specifies the maximum number of concurrent Telnet sessions in a range from 0–8. The default is 8.
Timeout	Specifies the number of seconds of inactivity for a Telnet before the system initiates automatic timeout and disconnect, expressed in a range from 30–65535. The default is 900 seconds.
NumAccessViolations	Indicates the number of CLI access violations detected by the system. This variable is a read-only field.
CustomBannerText	Specifies the text message that is displayed to users on the CLI before authentication. The message can be company information, such as company name and contact, or a warning message for the users of CLI. With character limitation from 1-1800, the text box displays 79 characters per line.
CustomBannerEnable	Specifies whether custom logon banner is enabled or disabled. The default is enabled.

Create an Access Policy

About This Task

Create an access policy to control access to the switch. An access policy specifies the hosts or networks that can access the switch through various services, such as Telnet, SNMP, HTTP, and SSH.

You can allow network stations access the switch or forbid network stations to access the switch. For each service, you can also specify the level of access, such as read-only or read-write-all.

HTTP and HTTPS support IPv4 and IPv6 addresses.

Important

EDM does not provide SNMPv3 support for an access policy. If you modify an access policy with EDM, SNMPV3 is disabled.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **Access Policies**.
3. Select the **Access Policies** tab.
4. Select **Insert**.
5. In **ID**, type the policy ID.
6. In **Name**, type the policy name.
7. Select **PolicyEnable**.
8. Select the **Mode** option to allow or deny a service.

If you configure the access policy mode to **deny**, the system checks the mode and service, and if they match the system denies the connection. With the access policy mode configured to **deny**, the system does not check **AccessLevel** and **AccessStrict** information. If you configure the access policy mode to allow, the system continues to check the **AccessLevel** and **AccessStrict** information.

9. From the **Service** options, select a service.
10. In **Precedence**, type a precedence number for the service (lower numbers mean higher precedence).
11. Select the **NetInetAddrType**.
12. In **NetInetAddress**, type an IP address.
13. In **NetInetAddrPrefixLen**, type the prefix length.
14. Select an **AccessLevel** for the service.
15. Select **AccessStrict**, if required.

Important

If you select **AccessStrict**, you specify that a user must use an access level identical to the one you select.

16. Select **Insert**.

Access Policies Field Descriptions

Use the data in the following table to use the **Access Policies** tab.

Name	Description
Id	Specifies the policy ID.
Name	Specifies the name of the policy.
PolicyEnable	Activates the access policy. The default is enabled.

Name	Description
Mode	Indicates whether a packet with a source IP address matching this entry is permitted to enter the device or is denied access. The default is allow. If you configure the access policy mode to deny , the system checks the mode and service, and if they match the system denies the connection. With the access policy mode configured to deny , the system does not check AccessLevel and AccessStrict information. If you configure the access policy mode to allow, the system continues to check the AccessLevel and AccessStrict information.
Service	Indicates the protocol to which this entry applies. The default is no service enabled.
Precedence	Indicates the precedence of the policy expressed in a range from 1-128. The lower the number, the higher the precedence. The default is 10.
NetInetAddrType	Indicates the source network Internet address type as one of the following. <ul style="list-style-type: none"> • any • IPv4 • IPv6 IPv4 is expressed in the format a.b.c.d. Express IPv6 in the format x:x:x:x:x:x.
NetInetAddress	Indicates the source network Inet address (prefix/network). If the address type is IPv4, you must enter an IPv4 address and its mask length. You do not need to provide this information if you select the NetInetAddrType of any. If the type is IPv6, you must enter an IPv6 address. You do not need to provide this information if you select the NetInetAddrType of any.
NetInetAddrPrefixLen	Indicates the source network Inet address prefix-length/mask. If the type is IPv4, you must enter an IPv4 address and mask length. If the type is IPv6, you must enter an IPv6 address and prefix length. You do not need to provide this information if you select the NetInetAddrType of any.
AccessLevel	Specifies the access level of the trusted host as one of the following: <ul style="list-style-type: none"> • readOnly • readWrite • readWriteAll The default is readOnly.

Name	Description
Usage	Counts the number of times this access policy applies.
AccessStrict	<p>Activates or disables strict access criteria for remote users. If selected, a user must use an access level identical to the one you selected in the dialog box to use this service.</p> <ul style="list-style-type: none"> selected: remote login users can use only the currently configured access level cleared: remote users can use all access levels <p>Note: If Mode is configured as allow the system checks AccessStrict information. If Mode is configured as deny, the system does not check AccessStrict information.</p> <p>Important: If you do not select true or false, user access is governed by criteria specified in the policy table. For example, a user with an rw access level specified for a policy ID in the policy table is allowed rw access, and ro is denied access.</p> <p>The default is false (cleared).</p>

Enable an Access Policy

About This Task

Enable the access policy feature globally to control access across the switch.

You can create an access policy to control access to the switch. An access policy specifies the hosts or networks that can access the switch through access services; for example Telnet, SNMP, and Hypertext Transfer Protocol (HTTP).

Procedure

1. In the Device Physical View tab, select the Device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Chassis**.
4. Click the **System Flags** tab.
5. Select the **EnableAccessPolicy** check box.
6. Click **Apply**.

Creating Multiple Users

You can create up to seven new CLI user roles on the switch, in addition to the three default CLI user roles. The username must be unique. If you enable the hsecure flag, password complexity rules apply to all users.

Before You Begin

You must use an EDM account with read-write-all privileges to create new CLI users.

About This Task

Use this task to create multiple CLI users on the switch using EDM.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **Multiple Users** tab.
4. Click **Insert**.
5. Type the ID.
6. Type a unique user name.
7. Type a password.
8. Select the access level.
9. Select **Enable** to activate the user account.
10. Click **Insert**.

Multiple Users field descriptions

Use the data in the following table to use the **Multiple Users** tab.

Name	Description
Id	Specifies the unique ID.
Name	Specifies the username.
Password	Specifies the password.
Level	Specifies the user access level. <ul style="list-style-type: none"> • ro • rw • rwa
Enable	Enables the user access on the switch.
Type	Specifies the user type.

Modify User Passwords

About This Task

Use this task to modify user account passwords using EDM.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **Multiple Users** tab.
4. To change the user account password, double-click the **Password** field.
5. Click **Apply**.

Disable a User Account

About This Task

Use this task to disable a user account using EDM.

Note

Users with rwa access rights cannot be disabled. Only users with ro and rw access rights can be disabled.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **Multiple Users** tab.
4. View whether the user account is enabled. To modify, double-click on the cell and select false from the list.
5. Click **Apply**.

Delete a User Account

About This Task

Note

DEMO FEATURE - Multiple CLI Users Per Role is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [Fabric Engine Feature Support Matrix](#).

Use this task to delete a user account using EDM. You cannot delete default ro, rw, and rwa users.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **Multiple Users** tab.
4. Select the row with the user account to delete and click **Delete**.
5. Click **Yes** to confirm.

System access security enhancements using EDM

The section provides information to enable enhanced secure mode.

Enable Enhanced Secure Mode

Use the following procedure to enable enhanced secure mode in either the JITC or non-JITC sub-modes.

The enhanced secure mode is disabled by default.

About This Task

After you enable enhanced secure mode, the system can provide role-based access levels, stronger password requirements, and stronger rules on password length, password complexity, password change intervals, password reuse, and password maximum age use.

After you disable enhanced secure mode, the authentication, access-level, and password requirements work similarly to any of the existing commercial releases.

Note

You can use EDM to enable or disable enhanced secure mode. To configure the security enhancements this feature provides, you must use CLI.

Procedure

1. On the Device Physical View, select the device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Chassis**.
4. Click the **Boot Config** tab.
5. In the **EnableEnhancedsecureMode** option box, select either **jitc** or **non-jitc** to enable the enhanced secure mode in one of these sub-modes. Select **disable** to disable the enhanced secure mode.

Note

As a best practice, enable the non-JITC sub-mode. The JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.

6. Click **Apply**.
7. Save the configuration, and restart the switch.

TACACS+

- [TACACS+ configuration using EDM on page 2946](#)
- [TACACS+ Configuration Examples on page 2951](#)

Table 215: TACACS+ product support

Feature	Product	Release introduced
TACACS+	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
TACACS+ secure communication using IPSec for IPv4	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5

TACACS+ Fundamentals

The switch supports the TACACS+ client. TACACS+ is a remote authentication protocol that provides centralized validation of users who attempt to gain access to a router or Network Access Server (NAS).

The TACACS+ feature is a client and server-based protocol that allows the switch to accept a user name and password and send a query to a TACACS+ authentication server, sometimes called a TACACS+ daemon. The TACACS+ server allows access or denies access based on the response by the client.

The TACACS+ feature facilitates the following services:

- Login authentication and authorization for CLI access through Secure Shell (SSH), Telnet, or serial port.
- Login authentication for web access through EDM.
- Command authorization for CLI through SSH, Telnet, or serial port.
- Accounting of CLI through SSH, Telnet, and serial port.

The following figure displays the basic layout of the switch and the TACACS+ server.

Figure 231: Switch and TACACS+ server

The TACACS+ feature uses Transmission Control Protocol (TCP) for its transport to ensure reliable delivery of packets. TACACS+ provides security by encrypting all traffic between the switch, which acts as the Network Access Server, and the TACACS+ server.

TACACS+ is a newer version of TACACS and provides separate authentication, authorization, and accounting (AAA) services. TACACS+ does not support earlier versions of TACACS.

TACACS+ is a base license feature. The TACACS+ feature is disabled by default.

TACACS+ Operation

The switch acts as an NAS to provide a connection to a single user, to a network, subnetwork or interconnected networks. The switch acts as a gateway to guard access to the TACACS+ server and network. Encryption relies on a secret key that is known to the client and the TACACS+ server.

Similar to the Remote Access Dial-In User Services (RADIUS) protocol, TACACS+ provides the ability to centrally manage the users who want to access a remote device. TACACS+ provides management of remote and local users who try to access a device through:

- Secure Shell (SSHv2)
- Telnet
- serial port
- web management

A TACACS+ daemon, which typically runs on a UNIX or Windows NT workstation, maintains the TACACS+ authentication, authorization, and accounting services.

Extreme Networks Identity Engines supports the TACACS+ daemon.

As a best practice, use the Identity Engines Ignition Server as your TACACS+ server.

You configure users in the TACACS+ server. If you enable authentication, authorization, and accounting services, the following occurs:

- During the logon process, the TACACS+ client initiates the TACACS+ authentication session with the TACACS+ server.
- After successful authentication the TACACS+ client initiates the TACACS+ authorization session with the TACACS+ server. This is transparent to the user. The switch receives the user access level after a successful TACACS+ authorization. The TACACS+ server authorizes every command the user issues if TACACS+ command authorization is enabled for that user access level.

- After successful authorization, if you enable TACACS+ accounting, the TACACS+ client sends accounting information to the TACACS+ server.

A TACACS+ session establishes with the server in one of two ways:

- Multi-connection mode (also known as per-session): For every authentication, authorization, and accounting (AAA) request the switch establishes a session with the TACACS+ server, and then after the request finishes, the session is torn down. Multi-connection mode is the default mode.
- Single-connection mode: The first AAA request establishes the session, which is only torn down if TACACS+ is disabled or due to inactivity.

TACACS+ Architecture

You can connect the TACACS+ server to the switch:

- In-band through one of the data ports.
- Out-of-band through the management port.

Connect the TACACS+ server through a local interface. Management PCs can reside on an out-of-band management Ethernet port, or on the corporate network. Place the TACACS+ server on the corporate network so you can route it to the switch.

Before you configure the switch, you must configure at least one TACACS+ server and a key.

The TACACS+ server and the switch must have the same:

- Encryption key
- Connection mode (single connection or per-session connection. Per-session connection is the same as multi-connection mode.)
- TCP port number

You can configure a secondary TACACS+ server for backup authentication. You specify the primary authentication server when you configure the switch.

Authentication, authorization, and accounting

A fundamental feature of TACACS+ is the separation of authentication, authorization, and accounting (AAA) services, which allows you to selectively implement one or more TACACS+ services.

TACACS+ authentication

TACACS+ authentication provides control of authentication through login and password.

Authentication uses a database of users and passwords to determine:

- who a user is

- whether to allow the user access to the NAS

Important

Prompts for log on and password occur prior to the authentication process. If TACACS+ fails because no valid servers exist, the device uses the user name and password from the local database. If TACACS+ or the local database returns an access denied packet, the authentication process stops. The device attempts no other authentication methods.

The following figure illustrates the authentication process.

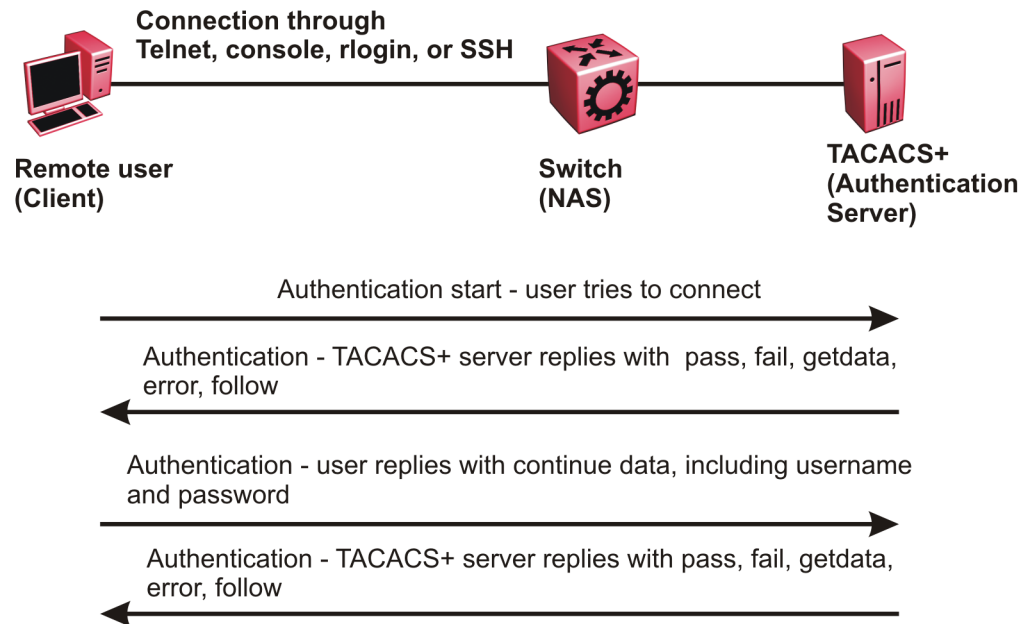

Figure 232: Authentication process

TACACS+ authorization

The transition from TACACS+ authentication to the authorization phase is transparent to the user. After successful completion of the authentication session, an authorization session starts with the authenticated user name. The authorization session provides access level functionality.

Authorization cannot occur without authentication.

Authorization:

- determines what a user can do
- allows administrators fine-grained control over the capabilities of users during sessions

The following figure illustrates the authorization process.

Figure 233: Authorization process

Authorization determines what a user can do. Authorization gives you the ability to limit network services to certain users and to limit the use of certain commands to certain users. The TACACS+ feature enhances the security by tightly policing the command execution for a particular user. After you enable command authorization, all commands, no matter the access level to which they belong, are sent to the TACACS+ server for authorization. Authorization cannot occur without first enabling authentication. You must configure command authorization globally and at individual access levels.

Two kinds of authorization requests exist:

1. Login authorization: Login authorization happens immediately after authentication and is transparent to the user. When the user logs on to the device, authorization provides the user access level. With log on, the device does not send a command to the TACACS+ server. You cannot configure login authorization.
2. Command authorization: When you configure command authorization for a particular level, all commands that you issue are sent to the TACACS+ server for authorization. The device can only issue the commands the TACACS+ server authorizes. You need to configure command authorization globally and at individual access levels, which are visible to the users.

Note

You must verify that the switch can reach the TACACS+ server and that you configure TACACS+ properly before you enable command authorization.

If a user is TACACS+ authenticated and command authorization is enabled for that level, then if the switch cannot reach the TACACS+ server, the switch does not allow the user to issue any command that has privilege level command authorization enabled. In such a case, the user can only issue logout and exit commands.

If a user tries to log in and the TACACS+ server does not exist or is not reachable, then, as discussed before, a local database in the switch authenticates the user. The switch authorizes a locally authenticated user and a locally authenticated user is not eligible for TACACS+ command authorization.

After the switch requests authorization, the logon credentials are sent to the TACACS+ daemon for authorization. If logon authorization fails, the user receives a permission denied message.

If TACACS+ logon authorization succeeds, the switch uses information from the user profile, which exists in the local user database or on the TACACS+ server, to configure the session for the user.

After you enable TACACS+ command authorization all commands are visible to all users; however, the user can only issue those commands that the TACACS+ server configuration allows.

The switch cannot enforce command access level. The TACACS+ server returns an access level to the switch. The switch allows the user to access the switch according to the access level. The device grants the user access to a command only if the profile for the user allows the access level.

You preconfigure command authorization on the TACACS+ server. You specify a list of regular expressions that match command arguments, and you associate each command with an action to deny or permit.

All members in a group have the same authorization. If you place a user in a group, the daemon looks in the group for authorization parameters if it cannot find them in the user profile.

TACACS+ Accounting

TACACS+ accounting enables you to track the services users access and the amount of network resources users consume.

TACACS+ accounting allows you to track:

- what a user does
- when a user does certain actions

The accounting record includes the following information:

- User name
- Date
- Start/stop/elapsed time
- Access server IP address
- Reason

You can use accounting for an audit trail, to bill for connection time or resources used, or for network management. TACACS+ accounting provides information about user sessions using the following connection types: Telnet, SSH, and web-based management.

With separation of AAA, accounting can occur independently from authentication and authorization.

The following figure illustrates the accounting process.

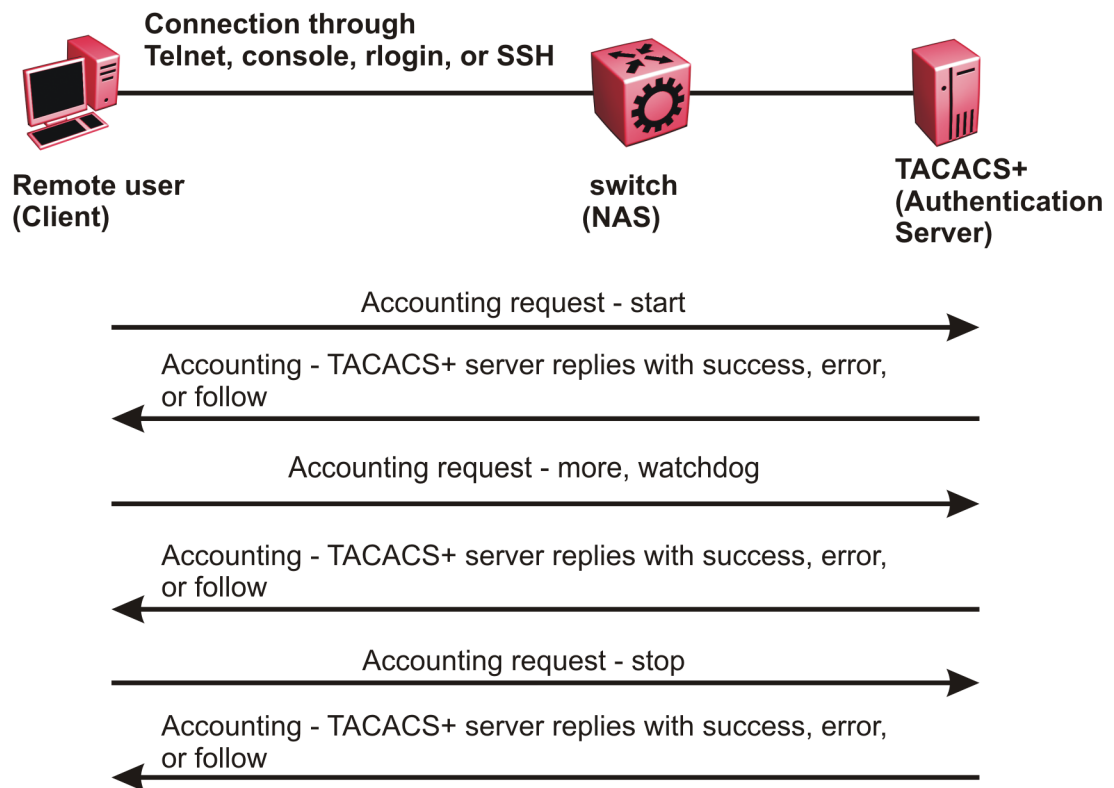

Figure 234: Accounting process

After you enable accounting, the switch reports user activity to the TACACS+ server in the form of accounting records. Each accounting record contains accounting attribute value (AV) pairs. AV pairs are strings of text in the form “attribute-value” sent between the switch and a TACACS+ daemon as part of the TACACS+ protocol. The TACACS+ server stores the accounting records.

You cannot customize the set of events the switch monitors and logs with TACACS+ accounting. TACACS+ accounting logs the following events:

- User logon and logoff
- Logoff generated because of activity timeout
- Unauthorized command
- Telnet session closed (not logged off)

Privilege Level Changes at Runtime

You can change your privilege level at runtime with the **tacacs switch level** command.

You need to configure separate profiles in the TACACS+ server configuration file for the switch level. The switch supports only levels 1 to 6 and level 15. The switch uses the profile when you issue the command **tacacs switch level <1-15>**. As part of the profile, you specify a user name, level, and password. To preconfigure a dummy user for that level on the TACACS+ daemon, the format of the user

name for the dummy user is **\$enab<n>\$**, where <n> is the privilege level to which you want to allow access.

The following is an example of a TACACS+ server profile, which you configure on the TACACS+ server:

```
user = $enab6$ {
member = level6
login = cleartext get-me-on-6
}
```

The following table maps user accounts to TACACS+ privilege level.

Switch access level	TACACS+ privilege level	Description
NONE	0	If the TACACS+ server returns an access level of 0, the user is denied access. You cannot log into the device if you have an access level of 0.
READ ONLY	1	Permits you to view only configuration and status information.
LAYER 1 READ WRITE	2	Permits you to view most of the switch configuration and status information and change physical port settings.
LAYER 2 READ WRITE	3	Permits you to view and change configuration and status information for Layer 2 (bridging and switching) functions.
LAYER 3 READ WRITE	4	Permits you to view and change configuration and status information for Layer 2 and Layer 3 (routing) functions.
READ WRITE	5	Permits you to view and change configuration and status information across the switch. This level does not allow you to change security and password settings.
READ WRITE ALL	6	Permits you to have all the rights of read-write access and the ability to change security settings, including command line interface (CLI) and web-based management user names and passwords, and the SNMP community strings.

Switch access level	TACACS+ privilege level	Description
NONE	7 to 14	If the TACACS+ server returns an access level of 7 to 14, the user is denied access. You cannot log into the device if you have an access level of 7 to 14.
READ WRITE ALL	15	Permits you to have all the rights of read-write access and the ability to change security settings, including command line interface (CLI) and web-based management user names and passwords, and the SNMP community strings. Note: Access level 15 is internally mapped to access level 6, which ensures consistency with other vendor implementations. The switch does not differentiate between an access level of 6 and an access level of 15.

Note

If you enable enhanced secure mode with the **boot config flags enhancedsecure-mode** command, you enable different access levels, along with stronger password complexity, length, and minimum change intervals. With enhanced secure mode enabled, the switch supports the following access levels for RADIUS authentication:

- Administrator
- Privilege
- Operator
- Auditor
- Security

The switch associates each username with a certain role and appropriate authorization rights to view and configure commands. For more information, see [Enhanced Secure Mode](#) on page 2887.

TACACS+ command authorization

After you enable TACACS+ authorization, the current privilege-level to command mapping on the switch is no longer relevant because the TACACS+ server has complete responsibility for command authorization. TACACS+ authorization provides access to the system based on username, not based on privilege level.

After you enable TACACS+ command authorization for a particular privilege level, and a user with that privilege level logs on, the user can access commands based on his user name.

TACACS+ switch level and TACACS+ switch back commands

The user can only issue the **tacacs switch level** command after TACACS+ authenticates the user. Locally authenticated users, which means users authenticated only by the switch and not by the TACACS+ server, cannot use the **tacacs switch level** command.

Consider a user, called X, with a privilege level of 4, who uses the **tacacs switch level <1-15>** command to change the privilege level from 4 to 6.

If user X successfully changes the switch level to 6, the user name changes from X to "\$enab6\$", and the privilege level changes from 4 to 6. If TACACS+ command authorization is enabled for privilege level 6, then the TACACS+ server authorizes commands issued based on the rules defined for (dummy) user "\$enab6\$".

If TACACS+ command authorization is not enabled for privilege level 6, then the switch locally authorizes the user X based on the privilege level of the user.

The user can return to his previous privilege level using the **tacacs switch back** command. In the preceding scenario, if the user issues the **tacacs switch back** command, the user name changes for user X from "\$enab6\$" to X, and the privilege level changes from 6 to 4.

TACACS+ switch level supports up to eight levels, and TACACS+ switch level allows a user to switch level up to eight times from his original privilege level. The switch stores all of the previous privilege levels in the same order in which the user switches levels. After switching eight times, if the user tries to switch a level the ninth time, the following error message displays:

```
Only allowed to switch level 8 times!
```

The user can switch back to his previous privilege levels using the **tacacs switch back** command. The **tacacs switch back** command switches back in the reverse order in which you issued the **tacacs switch level** command. Consider a user who switched levels from 4 to 5, and then to 6. If the user used the **tacacs switch back** command, the user first moves from 6 to 5, and then using the **tacacs switch back** command again moves from 5 to 4.

**Note**

If you want to switch to a privilege level 'X' using **tacacs switch level <1-15>** command, you must create a user "\$enabX\$" on the TACACS+ server. X is the privilege level that you want to change.

TACACS+ switch level functionality:

The following table explains TACACS+ switch level functionality.

User logs in with	TACACS+ server available	Result
TACACS+ authentication	Yes	The user can issue the tacacs switch level <1-15> command.
Local authentication	No	The user cannot issue the tacacs switch level <1-15> command.
Local authentication	Yes	Even if a TACACS+ server becomes reachable, the user remains locally authenticated and cannot issue the tacacs switch level <1-15> command.

TACACS+ command authorization functionality:

The following table explains TACACS+ command authorization functionality.

User logs in with	Command authorization	Result
Local authentication	—	The switch authorizes the user locally.
TACACS+ authentication	Not enabled for the logged-in level.	The switch authorizes the user locally. If the server connection is lost, the switch authorizes the user locally.
TACACS+ authentication	Enabled for the logged-in level.	The TACACS+ server authorizes the user. If the server connection is lost, the user can only issue exit and logout commands.

**Note**

A user who configures TACACS+ is locally authenticated and authorized by the switch, so even after the user configures TACACS+, the switch continues to locally authorize the user.

TACACS+ and RADIUS differences

TACACS+ and RADIUS are security protocols that you can use on network devices.

You can enable TACACS+ and RADIUS together. However, TACACS+ has a higher priority. If the TACACS+ server is not available the authentication is sent to RADIUS, if RADIUS is enabled. However, if TACACS+ authentication fails, then requests are not sent to RADIUS.

Following is a list of differences between TACACS+ and RADIUS.

TACACS+	RADIUS
Separates Authorization, Authentication and Accounting (AAA). As a result, you can selectively implement one or more TACACS+ services. With TACACS+ you can use different servers for each service.	Combines authentication and authorization.
Uses TCP. TCP is connection-oriented. TCP immediately indicates if a server crashes or is not running. TCP offers an acknowledgement that a request has been received.	Uses UDP. UDP is best-effort delivery. RADIUS uses re-transmit attempts and timeouts to make up for the support TCP has.
Encrypts the entire body of the packet, which includes the password and username.	Encrypts only the password from the client to the server.
Used for administrator access. Usually used for administrator access to network devices.	Used for subscriber access. Usually used to authenticate remote users to a network.
Can control which access level of commands a user or group can access.	Cannot control which access level of commands can be used.

TACACS+ Feature Limitations

TACACS+ does not support the following features:

- Point-to-Point Protocol (PPP) authentication and accounting
- IPv6 for TACACS+
- S/KEY (One Time Password) authentication
- PAP/CHAP/MSCHAP authentication methods
- The FOLLOW response of a TACACS+ server, in which the AAA services are redirected to another server. The response is interpreted as an authentication failure.
- User capability to change passwords at runtime over the network. The system administrator must change user passwords locally, on the server.
- TACACS+ command authorization when the user accesses the switch through EDM and SNMP.
- Restriction of command authorization for a specific kind of access. After you enable command authorization, command authorization applies for Telnet, SSH, and serial-port access. You cannot restrict command authorization to just one kind of access.

If a user is TACACS+ authenticated and command authorization is enabled for that level, then if the switch cannot reach the TACACS+ server, the switch does not permit the user to execute any command that has privilege level command authorization enabled.

TACACS+ configuration using CLI

Enabling TACACS+

Enable TACACS+ globally on the switch.

The switch supports the TACACS+ client. TACACS+ is a security application implemented as a client and server-based protocol that provides centralized validation of users who attempt to gain access to a router or network access server (the switch).

By default, TACACS+ is disabled.

Before You Begin

- You must have access to and you must configure a TACACS+ server before the TACACS+ features on your switch are available.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Enable TACACS+ globally:
`tacacs protocol enable`
3. Disable TACACS+ globally:
`no tacacs protocol enable`
`default tacacs protocol enable`

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#tacacs protocol enable
```

Add a TACACS+ Server

Add a primary and secondary TACACS+ server and specify the authentication process.

If you have a backup server configured, the AAA request goes to the backup server if the primary server is not available.

As a best practice, use the Identity Engines Ignition server as your TACACS+ server.

About This Task

The TACACS+ server and the switch must have the same:

- Encryption key
- Connection mode (single connection or per-session connection. Per-session connection is the same as multi-connection mode)
- TCP port number

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Add a primary TACACS+ server with an encryption key:

```
tacacs server host {A.B.C.D} key WORD<0-128>
```

3. (Optional) Configure the parameters for the primary TACACS+ server as required.

- a. (Optional) Specify a single connection to maintain a constant connection between the switch and the TACACS+ daemon:

```
tacacs server host {A.B.C.D} single-connection
```

Note

The TACACS+ daemon must also support this mode. If you do not configure this, the switch uses the default connection type, which is the per-session connection. Per-session is the same as multi-connection mode.

- b. (Optional) Specify the TCP port to use when the switch connects to the TACACS+ daemon:

```
tacacs server host {A.B.C.D} port <1-65535>
```

The default port is 49.

- c. (Optional) Specify the period of time (in seconds) the switch waits for a response from the TACACS+ daemon before it times out and shows an error:

```
tacacs server host {A.B.C.D} timeout <10-30>
```

4. Specify the IP address of the secondary TACACS+ server and specify an encryption key:

```
tacacs server secondary-host {A.B.C.D} key WORD<0-128>
```

5. (Optional) Configure the optional parameters on the secondary TACACS+ server as required.

- a. (Optional) Specify a single connection for the secondary TACACS+ server to maintain a constant connection between the switch and the TACACS+ daemon:

```
tacacs server secondary-host {A.B.C.D} single-connection
```

Note

The TACACS+ daemon must also support this mode. If you do not configure this, the switch uses the default connection type, which is the per-session connection. Per-session is the same as multi-connection mode.

- b. (Optional) Specify the TCP port to use when the switch connects to the TACACS+ daemon:

```
tacacs server secondary-host {A.B.C.D} port <1-65535>
```

- c. (Optional) Specify the period of time (in seconds) the switch waits for a response from the TACACS+ daemon before it times out and shows an error:

```
tacacs server secondary-host {A.B.C.D} timeout<10-30>
```

6. Display the status of the TACACS+ configuration:

```
show tacacs
```

7. (Optional) Delete a primary TACACS+ server:

```
no tacacs server host {A.B.C.D} [single-connection] [source source-ip-interface enable]
```
8. (Optional) Delete a backup TACACS+ server:

```
no tacacs server secondary-host {A.B.C.D} [single-connection] [source source-ip-interface enable]
```
9. (Optional) Configure a primary TACACS+ server or secondary TACACS+ server to the default settings:

```
default tacacs server {A.B.C.D} [port] [single-connection] [source source-ip-interface enable] [timeout]
```

Example

Configure the primary server with the IP address 192.0.2.1 and the encryption key 1dt41y. Configure the secondary server with the IP address 198.51.100.2 with the same encryption key 1dt41y. Display the configuration to ensure proper configuration.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#tacacs server host 192.0.2.1 key 1dt41y
Switch:1(config)#tacacs server secondary-host 198.51.100.2 key 1dt41y
Switch:1(config)#show tacacs

Global Status:

  global enable : true

  authentication enabled for : cli

  accounting enabled for : none

  authorization : disabled

  User privilege levels set for command authorization : None

Server:
      create :

Prio      Status  Key          Port  IP address      Timeout Single Source

Backup   NotConn *****    49    198.51.100.2    10     false  0.0.0.0
false

Switch:1(config)#no tacacs server host 192.0.2.1
Switch:1(config)#no tacacs server secondary-host 198.51.100.2
```

Variable Definitions

The following table defines parameters for the **tacacs server host** and the **tacacs server secondary-host** commands.

Variable	Value
<i>{A.B.C.D}</i>	Specifies the IP address of the TACACS+ server you want to add. Only IPv4 addresses are valid.
<i>key WORD</i> <0-128>	Configures the authentication and encryption key for all TACACS+ communications between the device and the TACACS+ server. If the key length is zero, that indicates no encryption is used. You must configure the same encryption key for the TACACS+ server and the switch.
<i>port</i> <1-65535>	Configures the TCP port, on which the client establishes a connection to the server. A value of 0 indicates the system specified default value is used. The default is 49. You must configure the same TCP port for the TACACS+ server and the switch.
<i>single-connection</i>	Specifies if the TCP connection between the device and the TACACS+ server is a single connection. If you specify the single connection parameter, the connection between the switch and the TACACS+ daemon remains open, which is more efficient because it allows the daemon to handle a higher number of TACACS+ operations. The single-connection is torn down if TACACS+ is disabled due to inactivity. If you do not configure this, the switch uses the default connection type, which is the multi-connection. With the multi-connection, the connection opens and closes each time the switch and TACACS+ daemon communicate. Note: You must configure the same connection mode for the TACACS+ server and the switch. To enable single-connection, the TACACS+ daemon has to support this mode as well.
<i>timeout</i> <10-30>	Configures the maximum time, in seconds, to wait for this TACACS+ server to reply before it times out. The default value is 10 seconds.

Configuring TACACS+ authentication

Configure what application TACACS+ authenticates: CLI, web, or all.

TACACS+ authentication provides control of authentication through login and password.

By default, CLI authentication is enabled.

Before You Begin

- You must enable TACACS+ globally for TACACS+ authentication to function.

Procedure

- Enter Global Configuration mode:

```
enable
configure terminal
```
- Configure TACACS+ authentication:

```
tacacs authentication <all/cli/web>
```

3. (Optional) Disable TACACS+ authentication:

```
no tacacs authentication <all/web>
```
4. (Optional) Configure TACACS+ authentication to the default settings (default is cli authentication enabled):

```
default tacacs authentication <all/cli/web>
```
5. Display the configuration:

```
show tacacs
```

Example

Configure TACACS+ to authenticate CLI and display the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#tacacs authentication cli
Switch:1(config)#show tacacs
Global Status:

  global enable : true

  authentication enabled for : cli

  accounting enabled for : none

Server:

      create :

Prio   Status  Key      Port  IP address  Timeout  SingleSource  Source  Enabled
Primary Conn   ***** 49    192.0.2.1   10     false        0.0.0.0 false
Backup NotConn ***** 49    198.51.100.2 10     false        0.0.0.0 false
```

Variable Definitions

The following table defines parameters for the **tacacs authentication** command.

Variable	Value
<i>all</i>	Specifies TACACS+ authentication for all applications. By default, CLI authentication is enabled.
<i>cli</i>	Specifies TACACS+ authentication for command line connections. By default, CLI authentication is enabled.
<i>web</i>	Specifies TACACS+ authentication for web connections. By default, CLI authentication is enabled.

Configuring TACACS+ accounting

Determines for which applications TACACS+ collects accounting information. Use TACACS+ accounting to track the services that users access and the amount of network resources that users consume. If unassigned, TACACS+ does not perform the accounting function.

If enabled, TACACS+ accounting logs the following events:

- User log on and log off
- Log off generated because of activity timeout

- Unauthorized command
- Telnet session closed (not logged off)

If unassigned, TACACS+ does not perform the accounting function. No default value exists.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Enable TACACS+ accounting:
`tacacs accounting enable cli`
3. (Optional) Disable TACACS+ accounting:
`no tacacs accounting cli`

`tacacs accounting disable [cli]`

Example

Enable TACACS+ accounting:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#tacacs accounting enable cli
```

Configuring command authorization with TACACS+

Use this procedure to enable TACACS+ authorization for a particular privilege level. Use this option to limit the use of certain commands to certain users.

If command authorization fails, the following log message displays: `Command <command> not authorized for user <username>`.

By default, command authorization is disabled on the switch. The default for the command authorization level is none.

Before You Begin

- You must have access to and you must configure a TACACS+ server before the TACACS+ features on your switch are available. You must verify that the switch can reach the TACACS+ server and that you configure TACACS+ properly before you enable command authorization. If a user is TACACS+ authenticated and command authorization is enabled for that level, then if the switch cannot reach the TACACS+ server, the switch does not allow you to issue any command that has privilege level command authorization enabled. If the switch cannot reach the TACACS+ server, you can only issue logout and exit commands.
- To use TACACS+ authorization, you must enable TACACS+ authentication.

About This Task

Two kinds of authorization requests exist:

1. Login authorization: Login authorization happens immediately after authentication when the user logs on to the device, authorization provides the user access level. You cannot configure login authorization.
2. Command authorization: When you configure command authorization for a particular level, all commands that you issue are sent to the TACACS+ server for authorization. You need to configure command authorization globally and at individual access levels.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Enable TACACS+ authorization:

```
tacacs authorization enable
```
3. Configure TACACS+ privilege level for TACACS+ command authorization:

```
tacacs authorization level <1-6>

tacacs authorization level all

tacacs authorization level none
```
4. (Optional) Disable TACACS+ authorization:

```
tacacs authorization disable

default tacacs authorization
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#tacacs authorization enable
Switch:1(config)#tacacs authorization level 6
```

Variable Definitions

The following table defines parameters for the **tacacs authorization** command.

Variable	Value
<i>level <1-6></i>	Enables command authorization for a specific privilege level. The default for the command authorization level is none.
<i>level all</i>	Enables command authorization for all privilege levels. The default for the command authorization level is none.
<i>level none</i>	Disables command authorization for all privilege levels. The default for the command authorization level is none.

Changing privilege levels at runtime

Users can change their privilege levels at runtime. The privilege level determines what commands a user can access through TACACS+ server authorization.

A user can only use the **tacacs switch level** command, after TACACS+ authenticates the user. Locally authenticated users, which means users authenticated only by the switch and not by the TACACS+ server, cannot use the **tacacs switch level** command.

Before You Begin

- You need to configure separate profiles in the TACACS+ server configuration file for switch level. As part of the profile, you specify a user name, level, and password.

About This Task

After you enable TACACS+ authorization, the current privilege-level to command mapping on the switch is no longer relevant because the TACACS+ server has complete responsibility for command authorization. TACACS+ authorization provides access to the system based on username, not based on privilege level.

After you enable TACACS+ command authorization for a particular privilege level, and a user with that privilege level logs on, the user can access commands based on his user name.

Note

If you want to switch to a privilege level 'X' using **tacacs switch level <1-15>** command, you must create a user "\$enabX\$" on the TACACS+ server. X is the privilege level to which you want to change.

Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
- Change the privilege level for a user at runtime:

```
tacacs switch level <1-15>
```
- Return to the original privilege level:

```
tacacs switch back
```

Example

Change the privilege level for a user at runtime. Return to the original privilege level:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#tacacs protocol enable
Switch:1(config)#tacacs switch level 5
Password:*****
```

Return to the original privilege level:

```
Switch:1(config)#tacacs switch back
```

Variable Definitions

The following table defines parameters for the **tacacs switch** command.

Variable	Value
<i>level</i> <1–15>	Specifies the privilege level you want to access. You can change your privilege level at runtime by using this parameter. You are prompted to provide the required password. If you do not specify a level in the command, the administration level is selected by default. Note: For switch level, you need to configure separate profiles in the TACACS+ server configuration file. As part of the profile, you specify a username, level, and password. To preconfigure a dummy user for that level on the TACACS+ daemon, the format of the username for the dummy user is \$enab<n>\$, where <n> is the privilege level to which you want to allow access.
<i>back</i>	Specifies that you want to return to the original privilege level.

TACACS+ configuration using EDM

Configure TACACS+ Globally

Enable TACACS+ globally on the switch. TACACS+ is a security application implemented as a client and server-based protocol that provides centralized validation of users. By default, TACACS+ is disabled.

Before You Begin

- You must have access to and you must configure a TACACS+ server before the TACACS+ features on your switch (network access server) are available.

You must verify that the switch can reach the TACACS+ server and that you configure TACACS+ properly before you enable command authorization.

- If a user is TACACS+ authenticated and command authorization is enabled for that level, then if the switch cannot reach the TACACS+ server, the switch does not allow the user to issue any command that has privilege level command authorization enabled. In such a case, the user can only issue logout and exit commands.
- You must enable TACACS+ globally for TACACS+ authentication to function.
- You must enable TACACS+ authentication for TACACS+ authorization to function.

About This Task

Configure what application TACACS+ authenticates. TACACS+ authentication provides control of authentication through login and password dialog, challenge and response. By default, CLI authentication is enabled.

After authentication is complete, the switch starts the authorization process. By default, command authorization is disabled on the switch. The default for the command authorization level is none. If command authorization fails, the following log message displays: `Command <command> not authorized for user <username>.`

Two kinds of authorization requests exist:

1. Login authorization: Login authorization happens immediately after authentication when the user logs on to the device, authorization provides the user access level. You cannot configure login authorization.
2. Command authorization: When you configure command authorization for a particular level, all commands that you issue are sent to the TACACS+ server for authorization. You need to configure command authorization globally and at individual access levels.

Enable TACACS+ accounting function and determine which application TACACS+ accounts. After you enable accounting, the switch reports user activity to the TACACS+ server in the form of accounting records. The default for accounting is none.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **TACACS+**.
3. Click the **TACACS+ Globals** tab.
4. Select the **GlobalEnable** check box to enable TACACS+ globally.
5. Select the **cli** check box to enable the **Accounting** option.
6. Select the **cli** or **web** check box to enable the **Authentication** option.
7. Click the **CliCommandAuthorizationEnabled** box to enable TACACS+ authorization.
8. Select the level in the **CliCommandAuthorizationLevels** box.
9. Click **Apply**.

TACACS+ Globals field descriptions

Use the data in the following table to use the **TACACS+ Globals** tab.

Name	Description
GlobalEnable	Enables or disables the TACACS+ feature globally.
Accounting	<p>Determines for which applications TACACS+ collects accounting information. Use TACACS+ accounting to track the services that users access and the amount of network resources that users consume. If unassigned, TACACS+ does not perform the accounting function. The default is none.</p> <p>If enabled, TACACS+ accounting logs the following events:</p> <ul style="list-style-type: none"> • User log on and log off • Log off generated because of activity timeout • Unauthorized command • Telnet session closed (not logged off)

Name	Description
Authentication	Configures what application TACACS+ authenticates. The options include: <ul style="list-style-type: none"> cli web TACACS + authentication provides control of authentication through login and password dialog, challenge and response. By default, CLI authentication is enabled.
LastUserName	Displays the last user for which the system attempted authentication.
LastAddressType	Displays the type of address to access the TACACS+ server.
LastAddress	Displays the last address to access the TACACS+ server.
CliCommandAuthorizationEnabled	Enables TACACS+ authorization for a particular privilege level. Use this option to limit the use of certain commands to certain users. To use TACACS+ authorization, you must also use TACACS+ authentication. The switch allows the user to access the switch according to the access level. The default is disabled.
CliCommandAuthorizationLevels	Enables command authorization for a specific privilege level. The default for the command authorization level is none.

Add a TACACS+ Server

Add a TACACS+ server, configure the TACACS+ server, and specify the authentication process.

If you have a secondary server configured, the AAA request goes to the backup server if the primary server is not available.

As a best practice, use the Identity Engines Ignition Server as your TACACS+ server.

Before You Begin

You must have access to and you must configure a TACACS+ server before the TACACS+ features on your switch are available.

About This Task

The TACACS+ server and the switch must have the same:

- Encryption key
- Connection mode (single connection or per-session connection. Per-session is the same as multi-connection mode.)
- TCP port number

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **TACACS+**.
3. Select the **TACACS+ Servers** tab.
4. Select **Insert**.
5. In the **AddressType** box, select **ipv4**.
6. In the **Address** field, type the IP address of the TACACS+ server.
7. (Optional) In the **PortNumber** field, type the TCP port on which the client establishes a connection to the TACACS+ server.
8. (Optional) In the **ConnectionType** box, select either **singleConnection** or **perSessionConnection** to specify the TCP connection type between the switch and TACACS+ server.
9. (Optional) In the **Timeout** field, type the period of time (in seconds) the switch waits for a response from the TACACS+ server.
10. In the **Key** field, enter the key that the switch and the TACACS+ server share.
11. In the **Priority** box, select either **primary** or **backup** to determine the order the switch uses the TACACS+ servers.
12. Select **Insert**.

TACACS+ Servers field descriptions

Use the data in the following table to use the **TACACS+ Servers** tab.

Name	Description
AddressType	Specifies the type of IP address to use on the TACACS+ server. You must set the value to IPv4.
Address	Specifies the IP address of the TACACS+ server.
PortNumber	Configures the TCP port on which the client establishes a connection to the server. The default is 49. A value of 0 indicates that the system specified default value is used. You must configure the same TCP port for the TACACS+ server and the switch.

Name	Description
ConnectionType	<p>Specifies if the TCP connection between the device and the TACACS+ server is a single connection. If you specify the single connection parameter, the connection between the switch and the TACACS+ daemon remains open, which is more efficient because it allows the daemon to handle a higher number of TACACS+ operations. The single-connection session is torn down if TACACS+ is disabled due to inactivity. If you do not configure this parameter, the switch uses the default connection type, which is the multi-connection. With the multi-connection, the connection opens and closes each time the switch and TACACS+ daemon communicate.</p> <p>Note: You must configure the same connection mode for the TACACS+ server and the switch. To enable single-connection, the TACACS+ daemon has to support this mode as well.</p>
ConnectionStatus	Specifies if the TCP connection between the device and TACACS+ server is connected or not connected.
Timeout	Configures the maximum time, in seconds, to wait for this TACACS+ server to reply before it times out. The default value is 10 seconds.
Key	Configures the authentication and encryption key for all TACACS+ communications between the device and the TACACS+ server. If the key length is zero, that indicates no encryption is used. You must configure the same encryption key for the TACACS+ server and the switch.
Priority	Determines the order in which the switch uses the TACACS+ servers, where 1 is the highest priority. The priority values are primary and backup. If more than one server shares the same priority, the device uses the servers in the order they exist in the table.

Modify a TACACS+ Configuration

Modify an existing TACACS+ configuration to customize the server.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **TACACS+**.
3. Click **TACACS+ Servers** tab.

4. Double-click in the fields that you want to modify.
In some of the fields, the text becomes bold, which indicates that you can edit them. In other fields, the system displays a list.
5. In the fields that you can edit, type the desired values.
6. In the fields with lists, select the desired option.
7. Click **Apply**.

TACACS+ Configuration Examples

This section provides configuration examples to configure the switch and Identity Engines Ignition Server to use TACACS+.

Figure 235: Switch connects to the TACACS+ server

TACACS+ Configuration on the Switch

The following section shows the steps required to configure TACACS+ on the switch.

The example displays how to:

- Configure a key to be used by the TACACS+ server and the switch. In the example, the key is configured to the word `secret`.
- Configure an IP address for the TACACS+ server. In the example the IP address for the primary server is 192.0.2.8, which is accessible by the management interface.
- Configure the TACACS+ server to authenticate CLI sessions.
- Enable TACACS+.

Switch

```
TACACS CONFIGURATION

tacacs server host 192.0.2.8 key *****
tacacs protocol enable
tacacs accounting enable cli
tacacs authorization enable
tacacs authorization level 6
```

Verify your configuration

The **show tacacs** output must show as `global enable: true` to confirm TACACS is enabled.

The output for the **show tacacs** command must display the IP addresses for the TACACS+ server. The IP addresses must be accessible to the management interface on the switch.

If you want to use the TACACS+ server to authenticate sessions in CLI, the output must display as `authentication enabled for: cli`. If you want to authenticate EDM sessions, the output must display as `authentication enabled for: web`.

Ensure the other parameters match what you have configured.

```
Global Status:

  global enable : true

  authentication enabled for : cli

  accounting enabled for : cli

  authorization : enabled

  User privilege levels set for command authorization : rwa

Server:

      create :

Prio      Status  Key          Port  IP address    Timeout Single Source
SourceEnabled
Primary  Conn   *****    49    192.0.2.8     10    false  0.0.0.0
false
```

Identity Engines Ignition Server TACACS+ Configuration Example

The following section shows the steps required to configure TACACS+ on Identity Engines Ignition Server, Release 8.0. Use the preceding information to configure the switch.

A TACACS+ server responds to and audits network access requests. In an installation, the Identity Engines Ignition Server is the TACACS+ server.

The example displays how to do the following:

- Enable TACACS+
- Configure a user
- Create a command set
- Configure the authentication protocol policy
- Create the authorization policy
- Configure TACACS+ authenticators

For more information on the Ignition Server, see *Identity Engines Ignition Server Administration*.

Before You Begin

- Configure the Ignition Server appliance and set up its network settings. For more information, see *Identity Engines Ignition Server Getting Started*.
- Install the Ignition Dashboard on your Windows OS.

- Configure each authenticator (switch) to recognize the Ignition Server appliance as its TACACS+ server.
- Configure your switch to send packets to the Ignition Server appliance with the appropriate IP address and port.
- Ensure licenses are up-to-date.

Procedure

1. If the Ignition Server Dashboard is not connected to your Ignition Server, select **Administration: Login** to connect.
 - a. The default login credentials for **User Name** and **Password** are `admin/admin`. change the default values.
 - b. In the **Connect to** field enter the IP address of the Ignition Server for TACACS+. In this example, the IP address for the TACACS+ server is 192.0.2.8.
2. Enable TACACS+.
 - a. In the Ignition Server Dashboard, select **Site 0**.
 - b. In the Sites window, select the **Services** tab.
 - c. Under the Services tab, select the **TACACS+** tab.
 - d. Click the **Edit** button in the TACACS+ tab.
 - e. In the **Edit TACACS+ Configuration** dialog box, select the **Protocol is enabled** box.
 - f. In the **Bound Interface** field, select **Admin Port**.
 - g. In the **Port** field, enter 49.
 - h. Select **Accept Requests from Any Authenticator**.

Select this option if you want to create a global TACACS+ authenticator that sets policy for all authenticators that do not match a specific TACACS+-enabled authentication in your Ignition Server configuration.
 - i. In the **Access Policy** field, select **default-tacacs-admin**.

Use this configuration in the case of a global TACACS+ authenticator. Choose your global TACACS+ policy that you want applied if the device finds no better matching authenticator.
 - j. In **TACACS+ Shared Secret** field, enter the secret that the switch and TACACS+ Ignition Server share. In this example, the shared secret is `secret`.
 - k. Click **OK**.
3. Configure a user recognized by the TACACS + server.
 - a. In the Ignition Server Dashboard, expand the Configuration tree: **Site Configuration > Directories > Internal Store > Internal Users**.
 - b. Click **New**.

- c. Fill in the appropriate fields.
As an example:
User Name: jsmith
First Name: John
Last Name: Smith
Password: test
Confirm password: test
4. If your TACACS+ policy uses per-command authorization, create a command set.
 - a. In the Ignition Server Dashboard, expand the Configuration tree: **Site Configuration > Access Policies > TACACS+**.
 - b. Click **Define Command Sets**.
 - c. Click **New**.
 - d. In the New Device Command Set window, type a **Name** and **Description** for the command set; for instance, level5.

In this window you build your command set by adding commands to the list. You can build the command list manually or you can import a list. For more information on importing a command list, see *Identity Engines Ignition Server Administration*.
 - e. To manually add the commands, click **Add** in the New/Edit Device Command Set window.
 - f. Click the **Simple Command Using Keywords and Arguments** box.
 - g. In the **Command** field, type the command, and optionally its arguments.
 - h. To allow the command to be used with any argument, select the **Allow** box.
 - i. To allow only the specific command and arguments you have types, tick the **Deny** box.
 - j. Click **OK** to add the command to the list.
 - k. Continue to add the commands that you want.
5. If your TACACS+ policy uses privilege-level authorization, create the TACACS+ access policy to allow the TACACS+ Ignition Server to communicate with the switch.
 - a. In the Ignition Server Dashboard, expand the Configuration tree: **Site Configuration > Access Policies > TACACS+**.
 - b. Select **default-tacacs-admin**.
 - c. Click on the **Authorization Policy** tab and select the name of the policy you want to edit.
 - d. Click **Edit** and the **Edit Authorization Policy** window opens.
 - e. In the **Rules** section, select the rule you want to edit. In this case select level5, to which you have already added commands.

The **Rules** list at the left lets you browse and sort the rules in your policy. Use the up and down arrow buttons at the right to set the rule sequence, and click a rule name in the list to edit that rule. The Selected Rule Details section lets you edit the rule you have selected.
 - f. In the Selected Rule Details section, under **Rule Name**, for this example, it reads level5.
 - g. Select **Rule Enabled**.
 - h. With level5 selected in the Rules list, go to the buttons to the right of the **Constraint** list and click **New**.
 - i. In the Action section, select **Allow**.

- j. Select the **Command Sets** tab, in the Action section. Allow Commands in Set should read level-5, in this example, and under All Command Sets all the commands that are accessible under level5 should be listed.
- k. Click **OK**.

For this example to function properly, the summary window must display:

```
IF User: user-id = level5 THEN Allow
```

```
Permit commands in Command Set: level-5
```

6. Configure the Ignition Server to connect to authenticators, which is the switch:
 - a. In the Ignition Server Dashboard, expand **Site Configuration** > **Authenticators** > **default** and the Authenticator Summary window opens.
 - b. Click **New**, and the Authenticator Details window appears.
 - c. For this example, type `switch1` under name.
 - d. To the right select **Enable Authenticator**.
 - e. Type the IP address for the switch, which is the authenticator. Use the primary CPU address or the management virtual address.
 - f. In the **Vendor** field, select **Nortel**.
 - g. In the **Device template** field, select **ers-switches-nortel**.
 - h. Select the **TACACS+ Settings** tab.
 - i. Select **Enable TACACS+ Access**.
 - j. In the **TACACS+ Shared Secret** field, type the key value you entered into the switch. In this example, the key is the word `secret`.

To connect using TACACS+, you must use the shared secret for each device. In your switch documentation, the shared secret can also be referred to as a specific key string or an encryption string.
 - k. Under **Access Policy**, select **default-tacacs-user**.
 - l. Click **OK**.

Traffic Filtering

[Traffic filtering fundamentals on page 2956](#)

[Access control list configuration using CLI on page 2978](#)

[Access control list configuration using EDM on page 2990](#)

[Access Control Entry Configuration using CLI on page 2999](#)

[Access Control Entry Configuration using EDM on page 3024](#)

Traffic filtering can generally provide a mechanism to accurately manage and secure network flows or prioritize crucial information over other network traffic.

The following topics provide necessary concepts and procedures to configure an access control list (ACL) and access control entry (ACE) to filter traffic.

Traffic filtering fundamentals

Use the information in this section to help you understand filtering. This section describes a range of features that you can use with the switch to allocate network resources to apply filters.

In a large and busy network, traffic management is very important and can be complex. Traffic filtering can generally provide a mechanism to accurately manage and secure network flows or prioritize crucial information over other network traffic. Some of the primary uses of filtering are:

- Manage traffic flows.
- Implement security permissions on network traffic.
- Prioritize mission critical traffic flows.
- Redirect traffic to firewalls or other devices to efficiently manage bandwidth.

Overview of Traffic Filtering

Traffic filtering on the switch is based on ACL filter implementation. Access Control List (ACL) based filters are a means to provide predictable and flexible traffic filtering. ACL Traffic filters can be configured using the Command Line Interface (CLI) or the Enterprise Device Manager (EDM). ACL filters set a list of criteria for the network traffic to be matched against, performing a predefined set of actions. Access Control Lists and Action Control Entries provide traffic filtering services on the switch.

Traffic filtering supports IPv6 ingress and egress port/vlan security and QoS ACL/filters. IPv6 egress QoS ACL/filters are not supported.

QoS and Filters

The switch has functions you can use to provide appropriate QoS levels to traffic for each customer, application, or packet. These functions include port-based shapers, DiffServ access or core port settings, and ingress port-rate limiting or policing. The switch also provides access control list (ACL)-based filters. You do not need to use filters to provide QoS; however, filters aid in prioritizing customer traffic. Filters also provide protection by blocking unwanted traffic.

Port rate limiting or policing apply at ingress; shapers apply at egress. ACL-based filters apply at ingress and egress.

There are four ingress filter groups:

- Port-based Security ACEs
- Port-based QoS ACEs
- VLAN-based Security ACEs
- VLAN-based QoS ACEs

Note

On 5320 Series, two ingress filter groups exist: port-based and VLAN-based ACEs. Each type can hold both Security and QoS actions. No parallel look up is performed.

Filters help you provide QoS by permitting or dropping traffic based on the parameters you configure. You can use filters to mark packets for specific treatment.

Typically, filters act as firewalls or are used for Layer 3 redirection. In more advanced cases, traffic filters can identify Layer 3 and Layer 4 traffic streams. The filters cause the streams to be re-marked and classified to attain a specific QoS level at both Layer 2 (802.1p) and Layer 3 (DSCP).

Traffic filtering is a key QoS feature. The switch, by default, determines incoming packet 802.1p or DiffServ markings, and forwards traffic based on their assigned QoS levels. However, situations exist where the markings are incorrect, or the originating user application does not have 802.1p or DiffServ marking capabilities. Also, you can give a higher priority to select users (executive class). In these situations, use filters to prioritize specific traffic streams.

You can use filters to assign QoS levels to devices and applications. To help you decide whether to use a filter, key questions include:

1. Does the user or application have the ability to mark QoS information on data packets?
2. Is the traffic source trusted? Are the QoS levels configured appropriately for each data source?

Users can maliciously configure QoS levels on their devices to take advantage of higher priority levels.

3. Do you want to prioritize traffic streams?

This decision-making process is outlined in the following figure.

Figure 236: Filter decision-making process

Configure filters through the use of Access Control Lists (ACL) and Access Control Entries (ACE), which are implemented in hardware. An ACL can include both security and QoS type ACEs.

The following steps summarize the filter configuration process:

1. Determine your desired match fields.
2. Create an ACL.
3. Create an ACE within the ACL.
4. Configure the desired precedence, traffic type, and action.

You determine the traffic type by creating an ingress or egress ACL.

5. Modify the parameters for the ACE.

Access control lists

Table 216: Access Control List product support

Feature	Product	Release introduced
Access Control List (ACL)-based filtering, including egress ACLs, ingress ACLs, Layer 2 to Layer 4 filtering, port-based, and VLAN-based	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
InVSN Filter	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
IPv6 ingress filters	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5

Table 216: Access Control List product support (continued)

Feature	Product	Release introduced
IPv6 egress filters	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
IPv6 ACL DSCP Remarking	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.5
	5520 Series	VOSS 8.5

Apply rules to incoming and outgoing traffic. The total number of ACLs that you can configure differs depending on the switch.

An ACL can filter either IPv6 or non-IPv6 packets. By default, an ACL filters non-IPv6 packets. You must specify the packet type as IPv6 at the ACL level to enable IPv6 filtering. You cannot change the packet type for the ACL after you configure it. If you need a different packet type, you must delete the ACL, and then re-create it with the other packet type.

You can associate an ACL with the following interfaces:

- Ingress port (inPort)
- Ingress VLAN (inVLAN)
- Ingress VSN (inVSN)
- Egress port (outPort)

**Note**

VLAN-based ACL filters are not supported on a DvR Leaf node.

**Note**

All ACLs are enabled when a DvR Leaf node is created. When creating the DvR Leaf node, or when you enable IS-IS globally, the message `dvr leaf [x]` displays in CLI. If the DvR Leaf node is reset or reconnects to the DvR domain, this message does not display but the same principle applies. As a best practice, delete ACLs not used on DvR Leaf nodes, rather than disable them, because the ACLs re-enable without warning after a DvR domain transition caused by reset, or protocol or link bounce.

The ingress VLAN ACL associations apply to all active port members of a VLAN. An ACL is created in the enabled state by default.

The InVSN Filter is an Access Control List (ACL) that can be used with MAC-in-MAC (MIM) encapsulated packets that are received on the Network Node Interface (NNI) ingress ports and are routed or bridged to UNI ports or terminated on the fabric node. The InVSN Filter matches and filters IPv4 and IPv6 packet headers coming on UNI ports only, NNI ports only, or both UNI and NNI ports. The InVSN Filter does not filter packets that arrive on NNI ingress ports but are bridged to other NNI ports or are for transit traffic.

An ACL can contain multiple filter rules called Access Control Entries (ACE). ACEs provide match criteria and rules for ACL-based filters. An ACE can provide actions such as dropping a packet,

monitoring a packet, or remarking QoS on a packet. Complete lists of actions are provided in the Access Control Entries section. After an ingress or egress packet meets the match criteria specified in ACEs within an ACL, the system executes the predefined action.

ACLs provide the ability to configure default and global actions. A default action is applied when no filter rule (ACE) matches on a packet flow. The global action is executed when any filter rule (ACE) matches on a packet flow. The default action mode for ACLs is permit. ACL global actions are:

- monitor-dst-mlt
- monitor-dst-ports

The following figure shows the relationships between ACEs and VLAN- and port-based ACLs.

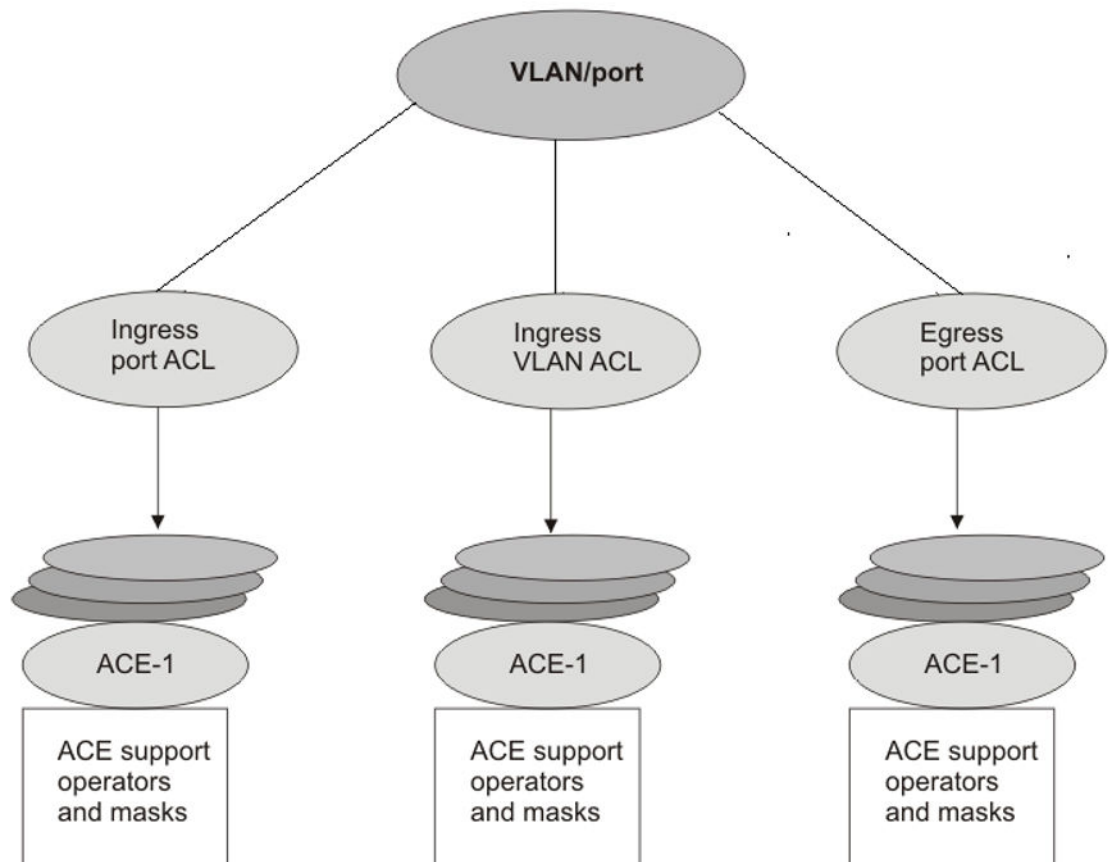

Figure 237: ACE and ACL relationships

Access control entries

Table 217: Access Control Entry product support

Feature	Product	Release introduced
QoS Access Control Entries (ACE)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
Security ACEs	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
Filter enhancement - Apply ACE to Routed Packets only	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.4
Policy Based Routing (redirect-next-hop)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
Policy Based Routing (redirect-next-hop) with VRF support	5320 Series	Fabric Engine 8.6 Only 5320-48P-8XE and 5320-48T-8XE support more than one VRF with IP configuration.
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5

The switch filter rules are defined using Access Control Entries (ACE). An ACE is an ordered set of filter rules contained in an Access Control List (ACL). ACE rules are divided into the following three components:

- Operators
- Attributes
- Actions

An ACE generally operates on fields in a packet. If a packet field matches an ACE rule, the system executes the action specified. As each packet enters through an interface with an associated ACL, the system scans the ACE list configured on that ACL and matches on the packet fields. If multiple ACE rules are associated with the ACL, the lower ACE ID will have a higher precedence.

Operators

ACEs use operators to match on packet fields. The switch supports the following operators:

- Equal-to

This rule operator looks for an exact match with the field defined. If the field matches exactly with the rule, the system will return a match (hit). If the rule does not match, the search continues and at the end of the search a miss is returned.

- Mask

ACL-based filters provide the mask operator to match on Layer 2, Layer 3, and Layer 4 packet fields. The mask operator is used to mask bits in packet fields during a search or to match on a partial value of a packet field. This section provides examples of the mask operator.

If a mask bit is set to 1, it means it is not part of the match criteria (treated as do not care), and a mask bit of 0 means that the value represented is part of the match criteria. You can use the mask operator for the following attributes:

- source MAC address
- destination MAC address
- VLAN ID
- Dot1p
- IPv4/IPv6 source address
- IPv4/IPv6 destination address
- destination IP address
- DSCP
- Layer 4 source port
- Layer 4 destination port
- TCP flags

**Note**

MAC Address cannot be configured as attributes for IPv6 filters.

The syntax for ACL and ACE configuration of a mask is similar to the use of equal operator, except that you provide the mask value. You can specify a mask value (number) to represent the bits to mask in the attribute. You can define a mask in different ways depending on the attribute you need to mask:

- If you use a decimal number for an IP address mask, it specifies the most significant bits of the provided IP address to match on. For example, a mask of 24 used with an IP address is the same as a mask of 0.0.0.255, and a mask of 8 used with an IP address is the same as a mask of 0.255.255.255.
- If you use a decimal number for a MAC address mask, it specifies the least significant bits of the provided MAC address to ignore. For example, a mask of 32 used with a MAC address is the same as a mask of 0x0000ffffff, and a mask of 16 used with a MAC address is the same as a mask of 0x00000000ffff.

**Note**

Unlike the standard convention, for ACL filter configuration, a mask bit value of '1' specifies a do-not-care bit, and value of '0' signifies must-match bit.

The following table explains the mask operator for MAC addresses.

Table 218: Mask operator for MAC address

Rule	Result
<pre>filter acl ace ethernet 10 10 dst- mac mask 01:00:5e:00:00:01 0x000000FFFFFF</pre>	The rule matches only on the most significant 24 bits as they are not masked, for example, 01:00:5e, and does not care about the least significant 24 bits because they are masked; the least significant 24 bits can have a value of 00:00:00 - FF:FF:FF.
<pre>filter acl ace ethernet 10 10 dst- mac mask 0x01:00:5e:00:00:01 0xFFFFFFFF0000</pre>	The rule matches only on the least significant 16 bits because they are not masked, for example, 00:01, and does not care about the most significant 32 bits because they are masked; the most significant 32 bits can have a value of 00:00:00:00 - FF:FF:FF:FF.
<pre>filter acl ace ethernet 10 10 dst- mac mask 0x01:00:5e:00:00:01 0xFF00FF0000FF</pre>	The rule matches only on the unmasked bits, for example, 0xXX:00:XX:00:00:XX. The rule matches only on the bits not masked, for example, all the zeroes and the x represents a do not care (0xXX:00:XX:00:00:XX)

The following table explains the mask operator for IP addresses.

Table 219: Mask operator for IP address

Rule	Result
<pre>filter acl ace ip 10 10 src-ip mask 2.10.10.12 0.255.255.255</pre>	The rule matches only the most significant 8 bits, and does not care about the value of the remaining 24 bits as they are considered masked. For example, 10.10.12. Packets with a source IP address of 2.15.16.122 or 2.3.4.5 match on the filter rule while packets with a source IP address of 3.10.10.12 and 4.10.10.12 do not match on the filter rule.
<pre>filter acl ace ip 10 10 src-ip mask 3.4.5.6 255.255.255.0</pre>	The rule matches only the least significant 8 bits, for example, 6, and does not care about the most significant 24 bits, 3.4.5. Packets with a source IP address of 17.16.5.6 or 192.168.1.6 match on the filter rule while packets with a source IP address of 3.4.5.4 or 3.4.5.7 do not match on the filter rule.

The following table explains the mask operator for Layer 4 source port.

Table 220: Mask operator for Layer 4 source port

Rule	Result
<pre>filter acl ace protocol 10 10 src- port mask 80 0xF</pre>	The filter rule matches on Layer 4 source port 80 (1010000). The mask value 0xF (1111) masks the least significant 4 bits, which means source port 81 (1010001) through 95 (1011111) also match this filter rule. This means the range 80–95 is a match on this rule.

The following table demonstrates the resulting action based on mask configuration and example packets.

Table 221: Mask operator configuration examples

Filter configuration	Address examples that match the filter	Address examples that do not match the filter
<pre>Ethernet mask: filter acl 1000 type inport filter acl port 1000 6/5,9/11 filter acl ace 1000 12 filter acl ace ethernet 1000 12 src- mac mask 00:00:11:11:16:00 0x00ff000000f0 filter acl ace action 1000 12 permit count filter acl ace 1000 12 enable</pre>	<pre>Source MAC: 00:01:11:11:16:10 00:10:11:11:16:f0 00:1f:11:11:16:10 00:ff:11:11:16:f0 00:00:11:11:16:60 00:e6:11:11:16:e0</pre>	<pre>Source MAC: 00:00:11:11:16:01 00:ff:11:11:16:f1</pre>
<pre>filter acl ace 1000 1000 filter acl ace ethernet 1000 1000 dst-mac mask 00:00:00:64:16:00 0x00000060001f filter acl ace action 1000 1000 deny count filter acl ace 1000 1000 enable</pre>	<pre>Destination MAC: 00:00:00:64:16:01 00:00:00:04:16:01 00:00:00:24:16:1f 00:00:00:64:16:1f 00:00:00:44:16:10 00:00:00:04:16:05</pre>	<pre>Destination MAC: 00:00:00:24:16:20 00:00:00:64:16:20 00:00:00:63:16:01 00:00:00:65:16:01</pre>
<pre>IP mask (dotted decimal notation): filter acl 10 type outport filter acl port 10 5/13 filter acl ace 10 11 filter acl ace ethernet 10 11 ether- type eq ip filter acl ace ip 10 11 src-ip mask 192.168.4.0 0.0.0.31 filter acl ace action 10 11 permit count filter acl ace 10 11 enable</pre>	<pre>Source IP: 192.168.4.1 192.168.4.10 192.168.4.30 192.168.4.31</pre>	<pre>Source IP: 192.168.3.1 192.168.4.32</pre>

Table 221: Mask operator configuration examples (continued)

Filter configuration	Address examples that match the filter	Address examples that do not match the filter
<pre>filter acl ace 10 12 filter acl ace ethernet 10 12 ether- type eq ip filter acl ace ip 10 12 dst-ip mask 192.168.7.0 0.0.0.3 filter acl ace action 10 12 deny count filter acl ace 10 12 enable</pre>	Destination IP: 192.168.7.1 192.168.7.3	Destination IP: 192.168.7.4 192.168.7.5
<p>IP mask (decimal notation):</p> <pre>filter acl 10 type outport filter acl port 10 5/13 filter acl ace 10 11 filter acl ace ethernet 10 11 ether- type eq ip filter acl ace ip 10 11 src-ip mask 192.168.4.0 255.255.255.31 filter acl ace action 10 11 permit count filter acl ace 10 11 enable</pre>	Source IP: 192.168.4.1 192.168.4.10 192.168.4.30 192.168.4.31	Source IP: 192.168.3.1 192.168.4.32

<p>Protocol mask:</p> <pre>filter acl 901 type inport filter acl port 901 6/2 filter acl ace 901 1 filter acl ace ip 901 1 ip-protocol- type eq tcp filter acl ace protocol 901 1 src- port mask 256 0xff filter acl ace action 901 1 deny count filter acl ace 901 1 enable</pre> <p>This mask implies packets with TCP source port 256-511 match the filter, while 0-255 and > 511 miss the filter.</p>	TCP source port 256 TCP source port 356 TCP source port 511	TCP source port 255 TCP source port 512

Attributes

Attributes are fields in a packet (Layer 2, Layer 3, Layer 4) or other information related to the packet on which an ACE rule is applied like slot/port. The list of all the attributes and the operators that could be applied on them are listed below.

If you want to configure IPv6 attributes, you must configure an ACL to filter either IPv6 or non-IPv6 traffic. You can only configure IPv6 attributes for IPv6 packets. You cannot configure IPv6 attributes for non-IPv6 packets.

Table 222: Attribute list

Attribute Name	Operator
Slot/Port	Equal
Destination MAC (IPv4 filters only)	Equal, Mask
Source MAC (IPv4 filters only)	Equal, Mask
VLAN ID	Equal, Mask
.1p bits	Equal, Mask
Ether Type	Equal
ARP Opcode	Equal
Source IP	Equal, Mask
Destination IP	Equal, Mask
Protocol Type	Equal
Type of Service	Equal, Mask
IP Fragmentation	Equal
IP Options	Equal
Layer 4 Destination Port	Equal, Mask
Layer 4 Source Port	Equal, Mask
TCP Flags	Equal, Mask
ICMP Message Type	Equal
Source IPv6 (IPv6 only)	Equal, Mask
Destination IPv6 (IPv6 only)	Equal, Mask
Next header (IPv6 only)	Equal
Traffic class (IPv6 only)	Equal
Routed only	Equal

5320 Series Restrictions

Note the following restrictions to the attribute list:

- 48-port 5320 Series models support .1p bits for both IPv4 and IPv6 ACLs. 16-port and 24-port 5320 Series models support .1p bits for IPv4 ACLs only.
- 16-port and 24-port 5320 Series models are restricted to a maximum of 15 distinct values for each source/destination port. The following list identifies the reserved entries in the 15 number set:
 - 67-68 [DHCP]
 - 546-547 [DHCPv6]
 - 53 [DNS]
 - 23, 2323 [Telnet]

- 48-port 5320 Series models support TCP flags for both IPv4 and IPv6 ACLs. 16-port and 24-port 5320 Series models support TCP flags for IPv4 ACLs only.
- 48-port 5320 Series models support ICMP Message Type for both IPv4 and IPv6 ACLs. 16-port and 24-port 5320 Series models support ICMP Message Type for IPv4 ACLs only.
-
- Only the 48-port 5320 Series models support the attributes identified as IPv6 only.

Actions

Actions occur when the filter rule is hit or missed. The types of actions that the filter configuration can execute are split into two categories:

- security actions supported by the ACE IDs.
- QoS actions supported by the ACE IDs.

Note

- Ingress ACLs support security and QoS ACE actions. Egress ACLs do not support QoS ACEs.

Filter rules that support Security actions and QoS actions are stored separately. If an ACL filter is applied to a traffic flow, the switch performs a parallel search, if supported, on both Security and QoS ACE lists, which results in distinct and non-conflicting actions.

Note

The ACE ID range for both security and QoS actions is different for different hardware platforms. Parallel search is not supported on all hardware platforms. For more information, see [ACL Filters Behavior Differences](#) on page 2976.

The following tables show the supported switch actions:

Table 223: Security ACE Actions

Security ACE Actions	User supplied parameters	Comments
mode	Permit or Deny	Applies to both Ingress and Egress ACLs.
redirect-next-hop	IP address, Mode	<p>Redirects the packet to the user supplied IP address. If the switch cannot resolve ARP for the user-specified next-hop, packets that match the filter are dropped.</p> <p>Note: The filter does not redirect packets with a time-to-live (TTL) of 1 nor does it send them to the CPU where the CPU would generate ICMP TTL expired messages. IP Traceroute reports a timeout for the hop.</p> <p>Note: The filter with policer only redirects the traffic that passes the policer. For instance, if the stream is 100 Mbps and the policer peak rate is 50 Mbps, only 50 Mbps is redirected.</p> <p>Applies to ingress IPv4 ACLs only (routed and Layer 2).</p>
count	None	Collect ACE statistics. Applies to Ingress and Egress ACLs.
monitor-dst-mlt	mlt-id	Applies to Ingress ACLs only.
monitor-dst-ports	Port	Applies to Ingress ACLs only.
monitor I-SID offset	None	<p>The actual monitor I-SID value to which packets are mirrored.</p> <p>Note: This action is not supported on all hardware platforms.</p>

Table 224: QoS ACE Actions

QoS ACE Actions	User supplied parameters	Comments
<ul style="list-style-type: none"> • remark-dscp • remark-dot1p • internal-qos 	<ul style="list-style-type: none"> • DCSP • dot1p (ingress only) • Internal-qos 	<p>Applies to Ingress ACLs.</p> <p>Note: remark-dot1p and internal-qos do not apply to IPv6 filtering.</p> <p>Each QoS action has its own user-supplied parameters.</p> <p>Note: Some hardware platforms do not support remark-dot1p and supports remark-DSCP for Layer 3 routed packets only.</p>
count	None	Applies to Ingress and Egress ACLs.

When you configure an IPv6 ACL with an ACE action of remark DSCP for a mirrored packet, the mirrored copy does not include the remark DSCP value. Because of port-mirroring functionality, the mirrored copy does not reflect the changes that occur in the switch to the outgoing packet. As a result, the mirrored copy is not identical to the outgoing packet. For more information, see [Port Mirroring](#) on page 3133.

Internal QoS Level and Remarking

Setting the internal QoS level is an ingress action. Remarking is an egress action.

The internal-qos action assigns a new value to the packet internal-qos. It determines the packet egress queue, outgoing packet dot1p value and egress-DSCP value.

The remark-dot1p action assigns a new dot1p value to the outgoing packet. The remark-DSCP action assigns a new DSCP value to the outgoing packet.

If a packet is filtered by a rule set to internal-qos action only, then the packet internal qos, egress queue, egress dot1p and egress DSCP will be derived from the filter internal-qos value.

If a packet is filtered by a rule set to remark-dot1p only or remark-DSCP only or both remark actions, then the packet will be remarked with the new dot1p or DSCP, or both. However, these remarked values will not have any impact on the internal-qos packet. It will be based on the native packet coming into the switch.

If a packet is filtered by a rule set with all three qos actions, then the internal-qos will determine the egress queue, but the remark-dot1p determines the egress dot1p and the remark-DSCP determines the egress DSCP.

If you want to change the internal QoS for remarked incoming packets, you have to add the **permit internal-qos** command as shown in the following ACL filter example.

```
filter acl 10 type inPort name "ACL-CTI"
filter acl port 10 1/2-1/50
filter acl ace 10 1302 name "CIFS-SCCM Source"
filter acl ace action 10 1302 permit remark-dscp phbaf11 remark-dot1p 1 count
filter acl ace action 10 1302 permit internal-qos 0
filter acl ace ethernet 10 1302 ether-type eq ip
filter acl ace ip 10 1302 src-ip mask 0.0.0.0 255.255.255.255
filter acl ace ip 10 1302 ip-protocol-type eq tcp
filter acl ace protocol 10 1302 src-port mask 0 0xffff
```

When a packet goes through the switch, the internal QoS level governs which queue the packet uses on egress. To verify which queue the packets are egressing on, use the **show qos cosq-stats interface [value]** command. For more information, see [View Port Egress CoS Queue Statistics](#) on page 2307 or [Viewing port egress CoS queue statistics](#) on page 2317.

Conflict and Precedence

The switch supports both port-based and VLAN-based ACLs. A port can be associated with both Port-based ACL and a VLAN-based ACL, as shown in [Access control lists](#) on page 2958. Within an ACL, a rule match can generate security actions and QoS actions. The system goes through a set of precedence levels to resolve any conflicting actions between port-based ACL and VLAN-based ACL lookup. The

following table provides a list of search results and actions for all possible conflicts between port and VLAN-based ACLs and security and QoS ACE for each ACL.

Table 225: Conflict and Precedence resolution

Port-based ACL look up		Actions performed on Port-based ACL		If VLAN-based ACL is enabled		Actions performed on VLAN-based ACL search	
Security	QoS	Security action	QoS action	Security	QoS	Security action	QoS action
Security ACE search is a Miss and ACL mode is Permit.	QoS ACE search is a Miss	Default security statistics collected	Default QoS statistics collected	Security ACE search is a Miss and mode is set to Permit	QoS ACE search is a Miss	Collect default Miss statistics	Collect default Miss statistics
				Security ACE search is a Miss and mode is set to Permit	QoS ACE search returns a Hit	Collect default Miss statistics	Execute configured ACE and default ACL actions
				Security ACE search is a Miss and mode is set to Deny	Search result is invalid, since security mode is set to Deny	Drop packet and collect default Miss statistics	No action is executed
				Security ACE search is a Hit and mode is set to Permit	QoS ACE search returns a Miss	Execute configured ACE and default ACL actions	Collect default Miss statistics
				Security ACE search is a Hit and mode is set to Permit	QoS ACE search is a Hit	Execute configured ACE and default ACL actions	Execute configured ACE and default ACL actions
				Security ACE search is a Hit and mode is set to Deny	QoS ACE search returns a Hit	Discard the packet and execute configured ACE and global actions	No action is executed
Security ACE is Miss and ACL mode is Deny	Search result is invalid since security mode is set to Deny	Discard the packet and collect default statistics	No action is executed	VLAN-based ACL is not configured	VLAN-based ACL is not configured	No action is executed	No action is executed

Table 225: Conflict and Precedence resolution (continued)

Port-based ACL look up		Actions performed on Port-based ACL		If VLAN-based ACL is enabled		Actions performed on VLAN-based ACL search	
Security	QoS	Security action	QoS action	Security	QoS	Security action	QoS action
Security ACE search is a Miss and ACL mode is set to Permit	QoS ACE search is a Hit	Default search statistics collected	Execute configured ACE and default ACL actions	Security ACE search is a Miss and mode is set to Permit	Port-based ACL's QoS action take precedence. QoS search result invalid.	Collect default Miss statistics	No action is executed
				Security ACE search is a Miss and mode is set to Deny	Port-based ACL's QoS action take precedence. QoS search result invalid.	Drop packet and collect default Miss statistics	No action is executed
				Security ACE search is a Hit and mode is set to Permit	Port-based ACL's QoS action take precedence. QoS search result invalid.	Execute configured ACE and default ACL actions	No action is executed
				Security ACE search is a Hit and mode is set to Deny	Port-based ACL's QoS action take precedence. QoS search result invalid.	Discard the packet and execute configured ACE and global Actions	No action is executed
Security ACE search is a Hit and ACE mode is Permit	QoS ACE search is a Miss	Execute configured ACE and default ACL actions	Collect default Miss statistics	Port-based ACL's Security action take precedence. Security search result invalid	QoS ACE search returns a Miss	No action is executed	Collect default Miss statistics
				Port-based ACL's Security action take precedence. Security search result invalid.	QoS ACE search returns a Hit	No action is executed	Execute configured ACE and default ACL actions

Table 225: Conflict and Precedence resolution (continued)

Port-based ACL look up		Actions performed on Port-based ACL		If VLAN-based ACL is enabled		Actions performed on VLAN-based ACL search	
Security	QoS	Security action	QoS action	Security	QoS	Security action	QoS action
Security ACE search is a Hit and ACE mode is Permit	QoS ACE search is a Hit	Execute configured ACE and default ACL actions	Execute configured ACE and default ACL actions.	Port-based ACL's Security action take precedence. Security search result invalid	Port-based ACL's QoS action take precedence. QoS search result invalid.	No action is executed	No action is executed
Security ACE search is a Hit and ACE mode is Deny	Search result is invalid since Security mode is set to Deny	Discard the packet and collect default statistics	No action is executed	Port-based ACL's Security action take precedence. Security search result invalid	Port-based ACL's QoS action take precedence. QoS search result invalid.	No action is executed	No action is executed

Common ACE uses and configuration

The following table describes configurations you can use to perform common actions.

Table 226: Common ACE uses and configurations

Function	ACE configuration
Permit a specific host to access the network	<ul style="list-style-type: none"> Use action permit. Configure the source IP address to be the host IP address. <pre>filter acl ace 1 5 name "Permit_access_to_198.51.100.0" filter acl ace action 1 5 permit filter acl ace ethernet 1 5 ether-type eq ip filter acl ace ip 1 5 src-ip eq 198.51.100.0 filter acl ace 1 5 enable</pre>
Deny a specific host from accessing the network	<ul style="list-style-type: none"> Use action deny. Configure the source IP address to be the host IP address. <pre>filter acl ace 1 5 name "Deny_access_to_198.51.100.0" filter acl ace action 1 5 deny filter acl ace ethernet 1 5 ether-type eq ip filter acl ace ip 1 5 src-ip eq 198.51.100.0 filter acl ace 1 5 enable</pre>

Table 226: Common ACE uses and configurations (continued)

Function	ACE configuration
Permit a specific range of hosts to access the network	<ul style="list-style-type: none"> Use action permit. Configure the source IP address to be the range of host IP addresses. <pre>filter acl ace 1 5 name "Permit_access_to_1.2.3.4-1.2.3.7" filter acl ace action 1 5 permit filter acl ace ethernet 1 5 ether-type eq ip filter acl ace ip 1 5 src-ip mask 1.2.3.4 0.0.0.3 filter acl ace 1 5 enable</pre>
Deny Telnet traffic	<ul style="list-style-type: none"> Use action deny. Deny FTP traffic	<ul style="list-style-type: none"> Use action deny. Configure the protocol as TCP and the TCP destination port to be 21. <pre>filter acl ace 1 5 name "Deny_ftp" filter acl ace action 1 5 deny filter acl ace ethernet 1 5 ethertype eq ip filter acl ace ip 1 5 ip-protocoltype eq tcp filter acl ace protocol 1 5 dst-port eq 21 filter acl ace 1 5 enable</pre>

Switched UNI ACL Filters

InPort and OutPort filters are supported on Switched UNI (S-UNI) and Fabric Attach ports.

Note

InPort and outPort filters are supported on S-UNI and Fabric Attach ports for the traffic mapped to an I-SID which does not have platform VLAN associated. The Customer VLAN-ID (CVID) can be applied as VLAN-ID qualifier in inPort and outPort filters.

Note

InPort, outPort, and inVLAN filters are supported on S-UNI and Fabric Attach ports for the traffic mapped to an I-SID which has platform VLAN associated. The platform VLAN should be used as VLAN-ID in inPort and inVLAN filters, and the CVID as VLAN-ID in the outPort filter.

Traffic filter configuration

Traffic filtering manages traffic by defining filtering conditions and associating these conditions with specific actions. The following steps summarize the filtering configuration process:

1. Determine your desired match fields.
2. Configure an ACL and associate it with Ingress or Egress traffic flow.
3. Configure an ACE within the ACL.
4. Configure the desired precedence, attributes, and action.
5. Enable the ACE.

Ingress Bandwidth Rate Limiter

Table 227: Port-Based Rate Limiting, Policing, and Shaping product support

Feature	Product	Release introduced
Egress port shaper	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
Ingress dual rate port policers	5320 Series	Not Supported
	5420 Series	Not Supported
	5520 Series	Not Supported
Ingress policer and port rate limiter	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.5
	5520 Series	VOSS 8.5
QoS ingress port rate limiter	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5

Ingress bandwidth rate limiter functionality handles congestion, meters traffic, and takes action based on the ACL filter rules. A policer can be attached directly to an ACL ACE entry to perform flow-based rate limiting. You can configure the service rate and peak rate. All traffic that qualifies for a filter is metered. Every packet that exceeds the service rate is marked as yellow, and every packet that exceeds the peak rate is marked as red and is dropped.

The ingress flow-based policer limits the traffic rate accepted by the specified ingress port. The port drops or re-marks violating traffic. The line rate of the port is the maximum rate that can be configured.

The ingress flow-based policer is available on the following interfaces:

- Ingress port (inPort)
- Ingress VLAN (inVLAN)
- Ingress VSN (inVSN)

Operation Considerations

The following section describes operational considerations for ingress bandwidth rate limiter functionality:

- IPv4 policer statistics are available for red, yellow, and green packets and bytes.
- Egress port (outPort) interface is not supported.
- Policers are not supported on IPv6 ACLs.
- Supports QoS ACEs only.
- You can configure the default action policer within an ACL for permit action mode only.
- Drop action mode is not supported.
- **monitor-dst-ports**, **monitor-dst-mlt**, or **monitor-isid-offset** actions are supported. All traffic received is mirrored.
- The filter with policer and redirect-next-hop actions redirect only the traffic that passes the policer (if the stream is 100 Mbps, and the policer peak-rate is 50 Mbps, only 50 Mbps is redirected).
- Ingress policer/port rate limiter and QoS port rate limiter features are partially incompatible. Configuring both of these features together that can affect the same traffic can result in more traffic drop than expected. The best practices are as follows:
 - If ACL type is inPort, do not configure Qos port limiter on any of the ports that are part of ACL
 - If ACL type is inVlan, do not configure Qos port limiter on ports that are part of any VLAN in the ACL
 - If ACL type is inVsn, do not configure Qos port limiter on ports that are part of any VSN in the ACL

ACL and ACE configuration guidelines

To find the maximum number of ACLs and ACEs that the switch supports, see the [Fabric Engine Release Notes](#).

ACL Filters Behavior Differences

The implementation of ACL filters is similar in all switches but there are some differences as summarized in the following tables.

Note

The InVSN Filter shares the port-based groups in the following table.

Table 228: Hardware filter engine resources

5320 Series	5420 Series 5520 Series
If you enable Application Telemetry, IPv6 security filter commands and configurations are supported.	If you enable Application Telemetry, IPv6 security filter commands and configurations are supported.
The switch supports two ingress filter groups, where each type can hold both Security and QoS actions: <ol style="list-style-type: none"> port-based VLAN-based 	The switch supports two ingress filter groups, where each group is shared by two filter types: <ol style="list-style-type: none"> port-based and VLAN-based Security ACEs port-based and VLAN-based QoS ACEs
For each ingress packet, one ACE rule is matched based on the configuration. A parallel search is not performed on the two filter groups.	For each ingress packet, a parallel search is performed on each of the two filter groups.

Table 229: Action behavior

Filter	5320 Series	5420 Series 5520 Series
ACE ID ranges supported	<ul style="list-style-type: none"> IPv4 and IPv6 filters: <ul style="list-style-type: none"> ACEs: 1–2000 support both Security and QoS actions 	<ul style="list-style-type: none"> IPv4 filters: <ul style="list-style-type: none"> Security ACEs: 1–1000 QoS ACEs: 1001–2000 IPv6 filters: <ul style="list-style-type: none"> ACEs: 1–2000 support both Security and QoS actions
redirect-next-hop support	Supported in both the Global Routing Table and VRF contexts. <p>Note: Only 5320-48P-8XE and 5320-48T-8XE support more</p>	Supported in both the Global Routing Table and VRF contexts.

Table 229: Action behavior (continued)

Filter	5320 Series	5420 Series 5520 Series
	than one VRF with IP configuration.	

Table 230: ACL statistics behavior

5320 Series	5420 Series 5520 Series
Does not support viewing ACL statistics by the ACE type, Security and QoS. The output displays N/A.	Supports viewing ACL statistics by the ACE type, Security and QoS.

Table 231: ACE match criteria

5320 Series	5420 Series 5520 Series
<p>The 16-port and 24-port 5320 Series models support the following ACE match criteria for IPv6 ACLs:</p> <ul style="list-style-type: none"> • ethernet ACE: <ul style="list-style-type: none"> ◦ ether-type ◦ port ◦ vlan-id • IPv6 ACE: <ul style="list-style-type: none"> ◦ dst-ipv6 ◦ nxt-hdr ◦ routed-only ◦ src-ipv6 • protocol ACE: <ul style="list-style-type: none"> ◦ dst-port ◦ src-port <p>Note: 16-port and 24-port 5320 Series models are restricted to a maximum of 15 distinct values for each source/destination port. For more information, see Attributes on page 2965.</p> <p>Support on the 48-port 5320 Series models is the same as 5420 Series and 5520 Series.</p>	<p>Supports the following ACE match criteria for IPv6 ACLs:</p> <ul style="list-style-type: none"> • ethernet ACE: <ul style="list-style-type: none"> ◦ ether-type ◦ port ◦ vlan-id ◦ vlan-tag-prio • IPv6 ACE: <ul style="list-style-type: none"> ◦ dst-ipv6 ◦ nxt-hdr ◦ routed-only ◦ src-ipv6 ◦ traffic-class • protocol ACE: <ul style="list-style-type: none"> ◦ dst-port ◦ icmpv6-msg-type ◦ src-port ◦ tcp-flags

For QoS scaling and filter scaling information, see [Fabric Engine Release Notes](#).

Access control list configuration using CLI

Use an access control list (ACL) to specify an ordered list of access control entries (ACEs), or filter rules. The ACEs provide specific actions that you want the filter to perform.

Creating an IPv4 ACL

Create an ACL to specify an ordered list of ACEs, or filter rules.

About This Task

Do not configure IPv4 egress ACL filters on NNI ports because the system-generated egress vIST filter rules and the user-created IPv4 egress rules use the same filter hardware.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Create an ACL:

```
filter acl <acl-id> type <inVlan|inPort|outPort|inVsn> [matchType
<both|terminatingNNIOnly|uniOnly> ] [name WORD<0-32>] [enable]
```
3. Enable an ACL:

```
filter acl [enable]
```
4. Ensure the configuration is correct:

```
show filter acl [<acl-id>]
```

Variable definitions

Use the data in the following table to use **filter acl** command.

Variable	Value
<code><acl-id></code>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<code>enable</code>	Enables the ACL state, and all associated ACEs. Enabled is the default state.
<code>matchType <both terminatingNNIOnly uniOnly></code>	For inVsn ACL types, specifies the match type to associate with the ACL. Valid options are: <ul style="list-style-type: none"> • <i>both</i> for traffic ingressing on both UNI ports and NNI ports terminating on this node • <i>terminatingNNIOnly</i> for traffic ingressing on NNI ports only and terminating on this node • <i>uniOnly</i> for traffic ingressing on UNI ports only The default value is <i>both</i> .

Variable	Value
<code>name WORD<0-32></code>	Specifies an optional descriptive name for the ACL.
<code>type <inVlan inPort outPort inVsn></code>	Specifies the ACL type. The values inVlan, inPort, and inVsn are ingress ACLs, and outPort is an egress ACL. A port-based ACL has precedence over a VLAN-based ACL.

Create an IPv6 ACL

Create an IPv6 ACL to specify an ordered list of ACEs, or filter rules.

You must specify the packet type as IPv6 at the ACL level to enable IPv6 filtering. By default, an ACL filters non IPv6 packets.

Note

You cannot change packet type for the ACL after you have configured it. If you want a different packet type, you must delete the ACL and re-create it using the other packet type.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create an IPv6 ACL:

```
filter acl <acl-id> type <inVlan|inPort|outPort|inVsn> [matchType
<both|terminatingNNIOnly|uniOnly> ] [name WORD<0-32>] [pktType ipv6]
[name <0-32>]
```

Note

IPv6 egress QoS ACL/Filters are not supported.

3. Enable the ACL:

```
filter acl <acl-id> enable
```

4. Ensure the configuration is correct:

```
show filter acl [<acl-id>]
```

Variable definitions

Use the data in the following table to use the **filter acl** command.

Variable	Value
<code><acl-id></code>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<code>enable</code>	Enables the ACL state, and all associated ACEs. Enabled is the default state.

Variable	Value
<code>matchType</code> <both terminatingNNIOnly uniOnly>	For inVsn ACL types, specifies the match type to associate with the ACL. Valid options are: <ul style="list-style-type: none"> <i>both</i> for traffic ingressing on both UNI ports and NNI ports terminating on this node <i>terminatingNNIOnly</i> for traffic ingressing on NNI ports only and terminating on this node <i>uniOnly</i> for traffic ingressing on UNI ports only The default value is <i>both</i> .
<code>name</code> WORD<0-32>	Specifies an optional descriptive name for the ACL.
<code>type</code> <inVlan inPort outPort inVsn>	Specifies the ACL type. The values <i>inVlan</i> , <i>inPort</i> , and <i>inVsn</i> are ingress ACLs. The value <i>outPort</i> configures IPv6 egress filters. A port-based ACL has precedence over a VLAN-based ACL.
<code>pktType</code> <ipv6>	Specifies the IP version as IPv6. The default is nonipv6. Note: You cannot change packet type for the ACL once you have configured it. If you want a different packet type, you must delete the ACL and re-create it using the other packet type.

Associating VLANs with an ACL

Associate VLANs with an ACL to apply filters to VLAN traffic.

A VLAN can be part of two different ACLs of different types: IPv6 and non-IPv6.

Before You Begin

- The ACL exists.

Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Add VLAN interfaces to an ACL:

```
filter acl vlan <acl-id> <1-4059>
```
- Remove specified VLAN interfaces from an ACL:

```
no filter acl vlan <acl-id> <1-4059>
```

Variable definitions

Use the data in the following table to use the **filter acl vlan** command.

Variable	Value
<code><acl-id></code>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<code><1-4059></code>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.

Associating ports with an ACL

Associate ports with an ACL to apply filters to port traffic.

A port can be part of two different ACLs of different types: IPv6 and non-IPv6.

Before You Begin

- The ACL exists.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Associate port interfaces with a particular ACL:

```
filter acl port <acl-id> {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

3. Remove port interfaces from a particular ACL:

```
no filter acl port <acl-id> {slot/port[/sub-port] [-slot/port[/sub-
port]][,...]}
```

Variable definitions

Use the data in the following table to use the **filter acl port** command.

Variable	Value
<code><acl-id></code>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Associate an I-SID with an ACL

Before You Begin

- The inVsn ACL exists.
- This I-SID is already configured on the fabric node.

About This Task

For inVsn ACL types, specify the I-SID associated with the customer VLAN (Layer 2 VSN), the customer VRF (Layer 3 VSN), or the IP Shortcut.

Note

For IP Shortcut traffic, the inVsn ACL match type must be *both*. In this case, the I-SID is zero (0).

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Specify the I-SID.

```
filter acl i-sid <acl-id> <0-15999999>
```

Variable definitions

Use the data in the following table to use the **filter acl i-sid** command.

Variable	Value
<acl-id>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<0-15999999>	Specifies the I-SID associated with the customer VLAN (Layer 2 VSN) or the customer VRF (Layer 3 VSN). This I-SID must already be configured on the fabric node. The InVSN Filter supports IP Shortcut traffic if the inVsn ACL match type is <i>both</i> . In this case, the I-SID is zero (0). Important: You can specify a Switched UNI I-SID if the I-SID is associated with a platform VLAN.

Configure Global and Default Actions for an ACL

Configure the default action to specify packet treatment if a packet does not match any ACE.

Configure the global action to specify packet treatment if a packet does match an ACE.

Global action can only be configured for Ingress ACLs.

Before You Begin

Ensure that the ACL exists.

Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Configure the global action for an ACL:

```
filter acl set <acl-id> global-action [monitor-dst-ports {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}] [monitor-dst-mlt <1-512>]
```
- Configure an ACL to the default global action settings:

```
default filter acl set <acl-id> global-action [monitor-dst-ports]
```
- Configure the default action for an ACL:

```
filter acl set <acl-id> default-action <permit|deny>
```
- Configure an ACL default policer.

```
filter acl set <acl-id> default-action permit policer svc-rate <0-4000000000> peak-rate <8-4000000000>
```
- Configure an ACL to the default action settings:

```
default filter acl set <acl-id> default-action
```

Variable Definitions

The following table defines parameters for the **filter acl set** commands.

Variable	Value
<code><acl-id></code>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<code>default-action <permit deny></code>	Specifies the default action to take when none of the ACEs match. Options are <code><permit deny></code> . The default is permit.
<code>monitor-dst-ports {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Specifies the global action to take for matching ACEs: <ul style="list-style-type: none"> monitor destination ports—Configures mirroring to a destination port or ports. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<code>monitor-dst-mlt <1-512></code>	Configures mirroring to a destination MLT in the range of 1 to 512.
<code>policer svc-rate <0-4000000000> peak-rate <8-4000000000></code>	Specifies the policer for filter with service rate and peak transfer rate of packets. The service rate value specifies the rate of traffic committed to be delivered. Packets above the specified peak rate value are dropped on ingress.

Renaming an ACL

Perform this procedure to change the name of an existing ACL.

Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Rename an ACL:

```
filter acl <acl-id> name WORD<0-32>
```
- Reset the ACL name to the default name:

```
default filter acl <acl-id> name
```

Variable definitions

Use the data in the following table to use **filter acl** command.

Variable	Value
<code><acl-id></code>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<code>enable</code>	Enables the ACL state, and all associated ACEs. Enabled is the default state.

Variable	Value
matchType <both terminatingNNIOnly uniOnly>	For inVsn ACL types, specifies the match type to associate with the ACL. Valid options are: <ul style="list-style-type: none"> <i>both</i> for traffic ingressing on both UNI ports and NNI ports terminating on this node <i>terminatingNNIOnly</i> for traffic ingressing on NNI ports only and terminating on this node <i>uniOnly</i> for traffic ingressing on UNI ports only The default value is <i>both</i> .
name WORD<0-32>	Specifies an optional descriptive name for the ACL.
type <inVlan inPort outPort inVsn>	Specifies the ACL type. The values inVlan, inPort, and inVsn are ingress ACLs, and outPort is an egress ACL. A port-based ACL has precedence over a VLAN-based ACL.

Disabling an ACL

Perform this procedure to disable an ACL and all ACEs that belong to it.

Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Disable an ACL:

```
no filter acl <acl-id> enable
```

Variable definitions

Use the data in the following table to use **filter acl** command.

Variable	Value
<acl-id>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
enable	Enables the ACL state, and all associated ACEs. Enabled is the default state.
matchType <both terminatingNNIOnly uniOnly>	For inVsn ACL types, specifies the match type to associate with the ACL. Valid options are: <ul style="list-style-type: none"> <i>both</i> for traffic ingressing on both UNI ports and NNI ports terminating on this node <i>terminatingNNIOnly</i> for traffic ingressing on NNI ports only and terminating on this node <i>uniOnly</i> for traffic ingressing on UNI ports only The default value is <i>both</i> .

Variable	Value
<code>name WORD<0-32></code>	Specifies an optional descriptive name for the ACL.
<code>type <inVlan inPort outPort inVsn></code>	Specifies the ACL type. The values inVlan, inPort, and inVsn are ingress ACLs, and outPort is an egress ACL. A port-based ACL has precedence over a VLAN-based ACL.

Resetting an ACL to default values

Reset an ACL to change the ACL name to the default name and the filter ACL mode to a default of enable.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Reset an ACL to default values:

```
default filter acl <acl-id>
```

Variable definitions

Use the data in the following table to use **filter acl** command.

Variable	Value
<code><acl-id></code>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<code>enable</code>	Enables the ACL state, and all associated ACEs. Enabled is the default state.
<code>matchType <both terminatingNNIOnly uniOnly></code>	For inVsn ACL types, specifies the match type to associate with the ACL. Valid options are: <ul style="list-style-type: none"> • <i>both</i> for traffic ingressing on both UNI ports and NNI ports terminating on this node • <i>terminatingNNIOnly</i> for traffic ingressing on NNI ports only and terminating on this node • <i>uniOnly</i> for traffic ingressing on UNI ports only The default value is <i>both</i> .
<code>name WORD<0-32></code>	Specifies an optional descriptive name for the ACL.
<code>type <inVlan inPort outPort inVsn></code>	Specifies the ACL type. The values inVlan, inPort, and inVsn are ingress ACLs, and outPort is an egress ACL. A port-based ACL has precedence over a VLAN-based ACL.

Deleting an ACL

Delete an ACL to remove an ordered list of filter rules.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Delete an ACL:

```
no filter acl <acl-id>
```

The system displays the following message:

```
WARNING: All ACE entries under this ACL will be Deleted.
Do you wish to delete this ACL? (y/n)?
```

3. Enter *y*.

Variable definitions

Use the data in the following table to use **filter acl** command.

Variable	Value
<i><acl-id></i>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<i>enable</i>	Enables the ACL state, and all associated ACEs. Enabled is the default state.
matchType <i><both terminatingNNIOnly uniOnly></i>	For inVsn ACL types, specifies the match type to associate with the ACL. Valid options are: <ul style="list-style-type: none"> • <i>both</i> for traffic ingressing on both UNI ports and NNI ports terminating on this node • <i>terminatingNNIOnly</i> for traffic ingressing on NNI ports only and terminating on this node • <i>uniOnly</i> for traffic ingressing on UNI ports only The default value is <i>both</i> .
<i>name WORD<0-32></i>	Specifies an optional descriptive name for the ACL.
<i>type <inVlan inPort outPort inVsn></i>	Specifies the ACL type. The values inVlan, inPort, and inVsn are ingress ACLs, and outPort is an egress ACL. A port-based ACL has precedence over a VLAN-based ACL.

Clear ACL Statistics

Clear default ACL statistics if you no longer require previous statistics.

**Note**

The ACL statistics do not support security action on some hardware platforms.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Enter the following command to clear default ACL statistics:

```
clear filter acl statistics default <acl-id>
```
3. Enter the following command to clear global ACL statistics:

```
clear filter acl statistics global <acl-id>
```
4. Enter the following command to clear all ACL statistics:

```
clear filter acl statistics all
```
5. Enter the following command to clear statistics associated with a particular ACL, ACE, or ACE type:

```
clear filter acl statistics <acl-id> <ace-id> [qos] [security]
```

Variable Definitions

Use the information in the following table to use the **clear filter acl statistics** command.

Variable	Value
<acl-id>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<ace-id>	Specifies the ACE ID. Different hardware platforms support different ACE ID ranges. Use the CLI Help to see the available range for the switch.

Enable IPv6 Egress Filters

Use the **boot config flags** command to enable IPv6 egress filters and to add IPv6 egress qualifiers at startup.

About This Task

This flag is disabled by default.

For 5320 Series and 5420 Series platforms, the **boot config flags ipv6-egress-filter** and **boot config flags macsec** commands are mutually exclusive.

Before You Begin

If more than 200 IPv4 egress entries exist in the configuration file, make a backup of the configuration file before you enable IPv6 egress filters. Only a maximum of 200 IPv4 egress entries are saved in the configuration file after you use the **save config** command.

For example, you can enter more than 200 IPv4 egress entries in the configuration file prior to enabling IPv6 egress filters. However, the entries are stored in ascending numerical order with ACL ID and ACE ID respectively, and not in the order in which they were added. Therefore, after you enable IPv6 egress filters and restart, and because the configuration file is read in ascending order, you receive an error message after the 200 maximum has been reached, such as:

```
CP1 [2017-09-28T00:44:24.077+05:30] 7K-Fi-94-I6:1 0x001049d4 00000000
GlobalRouter FILTER ERROR Unable to allocate data path resources for ACL
ID 12.
```

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Enable the IPv6-egress-filter boot config flag:
`boot config flags ipv6-egress-filter`
3. Save the configuration, and then restart the switch for the change to take effect.
4. After you restart the switch, verify that the IPv6-egress-filter boot config flag is configured to true:
`show boot config flags`

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#boot config flags ipv6-egress-filter
Warning: Please save the configuration and reboot the switch
        for this configuration to take effect.
```

Note

Flag support can vary across hardware models.

```
Switch:1#show boot config flags
flags advanced-feature-bandwidth-reservation low
flags block-snmp false
flags debug-config false
flags debugmode false

Display Filter Access Control List Configuration

About This Task

Perform this procedure to display the filter Access Control List (ACL) configuration on the switch.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display filter ACL configuration:
show filter acl

Example

```
Switch:1(config)#show filter acl
=====
=
                                Vlan/VSN ACL Table
=====

Access control list configuration using EDM

Use traffic filtering to provide security by blocking unwanted traffic and prioritizing other traffic.

Configuring an access control list

Use an access control list (ACL) to specify an ordered list of access control entries (ACE), or filter rules. The ACEs provide specific actions for the filter to perform.

About This Task

Do not configure IPv4 egress ACL filters on NNI ports because the system-generated egress vIST filter rules and the user-created IPv4 egress rules use the same filter hardware.

To modify an ACL parameter, double-click the parameter you wish to change. Change the value, and then click Apply. You cannot change a parameter that the system displays it dimmed; in this case, delete the ACL, and then configure a new one.

Procedure

1. In the navigation pane, expand the **Configuration > Security > Data Path** folders.
 2. Click **Advanced Filters (ACE/ACLs)**.
 3. Click the **ACL** tab.
 4. Click **Insert**.
 5. In the **ACLid** field, type an ACL ID, or accept the default value .
 6. In **Type**, specify the type of ACL.
 7. In the **Name** field, specify a name for the ACL.
 8. Perform one of the following if the ACL is VLAN-based or port-based:
 - a. If the ACL is VLAN-based, click the **VlanList** ellipsis, and then choose a VLAN list.
 - b. If the ACL is port-based, click the **PortList** ellipsis, and then choose a port list.
 9. Select the desired ports, and then click **Ok**.
 10. Configure the **DefaultAction**.
 11. Configure the **ControlPktAction**.
- 

Note
There is no control packet action support for the InVSN Filter. Control packets go to the CPU after termination.
12. Enable or disable the **State**, as required.
 13. In the **PktType** field, select the packet type to create either IPv4 or IPv6 ACLs.
 14. If the ACL type is inVsn, do the following:
 - a. In the **MatchType** field, select the match type to associate with the ACL that the traffic is ingressing on.
 - b. In the **Isid** field, enter the I-SID associated with the customer VLAN (Layer 2 VSN) or the customer VRF (Layer 3 VSN) or enter 0 for IP shortcut.
 15. Configure the remaining fields, as appropriate.
 16. Click **Insert**.
 17. To delete an ACL, select the ACL, and then click **Delete**.

ACL field descriptions

Use the data in the following table to use the **ACL** tab.

Name	Description
AcId	Specifies a unique identifier for the ACL.
Type	<p>Specifies the ACL type. Valid options are</p> <ul style="list-style-type: none"> • inVlan • inPort • outPort • inVsn <p>Important: The inVlan ACLs drop packets if you add a VLAN after ACE creation.</p> <p>Important: You can insert an inVsn ACL type for a Switched UNI only if the Switched UNI I-SID is associated with a platform VLAN.</p>
Name	Specifies a descriptive user-defined name for the ACL.
VlanList	For inVlan ACL types, specifies all VLANs to associate with the ACL.
PortList	For inPort and outPort ACL types, specifies the ports to associate with the ACL.
DefaultAction	Specifies the action taken when no ACEs in the ACL match. Valid options are deny and permit, with permit as the default. Deny means the system drops the packets; permit means the system forwards packets.
ControlPktAction	Specifies the action taken for control packets. Valid options are deny and permit.
State	Enables or disables all of the ACEs in the ACL. The default value is enable.
PktType	Indicates the packet type to which this ACL applies.
MirrorMltd	Configures mirroring to a destination MLT.
MirrorDstPortList	Configures mirroring to a destination port or ports.
MatchType	<p>For inVsn ACL types, specifies the match type to associate with the ACL. Valid options are:</p> <ul style="list-style-type: none"> • <i>both</i> for traffic ingressing on both UNI ports and NNI ports terminating on this node • <i>terminatingNNIOnly</i> for traffic ingressing on NNI ports only and terminating on this node • <i>uniOnly</i> for traffic ingressing on UNI ports only <p>The default value is <i>both</i></p>

Name	Description
Isid	For inVsn ACL types, specifies the I-SID associated with the customer VLAN (Layer 2 VSN) or the customer VRF (Layer 3 VSN). This I-SID should already be configured on the fabric node. The InVSN Filter supports IP Shortcut traffic if the inVsn ACL match type is <i>both</i> . In this case, the I-SID is zero (0). Important: You can specify a Switched UNI I-SID if the I-SID is associated with a platform VLAN.
Origin	Indicates the origin of the ACL: <ul style="list-style-type: none"> • config - ACL created by the user. • eap - ACL created by Extensible Authentication Protocol (EAP) through Remote Authentication Dial-In User Service (RADIUS) response.
DefaultSvcRate	Specifies the service rate limit in kbps {8-4000000000}.The granularity is 8 kbps.
DefaultPeakRate	Specifies the value when exceeded causes packets to drop on ingress. Peak rate limit in kbps {8-4000000000}.The granularity is 8 kbps.

Viewing ACL Statistics

About This Task

Graph statistics for a specific ACL ID to view default statistics.

Procedure

1. In the navigation pane, expand the **Configuration > Security > Data Path** folders.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select an ACL.
5. Click **Graph**.
6. You can click **Clear Counters** to clear the **Statistics** fields.

Statistics Field Descriptions

Use the data in the following table to use the **Statistics** tab.

Name	Description
AcId	Specifies the ACL ID.
MatchDefaultSecurityPkts	Shows a security packet count of traffic that does not match an ACE rule or hits the default action if count is configured in the ACL global action.
MatchDefaultSecurityOctets	Shows a security byte count of traffic that does not match an ACE rule or hits the default action if count is configured in the ACL global action.

Name	Description
MatchDefaultQosPkts	Shows a QoS packet count of traffic that does not match an ACE rule or hits the default action if count is configured in the ACL global action.
MatchDefaultQosOctets	Shows a QoS byte count of traffic that does not match an ACE rule or hits the default action if count is configured in the ACL global action.
MatchGlobalSecurityPkts	Shows a security packet count of traffic that matches an ACE rule or hits the default action if count is configured in the ACL global action.
MatchGlobalSecurityOctets	Shows a security byte count of traffic that matches an ACE rule or hits the default action if count is configured in the ACL global action.
MatchGlobalQosPkts	Shows a QoS packet count of traffic that matches an ACE rule or hits the default action if count is configured in the ACL global action.
MatchGlobalQosOctets	Shows a QoS byte count of traffic that matches an ACE rule or hits the default action if count is configured in the ACL global action.
DefaultGreenBytes	Shows byte count of traffic sent with a rate lower than committed-rate matching any of the ACE rules or hits on Default Action.
DefaultGreenPackets	Shows packet count of traffic sent with a rate lower than committed-rate matching any of the ACE rules or hits on Default Action.
DefaultYellowBytes	Shows byte count of traffic sent with a rate lower than peak-rate and higher than committed-rate matching any of the ACE rules or hits on Default Action.
DefaultYellowPackets	Shows packet count of traffic sent with a rate lower than peak-rate and higher than committed-rate matching any of the ACE rules or hits on Default Action.
DefaultRedBytes	Shows byte count of traffic sent with a rate higher than peak-rate matching any of the ACE rules or hits on Default Action.
DefaultRedPackets	Shows packet count of traffic sent with a rate higher than peak-rate matching any of the ACE rules or hits on Default Action.

Clearing ACL Statistics

About This Task

Clear ACL statistics when you want to gather a new set of statistics.

Procedure

1. In the navigation pane, expand the **Configuration > Security > Data Path** folders.
2. Click **Advanced Filters (ACE/ACLs)**.

3. Click the **ACL** tab.
4. Select a field.
5. Click **ClearStats**.

Enable IPv6 Egress Filters

Enable IPv6 egress filters to add IPv6 egress qualifiers at startup.

About This Task

This flag is disabled by default.

Before You Begin

If more than 200 IPv4 egress entries exist in the configuration file, make a backup of the configuration file before you enable IPv6 egress filters. Only a maximum of 200 IPv4 egress entries are saved in the configuration file after you save the configuration.

For example, you can enter more than 200 IPv4 egress entries in the configuration file prior to enabling IPv6 egress filters. However, the entries are stored in ascending numerical order with ACL ID and ACE ID respectively, and not in the order in which they were added. Therefore, after you enable IPv6 egress filters and restart, and because the configuration file is read in ascending order, you receive an error message after the 200 maximum has been reached, such as:

```
CP1 [2017-09-28T00:44:24.077+05:30] 7K-Fi-94-I6:1 0x001049d4 00000000
GlobalRouter FILTER ERROR Unable to allocate data path resources for ACL
ID 12.
```

Procedure

1. In the navigation pane, expand the **Configuration > Edit** folders.
2. Click **Chassis**.
3. Click the **Boot Config** tab.
4. Select the **EnableIpv6EgressFilterMode** check box.
5. Click **Apply**.
6. Save the configuration, and then restart the switch for the change to take effect.

Boot Config Field Descriptions

Use the data in the following table to use the **Boot Config** tab.

Name	Description
SwVersion	Specifies the software version that currently runs on the chassis.
LastRuntimeConfigSource	Specifies the last source for the run-time image.
PrimaryConfigSource	Specifies the primary configuration source.
PrimaryBackupConfigSource	Specifies the backup configuration source to use if the primary does not exist.

Name	Description
EnableFactoryDefaultsMode	<p>Specifies whether the switch uses the factory default settings at startup.</p> <ul style="list-style-type: none"> • false: The node does not use factory default settings at startup. • fabric: This mode is not supported. • noFabric: The node uses the factory default mode settings at startup. <p>The default value is false. This flag is automatically reset to the default setting after the switch restarts. If you change this parameter, you must restart the switch for the change to take effect.</p> <p>Note: The factorydefaults flag deletes the runtime, primary and backup configuration files, local password files, authentication keys, and certificates. After a factory default, you must change the password on first login.</p>
EnableDebugMode	<p>Enabling the debugmode allows a user to enable TRACE on any port by prompting the selection on the console during boot up. This allows the user start trace for debugging earlier on specified port. It only works on console connection. The default value is disabled.</p> <p>Important: Do not change this parameter.</p>
EnableRebootOnError	<p>Activates or disables automatic reboot on a fatal error. The default value is activated.</p> <p>Important: Do not change this parameter.</p>
EnableTelnetServer	<p>Activates or disables the Telnet server service. The default value is disabled.</p>
EnableFtpServer	<p>Activates or disables the FTP server on the switch. The default value is disabled. To enable FTP, ensure that the TFTPD flag is disabled.</p>
EnableTftpServer	<p>Activates or disables Trivial File Transfer Protocol server service. The default value is disabled.</p>
EnableSshServer	<p>Activates or disables the SSH server service. The default value is disabled.</p>
EnableSpbmConfigMode	<p>Enables you to configure SPB and IS-IS, but you cannot configure PIM and IGMP either globally or on an interface. The boot flag is enabled by default.</p>

Name	Description
EnableIpv6Mode	Enable this flag to support IPv6 routes with prefix-lengths greater than 64 bits. This flag is disabled by default.
EnableEnhancedsecureMode	<p>Enables or disables the enhanced secure mode. Select either jitc or non-jitc to enable the enhanced secure mode in one of these sub-modes. The default is disabled.</p> <p>Note: As a best practice, enable the enhanced secure mode in the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.</p>
EnableUrpfMode	Enables Unicast Reverse Path Forwarding (uRPF) globally. You must enable uRPF globally before you configure it on a port or VLAN. The default is disabled.
EnableFlowControlMode	Enables or disables flow control globally. When disabled, the system does not generate nor configure the transmission of flow control messages. The system always honors received flow control messages regardless of the flow control mode status. You must enable this mode before you configure an interface to send pause frames. The default is disabled.
<p>AdvancedFeatureBwReservation</p> <p>Note: Exception: vim level is only supported on 5520 Series.</p>	<p>Enables the switch to support advanced features by reserving ports as loopback ports. When disabled, you can use all ports on the switch, but advanced features do not work.</p> <ul style="list-style-type: none"> The low level means that the switch reserves less bandwidth to support minimum functionality for advanced features. The vim level means that the switch VIM ports as loopback ports and the Universal Ethernet ports for uplinks. <p>The default varies depending on the platform:</p> <ul style="list-style-type: none"> The default for 5320 Series and 5420 Series is enabled with low level. The default for 5520 Series is enabled with vim level if Versatile Interface Module (VIM) is not installed, else low level is enabled. <p>If you change this parameter, you must restart the switch.</p>
EnableDvrLeafMode	Enables the switch to be configured as a DvR Leaf. When enabled, you cannot configure the switch to operate as a DvR Controller.

Name	Description
EnableVrfScaling	<p>Changes the maximum number of VRFs and Layer 3 VSNs that the switch supports. If you select this check box, the maximum number increases. The default is disabled.</p> <p>Important: If you select both this check box and the EnableSpbmConfigMode check box, the switch reduces the number of configurable VLANs. For more information about maximum scaling numbers, see Fabric Engine Release Notes.</p>
EnableSyslogRfc5424Format	<p>Enables or disables the RFC 5424 syslog format. The default is enabled. If the pre-existing configuration file is for a release prior to this enhancement, then the flag is disabled automatically.</p>
NniMstp	<p>Enables MSTP, and allows non SPBM B-VLAN configuration on SPBM NNI ports. The default is disabled.</p> <p>Note: Spanning Tree is disabled on all SPBM NNIs.</p> <p>You cannot add an SPBM NNI port or MLT port to any non SPBM B-VLAN.</p>
EnableIpv6EgressFilterMode	<p>Enables IPv6 egress filters. The default is disabled. If you change this parameter, you must restart the switch.</p> <p>For 5320 Series and 5420 Series platforms, EnableIpv6EgressFilterMode and EnableMacsec are mutually exclusive.</p>
EnableMacsec Note: Exception: only required for 5320 Series and 5420 Series.	<p>Enables Media Access Control Security (MACsec) mode globally. To enable MACsec mode, you must configure the boot flag.</p> <p>EnableIpv6EgressFilterMode and EnableMacsec are mutually exclusive.</p>
Slot	Specifies the slot number.
TftpHash	Enables TFTP hashing.
TftpRetransmit	Set TFTP retransmit timeout counter.
TftpTimeout	Set TFTP timeout counter.
User	Configure host user.
Password	Configure host password.

Access Control Entry Configuration using CLI

Use an access control entry (ACE) to provide an ordered list of traffic filtering rules.

Note

Some hardware platforms support ACE IDs from the range 1-1000 for both security and QoS rules. For more information, see [ACL Filters Behavior Differences](#) on page 2976.

Configure ACEs

Use an ACE to define packet attributes and the desired behavior for packets that carry the attribute or list of attributes.

Before You Begin

- The ACL exists. If you want to use IPv6 filters, you must specify the packet type as IPv6 at the ACL level to enable IPv6 filtering.

About This Task

ACLs are by default created in enabled state while ACEs are by default created in disabled state. Use CLI commands to enable an ACE.

Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

- Create and name an ACE:

```
filter acl ace <acl-id> <ace-id> [name WORD<0-32>]
```

The ACE ID determines ACE precedence (that is, the lower the ID, the higher the precedence).

Note

For some hardware platforms, the ACE ID range is from 1 to 1000. If you try to create an ACE ID outside the range, the device displays the following error message:

```
Invalid input detected at '^' marker
```

- Configure the mode as deny or permit:

```
filter acl ace action <acl-id> <ace-id> <deny|permit>
```

- Configure ACE actions as required.

- Ensure the configuration is correct:

```
show filter acl ace <acl-id> <ace-id>
```

- Ensure the filter is enabled:

```
filter acl ace <acl-id> <ace-id> enable
```

- Optionally, reset an ACE to default values (reset the ACE name to the default name and the administrative state to the default value of disable):

```
default filter acl ace <acl-id> <ace-id>
```

- Optionally, delete an ACE ID:

```
no filter acl ace <acl-id> <ace-id>
```

Variable Definitions

Use the data in the following table to use the **filter acl ace** and the **filter acl ace action** commands.

Variable	Value
<code><acl-id></code>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<code><ace-id></code>	Specifies the ACE ID. Different hardware platforms support different ACE ID ranges. Use the CLI Help to see the available range for the switch.
<code><deny permit></code>	Configures the action mode for security ACEs. Note: For each Security ACE, you must define one or more actions as well as the associated action mode (permit or deny). Otherwise, the security ACE cannot be enabled. There is no default configuration for Security ACEs. With QoS ACE, the action mode is not configurable. QoS ACEs are always set to action mode permit.
<code>enable</code>	Enables an ACE within an ACL. After you enable an ACE, to make changes, first disable it.
<code>name WORD<0-32></code>	Specifies an optional descriptive name for the ACE that uses 0-32 characters.

Configure ACE actions

Configure ACE actions to determine the process that occurs after a packet matches an ACE.

Before You Begin

- Create ACE and ACL.

Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

- Configure ACE actions:

```
filter acl ace action <acl-id> <ace-id> <permit | deny>
```

- (Optional) Configure ACE actions to count matching packets:

```
filter acl ace action <acl-id> <ace-id> <permit | deny> count
```

4. (Optional) Configure the QoS level for matching packets:

```
filter acl ace action <acl-id> <ace-id> <permit | deny> internal-qos
<0-7>
```

Note

This step does not apply to IPv6 filtering.

5. (Optional) Enable mirroring on destination MLT for matching packets:

```
filter acl ace action <acl-id> <ace-id> <permit | deny> monitor-dst-
mlt <1-512>
```

6. (Optional) Enable mirroring on a port for matching packets:

```
filter acl ace action <acl-id> <ace-id> <permit | deny> monitor-dst-
ports {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

7. (Optional) Enable mirroring on destination I-SID for matching packets:

```
filter acl ace action <acl-id> <ace-id> <permit | deny> monitor-isid-
offset <1-1000>
```

8. (Optional) Configure the next hop IPv4 or IPv6 address for redirect mode for matching packets:

```
filter acl ace action <acl-id> <ace-id> <permit | deny> redirect-next-
hop WORD<1-45> [count | unreachable | vrf {WORD <1-16>}]
```

Important

Ensure you configure the ACE match rules so that you only collect the desired traffic. For example, routed packets.

9. (Optional) Configure the next hop IPv4 or IPv6 address for redirect mode for matching packets for a VRF:

Note

If the next hop is unreachable, you can also configure ACE actions to permit or deny packet dropping within the VRF.

```
filter acl ace action <acl-id> <ace-id> <permit | deny> redirect-next-
hop WORD<1-45> vrf WORD <1-16> unreachable <permit | deny>
```

10. (Optional) Configure the next hop IPv4 or IPv6 address for redirect mode for matching packets for a VRF:

Note

If the next hop is unreachable, you can also configure ACE actions to count matching packets, or to permit or deny packet dropping within the VRF

```
filter acl ace action <acl-id> <ace-id> <permit | deny> redirect-next-
hop WORD<1-45> vrf WORD <1-16> unreachable <permit | deny> count
```

11. (Optional) Configure the QoS dot1p priority for matching packets:

```
filter acl ace action <acl-id> <ace-id> <permit | deny> remark-dot1p
<0-7>
```

Note

This step does not apply to IPv6 filtering.

12. (Optional) Configure the QoS phb and dscp for matching packets:

```
filter acl ace action <acl-id> <ace-id> <permit | deny> remark-dscp
[phbcs0 | phbcs1 | phbaf11 | phbaf12 | phbaf13 | phbcs2 | phbaf21 |
phbaf22 | phbaf23 | phbcs3 | phbaf31 | phbaf32 | phbaf33 | phbcs4 |
phbaf41 | phbaf42 | phbaf43 | phbcs5 | phbef | phbcs6 | phbcs7]
```

13. (Optional) Configure the mode when next hop is unreachable:

```
filter acl ace action <acl-id> <ace-id> <permit | deny> unreachable
[permit | deny]
```

14. Ensure the configuration is correct:

- `show filter acl action <acl-id> <ace-id>`
- `show filter acl config`
- `show filter acl ace`

Example

Configure ACE actions:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#filter acl ace action 1 47 permit redirect-next-hop 192.0.2.5
unreachable deny count
```

Display the configuration using the **show filter ace action** command:

```
Switch:1(config)#show filter acl action

Variable Definitions

Use the data in the following table to use the **filter acl ace action** command.

-

Variable	Value
<code><acl-id></code>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<code><ace-id></code>	Specifies the ACE ID. Different hardware platforms support different ACE ID ranges. Use the CLI Help to see the available range for the switch.
<code>count</code>	Enables the ability to count matching packets. Use this parameter with either a security or QoS ACE. The default is disabled.

Variable	Value
<code><deny permit></code>	Configures the action mode for security ACEs. Note: For each Security ACE, you must define one or more actions as well as the associated action mode (permit or deny). Otherwise, the security ACE cannot be enabled. There is no default configuration for Security ACEs. With QoS ACEs, the action mode is not configurable. QoS ACEs are always set to action mode permit.
<code>monitor-isid-offset <1-1000></code>	Specifies the offset ID which will be mapped to the actual monitor I-SID where packets are mirrored. Monitor I-SID = base monitor I-SID + offset ID. The base monitor I-SID is 16776000.
<code>internal-qos <0-7></code>	This variable is a QoS action. The default value is 1. Note: This does not apply to IPv6 filtering.
<code>monitor-dst-ports {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Configures mirroring to a destination port or ports. This action is a security action. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<code>monitor-dst-mlt <1-512></code>	Configures mirroring to a destination MLT in the range of 1 to 512.
<code>redirect-next-hop WORD <1-45></code>	Specifies the nexthop IPv4 or IPv6 address for redirect node. This action is a security action. Note: redirect-next-hop is available for demonstration purposes on some products. For more information, see Fabric Engine Feature Support Matrix .
<code>unreachable <permit deny></code>	Denies or permits packet dropping when the next hop for the packet is unreachable. The default value is deny. This action is a security action. Note: unreachable is available for demonstration purposes on some products. For more information, see Fabric Engine Feature Support Matrix .

Variable	Value
<code>vrf WORD<1-16></code>	Specifies the direct next hop VRF name. The name must be in the ranger of 1 to 16 characters. Note: vrf is available for demonstration purposes on some products. For more information, see Fabric Engine Feature Support Matrix .
<code>remark-dscp <phbcs0 phbcs1 phbaf11 phbaf12 phbaf13 phbcs2 phbaf21 phbaf22 phbaf23 phbcs3 phbaf31 phbaf32 phbaf33 phbcs4 phbaf41 phbaf42 phbaf43 phbcs5 phbcs6 phbef phbcs7></code>	Specifies the new Per-Hop Behavior (PHB) for matching packets: phbcs0, phbcs1, phbaf11, phbaf12, phbaf13, phbcs2, phbaf21, phbaf22, phbaf23, phbcs3, phbaf31, phbaf32, phbaf33, phbcs4, phbaf41, phbaf42, phbaf43, phbcs5, phbef, phbcs6, phbcs7. This action is a QoS action. Note: This action applies to IPv6 filtering.
<code>remark-dot1p <0-7></code>	Specifies the new 802.1 priority bit for matching packets: zero, one, two, three, four, five, six, or seven. This action is a QoS action. Note: This does not apply to IPv6 filtering.

Configuring ARP ACEs

Use ACE Address Resolution Protocol (ARP) entries to ensure the filter looks for ARP requests or responses.

You cannot configure ARP attributes for IPv6 filters.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Configure an ACE for ARP packets:
`filter acl ace arp <acl-id> <ace-id> operation eq <arprequest | arpresponse>`
3. Ensure the configuration is correct:
`show filter acl arp <acl-id> <ace-id>`
4. Optionally, delete the individual attributes from the ARP portion of the ACE:
`no filter acl ace arp <acl-id> <ace-id> [operation]`

- Optionally, delete all the attributes from the ARP portion of the ACE:

```
default filter acl ace arp <acl-id> <ace-id>
```

Variable Definitions

Use the data in the following table to use the **filter acl ace arp** command.

Variable	Value
<i><acl-id></i>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<i><ace-id></i>	Specifies the ACE ID. Different hardware platforms support different ACE ID ranges. Use the CLI Help to see the available range for the switch.
<i>operation eq</i> <i><arprequest </i> <i>arpresponse></i>	Specifies the type of ARP operation to filter: arpRequest or arpResponse.

Configuring an Ethernet ACE

Configure an Ethernet ACE to filter on Ethernet parameters.

You do not need to configure Ethertype for IPv6 filters. If you try to configure an Ethertype other than 0x86dd or IPv6 the device displays an error.

Before You Begin

- The ACL exists.
- The ACE exists.

About This Task

The *eq* and *mask* parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.

Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure an ACE for the destination or source MAC address attribute:

```
filter acl ace ethernet <acl-id> <ace-id> <dst-mac|src-mac> eq WORD<1-1024>
```

OR

```
filter acl ace ethernet <acl-id> <ace-id> <dst-mac|src-mac> mask WORD<1-1024> WORD<1-1024>
```

Note

This is supported only for IPv4 filters.

3. Configure an ACE for an Ethernet type attribute:

```
filter acl ace ethernet <acl-id> <ace-id> ether-type eq WORD<1-200>
```

4. Configure an ACE for a port attribute:

```
filter acl ace ethernet <acl-id> <ace-id> port eq {slot/port[sub-port]}
```

5. Configure an ACE for a VLAN attribute:

```
filter acl ace ethernet <acl-id> <ace-id> vlan-id eq <1-4059>
```

OR

```
filter acl ace ethernet <acl-id> <ace-id> vlan-id mask <1-4059> <0-0xFFF>
```

6. Configure an ACE for a VLAN tagged priority attribute:

```
filter acl ace ethernet <acl-id> <ace-id> vlan-tag-prio eq <0-7>
```

OR

```
filter acl ace ethernet <acl-id> <ace-id> vlan-tag-prio mask <0-7> <0-0x7>
```

7. Ensure the configuration is correct:

```
show filter acl ethernet <acl-id> <ace-id>
```

8. Optionally, delete the individual attributes from the Ethernet portion of the ACE:

```
no filter acl ace ethernet <acl-id> <ace-id>
```

9. Optionally, delete all the attributes from the Ethernet portion of the ACE:

```
default filter acl ace ethernet <acl-id> <ace-id>
```

Variable definitions

Use the data in the following table to use the **filter acl ace ethernet** command.

Variable	Value
<0-7>	Specifies the priority bits (3-bit field) from the 802.1Q/p tag.
<0-0x7>	Specifies the mask value for VLAN tagged priority attribute.

Variable	Value
<0-0xFFF>	Specifies the mask value for a VLAN attribute. For example: filter acl ace ethernet 10 10 vlan-id eq 10 filter acl ace ethernet 10 10 vlan-id mask 1025 0xF
<ace-id>	Specifies the ACE ID. Different hardware platforms support different ACE ID ranges. Use the CLI Help to see the available range for the switch.
<acl-id>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
{slot/port[/sub-port]}	Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
WORD<1-200>	Specifies an ether-type name or number: <ul style="list-style-type: none"> • 0x0-0xffff • ip, arp, ipx802dot3, ipx802dot2, ipxSnap, ipxEthernet2, appleTalk, decLat, decOther, sna802dot2, snaEthernet2, netBios, xns, vines, ipv6, rarp, or PPPoE <p>Note: Ethernet ACE filter configured with ether-type eq ipx802dot3 does not match the packet with format destination MAC address, source MAC address, length, 0xFFFF, payload and FCS. Ethernet ACE filter configured with ether-type eq ipx802dot2 does not match the packet with format destination MAC address, source MAC address, length, 0xE0E0, payload and FCS.</p>
WORD<1-1024>	If the operator is mask, the <i>WORD<1-1024></i> parameter is {"" 1..48 , mac address mask 0x0..FFFFFFFFFFFF}} If the operator is eq, the <i>WORD<1-1024></i> parameter is the destination or source MAC address: AA:BB:CC:DD:EE:FF For example: filter acl ace ethernet 10 10 dst-mac eq 0x01:00:5:00:00:01 filter acl ace ethernet 10 10 dst-mac mask 0x01:00:5:00:00:01 24 filter acl ace ethernet 10 10 src-mac mask 0x01:00:5:00:00:01 0xFFFFFFFF0000

Configure an IP ACE

Configure an IP ACE to filter on the source IP address, destination IP address, DiffServ Code Point (DSCP), protocol, IP options, IP fragmentation, and routed packets only.

Before You Begin

- The ACL exists.
- The ACE exists.

About This Task

The *eq* and *mask* parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure an ACE for the DSCP attribute:

```
filter acl ace ip <acl-id> <ace-id> dscp eq {<0..63>|<0x00..0x3f>|
phbcs0|phbcs1|phbaf11|phbaf12|phbaf13|phbcs2|phbaf21|phbaf22|phbaf23|
phbcs3|phbaf31|phbaf32|phbaf33|phbcs4|phbaf41|phbaf42|phbaf43|phbcs5|
phbef|phbcs6|phbcs7}
```

OR

```
filter acl ace ip <acl-id> <ace-id> dscp mask {<0..63>|<0x00..0x3f>|
phbcs0|phbcs1|phbaf11|phbaf12|phbaf13|phbcs2|phbaf21|phbaf22|phbaf23|
phbcs3|phbaf31|phbaf32|phbaf33|phbcs4|phbaf41|phbaf42|phbaf43|phbcs5|
phbef|phbcs6|phbcs7} WORD<0x0-0x40>
```

3. Configure an ACE for the destination or source IP address attribute:

```
filter acl ace ip <acl-id> <ace-id> <dst-ip|src-ip> eq WORD<1-1024>
```

OR

```
filter acl ace ip <acl-id> <ace-id> <dst-ip|src-ip> mask WORD<1-1024>
{<0-32>|null|<A.B.C.D>}
```

4. Configure an ACE for the IP fragmentation attribute:

```
filter acl ace ip <acl-id> <ace-id> ip-frag-flag eq <noFragment|
anyFragment>
```

5. Configure an ACE for the IP options attribute:

```
filter acl ace ip <acl-id> <ace-id> ip-options any
```

6. Configure an ACE for the protocol type attribute:

```
filter acl ace ip <acl-id> <ace-id> ip-protocol-type eq WORD<1-256>
```

7. Configure an ACE for routed packets only:

```
filter acl ace ip <acl-id> <ace-id> routed-only
```

8. Ensure the configuration is correct:

```
show filter acl ip <acl-id> <ace-id>
```

9. (Optional) Delete all the attributes from the IP (Layer 3) portion of the ACE:

```
default filter acl ace ip <acl-id> <ace-id>
```

Example

```
Switch:1(config)#filter acl ace ip 1 12 dst-ip eq 198.51.100.0
```

Variable definitions

Use the data in the following table to use the **filter acl ace ip** command.

Variable	Value
<ace-id>	Specifies the ACE ID. Different hardware platforms support different ACE ID ranges. Use the CLI Help to see the available range for the switch.
<acl-id>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
{<0-32> null <A.B.C.D>}	Specifies the mask value for the destination or source IP address For example: <pre>filter acl ace ip 10 10 dst-ip mask 198.51.100.0 25 filter acl ace ip 10 10 dst-ip mask 198.51.100.1 203.0.113.0 filter acl ace ip 10 10 src-ip mask 198.51.100.2 22 filter acl ace ip 10 10 src-ip mask 198.51.100.3 203.0.113.1</pre>
<noFragment anyFragment>	Specifies a match option for IP fragments noFragment or anyFragment.

Variable	Value
<i>{<0..63> <0x00..0x3f> phbcs0 phbcs1 phbaf11 phbaf12 phbaf13 phbcs2 phbaf21 phbaf22 phbaf23 phbcs3 phbaf31 phbaf32 phbaf33 phbcs4 phbaf41 phbaf42 phbaf43 phbcs5 phbcs6 phbef phbcs7}</i>	Specifies the DSCP value using one of the following formats: <ul style="list-style-type: none"> Enter as an integer (0-63) or hex (0x00-0x3f), or as a string: <ul style="list-style-type: none"> phbcs0 — Enter as string “phbcs0”, integer 0 or hex 0x00 phbcs1 — Enter as string “phbcs1”, integer 8 or hex 0x08 phbaf11 — Enter as string “phbaf11”, integer 10 or hex 0x0a phbaf12 — Enter as string “phbaf12”, integer 12 or hex 0x0c phbaf13 — Enter as string “phbaf13”, integer 14 or hex 0x0e phbcs2 — Enter as string “phbcs2”, integer 16 or hex 0x10 phbaf21 — Enter as string “phbaf21”, integer 18 or hex 0x12 phbaf22 — Enter as string “phbaf22”, integer 20 or hex 0x14 phbaf23 — Enter as string “phbaf23”, integer 22 or hex 0x16 phbcs3 — Enter as string “phbcs3”, integer 24 or hex 0x18 phbaf31 — Enter as string “phbaf31”, integer 26 or hex 0x1a phbaf32 — Enter as string “phbaf32”, integer 28 or hex 0x1c phbaf33 — Enter as string “phbaf33”, integer 30 or hex 0x1e phbcs4 — Enter as string “phbcs4”, integer 32 or hex 0x20 phbaf41 — Enter as string “phbaf41”, integer 34 or hex 0x22 phbaf42 — Enter as string “phbaf42”, integer 36 or hex 0x24 phbaf43 — Enter as string “phbaf43”, integer 38 or hex 0x26 phbcs5 — Enter as string “phbcs5”, integer 40 or hex 0x28 phbef — Enter as string “phbef”, integer 46 or hex 0x2e phbcs6 — Enter as string “phbcs6”, integer 48 or hex 0x30 phbcs7 — Enter as string “phbcs7”, integer 56 or hex 0x38
<i>WORD<0x0-0x40></i>	Specifies the mask value, for example, <code>filter acl ace ip 10 10 dscp mask 129 0x40</code>
<i>WORD<1-256></i>	Specifies one or more IP protocol types: (1-256), or tcp, udp, ipsecesp, vrrp, snmp or undefined.
<i>WORD<1-1024></i>	Specifies the destination or source IP address (a.b.c.d).

Configure an IPv6 ACE

Configure an IPv6 ACE to filter traffic based on Source IPv6 address, Destination IPv6 address, IPv6 next header, and IPv6 traffic class, and routed packets only.

Source IPv6 and destination IPv6 support equal (eq) and mask operators. Next header and traffic class attributes support the equal (eq) operator. The equal to rule operator looks for an exact match with the field defined. If the field matches exactly with the rule, the system will return a match (hit). ACL-based filters provide the mask operator to match on Layer 2, Layer 3, and Layer 4 packet fields. The mask operator is used to mask bits in packet fields during a search or to match on a partial value of a packet field.

Before You Begin

- The ACL exists. The ACL exists with the IPv6 packet type. You can only configure ACE IPv6 attributes to filter on an IPv6 packet.
- The ACE exists.

About This Task

The *eq* and *mask* parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create and name an ACE:

```
filter acl ace <acl-id> <ace-id> [name Word<1-32>]
```

3. Configure an ACE for the destination IPv6 address attribute:

```
filter acl ace ipv6 <acl-id> <ace-id> dst-ipv6 eq WORD<0-255>
```

OR

```
filter acl ace ipv6 <acl-id> <ace-id> dst-ipv6 mask WORD<1-128>  
WORD<0-255>
```

4. Configure an ACE for the source IP address attribute:

```
filter acl ace ipv6 <acl-id> <ace-id> src-ipv6 eq WORD<0-255>
```

OR

```
filter acl ace ipv6 src-ipv6 <acl-id> <ace-id> mask WORD<1-128>  
WORD<0-255>
```

5. Specify the next header of the IP header:

```
filter acl ace ipv6 <acl-id> <ace-id> nxt-hdr eq {fragment|hop-by-hop|  
icmpv6|ipsecah|ipsecesp|noHdr|routing|tcp|udp|undefined}
```

You must configure next header to configure the protocol attributes.

6. Specify the traffic class attribute of the IPv6 header:

```
filter acl ace ipv6 <acl-id> <ace-id> traffic-class eq WORD<0-255>
```

7. Configure an ACE for routed packets only:

```
filter acl ace ipv6 <acl-id> <ace-id> routed-only
```

8. Ensure that your configuration is correct:

```
show filter acl ipv6 <acl-id> <ace-id>
```

Example

```
Switch:1(config)#filter acl ace ipv6 15 15 dst-ipv6 eq 30:0:0:0:0:0:ffff/64
```

Configuring a protocol ACE

Configure a protocol ACE to filter on the source port, destination port, ICMP and ICMPv6 message type, or TCP flags.

Note

For IPv6 filters, you must configure next header to configure the protocol attributes.

Before You Begin

- The ACL exists.
- The ACE exists.

About This Task

The *eq* and *mask* parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure an ACE for destination port attributes:

```
filter acl ace protocol <acl-id> <ace-id> dst-port eq WORD<1-60>
```

OR

```
filter acl ace protocol <acl-id> <ace-id> dst-port mask WORD<1-60>  
WORD<1-256>
```

3. Configure an ACE for source port attributes:

```
filter acl ace protocol <acl-id> <ace-id> src-port eq WORD<1-65535>
```

OR

```
filter acl ace protocol <acl-id> <ace-id> src-port mask WORD<1-65535>  
WORD<1-256>
```

4. Configure an ACE for ICMP message type attributes:

```
filter acl ace protocol <acl-id> <ace-id> icmp-msg-type eq WORD<1-200>
```

5. Configure an ACE for TCP flags attributes:

```
filter acl ace protocol <acl-id> <ace-id> tcp-flags eq WORD<1-50>
```

OR

```
filter acl ace protocol <acl-id> <ace-id> tcp-flags mask {0-0x3F|  
0-0x3F}
```

6. Ensure the configuration is correct:

```
show filter acl protocol <acl-id> <ace-id>
```

7. (Optional) Delete the individual attributes from the protocol portion of the ACE:
`no filter acl ace protocol <acl-id> <ace-id> [dst-port] [icmp-msg-type] [icmpv6-msg-type] [routing-type] [src-port] [tcp-flags]`
8. (Optional) Delete all the attributes from the protocol portion of the ACE:
`default filter acl ace protocol <acl-id> <ace-id>`

Specify ICMP packets:

```
Switch:1(config)#filter acl ace protocol 1 12 icmpv6-msg-type eq echoRequest
```

Table 232: TCP Flags Order in Packet

32 (decimal)	16 (decimal)	8 (decimal)	4 (decimal)	2 (decimal)	1 (decimal)
Urgent	Ack	Push	Reset	Syn	Fin

Configure an ACE for TCP flags attributes: Example 1

The mask is set for an 'ack' tcp flag bit regardless of whether any other tcp flag bits are also set:

```
Switch:1(config)#filter acl ace protocol 1 1 tcp-flags mask ack ?
<0-0x3F | 0-63> Mask value <Hex | Decimal>: This six bit mask is a reverse mask where
0:care
about, 1:do not care about
Switch:1(config)#filter acl ace protocol 1 1 tcp-flags mask ack 0x2f
Hex Value 20 10 8 4 2 1
TCP Flags _ ack _ _ _ _
Binary Value 1 0 1 1 1 1 or in hex = 0x2F
```

Configure an ACE for TCP flags attributes: Example 2

A packet will match this filter if the 3 tcpflag bits are set in the tcp header (and only those 3 bits).

```
Switch:1(config)#filter acl ace protocol 1 1 tcp-flags eq ?
WORD<1-50> Tcp flags
{none | fin | syn | rst | push | ack | urg | undefined}
Switch:1(config)#filter acl ace protocol 1 1 tcp-flags eq syn,push,urg
```

You can configure a functionally equivalent filter with the mask operator as follows:

```
Switch:1(config)#filter acl ace protocol 1 1 tcp-flags mask syn,push,urg 0x0
```

Configure an ACE for TCP flags attributes: Example 3

The mask operator provides more flexibility. For example a packet will match the following filter if the 'syn,push,urg' tcpflag bits are set, regardless of whether any other tcpflag bits are also set:

```
Switch:1(config)#filter acl ace protocol 1 1 tcp-flags mask syn,push,urg ?
<0-0x3F | 0-63> Mask value <Hex | Decimal>: This six bit mask is a reverse mask where
0:care
about, 1:do not care about
Switch:1(config)#filter acl ace protocol 1 1 tcp-flags mask syn,push,urg 0x15
```

Configure an ACE for ICMP message type: Example 4

```
filter acl 1 type inPort name "ICMP_TRAFFIC_FILTER"
filter acl port 1 1/3
filter acl ace 1 1
```

```

filter acl ace action 1 1 deny count
filter acl ace ethernet 1 1 ether-type eq ip
filter acl ace ip 1 1 src-ip mask 194.183.100.64 0.0.0.15
filter acl ace ip 1 1 dst-ip eq 146.97.137.42
filter acl ace ip 1 1 ip-protocol-type eq icmp
filter acl ace protocol 1 1 icmp-msg-type eq echo-request
filter acl ace 1 1 enable
filter acl ace 1 2
filter acl ace action 1 2 deny count
filter acl ace ethernet 1 2 ether-type eq ip
filter acl ace ip 1 2 src-ip mask 194.183.100.64 0.0.0.15
filter acl ace ip 1 2 dst-ip eq 146.97.137.42
filter acl ace ip 1 2 ip-protocol-type eq icmp
filter acl ace protocol 1 2 icmp-msg-type eq echoreply
filter acl ace 1 2 enable

```

Variable Definitions

Use the data in the following table to use the **filter acl ace protocol** command.

Variable	Value
{0-0x3F}	Specifies the mask value.
<ace-id>	Specifies the ACE ID. Different hardware platforms support different ACE ID ranges. Use the CLI Help to see the available range for the switch.
<acl-id>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
WORD<1-50>	Specifies one or more TCP flags—none, fin (finish connection), syn (synchronize), rst (reset connection), push, ack (acknowledge), urg (urgent), and undefined.
WORD<1-60>	Specifies the destination port: (0-65535), or echo, ftpdata, ftpcontrol, ssh, telnet, dns, http, hdot323, bootpServer, bootpClient, tftp, rtp, rtcp, or undefined.
WORD<1-200>	Specifies the ICMP message type: icmpmsg type (0-255), or echoreply, destunreach, sourcequench, redirect, echo-request, routeradv, routerselct, time-exceeded, param-problem, timestamp-request, timestamp-reply, addressmask-request, addressmask-reply, or traceroute.
WORD<1-200>	Specifies the ICMPv6 message type: icmpmsg type (0-255), or destUnreach, pktTooBig, timeExceeded, paramProblem, echoRequest, echoReply, mcastListenReq, mcastListenRpt, mcastListenDone, routerSolicit, routerAdvert, neighborSolicit, neighborAdvert, redirectMsg, nodeInfoReq, nodeInfoRsp, or v2McastListenRpt.
WORD<1-256>	Specifies the mask parameter, {0-0xFFFF}.
WORD<0-65535>	Specifies the source port (0-65535).

Configure Ingress Policer and Port Rate Limiter

Before You Begin

Ensure that both the ACL and the ACE exist.

About This Task

Perform this procedure to limit the number of packets that can be attached to an ACL ACE. If you want to modify the ingress bandwidth rate limiter values, you must first disable the ACE.

Note

You can attach one policer to ACL and ACE. Every policer is independent.

Procedure

1. Enter the Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure an ACL and ACE policer:

```
filter acl ace policer <acl-id> <ace-id> svc-rate <0-4000000000> peak-  
rate <8-4000000000>
```

Note

You must configure both svc-rate and peak-rate.

3. Ensure the configuration is correct:

```
show filter acl policer <acl-id> <ace-id>
```

Variable Definitions

The following table defines parameters for the **filter acl ace policer** command.

Variable	Value
<code><acl-id></code>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<code><ace-id></code>	Specifies the ACE ID. Different hardware platforms support different ACE ID ranges. Use the CLI Help to see the available range for the switch.
<code>svc-rate <0-4000000000></code>	Specifies the rate of the traffic committed to be delivered. Service rate limit in kbps {0-4000000000}.The granularity is 8 kbps.
<code>peak-rate <8-4000000000></code>	Specifies the value when exceeded causes packets to drop on ingress. Peak rate limit in kbps {8-4000000000}.The granularity is 8 kbps.

Viewing ACL and ACE configuration data

View your configuration to review the information and ensure it is correct.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. View ACL information:
`show filter acl <acl-id>`
3. View IPv6 ACL information:
`show filter acl ipv6 <acl-id> <ace-id>`
4. View the running configuration for an ACL and corresponding ACE:
`show filter acl config <acl-id> <ace-id>`

Variable Definitions

Use the data in the following table to use the **show filter acl** and **show filter acl config** commands.

Variable	Value
<ace-id>	Specifies the ACE ID. Different hardware platforms support different ACE ID ranges. Use the CLI Help to see the available range for the switch.
<acl-id>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.

View ACE Statistics

View ACE statistics to ensure that the filter operates correctly.

**Note**

The ACL statistics do not support security action on some hardware platforms.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. View ACE statistics for a specific ACL, ACE, or ACE type:
`show filter acl statistics <acl-id> <ace-id> [qos] [security]`
3. View all ACE statistics:
`show filter acl statistics all`
4. View default ACE statistics:
`show filter acl statistics default [<acl-id>]`
5. View global statistics for ACEs:
`show filter acl statistics global [<acl-id>]`
6. View filter policer statistics for ACL and ACE:
`show filter acl statistics <acl-id> <ace-id> policer`

Examples

View ACE statistics:

**Note**

Based on your hardware platform, the output can display all the ACL packets or segregate them as QoS and security ACL packets.

```
Switch:1>enable
Switch:1#show filter acl statistics all
```

```

Variable Definitions

The following table defines parameters for the **show filter acl statistics** command.

Variable	Value
<code><acl-id></code>	Specifies the ACL ID. Use the CLI Help to see the available range for the switch.
<code><ace-id></code>	Specifies the ACE ID. Different hardware platforms support different ACE ID ranges. Use the CLI Help to see the available range for the switch.
<code>policer</code>	Specifies the policer parameter for the command.

Access Control Entry Configuration using EDM

Use an access control entry (ACE) to define a pattern (found in a packet) and the desired behavior for packets that carry the pattern.

As a best practice, create access control lists (ACL) with a default action of permit, and with an ACE mode of deny. For deny or permit ACLs or ACEs, the default action and the mode must be opposite for the ACE (filter) to have meaning.

Note

Some hardware platforms support ACE IDs from the range 1-1000 for both security and QoS rules.

Configure an ACE

Before You Begin

- The ACL exists.

Procedure

- In the navigation pane, expand the **Configuration > Security > Data Path** folders.
- Click **Advanced Filters (ACE/ACLs)**.
- Click the **ACL** tab.
- Select the ACL to which to add an ACE.
- Click **ACE**.
- Click the **ACE Common** tab.
- Click **Insert**.
- Configure the ACE ID.
- Name the ACE.
- Choose the mode: **deny** (drop packets) or **permit** (forward packets).
- Configure the ACE actions as required.
- Click **Insert**.
- Configure the ACE attributes as required.
- To enable the ACE, in the **ACE Common** tab, configure **AdminState** to enable, and then click **Apply**.

15. To delete an ACE Common entry, select the entry, and then click **Delete**.

ACE Common field descriptions

Use the data in the following table to use the **ACE Common** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
Name	Specifies a descriptive user-defined name for the ACE. The system automatically assigns a name if you do not type one.
AdminState	Indicates the status of the ACE as enabled or disabled. You can modify an ACE only if you disable it.
OperState	Indicates the current operational state of the ACE.
Mode	Indicates the operating mode for this ACE. Valid options are deny and permit, with deny as the default.
RedirectNextHop	Redirects matching IPv4/IPv6 traffic to IPv4/IPv6 nexthop.
RedirectNextHopVrfname	Specifies the direct next hop VRF name. The name must be in the range of 1 to 16 characters.
RedirectUnreach	Denies or permits packet dropping when the next hop for the packet is unreachable. The default value is deny. This action is a security action.
InternalQos	This variable is a QoS action. The default value is 1.
RemarkDscp	Specifies whether the DSCP parameter marks nonstandard traffic classes and local-use Per-Hop Behavior. The default is disable. Use this option to create a QoS ACE.
RemarkDot1Priority	Specifies whether Dot1 Priority, as described by Layer 2 standards (802.1Q and 802.1p) is enabled. The default is disable. Use this option to create a QoS ACE.

Configure ACE Actions

Configure ACE actions to determine the process that occurs after a packet matches (or does not match) an ACE. Use debug actions (flags) to use filters for troubleshooting and monitoring procedures.

Before You Begin

- The ACE exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.

6. Select an **Aceld**.
7. Select **Action**.
8. Configure the actions as required, and then select **Apply**.

Action field descriptions

Use the data in the following table to use the **Action** tab.

Note

The table lists the options for both Security ACEs and QoS ACEs. Dependent upon the ACE, the system displays different options on the EDM interface.

Name	Description
AcId	Specifies the ACL ID.
Aceld	Specifies the ACE ID.
Mode	Configures the action mode for security ACEs. The default value is deny.
RemarkDscp	Specifies the new Per-Hop Behavior (PHB) for matching packets: phbcs0, phbcs1, phbaf11, phbaf12, phbaf13, phbcs2, phbaf21, phbaf22, phbaf23, phbcs3, phbaf31, phbaf32, phbaf33, phbcs4, phbaf41, phbaf42, phbaf43, phbcs5, phbef, phbcs6, phbcs7. This action is a QoS action.
RemarkDot1Priority	Specifies the new 802.1 priority bit for matching packets: zero, one, two, three, four, five, six, or seven. This action is a QoS action. Note: This does not apply to IPv6 filtering.
InternalQoS	This variable is a QoS action. The default value is 1. Note: This does not apply to IPv6 filtering.
RedirectNextHop	Specifies the next-hop IPv4 address (a.b.c.d) or IPv6 address (aaaa:bbbb:cccc:dddd:eeee:ffff:gggg:hhhh) for redirect mode. Applies to ingress ACLs (routed and Layer 2 packets).
Count	Enables the ability to count matching packets. Use this parameter with either a security or QoS ACE. The default is disabled.
DstPortList	Configures mirroring to a destination port or ports. This action is a security action.
DstMltId	Configures mirroring to a destination MLT. This action is a security action.

Name	Description
MonitoringIsidOffset	Configures the monitoring I-SID offset value. The offset ID is mapped to the actual monitor I-SID value to which the packets are mirrored.
MirroringQoS	Defines the Quality of Service (QoS) profiles for the mirrored packet into monitoring I-SID.

Configuring ACE ARP entries

Use ACE Address Resolution Protocol (ARP) entries so that the filter looks for ARP request or response packets.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select a parameter for the appropriate ACL.
5. Click **ACE**.
6. Select a parameter for the appropriate ACE.
7. Click **Arp**.
8. Click **Insert**.
9. Select ARP request or response.
10. Click **Insert**.

ARP field descriptions

Use the data in the following table to use the **ARP** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Type	Specifies the ACE ARP operation. The only option is operation.
Oper	Specifies the operator for the ACE ARP operation. The only option is eq (equal).
Value	Specifies the ARP packet type. Valid options are arpRequest and arpResponse.

Viewing all ACE ARP entries for an ACL

View all of the ACE ARP entries associated with an ACL.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **Arp**.
6. To modify a parameter, double-click the parameter, select the option, and then click **Apply**.

ARP field descriptions

Use the data in the following table to use the **ARP** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Type	Specifies the ACE ARP operation. The only option is operation.
Oper	Specifies the operator for the ACE ARP operation. The only option is eq (equal).
Value	Specifies the ARP packet type. Valid options are arpRequest and arpResponse.

Configuring an ACE Ethernet source address

Perform this procedure to filter on specific Ethernet source addresses.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **Eth**.
8. Click the **Source Address** tab.
9. Click **Insert**.
10. Specify the ACE Ethernet operation.
11. In the **List** dialog box, specify the Ethernet source address.
12. Click **Insert**.

Source Address *Field Descriptions*

Use the data in the following table to use the **Source Address** tab.

Variable	Value
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
List	Specifies the MAC address to match.
OperMask	Specifies the MAC Address mask value in hexadecimal format. The value for this variable is empty or 000000000000 if the Oper variable is eq.

Configuring an ACE Ethernet destination address

Perform this procedure to filter on specific Ethernet destination addresses.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **Eth**.
8. Click the **Destination Address** tab.
9. Click **Insert**.
10. Specify the ACE Ethernet operation.
11. In the **List** dialog box, specify the Ethernet source address.
12. Click **Insert**.

Destination Address *Field Descriptions*

Use the data in the following table to use the **Destination Address** tab.

Variable	Value
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.

Variable	Value
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
List	Specifies the MAC address to match.
OperMask	Specifies the MAC address mask value in hexadecimal format if the Oper variable is mask. The value of this variable is empty or 000000000000 if Oper is eq.

Configuring an ACE LAN traffic type

Perform this procedure to filter for specific LAN traffic packets.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **Eth**.
8. Click the **Ethernet Type** tab.
9. Click **Insert**.
10. Specify the operation type.
11. In the **TypeList** box, type the Ethernet types.
12. Click **Insert**.

Ethernet Type field descriptions

Use the data in the following table to use the **Ethernet Type** tab.

Name	Description
AcId	Specifies the ACL ID.
Aceld	Specifies the ACE ID.

Name	Description
TypeOper	The eq parameter specifies an operator for a field match condition: equal to.
TypeList	Specifies the Ethernet type. Entries include: 0 to 0xffff or ip, arp, ipx802.3, ipx802.2, ipxSnap, ipxEthernet2, appleTalk, appleTalk-ARP, sna802.2, snaEthernet2, netBios, xns, vines, ipv6, rarp, PPPoE-discovery, and PPPoE-session. Note: Ethernet ACE filter configured with Ethernet Type ipx802.3 does not match the packet with format destination MAC address, source MAC address, length, 0xFFFF, payload and FCS. Ethernet ACE filter configured with Ethernet Type ipx802.2 does not match the packet with format destination MAC address, source MAC address, length, 0xE0E0, payload and FCS.

Configuring an ACE Ethernet VLAN tag priority

Perform this procedure to filter for specific VLAN tag priorities.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **Eth**.
8. Click the **Vlan Tag Priority** tab.
9. Click **Insert**.
10. Specify the operation type.
11. In the **VlanTagPrio** box, select the priority bits.
12. Click **Insert**.

VLAN Tag Priority field descriptions

Use the data in the following table to use the **Vlan Tag Priority** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.

Name	Description
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
VlanTagPrio	Specifies the priority bits (3-bit field) from the 802.1Q/p tag: <ul style="list-style-type: none"> • zero • one • two • three • four • five • six • seven
OperMask	Specifies the mask value in hexadecimal format if the Oper value is mask.

Configuring an ACE Ethernet port

Use ACE Ethernet port entries so that the filter looks for traffic on specific ports. You can only insert an ACE Common Ethernet port for VLAN ACL types.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **Eth**.
8. Click the **Port** tab.
9. Click **Insert**.
10. Specify the operation type.
11. Click the **Port** ellipses (...).
12. Choose the ports.
13. Click **OK**.
14. Click **Insert**.

Port field descriptions

Use the data in the following table to use the **Port** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
Oper	The eq parameter specifies an operator for a field match condition: equal to.
Port	Specifies the port or port list on which to perform a match.

Configuring an ACE Ethernet VLAN ID

Use ACE Ethernet VLAN ID entries so that the filter looks for traffic on specific VLANs. You can insert an ACE Ethernet VLAN ID only for ACL VLAN types.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **Eth**.
8. Click the **Vlan Id** tab.
9. Click **Insert**.
10. Specify the operation type.
11. Enter the VLAN ID or select from a list.
12. Click **Insert**.

VLAN ID field descriptions

Use the data in the following table to use the **Vlan Id** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
Oper	The eq parameter specifies an operator for a field match condition: equal to.
VlanId	Specifies the VLAN ID on which to perform a match.
OperMask	Specifies the mask value for a VLAN attribute.

Viewing all ACE Ethernet entries for an ACL

View all of the ACE Ethernet entries associated with an ACL.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **Eth**.

Ethernet field descriptions

Use the data in the following table to use the **Ethernet** tab.

Name	Description
AcId	Shows the ACL ID.
AceId	Specifies the ACE ID.
SrcAddrList	Shows the list of Ethernet source addresses to match.
SrcAddrOper	Shows the operators for the ACE Ethernet source MAC address.
SrcAddrOperMask	Shows the source MAC address mask value in hexadecimal format if the SrcAddrOper variable is mask. The value of this field is empty or 000000000000 if the SrcAddrOper field is eq.
DstAddrList	Shows the list of Ethernet destination addresses to match.
DstAddrOper	Shows the operators for the ACE Ethernet destination MAC address.
DstAddrOperMask	Shows the destination MAC address mask value in hexadecimal format if the DstAddrOper variable is mask. The value for this field is empty or 000000000000 if the DstAddrOper field is eq
EtherTypeList	Shows the EtherType value from the Ethernet header. For example, ARP uses 0x0806 and IP uses 0x0800. Platform support determines the behavior for 802.1Q/p tagged packets. The EtherType for 802.1Q tagged frames is 0x8100. The range is 0–65535 and supports lists and ranges of values. An invalid Ether-type of 65536 indicates that you do not want the parameter in the match criteria.
EtherTypeOper	Shows the Ethernet type operators.
VlanTagPrio	Shows the priority bits (3-bit field) from the 802.1Q/p tag.
VlanTagPrioOper	Shows the operators for the ACE Ethernet VLAN tag priority.
VlanTagPrioOperMask	Shows the VLAN tag priority mask value in hexadecimal format if the VlanTagPrioOper field is mask.
Port	Shows the port number or port list to match.
PortOper	Shows the operator for the ACE Ethernet port.

Name	Description
VlanId	Shows the VLAN ID to match.
VlanIdOper	Shows the operator for the ACE Ethernet VLAN ID.
VlanIdOperMask	Shows the VLAN ID mask value in hexadecimal format if the VlanIdOper field is mask.

Configuring an ACE IP source address

Configure ACE IP source address entries to have the filter look for specific source IP addresses.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **IP**.
8. Click the Source Address tab.
9. Click **Insert**.
10. Specify the operation type.
11. In the **IPAddr** box, enter the source IP address.
12. Click **Insert**.

Source Address field descriptions

Use the data in the following table to use the **Source Address** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
IPAddr	Specifies the source IP address.
OperMask	Specifies the mask value for the source IP address.

Configuring an ACE IP destination address

Configure ACE IP destination address entries to have the filter look for specific destination IP addresses.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **IP**.
8. Click the **Destination Address** tab.
9. Click **Insert**.
10. Specify the operation type.
11. In the **IPAddr** box, enter the destination IP address.
12. Click **Insert**.

Destination Address field descriptions

Use the data in the following table to use the **Destination Address** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
IPAddr	Specifies the destination IP address.
OperMask	Specifies the mask value for the destination IP address.

Configuring an ACE IP DSCP

Configure ACE IP DSCP entries to have the filter look for packets with specific DSCP markings.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.

5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **IP**.
8. Click the **DSCP** tab.
9. Click **Insert**.
10. Specify the operation type.
11. In the **List** box, enter the count for the DSCP values.
12. Click **Insert**.

DSCP field descriptions

Use the data in the following table to use the **DSCP** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
List	Specifies a count for the number of discrete ranges entered for the DSCP values. Entries include 0–256, disable, phbcs0, phbcs1, phbaf11, phbaf12, phbaf13, phbcs2, phbaf21, phbaf22, phbaf23, phbcs3, phbaf31, phbaf32, phbaf33, phbcs4, phbaf41, phbaf42, phbaf43, phbcs5, phbef, phbcs6, and phbcs7.
OperMask	Specifies the mask value.

Configuring an ACE IP protocol

Configure ACE IP protocol entries to have the filter look for packets of specific protocols.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **IP**.
8. Click the **Protocol** tab.
9. Click **Insert**.
10. Specify the operation type.

11. In the **List** box, enter the IP protocol type.
12. Click **Insert**.

Protocol field descriptions

Use the data in the following table to use the **Protocol** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Oper	The eq parameter specifies an operator for a field match condition: equal to.
List	Specifies the IP protocol type. Entries include 0–256, undefined, tcp, udp, ipsecesp, vrrp, and undefined.

Configuring ACE IP options

Configure ACE IP option entries to have the filter look for packets with an IP option specified.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **IP**.
8. Click the **Options** tab.
9. Click **Insert**.
10. Specify the logical operator.
Any is the only choice.
11. Click **Insert**.

Options field descriptions

Use the data in the following table to use the **Options** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
Oper	Specifies the logical operator for the ACE IP options. Any is the only option.

Configuring ACE IP fragmentation

Configure ACE IP fragmentation entries to have the filter look for packets with the fragmentation flag.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **IP**.
8. Click the **Fragmentation** tab.
9. Click **Insert**.
10. Specify the operator for IP fragmentation.
Eq is the only choice.
11. Specify the fragmentation bits to match from the IP header.
12. Click **Insert**.

Fragmentation field descriptions

Use the data in the following table to use the **Fragmentation** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.

Name	Description
Oper	Specifies the logical operator for the ACE IP options. Any is the only option.
Fragmentation	Specifies the IP fragmentation bits to match from the IP header: <ul style="list-style-type: none"> noFragment anyFragment The default is noFragment.

Viewing all ACE IP entries for an ACL

View all of the ACE IP entries associated with an ACL.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **IP**.

IP field descriptions

Use the data in the following table to use the **IP** tab.

Name	Description
AcId	Shows the ACL IP ID.
AceId	Shows the ACE ID.
SrcAddrOper	Shows the operators for the ACE IP source address.
SrcAddrIpAddr	Shows the IP source address to match from the IP header.
SrcAddrOperMaskRange	Shows the IP mask value if SrcAddrOper is set to mask, or the highest IP address if SrcAddrOper is set to range.
DstAddrOper	Shows the operators for the ACE IP destination address.
DstAddrIpAddr	Shows the IP destination address to match from the IP header.
DstAddrOperMaskRange	Shows the IP mask value if DstAddrIpAddr is set to mask, or the highest IP address if DstAddrIpAddr is set to range.
DscpList	Shows how the 6-bit DSCP parameter from the TOS byte in the IPv4 header encodes PHB information following RFC 2474.
DscpOper	Shows the operators for the ACE IP DSCP.
DscpOperMask	Shows the mask value in hexadecimal format when the mask option is selected in DscpOper .
ProtoList	Shows the IP protocol type from the IP header to match. The range is 0–255.

Name	Description
ProtoOper	Shows the operators for the ACE IP protocols.
Options	Shows the IP options to match from the IP header.
OptionsOper	Shows the logical operator. Any is the only option.
Fragmentation	Shows the IP fragmentation bits to match from the IP header.
FragOper	Shows the operator for IP fragmentation.

Configuring an ACE IPv6 source address

Configure ACE IPv6 source address entries to have the filter look for specific source IP addresses.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **IPv6**.
8. Click the **Source Address** tab.
9. Click **Insert**.
10. In the **Oper** field, select the operation type.
11. In the **List** field, enter the source IP address.
12. In the **OperMask** field, enter the operation mask value.
13. Click **Insert**.

Source Address field descriptions

Use the data in the following table to use the **Source Address** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
List	Specifies the source IP address.
OperMask	Specifies the mask value for the source IP address.

Configuring an ACE IPv6 destination address

Configure ACE IPv6 destination address entries to have the filter look for specific destination IP addresses.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **IPv6**.
8. Click the **Destination Address** tab.
9. Click **Insert**.
10. In the **Oper** field, select the operation type.
11. In the **List** field, enter the destination IP address.
12. In the **OperMask** field, enter the operation mask value.
13. Click **Insert**.

Destination Address field descriptions

Use the data in the following table to use the **Destination Address** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
List	Specifies the destination IP address.
OperMask	Specifies the mask value for the destination IP address.

Configuring an ACE IPv6 next header

Configure ACE IPv6 next header entries to have the filter look for specific next headers.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **IPv6**.
8. Click the **Next Hdr** tab.
9. Click **Insert**.
10. In the **Oper** field, select the operation type.
11. In the **NextHdr** field, select the next header type.
12. Click **Insert**.

Next Header field descriptions

Use the data in the following table to use the **Next Hdr** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Oper	The eq parameter specifies an operator for an “equal to” field match condition.
NextHdr	Specifies the next header of the IPv6 header. Specifies hop-by-hop, tcp, udp, routing, fragment, ipsecESP, ipsecAH, icmpv6, noNxtHdr, or undefined.

Configuring an ACE IPv6 traffic class

Configure ACE IPv6 traffic class.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **IPv6**.
8. Click the **Traffic Class** tab.

9. Click **Insert**.
10. In the **Oper** field, select the operation type.
11. In the **TrafficCls** field, enter the traffic class number.
12. Click **Insert**.

Traffic Class field descriptions

Use the data in the following table to use the **Traffic Class** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Oper	The eq parameter specifies an operator for an “equal to” field match condition.
TrafficCls	Specifies the traffic class attribute of the IPv6 header. Traffic class identifies different classes or priorities of IPv6 packets. The range is 0–255.

Viewing all ACE IPv6 entries for an ACL

View all of the ACE IPv6 entries associated with an ACL.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **IPv6**.
8. Click the **IPv6** tab.

IPv6 field descriptions

Use the data in the following table to use the **IPv6** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
SrcAddrList	Shows the source IP address.
SrcAddrOper	Shows the operators for the ACE IP source address.

Name	Description
DstAddrList	Shows the destination IP address.
DstAddrOper	Shows the operators for the ACE IP destination address.
NxtHdrNxtHdr	Shows the next header of the IPv6 header.
NxtHdrOper	Shows the operators for the next header.
TrafficClsOper	Shows the operators for the traffic class.
TrafficCls	Shows the traffic class attribute of the IPv6 header.
SrcAddrMask	Shows the mask value for the source IP address.
DstAddrMask	Shows the mask value for the destination IP address.

Configuring an ACE source port

Configure ACE source port entries to have the filter look for packets with a specific source port.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **Proto**.
8. Click the **Source Port** tab.
9. Click **Insert**.
10. Specify the operator for the source port.
11. Specify the port number or port list to match.
12. Click **Insert**.

Source Port field descriptions

Use the data in the following table to use the **Source Port** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Port	Specifies the source port (1–65535).

Name	Description
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
OperMask	Specifies the mask parameter, {0-0xFFFF}.

Configuring an ACE destination port

Configure ACE destination port entries to have the filter look for packets with a specific destination port.

Before You Begin

- The ACE exists.
- The ACL exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **Proto**.
8. Click the **Destination Port** tab.
9. Click **Insert**.
10. Specify the operator for the destination port.
11. Specify the port number or port list to match.
12. Click **Insert**.

Destination Port field descriptions

Use the data in the following table to use the **Destination Port** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
Port	Specifies the port number. As noted at the bottom of the tab, potential entries include 0-65535, echo, ftpdata, ftpcontrol, ssh, telnet, dns, http, h.323, and undefined.
OperMask	Specifies the mask parameter, {0-0xFFFF}.

Configuring an ACE ICMP message type

Configure ACE Internet Control Message Protocol (ICMP) message type entries to have the filter look for packets of a specific ICMP message type.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **Proto**.
8. Click the **Icmp Msg Type** tab.
9. Click **Insert**.
10. Specify the operator for the ICMP message type.
11. In the **List** box, specify the ICMP messages to match.
12. Click **Insert**.

Icmp Msg Type field descriptions

Use the data in the following table to use the **Icmp Msg Type** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Oper	Specifies the operator for the ACE protocol ICMP message type. Equal (eq) is the only option.
List	Specifies the ICMP message type (0-255), or echoreply, destunreach, sourcequench, redirect, echo-request, routeradv, routerselct, time-exceeded, param-problem, timestamp-request, timestamp-reply, addressmask-request, addressmask-reply, or traceroute.

Configuring an ACE ICMPv6 message type

About This Task

Configure ACE Internet Control Message Protocol v6 (ICMPv6) message type entries to have the filter look for packets of a specific ICMPv6 message type.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > Security > Data path**
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **Proto**.
8. Click the **Icmpv6 Msg Type** tab.
9. Click **Insert**.
10. Specify the operator for the ICMPv6 message type.
11. In the **List** field, specify the ICMPv6 messages to match.
12. In the **Count** field, specify 1 through 100.
13. Click **Insert**.

Icmpv6 Msg Type field descriptions

Use the data in the following table to use the **Icmpv6 Msg Type** tab.

Name	Description
AclId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Oper	Specifies the operator for the ACE protocol ICMPv6 message type. Equal (eq) is the only option.
List	Specifies the ICMPv6 message type (0-255), or echoreply, destunreach, sourcequench, redirect, echo-request, routeradv, routerselect, time-exceeded, param-problem, timestamp-request, timestamp-reply, addressmask-request, addressmask-reply, or traceroute.
Count	Specifies 1-100. Enables the ability to count matching packets. Use this parameter with either a security or QoS ACE. The default is disabled.

Configuring an ACE TCP flag

Configure ACE TCP flag entries to have the filter look for packets with a specific TCP flag.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.

4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **Proto**.
8. Click the **TCP Flags** tab.
9. Click **Insert**.
10. Specify the operator for the TCP flags entry.
11. In the **List** box, specify the TCP flags to match.
12. Click **Insert**.

TCP Flags field descriptions

Use the data in the following table to use the **TCP Flags** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
List	Specifies one or more TCP flags—none, fin (finish connection), syn (synchronize), rst (reset connection), push, ack (acknowledge), urg (urgent), and undefined.
OperMask	Specifies the mask value.

Configure an ACE to Filter IPv4 Routed Packets

Configure an ACE to filter IPv4 routed packets.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select **IpRouted** tab.
4. Select **Insert**.
5. In the **AcId** field, type the appropriate ACL ID.
6. In the **AceId** field, type the appropriate ACE ID.
7. **RoutedOnly**
8. Select **Insert**.

IpRouted Field Descriptions

The following table describes values on the **IpRouted** tab.

Name	Description
AcId	Specifies the ACL ID. Value range of 1 to 2048.
AceId	Specifies the ACE ID. Value range of 1 to 2000.

Configure an ACE to Filter IPv6 Routed Packets

Configure an ACE to filter IPv6 routed packets only.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **Ipv6Routed** tab.
4. Select **Insert**.
5. In the **AcId** field, type the appropriate ACL ID.
6. In the **AceId** field, type the appropriate ACE ID.
7. Select **RoutedOnly**.
8. Select **Insert**.

Ipv6Routed Field Descriptions

The following table describes values on the **Ipv6Routed** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
RoutedOnly	Specifies the match for IPv6 routed packets only.

Configure Ingress Policer and Port Rate Limiter

Perform this procedure to limit the number of packets that can be attached to an ACL ACE. If you want to modify the ingress bandwidth rate limiter values, you must first disable the ACE.

Note

You can attach one policer to ACL and ACE. Every policer is independent.

Before You Begin

Ensure that both the ACL and the ACE exist.

Procedure

1. In the navigation tree, expand **Configuration > Security > Data Path**.

2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the appropriate ACL.
4. Select the appropriate ACE.
5. Select **Policer**.
6. Select **Insert**.
7. For **SvcRateValue**, type the service rate value.
8. For **PeakRateValue**, type the peak rate value.
9. Select **Insert**.
10. Select **Apply**.

Policer Field Descriptions

Name	Description
AcId	Specifies the ACL identifier numeric value for the filter.
AceId	Specifies the ACE identifier numeric value for the filter.
SvcRateValue	Specifies the service rate in kilobits for the flow of packets from the filter. The range is 8 to 4000000000 and the granularity is 8 kilobits.
PeakRateValue	Specifies peak rate in kilobits for the flow of packets from the filter. The range is 8 to 4000000000 and the granularity is 8 kilobits.
Oper	Specifies the operational status of the policer.

Viewing ACE Port Statistics

About This Task

Use port statistics to ensure that the ACE is operating correctly.

Procedure

1. In the navigation pane, expand the **Configuration > Security > Data Path** folders.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select a field on the **ACL** tab.
5. Click **ACE**.
6. Click the **Statistics** tab.

Statistics Field Descriptions

Use the data in the following table to use the **Statistics** tab.

Name	Description
AcId	Specifies the associated ACL index.
AceId	Specifies the ACE index.
MatchCountPkts	Specifies a packet count of the matching packets.
MatchCountOctets	Specifies the number of octets of the matching packets.

Name	Description
GreenBytes	Specifies the number of bytes sent with a rate lower than the committed-rate of the matching ACE.
GreenPackets	Specifies the number of packets sent with a rate lower than the committed-rate of the matching ACE.
YellowBytes	Specifies the number of bytes sent with a rate lower than peak-rate and higher than the committed-rate of the matching ACE.
YellowPackets	Specifies the number of packets sent with a rate lower than the peak-rate and higher than the committed-rate of the matching ACE.
RedBytes	Specifies the number of bytes sent with a rate higher than the peak-rate of the matching ACE.
RedPackets	Specifies the number of packets sent with a rate higher than the peak-rate of the matching ACE.

Viewing all ACE protocol entries for an ACL

View all of the ACE protocol entries associated with an ACL.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **Proto**.

Protocol field descriptions

Use the data in the following table to use the **Protocol** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
SrcPort	Specifies the port number or port list to match.
SrcPortOper	Specifies the operator for the ACE protocol source port.
SrcPortOperMaskRange	The value is displayed in hexadecimal format when SrcPortOper is set to mask. When SrcPortOper is set to range, this field is used as the high range value. In this case, the value is displayed in decimal format. When SrcPortOper is set to eq, this field is set to 0.
DstPort	Specifies port number or port list to match.
DstPortOper	Specifies the operator for the ACE protocol destination port.

Name	Description
DstPortOperMaskRange	The value is displayed in hexadecimal format when DstPortOper is set to mask. When DstPortOper is set to range, this field is used as the high range value. In this case, the value is displayed in decimal format. When SrcPortOper is set to eq, this field is set to 0.
IcmpMsgTypeList	Specifies one or a list of ICMP messages to match. The valid range is 0-255 (reserved).
IcmpMsgTypeOper	Specifies the operator for the ACE protocol ICMP message types.
TcpFlagsList	Specifies one or a list of TCP flags to match. The valid range is 0-63.
TcpFlagsOper	Specifies the operator for the ACE protocol TCP flags.
TcpFlagsOperMask	Displays the mask value in hexadecimal format when TcpFlagsOper is set to mask. When TcpFlagsOper is set to eq, this field displays 0x0.

[Upper Layer Troubleshooting](#) on page 3242

[Traps Reference](#) on page 3261

The Troubleshooting section describes common problems and error messages with the techniques to resolve them, as well as information about troubleshooting tools.

The topics in this section provide necessary concepts and procedures to troubleshoot issues with the switch and connectivity issues in the network.

Data Collection Required for Technical Support Cases

Use the following sections to learn about how to gather information before you contact Technical Support.

Data Collection for an Outage

Perform the following data collection procedures when the switch is in an outage condition and you require Technical Support to perform a root cause analysis.

Collecting Data Before You Restart

Perform this procedure before you restart the chassis.

Procedure

1. Capture the current state of the chassis:

```
terminal more disable
```

```
show tech
```

2. Capture Flight Recorder trace information.

```
flight-recorder all {slot[-slot][,...]}
```

The **all** command executes three separate commands: `flight-recorder snapshot`, `flight-recorder trace`, and `flight-recorder archive`.

3. Reset the chassis:

- a. Reset the chassis without creating a core file.

```
reset -y
```

- b. For all other platforms, create an ssio core file and a cbc-p-main.x core file, skip the confirmation question, and then reset the chassis.

```
reset -coredump -y
```

- c. Create an ssio core file and a cbc-p-main.x core file, prompt for the confirmation question, and then reset the chassis.

```
reset -coredump
```

Note

Create a core file only when there is a need to analyze a problem. If you reset the switch for any other reason the command is `reset -y`.

4. Continue with [Collecting data after you restart](#).

Example

The following example shows output of the `flight-recorder all 1` command.

```
Switch:1#flight-recorder all 1
Processing Flight-recorder snapshot for 1 ....

Flight-recorder snapshot for slot 1 complete, filename is /intflash/PMEM/1/pmem.
20111019114431.1.bin.gz.

Processing Flight-recorder trace for 1 ....

Flight-recorder trace for slot 1 complete, filename is /intflash/flrec/1/trace.2
0111019114434.1.txt.

Processing Flight-recorder archive for slot 1 ....

Flight-recorder archive for slot 1 complete, filename is /intflash/archive/1/arc
hive.20111019114446.1.tar.
```

Collecting Data After You Restart

About This Task

Perform this procedure after you restart the affected chassis.

Procedure

1. Use FTP to transfer the following information:

- Configuration files from each chassis: Stored on the internal flash at `/intflash/`.
- Log files from each chassis: Stored on the internal flash at `/intflash/`.
- Generated archive files for slot: Stored on the internal flash. For example: `/intflash/archive/<slot>`

Note

For , if the core file is not on the primary control processor (CP), you can use FTP to connect to the internal flash of the primary CP. For example, `cp mnt/intflash/archive/<slot>/<filename> /intflash/<filename>`

To copy the file to internal flash or usb device in the primary CP, use the following command: `cp mnt/intflash/archive/<slot>/<filename> {/intflash/<filename> | /usb/<filename>}`

2. Show core information:

```
show core-files
```

If the timestamp for an entry in the command output matches the time the outage first occurred, or is later than that time, transfer that core file to an FTP server. Core files are stored on the internal flash at: `/intflash/coreFiles/`

3. Obtain the network diagram of the relevant nodes, down to the port level.

Data Collection for Non Outage Problems

Use the information in this section to collect data for problems that are less service-impacting than an outage.

Gathering Critical Information

This section identifies the critical information that you must gather before you contact Technical Support.

You must attempt to resolve the problem using this document. Contact Technical Support as a final step taken only after you are unable to resolve the issue using the information and steps provided in this document.

Gather the following information before you contact Technical Support:

- a detailed description of the problem
- the date and time when the problem started
- the frequency of the problem
- if this is a new installation
- if there is relevant information recorded on the support portal — Were related problem solutions found? Is there currently a work around for this issue? For more information, see support on the Extreme Portal at <https://extremeportal.force.com/ExtrSupportHome>.
- if the system was recently upgraded — Have you recently changed or upgraded the system, the network, or a custom application? (For example, has configuration or code been changed?) When

were these changes made? Provide the date and time. Who made these changes? Were the changes made by a partner or customer? Provide the names of the individuals who made the changes.

Troubleshooting Planning Fundamentals

You can better troubleshoot the problems on the network by planning for these events in advance. To do this, you must know the following:

- that the system is properly installed and routinely maintained
- the configuration of the network
- the normal behavior of the network

Proper Installation and Routine Maintenance

The following table lists the documents that provide maintenance and installation procedures.

To prevent problems, follow proper maintenance and installation procedures.

Table 233: Maintenance and installation documentation

Subject area	Document
Installation, environmental requirements	ExtremeSwitching 5320 Series Hardware Installation Guide ExtremeSwitching 5420 Series Hardware Installation Guide ExtremeSwitching 5520 Series Hardware Installation Guide
Transceiver installation and requirements	Extreme Optics website

Network Configuration

To keep track of the network configuration, gather the information described in the following sections. This information, when kept up-to-date, is extremely helpful for locating information if you experience network or device problems.

Site network map

A site network map identifies where each device is physically located on site, which helps locate the users and applications that a problem affects. You can use the map to systematically search each part of the network for problems.

Logical connections

The switch supports virtual LANs (VLAN). With VLANs, you must know how the devices connect logically as well as physically.

Device configuration information

Maintain online and paper copies of the device configuration information. Store all online data with the regular data backup for the site. If the site does not use a backup system, copy the information onto an external storage device, and store the backup at an offsite location.

You can use the File Transfer Protocol (FTP) and Trivial FTP (TFTP) to store configuration files on a remote server.

Other important data about the network

For a complete picture of the network, have the following information available:

- all passwords

Store passwords in a safe place. A good practice is to keep records of previous passwords in case you must restore a device to a previous software version and need to use the old password that was valid for that version.

- device inventory

Maintain a device inventory, which lists all devices and relevant information for the network. The inventory allows you to easily see the device type, IP address, ports, MAC addresses, and attached devices.

- MAC address-to-port number list

If you do not manage the hubs or switches, you must keep a list of the MAC addresses that correlate to the ports on the hubs and switches.

- change control

Maintain a change control system for all critical systems. Permanently store change control records.

- contact details

Store the details of all support contracts, support numbers, engineer details, and telephone and fax numbers.

Normal Behavior on the Network

If you are familiar with the network when it is fully operational, you can be more effective at troubleshooting problems that arise. To understand the normal behavior of the network, monitor the network over a long period of time. During this time you can see a pattern in the traffic flow, such as which devices users access most or when peak usage times occur.

To identify problems, you can use a baseline analysis, which is an important indicator of overall network health. A baseline serves as a useful reference of network traffic during normal operation, which you can then compare to captured network traffic while you troubleshoot network problems. A baseline analysis speeds the process of isolating network problems. By running tests on a healthy network, you compile normal data for your network. You can compare this normal data against the results that you get when the network experiences trouble.

For example, ping each node to discover how long it typically takes to receive a response from devices on your network. Capture and save each response time and you can use these baseline response times to help you troubleshoot. You can also use the **show tech** and **show khi performance**

{buffer-pool | cpu | memory | process | pthread | slabinfo} commands to obtain baseline output for normal system behavior.

Note

Depending on the hardware platform, the output of **show khi performance memory** command can differ.

In the following example, the **show khi performance memory** command shows the average memory utilization at various time intervals. The **show khi performance memory history** command shows the VMSize utilization values in kilobytes for each process at various time intervals. After 1 hour elapses, the system stores this information in `/intflash/coreFiles/slot/khi_mem_log`.

```
Switch:1#show khi performance memory
Slot:1Slot:1
  Used: 1609636 (KB)
  Free: 2396068 (KB)
  Current utilization: 40 %
  5-minute average utilization: 40 %
  5-minute high water mark: 40 (%)
  10-minute average utilization: 39 %
  10-minute high water mark: 39 (%)
  1-Hour average utilization: 37 %
  1-Day average utilization: 0 %
  1-Month average utilization: 0 %
  1-Year average utilization: 0 %

Switch:1#show khi performance memory history

Troubleshooting Fundamentals

This section provides conceptual information and helpful tips for common problems.

Connectivity Problems

Use the following general tasks to isolate connectivity problems:

- Check physical connectivity. Verify if an alarm for link or port down exists.
- Check the link state by viewing the **show interface {gigabitEthernet|loopback|vlan}** command output.
- Use tools like ping or trace to verify if the connectivity issue is localized to an individual port or VLAN.
- Try to localize the affected range of ports and slot.

If you contact technical support staff to help troubleshoot connectivity problems, always provide source and destination IP pairs to facilitate in troubleshooting. Be sure to provide both working and non-working pairs for comparison.

```

Routing Table Problems

Routing table problems include but are not limited to:

- inactive routes
- unnecessary routes
- black hole routes

Note

Only black hole routes that belong to the static type protocol are supported. An inter-VRF black hole route is not installed in the routing table of the destination VRF on the same switch.

- flapping links (links that go up and come down) that cause the routes to flap
- incorrect route tables
- invalid Address Resolution Protocol (ARP) cache that causes incorrect IP to MAC assignment
- problems with administrative distance or other parameters

Important

Do not restart a device to clear a problem. In restarting the device, you also clear the logs. Logs are vital and can help determine many problems.

Cable Connection Problems

You can usually trace port connection problems to a poor cable connection or to an improper connection of the port cables at either end of the link. To remedy such problems, make sure that the cable connections are secure and that the cables connect to the correct ports at both ends of the link. If you use homemade cables, ensure that the cables are wired correctly.

1000BASE-T cables

1 Gb/s ports operate using Category 5 UTP cabling only. Category 5 UTP cable is a two-pair cable. To minimize crosstalk noise, maintain the twist ratio of the cable up to the point of termination; untwist at termination cannot exceed 0.5 in. (1.27 cm).

Pluggable optic cables

Cables for the optical transceivers vary depending on the specific device type.

For more information about the cable requirements for optical transceivers, see [Extreme Optics](#) website.

Alarm Database

The switch contains a local alarms mechanism. Local alarms are raised and cleared by applications running on the switch. View active alarms by using the **show alarm database** command in the CLI. Local alarms are an automatic mechanism run by the system that do not require additional configuration.

Check local alarms regularly to ensure no alarms require additional attention. The raising and clearing of local alarms also creates a log entry for each event. For more information about viewing logs, see [Viewing Logs](#) on page 1921.

View the alarm database regularly to monitor alarm conditions, even if you do not observe a performance problem. Review the alarm messages to determine if the system performs as expected.

Not all alarm conditions indicate a problem so you must be familiar with expected behavior.

The alarm database shows the following alarm text:

```
CP1 [01/01/70 00:03:06.796] 0x00010844 00000000 Global Router HW WARNING
USB found in slot 1 has VendorId 05dc ProductId a01a and Manufacturer
Lexar and did not match supported devices
```

This alarm means that you have tried to insert an unsupported USB device into the USB slot. Only the USB device provided with your system can be inserted into the USB slot.

LED Indications of Problems

For information on LEDs on the chassis, see the hardware installation documentation.

Connectivity Fault Management

Table 234: Connectivity Fault Management product support

Feature	Product	Release introduced
IEEE 802.1ag Connectivity Fault Management (CFM): <ul style="list-style-type: none"> • Layer 2 Ping • TraceRoute • TraceTree 	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
CFM configuration on C-VLANs	5320 Series	Not Supported
	5420 Series	Not Supported
	5520 Series	Not Supported

CFM Fundamentals

The Shortest Path Bridging MAC (SPBM) network needs a mechanism to debug connectivity issues and to isolate faults. This is performed at Layer 2, not Layer 3. Connectivity Fault Management (CFM) operates at Layer 2 and provides an equivalent of ping and traceroute. To support troubleshooting of the SPBM cloud, the switch supports a subset of CFM functionality. Configure CFM on all SPBM VLANs.

CFM is based on the IEEE 802.1ag standard.

IEEE 802.1ag Connectivity Fault Management (CFM) provides OAM tools for the service layer, which allows you to monitor and troubleshoot an end-to-end Ethernet service instance. CFM is the standard for Layer 2 ping, Layer 2 traceroute, and the end-to-end connectivity check of the Ethernet network.

The 802.1ag feature divides or separates a network into administrative domains called Maintenance Domains (MD). Each MD is further subdivided into logical groupings called Maintenance Associations (MA). A single MD can contain several MAs.

Each MA is defined by a set of Maintenance Points (MP). An MP is a demarcation point on an interface that participates in CFM within an MD. Two types of MP exist:

- Maintenance End Point (MEP)
- Maintenance Intermediate Point (MIP)

CFM supports three kinds of standard CFM messages: Continuity Check Message (CCM), Loopback Message (LBM), and Linktrace Message (LTM). Messages are sent between Maintenance Points (MP) in the system.

On the switch, CFM is implemented using the LBM and LTM features only to debug SPBM. CCM messages are not required or supported.

You can assign maintenance levels for each CFM SPBM MEP and MIP to each SPBM B-VLAN individually or you can assign maintenance levels and global MEPs for all SPBM VLANs.

Autogenerated CFM and Explicitly Configured CFM

The switch simplifies CFM configuration with autogenerated CFM. With autogenerated CFM, you use the **cfm spbm enable** command and the switch creates default MD, MA, MEPs, and MIPs for SPBM B-VLANs.

If you choose to configure CFM explicitly, you must configure an MD, MA, MEPs, and MIPs.

Autogenerated CFM

You can use autogenerated CFM at a global level to create a MEP and a MIP at a specified level for every SPBM B-VLAN on the chassis. If you use autogenerated CFM commands, you do not have to configure explicit MDs, MAs, MEPs, or MIPs, and associate them with multiple VLANs.

If you do not want to use autogenerated CFM commands, you can choose to configure explicit MDs, MAs, MEPs, and MIPs for SPBM B-VLANs. However, you cannot use both an autogenerated CFM configuration and an explicit CFM configuration together.

Note

Previous explicit CFM configurations of MDs, MAs, and MEPs on SPBM B-VLANs continue to be supported. However, if you want to enable the autogenerated commands you must first remove the existing MEP and MIP on the SPBM B-VLANs. The switch only supports one type of MEP or MIP for each SPBM B-VLAN.

For information on autogenerated CFM configuration using CLI see [Configuring Autogenerated CFM on SPBM B-VLANs](#) on page 3072. For information on autogenerated CFM configuration using EDM see [Configure Autogenerated CFM on SPBM B-VLANs](#) on page 3095.

Explicitly configured CFM

If you choose to explicitly configure CFM, you must configure an MD, MA, MEPs, and MIPs. You can configure explicit CFM only on SPBM B-VLANs.

For explicit configuration information for CLI see [Configuring Explicit Mode CFM](#) on page 3074.

For explicit configuration information for EDM see [Configuring Explicit CFM](#) on page 3096.

Using CFM

For SPBM B-VLANs, the autogenerated MEPs and MIPs respond to **12 ping**, **12 traceroute**, and **12 tracetest** in the same manner as the MEPs and MIPs created explicitly. The CFM show commands that display MD, MA, and MEP information work for both autogenerated and explicitly configured CFM MEPs.

You can use CFM to troubleshoot networks and hosts that support the CFM protocol. After you configure CFM, CFM works in the network whether or not SPBM is in use.

You cannot use CFM to troubleshoot networks and hosts that do not support the CFM protocol, such as a customer domain that does not support CFM. Only devices that support the CFM protocol respond to **12 ping** and **12 traceroute** requests.

Maintenance Domain (MD)

A Maintenance Domain (MD) is the part of a network that is controlled by a single administrator. For example, a customer can engage the services of a service provider, who, in turn, can engage the services of several operators. In this scenario, there can be one MD associated with the customer, one MD associated with the service provider, and one MD associated with each of the operators.

You assign one of the following eight levels to the MD:

- 0-2 (operator levels)
- 3-4 (provider levels)
- 5-7 (customer levels)

The levels separate MDs from each other and provide different areas of functionality to different devices using the network. An MD is characterized by a level and an MD name (optional).

A single MD can contain several Maintenance Associations (MA).

Maintenance Association (MA)

An MA represents a logical grouping of monitored entities within its Domain. It can therefore represent a set of Maintenance association End Points (MEPs), each configured with the same Maintenance Association ID (MAID) and MD Level, established to verify the integrity of a single service instance.

The following figure shows MD level assignment in accordance with the 802.1ag standard. As shown in the figure, MIPs can be associated with MEPs. However, MIPs can also function independently of MEPs.

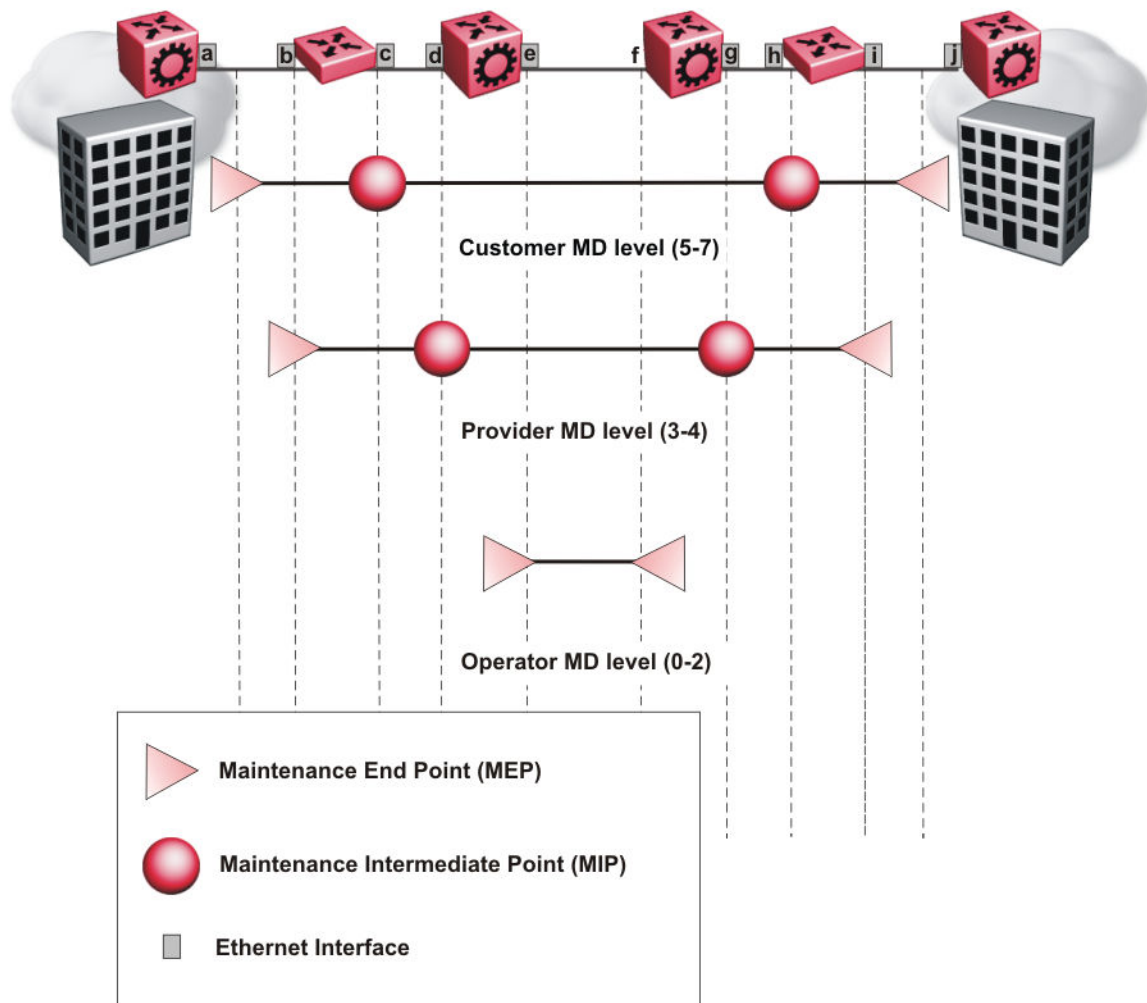

Figure 238: MD level assignment

Maintenance Association Endpoint (MEP)

A Maintenance Endpoint (MEP) represents a managed CFM entity, associated with a specific Domain Service Access Point (DoSAP) of a service instance, which can generate and receive CFM Protocol Data Units (PDU) and track any responses. A MEP is created by MEP ID under the context of an MA. MEP functionality can be divided into the following functions:

- Fault Detection
- Fault Verification
- Fault Isolation
- Fault Notification

Fault detection and notification are achieved through the use of Continuity Check Messages (CCM). CCM messages are not supported.

Fault Verification

Fault verification is achieved through the use of Loopback Messages (LBM). An LBM is a unicast message triggered by the operator issuing an operational command. LBM can be addressed to either a MEP or Maintenance Intermediate Point (MIP) but only a MEP can initiate an LBM. The destination MP can be addressed by its MAC address. The receiving MP responds with a Loopback Response (LBR). LBM can contain an arbitrary amount of data that can be used to diagnose faults as well as performance measurements. The receiving MP copies the data to the LBR.

LBM Message

The LBM packet is often compared to a ping. A MEP transmits the LBM packet. This packet can be addressed to another MEP or to the MAC address of the MP; in the case of SPBM, this is the SPBM system ID or its virtual SMLT MAC. Only the MP for which the packet is addressed responds with an LBR message.

- Provides “ICMP ping like” functionality natively at Layer-2.
- DA is the MAC address of the target.
- Includes a transaction identifier that allows the corresponding LBR to be identified when more than one LBM request is waiting for a response.
- Bridges forward the frame using the normal FDB rules.
- Only the target (MIP or MEP) responds.
- Initiator can choose the size and contents data portion of the LBM frame.
- Can be used to check the ability of the network to forward different sized frames.

L2 Ping

The **l2 ping** command is a proprietary command that allows a user to trigger an LBM message.

For B-VLANs, specify either the destination MAC address or node name.

Note

The virtual node MAC address does not support CFM Layer 2 ping.

This provides a simpler command syntax than the standard LBM commands, which require the user to specify the MD, MA, and MEP ID information. The **l2 ping** command provides a ping equivalent at Layer 2 for use with nodes on the SPBM B-VLAN in the customer domain. SPBM B-VLANs support the SMLT virtual option for the source mode.

Fault Isolation

Fault isolation is achieved through the use of Linktrace Messages (LTM). LTM is intercepted by all the MPs on the way to the destination MP. The switch supports two types of LTM.

The first type, the unicast LTM, can be addressed to either MEP or MIP MAC address. Each MP on the way decrements the TTL field in the LTM frame, sends Linktrace Reply (LTR), and forwards the original LTM to the destination. The LTM is forwarded until it reaches its destination or the TTL value is decremented to zero. LTR is a unicast message addressed to the originating MEP.

The second type, the proprietary LTM, is used to map the MAC addresses of the SPBM network; in this case the target MAC is not an MP, but rather a service instance identifier (I-SID).

Link Trace Message

Connectivity Fault Management offers link trace messaging for fast fault detection. Link trace messages allow operators, service providers and customers to verify the connectivity that they provide or use and to debug systems.

Link trace message — unicast

The link trace message (LTM) is often compared to traceroute. A MEP transmits the LTM packet. This packet specifies the target MAC address of an MP which is the SPBM system id or the virtual SMLT MAC. MPs on the path to the target address respond with an LTR.

- Trace the path to any given MAC address.
- DA is unicast
- LTM contains:
 - Time to live (TTL)
 - Transaction Identifier
 - Originator MAC address
 - Target MAC address
- CFM unaware entities forward the frame as is like any other data frame.
- MIP or MEP that is not on the path to the target discards the LTM and does not reply.
- MIP that is on the path to the target
 - Forwards the LTM after decrementing the TTL and replacing the SA with its own address.
 - Sends a reply (LTR) to the originator.
 - Identifies itself in the forwarded LTM and LTR by modifying TLV information.
- If the MIP or MEP is a target
 - Sends an LTR to the originator.
 - Identifies itself in the forwarded LTM and LTR by modifying TLV information.
- A MEP that is not the target but is on the path to the target
 - Generates a reply as described above.
 - It also sets one of the flags fields in the reply to indicate that it is the terminal MEP.

Link trace message — multicast

The multicast link trace message (LTM) can be used to trace the multicast tree from any node on any I-SID using the nickname MAC address and the I-SID multicast address.

Specifying a multicast target address for an LTM allows for the tracing of the multicast tree corresponding to that destination address (DA). With a multicast target every node that is in the active topology for that multicast address responds with a Linktrace reply and also forwards the LTM frame along the multicast path. Missing Linktrace replies (LTRs) from the nodes in the path indicate the point of first failure.

This functionality allows you to better troubleshoot I-SID multicast paths in a SPBM network.

L2 Traceroute

The **12 traceroute** command is a proprietary command that allows you to trigger an LTM message.

For B-VLANs, specify either the destination MAC address or node name.

**Note**

The virtual node MAC address does not support CFM Layer 2 traceroute.

This command provides a simpler command syntax than the standard LTM commands, which require you to specify the MD, MA, and MEP ID information. The **l2 traceroute** command provides a trace equivalent at Layer 2 for use with nodes on the SPBM B-VLAN in the customer domain.

You can use CFM to troubleshoot networks and hosts that support the CFM protocol. After you configure CFM, CFM works in the network whether or not SPBM is in use.

You cannot use CFM to troubleshoot networks and hosts that do not support the CFM protocol, such as a customer domain that does not support CFM. Only devices that support the CFM protocol respond to **l2 ping** and **l2 traceroute** requests.

l2 traceroute with IP address

You can specify an IP address as the destination address for the **l2 traceroute** command.

The **l2 traceroute** command converts Layer 3 IP information to an appropriate Layer 2 VLAN and MAC combination. The system can also target IP addresses that are not SPBM derived routes.

If you enable ECMP, **l2 traceroute** runs internally for each of the VLAN paths returned, and displays a summary of the results. If you disable ECMP, the results display only one path.

**Note**

If you use the **l2 traceroute ip-address** command on a DvR Leaf node, the output only shows DvR Controller IP addresses if the IP address or host route specified is unknown in the DvR domain.

L2 Tracetree

The **l2 tracetree** command is a proprietary command that allows a user to trigger a multicast LTM message by specifying the B-VLAN and I-SID. This command allows the user to view a multicast tree on the SPBM B-VLAN from the source node to the destination nodes for a particular I-SID.

L2 Tracetree-fan

The **l2 tracetree-fan** command allows a user to trigger an LTM on the internal Fabric Area Network I-SID. This command allows the user to trace the FAN tree.

Maintenance Domain Intermediate Point (MIP)

MIPs do not initialize any CFM messages. MIPs passively receive CFM messages, process the messages received and respond back to the originating MEP. By responding to received CFM messages, MIPs can support discovery of hop-by-hop path among MEPs, allow connection failures to be isolated to smaller segments of the network to help discover location of faults along the paths. MIPs can be created independent of MEPs. MIP functionality can be summarized as:

- Respond to Loopback (ping) messages at the same level as itself and addressed to it.
- Respond to Linktrace (traceroute) messages.

- Forward Linktrace messages after decrementing the TTL.

Layer 2 Tracemroute

The **l2tracemroute** command is a proprietary command that allows the user to trace the multicast tree for a certain multicast flow. The user specifies source, group, and service context (either VLAN or VRF) for the multicast flow to trace.

CFM sends a multicast LTM using an internal calculation to map the source, group, and context to the corresponding target address. The LTR comes from all leaves of the multicast tree for that flow, as well as transit nodes. The target MAC used in the LTM is a combination of the data I-SID and the nickname and the packet is sent on the appropriate SPBM B-VLAN. The user can see the generated multicast tree for that flow, which includes the data I-SID and nickname.

Nodal MPs

Nodal MPs provide both MEP and MIP functionality for SPBM deployments. Nodal MPs are associated with a B-VLAN and are VLAN encapsulated packets. The Nodal MEP provides traceability and troubleshooting at the system level for a given B-VLAN. Each node (chassis) has a given MAC address and communicates with other nodes. The SPBM instance MAC address is used as the MAC address of the Nodal MP. The Nodal B-VLAN MPs supports eight levels of CFM and you configure the Nodal B-VLAN MPs on a per B-VLAN basis. Virtual SMLT 10 MAC addresses are also able to respond for LTM and LBM.

Nodal B-VLAN MEPs

The Nodal B-VLAN MEPs created on the CP and function as if they are connected to the virtual interface of the given B-VLAN. Because of this they are supported for both port and MLT based B-VLANs. To support this behavior a MAC Entry is added to the FDB and a new CFM data-path table containing the B-VLAN and MP level are added to direct CFM frames to the CP as required.

Nodal B-VLAN MIPs

The Nodal MIP is associated with a B-VLAN. VLAN and level are sufficient to specify the Nodal MIP entity. The Nodal MIP MAC address is the SPBM system ID for the node on which it resides. If the fastpath sends a message to the CP, the MIP responds if it is not the target and the MEP responds if it is the target.

Nodal B-VLAN MIPs with SMLT

When Nodal MEPs or MIPs are on SPBM B-VLANs the LTM code uses a unicast MAC DA. The LTM DA is the same as the target MAC address, which is the SPBM MAC address or the SMLT MAC address of the target node.

The switch supports SMLT interaction with SPBM. This is accomplished by using two B-VIDs into the core from each pair of SMLT terminating nodes. Both nodes advertise the Nodal B-MAC into the core on both B-VIDS. In addition each node advertises the SMLT virtual B-MAC on one of the two B-VLANs.

The Nodal MEP and MIP are expanded to respond to both the Nodal MAC address as well as the Virtual SMLT MAC address if both MACs are being advertised on its B-VLAN. In addition a source mode is added to the LTM and LBM command to use either the Nodal MAC or the SMLT virtual MAC address as the source MAC in the packet.

Configuration Considerations

When you configure CFM, be aware of the following configuration considerations.

General CFM

- A single switch has a limit of one MEP and one MIP on B-VLAN.
- The maintenance level for MEPs and MIPs on a given B-VID (in a network) must be configured to the same level for them to respond to a given CFM command.
- You can configure global CFM at only one MD level for each switch.
- All nodal MEPs and MIPs are restricted to SPBM B-VIDs.

Autogenerated CFM

- Autogenerated MEPs are not unique across the entire network unless you configure the global MEP ID on each switch to a different value. You must configure a unique MEP ID at a global level, for CFM.
- A single switch can have only one autogenerated MEP or MIP for each B-VLAN.

Explicit CFM

- Previous explicit CFM configurations of MDs, MAs and MEPs on SPBM B-VLANs continue to be supported. However, if you want to enable autogenerated CFM you must first remove the existing MEP and MIP on the SPBM B-VLAN.
- You can assign maintenance levels for each CFM SPBM MEP and MIP to each SPBM B-VLAN individually or you can assign maintenance levels and global MEPs for all SPBM VLANs by following the appropriate procedure:
 - [Assigning a MEP/MIP Level to an SPBM B-VLAN](#) on page 3077
 - [Assigning MEP/MIP Levels to SPBM B-VLANs Globally](#) on page 3079
 - [Configure CFM Nodal MEP](#) on page 3099

CFM Configuration Using CLI

This section provides procedures to configure and use Connectivity Fault Management (CFM) using Command Line Interface (CLI). The Shortest Path Bridging MAC (SPBM) network needs a mechanism to debug connectivity issues and to isolate faults. This is performed at Layer 2, not Layer 3. To support troubleshooting of the SPBM cloud, the switch supports a subset of CFM functionality.

Note

When you enable CFM in an SBPM network, as a best practice, enable CFM on the Backbone Edge Bridges (BEB) and on all Backbone Core Bridges (BCB). If you do not enable CFM on a particular node, you cannot obtain CFM debug information from that node.

You can configure CFM using one of two modes: simplified or explicit. Both modes are described in the following sections, but the simplified mode should be used.

Note

If you enable the `cfm spbm enable` command, you cannot assign a MEP/MIP level to an individual SPBM B-VLAN or configure CFM MD maintenance levels individually.

Regardless of whether you have chosen to configure individually or globally, there is one MEP per SPBM B-VLAN and one MIP level per SPBM B-VLAN.

Autogenerated CFM

CFM provides two methods for configuration; autogenerated and explicit. You cannot use both. You must choose one or the other. Use the procedures in this section to configure autogenerated MEPs that eliminate the need to configure a MD, MA, and MEP ID to create a MEP.

For SPBM B-VLANs, you can use either autogenerated or explicitly configured CFM MEPs.

The CFM show commands that display MD, MA, and MEP information work for both autogenerated and explicitly configured CFM MEPs.

Previous explicit CFM configurations of MDs, MAs and MEPs on SPBM B-VLANs continue to function. However, if you want to enable the autogenerated commands you must first remove the existing MEP and MIP on the SPBM B-VLAN.

The switch only supports one MEP and one MIP, either autogenerated or explicitly configured, on the SPBM B-VLAN. This means that if you want to use these autogenerated MEPs, you cannot use your existing CFM configuration. You must first remove the existing MEP or MIP on the SPBM B-VLAN.

Configuring Autogenerated CFM on SPBM B-VLANs

Use this procedure to configure the autogenerated CFM MEP and MIP level for every SPBM B-VLAN on the chassis. This eliminates the need to explicitly configure an MD, MA, and MEP ID, and to associate the MEP and MIP level to the SPBM B-VLAN.

When you enable this feature, the device creates a global MD (named spbm) for all the SPBM Nodal MEPs. This MD has a default maintenance level of 4, which you can change with the level attribute. All the MEPs that the device creates use the MEP ID configured under the global context, which has a default value of 1.

The nodal MEPs are automatically associated with the SPBM B-VLANs configured. The MIP level maps to the global level. When you enable the feature, the device automatically associates the MIP level with the SPBM B-VLANs configured. The feature is disabled by default.

Important

CFM supports one MEP or MIP for each SPBM B-VLAN only. This means that if you want to use these autogenerated MEPs, you cannot use your existing CFM configuration. You must first remove the existing MEP or MIP on the SPBM B-VLAN. If you want to continue configuring MEPs manually, skip this procedure.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

- Configure the maintenance level for every CFM SPBM MEP and MP level on all the SPBM B-VLANs:
`cfm spbm level <0-7>`

You can change this level from the default of 4 either before or after the feature is enabled.

Only configure global CFM at one MD level for each chassis for each VLAN type.

- Assign a global CFM MEP ID for all CFM SPBM MEPs:
`cfm spbm mepid <1-8191>`
- Enable the autogenerated CFM for SPBM B-VLANs globally:
`cfm spbm enable`
- (Optional) Configure the maintenance level for every CFM SPBM MEP and MP level on all the SPBM B-VLANs to the default:
`default cfm spbm level`
- (Optional) Assign a global CFM MEP ID for all CFM SPBM MEPs to the default:
`default cfm spbm mepid`
- (Optional) Disable the global CFM MEPs and MIPs:
`no cfm spbm enable`
- Display the global CFM MEP configuration:
`show cfm spbm`

Example

Configure autogenerated CFM MEPs and MIPs:

```
Switch>enable
Switch#configure terminal
Switch(config)#cfm spbm level 6
Switch(config)#cfm spbm mepid 4
Switch(config)#cfm spbm enable
Switch(config)#show cfm spbm

LEVEL ADMIN      MEPID      MAC
=====
6         enable      4          00:15:e8:b8:a3:df
```

Variable Definitions

The following table defines parameters for the **cfm spbm** command.

Variable	Value
<i>level</i> <0-7>	Specifies the global SPBM CFM maintenance level for the chassis within the range of 0 to 7. The default is 4. Only configure global CFM at one MD level for each chassis for each VLAN type.
<i>mepid</i> <1-8191>	Specifies the global MEP ID within the range of 1-8191. Select a unique ID for each switch to ensure that the MEPs are unique across the network. The default is 1.
<i>enable</i>	Enables autogenerated CFM on all SPBM B-VLANs.

Configuring Explicit Mode CFM

In the explicit mode of configuring CFM, you can manually configure an MD, MA, MEP and then associate the MEP to a B-VLAN and assign a MIP level to a B-VLAN.

Note

If you use autogenerated CFM, these steps are unnecessary.

Configuring CFM MD

Use this procedure to configure the Connectivity Fault Management (CFM) Maintenance Domain (MD). An MD is the part of a network that is controlled by a single administrator. A single MD can contain several Maintenance Associations (MA).

Procedure

1. Enter Global Configuration mode:
enable

configure terminal
2. Create the CFM MD:
cfm maintenance-domain WORD<0-22> [index <1-2147483647>] [maintenance-level <0-7>] [level <0-7>]
3. Display the CFM MD configuration:
show cfm maintenance-domain
4. Delete the CFM MD:
no cfm maintenance-domain WORD<0-22>

Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

```
Switch:1(config)# cfm maintenance-domain mdl index 99 maintenance-level 3
```

```
Switch:1(config)# show cfm maintenance-domain
```

```
=====
                        Maintenance Domain
=====
Domain Name           Domain Index   Level Domain Type
-----
mdl                   99             3      NODAL
Total number of Maintenance Domain entries: 1.
```

```
Switch:1(config)# no cfm maintenance-domain mdl
```

```
Switch:1(config)# show cfm maintenance-domain
```

```
=====
                        Maintenance Domain
=====
Domain Name           Domain Index   Level Domain Type
```

```
-----
Total number of Maintenance Domain entries: 0.
```

Variable Definitions

The following table defines parameters for the **cfm maintenance-domain** command.

Variable	Value
<i>WORD</i> <0-22>	Specifies the maintenance domain name.
<i>index</i> <1-2147483647>	Specifies a maintenance domain entry index.
<i>maintenance-level</i> <0-7>	Specifies the MD maintenance level when creating the MD. The default is 4.
<i>level</i> <0-7>	Modifies the MD maintenance level for an existing MD. The default is 4.

Configuring CFM MA

Use this procedure to configure the CFM Maintenance Association (MA). An MA represents a logical grouping of monitored entities within its domain. It can therefore represent a set of Maintenance Association End Points (MEPs), each configured with the same Maintenance Association ID (MAID) and MD Level, established to verify the integrity of a single service instance.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Create the CFM MA:

```
cfm maintenance-association WORD<0-22> WORD<0-22> [index <1-2147483647>]
```
3. Display the CFM MA configuration:

```
show cfm maintenance-association
```
4. Use the following command, if you want to delete the CFM MA:

```
no cfm maintenance-association WORD<0-22> WORD<0-22>
```

Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

```
Switch:1(config)# cfm maintenance-association md1 ma1 index 98
```

```
Switch:1(config)# show cfm maintenance-association
```

```
=====
Maintenance Association Status
=====
```

Domain Name	Assn Name	Domain Idx	Assn Idx
-------------	-----------	------------	----------

```

-----
md1                mal                1                98

Total number of Maintenance Association entries: 1.

=====
Maintenance Association config
=====
Domain Name        Assn Name
-----
md1                mal

Total number of MA entries: 1.

```

Variable Definitions

The following table defines parameters for the **cfm maintenance-association** command.

Variable	Value
<i>WORD</i> <0-22> <i>WORD</i> <0-22>	Creates the CFM MA. The first parameter, specifies the MD name. The second parameter, specifies the MA short name.
<i>index</i> <1-2147483647>	Specifies a maintenance association entry index.

Configuring CFM MEP

Use this procedure to configure the CFM Maintenance Endpoint (MEP). A MEP represents a managed CFM entity, associated with a specific Domain Service Access Point (DoSAP) of a service instance, which can generate and receive CFM Protocol Data Units (PDU) and track any responses. A MEP is created by MEP ID under the context of an MA.

Procedure

- Enter Global Configuration mode:
enable

configure terminal
- Create the CFM MEP:
cfm maintenance-endpoint WORD<0-22> WORD<0-22> <1-8191> enable [state <enable>]
- Enable an existing CFM MEP:
cfm maintenance-endpoint WORD<0-22> WORD<0-22> <1-8191> enable
- Disable an existing CFM MEP:
no cfm maintenance-endpoint WORD<0-22> WORD<0-22> <1-8191> enable
- Display the CFM MEP configuration:
show cfm maintenance-endpoint
- Delete an existing CFM MEP:
no cfm maintenance-endpoint WORD<0-22> WORD<0-22> <1-8191>

Example

```

Switch:1> enable

Switch:1# configure terminal

```

```
Switch:1(config)# cfm maintenance-endpoint mdl ma1 1 state enable

Switch:1(config)# show cfm maintenance-endpoint
```

```
=====
Maintenance Endpoint Config
=====
DOMAIN ASSOCIATION MEP ADMIN

-----
mdl ma1 1 enable

Total number of MEP entries: 1.

=====
Maintenance Endpoint Service
=====
DOMAIN_NAME ASSN_NAME MEP_ID TYPE SERVICE_DESCRIPTION
-----
mdl ma1 1 nodal Vlan 1, Level 4

Total number of MEP entries: 1.
```

Variable Definitions

The following table defines parameters for the **cfm maintenance-endpoint** command.

Variable	Value
<i>WORD<0-22></i>	The first parameter, specifies the MD name.
<i>WORD<0-22></i>	The second parameter, specifies the MA short name.
<i><1-8191></i>	Specifies the MEP ID.
<i>enable</i>	Enables an existing MEP. Use this parameter with the no option to disable an existing MEP.
<i>state {enable disable}</i>	Enables or disables the MEP when creating the MEP. The default is disabled.

Assigning a MEP/MIP Level to an SPBM B-VLAN

Use this procedure to assign a nodal MEP to an SPBM B-VLAN. The Nodal MEP provides traceability and troubleshooting at the system level for a given B-VLAN. The Nodal B-VLAN MEPs created on the CP and function as if they are connected to the virtual interface of the given B-VLAN. Because of this they are supported for both port and MLT based B-VLANs.

Nodal MPs provide both MEP and MIP functionality for SPBM deployments. Nodal MPs are associated with a B-VLAN and are VLAN encapsulated packets. Each node (chassis) has a given MAC address and communicates with other nodes. The SPBM instance MAC address is used as the MAC address of the Nodal MP.

Before You Begin

- You must configure a CFM MD, MA, and MEP.

Procedure

1. Add nodal MEPs to the B-VLAN:

```
vlan nodal-mep <1-4059> WORD<0-22> WORD<0-22> <1-8191>
```
2. Display the nodal MEP configuration:

```
show vlan nodal-mep <1-4059>
```
3. Remove the nodal MEPs from the B-VLAN:

```
no vlan nodal-mep <1-4059> WORD<0-22> WORD<0-22> <1-8191>
```
4. Add nodal MIP level to the B-VLAN:

```
vlan nodal-mip-level <1-4059> WORD<0-15>
```
5. Display the nodal MIP level configuration:

```
show vlan nodal-mip-level [<1-4059>]
```
6. Remove the nodal MIP level from the B-VLAN:

```
no vlan nodal-mip-level <1-4059> WORD<0-15>
```

Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

```
Switch:1(config)#vlan nodal-mep 100 mdl ma1 2
```

```
Switch:1(config)#show vlan nodal-mep
```

```
=====
                                Vlan Nodal Mep
                                =====
VLAN_ID   DOMAIN_NAME.ASSOCIATION_NAME.MEP_ID
-----
100       spbm.100.6

216
304
41000
1001
```

Variable Definitions

The following table defines parameters for the **vlan nodal-mep** command.

Variable	Value
<1-4059>	Specifies the VLAN ID.
WORD<0-22>	The first parameter, specifies the Maintenance Domain name.
WORD<0-22>	The second parameter, specifies the Maintenance Association name.
<1-8191>	Specifies the nodal MEPs to add to the VLAN.

The following table defines parameters for the **vlan nodal-mip-level** command.

Variable	Value
<1-4059>	Adds the nodal MIP level. Specifies the VLAN ID.
WORD<0-15>	Adds the nodal MIP level, which has up to eight levels, ranging from 0 to 7.

Assigning MEP/MIP Levels to SPBM B-VLANs Globally

Note

If you enable the **cfm spbm enable** command, you cannot assign a MEP/MIP level to an individual SPBM B-VLAN or configure CFM MD maintenance levels individually.

About This Task

Enables the global CFM MEP and MIPs for all SPBM B-VLANs.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable simplified CFM configuration for SPBM VLANs:

```
cfm spbm enable
```
3. Enter the CFM SPBM level:

```
cfm spbm level <0-7>
```
4. Enter the CFM SPBM MEPID level:

```
cfm spbm mepid <1-8191>
```

Example

```
Switch:1(config)# cfm spbm level 7
Switch:1(config)# cfm spbm mepid 12
Switch:1(config)# cfm spbm enable
```

Variable Definitions

The following table defines parameters for the **simplified CFM** commands.

Variable	Value
<code>spbm level <0-7></code>	Configures the maintenance level for every CFM SPBM MEP and MIP level on all SPBM B-VLANs. The default is 4.
<code>mepid <1-8191></code>	Assigns a global MEP ID for all CFM SPBM MEPs. The default is 1.
<code>no cfm spbm enable</code>	Disables global configuration of CFM SPBM MEP and MIP levels on all SPBM B-VLANs.
<code>default cfm spbm level</code>	Returns maintenance level to default for all CFM SPBM MEP and MIP level on all SPBM B-VLANs.
<code>default cfm spbm mepid</code>	Returns MEP ID for all CFM SPBM MEPs to default.
<code>show cfm spbm</code>	Displays the global CFM MEP configuration for SPBM B-VLANs.

Trigger a Loopback Test (LBM)

Use this procedure to trigger a loopback test.

The LBM packet is often compared to ping. An MEP transmits the loopback message to an intermediate or endpoint within a domain for the purpose of fault verification. This can be used to check the ability of the network to forward different sized frames.

Before You Begin

- You must have a MEP that is associated with a B-VLAN.

Procedure

Trigger the loopback test:

```
loopback WORD<0-22> WORD<0-22> <1-8191> <0x00:0x00:0x00:0x00:0x00:0x00>
[burst-count <1-200>] [data-tlv-size <0-400>] [frame-size <64-1500>]
[interframe-interval <msecs>] [priority <0-7>] [source-mode {nodal|
smltVirtual}] [testfill-pattern <all-zero|all-zero-crc|pseudo-random-bit-
sequence|pseudo-random-bit-sequence-crc>] [time-out <1-10>]
```

Example

```
Switch:1# loopback md1 4001 13 00:14:0D:A2:B3:DF burst-count 10 priority
3 time-out 5
```

```
Result of LBM from mep: spbm.bvlan1000.8 to MAC address: 00:66:00:66:00:66 :
Sequence number of the first LBM is 150404162
The total number of LBMs sent out is 1
The number of LBRs received is 1
The number of LBRs lost is 0
The percentage of LBMs lost is 0.00%
The RTT Min is 15071 microsecs, Max is 15071 microsecs, Average is 15071.00 microsecs
The Standard Deviation of RTT is 0.00 microsecs
```

Variable Definitions

The following table defines parameters for the **loopback** command.

Variable	Value
<i>WORD</i> <0-22>	The first parameter, specifies the MD name.
<i>WORD</i> <0-22>	The second parameter, specifies the MA name.
<1-8191>	Specifies the MEP ID.
<0x00:0x00:0x00:0x00:0x00:0x00>	Specifies the remote MAC address to reach the MEP/MIP.
<i>burst-count</i> <1-200>	Specifies the burst-count.
<i>data-tlv-size</i> <0-400>	Specifies the data TLV size.
<i>frame-size</i> <64-1500>	Specifies the frame-size. The default is 0.
<i>priority</i> <0-7>	Specifies the priority. The default is 7.
<i>source-mode</i> { <i>nodal</i> <i>smltVirtual</i> }} Note: Exception: <i>smltVirtual</i> is not supported on 5320 Series.	Specifies the source mode: <ul style="list-style-type: none"> • <i>nodal</i> • <i>smltVirtual</i>—Use this value with B-VLANs only. The default is <i>nodal</i> .
<i>testfill-pattern</i> { <i>all-zero</i> <i>all-zero-crc</i> <i>pseudo-random-bit-sequence</i> <i>pseudo-random-bit-sequence-crc</i> }	Specifies the testfill pattern: <ul style="list-style-type: none"> • <i>all-zero</i> — null signal without cyclic redundancy check • <i>all-zero-crc</i> — null signal with cyclic redundancy check with 32-bit polynomial • <i>pseudo-random-bit-sequence</i> — pseudo-random-bit-sequence without cyclic redundancy check • <i>pseudo-random-bit-sequence-crc</i> — pseudo-random-bit-sequence with cyclic redundancy check with 32-bit polynomial. A cyclic redundancy check is a code that detects errors. The default is 1: <i>all-zero</i> .
<i>time-out</i> <1-10>	Specifies the time-out interval in seconds. The default is 3.

Trigger Linktrace (LTM)

Use the following procedure to trigger a linktrace.

The Linktrace Message is often compared to traceroute. An MEP transmits the Linktrace Message packet to a maintenance endpoint with intermediate points responding to indicate the path of the traffic within a domain for the purpose of fault isolation. The packet specifies the target MAC address of an MP, which is the SPBM system ID or the virtual SMLT MAC. MPs on the path to the target address respond with an LTR.

Before You Begin

- You must have a MEP that is associated with a VLAN.

Procedure

Trigger the linktrace:

```
linktrace WORD<0-22> WORD<0-22> <1-8191> <0x00:0x00:0x00:0x00:0x00:0x00>
[detail] [priority <0-7>] [source-mode <nodal|smltVirtual>] [ttl-value
<1-255>]
```

Example

```
Switch:1# linktrace mdl 4001 13 00:bb:00:00:14:00 priority 7
```

```
Please wait for LTM to complete or press any key to abort

Received LTRs:

SeqNum: 10575 MD: mdl MA:4001 MepId: 13 Priority: 7
-----
TTL SRC MAC FWDYES TERMMEP RELAY ACTION
-----
63 00:bb:00:00:10:00 true false Fdb
62 00:bb:00:00:14:00 false true Hit
```

Variable Definitions

The following table defines parameters for the **linktrace** command.

Variable	Value
<i>WORD<0-22></i>	The first parameter, specifies the MD name.
<i>WORD<0-22></i>	The second parameter, specifies the MA name.
<i><1-8191></i>	Specifies the MEP ID.
<i><0x00:0x00:0x00:0x00:0x00:0x00:0x00></i>	Specifies the target MAC address to reach the MEP.
<i>detail</i>	Displays linktrace result details.
<i>priority <0-7></i>	Specifies the priority. The default is 7.
<i>source-mode{nodal smltVirtual}}</i>	Specifies the source mode: <ul style="list-style-type: none"> 1: nodal 2: smltVirtual—Use this value with B-VLANs only.
Note: Exception: smltVirtual is not supported on 5320 Series.	The default is 1: nodal.
<i>ttl-value <1-255></i>	Specifies the Time-to-Live value. The default is 64.

Trigger a Layer 2 Ping

Use this procedure to trigger a Layer 2 ping, inside an SPBM cloud or network, which acts like native **ping**. This feature enables CFM to debug Layer 2. It can also help you debug IP shortcuts and the record for the shortcuts' ARP.

Before You Begin

- You must have a MEP that is associated with a VLAN.

Procedure

Trigger a Layer 2 ping:

```
l2 ping {vlan <1-4059> routernodename WORD<0-255> | vlan <1-4059> mac
<0x00:0x00:0x00:0x00:0x00:0x00>} [burst-count <1-200>] [data-tlv-size
<0-400>] [frame-size <64-1500>] [priority <0-7>] [source-mode <nodal|
smltVirtual>] [testfill-pattern <all-zero|all-zero-crc|pseudo-random-
bit-sequence|pseudo-random-bit-sequence-crc>] [time-out <1-10>]
```

OR

```
l2 ping {ip-address WORD<0-255>} [burst-count <1-200>] [data-tlv-size
<0-400>] [frame-size <64-1500>] [priority <0-7>] [source-mode <nodal|
smltVirtual>] [testfill-pattern <all-zero|all-zero-crc|pseudo-random-
bit-sequence|pseudo-random-bit-sequence-crc>] [time-out <1-10>] [vrf
WORD<1-16>]
```

Example

```
Switch:1# l2 ping vlan 2 mac 00.14.0d.bf.a3.df
```

```
Please wait for l2ping to complete or press any key to abort
----00:14:0d:bf:a3:df L2 PING Statistics---- 0(68) bytes of data
1 packets transmitted, 0 packets received, 100.00% packet loss
```

```
Switch:1# l2 ping vlan 2 routernodename MONTIO
```

```
Please wait for l2ping to complete or press any key to abort
----00:14:0d:a2:b3:df L2 PING Statistics---- 0(68) bytes of data
1 packets transmitted, 1 packets received, 0.00% packet loss
round-trip (us) min/max/ave/stdv = 26895/26895/26895.00/ 0.00
```

```
Switch:1# l2 ping ip-address 192.0.2.10
```

```
Please wait for l2ping to complete or press any key to abort

L2 PING Statistics : IP 192.0.2.10, paths found 1, paths attempted 1
=====
TX    RX    PERCENT  ROUND TRIP TIME          PKTS  PKTS  LOSS    MIN/MAX/AVE
VLAN NEXT HOP                                     (us)
=====
2  SHAMIM          (00:1a:8f:08:53:df)  1    0    100.00%  0/0/0.00
```

Variable Definitions

The following table defines parameters to configure the Layer 2 ping parameters.

Variable	Value
<code>{vlan <1-4059> routernodename WORD<0-255> } {vlan <1-4059> mac <0x00:0x00:0x00:0x00:0x00:0x00> } {ip-address WORD<0-255> }</code>	Specifies the destination for the Layer 2 ping: <ul style="list-style-type: none"> • <1-4059> — Specifies the VLAN ID. • WORD<0-255> — Specifies the Router node name. • <XX:XX:XX:XX:XX:XX> — Specifies the MAC address. • <A.B.C.D> — Specifies the IP address.
<code>burst-count <1-200></code>	Specifies the burst count.
<code>data-tlv-size <0-400></code>	Specifies the data TLV size. The default is 0.
<code>frame-size <64-1500>]</code>	Specifies the frame size. The default is 0.
<code>testfill-pattern <all-zero all-zero-crc pseudo-random- bit-sequence pseudo-random- bit-sequence-crc></code>	Specifies the testfill pattern: <ul style="list-style-type: none"> • all-zero — null signal without cyclic redundancy check • all-zero-crc — null signal with cyclic redundancy check with 32-bit polynomial • pseudo-random-bit-sequence — pseudo-random-bit-sequence without cyclic redundancy check • pseudo-random-bit-sequence-crc — pseudo-random-bit-sequence with cyclic redundancy check with 32-bit polynomial. <p>A cyclic redundancy check is a code that detects errors. The default is all-zero.</p>
<code>priority <0-7></code>	Specifies the priority. The default is 7.
<code>time-out <1-10></code>	Specifies the interval in seconds. The default is 3.
<code>source-mode{nodal smltVirtual}}]</code> Note: Exception: smltVirtual is not supported on 5320 Series.	Specifies the source mode: <ul style="list-style-type: none"> • 1: nodal • 2: smltVirtual—Use this value with B-VLANs only. <p>The default is 1: nodal.</p>
<code>vrf WORD<1-16></code>	Specifies the VRF name.

Trigger a Layer 2 Traceroute

Use this procedure to trigger a Layer 2 traceroute, which acts like native **traceroute**. This feature enables CFM to debug Layer 2 in an SPBM cloud or network. It can determine the path used by IS—IS to get from one MEP to another, by showing all the hops between. Therefore, it can show where connectivity is lost. It can also work for IP shortcuts.

Important

To trace a route to a MAC address, the MAC address must be in the VLAN FDB table.

- For B-VLANs, you do not have to trigger an **l2ping** to learn the MAC address because IS-IS populates the MAC addresses in the FDB table.

linktrace traces the path up to the closest device to that MAC address that supports CFM.

Before You Begin

- You must have a MEP that is associated with a VLAN.

Procedure

Trigger a Layer 2 traceroute:

```
l2 traceroute {ip-address WORD<0-255>} [ttl <1-255>] [vrf WORD<1-16>]
```

```
l2 traceroute {<vlan <1-4059> routernodename WORD<0-255> | <vlan <1-4059> mac <0x00:0x00:0x00:0x00:0x00:0x00>} [priority <0-7>] [source-mode <nodal|smltVirtual>] [ttl <1-255>]
```

Examples

```
Switch:1#l2 traceroute vlan 2 routernodename Switch-MONTIO
Please wait for l2traceroute to complete or press any key to abort

l2traceroute to Switch-MONTIO (00:14:0d:a2:b3:df),  vlan 2
0   Switch-PETER4 (00:15:9b:11:33:df)
1   Switch-MONTIO (00:14:0d:a2:b3:df)

Switch:1#l2 traceroute ip-address 192.0.2.10
Please wait for l2trace to complete or press any key to abort

L2 Trace  Statistics : IP 192.0.2.10, paths found 1
=====
Switch-SHAMIM (00:1a:8f:08:53:df),  vlan 2
0   Switch-PETER4 (00:15:9b:11:33:df)
1   Switch-MONTIO (00:14:0d:a2:b3:df)
```

Variable Definitions

The following table defines parameters for the **l2 traceroute** command.

Variable	Value
<code>{vlan <1-4059> routernodename WORD<0-255> } {vlan <1-4059> mac <0x00:0x00:0x00:0x00:0x00:0x00> } {ip-address WORD<0-255> }</code>	Specifies the destination for the Layer 2 traceroute: <ul style="list-style-type: none"> <code><1-4059></code> – Specifies the VLAN ID <code>WORD<0-255></code> – Specifies the Router Node Name <code><XX:XX:XX:XX:XX:XX></code> – Specifies the MAC address <code>WORD<0-255></code> – Specifies the IP address
<code>ttl-value <1-255></code>	Specifies the TTL value. The default is 64.
<code>priority <0-7></code>	Specifies the priority. The default is 7.
<code>source-mode {nodal smltVirtual} </code> Note: Exception: smltVirtual is not supported on 5320 Series.	Specifies the source mode: <ul style="list-style-type: none"> 1: nodal 2: smltVirtual—Use this value with B-VLANs only. The default is 1: nodal.
<code>vrf WORD<1-16></code>	Specifies the VRF name.

Trigger a Layer 2 Tracetable

Use this procedure to trigger a Layer 2 tracetable. Layer 2 tracetable allows a user to trigger a multicast LTM message by specifying the B-VLAN and I-SID. The command allows the user to view a multicast tree on the SPBM B-VLAN from the source node to the destination nodes for a particular I-SID.

Before You Begin

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP.
- Enable the MEP.
- Assign a nodal MEP to the B-VLAN.

Procedure

Trigger a Layer 2 tracetable:

```
12 tracetable {<1-4059> <1-16777215> [routernodename WORD<0-255> |
<1-4059> <1-16777215>] [mac <0x00:0x00:0x00:0x00:0x00:0x00>]} [priority
<0-7>] [source-mode <nodal|smltVirtual>] [ttl-value <1-255>]
```

Example

```
Switch:1#12 tracetable 500 1
Switch:1# 12 tracetable 500 1

Please wait for 12tracetable to complete or press any key to abort

12tracetable to 53:55:10:00:00:01, vlan 500 i-sid 1 nickname 5.55.10
hops 64
1  Switch-PETER4          00:15:9b:11:33:df -> Switch-MONTI0      00:14:0d:a2:b3:df
2  Switch-MONTI0         00:14:0d:a2:b3:df -> Switch-LEE2        00:15:e8:b8:a3:df
```

Variable Definitions

The following table defines parameters for the **12 tracetable** command.

Variable	Value
<code>{ <1-4059><1-16777215> routernodename WORD<0-255> <1-4059><1-16777215> mac <0x00:0x00:0x00:0x00:0x00:0x00> }</code>	<ul style="list-style-type: none"> • <code><1-4059></code> – Specifies the VLAN ID. • <code><1-16777215></code> – Specifies the I-SID. • <code>WORD<0-255></code> – Specifies the Router Node Name. • <code><0x00:0x00:0x00:0x00:0x00:0x00></code> – Specifies the MAC address.
<code>ttl-value <1-255></code>	Specifies the TTL value. The default is 64.
<code>priority <0-7></code>	Specifies the priority value. The default is 7.
<code>source-mode<nodal smltVirtual></code>	Specifies the source mode. The default is nodal.
Note: Exception: smltVirtual is not supported on 5320 Series.	

Triggering a Layer 2 Tracetree-fan

About This Task

Use this procedure to trigger a Layer 2 tracetree-fan from the nickname server to make sure that all the nodes towards the nickname client support the FAN protocol. Layer 2 tracetree-fan allows a user to trigger an LTM on the internal Fabric Area Network (FAN) I-SID. This command allows the user to trace the FAN tree.

Procedure

Trigger a Layer 2 tracetree-fan:

```
l2 tracetree-fan [mac <0x00:0x00:0x00:0x00:0x00:0x00>] [priority <0-7>]
[routernodename WORD<0-255>] [ttl-value <1-255>]
```

Example

Switch:1# l2 tracetree-fan

```
Switch:1# l2 tracetree-fan

Please wait for l2tracetree to complete or press any key to abort

l2tracetree to b1:ad:aa:41:b0:84, vlan 4051 i-sid 16777001 nickname 0.00.00 hops 64

1  Switch-PETER4          b0:ad:aa:41:b0:84 -> Switch-MONTI0      b0:ad:aa:41:48:84
1  Switch-PETER4          b0:ad:aa:41:b0:84 -> Switch-MONTI1      b0:ad:aa:42:88:84
2  Switch-MONTI0           b0:ad:aa:41:48:84 -> Switch-LEE2         b0:ad:aa:43:3c:84
```

Trigger a Layer 2 Tracemroute

Use this procedure to debug the IP Multicast over Fabric Connect stream path using **l2 tracemroute** on the VLAN (Layer 2) or the VRF (Layer 3). This procedure queries the SPBM multicast module to determine the B-VLAN, I-SID and nickname for the S and G streams. The nickname and I-SID are used to create a multicast MAC address.

Note

The VLAN option is only valid for a VLAN that has an I-SID configured and IGMP snooping enabled.

Before You Begin

- On the source and destination nodes, you must configure an autogenerated or an explicit CFM MD, MA, and MEP.
- Enable the MEP.
- Assign a nodal MEP to the B-VLAN.

Procedure

1. To enter User EXEC mode, log on to the switch.

2. Trigger a Layer 2 tracemroute on the VLAN:

```
l2 tracemroute source <A.B.C.D> group <A.B.C.D> vlan <1-4059>[priority
<0-7>] [ttl-value <1-255>]
```

Note

For the preceding command, if you do not specify a VLAN, **l2 tracemroute** uses the global default VRF.

Wait for the l2 tracemroute to complete or press any key to abort.

3. Trigger a Layer 2 tracemroute on the VRF:

```
l2 tracemroute source <A.B.C.D> group <A.B.C.D> vrf WORD<1-16>
[priority <0-7>] [ttl-value <1-255>]
```

Note

For the preceding command, if you do not specify a VRF, **l2 tracemroute** uses the global default VRF.

Wait for the l2 tracemroute to complete or press any key to abort.

Examples

The following is a sample output for a Layer 2 tracemroute on a VLAN:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#l2 tracemroute source 192.0.2.81 233.252.0.1 vlan 201

Please wait for l2 tracemroute to complete or press any key to abort.

Source 192.0.2.81

Group: 233.252.0.1

VLAN:201

EMAC: 03:00:03:f4:24:01

B-VLAN: 10

I-SID: 16000001

=====
1 PETER4 00:03:00:00:00:00 -> LEE1 00:14:0d:bf:a3:df
2 LEE1 00:14:0d:bf:a3:df -> LEE2 00:15:e8:b8:a3:df
```

The following is a sample output for a Layer 2 tracemroute on a VRF:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#l2 tracemroute source 192.0.2.10 group 233.252.0.1 vrf red

Please wait for l2 tracemroute to complete or press any key to abort.

Source 192.0.2.10

Group: 233.252.0.1

VRF: redID 1
```

```

EMAC: 03:00:04:f4:24:01

B-VLAN: 20

I-SID: 16000001

=====
1 PETER4 00:03:00:00:00:00 -> LEE1 00:14:0d:bf:a3:df
2 LEE1 00:14:0d:bf:a3:df -> LEE2 00:15:e8:b8:a3:df
    
```

Variable Definitions

The following table defines parameters for the **12 tracemroute** command.

Variable	Value
<i>source</i> <A.B.C.D>	Specifies the source IP address.
<i>group</i> <A.B.C.D>	Specifies the IP address of the multicast group.
<i>vlan</i> <1-4084>	Specifies the VLAN value.
<i>vrf</i> WORD<1-16>	Specifies the VRF name. If you do not specify a VRF name, then the results are shown for the flow in the Global Router (default) context.
<i>priority</i> <0-7>	Specifies the priority value.
<i>ttl</i> <1-255>	Specifies the time-to-live (TTL) for the trace packet, which is how many hops the trace packet takes before it is dropped.

Using trace CFM to Diagnose Problems

Use the following procedure to display trace information for CFM.

About This Task

Use trace to observe the status of a software module at a certain time.

For example, if you notice a CPU utilization issue (generally a sustained spike above 90%) perform a trace of the control plane activity.

Use the **trace level 120 <0-4>** command to trace CFM module information, including CLI, instrumentation, show config, and platform dependent code. The CFM module ID is 120.

Use the **trace cfm level <0-4>** command to trace platform independent code and CFM protocol code.

Caution
Risk of traffic loss

Using the trace tool inappropriately can cause primary CPU lockup conditions, loss of access to the device, loss of protocols, and service degradation.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Clear the trace:

```
clear trace
```

3. Begin the trace operation:

```
trace cfm level <0-4>
```

Wait approximately 30 seconds, and then stop trace.

4. Stop tracing:

```
trace shutdown
```

5. View the trace results:

```
show trace cfm
```

6. Begin the trace operation for the CFM module:

```
trace level 120 <0-4>
```

Wait approximately 30 seconds, and then stop trace.

7. View trace results:

```
trace screen enable
```

**Important**

If you use trace level 3 (verbose) or trace level 4 (very verbose), do not use the screen to view commands due to the volume of information the system generates and the effect on the system.

8. Save the trace file to the Compact Flash card for retrieval.

```
save trace [file WORD<1-99>]
```

If you do not specify a file name, the file name is systrace.txt. By default, the system saves the file to the external flash.

9. Search trace results for a specific string value, for example, the word error:

```
trace grep [WORD<0-128>]
```

If you use this command and do not specify a string value, you clear the results of a previous search.

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)# clear trace
Switch:1(config)# trace cfm level 3
Switch:1(config)# trace shutdown
Switch:1(config)# show trace cfm
```

```
=====
                          CFM Tracing Info
=====
```

```
Status      : Enabled
Level       : VERBOSE
Switch:1(config)#trace level 120 3
Switch:1(config)# save trace
Switch:1(config)# trace grep error
Switch:1(config)#trace grep 00-1A-4B-8A-FB-6B
```

Variable Definitions

The following table defines parameters for the **trace** command.

Variable	Value
<i>cfm level</i> [<0-4>]	Starts the trace by specifying the level. <ul style="list-style-type: none"> <0-4> specifies the trace level from 0-4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose.
<i>filter</i>	Configures a filter trace for a file or module.
<i>flags</i>	Configures trace flags for IS-IS or OSPF.
<i>grep</i> [WORD<0-128>]	Searches trace results for a specific string value, for example, the word error. Performs a comparison of trace messages.
<i>level</i> [<Module_ID>] [<0-4>]	Starts the trace by specifying the module ID and level. <ul style="list-style-type: none"> <Module_ID> specifies the module for the trace. Different hardware platforms support different ID ranges because of feature support differences. To see which module IDs are available on the switch, use the show trace modid-list command or CLI command completion Help. <0-4> specifies the trace level from 0-4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose.
<i>route-map</i>	Enables or disables the trace route-map. The values are on and off.
<i>screen</i> {disable enable}	Enables the display of trace output to the screen.
<i>shutdown</i>	Stops the trace operation.
<i>spbm isis level</i> [<0-4>]	Starts the trace by specifying the level. <ul style="list-style-type: none"> <0-4> specifies the trace level from 0-4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose. The default is 1, very terse.

The following table defines parameters for the **save trace** command.

Variable	Value
<code>file WORD<1-99></code>	<p>Specifies the file name in one of the following formats:</p> <ul style="list-style-type: none"> • a.b.c.d:<file> • x:x:x:x:x:x:<file> • /intflash/<file> • /extflash/<file> • /usb/<file> • /mnt/intflash/ <file> • /mnt/extflash/ <file> <p>/mnt/intflash is the internal flash of the CPU. /mnt/extflash is the external flash of the CPU.</p>

Using trace SPBM to Diagnose Problems

Use the following procedure to display trace information for SPBM IS-IS. In the case of IS-IS, this procedure also provides information related to the flags set.

About This Task

Use the **trace level 119 <0-4>** command to trace IS-IS module information, including CLI, instrumentation, show config and platform dependent code. The IS-IS module ID is 119.

Use the **trace level 125 <0-4>** command to trace SPBM module information, including CLI, instrumentation, show config and platform dependent code. The SPBM module ID is 125.

Use the **trace spbm isis level** command to trace platform independent code, IS-IS protocol, IS-IS hello, IS-IS adjacency, LSP processing, and IS-IS computation.

Caution

Risk of traffic loss

Using the trace tool inappropriately can cause primary CPU lockup conditions, loss of access to the device, loss of protocols, and service degradation.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Clear the trace:

```
clear trace
```
3. Begin the trace operation:

```
trace spbm isis level <0-4>
```

Wait approximately 30 seconds, and then stop trace.
4. Stop tracing:

```
trace shutdown
```

5. Display the trace information for SPBM IS-IS:

```
show trace spbm isis
```

6. Begin the trace operation for the SPBM module:

```
trace level 125 <0-4>
```

Wait approximately 30 seconds, and then stop trace.

7. Begin the trace operation for the IS-IS module:

```
trace level 119 <0-4>
```

Wait approximately 30 seconds, and then stop trace.

8. View trace results:

```
trace screen enable
```

Important

If you use trace level 3 (verbose) or trace level 4 (very verbose), do not use the screen to view commands due to the volume of information the system generates and the effect on the system.

9. Save the trace file to the Compact Flash card for retrieval.

```
save trace [file WORD<1-99>]
```

If you do not specify a file name, the file name is systrace.txt. By default, the system saves the file to the external flash.

10. Search trace results for a specific string value, for example, the word error:

```
trace grep [WORD<0-128>]
```

If you use this command and do not specify a string value, you clear the results of a previous search.

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)# clear trace
Switch:1(config)# trace spbm isis level 3
Switch:1(config)# trace shutdown
Switch:1(config)# show trace spbm isis
=====
                        SPBM ISIS Tracing Info
=====
Status      : Enabled
Level       : VERY_TERSE
Flag Info   :
Switch:1(config)#trace level 125 3
Switch:1(config)#trace level 119 3
Switch:1(config)# save trace
Switch:1(config)# trace grep error
Switch:1(config)#trace grep 00-1A-4B-8A-FB-6B
```

Variable Definitions

The following table defines parameters for the **trace** command.

Variable	Value
<i>cfm level</i> [<0-4>]	Starts the trace by specifying the level. <ul style="list-style-type: none"> • <0-4> specifies the trace level from 0-4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose.
<i>filter</i>	Configure a filter trace for a file or module.
<i>flags</i>	Configure trace flags for IS-IS or OSPF.
<i>grep</i> [WORD<0-128>]	Searches trace results for a specific string value, for example, the word error. Performs a comparison of trace messages.
<i>level</i> [<Module_ID>] [<0-4>]	Starts the trace by specifying the module ID and level. <ul style="list-style-type: none"> • <Module_ID> specifies the module for the trace. Different hardware platforms support different ID ranges because of feature support differences. To see which module IDs are available on the switch, use the show trace modid-list command or CLI command completion Help. • <0-4> specifies the trace level from 0-4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose.
<i>route-map</i>	Enables or disables the trace route-map. The values are on and off.
<i>screen</i> {disable enable}	Enables the display of trace output to the screen.
<i>shutdown</i>	Stops the trace operation.
<i>spbm isis level</i> [<0-4>]	Starts the trace by specifying the level. <ul style="list-style-type: none"> • <0-4> specifies the trace level from 0-4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose. <p>The default is 1, very terse.</p>

The following table defines parameters for the **save trace** command.

Variable	Value
<code>file WORD<1-99></code>	<p>Specifies the file name in one of the following formats:</p> <ul style="list-style-type: none"> • a.b.c.d:<file> • x:x:x:x:x:x: <file> • /intflash/<file> • /extflash/<file> • /usb/<file> • /mnt/intflash/ <file> • /mnt/extflash/ <file> <p>/mnt/intflash is the internal flash of the CPU. /mnt/extflash is the external flash of the CPU.</p>

CFM Configuration Using EDM

This section provides procedures to configure Connectivity Fault Management (CFM) using Enterprise Device Manager (EDM).

Note

When you enable CFM in an SPBM network, as a best practice, enable CFM on the Backbone Edge Bridges (BEB) and on all Backbone Core Bridges (BCB). If you do not enable CFM on a particular node, you cannot obtain CFM debug information from that node.

Autogenerated CFM

CFM provides two methods for creating MEPs: autogenerated and explicit. You cannot use both. You must choose one or the other. Use the procedures in this section to configure autogenerated MEPs that eliminate the need to configure an MD, MA, and MEP ID to create a MEP.

Previous explicit CFM configurations of MDs, MAs and MEPs on SPBM B-VLANs continue to function. However, if you want to enable the autogenerated commands, you must first remove the existing MEP and MIP on the SPBM B-VLAN. The switch only supports one MEP or MIP on the SPBM B-VLAN, either explicitly configured or autogenerated.

Configure Autogenerated CFM on SPBM B-VLANs

Use this procedure to configure the autogenerated CFM MEP and MIP level for every SPBM B-VLAN on the chassis. This configuration eliminates the need to explicitly configure an MD, MA, and MEP ID and to associate the MEP and MIP level to the SPBM B-VLAN.

About This Task

When you enable this feature, the device creates a global MD (named `spbm`) for all the SPBM Nodal MEPs. This MD has a default maintenance level of 4, which you can change with the `level` attribute. All the MEPs that the device creates use the MEP ID configured under the global context, which has a default value of 1. The nodal MEPs are automatically associated with the SPBM B-VLANs configured.

The MIP level maps to the global level. When you enable the feature, the device automatically associates the MIP level with the SPBM B-VLANs configured. The feature is disabled by default.

Important

CFM supports one MEP or MIP for each SPBM B-VLAN only. This means that if you want to use these autogenerated MEPs, you cannot use your existing CFM configuration. You must first remove the existing MEP or MIP on the SPBM B-VLAN. If you want to continue configuring MEPs manually, skip this procedure.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **CFM**.
3. Select the **Global** tab.
4. Select **enable** next to **SpbmAdminState**.
5. Select **Apply**.

Global Field Descriptions

Use the data in the following table to configure the global MEP and MIP parameters.

Name	Description
SpbmAdminState	Enables or disables autogenerated CFM for B-VLANs. The default is disable.
SpbmLevel	Specifies the global SPBM CFM maintenance level for the chassis within the range of 0 to 7. The default is 4. Only configure global CFM at one MD level for each chassis for each VLAN type.
SpbmMepld	Specifies the global MEP ID within the range of 1 to 8191. Select a unique ID for each switch to ensure that the MEPs are unique across the network. The default is 1.

Configuring Explicit CFM

For SPBM B-VLANs, CFM provides two methods for creating MEPs: autogenerated and explicit. You cannot use both. Use the procedures in this section to configure MEPs explicitly.

If you want to create autogenerated CFM MEPs that eliminate the need to configure an MD, MA, and MEP ID, see the procedures in [Autogenerated CFM](#) on page 3095.

Note

The CFM show commands that display MD, MA, and MEP information work for both autogenerated and explicitly-configured CFM MEPs.

Configure CFM MD

Use this procedure to configure a Connectivity Fault Management (CFM) Maintenance Domain (MD). An MD is the part of a network that is controlled by a single administrator. A single MD can contain several Maintenance Associations (MA).

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **CFM**.
3. Click the **MD** tab.
4. Click **Insert**.
5. In the fields provided, specify an index value, name, and level for the MD.
6. Click **Insert**.

MD Field Descriptions

Use the data in the following table to use the **MD** tab.

Name	Description
Index	Specifies a maintenance domain entry index.
Name	Specifies the MD name.
NumOfMa	Indicates the number of MAs that belong to this maintenance domain.
Level	Specifies the MD maintenance level. The default is 4.
NumOfMip	Indicates the number of MIPs that belong to this maintenance domain
Type	Indicates the type of domain.

Configure CFM MA

Use this procedure to configure a CFM Maintenance Association (MA). An MA represents a logical grouping of monitored entities within its Domain. It can therefore represent a set of Maintenance Endpoints (MEPs), each configured with the same Maintenance Association ID (MAID) and MD Level, established to verify the integrity of a single service instance.

Before You Begin

- You must configure a CFM MD.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **CFM**.
3. Click the **MD** tab.
4. Highlight an existing MD, and then click **MaintenanceAssociation**.
5. In the **MA** tab, click **Insert**.
6. In the fields provided, specify an index value and name for the MA.
7. Click **Insert**.

MA Field Descriptions

Use the data in the following table to use the **MA** tab.

Name	Description
DomainIndex	Specifies the maintenance domain entry index.
AssociationIndex	Specifies a maintenance association entry index.
DomainName	Specifies the MD name.
AssociationName	Specifies the MA name.
NumOfMep	Indicates the number of MEPs that belong to this maintenance association.

Configure CFM MEP

Use this procedure to configure the CFM Maintenance Endpoint (MEP). A MEP represents a managed CFM entity, associated with a specific Domain Service Access Point (DoSAP) of a service instance, which can generate and receive CFM Protocol Data Units (PDU) and track any responses. A MEP is created by MEP ID under the context of an MA.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **CFM**.
3. Click the **MD** tab.
4. Highlight an existing MD, and then click **MaintenanceAssociation**.
5. In the **MA** tab, highlight an existing MA, and then click **MaintenanceEndpoint**.
6. Click **Insert**.
7. In the fields provided, specify the ID and the administrative state of the MEP.
8. Click **Insert**.

MEP Field Descriptions

Use the data in the following table to use the **MEP** tab.

Name	Description
DomainIndex	Specifies the MD index.
AssociationIndex	Specifies the MA index.
Id	Specifies the MEP ID.
DomainName	Specifies the MD name.
AssociationName	Specifies the MA name.
AdminState	Specifies the administrative state of the MEP. The default is disable.

Name	Description
MepType	Specifies the MEP type: <ul style="list-style-type: none"> • trunk • sg • endpt • vlan • port • endptClient • nodal • remotetrunk • remotesg • remoteendpt • remoteVlan • remotePort • remoteEndptClient
ServiceDescription	Specifies the service to which this MEP is assigned.

Configure CFM Nodal MEP

Use this procedure to configure the CFM nodal Maintenance Endpoint (MEP). The Nodal MEP provides traceability and troubleshooting at the system level for a given B-VLAN. The Nodal B-VLAN MEPs created on the CP and function as if they are connected to the virtual interface of the given B-VLAN. Because of this they are supported for both port and MLT based B-VLANs.

Nodal MPs provide both MEP and Maintenance Intermediate Point (MIP) functionality for SPBM deployments. Nodal MPs are associated with a B-VLAN and are VLAN encapsulated packets. Each node (chassis) has a given MAC address and communicates with other nodes. The SPBM instance MAC address is used as the MAC address of the Nodal MP.

Before You Begin

- You must configure a CFM MD, MA, and MEP.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the **Advanced** tab.
4. Select a VLAN with a type of spbm-bvlan.
5. Click **Nodal**.
6. In the **NodalMepList** field, specify the nodal MEPs to add to the VLAN.
7. Click **Apply**.

Nodal MEP/MIP Field Descriptions

Use the data in the following table to use the **Nodal MEP/MIP** tab.

Name	Description
NodalMepList	Specifies the nodal MEPs to add to the VLAN, in the format <mdName.maName.mepId>, for example md10.ma20.30.
NumOfNodalMep	Indicates the number of nodal MEPs assigned to this VLAN.
NodalMipLevelList	Specifies a MIP level list.
NumOfNodalMipLevel	Indicates the number of nodal MIP levels assigned to this VLAN that allows MIP functionality to be enabled on a per level per VLAN basis.

Configure Layer 2 Ping

Use this procedure to configure a Layer 2 ping inside an SPBM cloud or network. This feature enables CFM to debug Layer 2. It can also help you debug IP shortcuts and the record for the shortcuts' ARP.

Before You Begin

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP, and assign a nodal MEP to the B-VLAN.

Procedure

- In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
- Click **L2Ping/L2Trace Route**.
- From the **L2Ping** tab, configure the Layer 2 ping properties.
- To initiate a Layer 2 ping, highlight an entry and click the **Start** button.
- To update a Layer 2 ping, click the **Refresh** button.
- To stop the Layer 2 ping, click the **Stop** button.

L2Ping Field Descriptions

Use the data in the following table to use the **L2Ping** tab.

Name	Description
VlanId	Identifies the backbone VLAN.
DestMacAddress	Specifies the target MAC address.
HostName	Specifies the target host name.
DestIsHostName	Indicates whether the host name is (true) or is not (false) used for L2Ping transmission.
Messages	Specifies the number of L2Ping messages to be transmitted. The default is 1.

Name	Description
Status	<p>Specifies the status of the transmit loopback service:</p> <ul style="list-style-type: none"> • ready: the service is available. • transmit: the service is transmitting, or about to transmit, the L2Ping messages. • abort: the service aborted or is about to abort the L2Ping messages. <p>This field is also used to avoid concurrency or race condition problems that can occur if two or more management entities try to use the service at the same time. The default is ready.</p>
ResultOk	<p>Indicates the result of the operation:</p> <ul style="list-style-type: none"> • true: the L2Ping Messages will be (or have been) sent. • false: the L2Ping Messages will not be sent. <p>The default is true.</p>
Priority	<p>Specifies a 3-bit value to be used in the VLAN header, if present in the transmitted frame. The default is 7.</p>
TimeoutInt	<p>Specifies the interval to wait for an L2Ping timeout. The default value is 3 seconds.</p>
TestPattern	<p>Specifies the test pattern to use in the L2Ping PDU:</p> <ul style="list-style-type: none"> • allZero: null signal without cyclic redundancy check • allZeroCrc: null signal with cyclic redundancy check with 32-bit polynomial • pseudoRandomBitSequence: pseudo-random-bit-sequence without cyclic redundancy check • pseudoRandomBitSequenceCrc: pseudo-random-bit-sequence with cyclic redundancy check with 32-bit polynomial. <p>A cyclic redundancy check is a code that detects errors. The default value is allZero.</p>
DataSize	<p>Specifies an arbitrary amount of data to be included in the data TLV, if the data size is selected to be sent. The default is 0.</p>
FrameSize	<p>Specifies the frame size. If the frame size is specified then the data size is internally calculated and the calculated data size is included in the data TLV. The default is 0.</p>

Name	Description
SourceMode Note: Exception: smltVirtual is not supported on 5320 Series.	Specifies the source mode of the transmit loopback service: <ul style="list-style-type: none"> • nodal • smltVirtual — Use the smltVirtual option with B-VLANs only. The default is nodal.
SeqNumber	The transaction identifier/sequence number of the first loopback message (to be) sent. The default is 0.
Result	Displays the Layer 2 Ping result.

Initiate a Layer 2 Traceroute

Use this procedure to trigger a Layer 2 traceroute. This feature enables CFM to debug Layer 2 in an SPBM cloud or network. It can determine the path used by IS—IS to get from one MEP to another, by showing all the hops between. Therefore, it can show where connectivity is lost. It can also work for IP shortcuts.

If you configure **IsTraceTree** to false then EDM performs Traceroute on the unicast path. If you configure **IsTraceTree** to true then EDM performs TraceTree on the multicast tree.

For more information on configuring tracetree, see [Configure a Layer 2 Tracetree](#) on page 3117.

Important

To trace a route to a MAC address, the MAC address must be in the VLAN FDB table.

For B-VLANs, you do not have to trigger an **L2Ping** to learn the MAC address because IS-IS populates the MAC addresses in the FDB table.

Linktrace traces the path up to the closest device to that MAC address that supports CFM.

Before You Begin

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP, and assign a nodal MEP to the B-VLAN.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **L2Ping/L2Trace Route**.
3. Select the **L2 Traceroute/TraceTree** tab.
4. To start the traceroute, highlight an entry, and then select **Start**.
5. To update the traceroute, select **Refresh**.
6. To stop the traceroute, select **Stop**.

L2 Traceroute/TraceTree Field Descriptions

Use the data in the following table to use the **L2 Traceroute/TraceTree** tab.

Name	Description
VlanId	Specifies a value that uniquely identifies the Backbone VLAN (B-VLAN).
Priority	Specifies a 3-bit value to be used in the VLAN header, if present in the transmitted frame. The default is 7.
DestMacAddress	Specifies the target MAC address.
HostName	Specifies the target host name.
DestIsHostName	Specifies whether the host name is (true) or is not (false) used for the L2Trace transmission.
Isid	Specifies the Service Instance Identifier (I-SID).
IsTraceTree	<p>Specifies whether the multicast tree or unicast path is traced:</p> <ul style="list-style-type: none"> • If you configure IsTraceTree to false then EDM performs Traceroute on the unicast path. • If you configure IsTraceTree to true then EDM performs TraceTree on the multicast tree.
Status	<p>Indicates the status of the transmit loopback service:</p> <ul style="list-style-type: none"> • ready: the service is available. • transmit: the service is transmitting, or about to transmit, the L2Trace messages. • abort: the service aborted or is about to abort the L2Trace messages. <p>This field is also used to avoid concurrency or race condition problems that can occur if two or more management entities try to use the service at the same time. The default is ready.</p>
ResultOk	<p>Indicates the result of the operation:</p> <ul style="list-style-type: none"> • true: the L2Trace messages will be (or have been) sent. • false: the L2Trace messages will not be sent. <p>The default is true.</p>
Ttl	<p>Specifies the number of hops remaining to this L2Trace.</p> <p>This value is decremented by 1 by each Bridge that handles the L2Trace. The decremented value is returned in the L2Trace. If 0 on output, the L2Trace is not transmitted to the next hop. The value of the time-to-live (TTL) field in the L2Trace is defined by the originating MEP. The default value is 64.</p>

Name	Description
SourceMode Note: Exception: smltVirtual is not supported on 5320 Series.	Specifies the source mode: <ul style="list-style-type: none"> • 1: nodal • 2: smltVirtual—Use this value with B-VLANs only. The default is 1: nodal.
SeqNumber	Specifies the transaction identifier/sequence number of the first loopback message (to be) sent. The default is 0.
Flag	L2Trace result flag that indicates L2Trace status or error code: <ul style="list-style-type: none"> • none (1): No error • internalError (2): L2Trace internal error • invalidMac (3): Invalid MAC address • mepDisabled (4): MEP must be enabled in order to perform L2Trace • noL2TraceResponse (5): No L2Trace response received • l2TraceToOwnMepMac (6): L2Trace to own MEP MAC is not sent • l2TraceComplete (7): L2Trace completed • l2TraceLookupFailure (8): Lookup failure for L2Trace • l2TraceLeafNode (9): On a leaf node in the I-SID tree • l2TraceNotInTree (10): Not in the I-SID tree • l2TraceSmltNotPrimary (11): Requested SMLT source from non-primary node

View Layer 2 Traceroute Results

Use this procedure to view Layer 2 traceroute results. This feature enables CFM to debug Layer 2. It can also help you debug ARP problems by providing the ability to troubleshoot next hop ARP records.

About This Task

You can display Layer 2 tracetable results to view a multicast tree on the SPBM B-VLAN from the source node to the destination nodes for a particular I-SID. For more information, see [View Layer 2 Tracetable Results](#) on page 3119.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **L2Ping/L2Trace Route**.
3. Select the **L2Traceroute/TraceTree** tab.
4. Select **Refresh** to update the results.
5. To view the traceroute results, highlight an entry, and then select **Result**.

L2 Traceroute/Tracetree Result Field Descriptions

Use the data in the following table to use the **L2 Traceroute/Tracetree Result** tab.

Name	Description
VlanId	A value that uniquely identifies the Backbone VLAN (B-VLAN).
SeqNumber	The transaction identifier/sequence number returned by a previous transmit linktrace message command, indicating which L2Trace's response of the L2Trace is going to be returned. The default is 0.
Hop	The number of hops away from L2Trace initiator.
ReceiveOrder	An index to distinguish among multiple L2Trace responses with the same Transaction Identifier field value. This value is assigned sequentially from 1, in the order that the Linktrace Initiator received the responses.
Ttl	Time-to-Live (TTL) field value for a returned L2Trace response.
SrcMac	MAC address of the MP that responds to the L2Trace request for this L2TraceReply.
HostName	The host name of the replying node.
LastSrcMac	The MAC address of the node that forwarded the L2Trace to the responding node.
LastHostName	The host name of the node that forwarded the L2Trace to the responding node.

Configure Layer 2 IP Ping

Use this procedure to configure Layer 2 IP ping

Before You Begin

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP, and assign a nodal MEP to the B-VLAN.
- If you want to run a Layer 2 IP Ping for a specific VRF, you must use EDM in the specific VRF context first. For more information, see the procedure for selecting and launching a VRF context view in [Select and Launch a VRF Context View](#) on page 3395.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **L2Ping/L2Trace Route**.
3. Click the **L2 IP Ping** tab.
4. To add a new entry, click **Insert**, specify the destination IP address and optional parameters, and then click **Insert**.
5. To start the Layer 2 IP ping, highlight an entry, and then click **Start**.
6. To update the Layer 2 IP ping, click the **Refresh** button.
7. To stop the Layer 2 IP ping, click **Stop**.

L2 IP Ping Field Descriptions

Use the data in the following table to use the **L2 IP Ping** tab.

Name	Description
IpAddrType	Specifies the address type of destination IP Address (only IPv4 is supported).
IpAddr	Specifies the destination IP Address.
VrfId	Specifies the VRF ID.
VrfName	Specifies the name of the virtual router.
Messages	Specifies the number of L2IpPing messages to be transmitted per MAC/VLAN pair. Range is 1–200. The default is 1.
Status	<p>Specifies the status of the transmit loopback service:</p> <ul style="list-style-type: none"> ready: the service is available. transmit: the service is transmitting, or about to transmit, the L2IpPing messages. abort: the service is aborted or about to abort the L2IpPing messages. <p>This field is also used to avoid concurrency or race condition problems that could occur if two or more management entities try to use the service at the same time. The default is ready.</p>
ResultOk	<p>Indicates the result of the operation:</p> <ul style="list-style-type: none"> true: L2IpPing Messages will be or have been sent. false: L2IpPing Messages will not be sent. <p>The default is true.</p>
TimeoutInt	Specifies the interval to wait for an L2IpPing time-out with a range of 1–10 seconds with a default value of 3 seconds.
TestPattern	<p>Specifies the test pattern to use in the L2IPPing PDU:</p> <ul style="list-style-type: none"> allZero — null signal without cyclic redundancy check allZeroCrc — null signal with cyclic redundancy check with 32-bit polynomial pseudoRandomBitSequence — pseudo-random-bit-sequence without cyclic redundancy check pseudoRandomBitSequenceCrc — pseudo-random-bit-sequence with cyclic redundancy check with 32-bit polynomial. <p>A cyclic redundancy check is a code that detects errors. The default value is allZero.</p>

Name	Description
DataSize	Specifies an arbitrary amount of data to be included in the data TLV, if the data size is selected to be sent. The range is 0–400. The default is 0.
PathsFound	Specifies the number of paths found to execute the command. The default is 0.

View Layer 2 IP Ping Results

Use this procedure to view Layer 2 IP ping results.

Note

After you trigger Layer 2 IP Ping, you must click the **Refresh** button to update the results.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **L2Ping/L2Trace Route**.
3. Click the **L2 IP Ping** tab.
4. To view the Layer 2 IP ping results, highlight an entry, and then click **Result**.

L2 IP Ping Result Field Descriptions

Use the data in the following table to use the **L2 IP Ping Result** tab.

Name	Description
IpAddrType	The address type of the destination IP Address.
IpAddr	Destination IP Address.
SendOrder	Specifies the order that sessions were sent. It is an index to distinguish among multiple L2Ping sessions. This value is assigned sequentially from 1. It correlates to the number of paths found.
VrfId	Specifies the VRF ID.
VlanId	Specifies the VLAN ID found from the Layer 3 lookup and used for transmission.
DestMacAddress	An indication of the target MAC Address transmitted.
PortNum	Either the value '0', or the port number of the port used for the l2 IP ping.
DestHostName	The host name of the responding node.
Size	The number of bytes of data sent.
PktsTx	Number of Packets transmitted for this VLAN/MAC.
PktsRx	Number of Packets received for this VLAN/MAC.
PercentLossWhole	Percentage of packet loss for this VLAN/MAC.
PercentLossFract	Percentage of packet loss for this VLAN/MAC.

Name	Description
MinRoundTrip	Minimum time for round-trip for this VLAN/MAC in us.
MaxRoundTrip	Maximum time for round-trip for this VLAN/MAC in us.
RttAvgWhole	Average time for round-trip for this VLAN/MAC in us.
RttAvgFract	Fractional portion of average time for round-trip.
Flag	Result flag indicating status or error code: <ul style="list-style-type: none"> • 1 - No error • 2 - Internal error • 3 - Invalid IP • 4 - L2Trace completed • 5 - Lookup failure for IP (no VLAN/MAC entries)

Configure Layer 2 IP Traceroute

Use this procedure to configure Layer 2 IP traceroute.

Before You Begin

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP, and assign a nodal MEP to the B-VLAN
- If you want to run a Layer 2 IP Traceroute for a specific VRF, you must use EDM in the specific VRF context first. For more information, see the procedure for selecting and launching a VRF context view in [Select and Launch a VRF Context View](#) on page 3395.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **L2Ping/L2Trace Route**
3. Click the **L2 IP Traceroute** tab.
4. To add a new entry, click **Insert**, specify the destination IP address and, optionally, the TTL value, and then click **Insert**.
5. To start the Layer 2 IP traceroute, highlight an entry, and then click the **Start** button.
6. To update the Layer 2 IP traceroute, click the **Refresh** button.
7. To stop the Layer 2 IP traceroute, click the **Stop** button.

L2 IP Traceroute Field Descriptions

Use the data in the following table to use the **L2 IP Traceroute** tab.

Name	Description
IpAddrType	Specifies the address type of destination IP address (only IPv4 is supported).
IPAddr	Specifies the destination IP Address.
Vrflid	Specifies the VRF ID.

Name	Description
VrfName	Specifies the name of the virtual router.
Ttl	Specifies the number of hops remaining to this L2Trace. This value is decremented by 1 by each Bridge that handles the L2Trace. The decremented value is returned in the L2Trace. If 0 on output, the L2Trace is not transmitted to the next hop. The default value is 64
Status	<p>Indicates the status of the transmit loopback service:</p> <ul style="list-style-type: none"> • ready: the service is available. • transmit: the service is transmitting, or about to transmit, the L2Trace messages. • abort: the service is aborted or about to abort the L2Trace messages. <p>This field is also used to avoid concurrency or race condition problems that could occur if two or more management entities try to use the service at the same time. The default is ready.</p>
ResultOk	<p>Indicates the result of the operation:</p> <ul style="list-style-type: none"> • true: the Trace Messages will be or have been sent. • false: the Trace Messages will not be sent <p>The default is true.</p>
PathsFound	Specifies the number of paths found to execute the L2trace. The default is 0.

View Layer 2 IP Traceroute Results

Use this procedure to view Layer 2 IP traceroute results.

Note

After you trigger Layer 2 IP traceroute, you must click the **Refresh** button to update the results.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **L2Ping/L2Trace Route**.
3. Click the **L2 IP Traceroute** tab.
4. To view the Layer 2 IP traceroute results, highlight an entry, and then click **Result**.

L2 IP Traceroute Result Field Descriptions

Use the data in the following table to use the **L2 IP Traceoute Result** tab.

Name	Description
IpAddrType	Specifies the address type of destination IP address.
IpAddr	Specifies the destination IP address.
SendOrder	Denotes the order that sessions are sent. It is an index to distinguish among multiple L2Trace sessions. It correlates to the number of paths found. This value is assigned sequentially from 1.
Hop	Specifies the number of Layer 2 hops away from L2Trace initiator.
ReceiveOrder	Specifies the order that sessions are sent. It is an index to distinguish among multiple L2Trace responses with the same Send Transaction Identifier field value. This value is assigned sequentially from 1, in the order that the Linktrace Initiator received the responses.
Ttl	Specifies the time-to-live (TTL) field value for a returned L2Trace response.
VrfId	Specifies the VRF ID.
VlanId	Specifies the VLAN found from Layer 3 lookup and used for transmission.
DestMacAddress	Indicates the target MAC address transmitted.
PortNum	Specifies either the value '0', or the port number of the port used for the l2trace.
SeqNumber	Specifies the transaction identifier/sequence number used in linktrace message packet. The default is 0.
SrcMac	Specifies the MAC address of the MP that responded to L2Trace request for this L2traceReply.
HostName	Specifies the host name of the replying node.
LastSrcMac	Specifies the MAC address of the node that forwarded the L2Trace to the responding node.

Name	Description
LastHostName	Specifies the host name of the node that forwarded the L2Trace to the responding node.
Flag	L2Trace result flag indicating status or error code: <ul style="list-style-type: none"> • none (1): No error • internalError (2): L2Trace internal error • invalidMac (3): Invalid MAC address • mepDisabled (4): MEP must be enabled in order to perform L2Trace • noL2TraceResponse (5): No L2Trace response received • l2TraceToOwnMepMac (6): L2Trace to own MEP MAC is not sent • l2TraceComplete (7): L2Trace completed • l2TraceLookupFailure (8): Lookup failure for L2Trace

Trigger a Loopback Test

Use this procedure to trigger a loopback test.

The LBM packet is often compared to ping. An MEP transmits the loopback message to an intermediate or endpoint within a domain for the purpose of fault verification. This can be used to check the ability of the network to forward different sized frames.

Before You Begin

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP.
- Enable the MEP.
- Assign a nodal MEP to the B-VLAN.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **CFM**.
3. Click the **LBM** tab.
4. Configure the loopback test properties as required.
5. Click **Apply**.
6. To trigger the loopback test, double-click in the **Status** field, select **transmit**.
7. Click **Apply**.
8. To update the loopback test, click the **Refresh** button.

LBM Field Descriptions

Use the data in the following table to use the **LBM** tab.

Name	Description
DomainIndex	Specifies the MD index value.
AssociationIndex	Specifies the MA index value.
Index	Specifies the Maintenance Endpoint index value.
DomainName	Specifies the MD name.
AssociationName	Specifies the MA name.
DestMacAddress	Specifies the remote MAC address to reach the MEP/MIP.
Messages	Specifies the number of loopback messages to be transmitted. The default is 1.
VlanPriority	Specifies the priority. The default is 7.
SeqNumber	Specifies the transaction identifier/sequence number of the first loopback message (to be) sent. The default is 0.
ResultOk	Indicates the result of the operation: <ul style="list-style-type: none"> • true: The Loopback Messages will be (or have been) sent. • false: The Loopback Messages will not be sent. The default is true.
Status	Indicates the status of the transmit loopback service: <ul style="list-style-type: none"> • ready: The service is available. • transmit: The service is transmitting, or about to transmit, the Loopback messages. • abort: The service is aborted or about to abort the Loopback messages. The default is ready.
Result	Displays the LBM result.
TimeoutInt	Specifies the timeout interval in seconds. The default value is 3 seconds.
InterFrameInt	Specifies the interval between LBM frames with a range of (0..1000) msec and a default value of 500 msec. The value of 0 msec indicates to send the frames as fast as possible. The default is 500.

Name	Description
TestPattern	Specifies the testfill pattern: <ul style="list-style-type: none"> • allZero — null signal without cyclic redundancy check • allZeroCrc — null signal with cyclic redundancy check with 32-bit polynomial • pseudoRandomBitSequence — pseudo-random-bit-sequence without cyclic redundancy check • pseudoRandomBitSequenceCrc — pseudo-random-bit-sequence with cyclic redundancy check with 32-bit polynomial. A cyclic redundancy check is a code that detects errors. The default value is allZero.
DataSize	Specifies the data type-length-value (TLV) size. The default is 0.
FrameSize	Specifies the frame-size. The default is 0.
Sourcemode Note: Exception: smltVirtual is not supported on 5320 Series.	Specifies the source mode of the transmit loopback service: <ul style="list-style-type: none"> • nodal • smltVirtual — Use the smltVirtual option with B-VLANs only. The default is nodal.

Trigger Linktrace

Use the following procedure to trigger a linktrace. The link trace message is often compared to traceroute. An MEP transmits the Linktrace Message packet to a maintenance endpoint with intermediate points responding to indicate the path of the traffic within a domain for the purpose of fault isolation. The packet specifies the target MAC address of an MP, which is the SPBM system ID or the virtual SMLT MAC. MPs on the path to the target address respond with an LTR.

Before You Begin

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP.
- Enable the MEP.
- Assign a nodal MEP to the B-VLAN.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
 2. Click **CFM**.
 3. Click the **LTM** tab.
 4. Configure the linktrace test properties as required.
 5. Click **Apply**.
 6. To trigger the linktrace test, double-click in the Status field, select **transmit**, and then click **Apply**.
- OR

Highlight an entry, and then click **Start**.

7. To update the linktrace, click the **Refresh** button.
8. To stop the linktrace, click **Stop**.
9. To view the results of the linktrace, click **Result**.

LTM Field Descriptions

Use the data in the following table to use the **LTM** tab.

Name	Description
DomainIndex	Specifies the MD index value.
AssociationIndex	Specifies the MA index value.
Index	Specifies the MEP index value.
DomainName	Specifies the MD name.
AssociationName	Specifies the MA name.
VlanPriority	Specifies the VLAN priority, a 3-bit value to be used in the VLAN tag, if present in the transmitted frame. The default is 7.
DestMacAddress	Specifies the remote MAC address to reach the MEP.
Ttl	Indicates the number of hops remaining to this LTM. This value is decremented by 1 by each bridge that handles the LTM. The decremented value is returned in the LTR. If the value is 0 on output, the LTM is not transmitted to the next hop. The value of the TTL field in the LTM is specified at the originating MEP. The default value is 64.
SeqNumber	Specifies the transaction identifier/sequence number of the first loopback message (to be) sent. The default is 0.
ResultOk	Indicates the result of the operation: <ul style="list-style-type: none"> • true: The Loopback Messages will be (or have been) sent. • false: The Loopback Messages will not be sent. The default is true.
Status	Indicates the status of the transmit loopback service: <ul style="list-style-type: none"> • ready: The service is available. • transmit: The service is transmitting, or about to transmit, the LTM messages. • abort: The service is aborted, or about to abort, the LTM message. The default is ready.

Name	Description
Flag	Displays the LTM result flag indicating LTM status or error code. Each value represents a status or error case: <ul style="list-style-type: none"> • 1 - No error • 2 - LTM internal error • 3 - Unknown Remote Maintenance Endpoint • 4 - Invalid Remote Maintenance Endpoint MAC Address • 5 - Unset Remote Maintenance Endpoint MAC address • 6 - MEP must be enabled in order to perform LTM • 7 - No LTR response received • 8 - Linktrace to own MEP MAC is not sent • 9 - Endpoint must be enabled in order to perform LTM • 10 - Pbt-trunk must be enabled in order to perform LTM • 11 - LTM completed • 12 - LTM leaf node
SourceMode Note: Exception: smltVirtual is not supported on 5320 Series.	Specifies the source mode of the transmit loopback service: <ul style="list-style-type: none"> • nodal • smltVirtual — Use the smltVirtual option with B-VLANs only. The default is nodal.

View Linktrace Results

Use this procedure to view linktrace results.

Note

After you trigger linktrace, you must click the **Refresh** button to update the results.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **CFM**.
3. Click the **LTM** tab.
4. Highlight an entry, and then click **Result**.

Link Trace Replies Field Descriptions

Use the data in the following table to use the **Link Trace Result** tab.

Name	Description
DomainIndex	Indicates the Maintenance Domain Index.
AssociationIndex	Indicates the Maintenance Association Index.

Name	Description
Mepld	Indicates the Maintenance EndPoint ID.
SeqNumber	Indicates the transaction identifier/sequence number returned by a previous transmit linktrace message command, indicating which LTM response is going to be returned. The default is 0.
Hop	Indicates the number of hops away from the LTM initiator.
ReceiveOrder	Indicates the index value used to distinguish among multiple LTRs with the same LTR Transaction Identifier field value. This value is assigned sequentially from 1, in the order that the Linktrace Initiator received the LTRs.
Ttl	Indicates the TTL field value for a returned LTR.
DomainName	Indicates the Maintenance Domain Name.
AssociationName	Indicates the Maintenance Association Name.
Forwarded	Indicates if a LTM was forwarded by the responding MP, as returned in the FwdYes flag of the flags field.
TerminalMep	Displays a boolean value stating whether the forwarded LTM reached a MEP enclosing its MA, as returned in the Terminal MEP flag of the Flags field.
LastEgressIdentifier	Displays an octet field holding the Last Egress Identifier returned in the LTR Egress Identifier TLV of the LTR. The Last Egress Identifier identifies the MEP Linktrace Indicator that originated, or the Linktrace Responder that forwarded, the LTM to which this LTR is the response. This is the same value as the Egress Identifier TLV of that LTM.
NextEgressIdentifier	Displays an octet field holding the Next Egress Identifier returned in the LTR Egress Identifier TLV of the LTR. The Next Egress Identifier identifies the Linktrace Responder that transmitted this LTR, and can forward the LTM to the next hop. This is the same value as the Egress Identifier TLV of the forwarded LTM, if any. If the FwdYes bit of the Flags field is false, the contents of this field are undefined, and the field is ignored by the receiver.
RelayAction	Indicates the value returned in the RelayAction field.
SrcMac	Displays the MAC address of the MP that responded to the LTM request for this LTR.
IngressAction	Displays the value returned in the IngressAction Field of the LTM. The value ingNoTlv indicates that no Reply Ingress TLV was returned in the LTM.

Name	Description
IngressMac	Displays the MAC address returned in the ingress MAC address field. If the rcCfmLtrReplyIngress object contains the value ingNoTlv(5), then the contents of this field are meaningless.
EgressAction	Displays the value returned in the Egress Action Field of the LTM. The value egrNoTlv(5) indicates that no Reply Egress TLV was returned in the LTM.
EgressMac	Displays the MAC address returned in the egress MAC address field. If the rcCfmLtrReplyEgress object contains the value egrNoTlv(5), then the contents of this field are meaningless.

Configure a Layer 2 Tracetree

Use this procedure to configure a Layer 2 Tracetree. This feature enables CFM to debug Layer 2. Layer 2 Tracetree allows a user to trigger a multicast LTM message by specifying the B-VLAN and I-SID. The command allows the user to view a multicast tree on the SPBM B-VLAN from the source node to the destination nodes for a particular I-SID.

Note

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see [Fabric Engine Release Notes](#). As an alternative, use CLI.

Before You Begin

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP.
- Enable the MEP.
- Assign a nodal MEP to the B-VLAN.

About This Task

If you configure **IsTraceTree** to false, then EDM performs Traceroute on the unicast path. If you configure **IsTraceTree** to true, then EDM performs TraceTree on the multicast tree.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **L2Ping/L2Trace Route**.
3. From the **L2 Traceroute/TraceTree** tab, configure the Layer 2 tracetree properties.
4. In the **IsTraceTree** field double-click and select **true** for EDM to perform Tracetree on the multicast tree.
5. Select **Apply**.
6. Select **Refresh** to update the results.

L2Tracetree Field Descriptions

Use the data in the following table to use the **L2Tracetree** tab.

Name	Description
VlanId	Identifies the Backbone VLAN.
Priority	Specifies a 3-bit value to be used in the VLAN header, if present in the transmitted frame. The default is 7.
DestMacAddress	Specifies the target MAC address.
HostName	Specifies the target host name.
DestIsHostName	Indicates whether the host name is (true) or is not (false) used for L2Tracetree transmission.
Isid	Specifies the service instance identifier (I-SID).
IsTraceTree	Specifies whether the multicast tree or unicast path is traced. If you configure IsTraceTree to false then EDM performs Traceroute on the unicast path. If you configure IsTraceTree to true then EDM performs TraceTree on the multicast tree.
Status	<p>Specifies the status of the transmit loopback service:</p> <ul style="list-style-type: none"> • ready: the service is available. • transmit: the service is transmitting, or about to transmit, the L2Tracetree messages. • abort: the service aborted or is about to abort the L2Tracetree messages. <p>This field is also used to avoid concurrency or race condition problems that can occur if two or more management entities try to use the service at the same time. The default is ready.</p>
ResultOk	<p>Indicates the result of the operation:</p> <ul style="list-style-type: none"> • true: the L2Tracetree Messages will be (or have been) sent. • false: the L2Tracetree Messages will not be sent <p>The default is true.</p>
Ttl	<p>Specifies the Time-to-Live value. Indicates the number of hops remaining to this L2Tracetree. The tracetree is decremented by one by each bridge that handles the Layer 2 tracetree and the decremented value is returned to the tracetree. If the output is 0, then the L2Tracetree is not transmitted to the next hop. The value of the TTL field in the L2Tracetree is transmitted by the originating MEP is controlled by a managed object. The default is 64.</p>

Name	Description
<p>SourceMode</p> <p>Note: Exception: smltVirtual is not supported on 5320 Series.</p>	<p>Specifies the source mode of the transmit loopback service:</p> <ul style="list-style-type: none"> • nodal • smltVirtual — Use the smltVirtual option with B-VLANs only. <p>The default is nodal.</p>
<p>SeqNumber</p>	<p>The transaction identifier/sequence number of the first loopback message (to be) sent. The default is 0.</p>
<p>Flag</p>	<p>Specifies the L2Tracetree result flag, which indicates the L2Tracetree status or error code. Each sum represents a status or error:</p> <ul style="list-style-type: none"> • 1 — No error • 2 — L2Tracetree internal error • 3 — Invalid MAC address • 4 — MEP must be enabled in order to perform L2Tracetree • 5 — No L2Tracetree response received • 6 — L2Tracetree to own MEP MAC is not sent • 7 — L2Tracetree completed • 8 — Lookup failure for L2Tracetree • 9 — On a leaf node in the I-SID tree • 10 — Not in the I-SID tree • 11 — Requested SMLT source from nonprimary node

View Layer 2 Tracetree Results

Use this procedure to view Layer 2 Tracetree results. The Layer 2 Tracetree command is a proprietary command that allows a user to trigger a multicast LTM message by specifying the B-VLAN and I-SID. This command allows the user to view a multicast tree on the SPBM B-VLAN from the source node to the destination nodes for a particular I-SID.

Note

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see [Fabric Engine Release Notes](#). As an alternative, use CLI.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **L2Ping/L2Trace Route**.
3. Select the **L2 Traceroute/TraceTree** tab.
4. In the **IsTraceTree** field double-click and select **true** for EDM to perform Tracetree on the multicast tree.
5. Select **Apply**.
6. Select **Refresh** to update the results.
7. To view the tracetre results, highlight an entry, and then select **Result**.

L2 Traceroute/Tracetree Result Field Descriptions

Use the data in the following table to use the **L2 Traceroute/Tracetree Result** tab.

Name	Description
VlanId	A value that uniquely identifies the Backbone VLAN (B-VLAN).
SeqNumber	The transaction identifier/sequence number returned by a previous transmit linktrace message command, that indicates which response of the L2Tracetree is going to be returned. The default is 0.
Hop	The number of hops away from L2Tracetree initiator.
ReceiveOrder	An index to distinguish among multiple L2Tracetree responses with the same Transaction Identifier field value. This value is assigned sequentially from 1, in the order that the Linktrace Initiator received the responses.
Ttl	Time-to-Live (TTL) field value for a returned L2Tracetree response.
SrcMac	MAC address of the MP that responds to the L2Tracetree request for this L2tractreeReply.
HostName	The host name of the replying node.
LastSrcMac	The MAC address of the node that forwarded the L2Tracetree to the responding node.
LastHostName	The host name of the node that forwarded the L2Tracetree to the responding node.

Configure Layer 2 Trace Multicast Route on a VLAN

Use this procedure to configure the Layer 2 tracemroute on the VLAN (Layer 2). This procedure queries the SPBM multicast module to determine the B-VLAN, I-SID, and nickname for the S and G streams. The nickname and I-SID are used to create a multicast MAC address.

Note

If you want to run a Layer 2 tracemroute on a VRF, make sure you are in the proper VRF context.

Before You Begin

On the source and destination nodes, you must configure a CFM MD, MA, and MEP, and assign a nodal MEP to the B-VLAN.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics > L2Ping/L2Trace Route**.
2. Select the **L2MCAST Traceroute** tab.
3. Select **Insert** to insert the Layer 2 MCAST Traceroute.

4. Enter the **SrclpAddr**.
5. Enter the **GroupIpAddr**.
6. Enter the **ServiceType**. If you want to perform a Layer 2 tracemroute on a VLAN, select **vlan**. If you want to perform a Layer 2 tracemroute on a Layer 3 GRT, select **vrfid**.

Note

If you want to perform a Layer 2 tracemroute on a Layer 2 or a Layer 3 VRF, review the following procedure [Configuring Layer 2 tracemroute on a VRF](#).

7. In the **ServiceId** field, enter the VLAN ID.
8. Enter the **Priority**.
9. Enter the **Ttl** value.
10. Select **Insert**.
11. Select **Apply** to save your changes.
12. To start the Layer 2 tracemroute, set the Status to transmit and select **Start**.
13. Update the Layer 2 tracemroute by selecting **Refresh**.
14. To stop the Layer 2 tracemroute, select **Stop**.
15. To see the result, select **Result**.

L2 MCAST Traceroute Field Descriptions

Use the data in the following table to use the **L2 MCAST Traceroute** tab.

Name	Description
SrclpAddrType	Specifies the source IP address type as IPv4.
SrclpAddr	Specifies the source IP address of the flow where the multicast trace tree originates.
GroupIpAddrType	Specifies the group IP address type as IPv4.
GroupIpAddr	Specifies the group IP address.
ServiceType	Specifies where you configure the Layer 2 tracemroute. This is either VLAN or VRF.
ServiceId	Specifies the VLAN ID.
VRFName	Specifies the VRF name.
Priority	Specifies the priority value. The value is between 0 and 7.
Ttl	Specifies the returned trace response. The TTL value is between 1 and 255.
SeqNumber	Specifies the transaction identifier/sequence number of the first message to be sent.

Name	Description
Status	<p>Specifies the status of the transmit loopback service:</p> <ul style="list-style-type: none"> ready: Specifies the service is available. transmit: Specifies the service is transmitting, or about to transmit the trace messages. abort: Specifies the services is aborted or about to abort the trace messages. <p>The column will also be used to avoid concurrency or race condition problems that can occur if two or more management entities try to use the service at the same time.</p>
ResultOK	<p>Specifies the result of the operation:</p> <ul style="list-style-type: none"> true: The trace messages will be or have been sent. false: The trace messages will not be sent.
Flag	<p>Specifies the result flag indicating that the Layer 2 trace status or error code. Each value represents a status or error case.</p> <ul style="list-style-type: none"> 1 – No error 2 – Internal Error 3 – Mep must be enabled to perform the trace 4 – No response received 5 – Trace completed 6 – On a leaf node in the I-SID tree 7 – No data I-SID was found for S, G

Configure Layer 2 Traceroute on a VRF

Use this procedure to configure the Layer 2 traceroute on the VRF (Layer 3). This procedure queries the SPBM multicast module to determine the B-VLAN, I-SID and nickname for the S and G streams. The nickname and I-SID are used to create a multicast MAC address.

Note

If you want to run a Layer 2 traceroute on a VRF, make sure you are in the proper VRF context.

To perform a Layer 3 traceroute on a VLAN, see [Configure Layer 2 Trace Multicast Route on a VLAN](#) on page 3120.

Before You Begin

On the source and destination nodes, you must configure a CFM MD, MA, and MEP, and assign a nodal MEP to the B-VLAN.

Procedure

1. In the navigation pane, expand **Configuration > VRF Context View > Set VRF Context View**.
2. Select a VRF, and then select the **Launch VRF Context View** tab.
3. In the navigation pane, expand **Configuration > Serviceability > Diagnostics > L2Ping/L2Trace Route**.
4. Select the **L2MCAST Traceroute** tab.

5. Select **Insert** .
6. Type the **SrclpAddr**.
7. Type the **GroupIpAddr**.
8. Select the **ServiceType**. If you want to perform a Layer 2 tracemroute on a Layer 2 VRF, select **vlan**. If you want to perform a Layer 2 tracemroute on a Layer 3 VRF, select **vrfid**.
9. In the **ServiceId**, type the VLAN ID.
10. Type the **Priority**.
11. Type the **Ttl** value.
12. Select **Insert**.
13. Select **Apply** to save your changes.
14. To start the Layer 2 tracemroute, configure the Status to transmit, and then select **Start**.
15. To update the Layer 2 tracemroute, select **Refresh** .
16. To stop the Layer 2 tracemroute, select **Stop** .
17. To see the result, select **Result**.

L2 MCAST Traceroute Field Descriptions

Use the data in the following table to use the **L2 MCAST Traceroute** tab.

Name	Description
SrclpAddrType	Specifies the source IP address type as IPv4.
SrclpAddr	Specifies the source IP address of the flow where the multicast trace tree originates.
GroupIpAddrType	Specifies the group IP address type as IPv4.
GroupIpAddr	Specifies the group IP address.
ServiceType	Specifies where you configure the Layer 2 tracemroute. This is either VLAN or VRF.
ServiceId	Specifies the VLAN ID.
VRFName	Specifies the VRF name.
Priority	Specifies the priority value. The value is between 0 and 7.
Ttl	Specifies the returned trace response. The TTL value is between 1 and 255.
SeqNumber	Specifies the transaction identifier/sequence number of the first message to be sent.
Status	<p>Specifies the status of the transmit loopback service:</p> <ul style="list-style-type: none"> • ready: Specifies the service is available. • transmit: Specifies the service is transmitting, or about to transmit the trace messages. • abort: Specifies the services is aborted or about to abort the trace messages. <p>The column will also be used to avoid concurrency or race condition problems that can occur if two or more management entities try to use the service at the same time.</p>

Name	Description
ResultOK	Specifies the result of the operation: <ul style="list-style-type: none"> true: The trace messages will be or have been sent. false: The trace messages will not be sent.
Flag	Specifies the result flag indicating that the Layer 2 trace status or error code. Each value represents a status or error case. <ul style="list-style-type: none"> 1 – No error 2 – Internal Error 3 – Mep must be enabled to perform the trace 4 – No response received 5 – Trace completed 6 – On a leaf node in the I-SID tree 7 – No data I-SID was found for S, G

View Layer 2 Trace Multicast Route Results

Use this procedure to view Layer 2 tracemroute results.

Note

If you want to run a Layer 2 tracemroute on a VRF, make sure you are in the proper VRF context.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics > L2Ping/L2Trace Route**.
2. Select the **L2 MCAST Traceroute** tab.
3. To view the CFM2 trace multicast route results, highlight an entry and select **Result**.

L2tracemroute Result Field Descriptions

Use the data in the following table to use the **L2tracemroute Result** tab.

Name	Description
VlanId	Specifies a value that uniquely identifies the C-VLAN.
SeqNumber	Specifies the transaction identifier/sequence number returned by a previous transmit linktrace message command. Indicates which I2 tracemroute response is going to be returned.
Hop	Specifies the number of hops away from the I2 tracemroute initiator.
ReceiveOrder	Specifies an index to distinguish among multiple I2 tracemroute responses with the same transaction identifier field value. This value is assigned sequentially from 1, in the order that the linktrace initiator received the responses.
Ttl	Specifies the TTL value for a returned I2 tracemroute response.

Name	Description
SrcMac	Specifies the MAC address of the MP that responds to the I2 tracemroute request for this I2 tracemrouteReply.
HostName	Specifies the host name of the replying node.
LastSrcMac	Specifies the MAC address of the node that forwarded the I2 tracemroute to the responding node.
LastHostName	Specifies the host name of the node that forwarded the I2 tracemroute to the responding node.

CFM Configuration Example

This section provides a configuration example for Connectivity Fault Management (CFM).

CFM Configuration Example

The following sections show the steps required to configure CFM.

Note

The following commands are not supported on all hardware platforms:

- cfm maintenance-domain
- cfm maintenance-association
- vlan nodal-mip-level

Switch A

```

MAINTENANCE-DOMAIN CONFIGURATION

cfm maintenance-domain "spbm" index 1 maintenance-level 6

MAINTENANCE-ASSOCIATION CONFIGURATION

cfm maintenance-association "spbm" "2" index 1
cfm maintenance-association "spbm" "3" index 2

MAINTENANCE-ENDPOINT CONFIGURATION

cfm maintenance-endpoint "spbm" "2" 1 state enable
cfm maintenance-endpoint "spbm" "3" 1 state enable

VLAN NODAL MEP/MIP CONFIGURATION

vlan nodal-mep 2 spbm 2 1
vlan nodal-mip-level 2 6
vlan nodal-mep 3 spbm 3 1
vlan nodal-mip-level 3 6
    
```

Switch B

```

MAINTENANCE-DOMAIN CONFIGURATION

cfm maintenance-domain spbm index 1 maintenance-level 6

MAINTENANCE-ASSOCIATION CONFIGURATION
    
```

```

cfm maintenance-association "spbm" "2" index 1
cfm maintenance-association "spbm" "3" index 2

MAINTENANCE-ENDPOINT CONFIGURATION

cfm maintenance-endpoint "spbm" "2" 2 state enable
cfm maintenance-endpoint "spbm" "3" 2 state enable

VLAN NODAL MEP/MIP CONFIGURATION

vlan nodal-mep 2 spbm 2 2
vlan nodal-mip-level 2 6
vlan nodal-mep 3 spbm 3 2
vlan nodal-mip-level 3 6

```

CFM Sample Output

The following sections show sample CFM output.

L2ping can use the system ID or the router name. The example below shows a case where the VLAN and MAC are given.

show isis adjacencies

```

Software Troubleshooting Tool Configuration

Troubleshooting Tool Fundamentals

This section provides conceptual information about the methods and monitoring tools you can use for troubleshooting problems. This section also contains precautionary notices that you must read for the safe operation of the network.

Troubleshooting Overview

The types of problems that typically occur with networks involve connectivity and performance. This section also contains precautionary notices that you must read for the safe operation of the switch. The switch supports a diverse range of network architectures and protocols, some of which maintain and monitor connectivity and isolate connectivity faults.

In addition, the switch supports a wide range of diagnostic tools that you can use to monitor and analyze traffic, capture and analyze data packets, trace data flows, view statistics, and manage event messages.

Certain protocols and tools are tailored for troubleshooting specific switch network topologies. Other tools are more general in their application and you can use them to diagnose and monitor ingress and egress traffic on the switch.

If connectivity problems occur and the source of the problem is unknown, it is usually best to follow the Open Systems Interconnection (OSI) network architecture layers. Confirm that your physical environment, such as the cable and port connections, operates without failures before moving up to the network and application layers.

To gather information about a problem, consider the following information:

- Consider the OSI model when you troubleshoot. Start at Layer 1 and move upwards. The Address Resolution Protocol (ARP) can cause problems; ARP operates at Layer 2 to resolve MAC addresses to IP addresses (Layer 3).
- Device-specific tools and protocols can help you gather information. This document outlines switch-specific tools.
- You can use client- and server-based tools from Microsoft, Linux, and UNIX. For example, you can use Windows tools like `ifconfig`, `ipconfig`, `windowsipconfig`, and `route print` to obtain IP information and routing tables. Servers also maintain route tables.

The following command output shows example output of the `route print` command.

- Other network problems can give the impression that a device has a problem. For instance, problems with a Domain Name Service (DNS) server, another switch, firewall, or access point can appear to be routing problems.

Debug Files

The switch stores debug files in the intflash directory.

The debug file is in a zipped format and contains information to help debug the device, including:

- a memory snapshot
- logs
- traces

This best practice is to delete these files to ensure enough space exists in the internal flash. New files do not overwrite old files. You must remove the files; otherwise, the internal flash may not have enough free space for necessary activities, for example, to store a core dump file if the switch fails, or you may not have the space to transfer a new release to the internal flash to upgrade your switch.

The switch stores a maximum of 32 files for each debug file for each slot, depending on the file size of each debug file. The internal flash provides 2 GB of storage. The system displays a message on the console to inform you when less than 700 MB is available.

The **debug-file remove** command can delete the following types of debug files:

- core
- archive

- PMEM
- dmalloc
- flrec
- wd_stats

If you want to delete a specific file, you must use the **remove** command.

SNMP

The switch does not support SNMP for the **show debug-file** or the **debug-file remove** commands.

Digital Diagnostic Monitoring

Use Digital Diagnostic Monitoring (DDM) to monitor laser operating characteristics such as temperature, voltage, current, and power. This feature works during active laser operation without affecting data traffic. Transceivers in various form factors support DDM. Use the CLI command **show pluggable-optical-modules {basic|config|detail|temperature|voltage}** to make use of DDM functionality.

An interface that supports DDM is a Digital Diagnostic Interface (DDI). These devices provide real-time monitoring of individual DDI transceivers on a variety of switches and routers. The DDM software provides warnings or alarms when the temperature, voltage, laser bias current, transmitter power or receiver power fall outside of vendor-specified thresholds during initialization.

For information about DDM and supported transceivers, see [Extreme Optics](#) website and [Port Performance Management](#) on page 2222.

```

Flight Recorder

Table 235: Flight Recorder product support

Feature	Product	Release introduced
Flight Recorder for system health monitoring	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5

The Flight Recorder is a high level term for the framework in place on the switch to store both history and current state information for various kernel, system, and application data with minimal overhead to execution. This data can later be accessed on-demand when debugging systems issues to give engineers the best possible troubleshooting information. Functionally, the Flight Recorder consists of two elements; Persistent Memory and Always-on Trace.

The Persistent Memory feature stores information in volatile memory outside of any process. This feature provides information on crashes, errors, and outages that are not the result of a power failure. Persistent Memory data not saved to non-volatile storage before a power failure will be lost. Persistent Memory snapshots are taken when:

- a critical process stops functioning
- a process stops responding
- the hardware watchdog activates
- the user initiates a snapshot in the CLI

The Always-on Trace feature creates an ongoing, circular log of every trace call recently executed regardless of the trace level enabled by the user. The Always-On Trace feature uses circular logging, and therefore stores the most recent traces of the process.

Flight Recorder functionality is provided only through CLI. The following commands are used to make use of this feature:

- **flight-recorder all {slot[-slot][, ...]}**

The command creates a flight-recorder snapshot, trace and archive.

- **flight-recorder archive {slot[-slot][, ...]}**

This command creates a tarball of flight-recorder files, log files, and configuration files.

- **flight-recorder snapshot {slot[-slot][, ...]}.**

This command takes a snapshot of PMEM data.

- **flight-recorder trace {slot[-slot][, ...]}**

This command takes snapshot of always-on-trace data.

Port Mirroring

Table 236: Port Mirroring product support

Feature	Product	Release introduced
Ingress mirroring (port and flow-based)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
Egress mirroring (port-based)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5

True egress port-based mirroring that produces an identical copy of an outgoing packet is not supported. The mirrored copy does not reflect changes that occur in the switch to the outgoing packet (for example, packet fields that are updated during IP routing). As a result, the mirrored copy is not identical to the outgoing packet.

Use the port mirroring feature to monitor and analyze network traffic. Port mirroring supports both ingress (incoming traffic) and egress (outgoing traffic) port mirroring. When you enable port mirroring,

the system forwards ingress or egress packets normally from the mirrored (source) port, and sends a copy of the packet to the mirroring (destination) port.

Port Mirroring Overview

Port mirroring causes the switch to make a copy of a traffic flow and send the copy to a device for analysis. Use port mirroring in diagnostic sniffing—use the mirror to view the packets in the flow without breaking the physical connection to place a packet sniffer inline. You can also use mirroring for security reasons.

You can use egress mirroring to monitor packets as they leave specified ports. Egress mirroring on the switch is done at the end of the ingress pipeline. Since packet modifications occur in the egress pipeline, some of the changes will not be reflected in the mirrored version of the packet. Changes that occur in the egress pipeline may be reflected in the mirrored packet due to the metadata that is carried with the packet. Metadata notifies the egress pipeline what to change.

Use a network analyzer to observe and analyze packet traffic at the mirroring port. Unlike other methods that analyze packet traffic, the packet traffic is uninterrupted and packets flow normally through the mirrored port.

You can mirror to a port or list of ports or a MultiLink Trunking (MLT) group. The switch supports one-to-many, many-to-one, and many-to-many mirroring configurations.

Ingress and Egress Mirrored Ports

You can use all ports in the system to function as an ingress port for mirroring (mirrored port), an egress port for mirroring (mirrored port), or as a mirroring port (where all the mirrored traffic is redirected). The number of mirroring ports (also called destination ports) that you can configure is limited by the hardware. The hardware limitation is four ports simultaneously (where each mirroring direction counts as one). For example, if two mirroring ports are designated to mirror both ingress and egress traffic then all four mirroring ports are consumed.

The following table describes ingress mirroring functionality. Only one type of mirroring destination is supported at a time. You cannot mirror the same port to multiple classes of destinations, for example, MLT. However, you can mirror to multiple physical destinations.

Important

Mirroring packets from one NNI port to another NNI port is not supported. Mirror to access ports, not NNI ports.

Table 237: Ingress mirroring functionality

Function	Support information
Ingress port mirroring and ingress flow mirroring	Supported. Maximum of four mirror-to-ports per box.
One port to one port	Supported
One to MLT group [for threat protection system (TPS applications)]	Supported
One to many (multicast group ID/VLAN)	Not supported
One to one (remote mirrored destination)	Not supported
Many to one (multiple mirrored ports to one mirroring port)	Supported

Table 237: Ingress mirroring functionality (continued)

Function	Support information
Many to MLT group	Supported
Many to many (VLAN/multicast group ID) (multiple ports with several different destinations)	Not supported
Many to one (relation between Remote Mirror Source [RMS] and Remote Mirror Termination [RMT])	Not supported
VLAN and port combination as a mirroring destination	Not supported
Ingress flow mirroring	Supported
Allow filters to specify a separate destination for each access control entry	Supported

The following table describes egress mirroring functionality.

Table 238: Egress mirroring functionality

Function	Support information
Egress port mirroring	Supported
One port to one port	Supported
One to MLT groups (for TPS applications)	Supported
One to many (multicast group ID/VLAN)	Not supported
Many to one (multiple mirrored ports to one mirroring port)	Supported
Many to MLT group	Supported
Many to many (multicast group ID) (multiple ports with several different destinations)	Supported
Many to one (relation between Remote Mirror Source [RMS] and Remote Mirror Termination [RMT])	Not supported
VLAN and port combination as mirroring destination	Not supported
Egress flow mirroring	Supported
Allow filter to specify a separate destination for each access control entry	Supported

Port Configuration

You can specify a destination multilink trunking (MLT) group, a destination port or set of ports.

There are two port mirroring modes: rx (ingress, that is, inPort) and tx (egress, that is, outPort). In rx mode, when you configure the ACE mirror or ACL global options to mirror packets, use the ACE to configure the mirroring destination port.

To modify a port mirroring instance, first disable the instance. Also, to change a port or MLT entry, first remove whichever parameter is attached to the entry, and then add the required entry.

ACLs, ACEs, and Port Mirroring

You can use filters to reduce the amount of mirrored traffic. You can configure the mirroring action globally in an access control list (ACL), or for a specific access control entry (ACE) by using the ACE mirror actions. If you use the global action, mirroring applies to all ACEs that match in an ACL.

To use filters with port mirroring, apply an ACL to the mirrored port in the egress and ingress directions. Traffic patterns that match the ACL or ACE with an action of permit are forwarded to the destination and also to the mirroring port. Traffic patterns that match an ACE with an action of drop (deny) are not forwarded to the destination, but still reach the mirroring port. For example, for an ACL or ACE with a match action of permit, packets are mirrored to the specified mirroring destination on the ACE. If you enable a port or VLAN filter, then that filter is the mirroring filter.

You can specify more than one mirroring destination by using multiple ACEs. Use each ACE to specify a different destination.

You can configure a port-based and a flow-based mirroring filter on the same port. If such a case occurs, then the flow-based mirror takes precedence.

For information about how to configure ACLs and ACEs for port mirroring using CLI, see the following sections:

- [Configuring Global Mirroring Actions with an ACL](#) on page 3158
- [Configure ACE Actions to Mirror](#) on page 3159

For information about how to configure ACLs and ACEs for port mirroring using EDM, see the following sections:

- [Configure ACLs for Mirroring](#) on page 3181
- [Configure ACEs for Mirroring](#) on page 3182

Port Mirroring Considerations and Restrictions

Although you can configure the switch to monitor both ingress and egress traffic, some restrictions apply:

- The software does not support true egress mirroring because packets are mirrored prior to the completion of packet processing, so egress mirrored packets can differ from the packets egressing the port.

Note

To mirror the egress traffic, you can use the NEXT-hop device ingress mirroring to capture the egress packets of the switch.

- Mirrored traffic shares ingress queue and fabric bandwidth with normal traffic and therefore can impact normal traffic. Therefore, use these features with this potential consequence in mind and enable them only for troubleshooting, debugging, or for security purposes such as packet sniffing, intrusion detection, or intrusion prevention.
- You can configure as many ingress mirroring flows as you have filters.
- To avoid VLAN members from seeing mirrored traffic, you must remove mirroring (destination) ports from all VLANs.
- The MAC drops an error packet, for example, packets that are too short or too long. Control packets consumed by the MAC (802.3x flow control) are also not mirrored.

- Certain control packets generated by the CP cannot be egress mirrored, such as those in the following list:
 - BPDU
 - EAPoL
 - IP Directed Broadcast
 - LACP
 - LLDP
 - Multicast routed packets
 - NAAP
 - NLB
 - Nodal CFM
 - TDP
 - VLACP
- The system displays ingress multicast packets in egress mirroring.
- Incoming traffic that does not contain a VLAN tag is not mirrored into an I-SID if the offset ID is in the range 2 to 1000. It is mirrored to an I-SID only if the offset ID is 1.
- The original CVLAN tag on the mirrored packet is preserved for only one mirrored I-SID if the offset ID is 1. The original CVLAN tag is not preserved in a mirrored packet for all other remaining mirrored I-SIDs if the offset ID is in the range 2 to 1000.

Port Mirroring Resources

Port mirroring resources are limited to four ports simultaneously (where each mirroring direction counts as one). For example, if two mirroring ports are designated to mirror both ingress and egress traffic then all four mirroring ports are consumed.

Port mirroring shares these four resources with other applications such as port mirroring RSPAN, Fabric Extend, Application Telemetry, IPFIX, and ACL with mirror action. Each one of these applications consumes at least one port mirroring resource. (port mirroring RSPAN consumes two if you configure both Ingress and Egress modes.)

Important

To enable any one of the preceding applications, you must have at least one free mirroring resource. If all four port mirroring resources are already in use, the switch displays a `Resource not available` error message when you try to enable the application.

If you receive a `Resource not available` error message, you can use the **`show mirror-resources`** command to view information about mirror resource usage. For more information, see [Displaying Mirror Resource Usage](#) on page 3158.

General Diagnostic Tools

The switch has diagnostic features available with Enterprise Device Manager (EDM) and Command Line Interface (CLI). You can use these diagnostic tools to help you troubleshoot operational and configuration issues. You can perform such tasks as configuring and displaying log files, viewing and monitoring port statistics, tracing a route, running loopback and ping tests, and viewing the address resolution table.

Traceroute

Traceroute determines the path a packet takes to reach a destination by returning the sequence of hops (IP addresses) the packet traverses.

According to RFC1393, traceroute operates by: "sending out a packet with a time-to-live (TTL) of 1. The first hop then sends back an ICMP error message indicating that the packet could not be forwarded because the TTL expired. The packet is then resent with a TTL of 2, and the second hop returns the TTL expired. This process continues until the destination is reached. The purpose behind this is to record the source of each ICMP TTL exceeded message to provide a trace of the path the packet took to reach the destination."

Ping

Ping is a simple and useful diagnostic tool to determine reachability. When you use ping, the switch sends an ICMP echo request to a destination IP address. If the destination receives the packet, it responds with an ICMP echo response.

If a ping test is successful, the destination is alive and reachable. Even if a router is reachable, it could have improperly working interfaces or corrupted routing tables.

Trace

Use trace commands to provide detailed data collection about software modules on the switch. The trace toolset can be used to trace multiple modules simultaneously and provides options to specify the verbosity level of the output.

You can enable trace logging through the boot config trace-logging flag.

Caution

Risk of traffic loss

Using the trace tool inappropriately can cause a CPU lockup conditions, loss of access to the switch, loss of protocols, and service degradation.

Tip

While these occurrences are uncommon, when using the trace level tool, minimize this risk. The following actions are:

- In situations where trace data is required concurrently from multiple modules, consider troubleshooting during a maintenance window if feasible. Consider a maintenance window period if the switch is stable but CPU utilization is high and CPU traces (example trace levels 9 and 11) are required to diagnose the cause.
- Run trace commands from the console port when the CPU utilization is already high. While you can enable or disable tracing when directly connected to the console port.

Activate tracing on one software module at a time.

- Initially activate tracing at lower verbosity settings (that is, 2 rather than 3). Increase to verbosity level 3 or 4 only if required, and after level 2 runs safely.
- Avoid leaving traces active for extended periods of time. For high CPU utilizations, a few seconds (typically less than 5 seconds) is generally sufficient to identify the cause for sustained high CPU utilization.

Fabric RSPAN (Mirror to I-SID)

Table 239: Fabric RSPAN product support

Feature	Product	Release introduced
Fabric RSPAN (Mirror to I-SID)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5

Remote mirroring is an important functionality that helps in:

- Intrusion Detection or Intrusion Prevention Systems
- Network Port debugging and packet capture
- Mirror and Monitor traffic to central collector or analyzers
- Mirror and Monitor traffic to distributed collectors or analyzers

With the Fabric RSPAN (Mirror to I-SID) feature, mirrored traffic captured from any switch in the network is sent to a remote switch over an SPB cloud for traffic analysis. With this feature, you can monitor traffic on ports from different switches connected in the network, using just one network analyzer connected to a remote switch which acts as a collector. The source device where the traffic is mirrored to an I-SID, is known as Mirroring BEB (Backbone Edge Bridge), and the remote device where the traffic analyzer is connected for mirrored traffic analysis is known as Monitoring BEB.

The traffic source on the mirroring BEB is supported in the following ways:

- Port based mirroring — Any packet incoming or outgoing through a port is mirrored to a monitoring I-SID configured for that port.
- Flow based mirroring — Any particular packet flow configured in the system using filter based ACLs is mirrored to a monitoring I-SID configured for that flow.

Fabric RSPAN (Mirror to I-SID) Restrictions and Requirements

- Remote mirroring of traffic is not supported on NNI ports or Fabric Extend Layer 2 core ports.
- Mirroring resources will be shared between Fabric RSPAN and regular port mirroring. Fabric RSPAN uses one out of four resources for mirroring if the mode is configured as Rx (Ingress) mirroring. In case of mode Tx (Egress) mirroring, it uses one more entry with same TX-LB port. Hence if mode Rx and Tx are configured for Fabric RSPAN, then only two unique destination ports can be used for regular port mirroring. For example, if you configure Fabric RSPAN on the switch, the regular port mirroring functionality can use only three unique destination ports. And, if all the four unique ports are used by the port mirroring functionality, you cannot configure Fabric RSPAN functionality on that node.
- When the monitor I-SID used for mirroring Fabric RSPAN traffic ingressing to I-SID is used to mirror regular traffic into SPB network, it will remove the customer tag in the mirrored packets. Hence, as a best practice, use different monitor I-SIDs for mirroring regular traffic and Fabric RSPAN traffic.
- Monitoring egress-ports and egress-mlt will not support regular production network traffic.
- The QoS value must be same for all mirror entries having common monitor I-SID, as the BMAC QoS is mapped to a monitor I-SID. QoS value configured for a specific monitor I-SID offset overrides the existing value for all mirroring entries sharing the same monitor I-SID.
- Do not configure the source of mirrored traffic (mirroring to an I-SID) and the analyzer (monitoring an I-SID) on the same local device with the same I-SID offset. If you require mirroring and monitoring

on the same local device, use standard port-based mirroring instead of Fabric RSPAN. Fabric RSPAN mirrors traffic into an I-SID of the SPB Fabric network and monitors traffic on the remote device; the network analyzer resides on the remote monitoring device and not on the same local device.

- Egress flow-based I-SID mirroring is not supported.
- 5520 Series does not support the following combinations for I-SID mirroring:
 - Deny option for Filter ACL with monitor-isid-offset for Inport/Invlan/InVSN
 - Redirect-Next-Hop along with monitor-isid-offset when monitor-isid-offset is greater than 1
 - Remove Tag option along with monitor-isid-offset

Software Troubleshooting Tool Configuration Using CLI

Use the tools described in this section to perform troubleshooting procedures using CLI.

Using CLI for Troubleshooting

You can use CLI to provide diagnostic information.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Disable scrolling of the output display:

```
terminal more disable
```
3. View configuration file information:

```
more WORD<1-99>
```
4. Capture the output for the following command after you observe a problem with the device:

```
show running-config [verbose] [module {app-telemetry | boot | cfm |
cli | diag | dvr | eap | endpoint-tracking | energy-saver | fa | fhs |
filter | ike | ip | ipfix | ipsec | ipv6 | iqagent | isis | i-sid |
lACP | license | lldp | lst | macsec | mlt | naap | nls | ntp | ovsdb
| port | qos | radius | restconf | rmon | sflow | security | slamon |
slpp | smtp | spbm | stg | sys | tacacs | virtualservice | vlan | web
| vxlan}]
```
5. Capture the output for the following command after you observe a problem with the device:

```
show tech
```
6. Capture the output for the following commands after you observe a problem with the device:

Note

The **show interfaces gigabitEthernet statistics rmon** command displays information only if you previously configured **rmon stats** or **rmon history**.

- `show interfaces gigabitEthernet statistics <dhcp-relay [vrf WORD<1-16>][vrfids WORD<0-512>] [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]`
- `show interfaces gigabitEthernet statistics lACP [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]`

- `show interfaces gigabitEthernet statistics rate-limiting [{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]]`
 - `show interfaces gigabitEthernet statistics rmon [{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]]`
 - `show interfaces gigabitEthernet statistics verbose [{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]]`
 - `show interfaces gigabitEthernet statistics vlacp [{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]]`
7. Capture the output for the following command after you observe a problem with the device:
- ```
show interfaces gigabitEthernet error [collision|ospf|verbose] [{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]]
```

### Examples

Due to the length of command output, the following examples are truncated.

Capture the output for the following commands after you observe a problem with the device:

```
Switch:1>enable
Switch:1#show running-config module cli

**Variable Definitions**

The following table defines parameters for the **more** command.

| Variable                      | Value                                                                                                                       |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <code>WORD&lt;1-99&gt;</code> | Specifies the file name to view. Provide the filename in one of the following formats:<br>a.b.c.d:<file>, /intflash/<file>. |

The following table defines parameters for the **show running-config** command.

| Variable                                                                                                                                                                                                                                                                                                                                                                                                                | Value                                                                                                                                                                                                                                                                     |

The following table defines parameters for the **show interfaces gigabitEthernet statistics** command.

| Variable                                                                                                                        | Value                                                                |
|---------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------|
| <code>dhcp-relay [vrf WORD&lt;1-16&gt; ] [vrfids WORD&lt;0-512&gt; {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Displays port Dynamic Host Configuration Protocol (DHCP) statistics. |
| <code>lacp {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>                                                         | Displays Link Aggregation Control Protocol (LACP) statistics.        |
| <code>rate-limiting {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>                                                | Displays port ingress rate-limiting statistics.                      |
| <code>rmon {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} [history]</code>                                               | Displays Remote Network Monitoring (RMON) statistics.                |

| Variable                                                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>verbose</code>                                                               | Displays a complete list of all statistics.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>vlacp [history] {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | <p>Displays port Virtual Link Aggregation Control Protocol (VLACP) statistics.</p> <ul style="list-style-type: none"> <li>• <code>history</code>—Displays the VLACP port counter profile.</li> <li>• <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code></li> </ul> <p>Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.</p> |

The following table defines parameters for the **show interfaces gigabitEthernet error** command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>collision</code>                                             | Displays port collision error information.                                                                                                                                                                                                                                                                                                                    |
| <code>ospf</code>                                                  | Displays ports Open Shortest Path First (OSPF) error information.                                                                                                                                                                                                                                                                                             |
| <code>verbose</code>                                               | Displays all port error information.                                                                                                                                                                                                                                                                                                                          |
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

### Using Software Record Dumps

#### About This Task

Capture a dump of the software records from ingress traffic to help troubleshoot performance problems. Generally, a verbosity level of 1 suffices.

#### Procedure

1. Enter Privileged EXEC mode:
 

```
enable
```
2. Dump software record information:
 

```
dump ar <1-12> WORD<1-1536> <0-3>
```

#### Example

```
Switch:1> enable
```

```
Switch:1# dump ar 1 vlan 1
```

**Variable Definitions**

The following table defines parameters for the **dump ar** command.

| Variable     | Value                                                                                                                  |
|--------------|------------------------------------------------------------------------------------------------------------------------|
| <1>          | Specifies the slot number.                                                                                             |
| WORD<1-1536> | Specifies a record type in the AR table. Options include vlan, ip_subnet, mac_vlan, mac, arp, ip, ipmc, protocol, all. |
| <0-3>        | Specifies the verbosity from 0-3. Higher numbers specify more verbosity.                                               |

*Use Trace to Diagnose Problems*

Use trace to observe the status of a software module at a given time.

**About This Task**

For example, if you notice a CPU utilization issue (generally a sustained spike above 90%) perform a trace of the control plane activity.

**Procedure**

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Clear the trace:  

```
clear trace
```
3. Identify the module ID for which you want to use the trace tool:  

```
show trace modid-list
```
4. Begin the trace operation:  

```
trace level [<Module_ID>] [<0-4>]
```
5. Wait approximately 30 seconds.  

The default trace settings for CPU utilization are:

  - High CPU Utilization: 90%
  - High Track Duration: 5 seconds
  - Low CPU Utilization: 75%
  - Low Track Duration: 5 seconds
6. Stop tracing:  

```
trace shutdown
```
7. View the trace results:  

```
show trace file [tail]
```

8. Search trace results for a specific string value, for example, the word error:

```
trace grep [WORD<0-128>]
```

If you use this command and do not specify a string value, you clear the results of a previous search.

9. Stop tracing:

```
trace shutdown
```

### Example

```
Switch:1> enable
```

Clear the trace:

```
Switch:1# clear trace
```

Identify the module ID for which you want to use the trace tool:

```
Switch:1# show trace modid-list
```

```
0 - COMMON
1 - SNMP
2 - RMON
3 - PORT_MGR
4 - CHAS_MGR
5 - BRIDGE
6 - HWIF
7 - SIM
8 - CPP
9 - NETDRV
10 - VLAN_MGR
11 - CLI
12 - MAIN
12 - P2IP
12 - RCIP
15 - WEBSRV
16 - ACIF
17 - GBIF
18 - WDT
19 - TDP
20 - MAN_DIAG
21 - MAN_TEST

--More-- (q = quit)
```

Begin the trace operation:

```
Switch:1# trace level 2 3
```

Stop tracing:

```
Switch:1# trace shutdown
```

Save the trace file to the internal flash card for retrieval:

```
Switch:1# save trace
```

Search trace results for a specific string value, for example, the word error:

```
Switch:1# trace grep error
```

Search trace results for a specific string value, for example, MAC address 00-1A-4B-8A-FB-6B:

```
Switch:1# trace grep 00-1A-4B-8A-FB-6B
```

**Variable Definitions**

The following table defines parameters for the **trace** command.

| Variable                                                         | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>grep</i> [ <i>WORD</i> <0-128>]                               | Search trace results for a specific string value, for example, the word error. Performs a comparison of trace messages.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>level</i> [ <i>&lt;Module_ID&gt;</i> ] [ <i>&lt;0-4&gt;</i> ] | Starts the trace by specifying the module ID and level. <ul style="list-style-type: none"> <li><i>&lt;Module_ID&gt;</i> specifies the module for the trace. Different hardware platforms support different ID ranges because of feature support differences. To see which module IDs are available on the switch, use the <b>show trace modid-list</b> command or CLI command completion Help.</li> <li><i>&lt;0-4&gt;</i> specifies the trace level from 0-4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose.</li> </ul> |
| <i>shutdown</i>                                                  | Stops the trace operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>screen</i> { <i>disable</i>   <i>enable</i> }                 | Enables the display of trace output to the screen.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

The following table defines parameters for the **save trace** command.

| Variable                       | Value                                                                                                                           |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <i>file</i> <i>WORD</i> <1-99> | Specifies the file name in one of the following formats: <ul style="list-style-type: none"> <li>a.b.c.d:&lt;file&gt;</li> </ul> |

*Use Trace to Diagnose IPv6 Problems*

Use trace to observe the status of IPv6 at a certain time.

**Before You Begin**

- Confirm that trace level 99 is set to a value of 1 before you use trace to diagnose IPv6 problems. Trace level 1 is very terse.

**Caution**  
**Risk of traffic loss**

Using the trace tool inappropriately can cause primary CPU lockup conditions, loss of access to the device, loss of protocols, and service degradation.

**Procedure**

1. Enter Privileged EXEC mode:  
enable

2. Activate or deactivate the trace for the IPv6 base:  

```
trace ipv6 base <disable|enable> <all|debug|error|icmp|info|ipclient|nbr|pkt|warn> [vrf WORD <1-16>]
```
3. Activate or deactivate the trace for IPv6 forwarding:  

```
trace ipv6 forwarding <disable|enable> <all|debug|error|info|pkt|warn> [vrf WORD <1-16>]
```
4. Activate or deactivate the trace for IPv6 neighbor discovery:  

```
trace ipv6 nd <disable|enable> <all|debug|error|info|nbr|pkt|redirect|warn> [vrf WORD <1-16>]
```
5. Activate or deactivate the trace for IPv6 OSPF:  

```
trace ipv6 ospf <disable|enable> <adj|all|config|error|import|info|lsa|pkt|spf|warn> [vrf WORD <1-16>]
```
6. Activate or deactivate the trace for the IPv6 routing table manager:  

```
trace ipv6 rtm <disable|enable> <all|change-list|debug|error|fib|info|redist|update|warn> [vrf WORD <1-16>]
```
7. Activate or deactivate the trace for IPv6 transport:  

```
trace ipv6 transport <disable|enable> <all|common|tcp|udp> [vrf WORD <1-16>]
```
8. Deactivate the trace to prevent service degradation:  

```
trace shutdown

clear trace
```

### Examples

```
Switch:1>enable
```

Activate the trace for all the IPv6 forwarding categories:

```
Switch:1#trace ipv6 forwarding enable all
```

Activate the trace for all the IPv6 neighbor discovery categories:

```
Switch:1#trace ipv6 nd enable all
```

Activate the trace for the all IPv6 routing table manager categories:

```
Switch:1#trace ipv6 rtm enable all
```

Activate the trace for all the IPv6 transport categories:

```
Switch:1#trace ipv6 transport enable all
```

Deactivate the trace:

```
Switch:1#trace shutdown
```

```
Switch:1#clear trace
```

```
Removed 5 files.
```

**Variable Definitions**

The following table defines parameters for the **trace ipv6** command.

| Variable                                                                              | Value                                                                         |
|---------------------------------------------------------------------------------------|-------------------------------------------------------------------------------|
| <i>base</i> <disable enable> <all debug error icmp info ipclient nbr pkt warn>        | Enables or disables a specific trace category for IPv6 base.                  |
| <i>forwarding</i> <disable enable> <all debug error info pkt warn>                    | Enables or disables a specific trace category for IPv6 forwarding.            |
| <i>nd</i> <disable enable> <all debug error info nbr pkt redirect warn>               | Enables or disables a specific trace category for IPv6 neighbor discovery.    |
| <i>ospf</i> <disable enable> <adj all config error import info lsa pkt spf warn>      | Enables or disables a specific trace category for IPv6 OSPF.                  |
| <i>rtm</i> <disable enable> <all change-list debug error fib info redist update warn> | Enables or disables a specific trace category for IPv6 routing table manager. |
| <i>transport</i> <disable enable> <all common tcp udp>                                | Enables or disables a specific trace category for IPv6 transport.             |
| <i>vrf</i> WORD<1-16>                                                                 | Specifies the VRF name.                                                       |

*View and Delete Debug Files*

Use this procedure to view and delete debug files.

Delete debug files to free space in the intflash, which has 2 GB of space. As a best practice, delete these files to ensure enough space exists in intflash. New debug files do not overwrite old debug files. You must remove the file; otherwise, enough free space may not exist in the intflash to store the core dump if the switch fails or enough space may not exist for you to transfer a new release to the intflash of the switch to upgrade your switch.

The **debug-file remove** command can delete the following types of files:

- core
- archive
- PMEM
- dmalloc
- flrec
- wd\_stats

If you want to delete a specific file, you must use the **remove** command. For more information, see [Fabric Engine CLI Commands Reference](#).

**Procedure**

1. To enter User EXEC mode, log on to the switch.

2. View debug files:  

```
show debug-file [all][{slot[-slot]}[,...]]
```
3. Delete debug files:  

```
debug-file remove [all][{slot[-slot]}[,...]]
```
4. Enter Privileged EXEC mode:  

```
enable
```
5. View core files:  

```
show core-files {slot[-slot]}[,...]]
```

### Example

The following example shows how you view all debug files for all slots, and then remove the debug files for slot 1.

```
Switch>show debug-file

## Variable Definitions

The following table defines parameters for the **show core-files** command.

| Variable                         | Value                                                 |
|----------------------------------|-------------------------------------------------------|
| <code>{slot[-slot][,...]}</code> | Displays the core files for the slot that you select. |

The following table defines parameters for the **show debug-file** command.

| Variable                         | Value                                                                                                                                                                                                                                                                           |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>all</code>                 | Displays all types of debug files                                                                                                                                                                                                                                               |
| <code>{slot[-slot][,...]}</code> | Displays debug files for the slot that you select. If you do not select a slot number, the device displays all types of the archived debug files present in a slot by slot basis. If you select a slot number, the device only displays archived files for the slot you select. |

The following table defines parameters for the **debug-file remove** command.

| Variable         | Value                                                                                                                                                                                                             |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>all</code> | Removes all types of debug files in all slots.<br>If you use the option <b>all</b> with the <b>remove debug-file</b> command, then the device deletes all types of debug files, including the latest debug files. |

## Configuring Port Mirroring

Use port mirroring to aid in diagnostic and security operations.

### About This Task

Use port mirroring to make a copy of a traffic flow and send that copy to a device for analysis, for example, for diagnostic sniffing. Use the mirror to see the packets in the flow without breaking into the physical connection to place a packet onto the sniffer inline. You can also use port mirroring for security. You can send flows to inspection engines for post processing.

Connect the sniffer (or other traffic analyzer) to the output port you specify in this procedure.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Create a port mirroring instance:
 

```
mirror-by-port <1-479> in-port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} {monitor-mlt <1-512>| out-port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```
3. Create an I-SID mirroring instance:
 

```
mirror-by-port <1-479> [in-port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} monitor-isid-offset <1-1000> [mode <rx|tx|both>] [qos <qos-level>]]
```

4. Configure the mode:

```
mirror-by-port <1-479> mode <both|rx|tx>
```

**Note**

- When you configure `tx` mode port mirroring on T-UNI and SPBM NNI ports, unknown unicast, broadcast and multicast traffic packets that ingress these ports and the system displays it on the mirror destination port, although they do not egress the mirror source port. This is because `tx` mode port mirroring happens on the mirror source port before the source port squelching logic drops the packets at the egress port.
- The available four mirroring resources are shared between Fabric RSPAN and regular port mirroring, and are allocated based on the mode configured, Ingress (`rx`) or Egress (`tx`). Each configured mode occupies one mirroring resource, but when you configure the mode as `both`, it occupies two mirroring resources (one for Rx and one for Tx).
- Do not configure the source of mirrored traffic (mirroring to an I-SID) and the analyzer (monitoring an I-SID) on the same local device with the same I-SID offset. If you require mirroring and monitoring on the same local device, use standard port-based mirroring instead of Fabric RSPAN. Fabric RSPAN mirrors traffic into an I-SID of the SPB Fabric network and monitors traffic on the remote device; the network analyzer resides on the remote monitoring device and not on the same local device.

5. Enable the mirroring instance:

```
mirror-by-port <1-479> enable
```

6. Modify existing mirroring entries as required:

```
mirror-by-port mirror-port <1-479> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

OR

```
mirror-by-port monitor-mlt <1-479> <1-512>
```

OR

```
mirror-by-port monitor-port <1-479> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

**Note**

Before you can modify an existing entry, you must disable the entry: `no mirror-by-port <1-479> enable`.

7. Modify QoS value for Fabric RSPAN mirroring session:

```
mirror-by-port <1-479> qos <0-5>
```

8. Verify the configuration:

```
show mirror-by-port
```

**Example**

Port mirroring configuration:

```
Switch:1> enable
Switch:1# configure terminal
```

Create the port mirroring instance:

```
Switch:1(config)# mirror-by-port 8 in-port 1/15 out-port 1/1
```

The analyzer connects to port 1/1.

Disable the entry:

```
Switch:1(config)# no mirror-by-port 8 enable
```

Mirror both ingress and egress traffic passing through port 1/16:

```
Switch:1(config)# mirror-by-port 8 mode both
```

Enable mirroring for the instance:

```
Switch:1(config)# mirror-by-port 8 enable
```

Fabric RSPAN configuration:

```
Switch:1> enable
Switch:1# configure terminal
```

Create the Fabric RSPAN mirroring instance:

```
Switch:1(config)# mirror-by-port 3 in-port 1/3 monitor-isid-offset 3 mode both qos 3
```

Disable the entry:

```
Switch:1(config)# no mirror-by-port 3 enable
```

Mirror the egress traffic passing through port 1/3:

```
Switch:1(config)# mirror-by-port 3 mode tx
```

Enable Fabric RSPAN for the instance:

```
Switch:1(config)# mirror-by-port 3 enable
```

The sample command output in the following example does not necessarily reflect the preceding examples.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#show mirror-by-port
```

```

| <code>enable</code>                                                                                                                                                  | Enables or disables a mirroring instance already created in the mirror-by-port table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>in-port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}{ monitor-mlt &lt;1-512&gt; out-port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Creates a new mirror-by-port table entry. <ul style="list-style-type: none"> <li><code>in-port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> specifies the mirrored port.</li> <li><code>monitor-mlt &lt;1-512&gt;</code> specifies the mirroring MLT ID from 1-512.</li> <li><code>out-port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> specifies the mirroring port.</li> </ul>                                                                                                                                                                               |
| <code>mirror-port &lt;1-479&gt; {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>                                                                         | Modifies the mirrored port. Before you can modify an existing entry, you must disable the entry: <code>no mirror-by-port &lt;1-479&gt; enable</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>monitor-ip &lt;1-479&gt; {A.B.C.D} [dscp &lt;0-63&gt;] [ttl &lt;2-255&gt;]</code>                                                                              | Creates a mirroring instance for Layer 3 mirroring. The destination must be an IP address {A.B.C.D}. The default DSCP is 0 and the default TTL is 255.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>monitor-mlt &lt;1-479&gt; &lt;1-512&gt;</code>                                                                                                                 | Modifies the monitoring MLT. <1-512> specifies the mirroring MLT ID. Before you can modify an existing entry, you must disable the entry: <code>no mirror-by-port &lt;1-479&gt; enable</code> .                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>monitor-port &lt;1-479&gt; {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>                                                                        | Modifies the monitoring ports. Before you can modify an existing entry, you must disable the entry: <code>no mirror-by-port &lt;1-479&gt; enable</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>monitor-vlan &lt;1-479&gt; &lt;1-4059&gt;</code>                                                                                                               | Modifies the monitoring VLAN. Before you can modify an existing entry, you must disable the entry: <code>no mirror-by-port &lt;1-479&gt; enable</code> . Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <code>vrf-scaling</code> and <code>spbm-config-mode</code> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |

| Variable                                        | Value                                                                                                                                                                                                                                                                           |
|-------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>mode &lt;both rx tx&gt;</code>            | Configures the mirroring mode. The default is <code>rx</code> . <ul style="list-style-type: none"> <li><code>both</code> mirrors both egress and ingress packets.</li> <li><code>rx</code> mirrors ingress packets.</li> <li><code>tx</code> mirrors egress packets.</li> </ul> |
| <code>monitor-isid-offset &lt;1-1000&gt;</code> | Specifies the offset ID that is mapped to the actual monitor I-SID where packets are mirrored.<br>Monitor I-SID = base monitor I-SID + offset ID.<br>The base monitor I-SID is 16776000.                                                                                        |
| <code>qos &lt;0-5&gt;</code>                    | Specifies the Quality of Service (QoS) profiles for the system. Monitoring I-SID supports six different QoS levels, each QoS level can be configured individually. Default value is 1.                                                                                          |

### Displaying Mirror Resource Usage

#### About This Task

Mirror resources can be consumed by internal processes that are not easily identified, which can lead to unexpected resource shortages. Use the following procedure to display mirror resource usage.

#### Procedure

- To enter User EXEC mode, log on to the switch.
- Display mirror resource usage:  
`show mirror-resources`

#### Example

```
Switch:1#show mirror-resources
<Switch> Mirror Resource Manager stats:
 2 unique mirror destinations allocated, system max is 4

Mirror | Mirror | Total | Mirror
Destination | Direction | Refs | Users

Port 1/2 | Egress | 1 | MBP ID 1
Port 1/2 | Ingress | 1 | MBP ID 1

Function execution completed successfully
```

### Configuring Global Mirroring Actions with an ACL

Configure the global action to mirror packets that match an access control list (ACL).

#### Before You Begin

- The ACL exists.

#### Procedure

- Enter Global Configuration mode:  
`enable`  
  
`configure terminal`

2. Configure the global action for an ACL:

```
filter acl set <1-2048> global-action {monitor-dst-mlt <1-512>|
monitor-dst-ports {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

**Example**

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

Configure the global action for an ACL:

```
Switch:1(config)# filter acl set 200 global-action monitor-dst-mlt 20
```

**Variable Definitions**

The following table defines parameters for the **filter acl set** command.

| Variable                                                                                                                                                                                | Value                                                                                                                                                                                                                                                                                                            |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-2048>                                                                                                                                                                                | Specifies an ACL ID from 1-2048.                                                                                                                                                                                                                                                                                 |
| <i>default-action</i> <deny permit>                                                                                                                                                     | Specifies the global action to take for packets that do not match an ACL.                                                                                                                                                                                                                                        |
| <i>global-action</i> { <i>monitor-dst-mlt</i> <i>PT_MLT</i> <1-512>  <i>monitor-dst-ports</i> { <i>slot/port</i> [/ <i>sub-port</i> ] [- <i>slot/port</i> [/ <i>sub-port</i> ]] [,...]} | Specifies the global action to take for matching ACLs: <ul style="list-style-type: none"> <li>• <i>monitor destination MLT</i>—Configures mirroring to a destination MultiLink Trunking (MLT) group.</li> <li>• <i>monitor destination ports</i>—Configures mirroring to a destination port or ports.</li> </ul> |

*Configure ACE Actions to Mirror*

Configure actions to use filters for flow-based mirroring.

**Before You Begin**

- The access control entry (ACE) exists.

**About This Task**

If you use the mirror action, ensure that you specify the mirroring destination: MLTs or ports.

**Procedure**

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure actions for an ACE:

```
filter acl ace action <1-2048> <1-2000> {permit|deny} monitor-dst-mlt
<1-512>
```

OR

```
filter acl ace action <1-2048> <1-2000> {permit|deny} monitor-dst-
ports {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

3. Ensure the configuration is correct:

```
show filter acl action [<1-2048>] [<1-2000>]
```

### Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

```
Switch:1(config)# filter acl ace action 901 1 permit monitor-dst-mlt 5
```

### Variable Definitions

The following table defines parameters for the **filter acl ace action** command.

| Variable                                                                       | Value                                                                      |
|--------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| <i>1-2048</i>                                                                  | Specifies the ACL ID from 1-2048                                           |
| <i>1-2000</i>                                                                  | Specifies the ACE ID from 1-2000.                                          |
| <i>monitor-dst-mlt &lt;1-512&gt;</i>                                           | Configures mirroring to a destination MLT group.                           |
| <i>monitor-dst-ports {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i> | Configures mirroring to a destination port or ports.                       |
| <i>{permit deny}</i>                                                           | Configures the action mode for security ACEs. The default value is permit. |

### Clearing ARP Information for an Interface

Clear the Address Resolution Protocol (ARP) cache as part of ARP problem resolution procedures.

#### Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Clear ARP information:

```
clear ip arp interface gigabitethernet {slot/port[/sub-port] [-slot/
port[/sub-port]] [,...]}
```

OR

```
clear ip arp interface vlan <1-4059>
```

**Example**

```
Switch:1> enable
```

```
Switch:1# clear ip arp interface gigabithethernet 1/1
```

**Variable Definitions**

The following table defines parameters for the **clear ip arp interface** command.

| Variable                                              | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059>                                              | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |

*Flush Routing, MAC, and ARP Tables for a Port*

Flush or clear the routing tables for administrative and troubleshooting purposes. The clear and flush commands perform the same function; they remove the contents of the table.

**Procedure**

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Flush IP routing tables by port:

```
action flushIp
```

3. Flush the MAC address tables by port:

```
action flushMacFdb
```

4. Flush ARP tables by port:

```
action flushArp
```

5. Flush all tables with one command:
 

```
action flushAll
```
6. Exit to Global Configuration mode:
 

```
exit
```
7. Clear a routing table for a port:
 

```
clear ip route gigabitEthernet {slot/port[sub-port]}
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config-if)#action flushAll
Switch:1(config-if)#exit
Switch:1(config)#clear ip route gigabitEthernet 1/1
```

### Variable Definitions

The following table defines parameters for the **clear ip route gigabitEthernet** command.

| Variable                      | Value                                                                                                                                                                        |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{slot/port[/sub-port]}</i> | Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

### *Flush Routing, MAC, and ARP Tables for a VLAN*

Flush or clear the routing tables for administrative and troubleshooting purposes. The clear and flush commands perform the same function; they remove the contents of the table.

### Procedure

1. Enter Global Configuration mode:
 

```
enable
```

```
configure terminal
```
2. Flush IP routing tables by VLAN:
 

```
vlan action <1-4059> flushIp
```
3. Flush the MAC address tables by VLAN:
 

```
vlan action <1-4059> flushMacFdb
```
4. Flush ARP tables by VLAN:
 

```
vlan action <1-4059> flushArp
```
5. Flush all tables with one command:
 

```
vlan action <1-4059> all
```
6. Clear a routing table for a VLAN:
 

```
clear ip route vlan <1-4059>
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
```

```
Switch:1(config-if)#vlan action 123 all
Switch:1(config)#clear ip route vlan 123
```

**Variable Definitions**

The following table defines parameters for the **vlan action** and **clear ip route vlan** commands.

| Variable | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059> | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |

*Ping an IP Device*

**About This Task**

Ping a device to test the connection between the switch and another network device. After you ping a device, the switch sends an Internet Control Message Protocol (ICMP) packet to the target device. If the device receives the packet, it sends a ping reply. After the switch receives the reply, a message displays that indicates traffic can reach the specified IP address. If the switch does not receive a reply, the message indicates the address does not respond.

Ping and traceroute can fail for VRF routes if you use large packet sizes for the operation. Do not use packet sizes larger than the following:

- Ping for VRF: 1480 bytes
- Traceroute for VRF: 1444 bytes

**Note**

Exception: large packets for VRF routes are supported on the CLIP Segmented Management Instance.

You can specify a management instance ID to use the correct source for the outgoing ICMP ECHO request packet.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Ping an IP network connection:

```
ping WORD<0-256> [-d] [-I <1-60>] [-s] [-t <1-120>] [count <1-9999>]
[datasize <28-9216|28-51200>] [grt] [interface gigabitEthernet {slot/
port[sub-port]}] | tunnel <1-2000> | vlan <1-4059>] [scopeid <1-9999>]
[source WORD<1-256>] [vrf WORD<1-16>]
```

3. Ping an IP network connection using a Global Routing Table (GRT):

```
ping WORD<0-256> [-d] [-I <1-60>] [-s] [-t <1-120>] [count <1-9999>]
[datasize <28-9216|28-51200>] grt [interface gigabitEthernet {slot/
port[sub-port]}] | tunnel <1-2000> | vlan <1-4059>] [source WORD<1-246>]
```

4. Ping a network connection using a Segmented Management Instance:

```
ping WORD<0-256> [-s] [-t <1-120>] [count <1-9999>] [datasize
<28-9216|28-51200>] mgmt [clip | oob | vlan]
```

#### Note

If you do not use the *mgmt* parameter, the **ping** command uses the IP routing stack to initiate the ping request.

If you ping a device using a management CLIP, the ping source IP address is configured as the management CLIP IP address. If you ping a device using a management VLAN, the ping source IP address is configured as the management VLAN IP address.

### Examples

Ping an IP device from a GRT VLAN IP interface:

```
Switch:1#ping 192.0.2.16 grt interface vlan 1
192.0.2.16 is alive
```

Ping a device using the management routing table:

```
Switch:1#ping 192.0.2.12 mgmt
```

Ping a device using a management CLIP:

```
Switch:1#ping 192.0.2.12 mgmt clip
```

Ping an IP device using a management VLAN:

```
Switch:1#ping 192.0.2.12 mgmt vlan
```

### Variable Definitions

The following table defines parameters for the **ping** command.

| Variable                           | Value                                                                                                                                                                                                                                                                                                    |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>count</i> <1-9999>              | Specifies the number of times to ping. The default is 1.                                                                                                                                                                                                                                                 |
| <i>-d</i>                          | Configures the ping debug mode. This variable detects local software failures (ping related threads creation or write to sending socket) and receiving issues (icmp packet too short or wrong icmp packet type). This parameter does not apply if you use the <i>mgmt</i> [clip   oob   vlan] parameter. |
| <i>datasize</i> <28-9216 28-51200> | Specifies the size of ping data sent in bytes. The <i>datasize</i> for IPv4 addresses is 28-9216. The <i>datasize</i> for IPv6 addresses is 28-51200. The default is 64.                                                                                                                                 |

| Variable                                                                                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>grt</code>                                                                                                   | Specifies the ping in Global Routing Table context.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>-I &lt;1-60&gt;</code>                                                                                       | Specifies the interval between transmissions in seconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>interface gigabitEthernet {slot/port[sub-port]}   tunnel &lt;1-2000&gt;   vlan &lt;1-4059&gt;</code>         | <p>Specifies the outgoing interface.</p> <p>Additional ping interface parameters:</p> <ul style="list-style-type: none"> <li>gigabitEthernet {slot/port[sub-port]}: gigabitEthernet port</li> <li>tunnel: tunnel ID as a value from 1 to 2000</li> <li>vlan:</li> </ul> <p>Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.</p> <p>This parameter does not apply if you use the <code>mgmt [clip   oob   vlan]</code> parameter.</p> |
| <code>mgmt [clip   oob   vlan]</code><br><b>Note:</b><br>Exception: <code>oob</code> not supported on 5320 Series. | <p>Specifies the Segmented Management Instance as the source for the outgoing ICMP ECHO packet. The packet goes out this specific interface only.</p> <p>If you do not specify the management interface type, the <b>ping</b> command uses the management routing table to determine the best management interface and selects the source IP based on the egress management interface.</p>                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>-s</code>                                                                                                    | Configures the continuous ping at the interval rate defined by the <code>[-I]</code> parameter or until you enter a <b>Ctrl + C</b> keystroke.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>scopeid &lt;1-9999&gt;</code>                                                                                | Specifies the circuit ID for IPv6. This parameter does not apply if you use the <code>mgmt [clip   oob   vlan]</code> parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>source WORD&lt;1-256&gt;</code>                                                                              | Specifies the source IP address for the ping command. This parameter does not apply if you use the <code>mgmt [clip   oob   vlan]</code> parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>-t &lt;1-120&gt;</code>                                                                                      | Specifies the no-answer timeout value in seconds. The default is 5.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>WORD&lt;0-256&gt;</code>                                                                                     | Specifies the host name or IPv4 (a.b.c.d) or IPv6 (x:x:x:x:x:x) address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>vrf WORD&lt;1-16&gt;</code>                                                                                  | Specifies the virtual router and forwarder (VRF) name. This parameter does not apply if you use the <code>mgmt [clip   oob   vlan]</code> parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Run a Traceroute Test

Use traceroute to determine the route packets take through a network to a destination.

### About This Task

Ping and traceroute can fail for VRF routes if you use large packet sizes for the operation. Do not use packet sizes larger than the following:

- Ping for VRF: 1480 bytes
- Traceroute for VRF: 1444 bytes

#### Note

Exception: large packet sizes are supported when running ping and traceroute on the Segmented Management Instance.

### Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Run a traceroute test:

```
traceroute WORD<0-256> [<1-1176>] [-m <1-255>] [-p <1-65535>] [-q
<1-255>] [-v] [-w <1-255>] [grt [source]] [mgmt [clip | oob | vlan]]
[source <WORD 1-256>] [vrf <WORD 1-16>]
```

3. Run a traceroute test using a Segmented Management Instance:

```
traceroute WORD<0-256> [<1-1176>] [-m <1-255>] [-p <1-65535>] [-q
<1-255>] [-w <1-255>] [grt [source]] mgmt [<clip | oob | vlan>]
```

#### Note

If you do not use the *mgmt* parameter, the **traceroute** command uses the IP routing stack to initiate the traceroute request.

### Examples

Run a traceroute test with a probe packet size of 200 and a max time to live of 60:

```
Switch:1>enable
Switch:1#traceroute 192.0.2.33 200 -m 60
```

Run a traceroute test for an IPv6 address:

```
Switch:1#traceroute 2001:db8::1
```

Run a traceroute test using the management routing table:

```
Switch:1#traceroute 192.0.2.12 mgmt
```

Run a traceroute test using a management CLIP:

```
Switch:1#traceroute 192.0.2.12 mgmt clip
```

Run a traceroute test using a management VLAN:

```
Switch:1#traceroute 192.0.2.12 mgmt vlan
```

**Variable Definitions**

The following table defines parameters for the **tracert** command.

| Variable                                      | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-m &lt;1-255&gt;</code>                 | Specifies the maximum time-to-live (TTL).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>-p &lt;1-65535&gt;</code>               | Specifies the base UDP port number. The default is 33434.<br><br><b>Note:</b><br>If the tracert action is directed to an IPv6 host address, Linux increments the UDP port on a per-TTL basis. For an IPv4 host address, Linux increments the UDP port on a per-probe basis.<br>Because the <b>tracert</b> command sends a default of three probes, three incrementing ports will be sent for an IPv4 host address. If you use the <code>-p</code> parameter with a value greater than 65533, the <b>tracert</b> command fails for an IPv4 host address because the maximum port number, 65535, is exceeded.<br>If you send a tracert probe into the device through the Segmented Management Instance or any VOSS routing interface, you must use the default UDP port range of 33434 to 33534. Using other ports will fail. |
| <code>-q &lt;1-255&gt;</code>                 | Specifies the number of probes per TTL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>-v</code>                               | Specifies verbose mode (detailed output). This parameter does not apply if you use the <code>mgmt [clip   oob   vlan]</code> parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>-w &lt;1-255&gt;</code>                 | Specifies the wait time for each probe.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>&lt;1-1176&gt;</code>                   | Specifies the size of the probe packet.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>grt</code>                              | Specifies the <b>tracert</b> command is executed in grt context.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>mgmt [&lt;clip   oob   vlan&gt;]</code> | Specifies the Segmented Management Instance as the source for the outgoing packet. The packet goes out this specific interface only.<br><br><b>Note:</b><br>Exception: <code>oob</code> not supported on 5320 Series<br>If you do not specify the management interface type, the <b>tracert</b> command uses the management routing table to determine the best management interface and selects the source IP based on the egress management interface.                                                                                                                                                                                                                                                                                                                                                                    |
| <code>source &lt;WORD 1-256&gt;</code>        | Specifies the source IP address. This parameter does not apply if you use the <code>mgmt [clip   oob   vlan]</code> parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>WORD&lt;0-256&gt;</code>                | Specifies the destination IPv4 or IPv6 address, or hostname.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>vrf &lt;WORD 1-16&gt;</code>            | Specifies the VRF instance by VRF name. This parameter does not apply if you use the <code>mgmt [clip   oob   vlan]</code> parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

### Showing SNMP Logs

Show the full SNMP logs. SNMP logs display the alarms and events that have been registered on the device.

#### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Show the logs:  

```
show fulltech file WORD<1-99>
```

#### Variable Definitions

The following table defines parameters for the **show fulltech** command.

| Variable                     | Value                                                                                                                                                                                        |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>file WORD&lt;1-99&gt;</i> | This variable represents the log file to be opened and displayed. It is displayed in the following format: <ul style="list-style-type: none"> <li>• <i>/intflash/&lt;file&gt;</i></li> </ul> |

### Using Trace to Examine IS-IS Control Packets

Use trace as a debug tool to examine the code flow and Intermediate-System-to-Intermediate-System (IS-IS) control packets. When you enable IS-IS trace flags, the system displays only trace information about the set flag.

#### Before You Begin

- You must know what you want to trace before you enable trace.

#### Procedure

1. Enter Privileged EXEC mode:  

```
enable
```
2. Enable the Intermediate-System-to-Intermediate-System trace flags:  

```
trace flags isis set { none | tx-hello | rx-hello | tx-pkt | rx-pkt |
adj | opt | tx-lsack | rx-lsack | tx-lsp | rx-lsp | pkt-err | nbr-
mismatch | flood | prefix | nbr-change | intf-change | decide | fdb |
dr | dd-masterslave | auth-fail | config | purge | policy | redist |
tx-snp | rx-snp | timer | global | perf | ucast-fib | node | mcast-fib
| isid | ip-shortcut }
```
3. Identify the module ID for which you want to use the trace tool:  

```
show trace modid-list
```
4. Clear the trace:  

```
clear trace
```

5. Begin the trace operation:

```
trace level [Module_ID] [<0-4>]
```

OR

```
trace spbm isis level [<0-4>]
```

OR

```
trace cfm level [<0-4>]
```

**Note**

- Module ID 119 represents the IS-IS module.

6. Wait approximately 30 seconds.

The default trace settings for CPU utilization are:

- High CPU Utilization: 90%
- High Track Duration: 5 seconds
- Low CPU Utilization: 75%
- Low Track Duration: 5 seconds

7. Stop tracing:

```
trace shutdown
```

8. View the trace results:

```
trace screen enable
```

**Important**

If you use trace level 3 (verbose) or trace level 4 (very verbose), do not use the screen to view commands due to the volume of information the system generates and the effect on the system.

9. Save the trace file.

```
save trace [file WORD<1-99>]
```

If you do not specify a file name, the file name is systrace.txt.

10. Display trace lines saved to a file:

```
show trace file [tail]
```

11. Search trace results for a specific string value:

```
trace grep [WORD<0-128>]
```

If you use this command and do not specify a string value, you clear the results of a previous search.

12. Stop tracing:

```
trace shutdown
```

13. Disable the Intermediate-System-to-Intermediate-System trace flags:

```
trace flags isis remove { none | tx-hello | rx-hello | tx-pkt | rx-pkt
| adj | opt | tx-lsack | rx-lsack | tx-lsp | rx-lsp | pkt-err | nbr-
mismatch | flood | spf-intra | spf-inter | spf-extern | prefix | nbr-
change | intf-change | decide | fdb | dr | dd-masterslave | auth-fail
| config | purge | policy | redist | tx-snp | rx-snp | timer | spbm-
decide | global | perf | ucast-fib | node | mcast-fib | isid | ip-
shortcut }
```

### Example

```
Switch:1> enable
```

Clear prior trace information:

```
Switch:1# clear trace
```

Enable IS-IS trace flags for received IS-IS hello packets:

```
Switch:1# trace flags isis set rx-hello
```

Enable IS-IS trace flags for transmitted IS-IS hello packets:

```
Switch:1# trace flags isis set tx-hello
```

Configure the module ID to 119 (IS-IS module) and the trace to 4 (very verbose):

```
Switch:1# trace level 119 4
```

Enable the display of trace output to the screen:

```
Switch:1# trace screen enable
Switch:1# Screen tracing is on
```

Disable the display of trace output to the screen:

```
Switch:1# trace screen disable
Switch:1# Screen tracing is off
```

**Variable Definitions**

The following table defines parameters for the **trace flags isis** command.

| Variable                                                                                                                                                                                                                                                                                                                                         | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|          | <ul style="list-style-type: none"> <li>• ucast-fib — Unicast Forwarding Information Base</li> <li>• node — Node</li> <li>• isid — I-SID</li> <li>• ip-shortcut — IP Shortcut</li> </ul> |

The following table defines parameters for the **show trace** command.

| Variable           | Value                                                                |
|--------------------|----------------------------------------------------------------------|
| <i>auto</i>        | Displays the current configuration for the automatic trace function. |
| <i>file [tail]</i> | Displays the trace results saved to a file.                          |
| <i>level</i>       | Displays the current trace level for all modules.                    |
| <i>modid-list</i>  | Specifies the module ID list.                                        |

The following table defines parameters for the **trace** command.

| Variable                                       | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>grep [WORD&lt;0-128&gt;]</i>                | Specifies the search keyword. You can use a specific MAC address. You can search for errors, using the command, <b>trace grep error</b> .                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>cfm level [&lt;0-4&gt;]</i>                 | Starts tracing by CFM. <ul style="list-style-type: none"> <li>• &lt;0-4&gt; specifies the trace level from 0-4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose.</li> </ul>                                                                                                                                                                                                                                                                                                                                |
| <i>spbm isis level [&lt;0-4&gt;]</i>           | Specifies exactly which IS-IS component to display. <ul style="list-style-type: none"> <li>• &lt;0-4&gt; specifies the trace level from 0-4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose.</li> </ul>                                                                                                                                                                                                                                                                                                   |
| <i>level [&lt;Module_ID&gt;] [&lt;0-4&gt;]</i> | Starts the trace by specifying the module ID and level. <Module_ID> specifies the module for the trace. Different hardware platforms support different ID ranges because of feature support differences. To see which module IDs are available on the switch, use the <b>show trace modid-list</b> command or CLI command completion Help. 0-4 specifies the trace level: <ul style="list-style-type: none"> <li>• 0 — Disabled</li> <li>• 1 — Very terse</li> <li>• 2 — Terse</li> <li>• 3 — Verbose</li> <li>• 4 — Very verbose</li> </ul> |

| Variable                       | Value                                                                                                                                                                                                                                                                          |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>shutdown</i>                | Stops the trace operation.                                                                                                                                                                                                                                                     |
| <i>screen {disable enable}</i> | Enables or disables the display of trace output to the screen.<br><br><b>Important:</b><br>Avoid using the screen to view commands if you use trace level 3 (verbose) or trace level 4 (very verbose) due to the volume of information generated and the effect on the system. |

The following table defines parameters for the **save trace** command.

| Variable                     | Value                                                                                                                                                                                                                                                                |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>file WORD&lt;1-99&gt;</i> | Specifies the file name in one of the following formats: <ul style="list-style-type: none"> <li>a.b.c.d: &lt;file&gt;</li> </ul> WORD<1-99> is a string of 1-99 characters.<br><br><b>Note:</b><br>If you do not specify a file name, the file name is systrace.txt. |

*Viewing the Metric Type of IS-IS Route in TLVs - Detailed*

**About This Task**

Use the following procedure to view the detailed information about metric type of IS-IS routes in TLVs in Link State Packets (LSP).

**Procedure**

1. Display the detail view of TLV 135:  
`show isis lsdb tlv 135 detail`
2. Display the detail view of TLV 184:  
`show isis lsdb tlv 184 detail`

**Example**

Viewing the metric type of IS-IS route in TLV 135

```
Switch:1#show isis lsdb tlv 135 detail

=====
 ISIS LSDB (DETAIL)
=====

Level-1 LspID: 4072.0000.0000.00-02 SeqNum: 0x00000009 Lifetime: 1110
 Chksum: 0x31ce PDU Length: 46
 Host_name: evp4k
 Attributes: IS-Type 1
TLV:135 TE IP Reachability: 2
 Metric: 1 Metric Type:Internal Prefix Length: 32
 UP/Down Bit: FALSE Sub TLV Bit: FALSE
 IP Address: 15.15.15.72
```

```

Metric: 1 Metric Type:External Prefix Length: 24
UP/Down Bit: FALSE Sub TLV Bit: FALSE
IP Address: 192.0.2.5

```

Viewing the metric type of IS-IS route in TLV 184

```

Switch:1#show isis lsdb tlv 184 detail

=====
ISIS LSDB (DETAIL)

*Viewing the Metric Type of IS-IS Route in TLVs - Summarized*

### About This Task

Use the following procedure to view the summarized information about metric type of IS-IS routes in TLVs. You can also view the metric type of the prefix.

### Procedure

Display the summarized view of TLVs 135 and 184:

```
show isis lsdb ip-unicast
```

### Example

Display the summarized view of TLVs.

```

evp4k:1#show isis lsdb ip-unicast

=====
ISIS IP-UNICAST-ROUTE SUMMARY

## Configuring I-SID Monitoring

Use the following procedure to configure Fabric RSPAN (Mirror to I-SID) on the Backbone Edge Bridge (BEB) connected to the monitor station.

### Note

Do not configure the source of mirrored traffic (mirroring to an I-SID) and the analyzer (monitoring an I-SID) on the same local device with the same I-SID offset. If you require mirroring and monitoring on the same local device, use standard port-based mirroring instead of Fabric RSPAN. Fabric RSPAN mirrors traffic into an I-SID of the SPB Fabric network and monitors traffic on the remote device; the network analyzer resides on the remote monitoring device and not on the same local device.

### Note

If you change the egress port or egress MLT for a particular session using a separate CLI command, it overwrites the existing egress port list or egress MLT.

## Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create a monitor by I-SID entry:

```
monitor-by-isid <1-1000> [monitor-isid-offset <1-1000> {egress-mlt <1-512> | egress-ports {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}} [map-to-vid <1-4093>]]
```

3. Configure map to VLAN ID:

```
monitor-by-isid <1-1000> map-to-vid <1-4093>
```

4. Configure egress MLT:

```
monitor-by-isid <1-1000> egress-mlt <1-512>
```

5. Configure egress port:

```
monitor-by-isid <1-1000> egress-ports {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
```

6. Enable monitoring by I-SID entry:

```
monitor-by-isid <1-1000> enable
```

### Note

Disable the entries (egress ports, MLT, and VLAN ID) to modify or remove parameters in the existing configuration.

## Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# monitor-by-isid 1 monitor-isid-offset 1 egress-port 1/6
Switch:1(config)# monitor-by-isid 2 monitor-isid-offset 2 egress-port 1/7 map-to-vid 200
Switch:1(config)# monitor-by-isid 3 monitor-isid-offset 3 egress-port 1/7 map-to-vid 201
Switch:1(config)# monitor-by-isid 2 egress-port 1/8
Switch:1(config)# monitor-by-isid 1 monitor-isid-offset 1000 egress-ports 1/1 egress-mlt
```

```
16 map-to-vid 1000
Switch:1(config)# monitor-by-isid 7 monitor-isid-offset 7 egress-mlt 2 map-to-vid 203
Switch:1(config)# monitor-by-isid 2 egress-mlt 3
```

### Variable Definitions

The following table defines parameters for the **monitor-by-isid** command.

| Variable                                                                                                      | Value                                                                                                                                                                              |
|---------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-1000>                                                                                                      | Specifies the monitoring session.                                                                                                                                                  |
| <i>monitor-isid-offset</i> <1-1000>                                                                           | Specifies the offset ID that is mapped to the actual monitor I-SID where packets are mirrored. Monitor I-SID = Base monitor I-SID + Offset ID. The base monitor I-SID is 16776000. |
| <i>egress-ports</i> { <i>slot/port</i> [/ <i>sub-port</i> ] [ <i>-slot/port</i> [/ <i>sub-port</i> ]] [,...]} | Specifies the port to which the analyzers connect.                                                                                                                                 |
| <i>egress-mlt</i> <1-512>                                                                                     | Specifies the MLT to which the analyzers connect.                                                                                                                                  |
| <i>map-to-vid</i> <1-4093>                                                                                    | Maps the mirrored packet to a specified VLAN ID for analysis. This parameter is optional.                                                                                          |

### Displaying I-SID Monitoring Diagnostics

Use the following procedure to display the **monitor-by-isid** entries on the monitoring BEB.

#### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Enter the following command:
 

```
show monitor-by-isid WORD<1-1024>
```

#### Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)# show monitor-by-isid 3
=====
 Diag Monitor-By-ISID
=====
ID MONITOR_ISID ISID_OFFSET EGRESS_PORTS EGRESS_MLT MAP_TO_VLAN ENABLE

3 16776000 1 1/4, 1/5 1 999 true
=====
```

### Variable Definitions

The following table defines parameters for the **show monitor-by-isid** command.

| Variable             | Value                                                 |
|----------------------|-------------------------------------------------------|
| <i>WORD</i> <1-1024> | Specifies the session ID list ranging from 1 to 1000. |

### Displaying I-SID Mirroring Statistics

Use the following procedure to display the statistics of the number of packets mirrored into I-SID on the mirroring BEB.

#### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enter the following command:  

```
show isid-mirroring stats [monitor-isid-offset WORD<1-1024>]
```

#### Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# show isid-mirroring stats monitor-isid-offset 1
=====
Mirror Statistics Info
=====
ISID ISID_OFFSET PACKETS

16776000 1 100

```

#### Variable Definitions

The following table defines parameters for the **show isid-mirroring stats** command.

| Variable                                      | Value                                                                                     |
|-----------------------------------------------|-------------------------------------------------------------------------------------------|
| <i>monitor-isid-offset WORD&lt;1-1024&gt;</i> | Specifies the offset ID mapped to monitor the I-SID. The offset ID ranges from 1 to 1000. |

### Clearing Fabric RSPAN (Mirror to I-SID) Statistics

Use the following procedure to clear Fabric RSPAN (Mirror to I-SID) statistics of packets mirrored into the specified mirroring I-SID or all mirroring I-SIDs on the BEB.

#### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enter the following command:  

```
clear isid-mirroring stats monitor-isid-offset WORD<1-1024>
```

#### Note

You must use this command on the Mirroring BEB to clear the statistics of packets mirrored into I-SID.

**Example**

```
Switch:1>enable
Switch:1#configure terminal
```

Clear all Fabric RSPAN statistics:

```
Switch:1(config)# clear isid-mirroring stats
```

Clear all Fabric RSPAN (Mirror to I-SID) statistics of packets mirrored into the specified mirroring I-SID

```
Switch:1(config)# clear isid-mirroring stats monitor-isid-offset 1
```

**Variable Definitions**

The following table defines parameters for the **clear isid-mirroring stats** command.

| Variable                                | Value                                                                                                                                                                                                                                        |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>monitor-isid-offset</i> WORD<1-1024> | Specifies the offset ID that is mapped to the actual monitor I-SID where packets are mirrored. Monitor I-SID = base monitor I-SID + offset ID. The range of the <i>monitor-isid-offset</i> is 1 to 1000. The base monitor I-SID is 16776000. |

**Software Troubleshooting Tool Configuration Using EDM**

Use the tools described in this section to perform troubleshooting procedures using Enterprise Device Manager (EDM).

*Flush Routing Tables by VLAN*

**About This Task**

For administrative and troubleshooting purposes, sometimes you must flush the routing tables. You can use EDM to flush the routing tables by VLAN or flush them by port. Perform this procedure to flush the IP routing table for a VLAN.

**Procedure**

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the **Advanced** tab.
4. In the **Vlan Operation Action** box for the VLAN you want to flush, double-click, and then select a flush option from the list.  
  
In a VLAN context, all entries associated with the VLAN are flushed. You can also flush the Address Resolution Protocol (ARP) entries and IP routes for the VLAN.
5. Click **Apply**.

### *Flush Routing Tables by Port*

#### **About This Task**

For administrative and troubleshooting purposes, sometimes you must flush the routing tables. You can use EDM to flush the routing tables by VLAN or flush them by port. Perform this procedure to flush the IP routing table for a port.

#### **Procedure**

1. On the Device Physical View, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Click **General**.
4. Click the Interface tab.
5. In the **Action** section, select **flushAll**.

In a port context, all entries associated with the port are flushed. You can flush the ARP entries and IP routes for a port. After you flush a routing table, it is not automatically repopulated. The repopulation time delay depends on the routing protocols in use.

6. Click **Apply**.

### *Configure Port Mirroring*

#### **Before You Begin**

- To change a port mirroring configuration, first disable mirroring.

#### **About This Task**

Use port mirroring to aid in diagnostic and security operations.

Use port mirroring to make a copy of a traffic flow and send that copy to a device for analysis, for example, for diagnostic sniffing. Use the mirror to see the packets in the flow without breaking into the physical connection to place a packet onto the sniffer inline. You can also use port mirroring for security. You can send flows to inspection engines for post processing.

Connect the sniffer (or other traffic analyzer) to the output port you specify in this procedure.

#### **Procedure**

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **General**.
3. Select the **Port Mirrors** tab.
4. Select **Insert**.
5. To enable port mirroring for the instance, select the **Enable** check box.

6. Configure mirroring as required.

**Note**

- When you configure `tx` mode port mirroring on T-UNI and SPBM NNI ports, unknown unicast, broadcast and multicast traffic packets that ingress these ports and the system displays on the mirror destination port, although they do not egress the mirror source port. This is because `tx` mode port mirroring happens on the mirror source port before the source port squelching logic drops the packets at the egress port.
- The available four mirroring resources are shared between Fabric RSPAN and regular port mirroring, and are allocated based on the mode configured, Ingress (`rx`) or Egress (`tx`). Each configured mode occupies one mirroring resource, but when you configure the mode as `both`, it occupies two mirroring resources (one for Rx and one for Tx).
- Do not configure the source of mirrored traffic (mirroring to an I-SID) and the analyzer (monitoring an I-SID) on the same local device with the same I-SID offset. If you require mirroring and monitoring on the same local device, use standard port-based mirroring instead of Fabric RSPAN. Fabric RSPAN mirrors traffic into an I-SID of the SPB Fabric network and monitors traffic on the remote device; the network analyzer resides on the remote monitoring device and not on the same local device.

7. Select **Insert**.

**Port Mirrors Field Descriptions**

Use the data in the following table to use the **Port Mirrors** tab.

| Name                        | Description                                                                                                                                                                                                                                                                                                          |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>                   | Specifies an assigned identifier for the configured port mirroring instance.                                                                                                                                                                                                                                         |
| <b>MirroredPortList</b>     | Specifies a port to be mirrored (the source port).                                                                                                                                                                                                                                                                   |
| <b>Enable</b>               | Enables or disables this port mirroring instance. The default value is Enable.                                                                                                                                                                                                                                       |
| <b>Mode</b>                 | Specifies the traffic direction of the packet being mirrored: <ul style="list-style-type: none"> <li>• <code>tx</code> mirrors egress packets.</li> <li>• <code>rx</code> mirrors ingress packets.</li> <li>• <code>both</code> mirrors both egress and ingress packets.</li> </ul> The default is <code>rx</code> . |
| <b>MirroringPortList</b>    | Specifies a destination port (the port to which the mirrored packets are forwarded). Configures the mirroring port.                                                                                                                                                                                                  |
| <b>MirroringMltId</b>       | Specifies the destination MultiLink trunking ID.                                                                                                                                                                                                                                                                     |
| <b>MonitoringIsidOffset</b> | Used to configure the monitoring I-SID offset value. The offset ID is mapped to the actual monitor I-SID value to which the packets are mirrored.                                                                                                                                                                    |
| <b>MonitoringIsid</b>       | Specifies the actual monitor I-SID value to which the packets are mirrored.                                                                                                                                                                                                                                          |
| <b>MirroringQos</b>         | Used to define the Quality of Service (QoS) profiles for the mirrored packet into monitoring I-SID.                                                                                                                                                                                                                  |

*Configure ACLs for Mirroring*

Configure the access control list (ACL) to mirror packets for an access control entry (ACE) that matches a particular packet.

**Before You Begin**

- The ACL exists.

**About This Task**

To modify an ACL parameter, double-click the parameter you wish to change. Change the value, and then click Apply. You cannot change a parameter that the system displays it dimmed; in this case, delete the ACL, and then configure a new one.

**Procedure**

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Double-click the parameter **MirrorMltId** to configure mirroring to a destination MLT group.
5. Double-click the parameter **MirrorDstPortList** to configure mirroring to a destination port or ports.

**ACL Field Descriptions**

Use the data in the following table to use the **ACL** tab.

| Name                    | Description                                                                                                                                                                                                                                                         |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AcId</b>             | Specifies a unique identifier for the ACL from 1-2048.                                                                                                                                                                                                              |
| <b>Type</b>             | Specifies whether the ACL is VLAN- or port-based. Valid options are <ul style="list-style-type: none"> <li>• inVlan</li> <li>• inPort</li> <li>• outPort</li> </ul> <p><b>Important:</b><br/>The inVlan ACLs drop packets if you add a VLAN after ACE creation.</p> |
| <b>Name</b>             | Specifies a descriptive user-defined name for the ACL.                                                                                                                                                                                                              |
| <b>VlanList</b>         | For inVlan type, specifies all VLANs to associate with the ACL.                                                                                                                                                                                                     |
| <b>PortList</b>         | For inPort and outPort ACL types, specifies the ports to associate with the ACL.                                                                                                                                                                                    |
| <b>DefaultAction</b>    | Specifies the action taken when no ACEs in the ACL match. Valid options are deny and permit. Deny means the system drops the packets; permit means the system forwards packets. The default is permit.                                                              |
| <b>ControlPktAction</b> | Specifies the action for control packets, if you configure DefaultAction to deny. If DefaultAction is permit, this value is ignored.                                                                                                                                |

| Name                     | Description                                                                    |
|--------------------------|--------------------------------------------------------------------------------|
| <b>State</b>             | Enables or disables all of the ACEs in the ACL. The default value is enable.   |
| <b>PktType</b>           | Indicates the packet type that this ACL is applicable to. The default is IPv4. |
| <b>MirrorMltd</b>        | Configures mirroring to a destination MLT group.                               |
| <b>MirrorDstPortList</b> | Configures mirroring to a destination port or ports.                           |

### Configure ACEs for Mirroring

#### Before You Begin

- The ACL exists.
- The ACE exists.

#### About This Task

Configure actions to use filters for flow mirroring. Use an ACE to define the mirroring actions the filter performs.

If you use the mirror action, ensure that you specify the mirroring destination: IP address, MLTs, ports, or VLANs.

#### Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the ACL for which to modify an ACE.
5. Click **ACE**.
6. Select an ACE, and then click **Action**.
7. Configure one of: **DstPortList**, **DstMltd**, or **DstIp**.
8. Click **Apply**.

#### Action Field Descriptions

Use the data in the following table to use the **Action** tab.

#### Note

The table lists the options for both Security ACEs and QoS ACEs. Dependent upon the ACE the system displays different options on the EDM interface.

| Name         | Description                                                                                                          |
|--------------|----------------------------------------------------------------------------------------------------------------------|
| <b>AcId</b>  | Specifies the ACL ID.                                                                                                |
| <b>AceId</b> | Specifies a unique identifier and priority for the ACE.                                                              |
| <b>Mode</b>  | Indicates the operating mode associated with this ACE. Valid options are deny, permit and none. The default is none. |

| Name                      | Description                                                                                                                                                                                                                                                                                                                  |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RemarkDscp</b>         | Specifies the new Per-Hop Behavior (PHB) for matching packets: phbcs0, phbcs1, phbaf11, phbaf12, phbaf13, phbcs2, phbaf21, phbaf22, phbaf23, phbcs3, phbaf31, phbaf32, phbaf33, phbcs4, phbaf41, phbaf42, phbaf43, phbcs5, phbef, phbcs6, phbcs7. This action is a QoS action. The ACE ID must be in the range of 1001–2000. |
| <b>RemarkDot1Priority</b> | Specifies the new 802.1 priority bit for matching packets: zero, one, two, three, four, five, six, or seven. This action is a QoS action. The ACE ID must be in the range of 1001–2000. The default is disable.                                                                                                              |
| <b>InternalQoS</b>        | This variable is a QoS action. The ACE ID must be in the range of 1001–2000. The default value is 1.                                                                                                                                                                                                                         |
| <b>RedirectNextHop</b>    | Redirects matching IP traffic to the next hop. The default is 0.0.0.0.                                                                                                                                                                                                                                                       |
| <b>RedirectUnreach</b>    | Configures the desired behavior for redirected traffic when the specified next-hop is not reachable. The default value is deny.                                                                                                                                                                                              |
| <b>Count</b>              | Enables the ability to count matching packets. Use this parameter with either a security or QoS ACE. The default is disabled.                                                                                                                                                                                                |
| <b>Log</b>                | This action logs to the switch. Use this parameter with either a security or QoS ACE. The default is disabled.                                                                                                                                                                                                               |
| <b>DstPortList</b>        | Specifies the ports to which to mirror traffic.                                                                                                                                                                                                                                                                              |
| <b>DstMtlId</b>           | Specifies the Multilink Trunking (MLT) group to which to mirror traffic.                                                                                                                                                                                                                                                     |
| <b>DstIp</b>              | Configures mirroring to a destination IP address for flow-based mirroring.                                                                                                                                                                                                                                                   |
| <b>DstIpDscp</b>          | Optionally, configures the DSCP value. The default is 256 (disabled).                                                                                                                                                                                                                                                        |
| <b>DstIpTtl</b>           | Optionally, configures the time-to-live value. The default TTL is 64.                                                                                                                                                                                                                                                        |

*Run a Ping Test*

**About This Task**

Use ping to determine if an entity is reachable.

**Note**

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see [Fabric Engine Release Notes](#). As an alternative, use CLI.

**Procedure**

1. From the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **Ping/Trace Route**.
3. Click the **Ping Control** tab.
4. Click **Insert**.
5. In the **OwnerIndex** box, type the owner index.

6. In the **TestName** box, type the name of the test.
7. In the **TargetAddress** box, type the host IP address.
8. From the **AdminStatus** options, select **enabled**.
9. In the remainder of the option boxes, type the desired values.
10. Click **Insert**.
11. Select and entry, and then click **Start**.  
Let the test run for several seconds.
12. Select an entry, and then click **Stop**.
13. View the Ping results.

### Ping Control Field Descriptions

Use the data in the following table to use the **Ping Control** tab.

| Name                 | Description                                                                                                                                                                                                                      |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OwnerIndex</b>    | Provides access control by a security administrator using the View-Based Access Control Model (VACM) for tables in which multiple users need to independently create or modify entries. This is a string of up to 32 characters. |
| <b>TestName</b>      | Specifies the name of the ping test.                                                                                                                                                                                             |
| <b>TargetAddress</b> | Specifies the host address to use at a remote host to perform a ping operation.                                                                                                                                                  |
| <b>DataSize</b>      | Specifies the size of the data portion (in octets) to transmit in a ping operation. The default is 16.                                                                                                                           |
| <b>TimeOut</b>       | Specifies the timeout value, in seconds, for a remote ping operation. The default is 3 seconds.                                                                                                                                  |
| <b>ProbeCount</b>    | Specifies the number of times to perform a ping operation at a remote host. The default is 1.                                                                                                                                    |
| <b>AdminStatus</b>   | Specifies the state of the ping control entry: enabled or disabled. The default is disabled.                                                                                                                                     |
| <b>DataFill</b>      | Determines the data portion of a probe packet.                                                                                                                                                                                   |
| <b>Frequency</b>     | Specifies the number of seconds to wait before repeating a ping test. The default is 0.                                                                                                                                          |
| <b>MaxRows</b>       | Specifies the maximum number of entries allowed in the PingProbeHistory table. The default is 50.                                                                                                                                |

| Name                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>TrapGeneration</b>         | Specifies when to generate a notification. The options are: <ul style="list-style-type: none"> <li>• ProbeFailure—Generates a PingProbeFailed notification subject to the value of TrapProbeFailureFilter. The object TrapProbeFailureFilter can specify the number of successive probe failures that are required before a pingProbeFailed notification is generated.</li> <li>• TestFailure—Generates a PingTestFailed notification. The object TrapTestFailureFilter can determine the number of probe failures that signal when a test fails.</li> <li>• TestCompletion—Generates a PingTestCompleted notification.</li> </ul> The value of this object defaults to zero, indicating that none of the above options have been selected. |
| <b>TrapProbeFailureFilter</b> | Specifies the number of successive probe failures that are required before a pingProbeFailed notification is generated. The default is 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>TrapTestFailureFilter</b>  | Determines the number of probe failures that signal when a test fails. The default is 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Descr</b>                  | Describes the remote ping test. The default is 0x00.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SourceAddress</b>          | Specifies the IP address (a.b.c.d) as the source address in outgoing probe packets.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>ByPassRouteTable</b>       | Enables (optionally) the bypassing of the route table. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

*View Ping Results*

**About This Task**

View ping results to view performance-related data.

**Note**

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see [Fabric Engine Release Notes](#). As an alternative, use CLI.

**Procedure**

1. From the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **Ping/Trace Route**.
3. Click the **Ping Control** tab.
4. Select a ping test entry.
5. Click **Ping Result**.

### Ping Result Field Descriptions

Use the data in the following table to use the **Ping Result** tab.

| Name                       | Description                                                                                            |
|----------------------------|--------------------------------------------------------------------------------------------------------|
| <b>OwnerIndex</b>          | Specifies the ping test owner.                                                                         |
| <b>TestName</b>            | Specifies the test name.                                                                               |
| <b>OperStatus</b>          | Indicates the operational status of the test. The default is disabled.                                 |
| <b>IpTargetAddressType</b> | Specifies the IP address type of the target. The default is unknown.                                   |
| <b>IpTargetAddress</b>     | Specifies the IP address of the target.                                                                |
| <b>MinRtt</b>              | Specifies the minimum ping round-trip-time (RTT) received. A value of 0 means that no RTT is received. |
| <b>MaxRtt</b>              | Specifies the maximum ping RTT received. A value of 0 means that no RTT is received.                   |
| <b>AverageRtt</b>          | Specifies the current average ping RTT.                                                                |
| <b>ProbeResponses</b>      | Specifies the number of responses to probes.                                                           |
| <b>SentProbes</b>          | Specifies the number of sent probes.                                                                   |
| <b>RttSumOfSquares</b>     | Specifies the sum of squares of RTT for all probes received.                                           |
| <b>LastGoodProbe</b>       | Specifies the date and time when the last response is received for a probe.                            |

#### View Ping Probe History

##### About This Task

View the ping probe history to view the history of ping tests performed by the switch.

##### Note

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see [Fabric Engine Release Notes](#). As an alternative, use CLI.

##### Procedure

1. From the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **Ping/Trace Route**.
3. Select a ping entry.
4. Click **Ping Probe History**.

### Ping Probe History Field Descriptions

Use the data in the following table to use the **Ping Probe History** tab.

| Name              | Description                           |
|-------------------|---------------------------------------|
| <b>OwnerIndex</b> | Specifies the owner index             |
| <b>TestName</b>   | Indicates the name given to the test. |

| Name            | Description                                                                                                                                                                                                |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>    | Specifies the index number.                                                                                                                                                                                |
| <b>Response</b> | Indicates the amount of time, measured in milliseconds, between request (probe) and response, or when the request timed out. Response is reported as 0 when it is not possible to transmit a probe.        |
| <b>Status</b>   | Indicates the status of the response; the result of a particular probe done by a remote host.                                                                                                              |
| <b>LastRC</b>   | Indicates the last implementation-method-specific reply code (RC) received. If ICMP Echo is used, then a successful probe ends when an ICMP response is received that contains the code ICMP_ECHOREPLY(0). |
| <b>Time</b>     | Indicates the timestamp for this probe result.                                                                                                                                                             |

*Run a Traceroute Test*

**About This Task**

Run a traceroute test to determine the route packets take through a network to a destination.

**Note**

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see [Fabric Engine Release Notes](#). As an alternative, use CLI.

**Procedure**

1. From the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **Ping/Trace Route**.
3. Click the **Trace Route Control** tab.
4. Click **Insert**.
5. Configure the instance as required.
6. Click **Insert**.
7. Select an entry, and then click **Start**.  
Let the test run for several seconds.
8. Select an entry, and then click **Stop**.
9. View the traceroute test results.

**Trace Route Control Field Descriptions**

Use the data in the following table to use the **Trace Route Control** tab.

| Name              | Description                                                                                                                                           |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OwnerIndex</b> | Provides access control by a security administrator using the VACM for tables in which multiple users need to independently create or modify entries. |
| <b>TestName</b>   | Specifies the name of the traceroute test.                                                                                                            |

| Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>TargetAddressType</b> | Specifies the type of host address to use on the traceroute request at the remote host. The default is IPv4.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>TargetAddress</b>     | Specifies the host address used on the traceroute request at the remote host.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>ByPassRouteTable</b>  | Enables bypassing of the route table. If you enable this variable, the remote host bypasses the normal routing tables and sends directly to a host on an attached network. If the host is not on a directly-attached network, an error is returned. You can use this variable to perform the traceroute operation to a local host through an interface that has no route defined. The default is disabled.                                                                                                                                                                                                                                                                                                                                     |
| <b>DataSize</b>          | Specifies the size of the data portion of a traceroute request in octets. The default is 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>TimeOut</b>           | Specifies the timeout value, in seconds, for a traceroute request. The default is 3.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>ProbesPerHop</b>      | Specifies the number of times to reissue a traceroute request with the same time-to-live (TTL) value. The default is 3.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Port</b>              | <p>Specifies the UDP port to which to send the traceroute request. Specify a port that is not in use at the destination (target) host. The default is the IANA assigned port 33434.</p> <p><b>Note:</b><br/>If the traceroute action is directed to an IPv6 host address, Linux increments the UDP port on a per-TTL basis. For an IPv4 host address, Linux increments the UDP port on a per-probe basis.<br/>Because the <b>traceroute</b> command sends a default of three probes, three incrementing ports will be sent for an IPv4 host address. If you use the <b>-p</b> parameter with a value greater than 65533, the <b>traceroute</b> command fails for an IPv4 host address because the maximum port number, 65535, is exceeded.</p> |
| <b>MaxTtl</b>            | Specifies the maximum time-to-live from 1–255. The default is 30.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DSField</b>           | Specifies the value to store in the Differentiated Services (DS) field in the IP packet used to encapsulate the traceroute probe. The default is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SourceAddressType</b> | Specifies the type of the source address to use at a remote host.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SourceAddress</b>     | Uses the specified IP address (which must be an IP number, not a hostname) as the source address in outgoing probe packets.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>IfIndex</b>           | Directs the traceroute probes to be transmitted over the specified interface. The default is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>MiscOptions</b>       | Enables an application to specify implementation-dependent options.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MaxFailures</b>       | Indicates the maximum number of consecutive timeouts allowed before terminating a remote traceroute request. The default is 5.                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>DontFragment</b>      | Enables setting of the do not fragment (DF) flag in the IP header for a probe. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>InitialTtl</b>        | Specifies the initial time-to-live (TTL) value to use. The default is 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Frequency</b>         | Specifies the number of seconds to wait before repeating a traceroute test as defined by the value of the various objects in the corresponding row. The default is 0.                                                                                                                                                                                                                                                                                                                                                                  |
| <b>StorageType</b>       | Specifies the storage type for this row.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>AdminStatus</b>       | Specifies the desired state for TraceRouteCtlEntry. The options are enabled or disabled. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>MaxRows</b>           | Specifies the maximum number of entries allowed in the TraceRouteProbeHistoryTable. The default is 50.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>TrapGeneration</b>    | Determines when to generate a notification for this entry. The options are <ul style="list-style-type: none"> <li>• <b>pathChange</b> —Generates a TraceRoutePathChange notification after the current path varies from a previously determined path.</li> <li>• <b>testFailure</b> —Generates a TraceRouteTestFailed notification after the full path to a target cannot be determined.</li> <li>• <b>testCompletion</b> —Generates a TraceRouteTestCompleted notification after the path to a target has been determined.</li> </ul> |
| <b>Descr</b>             | Describes the remote traceroute test.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>CreateHopsEntries</b> | Stores the current path for a traceroute test in the TraceRouteHopsTable on an individual hop basis when the value of this object is true. The default is false.                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Type</b>              | Reports or selects the implementation method to use for performing a traceroute operation.                                                                                                                                                                                                                                                                                                                                                                                                                                             |

*View Traceroute Results*

**About This Task**

View traceroute results to view performance-related data.

**Note**

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see [Fabric Engine Release Notes](#). As an alternative, use CLI.

**Procedure**

1. From the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **Ping/Trace Route**.
3. Click the **Trace Route Control** tab.
4. Select a traceroute entry.

5. Click **Trace Route Result**.

### Trace Route Result Field Descriptions

Use the data in the following table to use the **Trace Route Result** tab.

| Name                    | Description                                                                 |
|-------------------------|-----------------------------------------------------------------------------|
| <b>OwnerIndex</b>       | Specifies the index of the owner.                                           |
| <b>TestName</b>         | Specifies the name of the test.                                             |
| <b>OperStatus</b>       | Specifies the operational status of the test. The default is disabled.      |
| <b>CurHopCount</b>      | Specifies the current count of hops.                                        |
| <b>CurProbeCount</b>    | Specifies the current count of probes.                                      |
| <b>IpTgtAddressType</b> | Specifies the IP target address type                                        |
| <b>IpTgtAddr</b>        | Specifies the IP target address.                                            |
| <b>TestAttempts</b>     | Specifies the number of test attempts.                                      |
| <b>TestSuccesses</b>    | Specifies the number of successful test attempts.                           |
| <b>LastGoodPath</b>     | Specifies the date and time when the last response is received for a probe. |

*View the Traceroute History*

### About This Task

View the traceroute history to view the history of traceroute tests performed by the switch.

The traceroute probe history contains probe information for the hops in the routing path.

#### Note

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see [Fabric Engine Release Notes](#). As an alternative, use CLI.

### Procedure

1. From the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **Ping/Trace Route**.
3. Click the **Trace Route Control** tab.
4. Select an entry.
5. Click **Trace Route Probe History**.

**Route Probe History Field Descriptions**

Use the data in the following table to use the **Trace Route Probe History** tab.

| Name              | Description                                                                                                                                                   |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OwnerIndex</b> | Identifies the Trace Route entry to which a probe result belongs.                                                                                             |
| <b>TestName</b>   | Specifies the test name.                                                                                                                                      |
| <b>Index</b>      | Specifies the Index.                                                                                                                                          |
| <b>HopIndex</b>   | Indicates for which hop in a traceroute path the probe results are intended.                                                                                  |
| <b>ProbeIndex</b> | Specifies the index of a probe for a particular hop in a traceroute path.                                                                                     |
| <b>HAddrType</b>  | Specifies the IP address type of the hop to which this probe belongs.                                                                                         |
| <b>HAddr</b>      | Specifies the IP address of the hop to which this probe belongs.                                                                                              |
| <b>Response</b>   | Specifies the cumulative results at any time.                                                                                                                 |
| <b>Status</b>     | Specifies the status of the probe.                                                                                                                            |
| <b>LastRC</b>     | When a new entry is added, the old entry is purged if the total number of entries exceeds the specified maximum number of entries in the Control Table Entry. |
| <b>Time</b>       | Specifies the response time of the probe.                                                                                                                     |

*Configure I-SID Monitoring*

Use the following procedure to configure Fabric RSPAN on the Backbone Edge Bridge (BEB) connected to the monitor station.

**Note**

Do not configure the source of mirrored traffic (mirroring to an I-SID) and the analyzer (monitoring an I-SID) on the same local device with the same I-SID offset. If you require mirroring and monitoring on the same local device, use standard port-based mirroring instead of Fabric RSPAN. Fabric RSPAN mirrors traffic into an I-SID of the SPB Fabric network and monitors traffic on the remote device; the network analyzer resides on the remote monitoring device and not on the same local device.

**Note**

If you change the egress port or egress MLT for a particular session using a CLI command, it overwrites the existing egress port list or egress MLT.

**Procedure**

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **General**.
3. Click the **Monitor-By-ISID** tab.
4. Click **Insert**.
5. Configure the parameters as required.

6. Click **Insert**.
7. To modify mappings, double-click a parameter to view a list of options.
8. Click **Apply**.

### Monitor-By-ISID Field Descriptions

Use the data in the following table to use the **Monitor-By-ISID** tab.

| Name                     | Description                                                                                                                                |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>             | Specifies the entry that contains monitor by I-SID information.                                                                            |
| <b>MonitorIsidOffset</b> | Configures the monitoring I-SID offset value. The offset ID is mapped to the actual monitor I-SID value to which the packets are mirrored. |
| <b>MonitorIsid</b>       | Specifies the actual monitor I-SID value to which packets are mirrored.                                                                    |
| <b>EgressPortList</b>    | Specifies the egress ports to which traffic analyzers connect.                                                                             |
| <b>EgressMltId</b>       | Specifies the egress MLT ID to which traffic analyzers connect.                                                                            |
| <b>MapToVlanId</b>       | Specifies the VLAN ID to map with mirrored traffic on the monitoring node.                                                                 |
| <b>Enable</b>            | Enables or disables monitoring by I-SID.                                                                                                   |

### View and Clear Fabric RSPAN (Mirror to I-SID) Statistics

Use the following procedure to view or clear statistics of the number of packets mirrored into I-SID on the mirroring BEB.

#### Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **General**.
3. Click the **Isid-Mirroring Stats** tab.

### Isid-Mirroring Stats Field Descriptions

Use the data in the following table to use the **Isid-Mirroring Stats** tab.

| Name                   | Description                                                                 |
|------------------------|-----------------------------------------------------------------------------|
| <b>Index</b>           | Specifies the entry that contains Fabric RSPAN statistics information.      |
| <b>MonitorIsid</b>     | Specifies the actual monitor I-SID value to which the packets are mirrored. |
| <b>MirroredPackets</b> | Specifies the number of packets mirrored into I-SID on the mirroring BEB.   |
| <b>ClearStats</b>      | Clears the Fabric RSPAN statistics.                                         |

## General Troubleshooting

### Hardware Troubleshooting

The following sections provide troubleshooting information for common hardware problems.

#### Using Trace to Diagnose Hardware Problems

Use trace to observe the status of a hardware module at a given time.

#### Procedure

1. Enter Privileged EXEC mode:  

```
enable
```
2. Begin the trace operation:  

```
line-card 1 trace level [<Module_ID>]{<0-4>}
```
3. Search the trace for a specific string value:  

```
line-card 1 trace grep {WORD<0-1024>}
```

#### Example

```
Switch:1>enable
```

Begin the trace operation:

```
Switch:1#line-card 1 trace level 67 1
```

Search the trace for a specific string value:

```
Switch:1#line-card 1 trace grep 00-1A-4B-8A-FB-6B
```

#### Variable Definitions

The following table defines parameters for the **line-card 1** command.

| Variable                                        | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>&lt;Module_ID&gt;</i> { <i>&lt;0-4&gt;</i> } | Starts the trace by specifying the module ID and level.<br><i>&lt;Module_ID&gt;</i> specifies the module for the trace. Different hardware platforms support different ID ranges because of feature support differences. To see which module IDs are available on the switch, use the <b>show trace modid-list</b> command or CLI command completion Help.<br><i>&lt;0-4&gt;</i> specifies the trace level from 0-4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose. |
| <i>WORD&lt;0-1024&gt;</i>                       | Performs a string search in the trace.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Troubleshooting USB Viewing Problems

After you insert a USB device in the USB slot, the Linux system automatically detects and mounts the device. If you cannot view files on the device, perform this procedure.

### Note

Not all hardware platforms can use the USB device for additional file storage. Some platforms use the USB as part of the system operation and must never be removed. For more information, see your hardware documentation.

### Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Check the file system:

```
ls /usb/
```

3. Remove a USB device:

- a. Unmount the USB device:

```
usb-stop
```

- b. Wait for the response that indicates it is safe to remove the device.

- c. Physically remove the device.

4. Remove and then reinsert the device.

5. Check the device for errors:

```
dos-chkdisk /usb
```

Run the **dos-chkdisk /usb repair** command, if at the end of the **dos-chkdisk /usb** command output you see:

```
1) Correct
```

```
2) Don't correct
```

6. If errors are detected, then you can reformat the device:

```
dos-format /usb
```

### Caution

If you format the device, you erase all data on the device.

### Example

Check the file system:

```
Switch:1>enable
Switch:1#ls /usb/
Listing Directory /usb/:
drwxr-xr-x 4 0 0 4096 Jan 1 1970 ./
drwxrwxr-x
22 0 0 0 Sep 9 20:22 ../
drwxr-xr-x 2 0 0 4096 Mar 17 16:03 Photos-of-Flash-
drwxr-xr-x 2 0 0 4096 Jun 13 20:56 intflash/
```

Check the device for errors:

```
Switch:1#usb-stop
It is now safe to remove the USB device.
Switch:1#dos-chkdisk /usb
/usr/sbin/fsck.vfat /dev/usb1 -v >& /dev/console dosfsck 2.11a
(05 Mar 2010)
dosfsck 2.11a, 05 Mar 2010, FAT32, LFN
Checking we can access the last sector of the filesystem
Boot sector contents:
System ID "mkdosfs"
Media byte 0xf8 (hard disk)
512 bytes per logical sector
4096 bytes per cluster
32 reserved sectors
First FAT starts at byte 16384 (sector 32)
2 FATs, 32 bit entries
3897344 bytes per FAT (= 7612 sectors)
Root directory start at cluster 2 (arbitrary size)
Data area starts at byte 7811072 (sector 15256)
974240 data clusters (3990487040 bytes)
62 sectors/track, 124 heads
0 hidden sectors
7809178 sectors total
Checking for unused clusters.
Checking free cluster summary.
/dev/usb1: 17 files, 174804/974240 clusters
```

If errors are detected, reformat the disk:

```
Switch:1#dos-format /usb
```

## Software Troubleshooting

This section contains general troubleshooting information for the switch software.

### *Failure to Read Failed Configuration File*

The device can fail to read and load a saved configuration file after it starts. This situation occurs if you enable the factorydefaults boot configuration flag. Configure the flag to false: `no boot config flags factorydefaults`.

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

```
Switch:1(config)# no boot config flags factorydefaults
```

### *No Web Management Interface Access to a Device*

If the device and the PC that runs the web browser are in the same network, you can find that even though other applications, for example, Telnet, can access a particular switch, the web management interface cannot. This situation can occur if the web browser has a proxy server that resolves the www path and returns the reachable IP address to the browser. If no route exists from the proxy server to the device, the HTTP query does not reach the device, and does not receive a response.

To prevent this problem, ensure that if the web browser uses a proxy server, you specify a route from the proxy server to the device.

*Configuration in EDM is not applied using CLI*

In EDM, if you apply configuration that disrupts the connection to the web server, and you do not close the EDM session, you cannot apply the same configuration using CLI. This situation occurs if you, for example, delete the Segmented Management Instance, or the management IP address or the route used to access EDM, and you do not close the EDM session afterwards.

To prevent this issue, you must close the EDM session before you can apply the same configuration using CLI.

## Layer 1 Troubleshooting

---

Use the information in this section to troubleshoot Layer 1 (physical layer) problems.

### Troubleshooting Fiber Optic Links

#### About This Task

You can troubleshoot fiber optic links to ensure that the optical transmitters and receivers operate correctly, and to determine if a receiver is saturated, or does not receive enough power.

To troubleshoot optical links and devices, you can use Digital Diagnostic Monitoring (DDM), as well as published optical specifications.

For more information about transceivers, see [Extreme Optics](#) website.

#### Important

As a best practice, use transceivers documented in [Extreme Optics](#) website, as they have been through extensive qualification and testing. Extreme Networks is not responsible for issues related to third party transceivers.

#### Procedure

1. Measure the transmit power.
2. Compare the measured transmit power with the specified launch power.

The values are similar. If the measured power is far below the specified value, a faulty transmitter is a possible cause.
3. Compare the measured transmit power for the near-end optical device to the measured transmit power for the far-end device.

Large differences can mean that the optical devices are mismatched (that is, -SX versus -LX).
4. Measure the receive power at each end of the link.

5. Compare the receive power to the transmit power.
  - For short fiber links, the transmit and received power are similar (after taking into consideration connection losses).
  - For long fiber links, the transmit and received power are similar (after taking into consideration connection losses and fiber attenuation).

Large differences can mean a damaged fiber or dirty or faulty connectors. Large differences can also mean that the link does not use the right type of fiber (single mode or multimode). If the receiver power is measured to be zero, and the link worked previously, it is probable that the far-end transmitter is not operating or the fiber is broken.

6. Compare the measured receive power for the near-end optical device to the measured receive power for the far-end device.

Large differences could mean that the optical devices are mismatched (that is, -SX versus -LX). If optical devices are mismatched, the receiver can be saturated (overdriven).

7. If a receiver is saturated but still operable, install a suitable attenuator.

For long-haul optical devices, the receive power must be significantly less than the transmit power.
8. To help debug the link, loop back the local transmit and receive ports, and use the DDM parameters to help determine the fault.

## Reset a QSFP+ or QSFP28 Transceiver

Reset a transceiver to simulate removal and reinsertion of the transceiver, which can be helpful in troubleshooting. For example, if authentication of the transceiver fails but you believe the transceiver is a qualified Extreme Networks part, you can reset the transceiver to begin the authentication process again.

### About This Task

Resetting the transceiver stops traffic and triggers log messages similar to the removal and insertion of the transceiver.

### Before You Begin

- Before you use the **pluggable-optical-module reset** command, ensure the port is administratively down to avoid link flaps.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Reset the transceiver:

```
pluggable-optical-module reset {slot/port[/sub-port]}
```

#### Important

Not all hardware platforms support these port types. For more information, see your hardware documentation.

*Examples*

```

Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#pluggable-optical-module reset 1/41
Switch:1(config)#

*Variable Definitions*

The following table defines parameters for the **pluggable-optical-module reset** command.

| Variable                            | Value                                                                                                                                                                                                                        |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port]}</code> | Specifies location of the transceiver to reset. Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Layer 2 and 3 Troubleshooting

---

### Troubleshooting BPDU Guard

The following procedures provide information to troubleshoot issues with Bridge Protocol Data Unit (BPDU) Guard.

#### *No Packets Received on the Port*

For BPDU Guard to work on a port, the port must receive BPDU packets. Perform the following procedure to troubleshoot cases when the port does not receive packets.

#### **Procedure**

1. Enter Privileged EXEC mode:  
enable

2. Show the BPDU Guard status for the port:

```
show spanning-tree bpduguard {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
```

3. Use the following command to verify that the port receives packets:

```
show interface gigabitEthernet statistics verbose {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
```

4. Verify that the remote port is sending packets:

```
show spanning-tree {mstp|rstp} port role [{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
```

```
show spanning-tree {mstp|rstp} port statistics [{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
```

**Example**

Port 1/8 receives packets. The remote port is disabled and does not send BPDU packets.

The following example shows that BPDU Guard is enabled for port 1/8. The BPDU Guard administrative state for the port is enabled but the timer counter is 0.

```

### Variable Definitions

Use the data in the following table to use the **show spanning-tree bpduguard** command.

| Variable                                                     | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

Use the data in the following table to use the **show interface gigabitEthernet statistics verbose** command.

| Variable                                                     | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

Use the data in the following table to use the **show spanning-tree** command.

| Variable                                                     | Value                                                                                                                                                                                                                                                                                                                                                         |

| <i>{mstp rstp}</i>                                           | Specifies the spanning tree protocol.                                                                                                                                                                                                                                                                                                                         |
| <i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Troubleshooting IPv6 VRRP

The following sections describe troubleshooting information for IPv6 Virtual Router Redundancy Protocol (VRRP).

### VRRP Transitions

When a VRRP transition takes place with the backup taking over as the master, look for the following message in the syslog on the new master, as well as the old master. This message provides information to allow you to determine the cause of the transition.

IPv6 Vrrp State Transition Trap(Port/Vlan=200, Type=masterToInitialize, Cause=shutdownReceived, VrId=20,VrIpAddr=fe80:0:0:0:0:0:0:200, Addr=fe80:0:0:0:224:7fff:fe9d:1a03)

In this message, see the Type and Cause fields.

**Note**

Although all of the possible causes and types are listed below, the system does not display all of the listed causes and types in the trap/log message.

The following table describes the VRRP transition types.

**Table 240: Transition type**

| Type value | Type definition         |
|------------|-------------------------|
| 1          | None                    |
| 2          | Master to backup        |
| 3          | Backup to master        |
| 4          | Initialize to master    |
| 5          | Master to initialize    |
| 6          | Initialize to backup    |
| 7          | Backup to initialize    |
| 8          | Backup to backup master |
| 9          | Backup master to backup |

The following table describes the VRRP transition causes.

**Table 241: Transition cause**

| Cause value | Cause definition                                                            |
|-------------|-----------------------------------------------------------------------------|
| 1           | None                                                                        |
| 2           | Higher priority advertisement received                                      |
| 3           | Shutdown received                                                           |
| 4           | VRRP address and physical address match                                     |
| 5           | Master down interval                                                        |
| 6           | Preemption                                                                  |
| 7           | Critical IP goes down                                                       |
| 8           | User disabling VRRP                                                         |
| 9           | VRRP status synced from primary                                             |
| 10          | IPv6 interface on which VRRP is configured goes down                        |
| 11          | Lower priority advertisement received                                       |
| 12          | Advertisement received from higher interface IP address with equal priority |

**Table 241: Transition cause (continued)**

| Cause value | Cause definition                                                           |
|-------------|----------------------------------------------------------------------------|
| 13          | Advertisement received from lower interface IP address with equal priority |
| 14          | User enabled VRRP                                                          |
| 15          | Transition because of any other cause                                      |

### *Enabling Trace Messages for IPv6 VRRP Troubleshooting*

Use this procedure to enable trace messages for IPv6 VRRP.

When VRRP is enabled on two routing switches, the master-backup relationship forms with one router taking the responsibility of routing. If the master-backup relationship is not formed between the VRRP virtual routers, look for the following trace messages to ensure that the master is sending the advertisements correctly and the backup is processing them.

#### **Procedure**

1. Enter Privileged EXEC mode:  
`enable`
2. To troubleshoot IPv6 VRRP, you can enable RCIP6 trace messages with the command:  
`trace level 66 3`
3. And to provide additional trace information, you can also enable the following traces:  
`trace ipv6 nd enable`  
`trace ipv6 base enable all`  
`trace ipv6 forwarding enable all`  
`trace ipv6 rtm enable all`  
`trace ipv6 transport enable all`

4. When VRRP is enabled on two routing switches, the master-backup relationship forms with one router taking the responsibility of routing. If the master-backup relationship is not formed between the VRRP virtual routers, look for the following trace messages to ensure that the master is sending the advertisements correctly and the backup is processing them. On the master router, look for the following RCIP6 trace messages.

- tMainTask RCIP6: rcip6\_vrrp.c: 5118: VRF name: GlobalRouter (VRF id 0): ipv6VrrpTic: Am Master for Vrid 200 on IfIndex 2053 Timer 1

If VRRP is enabled on the interface, this timer kicks off every second and shows the state for the VRID.

- [11/18/09 15:08:20:383] tMainTask RCIP6: rcip6\_vrrp.c: 5924: ipv6VrrpSendAdvertisement: for Vrid 200 on IfIndex 2053

```
[11/18/09 15:08:20:583] tMainTask RCIP6: rcip6_vrrp.c: 5175: VRF
name: GlobalRouter (VRF id 0): ipv6VrrpTic:
ipv6VrrpSendAdvertisement
```

The preceding trace messages show that the VRRP master is sending the advertisements correctly at the end of advertisement interval for a VRID.

5. On the backup router, look for the following RCIP6 trace messages.

- tMainTask RCIP6: rcip6\_vrrp.c: 5236: VRF name: GlobalRouter (VRF id 0): ipv6VrrpTic: Am Backup for Vrid 200 on IfIndex 2052 Timer 1
- tMainTask RCIP6: rcip6\_vrrp.c: 4854: ipv6VrrpIn: Vrid 200 on IfIndex 2052
- tMainTask RCIP6: rcip6\_vrrp.c: 5545: VRF name: GlobalRouter (VRF id 0): rcIpVrrpProcessAdvt: Am backup for Vrid 200 on IfIndex 2052

The preceding trace messages show that the backup router is receiving the advertisements sent by the master and correctly processing them.

### *Risks Associated with Enabling Trace Messages*

When traces are enabled on VRRP master, VrrpTic messages are logged for every second and any other configured traces keep displaying, so there is no guarantee that the backup will receive the advertisement from the master within 3 seconds, so it can transit to master also. There is also the risk of toggling of VRRP states (from backup to master and back again).

Enable the limited traces based on whichever is required.

### *VRRP with Higher Priority Running as Backup*

The VRRP router with the higher priority can display as the backup for the following reasons

- Hold-down timer is running.
- The configured Critical IP is not reachable or does not exist.

If the critical-IP is configured for VRRP master, and the critical interface goes down or is deleted, the master transitions to the backup state. In this case, the log shows the transition cause as 1 like many other cases.

If the holddown timer is configured for VRRP master, the holddown timer delays the preemption, giving the device, which is becoming the master enough time to construct routing tables.

### Procedure

- To determine that the issue is with the critical interface, look for the following trace message.  

```
tMainTask RCIP6: rcip6_vrrp.c: 5152: VRF name: GlobalRouter (VRF id 0): ipv6VrrpTic: Becoming backup for Vrid 200 on IfIndex 2052 because of invalid critical IP
```
- If the holddown Timer is configured for VRRP master, the holddown timer delays the preemption, giving the device, which is becoming the master enough time to construct routing tables.  

```
tMainTask RCIP6: rcip6_vrrp.c: Enter in HoldDown processing,Vrid 200 LastRecvd 0 MasterDown 3, Holddown time remaining 970, Holddownstate 2
```

## Troubleshooting RSMLT

The following sections provide information for troubleshooting IPv4 Split Multi-Link Trunking (RSMLT).

### *RSMLT Peers Not Up*

If, after a series of reconfigurations, RSMLT peers do not transition to the up state, use the following procedure to troubleshoot the issue. You can observe this issue on dual-stack VLANs after multiple delete and re-adds of IPv4 interfaces.

### Procedure

- Display the RSMLT configuration. This command shows whether the peers are up:  

```
show ip rsmlt peer
```
- Enter VLAN Interface Configuration mode:  

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```
- To recover the peers if they are down, disable and reenble RSMLT on both IST peers:  

```
no ip rsmlt
```

```
ip rsmlt
```
- If the problem persists, boot from a saved configuration.

### Example

Display the RSMLT configuration:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 1
Switch:1(config-if)#show ip rsmlt peer
```

```
=====
Ip Rsmlt Peer Info - GlobalRouter
=====
```

```

VID IP MAC ADMIN OPER HDTMR HUTMR

2 198.51.100.1 00:1b:ca:1d:e3:1d Enable Up 60 180

VID HDT REMAIN HUT REMAIN SMLT ID

1 60 180 10
2 60 180 10, 16

VID IPv6 MAC ADMIN OPER HDTMR HUTMR

VID HDT REMAIN HUT REMAIN SMLT ID

Switch:1(config-if)#no ip rsmlt
Switch:1(config-if)#ip rsmlt

```

*Enabling Trace Messages for RSMLT Troubleshooting*

Use the following procedure to obtain additional RSMLT-related information.

**Procedure**

If the preceding information does not resolve the issue, you can use the following command to obtain additional RSMLT-related information:

```
trace level 173 4
```

**Important**

Enabling this trace on a loaded system can slow down the CPU, especially if executed through the console. Use Telnet if possible.

**Troubleshooting IPv6 Connectivity Loss**

If the switch experiences loss of IPv6 connectivity, use the following procedure to troubleshoot the issue.

**Procedure**

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Through the command line interface, make sure the required routes are in place and the corresponding neighbor entries are resolved (that is, in REACHABLE, PROBE, DELAY or STALE state).

3. INCOMPLETE neighbor state indicates a problem if the corresponding neighbor is used by some of the IPv6 routes. This applies to neighbor entries with link-local addresses.

**Note**

Global addresses are not normally used as next hops. Having a global IPv6 neighbor entry as INCOMPLETE does not usually lead to a connectivity issue.

4. If the corresponding route is not in place then this is a routing issue. If the neighbor is not present or is INCOMPLETE, then further debugging is needed on the network level (that is, the state of other nodes needs to be examined).
5. Disabling and re-enabling IPv6 on the VLAN often recovers connectivity.
6. Display the RSMLT and MLT status:

```
show ip rsmlt
```

```
show mlt
```

Make sure the RSMLT peer MAC is learned and the IST state is `ist`.

## Troubleshooting vIST Failure

### About This Task

When you use Virtual Inter-Switch Trunk (vIST), all critical network traffic runs on this link. If vIST fails, network protocols such as RIP, VRRP, OSPF, and VLACP go down and eventually cause a network outage.

vIST uses an SPBM tunnel to virtually connect two nodes that can be anywhere in the SPBM cloud. Even if the two vIST nodes are directly connected by an MLT link, the vIST VLAN does not have MLT ports as members. Instead, it is configured to be an SPBM C-VLAN.

**Note**

For more information on vIST and a configuration example, see [MultiLink Trunking and Split MultiLink Trunking](#) on page 1988.

The vIST tunnel is up as long as there is SPBM connectivity between the IST peers. If there is a vIST failure, check the following procedure for some possible reasons:

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Verify that the vIST VLAN is configured on the vIST switch:

```
show virtual-ist
```

3. Verify that an I-SID is associated with the vIST VLAN:

```
show isis spbm i-sid discover
```

#### Important

The I-SID associated with the vIST VLAN should be the same on the vIST peer, and this I-SID should not be used anywhere else in the network.

4. Verify that the vIST peers are on the same subnet.
5. If peer ARP is not resolved, enable **trace level 14** to see if ARP request/response are being sent/received.
6. If vIST is not up, check the **mac fdb table** and verify that the peer MAC is synchronized:
 

```
show vlan mac-address-entry <1-4059>
```
7. If the vIST peer MAC is learned, check to see if the peer IP address is reachable.
  - a. Use **show virtual-ist** to obtain the vIST peer IP address.
  - b. Ping the peer IP address.
8. If unable to **ping** the peer IP address, check to see if ARP is resolved.

```
show ip arp vlan <vid>
```

## Multicast Troubleshooting

Use the following information to troubleshoot multicast features and multicast routing.

### *Multicast Feature Troubleshooting*

Use the information in this section to troubleshoot multicast feature problems.

#### **Troubleshooting IGMP Layer 2 Querier**

The following sections provide troubleshooting information for the IGMP Layer 2 Querier feature.

##### Querier Not Elected

If a Querier is not elected, use the following procedure to troubleshoot the issue.

#### **Procedure**

1. Enter Privileged EXEC mode:
 

```
enable
```
2. As the IGMP Layer 2 Querier is based on IGMP snoop, check whether IGMP snoop is enabled on the VLAN:
 

```
show ip igmp interface vlan
```

If IGMP snoop is disabled, the Layer 2 Querier cannot work until IGMP snoop and IGMP Layer 2 Querier are reenabled.

#### **Example**

Check whether IGMP snoop is enabled on the VLAN:

```
Switch:1>enable
Switch:1#show ip igmp interface vlan
```

```

### Enable Trace Messages for IGMP Layer 2 Querier Troubleshooting

If the preceding information does not address your issue, you can also use the following trace command to view additional information related to Layer 2 querier.

#### Caution

Using the trace tool inappropriately can cause primary CPU lockup conditions, loss of access to the device, loss of protocols, and service degradation. If you use trace level 3 (verbose) or trace level 4 (very verbose), do not use the screen to view commands due to the volume of information the system generates and the effect on the system.

#### Procedure

1. Enter Privileged EXEC mode:  

```
enable
```
2. Use the following trace command to begin the trace operation for additional information related to Layer 2 querier:  

```
trace level 23 <1-4>
```
3. Stop tracing:  

```
trace shutdown
```

4. View the trace results:  

```
trace screen enable
```
5. View trace saved to a file:  

```
show trace file [tail]
```

Variable Definitions

Use the data in the following table to use the **trace** command.

| Variable                                 | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>level</i><br>[<Module_ID>]<br>[<1-4>] | Starts the trace by specifying the module ID and level. Module ID 23 represents the IGMP module<br><Module_ID> specifies the module for the trace. Different hardware platforms support different ID ranges because of feature support differences. To see which module IDs are available on the switch, use the <b>show trace modid-list</b> command or CLI command completion Help.<br><0-4> specifies the trace level: <ul style="list-style-type: none"> <li>• 0 – Disabled</li> <li>• 1 – Very terse</li> <li>• 2 – Terse</li> <li>• 3 – Verbose</li> <li>• 4 – Very verbose</li> </ul> |
| <i>shutdown</i>                          | Stops the trace operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>screen {disable enable}</i>           | Enables or disables the display of trace output to the screen.<br><br><b>Important:</b><br>Avoid using the screen to view commands if you use trace level 3 (verbose) or trace level 4 (very verbose) due to the volume of information generated and the effect on the system.                                                                                                                                                                                                                                                                                                               |

Use the data in the following table to use the **show trace** command.

| Variable           | Value                                             |
|--------------------|---------------------------------------------------|
| <i>file [tail]</i> | Displays the trace results saved to a file.       |
| <i>level</i>       | Displays the current trace level for all modules. |
| <i>modid-list</i>  | Specifies the module ID list.                     |

**Troubleshoot IGMPv3 Backwards Compatibility**

If you configure the switch to operate in v2-v3 compatibility mode, the switch supports all IGMPv2 and v3 messages. The switch parses the group address of the messages. If the group address is out of SSM range and it is a v3 message, the switch drops the message. If it is a v2 message, IGMP snoop processes handle the message.

To troubleshoot issues with the IGMPv3 backwards compatibility feature, perform the following procedure.

**Procedure**

1. Enter Privileged EXEC mode:  
enable
2. Verify that the SSM static channel is configured for the v1/v2 joins received. Display the configured SSM static channels:  
show ip igmp ssm-map
3. Verify that the SSM group range is configured for the v1/v2 joins received. Display the configured SSM group range:  
show ip igmp ssm

**Example**

Display the configured SSM static channels and display the configured SSM group range:

```
Switch:1#show ip igmp ssm-map
=====
 Igmp Ssm Channel - GlobalRouter
=====

*Multicast Routing Troubleshooting Using CLI***View IGMP Interface Information**

Perform this procedure to view the IGMP interface table.

**About This Task**

If an interface does not use an IP address, the system does not display it in the IGMP table. One exception is an IGMP snooping interface, which does not require an interface IP address.

If an interface uses an IP address, but neither IGMP snoop or PIM is enabled, the system displays the interface as inactive in the Status field.

**Procedure**

1. Enter Privileged EXEC mode:  

```
enable
```
2. View IGMP interfaces:  

```
show ip igmp interface [gigabitethernet {slot/port[/sub-port]}[-slot/port[/sub-port]][,...]|vlan <1-4059>] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

**Example**

View IGMP interfaces:

```
Switch:1#show ip igmp interface
=====
 Icmp Interface - GlobalRouter
=====

Variable Definitions

The following table defines parameters for the **show ip igmp interface** command.

| Variable                                                                    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>gigabitethernet {slot/port[/sub-port]}[-slot/port[/sub-port]] [,...]</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. If you do not specify a slot and port, the command output includes all IGMP interfaces.                                                        |
| <i>vlan &lt;1-4059&gt;</i>                                                  | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. If you do not specify a VLAN ID, the command output includes all IGMP interfaces. |
| <i>vrf WORD &lt;1-16&gt;</i>                                                | Optionally, identifies the VRF name. If you do not specify a VRF name, the results display information for the Global Router. If you specify a VRF name, the results display information only for the VRF you specify.                                                                                                                                                                                                                                                                                       |
| <i>vrfids WORD &lt;0-512&gt;</i>                                            | Optionally, identifies the VRF ID. If you do not specify a range of VRF IDs, the results display information for the Global Router. If you specify a VRF ID or range of VRF IDs, the results display information only for the VRF you specify.                                                                                                                                                                                                                                                               |

**View Multicast Group Trace Information for IGMP Snoop**

## About This Task

Multicast group trace tracks the data flow path of the multicast streams.

## Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display the multicast group trace for an IGMP snoop-enabled interface:  
show ip igmp snoop-trace [source {A.B.C.D}] [group {A.B.C.D}]

## Example

Display the multicast group trace for an IGMP snoop-enabled interface:

```
Switch:1# show ip igmp snoop-trace
```

```
=====
 Snoop Trace - GlobalRouter
=====
```

| GROUP ADDRESS | SOURCE ADDRESS | IN VLAN | IN PORT | OUT VLAN | OUT PORT | TYPE   |
|---------------|----------------|---------|---------|----------|----------|--------|
| 233.252.0.1   | 192.0.2.6      | 500     | 1/1     | 500      | 1/5      | ACCESS |
| 233.252.0.10  | 192.0.2.7      | 500     | 1/1     | 500      | 1/10     | ACCESS |

## Variable Definitions

The following table defines parameters for the **show ip igmp snoop-trace** command.

| Variable                | Value                                                  |
|-------------------------|--------------------------------------------------------|
| <i>group {A.B.C.D}</i>  | Specifies the group IP address in the format a.b.c.d.  |
| <i>source {A.B.C.D}</i> | Specifies the source IP address in the format a.b.c.d. |

## View IGMP Group Information

View information about IGMP groups to see the current group operation on the switch.

## Procedure

1. Enter Privileged EXEC mode:  
enable
2. View IGMP group information:  
show ip igmp group group <A.B.C.D> detail [port {slot/port[/sub-port]} [-slot/port[/sub-port]][,...]] [vlan <1-4059>] [vrf WORD <1-16>] [vrfids WORD <0-512>]  
  
show ip igmp group group <A.B.C.D> tracked-members [member-subnet <A.B.C.D./X>] [port {slot/port[/sub-port]} [-slot/port[/sub-port]][,...]] [source-subnet <A.B.C.D./X>] [vlan <1-4059>] [vrf WORD <1-16>] [vrfids WORD <0-512>]

**Example**

View IGMP group information:

```
Switch:1>enable
Switch:1#show ip igmp group group 232.0.0.0

=====
 Igmp Group - GlobalRouter

The following table defines parameters for the **show ip igmp group group <A.B.C.D> tracked-members** command.

| Variable                                                                | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>member-subnet {default   &lt;A.B.C.D&gt;}</code>                  | Specifies the IP address and mask of the IGMP member.                                                                                                                                                                                                                                                                                                                                                                      |
| <code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Specifies the port list.                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>source-subnet &lt;A.B.C.D/X&gt;</code>                            | Specifies the source IP address and the subnet mask.                                                                                                                                                                                                                                                                                                                                                                       |
| <code>vlan &lt;1-4059&gt;</code>                                        | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <code>vrf WORD&lt;1-16&gt;</code>                                       | Specifies the VRF name.                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>vrfids WORD&lt;0-512&gt;</code>                                   | Specifies the VRF ID.                                                                                                                                                                                                                                                                                                                                                                                                      |

### Determine the Data Stream Learned with IP Multicast over Fabric Connect on the VLAN

Use this procedure to determine the data stream learned when IP Multicast over Fabric Connect is configured on the VLAN.

#### About This Task

The following section shows sample output for the **show ip mroute route** command.

In this table, every stream uses one (\*,G) entry and x (S,G) entries, depending on how many servers forward traffic to the same group.

The 0.0.0.0 mask is always tied to a (\*,G) entry.

If you do not specify a VRF name or range of VRF IDs, the results display information for the Global Router. If you do specify a VRF name or range of VRF IDs, the results display information only for the VRFs you specify.

#### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Determine the data stream learned:

```
show ip mroute route [vrf WORD <0-32>] [vrfids <0-255>]
```

#### Example

Determine the data stream learned:

```
Switch:1>show ip mroute route

=====
Mroute Route - GlobalRouter
=====
GROUP SOURCE SRCMASK UPSTREAM_NBR IF EXPIR PROT

233.252.0.1 0.0.0.0 0.0.0.0 0.0.0.0 V3 30 spb-access
233.252.0.1 192.0.2.102 255.255.255.0 0.0.0.0 - 0 spb-network
233.252.0.2 0.0.0.0 0.0.0.0 0.0.0.0 V2 30 pimsm
225.1.1.1 198.51.100.99 255.255.255.0 0.0.0.0 V3 173 spb-pim-gw

Total 4
```

#### Variable Definitions

The following table defines parameters for the **show ip mroute route** command.

| Variable                          | Value                   |
|-----------------------------------|-------------------------|
| <code>vrf WORD&lt;0-32&gt;</code> | Specifies the VRF name. |
| <code>vrfids &lt;0-255&gt;</code> | Specifies the VRF ID.   |

### Display the SPBM Multicast Database

You can determine the database used by the SPBM multicast module by using the following procedure.

#### Procedure

1. To enter User EXEC mode, log on to the switch.

2. Show the SPBM multicast database:

```
show isis spbm ip-multicast-route [all][detail][group {A.B.C.D}][vlan
<2-4059>][vrf WORD<0-16>][vsn-isid <1-16777215>]
```

### Important

When you use this command without parameters or use the detail or group optional parameters without specifying a VLAN ID or VSN I-SID, the command output displays Layer 3 context only. No Layer 2 context is displayed.

### Example

Show the SPBM multicast database:

```
Switch(config)#show isis spbm ip-multicast-route

=====
 SPBM IP-MULTICAST FIB ENTRY INFO
=====
Source Group Data ISID BVLAN Source-BEB

192.2.0.1 233.252.0.246 16000001 101 EVP

Total Number of SPBM IP MULTICAST ROUTE Entries: 1

```

### Variable Definitions

The following table defines parameters for the **show isis spbm ip-multicast-route** command.

| Variable                                          | Value                                                                                                                                                         |
|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>all</i>                                        | Displays all IP Multicast over Fabric Connect route information.                                                                                              |
| <i>detail</i>                                     | Displays detailed IP Multicast over Fabric Connect route information.                                                                                         |
| <i>group {A.B.C.D}</i><br><i>source {A.B.C.D}</i> | Displays information on the group IP address for the IP Multicast over Fabric Connect route. If you select source it will also display the source IP address. |
| <i>vlan &lt;2-4059&gt;</i>                        | Displays IP Multicast over Fabric Connect route information by VLAN.                                                                                          |
| <i>vrf WORD&lt;0-16&gt;</i>                       | Displays IP Multicast over Fabric Connect route information by VRF.                                                                                           |
| <i>vsn-isid &lt;1-16777215&gt;</i>                | Displays IP Multicast over Fabric Connect route information by I-SID.                                                                                         |

### Troubleshoot IP Multicast over Fabric Connect for Layer 2 VSNs

If traffic is not moving properly, use the following procedure to determine the issue.

#### Procedure

1. Enter Privileged EXEC mode:
 

```
enable
```
2. Ensure that all switch nodes in the network operate with the most recent software release to support IP Multicast over Fabric Connect:
 

```
show software
```

3. If any ERS 8800 nodes exist in the network, ensure you upgrade them to the current release:  
`show software`
4. Ensure that you create and enable SPBM infrastructure globally.
  - a. Ensure that SPBM is enabled globally:  
`show spbm`
  - b. Ensure that IS-IS is enabled globally:  
`show isis`
  - c. Ensure an SPBM instance exists and at least one Backbone VLAN exists (B-VID). Also ensure multicast is enabled:  
`show isis spbm`
5. Ensure that you enable the CFM configuration.
  - a. Ensure a CFM maintenance-association exists:  
`show cfm maintenance-association`
  - b. Ensure a CFM maintenance-domain exists:  
`show cfm maintenance-domain`
  - c. Ensure a maintenance-endpoint exists in the MEP ID column and is enabled in the ADMIN column:  
`show cfm maintenance-endpoint`
6. Ensure a Customer VLAN (C-VLAN) exists and ensure you add UNI ports to the C-VLAN.
  - a. Display C-VLAN information:  
`show vlan i-sid`
  - b. Display ports for the C-VLAN:  
`show vlan members port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}`
  - c. Display NNI and UNI receivers:  
`show isis spbm ip-multicast-route detail`
7. Ensure that you assign the same I-SID to the C-VLAN on all of the BEBs where you configure the C-VLAN:  
`show vlan i-sid`
8. Ensure that you enable IP Multicast over Fabric Connect globally:  
`show isis spbm`
9. Ensure the you enable IGMP Snooping on the C-VLAN on all of the Backbone Edge Bridges (BEBs). Ensure the protocol configured on the VLAN added is snoop-spb in the MODE column, which indicates IGMP is enabled on a VLAN with an associated I-SID (IP Multicast over Fabric Connect for a Layer 2 VSN):  
`show ip igmp interface`
10. Ensure that you enable IGMP Snooping on access Layer 2 switches to prevent flooding of multicast traffic to non-receiver ports:  
`show ip igmp snoop-trace`  
`show ip igmp interface`

11. Ensure that the IGMP version used by the multicast hosts and the Layer 2 switches outside the SPBM network is the same as the IGMP version configured on the C-VLAN:

```
show ip igmp interface
```

### Troubleshooting IP Multicast over Fabric Connect for Layer 3 VSNs

If traffic is not moving properly, use the following procedure to determine the issue.

#### Procedure

1. Ensure that all switch nodes in the network operate with the most recent software release to support IP Multicast over Fabric Connect:

```
show software
```

2. If ERS 8800 nodes exist in the network, ensure you upgrade them to the current release:

```
show software
```

3. Ensure that you create and enable SPBM infrastructure globally.

- a. Ensure that SPBM is enabled globally:

```
show spbm
```

- b. Ensure that IS-IS is enabled globally:

```
show isis
```

- c. Ensure an SPBM instance exists with at least one Backbone VLAN (B-VID). Also ensure multicast is enabled:

```
show isis spbm
```

4. Ensure that you enable the CFM configuration.

- a. Ensure a CFM maintenance-association exists:

```
show cfm maintenance-association
```

- b. Ensure a CFM maintenance-domain exists:

```
show cfm maintenance-domain
```

- c. Ensure a maintenance-endpoint exists in the MEP ID column and is enabled in the ADMIN column:

```
show cfm maintenance-endpoint
```

5. Ensure the following on all the Backbone Edge Bridges (BEBs) where the Layer 3 VSN is present.

- a. Ensure that you enable IP multicast globally:

```
show isis spbm
```

- b. Ensure that you create an IPVPN for the VRF:

```
show ip ipvpn [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

- c. Ensure that you assign an I-SID to the VRF:

```
show isis spbm ip-multicast-route all
```

- d. Ensure that you enable the MVPN:

```
show ip vrf mvpn
```

6. On the VLANs that need Layer 3 VSN IP Multicast over Fabric Connect routing, create an IP interface on the VLAN if one does not exist. The address should be on the same subnet as the IGMP hosts connected to the VLAN. Also, ensure that you enable IP Multicast over Fabric Connect.

7. Enter VLAN Interface Configuration mode:  

```
enable

configure terminal

interface vlan <1-4059>
```
8. Create an IP interface on the VLAN and enable IP Multicast over Fabric Connect:  

```
ip address <A.B.C.D>

ip spb-multicast enable
```
9. Ensure that you enable IGMP Snooping on access Layer 2 switches to prevent flooding of multicast traffic to non-receiver ports:  

```
show ip igmp snoop-trace

show ip igmp interface
```
10. Ensure that the IGMP version used by the multicast hosts and the Layer 2 switches outside the SPBM network is the same as the IGMP version configured on the C-VLAN:  

```
show ip igmp interface
```

### Troubleshooting IP Multicast over Fabric Connect for IP Shortcuts

If traffic is not moving properly, use the following procedure to determine the issue.

#### Procedure

1. Ensure that all switch nodes in the network operate with the most recent software release to support IP Multicast over Fabric Connect:  

```
show software
```
2. Ensure that all ERS 8800 nodes in the network have the current release:  

```
show software
```
3. Ensure that you create and enable SPBM infrastructure globally.
  - a. Ensure that SPBM is enabled globally:  

```
show spbm
```
  - b. Ensure that IS-IS is enabled globally:  

```
show isis
```
  - c. Ensure an SPBM instance exists and at least one Backbone VLAN exists (B-VID). Also ensure multicast is enabled:  

```
show isis spbm
```
4. Ensure that you enable the CFM configuration.
  - a. Ensure a CFM maintenance-association exists:  

```
show cfm maintenance-association
```
  - b. Ensure a CFM maintenance-domain exists:  

```
show cfm maintenance-domain
```
  - c. Ensure a maintenance-endpoint exists in the MEP ID column and is enabled in the ADMIN column:  

```
show cfm maintenance-endpoint
```

5. Ensure the following on all BEBs where you want IP Multicast over Fabric Connect. Ensure that you enable IP Multicast over Fabric Connect globally:
 

```
show isis spbm
```
6. On the VLANs that need Layer 3 VSN IP Multicast over Fabric Connect routing, create an IP interface on the VLAN if one does not exist. The address should be on the same subnet as the IGMP hosts connected to the VLAN. Also, ensure that you enable IP Multicast over Fabric Connect. Create an IP interface on the VLAN and enable IP Multicast over Fabric Connect.
7. Enter VLAN Interface Configuration mode:
 

```
enable

configure terminal

interface vlan <1-4059>
```
8. Create an IP interface on the VLAN and enable IP Multicast over Fabric Connect:
 

```
ip address <A.B.C.D>

ip spb-multicast enable
```
9. Ensure that you enable IGMP Snooping on access Layer 2 switches to prevent flooding of multicast traffic to non-receiver ports:
 

```
show ip igmp snoop-trace

show ip igmp interface
```
10. Ensure that the IGMP version used by the multicast hosts and the Layer 2 switches outside the SPBM network is the same as the IGMP version configured on the C-VLAN:
 

```
show ip igmp interface
```

## View the Hardware Resource Usage

### About This Task

The switch can query the number of ingress and egress IP multicast streams traversing the switch. After you configure the thresholds for ingress and egress records, if the record-usage goes beyond the threshold, the device notifies you by way of a trap on the console, logged message, or both.

If you do not configure the thresholds, the switch displays only the ingress and egress records currently in use.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Show the hardware resource usage:

```
show ip mroute hw-resource-usage
```

### Example

Show the hardware resource usage:

```
Switch:1>show ip mroute hw-resource-usage
=====
 Multicast Hardware Resource Usage
=====
```

|            |            |           |           |         |           |           |
|------------|------------|-----------|-----------|---------|-----------|-----------|
| EGRESS     | INGRESS    | EGRESS    | INGRESS   | LOG MSG | SEND TRAP | SEND TRAP |
| REC IN-USE | REC IN-USE | THRESHOLD | THRESHOLD | ONLY    | ONLY      | AND LOG   |
| -----      |            |           |           |         |           |           |

**Using PIM Debugging Commands**

Use Protocol Independent Multicast (PIM) traces to aid in PIM troubleshooting.

**Procedure**

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Start debug trace message output:  

```
debug ip pim pimdbgtrace
```
3. Stop debug trace message output:  

```
no debug ip pim pimdbgtrace
```

```
default debug ip pim pimdbgtrace
```
4. Configure the system to display trace messages forwarded by the device:  

```
debug ip pim send-dbg-trace
```
5. Stop the system from displaying trace messages forwarded by the device:  

```
no debug ip pim send-dbg-trace
```

```
default debug ip pim send-dbg-trace
```
6. Configure the system to display trace messages received by the device:  

```
debug ip pim rcv-dbg-trace
```
7. Stop the system from displaying trace messages received by the device:  

```
no debug ip pim rcv-dbg-trace
```

```
default debug ip pim rcv-dbg-trace
```
8. Configure the system to display hello messages forwarded or received by the device:  

```
debug ip pim hello
```
9. Stop the system from displaying hello messages forwarded or received by the device:  

```
no debug ip pim hello
```

```
default debug ip pim hello
```
10. Configure the system to display and log debug trace messages:  

```
debug ip pim pimdbglog
```
11. Stop the system from displaying and logging debug trace messages:  

```
no debug ip pim pimdbglog
```

```
default debug ip pim pimdbglog
```
12. Configure the system to display register messages forwarded or received by the device:  

```
debug ip pim register
```

13. Stop the system from displaying register messages forwarded or received by the device:

```
no debug ip pim register
```

```
default debug ip pim register
```

14. Configure the system to display debug trace messages after an enabled message type, for example, hello or register, is received from a specific sender IP address:

```
debug ip pim source {A.B.C.D}
```

#### Variable Definitions

The following table defines parameters for the **debug ip pim** command.

| Variable                | Value                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------|
| <i>assert</i>           | Displays the assert debug traces. The default is false (disabled).                          |
| <i>bstrap</i>           | Displays bootstrap debug traces. The default is false (disabled).                           |
| <i>group {A.B.C.D}</i>  | Displays debug traces from a specific group IP address. The default is 0.0.0.0 (disabled).  |
| <i>hello</i>            | Displays hello debug traces. The default is false (disabled).                               |
| <i>joinprune</i>        | Displays join and prune debug traces. The default is false (disabled).                      |
| <i>pimdbglog</i>        | Logs debug traces. The default is false (disabled).                                         |
| <i>pimdbgtrace</i>      | Displays PIM debug traces. The default is false (disabled).                                 |
| <i>rcv-dbg-trace</i>    | Displays trace messages received by the switch. The default is false (disabled).            |
| <i>register</i>         | If enabled, the system displays register debug traces. The default is false (disabled).     |
| <i>regstop</i>          | Displays register stop debug traces. The default is false (disabled).                       |
| <i>rp-adv</i>           | Displays RP advertisement debug traces. The default is false (disabled).                    |
| <i>send-dbg-trace</i>   | Displays trace messages forwarded by the switch. The default is false (disabled).           |
| <i>source {A.B.C.D}</i> | Displays debug traces from a specific source IP address. The default is 0.0.0.0 (disabled). |

#### Determine the Protocol Configured on the Added VLAN

Use this procedure to determine the protocol configured on the added VLAN.

The protocol configured on the added VLAN can be one of the following values:

- snoop
- snoop-spb
- route-spb
- pim

**Procedure**

1. Enter Privileged EXEC mode:  
enable
2. Determine the protocol configured on the added VLAN:  
show ip igmp interface [gigabitethernet {slot/port[/sub-port]}[-slot/port[/sub-port]][,...]] [vlan <1-4059>] [vrf WORD<1-16>] [vrfids WORD<0-512>]

The protocol displays under the Mode column of the command output.

**Example**

Determine the protocol configured on the added VLAN:

```
Switch:1#show ip igmp interface
=====
 Icmp Interface - GlobalRouter
=====
IF QUERY OPER QUERY WRONG LASTMEM
INTVL STATUS VERS. VERS QUERIER MAXRSPT QUERY JOINS ROBUST QUERY MODE L2ISID

V100 125 activ 2 2 0.0.0.0 100 0 0 2 10 snoop-spb 1100
1 out of 1 entries displayed
```

Variable Definitions

The following table defines parameters for the **show ip igmp interface** command.

| Variable                                                                     | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>gigabitethernet</i> {slot/port[/sub-port]} [-slot/port[/sub-port]] [,...] | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |
| <i>vlan</i> <1-4059>                                                         | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <i>vrf</i> WORD<1-16>                                                        | Specifies the VRF instance by the VRF name.                                                                                                                                                                                                                                                                                                                                                                                |
| <i>vrfids</i> WORD<0-512>                                                    | Specifies the VRF ID for which to display statistics.                                                                                                                                                                                                                                                                                                                                                                      |

*Multicast routing troubleshooting using EDM*

Use the information in this section to help you troubleshoot multicast routing problems using Enterprise Device Manager (EDM).

### View IGMP Interface Information

Use the Interface tab to view the IGMP interface table. You can use this procedure to determine the protocol configured on the added VLAN.

The protocol configured on the added VLAN can be one of the following values:

- snoop
- pim

### About This Task

If an interface does not use an IP address, the system does not display it in the IGMP table. If an interface uses an IP address, but neither IGMP snoop or PIM is enabled, the system displays the interface as inactive in the Status field.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **IGMP**.
3. Select the **Interface** tab.

### Interface Field Descriptions

Use the data in the following table to use the **Interface** tab.

| Name                        | Description                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>              | Shows the interface where IGMP is enabled.                                                                                                                                                                                                                                                                                                                                  |
| <b>QueryInterval</b>        | Configures the frequency (in seconds) at which the interface transmits IGMP host query packets. The default is 125.                                                                                                                                                                                                                                                         |
| <b>Status</b>               | Shows the IGMP row status. If an interface uses an IP address and PIM-SM is enabled, the status is active. Otherwise, it is notInService.                                                                                                                                                                                                                                   |
| <b>Version</b>              | Configures the version of IGMP (1, 2, or 3) that you want to configure on this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default is version 2.                                                                                                                                                                         |
| <b>OperVersion</b>          | Shows the version of IGMP that currently runs on this interface.                                                                                                                                                                                                                                                                                                            |
| <b>Querier</b>              | Shows the address of the IGMP querier on the IP subnet to which this interface attaches.                                                                                                                                                                                                                                                                                    |
| <b>QueryMaxResponseTime</b> | Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1. Smaller values allow a router to prune groups faster. The default is 100 tenths of a second (equal to 10 seconds).<br><br><b>Important:</b><br>You must configure this value lower than the QueryInterval. |

| Name                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>WrongVersionQueries</b>         | Shows the number of queries received with an IGMP version that does not match the interface. You must configure all routers on a LAN to run the same version of IGMP. If the interface receives queries with the wrong version, this value indicates a version mismatch.                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Joins</b>                       | Shows the number of times this interface added a group membership, which is the same as the number of times an entry for this interface is added to the cache table. This number gives an indication of the amount of IGMP activity over time.                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Robustness</b>                  | Tunes for the expected packet loss of a network. This value is equal to the number of expected query packet losses for each serial query interval, plus 1. If you expect a network to lose query packets, increase the robustness value.<br>The default value of 2 means that the switch drops one query for each query interval without the querier aging out.                                                                                                                                                                                                                                                                                    |
| <b>LastMembQueryIntvl</b>          | Configures the maximum response time (in tenths of a second) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1.<br>Decrease the value to reduce the time to detect the loss of the last member of a group. The range is from 0–255 and the default is 10 tenths of second. As a best practice, configure this parameter to values greater than 3. If you do not need a fast leave process, you can configure values greater than 10. (The value 3 is equal to 0.3 seconds and 10 is equal to 1 second.) |
| <b>OtherQuerierPresent Timeout</b> | Shows the length of time that must pass before a multicast router determines that no other querier exists. If the local router is the querier, the value is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>FlushAction</b>                 | Configures the flush action to one of the following: <ul style="list-style-type: none"> <li>• none</li> <li>• flushGrpMem</li> <li>• flushMrouter</li> <li>• flushSender</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>RouterAlertEnable</b>           | Instructs the router to ignore IGMP packets that do not contain the router alert IP option. If you disable this variable (default configuration), the router processes IGMP packets regardless of the status of the router alert IP option.<br><br><b>Important:</b><br>To maximize network performance, configure this parameter according to the version of IGMP currently in use. <ul style="list-style-type: none"> <li>• IGMPv1—Disable</li> <li>• IGMPv2—Enable</li> <li>• IGMPv3—Enable</li> </ul>                                                                                                                                          |
| <b>SsmSnoopEnable</b>              | Enables SSM snoop.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SnoopQuerierEnable</b>          | Enables IGMP Layer 2 Querier.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Name                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SnoopQuerierAddr</b>           | Specifies the pseudo address of the IGMP snoop querier.                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>ExplicitHostTrackingEnable</b> | Enables or disables IGMPv3 to track hosts for each channel or group. The default is disabled. You must select this field if you want to use fast leave for IGMPv3.                                                                                                                                                                                                                                                                                          |
| <b>McastMode</b>                  | Indicates the protocol configured on the VLAN. <ul style="list-style-type: none"> <li>snoop — Indicates IGMP snooping is enabled on a VLAN.</li> <li>snoop-spb — Indicates IGMP is enabled on a VLAN with an associated I-SID (IP multicast over Fabric Connect for a Layer 2 VSN).</li> <li>pim — Indicates PIM is enabled.</li> <li>routed-spb — Indicates IP multicast over Fabric Connect is enabled on the Layer 3 VSN or for IP Shortcuts.</li> </ul> |
| <b>ExtnUpnpFilterEnable</b>       | Enables Universal Plug and Play (uPnP) Filtering to filter multicast packets destined for a specific range. The default is disabled.                                                                                                                                                                                                                                                                                                                        |
| <b>ExtnUpnpFilterAddress</b>      | Indicates the multicast destination IP address to filter on an IGMP-enabled interface. The default is 239.255.255.250/32.                                                                                                                                                                                                                                                                                                                                   |
| <b>ExtnUpnpFilterAddressMask</b>  | Indicates the IGMP uPnP Filtering IP subnet to which this interface is attached.                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SnoopOrigin</b>                | Specifies the origin of IGMP Snooping configuration on the port. The supported values are: <ul style="list-style-type: none"> <li>config - Set by the user.</li> <li>radius - Set by the Remote Authentication Dial-In User Service (RADIUS) attribute.</li> </ul>                                                                                                                                                                                          |

### Determine the Data Stream Learned when IP Multicast over Fabric Connect is Configured on the VLAN

Use the following procedure to determine the data stream learned when IP multicast is configured on the VLAN.

#### Procedure

1. In the navigation pane, expand **Configuration > IP > Multicast**.
2. Click the **Routes** tab.

### Multicast Field Descriptions

Use the information in the following table to help you use the **Multicast** tab.

| Field         | Description                                                                                                                                                                                             |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Group</b>  | Indicates the IP multicast group for which this entry specifies a next hop on an outgoing interface.                                                                                                    |
| <b>Source</b> | Indicates the network address that, when combined with the corresponding value of ipMRouteNextHopSourceMask, identifies the sources for which this entry specifies a next hop on an outgoing interface. |

| Field                   | Description                                                                                                                                                                                                                                                                                                |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SourceMask</b>       | Indicates the network mask, when combined with the corresponding value of ipMRouteNextHopSource, identifies the sources for which this entry specifies a next hop on an outgoing interface.                                                                                                                |
| <b>UpstreamNeighbor</b> | Indicates the address of the upstream neighbor from which IP datagrams from these sources to this multicast address are received, or 0.0.0.0 if the upstream neighbor is known.                                                                                                                            |
| <b>Interface</b>        | Indicates the value of ifIndex for the interface on which IP datagrams sent by these sources to this multicast address are received. A value of 0 indicates that datagrams are not subject to an incoming interface check, but can be accepted on multiple interfaces (for example, in CBT).               |
| <b>ExpiryTime</b>       | Indicates the minimum amount of time remaining before this entry ages out. The value 0 indicates that the entry is not subject to aging.                                                                                                                                                                   |
| <b>Protocol</b>         | Indicates the outgoing mechanism through which the switch learns this route. For IP Multicast over Fabric Connect, this value is spb-access or spb-network. Spb-access indicates the datastream learned was from the UNI ports. Spb-network indicates that the datastream learned was from the SPBM cloud. |

**Show the SPBM Multicast Database**

Determine the database used by the SPBM multicast module.

**Procedure**

1. In the navigation pane, expand **Configuration > ISIS > SPBM**.
2. Click the **IpMcastRoutes** tab.

IpMcastRoutes field descriptions

Use the data in the following table to use the **IpMcastRoutes** tab.

| Name             | Description                                                                           |
|------------------|---------------------------------------------------------------------------------------|
| <b>Vsnlsid</b>   | Specifies the VSN I-SID. Layer 2 VSN and Layer 3 VSN each require a VSN I-SID.        |
| <b>Group</b>     | Specifies the group IP address for the IP Multicast over Fabric Connect route.        |
| <b>Source</b>    | Specifies the IP address where the IP Multicast over Fabric Connect route originated. |
| <b>NickName</b>  | Specifies the nick name used to filter criteria.                                      |
| <b>SourceBeb</b> | Specifies the source BEB for the IP multicast route.                                  |
| <b>VlanID</b>    | Specifies the ID for the C-VLAN.                                                      |
| <b>VrfName</b>   | Specifies the VRF name.                                                               |

| Name                 | Description                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Datalsid</b>      | Specifies the data I-SID for the IP Multicast over Fabric Connect route. A a BEB receives IP multicast data from a sender, a BEB allocates a data I-SID in the range of 16,000,000 to 16,512,000 for the stream. The stream is identified by the source IP address, group IP address, and the local VLAN the stream is received on. The data I-SID is a child of the scope or VSN I-SID. |
| <b>Type</b>          | Specifies the type for the IP Multicast over Fabric Connect route.                                                                                                                                                                                                                                                                                                                       |
| <b>Bvlan</b>         | Specifies the B-VLAN for the IP Multicast over Fabric Connect route.                                                                                                                                                                                                                                                                                                                     |
| <b>NniInterfaces</b> | Specifies the NNI ports for the IP multicast route. SPBM runs in the core on the ports that connect to the core. These ports are NNI ports. Ports that face a customer VLAN are user-to-network interface (UNI) ports.                                                                                                                                                                   |

## Troubleshooting Fabric Attach

The following sections help you troubleshoot problems with Fabric Attach (FA) using either the Command Line Interface (CLI) or the Enterprise Device Manager (EDM).

### *Troubleshooting workflow*

Troubleshoot FA in the following sequence:

- **Verify FA configuration:**

As a first step, for proper operation, verify that FA is enabled properly at both the global and interface levels. Use the procedures in this section to verify FA configuration.

- **Verify LLDP port-level transmission and reception:**

LLDP operates at the interface level. Enabling FA at the port level automatically enables LLDP transmission and reception at the port level. Similarly, enabling FA at the MLT level automatically enables LLDP transmission and reception for all ports in that MLT. Use the procedures in this section to verify LLDP interface (port or MLT) statistics.

- **Verify FA discovery, I-SID-to-VLAN mapping assignments and Switched UNI I-SID creation:**

After you verify LLDP transmission, verify that FA element discovery completed successfully. After a successful FA discovery, FA clients can send I-SID-to-VLAN mapping assignments to the FA Server on an FA-enabled port or MLT. The FA server accepts or rejects these mapping assignments. A prerequisite to successful mapping assignments is that IS-IS and SPBM are properly configured on the FA server. Successful FA mappings result in the creation of ELAN I-SIDs with end-points of type Switched UNI on the FA Server switch.

*Troubleshoot Fabric Attach using CLI*

**View Fabric Attach Configuration**

To operate properly, Fabric Attach (FA) must be configured properly at both the global and interface level on the switch. Use this procedure to verify FA configuration.

**Procedure**

1. Enter Privileged EXEC mode:  

```
enable
```
2. To verify that FA is enabled globally, enter one of the following commands:
  - `show fa`
  - `show fa agent`
3. To view all FA interfaces (ports and MLTs), enter:  

```
show fa interface
```
4. To view FA interface configuration on ports, use one of the following commands:
  - To view FA configuration on all ports, enter:  

```
show fa interface port
```
  - To view FA configuration on a specific port, enter:  

```
show fa interface port [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]
```
5. To view FA interface configuration on MLTs, use one of the following commands:
  - To view FA configuration on all MLTs, enter:  

```
show fa interface mlt
```
  - To view FA configuration on a specific MLT, enter:  

```
show fa interface mlt [<1-512>]
```
  - To view FA interface configuration based on the authentication status, enter:  

```
show fa interface [enabled-auth] [disabled-auth]
```

**Example**

Verify that FA is configured globally.

```
Switch:1>show fa

=====
 Fabric Attach Configuration
=====
 FA Service : enabled
 FA Element Type : server
 FA Assignment Timeout : 240
 FA Discovery Timeout : 240
 FA Provision Mode : spbm
```

Verify FA configuration at the interface (port or MLT) level, on all interfaces.

In the following example output, note that:

- FA is enabled on interfaces 2/10, 4/11 and M1t2.
- Both FA and message authentication are disabled on port 4/6.
- Both FA and message authentication are enabled on port 4/11.

```
Switch:1#show fa interface
=====
 Fabric Attach Interfaces
=====
INTERFACE SERVER MGMT MGMT MSG AUTH MSG AUTH ORIGIN
 STATUS ISID CVID STATUS KEY

Port2/10 enabled 0 0 disabled ****
Port4/6 disabled 0 0 disabled ****
Port4/11 enabled 0 0 enabled ****
M1t2 enabled 0 0 disabled ****

4 out of 4 Total Num of fabric attach interfaces displayed

```

Verify FA configuration on a specific port, for example, on port 2/10.

```
Switch:1#show fa interface port 2/10
=====
 Fabric Attach Interfaces
=====
INTERFACE SERVER MGMT MGMT MSG AUTH MSG AUTH ORIGIN
 STATUS ISID CVID STATUS KEY

Port2/10 enabled 0 0 disabled ****

1 out of 1 Total Num of fabric attach interfaces displayed

```

Verify FA configuration on an MLT, for example, on M1t2.

```
Switch:1#show fa interface mlt 2
=====
 Fabric Attach Interfaces
=====
INTERFACE SERVER MGMT MGMT MSG AUTH MSG AUTH ORIGIN
 STATUS ISID CVID STATUS KEY

M1t2 enabled 0 0 disabled ****

1 out of 1 Total Num of fabric attach interfaces displayed

```

View the FA interfaces that have authentication enabled:

```
Switch:1#show fa interface enabled-auth
=====
 Fabric Attach Interfaces
=====
```

```

=====
INTERFACE SERVER MGMT MGMT MSG AUTH MSG AUTH ORIGIN
 STATUS ISID CVID STATUS KEY

Port4/11 enabled 0 0 enabled ****

1 out of 1 Total Num of fabric attach interfaces displayed
=====

```

View the FA interfaces that have authentication disabled:

```

Switch:1#show fa interface disabled-auth

=====
 Fabric Attach Interfaces
=====
INTERFACE SERVER MGMT MGMT MSG AUTH MSG AUTH ORIGIN
 STATUS ISID CVID STATUS KEY

Port2/10 enabled 0 0 disabled ****
Port4/6 disabled 0 0 disabled ****
Mlt2 enabled 0 0 disabled ****

3 out of 3 Total Num of fabric attach interfaces displayed
=====

```

*Troubleshoot Fabric Attach using EDM*

**Graph LLDP Reception Statistics**

Use this procedure to graphically view the LLDP reception statistics.

**About This Task**

LLDP operates at the port interface level. Enabling FA on a port automatically enables LLDP transmission and reception on that port. It also enables traffic tagging and disables spanning tree on that port.

Enabling FA on an MLT enables LLDP transmission and reception on all ports in that MLT.

**Note**

When a port is removed from an MLT, LLDP transmission on that port stops and spanning tree is enabled. Any I-SID-to-VLAN mappings on that port are removed, if not already learned on any other port in the MLT. This also causes the Switched UNI I-SID to be deleted from the MLT. However, if the mappings are learned on another port on the MLT, the Switched UNI I-SID continues to exist for that MLT.

For ports in an LACP MLT, when FA is enabled, tagging is enabled on all ports in the LACP MLT. The consistency check for FA is based on key membership. If all ports with the same key do not support FA, FA is not successfully enabled on those ports.

**Note**

If a slot is removed from the switch chassis, the statistics are not displayed on the slot ports. When the slot is inserted back again, the statistics counters are reset.

**Procedure**

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics > 802\_1ab.LLDP**.
2. Click the **RX Stats** tab.
3. To view the reception statistics graphically for a port:
  - a. Select a row, and click **Graph**.  
The system displays the **RX Stats-Graph,<port-number>** tab.
  - b. Select one of the parameters, and click the appropriate icon in the upper-left corner of the menu bar to draw a line chart, area chart, bar chart or a pie chart.
4. To clear the existing counters, and fix a reference point in time to restart the counters, click **Clear Counters**.
5. To export the statistical data to a file, click **Export**.
6. To configure a poll interval, select an appropriate value from the **Poll Interval** drop-down list.

RX Stats Field Descriptions

Use the data in the following table to use the **RX Stats** tab.

| Name                         | Description                                                                                                                                                                                                                                                                                               |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>FramesDiscardedTotal</b>  | Specifies the number of LLDP frames received on the port, but discarded, for any reason. This counter provides an indication of possible LLDP header formatting problems in the sending system, or LLDP PDU validation problems in the receiving system.                                                  |
| <b>FramesErrors</b>          | Specifies the number of invalid LLDP frames received on the port.                                                                                                                                                                                                                                         |
| <b>FramesTotal</b>           | Specifies the total number of LLDP frames received on the port.                                                                                                                                                                                                                                           |
| <b>TLVsDiscardedTotal</b>    | Specifies the number of LLDP TLVs discarded on the port, for any reason.                                                                                                                                                                                                                                  |
| <b>TLVsUnrecognizedTotal</b> | Specifies the number of LLDP TLVs on the port, that are unrecognized on that port. An unrecognized TLV is referred to as the TLV whose type value is in the range of reserved TLV types (000 1001-111 1110). An unrecognized TLV could be, for example, a basic management TLV from a later LLDP version. |

**Graph LLDP Transmission Statistics**

Use this procedure to view the LLDP transmission (TX) statistics. You can also view the statistics graphically.

**About This Task**

LLDP operates at the port interface level. Enabling FA on a port automatically enables LLDP transmission and reception on that port. It also enables traffic tagging and disables spanning tree on that port.

Enabling FA on an MLT enables LLDP transmission and reception on all ports in that MLT.

**Note**

When a port is removed from an MLT, LLDP transmission on that port stops and spanning tree is enabled. Any I-SID-to-VLAN mappings on that port are removed, if not already learned on any other port in the MLT. This also causes the Switched UNI I-SID to be deleted from the MLT. However, if the mappings are learned on another port on the MLT, the Switched UNI I-SID continues to exist for that MLT.

For ports in an LACP MLT, when FA is enabled, tagging is enabled on all ports in the LACP MLT. The consistency check for FA is based on key membership. If all ports with the same key do not support FA, FA is not successfully enabled on those ports.

**Note**

If a slot is removed from the switch chassis, the statistics are not displayed on the slot ports. When the slot is inserted back again, the statistics counters are reset.

**Procedure**

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics > 802\_1ab.LLDP**.
2. Click the **TX Stats** tab.  
The system displays the transmission statistics.
3. To view the transmission statistics graphically for a port:
  - a. Select a row, and click **Graph**.  
The system displays the **TX Stats-Graph,<port-number>** tab.
  - b. To view the graph, select one of the parameters, and click the appropriate icon on the upper-left corner of the menu bar to draw a line chart, area chart, bar chart or a pie chart.
4. To clear the existing counters, and fix a reference point in time to restart the counters, click **Clear Counters**.
5. To export the statistical data to a file, click **Export**.
6. To fix a poll interval, select an appropriate value from the **Poll Interval** drop-down list.

TX Stats Field Descriptions

Use the data in the following table to use the **TX Stats** tab.

| Name               | Description                                            |
|--------------------|--------------------------------------------------------|
| <b>FramesTotal</b> | Specifies the total number of LLDP frames transmitted. |

### Troubleshooting FA Server Rejection of I-SID-to-VLAN Assignments Using Trace

Consider an FA solution where the FA Server receives I-SID-to-VLAN assignment requests from a proxy device and some of these assignment requests are rejected by the FA Server. Use this procedure to help you troubleshoot the cause of the rejection.

#### Note

When the FA Server rejects an I-SID-to-VLAN assignment request, the error message in the log file lists a generic reason for the failure, such as `rejected due to application error (status 9)`. To troubleshoot further, you must use trace.

This procedure also demonstrates how you can configure trace for enhanced troubleshooting.

### Procedure

#### Begin troubleshooting on the FA Server

1. Enter Privileged EXEC mode:

```
enable
```

2. Verify that router IS-IS is enabled. This is required for proper FA operation.

```
show isis
```

#### Note

I-SID-to-VLAN assignments are always rejected if router IS-IS is disabled.

3. Verify that FA is enabled on the interface on which I-SID-to-VLAN assignments are expected.

```
show fa interface [disabled-auth] [enabled-auth] [mlt <1-512>] [port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]
```

4. Verify the discovery and authentication status of the proxy device, on the interface.

```
show fa elements [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]
```

5. Determine the I-SID-to-VLAN assignments received on the interface and which ones are rejected.

```
show fa assignment [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]
```

6. View the log file to determine the cause of the assignment rejection.

```
show log file module fa
```

#### Note

When the FA Server rejects an I-SID-to-VLAN assignment request, only a generic reason for the rejection is logged.

#### Enhanced troubleshooting using trace

7. Configure trace:

- a. Enable keyword search in the trace output:

```
trace grep WORD<0-128>
```

- b. Set the trace level for FA:

```
trace level <Module_ID>
```

**Note**

- <Module\_ID> specifies the module for the trace. Different hardware platforms support different ID ranges because of feature support differences. To see which module IDs are available on the switch, use the **show trace modid-list** command or CLI command completion Help.
- FA uses the trace level 221.

- c. Turn on trace:

```
trace screen [enable] |[disable]
```

**Example:**

The following example simulates a configuration error on the FA Server as a result of which the FA Server rejects I-SID-to-VLAN assignments from the proxy device. When the FA Server rejects an I-SID-to-VLAN assignment, the error message listed in the log file is a generic reason for the rejection, as demonstrated in this example. To troubleshoot further, set up trace.

On the FA Server, assume that the interface MLT 1 consists of ports 1/5 and 1/6. Assume that a proxy device sends I-SID-to-VLAN assignment mapping requests with I-SID 9005 and CVID 400, on this interface.

**Simulate a configuration error on the FA Server:**

Configure a management I-SID with a C-VID value that is different from that of the C-VID in the I-SID-to-VLAN assignment request from the proxy. So, for example, configure a management I-SID with C-VID 999, which is different from the C-VID advertised by the proxy, which is 400. This causes rejection of I-SID-to-VLAN assignment requests on the interface.

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface mlt 1
Switch:1(config-mlt)#no fa enable
Switch:1(config-mlt)#fa management i-sid 9005 c-vid 999
Switch:1(config-mlt)#fa enable
Switch:1(config-mlt)#exit
Switch:1(config)#exit
```

At this stage, the FA Server rejects I-SID-to-VLAN assignments as shown below.

```
Switch:1#show fa assignment

=====

## Troubleshooting FAN Transit

Use the following section to troubleshoot Fabric Area Network (FAN) Transit information on a switch.

*View FAN Transit information - Detailed*

### About This Task

Use this procedure to verify detailed FAN Transit information of a switch acting as a transit node in a FAN. Transit nodes are not members of the FAN and only forward FAN traffic.

This procedure also includes verification on the FAN member nodes.

### Procedure

#### Verification on FAN member nodes:

1. Verify that the node is a FAN member:
 

```
show isis
```
2. Verify that the node signals FAN membership on TLV 147:
 

```
show isis lsdB local tlv 147 detail
```
3. Verify that the node creates FAN multicast FIB entries for itself and the other member nodes:
 

```
show isis spbm multicast-fib
```
4. Verify that the transit node is a part of the FAN tree:
 

```
l2 tracetree-fan
```
5. Verify that the transit node is in the SPB path between the FAN member nodes:
 

```
show isis spbm unicast-tree <2-4059>
```

#### Verification on the transit node:

6. Verify that the transit node is not a member of the FAN and does not signal FAN membership on TLV 147:
 

```
show isis

show isis lsdB local tlv 147 detail
```
7. Verify that the transit node creates FAN multicast FIB entries for the FAN member nodes:
 

```
show isis spbm multicast-fib
```

### Example

Use the following example to verify FAN Transit information on a transit node between two end-point SPB nodes, BEB-A and BEB-B.

Verification on BEB-A:

**Note**

You can execute the following commands on either BEB-A or BEB-B. The following example displays the sample outputs for BEB-A.

Verify that BEB-A is a member of the FAN. The `FAN Member` attribute displays as `Yes`.

```

BEB-A:1#show isis

## Upper Layer Troubleshooting

### Troubleshooting SNMP

#### About This Task

Troubleshoot Simple Network Management Protocol (SNMP) if the network management station (NMS) does not receive traps.

Verify the management configurations for the management station. Also verify the management station setup. If the management station can reach a device but not receive traps, verify the trap configurations (that is, the trap destination address and the traps to be sent).

If you enable enhanced secure mode, the switch does not support the default SNMPv1 and default SNMPv2 community strings, and default SNMPv3 user name. The individual in the administrator access level role can configure a non-default value for the community strings, and the switch can continue to support SNMPv1 and SNMPv2. The individual in the administrator access level role can also configure a non-default value for the SNMPv3 user name and the switch can continue to support SNMPv3. If you disable enhanced secure mode, the SNMPv1 and SNMPv2 support for community strings remains the same, and the default SNMPv3 user name remains the same. Enhanced secure mode is disabled by default.

#### Procedure

1. From the NMS, ping the IP address for the switch. If you can ping successfully, the IP address is valid and you may have a problem with the SNMP setup.  
If you cannot ping the switch, you have a problem with either the path or the IP address.
2. Telnet to the switch.  
If you can Telnet, the switch IP address is correct.
3. If Telnet does not work, connect to the console port using a serial line connection and ensure that the IP address configuration is correct.
4. If the management station is on a separate subnet, make sure that the gateway address and subnet mask are correct.
5. Using a management application, perform an SNMP Get request and an SNMP Set request (that is, try to poll the device or change a configuration using management software).
6. If you cannot reach the device using SNMP, access the console port, and then ensure that the SNMP community strings and traps are correct.
7. Use sniffer traces to verify that the switch receives the poll.
8. Use sniffer traces to verify that the NMS receives the response.
9. Verify that the data in the response is the data that was requested.

### SNMP Trap not Received

Perform the following procedure to troubleshoot issues in which an SNMP trap is not received.

#### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Show the BPDU Guard status for the port:
 

```
show spanning-tree bpduguard {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
```
3. Configure the correct SNMP target information:
 

```
snmp-server host WORD<1-256> [port <1-65535>] v3 {noAuthNoPriv|
authNoPriv|authPriv WORD<1-32> [inform [timeout <1-2147483647>]
[retries <0-255>]] [filter WORD<1-32>]}
```

#### Example

In the following example, BPDU guard is enabled on port 1/8, BPDU packets are received, port 1/8 is disabled, and the TimerCount is incrementing, but no SNMP trap is ever received.

```
Switch:1>enable
Switch:1#show spanning-tree bpduguard 1/8

=====
 Bpdu Guard
=====
Port PORT PORT TIMER BPDUGUARD BPDUGUARD
NUM MLTID ADMIN_STATE OPER_STATE TIMEOUT COUNT ADMIN_STATE ORIGIN

1/8 Down Down 120 0 Disabled CONFIG
```

#### Variable Definitions

The following table defines parameters for the **show spanning-tree** command.

| Variable                                                      | Value                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

The following table defines parameters for the **snmp-server host** command.

| Variable                       | Value                                   |
|--------------------------------|-----------------------------------------|
| <i>filter WORD&lt;1-32&gt;</i> | Specifies a filter profile name.        |
| <i>host WORD&lt;1-256&gt;</i>  | Specifies the IPv4 or IPv6 host address |

| Variable                                                                                         | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>inform</i> [ <i>timeout</i><br><1-2147483647>]                                                | Specifies the notify type. The optional timeout parameter configures the timeout value, which specifies the time to wait for a reply before resending the inform message. Time is specified in centiseconds                                                                                                                                                   |
| <i>noAuthNoPriv</i>  <br><i>authNoPriv</i>   <i>authPriv</i><br><i>WORD</i> <1-32>               | Specifies the security level.                                                                                                                                                                                                                                                                                                                                 |
| <i>port</i> <1-65535>                                                                            | Specifies the port number that will be set as the destination port at the UDP level in the trap packet.                                                                                                                                                                                                                                                       |
| <i>retries</i> <0-255>                                                                           | Specifies the number of packets to be sent if no reply is received.                                                                                                                                                                                                                                                                                           |
| { <i>slot/port</i> [/ <i>sub-port</i> ] [-<br><i>slot/port</i> [/ <i>sub-port</i> ]]<br>[, ...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Troubleshooting DHCP

### About This Task

Perform this procedure to troubleshoot the following Dynamic Host Configuration Protocol (DHCP) scenarios:

- The client cannot obtain a DHCP address when in the same subnet.
- The client cannot obtain a DHCP address when in a different subnet.

When the DHCP server and client are on the different subnets or VLANs, you must configure the device as a DHCP relay agent. The device must forward DHCP requests to the DHCP server. You must perform extra troubleshooting steps to troubleshoot the DHCP relay agent.

### Procedure

1. Check the physical connectivity between the DHCP client and server.
2. Verify network connectivity by configuring a static IP address on a client workstation.  
If the workstation still cannot reach the network, the problem is not DHCP. Start troubleshooting network connectivity.
3. Attempt to obtain an IP address from the DHCP server by manually forcing the client to send a DHCP request.  
If the client obtains an IP address after the PC startup is complete, the issue is not the DHCP server.
4. Obtain an IP address on the same subnet or VLAN as the DHCP server.  
If the issue persists, the problem may be with the DHCP server. If DHCP is working on the same subnet or VLAN as the DHCP server, the DHCP issue can be with the DHCP relay agent.
5. Confirm the DHCP relay agent configuration is correct.
6. Obtain sniffer traces where the traffic ingresses and egresses the switch and also on the client side of the network.
7. Check the logs on the switch for errors such as size exceeded or incorrect packet format.

*Troubleshooting DHCP Relay***Before You Begin**

- Configure the server to reply to the client subnet. Check the server configuration file to verify the configuration.
- Configure a route on the server for the client subnet to create a path on which to send replies.

**About This Task**

Perform this procedure to troubleshoot the DHCP relay agent.

**Procedure**

1. Verify that the interfaces that link the client and server are up, and that the ports are in the forwarding state.
  - a. To verify client availability, you can configure a temporary static IP address on the client, and then use the `ping` command.

```
ping WORD<0-256>
```

- b. To verify the port is in the forwarding state, use the following command for the slot and port number:

```
show spanning-tree [rstp|mstp] port role [{slot/port[/sub-port]}[-slot/port[/sub-port]][, ...]]
```

**Note**

Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

If STP detects loops in the configuration, it blocks ports to avoid flooding in the network. In this situation, the port is not in the forwarding state.

2. Ensure that DHCP is enabled on the client interface and that a valid forwarding path exists and is enabled. Ensure the server is reachable.
3. View the statistics counters for the relay.
4. If request or reply counters do not increase, use a sniffer tool to ensure that the client sends the packets, and that the interface module receives the packets.

You can configure mirroring for the ingress port to verify if the packets reach the module.

- a. If the client sends the packets, check that the packets reach the CPP and search the trace results for the ingress port:

```
trace level 9 3
```

```
trace grep WORD<0-128>
```

- b. If the packets reach the CPP, check that they reach the DHCP protocol; check for errors or packet drop messages:

```
trace level 170 3
```

```
trace grep WORD<0-128>
```

- If Option 82 is enabled, check the statistic counters for dropped packets, and perform a trace for the DHCP protocol:

```
trace level 170 3
```

**Example**

```
Switch:1# ping 192.0.2.31
```

```
Switch:1#show spanning-tree mstp port role

**Variable Definitions**

Use the data in the following table to use the troubleshooting commands in this procedure.

| Variable                                                            | Value                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <code>WORD&lt;0-128&gt;</code>                                      | Specifies the text string to use as the search criterion.                                                                                                                                                                                                                                                                                                     |
| <code>WORD&lt;0-256&gt;</code>                                      | Specifies the IP address.                                                                                                                                                                                                                                                                                                                                     |

*Troubleshooting Client Connection to the DHCP Server*

**About This Task**

Perform this procedure if the client cannot reach the DHCP server.

**Procedure**

1. Check that the DHCP relay agent in the network switch is correctly configured.
2. Check that the DHCP server configuration is correct.
3. Check for routing issues.  
The routing in the network may not be configured so that DHCP request and reply packets are propagated. You can use ping and traceroute.
4. Check that the DHCP pools are correctly configured.
5. If the client cannot reach the server because the link is down, enable auto-negotiation on the link.

*Troubleshooting IPv6 DHCP Relay*

The following sections provide troubleshooting information for IPv6 DHCP Relay.

*IPv6 DHCP Relay Switch Side Troubleshooting*

With DHCP Relay, the switch only participates in forwarding the requests and replies to and from the client and the DHCP server. The switch always acts as the relay agent, on which you configure the forward path to the server.

To troubleshoot DHCP Relay issues on the switch, use the following procedure.

**Procedure**

1. Verify that the DHCP server is reachable using ping. If ping is working and the DHCP server is reachable, DHCP should work.
2. Verify that the relay agents and the forward path configured are reachable. Ping the server and the gateway to the server.
3. Check that the relay agent configurations are correct. Also verify that DHCP is enabled on the switch:  

```
show ipv6 dhcp-relay interface {gigabitEthernet {slot/port[/sub-port]}
[-slot/port[/sub-port]][,...]}|vlan <1-4059>
```
4. Verify that IPv6 forwarding is enabled globally:  

```
show ipv6 global
```
5. Verify that the IPv6 based VLAN where the DHCP relay agent is configured is enabled:  

```
show ipv6 interface vlan <1-4059>
```
6. In a scenario with VRRP and SMLT, configure VRRP IP as the DHCP relay agent.
7. When using the VRRP VRID as the relay agent, make sure the VRRP configurations are proper.
8. To verify that relay forward and relay receive are working, enable trace for DHCP with IPv6, and grep trace for relay:  

```
trace level 66 3

trace grep relay

trace screen enable
```
9. Display the count of DHCP Relay requests and replies to verify the system received requests and replies:  

```
show ipv6 dhcp-relay counters
```

### IPv6 DHCP Relay Server Side Troubleshooting

Use the following procedure to troubleshoot IPv6 DHCP Relay on the server side.

#### Procedure

1. Enable the services on the server side, and then create an IP pool.  
The IP pool must contain the range of addresses that you want to assign to the clients.  
Configure the IP pool with the same network subnet as that of the relay agent.
2. When the configuration is complete, initiate a DHCP request from a client.
3. Check the log file available on the server to verify the reason for packet drop.
4. Capture the packets on the server side using Ethereal.
5. From the server side, use ping to verify that the relay agent address is reachable.  
Ensure that a route to the relay is configured.
6. For more configuration aspects, see the Microsoft webpage for troubleshooting and configuration issues.

#### Note

You can receive some log messages that indicate the system cannot forward packets. However, certain situations are not DHCP failures.

Example 1: if you receive the message `0x00108796 (relayMsgSend): cannot find route entry for destination` on the console, you must ping the server. If the server is not reachable, the system cannot forward the packet. This is not a DHCP issue.

Example 2: if you receive the message `0x00108705` this indicates a problem at the transmission level. Check the server reachability and ensure that MAC learning is correct before you pursue DHCP issues.

### IPv6 DHCP Relay Client Side Troubleshooting

You can collect a client console dump, which can be used to analyze why the received packet cannot be processed and the allocated address cannot be used by the client.

In addition, restarting the client can also fix the issue in some cases.

Make sure the client supports IPv6 requests.

Connect the server directly to the client. If the IP is assigned, then the problem is with the relay.

### Enabling Trace Messages for IPv6 DHCP Relay

Use this procedure to enable trace for IPv6 DHCP Relay and enable IPv6 forwarding trace.

#### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. To troubleshoot IPv6 DHCP Relay, you can enable `rcip6` trace messages using the following command:  
`trace level 66 3`

3. You can also enable IPv6 forwarding trace using the following command:

```
trace ipv6 forwarding enable <all|debug|error|info|pkt|warn>
```

**Example**

Enable rcip6 trace messages and enable IPv6 forwarding trace:

```
Switch:1>enable
Switch:1#trace level 66 3
Switch:1#trace ipv6 forwarding
```

**Troubleshooting TACACS+**

The switch supports the Terminal Access Controller Access Control System plus (TACACS+) client. TACACS+ is a remote authentication protocol that provides centralized validation of users who attempt to gain access to a router or network access server (NAS). The TACACS+ feature is disabled by default.

The switch implementation of TACACS+ does not support:

- Earlier versions of TACACS
- Point-to-Point Protocol (PPP) authentication and accounting
- IPv6 addresses

See the following sections to troubleshoot TACACS+.

*Unable to Log On Using Telnet*

If you cannot log on using Telnet, perform the following steps.

**Procedure**

1. Check whether the TACACS+ server is available or unreachable.
2. On the TACACS+ server, check whether you configured the privilege level correctly. On successful authorization, the TACACS+ server returns an access level to the switch for the current user, which determines the user access privileges. The switch supports access levels 1 to 6 and access level 15.

The following table maps user accounts to TACACS+ privilege level.

| Switch access level | TACACS+ privilege level | Description                                                                                                                                     |
|---------------------|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| NONE                | 0                       | If the TACACS+ server returns an access level of 0, the user is denied access. You cannot log into the device if you have an access level of 0. |
| READ ONLY           | 1                       | Permits you to view only configuration and status information.                                                                                  |
| LAYER 1 READ WRITE  | 2                       | Permits you to view most of the switch configuration and status information and change physical port settings.                                  |

| Switch access level | TACACS+ privilege level | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LAYER 2 READ WRITE  | 3                       | Permits you to view and change configuration and status information for Layer 2 (bridging and switching) functions.                                                                                                                                                                                                                                                                                                                                                  |
| LAYER 3 READ WRITE  | 4                       | Permits you to view and change configuration and status information for Layer 2 and Layer 3 (routing) functions.                                                                                                                                                                                                                                                                                                                                                     |
| READ WRITE          | 5                       | Permits you to view and change configuration and status information across the switch. This level does not allow you to change security and password settings.                                                                                                                                                                                                                                                                                                       |
| READ WRITE ALL      | 6                       | Permits you to have all the rights of read-write access and the ability to change security settings, including command line interface (CLI) and web-based management user names and passwords, and the SNMP community strings.                                                                                                                                                                                                                                       |
| NONE                | 7 to 14                 | If the TACACS+ server returns an access level of 7 to 14, the user is denied access. You cannot log into the device if you have an access level of 7 to 14.                                                                                                                                                                                                                                                                                                          |
| READ WRITE ALL      | 15                      | Permits you to have all the rights of read-write access and the ability to change security settings, including command line interface (CLI) and web-based management user names and passwords, and the SNMP community strings.<br><br><b>Note:</b><br>Access level 15 is internally mapped to access level 6, which ensures consistency with other vendor implementations. The switch does not differentiate between an access level of 6 and an access level of 15. |

After you enable TACACS+ authorization, the current privilege-level to command mapping on the switch is no longer relevant because the TACACS+ server has complete responsibility for command

authorization. TACACS+ authorization provides access to the system based on username, not based on privilege level.

**Note**

If you want to switch to a privilege level 'X' using **tacacs switch level <1-15>** command, you must create a user "\$enabX\$" on the TACACS+ server. X is the privilege level that you want to change.

3. On the TACACS+ server, check whether you configured the password and user name correctly.
4. On the TACACS+ server, check whether you configured the switch IP address in the trust list.
5. Check whether you configured the encryption key, connection mode (single connection or per-session connection), and TCP port number the same on the TACACS+ server and switch.
6. If you can log on to the switch, check whether the TACACS+ server configured on the platform has the correct IP address:  

```
show tacacs
```
7. Use the output from the **show tacacs** command to verify whether you configured the single connection option on the platform, and whether the TACACS+ server supports the single connection.

**Example**

Check whether the TACACS+ server configured on the platform has the correct IP address:

```
Switch:1>enable
Switch:1(config)#show tacacs

Global Status:

 global enable : false

 authentication enabled for : cli

 accounting enabled for : none

 authorization : disabled

 User privilege levels set for command authorization : None

Server:

 create :

Prio Status Key Port IP address Timeout Single Source SourceEnabled

Primary NotConn ***** 3 192.0.2.254 30 true 5.5.5.5 true
Backup NotConn ***** 47 198.51.100.1 10 false 0.0.0.0 false
```

*Unable to Log On Using SSH*

If you cannot log on using Secure Shell (SSH), perform the following steps.

**Procedure**

1. Verify that the network, the switch, and the TACACS+ server is reachable.
2. Verify whether you configured the SSH client correctly.
3. Verify whether you enabled and configured the SSH function correctly on the switch:  

```
show ssh global
```

**Example**

Verify whether you enabled and configured SSH function correctly on the switch:

```
Switch:1>enable
Switch:1#show ssh global

Total Active Sessions : 0
 version : v2only
 port : 22
 max-sessions : 4
 timeout : 60
 action rsa-keygen : rsa-keysize 2048
 action dsa-keygen : dsa-keysize 2048
 rsa-auth : true
 dsa-auth : true
 pass-auth : false
 enable : true
```

**Job Aid**

The following table describes the fields in the output for the **show ssh global** command.

| Parameter             | Description                                                                                                                                                                                   |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Total active sessions | Specifies the number of active SSH sessions underway.                                                                                                                                         |
| version               | Specifies if SSH is version 1 or version 2. The default is v2. As a best practice, configure the version to v2 only.                                                                          |
| port                  | Specifies the SSH connection port. The default is 22. You cannot configure the following TCP ports as SSH connection ports: 0 to 1024 (except port 22), 1100, 4095, 5000, 5111, 6000, or 999. |
| max-sessions          | Specifies the maximum number of SSH sessions allowed. The default is 4.                                                                                                                       |
| timeout               | Specifies the SSH connection authentication timeout in seconds. The default is 60 seconds.                                                                                                    |
| action rsa-keygen     | Specifies the SSH RSA key size.                                                                                                                                                               |
| action dsa-keygen     | Specifies the SSH DSA key size.                                                                                                                                                               |
| rsa-auth              | Specifies if RSA authentication is enabled or disabled. The default is enabled.                                                                                                               |
| dsa-auth              | Specifies if DSA authentication is enabled or disabled. The default is enabled.                                                                                                               |
| pass-auth             | Specifies if password authentication is enabled or disabled. The default is enabled.                                                                                                          |
| enable                | Specifies if SSH secure mode is enabled. False is disabled. Secure is enabled.                                                                                                                |

*Unable to Log On by any Means*

If you cannot log on by any means, perform the following steps.

**Procedure**

1. Check whether the TACACS+ server runs properly and try to restart the TACACS+ server.

2. Check whether you enabled both TACACS+ and RADIUS on the switch.

```
show radius
```

```
show tacacs
```

If TACACS+ fails, RADIUS can take over the authentication, authorization, and accounting (AAA) process.

3. Check whether you configured the TACACS+ server to unencrypted mode, as the switch always sends encrypted TACACS+ messages.
4. Check whether you configured the switch properly. In particular, check the IP address and key.
5. Check whether you configured the encryption key, connection mode (single connection or per-session connection), and TCP port number the same on the TACACS+ server and switch.
6. If the server connects directly, check whether the administrative and operation status of the port is up:

```
show interface gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

7. If the server is connected in a network, check whether the switch has a route configured to the server network:

```
show ip route
```

8. If the server is connected in a network, check whether the switch has a route configured to the server network:

```
show ip route and show ipv6 route
```

9. For the Out-of-Band (OOB) or VLAN Segmented Management Instance, check whether the switch has a route configured to the server network:

```
show mgmt ip route, show mgmt ipv6 route, and show mgmt ip route static
```

10. For Segmented Management Instance troubleshooting, check the management network statistics:

```
show mgmt ip arp, show khi mgmt statistics, show mgmt ip ip-statistics, and show mgmt ip icmp-statistics
```

### Examples

Check if you enabled both TACACS+ and RADIUS on the switch:

```
Switch:1>enable
Switch:1(config)#show tacacs

Global Status:

 global enable : false

 authentication enabled for : cli

 accounting enabled for : none

 authorization : disabled

 User privilege levels set for command authorization : None

Server:

 create :
```

```
Prio Status Key Port IP address Timeout Single Source SourceEnabled
Primary NotConn ***** 3 192.0.2.254 30 true 5.5.5.5 true
Backup NotConn ***** 47 198.51.100.1 10 false 0.0.0.0 false
```

```
Switch:1>show radius
 acct-attribute-value : 193
 acct-enable : false
 acct-include-cli-commands : false
 access-priority-attribute : 192
 auth-info-attr-value : 91
 command-access-attribute : 194
 cli-commands-attribute : 195
 cli-cmd-count : 40
 cli-profile-enable : false
 enable : false
 igap-passwd-attrib : standard
 igap-timeout-log-fsize : 512
 maxserver : 10
 mcast-addr-attr-value : 90
 supported-vendor-ids : 1584, 562, 1916
 secure-flag : false
```

Check if the administrative and operation status of the port is up:

```
Switch:1#show interface gigabitethernet 1/2

*Administrator Unable to Obtain Accounting Information from the TACACS+ Server*

If the administrator is unable to obtain accounting information from the TACACS+ server, perform the following steps.

**Procedure**

1. Check whether you enabled accounting on the switch:  
`show tacacs`
2. Check whether you enabled accounting on the TACACS+ server.

**Example**

Check whether accounting is enabled on the switch:

```

Switch:1>enable
Switch:1(config)#show tacacs

Global Status:

 global enable : false

 authentication enabled for : cli

 accounting enabled for : none

```

```

authorization : disabled

User privilege levels set for command authorization : None

Server:

 create :

Backup NotConn ***** 47 198.51.100.1 10 false 0.0.0.0 false

```

*Trap Server Cannot Receive Trap Packets from the Switch*

If the trap server cannot receive trap packets from the switch, perform the following steps.

**Procedure**

1. Check whether you configured the trap server correctly on the switch:  
`show snmp-server host`
2. Check whether a firewall exists between the switch and the trap server.

**Example**

Check whether you configured the trap server correctly on the switch:

```

Switch:1>enable
Switch:1#show snmp-server host

*Troubleshooting TACACS+ Problems*

Use the **trace level** command to check traps and log files to see any TACACS+ failure. If TACACS+ experiences failure conditions, the TACACS+ module sends SNMP traps to notify the user. The TACACS+ module also logs the failure information into the system log file.

**About This Task**

**Caution**

Using the trace tool inappropriately can cause primary CPU lockup conditions, loss of access to the device, loss of protocols, and service degradation. If you use trace level 3 (verbose) or trace level 4 (very verbose), do not use the screen to view commands due to the volume of information the system generates and the effect on the system.

**Procedure**

1. Enter Privileged EXEC mode:  

```
enable
```
2. Configure the trace level for the TACACS+ module:  

```
trace level 109 <1-4>
```

The TACACS+ module ID is 109.
3. Stop trace:  

```
trace shutdown
```
4. View the trace results on screen:  

```
trace screen enable
```
5. View trace saved to a file:  

```
show trace file [tail]
```

6. Save the trace file to the Compact Flash card for retrieval:

```
save trace [file WORD<1-99>]
```

If you do not specify a file name, the file name is systrace.txt. By default, the system saves the file to the external flash.

7. Save the trace file for retrieval:

```
save trace [file WORD<1-99>]
```

If you do not specify a file name, the file name is systrace.txt.

### Variable Definitions

The following table defines parameters for the **trace** command.

| Variable                                 | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>level</i><br>[<Module_ID>]<br>[<1-4>] | Starts the trace by specifying the module ID and level. Module ID 23 represents the IGMP module<br><Module_ID> specifies the module for the trace. Different hardware platforms support different ID ranges because of feature support differences. To see which module IDs are available on the switch, use the <b>show trace modid-list</b> command or CLI command completion Help.<br><0-4> specifies the trace level: <ul style="list-style-type: none"> <li>• 0 – Disabled</li> <li>• 1 – Very terse</li> <li>• 2 – Terse</li> <li>• 3 – Verbose</li> <li>• 4 – Very verbose</li> </ul> |
| <i>shutdown</i>                          | Stops the trace operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>screen {disable enable}</i>           | Enables or disables the display of trace output to the screen.<br><br><b>Important:</b><br>As a best practice, avoid using the screen to view commands if you use trace level 3 (verbose) or trace level 4 (very verbose) due to the volume of information generated and the effect on the system.                                                                                                                                                                                                                                                                                           |

The following table defines parameters for the **show trace** command.

| Variable           | Value                                             |
|--------------------|---------------------------------------------------|
| <i>file [tail]</i> | Displays the trace results saved to a file.       |
| <i>level</i>       | Displays the current trace level for all modules. |
| <i>modid-list</i>  | Specifies the module ID list.                     |

## Using BGP Debugging Commands

Use global and peer debug commands to display specific debug messages for the global and peer Border Gateway Protocol (BGP) configuration, including the BGP neighbors.

You can use these commands to troubleshoot the BGP configuration.

**Procedure**

1. Enter BGP Router Configuration mode:  
enable  
  
configure terminal  
  
router bgp
2. Show specific debug messages for the global BGP configuration:  
global-debug mask *WORD*<1-100>
3. Display specific debug messages for the global BGP neighbors:  
neighbor-debug-all mask *WORD*<1-100>
4. Display specific debug messages for BGP peers or peer groups:  
neighbor <nbr\_ipaddr|peer-group-name> neighbor-debug-mask *WORD*<1-100>
5. Display debug messages on the console:  
debug-screen <on|off>

**Example**

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

```
Switch:1(config)# router bgp
```

Display the global debug messages for error and packet:

```
Switch:1(router-bgp)#global-debug mask error,packet
```

End (disable) the display of global debug messages:

```
Switch:1(router-bgp)#global-debug mask none
```

Display specific debug messages for the global BGP neighbors:

```
Switch:1(router-bgp)#neighbor-debug-all mask packet,event
```

Display specific debug messages for BGP peers or peer groups:

```
Switch:1(router-bgp)#neighbor 192.0.2.10 neighbor-debug-mask event,trace
```

Display debug messages on the console:

```
Switch:1(router-bgp)#debug-screen on
```

### Variable Definitions

The following table defines parameters for the **global-debug mask** and **neighbor-debug-all mask** commands.

| Variable            | Value                                                                                                                                                                                                                                        |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>WORD</i> <1-100> | Specifies one or more mask choices that you enter, separated by commas with no space between choices. For example: [<mask>,<mask>,<mask>...]. Options include: none, all, error, packet, event, trace, warning, state, init, filter, update. |

The following table defines parameters for the **neighbor** command.

| Variable                                       | Value                                                                                                                                                                                                                                        |
|------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| < <i>nbr_ipaddr</i>   <i>peer-group-name</i> > | Specifies the IP address or the group name of the peer.                                                                                                                                                                                      |
| <i>WORD</i> <1-100>                            | Specifies one or more mask choices that you enter, separated by commas with no space between choices. For example: [<mask>,<mask>,<mask>...]. Options include: none, all, error, packet, event, trace, warning, state, init, filter, update. |

### Job Aid

Use debug command values to control debug messages for global BGP message types, and for message types associated with a specified BGP peer or peer group. The following table identifies mask categories and messages.

**Table 242: Mask categories and messages**

| Mask category | Message                                                             |
|---------------|---------------------------------------------------------------------|
| none          | None disables the display of all debug messages.                    |
| all           | All configures the device to show all categories of debug messages. |
| error         | Error configures the device to show error debug messages.           |
| packet        | Packet configures the device to show packet debug messages.         |
| event         | Event configures the device to show event debug messages.           |
| warning       | Warning configures the device to show warning debug messages.       |
| init          | Init configures the device to show initialization debug messages.   |
| filter        | Filter configures the device to show filter-related debug messages. |
| update        | Update configures the device to show update-related debug messages. |

## Traps Reference

---

The switch generates alarms, traps, and logs. This section provides information about traps.

### Note

The OID values of the rclsisTrap (OID 1.3.6.1.4.1.2272.1.63.9) table are populated only when the Duplicate ISIS Sys-id & Nickname condition is present. This MIB table captures this specific condition only. Use other tables such as rclsisAdjTable (OID 1.3.6.1.4.1.2272.1.63.10) or isisSAdjTable (OID 1.3.6.1.3.37.1.6.1) to gather IS-IS information.

## Proprietary Traps

The following tables describe proprietary traps for the switch. All of the following traps have a status of current.

**Table 243: 1.3.6.1.4.1.45.5.17.0.xx series**

| OID                     | Notification type                    | Objects                                                                                                                                                                                                                                                              | Description                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1.3.6.1.4.1.45.5.17.0.1 | bsDhcpSnoopingBindingTableFull       | bsDhcpSnoopingNotificationClientMACAddr                                                                                                                                                                                                                              | A bsDhcpSnoopingBindingTableFull notification is generated when you try adding a new DHCP binding entry, and the binding table is full. The value of bsDhcpSnoopingNotificationClientMACAddr gives the MAC address that cannot be added to the binding table. This notification also indicates that additional untrusted DHCP packets will not be added to the binding table, and will be dropped. |
| 1.3.6.1.4.1.45.5.17.0.2 | bsDhcpSnoopingTrap                   | <ul style="list-style-type: none"> <li>bsDhcpSnoopingNotificationSourcePort</li> <li>bsDhcpSnoopingNotificationMsgType</li> <li>bsDhcpSnoopingNotificationSourceMACAddr</li> <li>bsDhcpSnoopingNotificationClientMACAddr</li> <li>bsDhcpSnoopingIfTrusted</li> </ul> | A bsDhcpSnoopingTrap notification is generated when a DHCP packet is dropped.                                                                                                                                                                                                                                                                                                                      |
| 1.3.6.1.4.1.45.5.17.0.4 | bsDhcpSnoopingStaticEntryMACConflict | bsDhcpSnoopingNotificationSourceMACAddr bsDhcpSnoopingIfIndex                                                                                                                                                                                                        | A bsDhcpSnoopingStaticEntryMACConflict notification is generated when a DHCP packet is dropped, because a static entry with the same MAC address was found in the binding table.                                                                                                                                                                                                                   |

**Table 244: 1.3.6.1.4.1.45.5.18.0.xx series**

| OID                     | Notification type                   | Objects                                                                                                                      | Description                                                                                                                                                                                                                                     |
|-------------------------|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1.3.6.1.4.1.45.5.18.0.1 | bsaiArpPacketDroppedOnUntrustedPort | <ul style="list-style-type: none"> <li>bsArpInspectionIfTrusted</li> <li>bsArpInspectionNotificationSourceMACAddr</li> </ul> | A bsaiArpPacketDroppedOnUntrustedPort trap signifies that an ARP packet is dropped on an untrusted port, due to an invalid IP or MAC address binding. The port is identified by the instance of bsArpInspectionIfTrusted generated by the trap. |

**Table 245: 1.3.6.1.4.1.45.5.20.0.xx series**

| OID                     | Notification type                | Objects                 | Description                                                                                                                                                                                                                                                                                                   |
|-------------------------|----------------------------------|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1.3.6.1.4.1.45.5.20.0.2 | bsSourceGuardCannotEnablePort    | bsSourceGuardConfigMode | A bsSourceGuardCannotEnablePort trap signifies that there are insufficient resources to enable IP Source Guard checking on a port because of internal state changes within the system such as system initialization. The port is identified by the instance of bsSourceGuardConfigMode generated by the trap. |
| 1.3.6.1.4.1.45.5.20.0.1 | bsSourceGuardReachedMaxIpEntries | bsSourceGuardConfigMode | A bsSourceGuardReachedMaxIpEntries trap signifies that the maximum number of IP address entries on a port has been reached. The port is identified by the instance of bssourceGuardConfigMode generated by the trap.                                                                                          |

**Table 246: 1.3.6.1.4.1.45.5.34.0.xx series**

| OID                     | Notification type        | Objects | Description                                                                                                |
|-------------------------|--------------------------|---------|------------------------------------------------------------------------------------------------------------|
| 1.3.6.1.4.1.45.5.34.0.1 | bsnesGloballyEnabled     | —       | A bsnesGloballyEnabled trap signifies that the Energy Saver feature was enabled globally.                  |
| 1.3.6.1.4.1.45.5.34.0.2 | bsnesGloballyDisabled    | —       | A bsnesGloballyDisabled trap signifies that the Energy Saver feature was disabled globally.                |
| 1.3.6.1.4.1.45.5.34.0.3 | bsnesManuallyActivated   | —       | A bsnesManuallyActivated trap signifies that the Energy Saver was activated manually.                      |
| 1.3.6.1.4.1.45.5.34.0.4 | bsnesManuallyDeactivated | —       | A bsnesManuallyDeactivated trap signifies that the Energy Saver feature was deactivated manually.          |
| 1.3.6.1.4.1.45.5.34.0.5 | bsnesScheduleNotApplied  | —       | A bsnesScheduleNotApplied trap signifies that a schedule was not applied because SNTP is not synchronized. |
| 1.3.6.1.4.1.45.5.34.0.6 | bsnesScheduleApplied     | —       | A bsnesScheduleApplied trap signifies that SNTP is synchronized and the schedule is being applied.         |
| 1.3.6.1.4.1.45.5.34.0.7 | bsnesActivated           | —       | A bsnesActivated trap signifies that the Energy Saver feature was activated by the schedule.               |
| 1.3.6.1.4.1.45.5.34.0.8 | bsnesDeactivated         | —       | A bsnesDeactivated trap signifies that the Energy Saver feature was deactivated by the schedule.           |

**Table 252: Virtual Link Aggregation Control Protocol (VLACP) product support**

| Feature                                           | Product     | Release introduced |
|---------------------------------------------------|-------------|--------------------|
| Virtual Link Aggregation Control Protocol (VLACP) | 5320 Series | Fabric Engine 8.6  |
|                                                   | 5420 Series | VOSS 8.4           |
|                                                   | 5520 Series | VOSS 8.2.5         |
| VLACP Flap Detect and Damping                     | 5320 Series | Fabric Engine 8.6  |
|                                                   | 5420 Series | VOSS 8.4           |
|                                                   | 5520 Series | VOSS 8.2.5         |

## Virtual Link Aggregation Control Protocol

Use Virtual Link Aggregation Control Protocol (VLACP) as an extension to LACP for end-to-end failure detection. VLACP is not a link aggregation protocol, it is a mechanism to periodically check the end-to-end health of a point-to-point connection. VLACP uses the Hello mechanism of LACP to periodically send Hello packets to ensure end-to-end communication. After Hello packets are not received, VLACP transitions to a failure state, which indicates a service provider failure and that the port is disabled.

The VLACP only works for port-to-port communications where there is a guarantee for a logical port-to-port match through the service provider. VLACP does not work for port-to-multiport communications where there is no guarantee for a point-to-point match through the service provider. You can configure VLACP on a port.

You can also use VLACP with MLT to complement its capabilities and provide quick failure detection.

VLACP trap messages are sent to the management stations if the VLACP state changes. If the failure is local, the only traps that are generated are port linkdown or port linkup.

The Ethernet cannot detect end-to-end failures. Functions such as remote fault indication or far-end fault indication extend the Ethernet to detect remote link failures. A major limitation of these functions is that they terminate at the next Ethernet hop. They cannot determine failures on an end-to-end basis.

For example, in [Figure 239](#), after the Enterprise networks connect the aggregated Ethernet trunk groups through a service provider network connection (for example, through a VPN), far-end failures cannot be signaled with Ethernet-based functions that operate end-to-end through the service provider network. The multilink trunk (between Enterprise switches S1 and S2) extends through the Service Provider (SP) network.

The following illustration shows an MLT running with VLACP. VLACP can operate end-to-end, but you can also use it as a point-to-point link.

**Figure 239: Problem description (1 of 2)**

In the following illustration, if the Layer 2 link on S1 (S1/L2) fails, the link-down failure is not propagated over the SP network to S2 and S2 continues to send traffic over the failed S2/L2 link.

**Figure 240: Problem description (2 of 2)**

Use VLACP to detect far-end failures, which causes MLT to failover if end-to-end connectivity is not guaranteed for links in an aggregation group. VLACP prevents the failure scenario.

The switch software uses the following VLACP timers:

- fast periodic timer—100 to 20 000 ms; default 200 ms
- slow periodic timer—10 000 to 30 000 ms; default 30 000 ms

## VLACP considerations

Use the information in this section to understand the considerations while configuring VLACP into your network.

- If a VLACP-enabled port does not receive a VLACP Data Unit (VLACPDU), it must enter the disabled state. There are occasions where a VLACP-enabled port does not receive a VLACPDU but remains in

the forwarding state. To avoid this situation, ensure that the VLACP configuration at the port level is consistent. You must either enable or disable both sides of the point-to-point connection.

- If VLACP is enabled on a MACsec Key Agreement-enabled link, it takes approximately 30 seconds for the VLACP session to begin.

You can configure VLACP on each port. The port can be either an individual port or an MLT member. VLACPDUs can be sent periodically on each port where VLACP is enabled to exchange VLACPDUs from an end-to-end perspective. If VLACPDUs are not received on a particular link, that link is taken down after the expiry timeout occurs (timeout scale x periodic time).

## VLACP Flap Detect and Damping

When there is instability or packet loss in a connection, the Virtual Link Aggregation Control Protocol (VLACP) state of the port flaps, causing services such as IP multicast to stop and start rapidly. This behavior causes system-wide instability, including high CPU utilization. In such cases, VLACP Flap Detect and Damping provides link flap detection capability, by configuring a specific time interval and frequency to count the number of VLACP flaps. After the system detects excessive VLACP flaps, it disables the specific VLACP port until the root cause is resolved.

For example, VLACP Flap Detect and Damping detects 3 VLACP flaps within 60 seconds, by default. After the system detects the first VLACP flap, the flap timer starts to count the number of VLACP flaps occurring within 60 seconds. If the flap count reaches 3 before the timer ends, the system disables the specific VLACP port, and generates a Simple Network Management Protocol (SNMP) trap. For more information about SNMP traps, see [Logs and Traps Fundamentals](#) on page 1900.

If you view the port state information, the port displays as operationally down and the reason provided is VLACP\_FLAP. The following example shows a port that is disabled because of VLACP flapping; only the relevant sections of the show command output is included.

```
Switch:1#show interface gigabitethernet 1/1
```

| Port Interface |       |             |              |              |      |                     |        |         |             |
|----------------|-------|-------------|--------------|--------------|------|---------------------|--------|---------|-------------|
| PORT<br>NUM    | INDEX | DESCRIPTION | LINK<br>TRAP | PORT<br>LOCK | MTU  | PHYSICAL<br>ADDRESS | STATUS |         |             |
|                |       |             |              |              |      |                     | ADMIN  | OPERATE |             |
| 1/1            | 192   | 1000BaseTX  | true         | false        | 1950 | e4:5d:52:3c:64:00   | up     |         | <b>down</b> |

| Port State |             |           |                   |                   |  |
|------------|-------------|-----------|-------------------|-------------------|--|
| PORT NUM   | ADMINSTATUS | PORTSTATE | REASON            | DATE              |  |
| 1/1        | up          | down      | <b>VLACP_FLAP</b> | 09/19/19 02:22:58 |  |

### Note

VLACP Flap Detect and Damping does not support auto-recovery of VLACP ports; you must reenble the ports manually.

### *VLACP Flap Detect and Damping Considerations*

Use the following information when configuring VLACP Flap Detect and Damping.

- Do not enable VLACP Flap Detect and Damping on Link Aggregation Control Protocol (LACP) enabled ports.

#### **Note**

Link flap detection takes priority if you enable both VLACP Flap Detect and Damping and link flap detection on the same port.

## **VLACP Configuration using CLI**

---

Configure Virtual LACP (VLACP) to implement link status control protocol at the port level. VLACP detects end-to-end failures in the switch. Virtual LACP cannot interoperate with Link Aggregation Control Protocol (LACP).

### **Configure VLACP on a port**

Configure VLACP on a port to ensure there is end-to-end reachability. VLACP uses the Hello mechanism of LACP to periodically send Hello packets to ensure there is an end-to-end approach. After Hello packets are not received, VLACP transitions to a failure state and disables the port.

#### **Important**

Changes made at the global level override and reset all port level settings.

#### **About This Task**

Use the following information to prevent flooding VLACP packets across a defaulted switch:

- Use the default MAC address, 01:80:c2:00:11:00, for end-to-end connections that traverse an intermediate network.
- Use the reserved multicast MAC address 01-80-c2-00-00-0f for directly-connected, peer-to-peer links.

#### **Procedure**

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### **Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure optional parameters for the port. If you do not configure these parameters, the system uses the default values.

- a. Configure the protocol identification for the port:

```
vlacp ethertype <1536-65535 | 0x600-0xffff> [funcmac-addr
0x00:0x00:0x00:0x00:0x00:0x00]
```

- b. Configure the fast or slow periodic times:

```
vlacp fast-periodic-time <100-20000> | slow-periodic-time
<10000-30000>
```

You can configure both parameters in the same command entry.

- c. Configure the timeout parameters:

```
vlacp timeout <long|short> timeout-scale <2-10>
```

You can configure both parameters in the same command entry.

3. Enable VLACP on a port:

```
vlacp enable
```

### Example

Configure VLACP on port 1/1:

```
Switch:1# configure terminal
```

```
Switch:1# interface GigabitEthernet 1/2
```

```
Switch:1# vlacp fast-periodic-time 400 timeout short
```

```
Switch:1# vlacp enable
```

### Variable Definitions

Use the data in the following table to help you use the **vlacp** command.

| Variable                                            | Value                                                                                                                                                           |
|-----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>enable</i>                                       | Enables VLACP for this port. The default is disabled.                                                                                                           |
| <i>ethertype</i> <1536-65535   0x600-0xffff>        | Configures the VLACP protocol identification for this port. Enter the type in decimal or hexadecimal format. The default is 0x8103.                             |
| <i>fast-periodic-time</i> <100-20000>               | Configures the fast periodic time (in milliseconds) for this port. The default is 200.                                                                          |
| <i>funcmac-addr</i> <0x00:0x00:0x00:0x00:0x00:0x00> | Configures the multicast MAC address used for the VLACPDU. Specify a MAC address in the format 0x00:0x00:0x00:0x00:0x00:0x00. The default is 01:80:c2:00:11:00. |
| <i>slow-periodic-time</i> <10000-30000>             | Configures the slow periodic time (in milliseconds) for a specific port type. The default is 30,000.                                                            |

| Variable                                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>timeout {long short}</code>       | Configures the port to use the long or short timeout: <ul style="list-style-type: none"> <li><code>long</code> sets the port to use the timeout-scale value multiplied by the slow periodic time.</li> <li><code>short</code> sets the port to use the timeout-scale value multiplied by the fast periodic time.</li> </ul> For example, if you specify a short timeout, set the timeout-scale value to 3, and the fast periodic time to 400 ms, the timer expires within 1000 to 1200 ms.<br>The default is long. |
| <code>timeout-scale &lt;2-10&gt;</code> | Configures a timeout scale for this port used to calculate the timeout. The default value is 3.                                                                                                                                                                                                                                                                                                                                                                                                                    |

## View the VLACP Port Configuration

View the VLACP port configuration to show the port VLACP configuration.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View the VLACP port configuration for all interfaces:

```
show vlacp interface gigabitethernet [vid <1-4059>] [{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]]
```

### Example

```
Switch:1>show vlacp interface gigabitethernet

Variable definitions

Use the data in the following table to use the **show vlacp interface gigabitethernet** command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>vid &lt;1-4059&gt;</code>                                    | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. The VLAN ID is in one of the following formats: A single VLAN ID (vlan-id), a range of VLAN IDs [(vlan-id)-(vlan-id)] or a series of VLAN IDs (vlan-id, vlan-id, vlan-id). |
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Specifies a port or list of ports to show only the VLACP information for those ports. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                                                                                                                   |

## Displaying VLACP Statistics for Specific Ports

Display VLACP statistics for specific ports to manage network performance.

**Note**

Slot and port information can differ depending on hardware platform.

### About This Task

You can enable sequence numbers for each VLACPDU to assist in monitoring performance. The switch counts mismatched PDU sequence numbers to determine packet loss information. By default, sequence numbers are enabled.

You can use the show commands from Privileged EXEC mode but must enter Global Configuration mode to enable or disable the sequence numbers.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Confirm sequence numbers are enabled:  

```
show vlacp
```

3. (Optional) Enable sequence numbers for VLACPDUs:  
`vlACP sequence-num`
4. View VLACP statistics:  
`show interfaces gigabitEthernet statistics vlACP [{slot/port[/sub-port]} [-slot/port[/sub-port]] [, ...] ]`
5. (Optional) View VLACP statistics history:  
`show interfaces gigabitEthernet statistics vlACP history [{slot/port[/sub-port]} [-slot/port[/sub-port]] [, ...] ]`
6. (Optional) Clear VLACP statistics:  
`clear vlACP stats [port {slot/port[/sub-port]} [-slot/port[/sub-port]] [, ...]]`
7. (Optional) Disable sequence numbers for VLACPDUs:  
`no vlACP sequence-num`

### Example

Determine if sequence numbers are enabled, and then view port statistics. Port numbering may differ depending on your product and configuration.

```
Switch:1(config)#show vlACP
=====
 VlACP Global Information
=====
 SystemId: 32:11:9f:20:00:00
 VlACP: enable
 VlACP Sequence Number: enable

Switch:1(config)#show interfaces gigabitEthernet statistics vlACP
=====
 Port Stats VlACP
=====
PORT TX RX SEQNUM
NUM VLACPDU VLACPDU MISMATCH

8/1 106058 105554 0
12/11 15 12 0
12/23 0 0 0
```

### Variable Definitions

Use the data in the following table to use the commands in this procedure.

| Variable                                                            | Value                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port]} [-slot/port[/sub-port]] [, ...]</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Enabling or disabling VLACP globally

Use VLACP as an extension to LACP for end-to-end failure detection. Enable or disable VLACP globally to reset the port level configuration. The default is disabled.

### About This Task

#### Important

Changes you make at the global level override and reset all port level settings.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable VLACP globally:

```
vlacp enable
```

3. Disable VLACP globally:

```
no vlacp enable
```

### Example

Enable VLACP globally:

```
Switch:1(config)# vlacp enable
```

## Configure VLACP Flap Detect and Damping on a Port

### About This Task

Perform the following procedure to control link state changes on VLACP ports. By default, VLACP Flap Detect and Damping is disabled on all VLACP ports.

#### Important

Do not enable VLACP Flap Detect and Damping on Link Aggregation Control Protocol (LACP) enabled ports.

### Before You Begin

- To configure VLACP Flap Detect and Damping on sub-ports, enable channelization. For more information about channelization, see [Channelization](#) on page 478.
- As a best practice, to modify an existing VLACP Flap Detect and Damping configuration, first disable VLACP on the interface.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable VLACP Flap Detect and Damping on the specified port:

```
vlACP flap-detect enable
```

3. Configure the time interval (in seconds) to record VLACP flaps:

```
vlACP flap-interval <10-600>
```

4. Configure the VLACP flap frequency:

```
vlACP flap-frequency <3-30>
```

5. View VLACP Flap Detect and Damping configuration on the specific port:

```
show vlACP interface gigabitEthernet {slot/port[/sub-port] [-slot/
port[/sub-port]][,...]}
```

## Example

Configure VLACP Flap Detect and Damping on port 1/3:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface GigabitEthernet 1/3
Switch:1(config-if)#vlACP flap-detect enable
Switch:1(config-if)#vlACP flap-interval 120
Switch:1(config-if)#vlACP flap-frequency 6
Switch:1(config-if)#show vlACP interface gigabitEthernet 1/3
```

```

=====
```

### Variable Definitions

Use data in the following table to use the **vlacp** command.

| Variable                      | Value                                                                                                                            |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <i>flap-detect enable</i>     | Enables VLACP Flap Detect and Damping on the specified port. By default, VLACP Flap Detect and Damping is disabled on all ports. |
| <i>flap-interval</i> <10-600> | Configures VLACP Flap Detect and Damping time interval in seconds. The default value is 60 seconds.                              |
| <i>flap-frequency</i> <3-30>  | Configures the VLACP Flap count permitted during the configured time interval. The default value is 3.                           |

## Clear VLACP Flap Detect and Damping Statistics for a Port

Perform the following procedure to clear the VLACP Flap Detect and Damping statistics for a specific VLACP port or all VLACP ports on the switch.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Clear VLACP Flap Detect and Damping statistics:  
clear vlacp flap-stats port [{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]]

### Example

```
Switch:1>enable
Switch:1#clear vlacp flap-stats port 2/11
```

### Variable Definitions

Use data in the following table to use the **clear vlacp flap-stats** command.

| Variable                                                           | Value                                                                                                                                                                        |
|--------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>port</i> {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]} | Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## VLACP Configuration using EDM

Configure Virtual LACP (VLACP) to implement link status control protocol at the port level. VLACP cannot interoperate with Link Aggregation Control Protocol (LACP).

### Enabling VLACP globally

Enable VLACP globally to detect for end-to-end failure. VLACP uses the Hello mechanism of LACP to periodically send Hello packets to ensure there is an end-to-end approach. After Hello packets are not received, the VLACP transitions to a failure state and the port is disabled.

**Procedure**

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **MLT/LACP**.
3. Click the **VLACP Global** tab.
4. Select the **VlACPEnable** check box.
5. Click **Apply**.

**VLACP Global** field descriptions

Use the data in the following table to use the **VLACP Global** tab.

| Name               | Description                                      |
|--------------------|--------------------------------------------------|
| <b>VlACPEnable</b> | Enables VLACP globally. The default is disabled. |

**Configure VLACP on a Port**

Perform the following procedure to enable VLACP on a port. VLACP periodically checks the end-to-end condition of a point-to-point connection. You can also configure VLACP Flap Detect and Damping to control link state changes on VLACP ports. By default, VLACP Flap Detect and Damping is disabled on all VLACP ports.

**Important**

Changes made at the global level override and reset all port level settings.

**Before You Begin**

- To configure VLACP Flap Detect and Damping on sub-ports, enable channelization.
- As a best practice, to modify an existing VLACP or VLACP Flap Detect and Damping configuration, first disable VLACP on the interface.

**About This Task**

Use the following information to prevent flooding VLACP packets across a defaulted switch:

- Use the default MAC address, 01:80:c2:00:11:00, for end-to-end connections that traverse an intermediate network.
- Use the reserved multicast MAC address 01-80-c2-00-00-0f for directly-connected, peer-to-peer links.

**Procedure**

1. On the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **VLACP** tab.
5. Configure the parameters, as required.
6. Select **Apply**.

**VLACP** Field Descriptions

Use data in the following table to use the **VLACP** tab.

| Name                      | Description                                                                                                                                                                                 |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdminEnable</b>        | Enables VLACP for the port. The default is disabled.                                                                                                                                        |
| <b>OperEnable</b>         | Specifies the VLACP operational status for the port. The default is false.                                                                                                                  |
| <b>FastPeriodicTimer</b>  | Specifies the number of milliseconds between periodic transmissions using short timeouts. Use the same value for all LACP-enabled ports. The default value is 200.                          |
| <b>SlowPeriodicTimer</b>  | Specifies the number of milliseconds between periodic transmissions using long timeouts. Use the same value for all LACP-enabled ports. The default value is 30000.                         |
| <b>Timeout</b>            | Specifies the timeout control value. Specify long or short timeout. The default value is long.                                                                                              |
| <b>TimeoutScale</b>       | Assigns the value used to calculate timeout from the periodic time for all VLACP-enabled ports. $\text{Timeout} = \text{PeriodicTime} \times \text{TimeoutScale}$ . The default value is 3. |
| <b>EtherType</b>          | Specifies the VLACP identification. The ID is in hexadecimal format. The default value is 0x8103.                                                                                           |
| <b>EtherMacAddress</b>    | Specifies the multicast MAC address exclusively used for VLACPDUs. The default is 01:80:c2:00:11:00.                                                                                        |
| <b>PortState</b>          | Specifies the VLACP port state.                                                                                                                                                             |
| <b>FlapDetectEnable</b>   | Enables VLACP Flap Detect and Damping on the port. By default, VLACP Flap Detect and Damping is disabled on all ports.                                                                      |
| <b>FlapFrequency</b>      | Specifies the number of VLACP flaps detected on the port. The port is shut down if the recorded flaps are within the configured time interval. The default value is 3.                      |
| <b>FlapInterval</b>       | Specifies the time interval (in seconds) during which the VLACP flaps on the port are monitored. The default value is 60 seconds.                                                           |
| <b>TotalFlapCount</b>     | Shows the total number of VLACP flaps detected on the port since you enabled VLACP Flap Detect and Damping or cleared the counters and timers.                                              |
| <b>FirstFlapTimeStamp</b> | Shows the timestamp of the first VLACP flap detected on the port since you enabled VLACP Flap Detect and Damping or cleared the counters and timers.                                        |

| Name                     | Description                                                                                                                                           |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>LastFlapTimeStamp</b> | Shows the timestamp of the latest VLACP flap detected on the port since you enabled VLACP Flap Detect and Damping or cleared the counters and timers. |
| <b>FlapClearStats</b>    | Clears all VLACP Flap Detect and Damping counters and timers.                                                                                         |

# VLAN Configuration

---

[VLAN Fundamentals](#) on page 3294

[VLAN Configuration Using CLI](#) on page 3314

[VLAN Configuration using EDM](#) on page 3346

A VLAN is a switched network that is logically segmented by functions, project teams, or applications without regard to the physical location of users. By using a VLAN, you can divide the Local Area Network into smaller groups without interfering with the physical network.

The following topics provide necessary concepts and procedures to configure VLANs.

## VLAN Fundamentals

---

The practical applications of a VLAN include the following:

- You can create VLANs, or workgroups, for common interest groups.
- You can create VLANs, or workgroups, for specific types of network traffic.
- You can add, move, or delete members from these workgroups without making physical changes to the network.

By dividing the network into separate VLANs, you can create separate broadcast domains. This arrangement conserves bandwidth, especially in networks supporting broadcast and multicast applications that flood the network with traffic. A VLAN workgroup can include members from a number of dispersed physical segments on the network, improving traffic flow between them.

The switch performs the Layer 2 switching functions necessary to transmit information within VLANs, as well as the Layer 3 routing functions necessary for VLANs to communicate with one another. You can define a VLAN for a single switch or spanning multiple switches. A port can be a member of multiple VLANs. A VLAN is associated with a spanning tree group.

A VLAN packet is classified before it is forwarded. If the packet matches a classification rule, the port membership is checked. If the port is not an allowed member (potential, static, or active), the system drops the packet.

## Port-based VLANs

A port-based VLAN is a VLAN in which you explicitly configure the ports to be in the VLAN. When you create a port-based VLAN on a device, you assign a VLAN identification number (VLAN ID) and specify the ports that belong to the VLAN. These port members are always active port members. The VLAN ID is used to coordinate VLANs across multiple switches. Any type of frame can be classified to a port-based VLAN.

The example in the following figure shows two port-based VLANs: one for the marketing department, and one for the sales department. Ports are assigned to each port-based VLAN. A change in the sales area can move the sales representative at port 1/1 to the marketing department without moving cables. With a port-based VLAN, you only need to indicate in the Command Line Interface (CLI) that port 1/1 in the sales VLAN now is a member of the marketing VLAN.

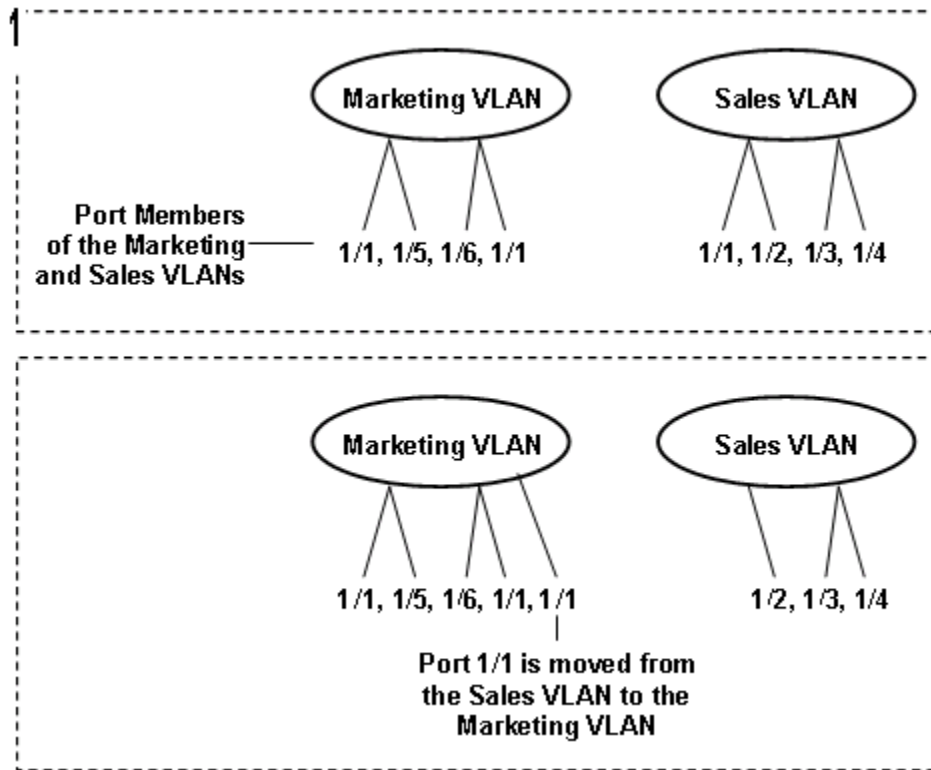

Figure 241: Port-based VLAN

## Private VLANs

Table 253: E-Tree and Private VLANs product support

| Feature                  | Product     | Release introduced |
|--------------------------|-------------|--------------------|
| E-Tree and Private VLANs | 5320 Series | Fabric Engine 8.6  |
|                          | 5420 Series | VOSS 8.4           |
|                          | 5520 Series | VOSS 8.2.5         |
| Routing on Private VLANs | 5320 Series | Fabric Engine 8.6  |
|                          | 5420 Series | VOSS 8.5           |
|                          | 5520 Series | VOSS 8.5           |

Private VLANs provide isolation between ports within a Layer-2 service.

The primary and secondary VLAN make the private VLAN. Standard VLAN configuration takes place on the primary VLAN. The secondary VLAN is used to label traffic ingressing isolated ports.

Ports in the private VLAN are configured as isolated, promiscuous, or trunk. The default value is None.

### Port Types

#### Note

Layer 2 and Layer 3 services based on port types also apply in any routing scenario between two private VLANs or E-trees.

**Table 254: Layer 2 services based on port types**

| Port type                                 | Description                                                                                                              |
|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| Promiscuous<br>(tagged or untagged ports) | Promiscuous ports communicate with all other ports within the private VLAN. Uses the primary VLAN.                       |
| Isolated<br>(tagged or untagged ports)    | Isolated ports communicate with the promiscuous ports, but not with any other isolated port. Uses the secondary VLAN.    |
| Trunk<br>(tagged ports)                   | Trunk ports carry traffic between other port members within the private VLANs. Accepts either primary or secondary VLAN. |

**Table 255: Layer 3 services based on port types**

| Port type                                 | Description                                                                                              |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------|
| Promiscuous<br>(tagged or untagged ports) | Promiscuous ports communicate with all other ports of any Layer 3 VLAN.                                  |
| Isolated<br>(tagged or untagged ports)    | Isolated ports communicate with any promiscuous or regular VLAN ports but not with other isolated ports. |
| Trunk<br>(tagged ports)                   | Trunk ports carry traffic between other port members within the private VLANs.                           |

Trunk ports must have VLAN encapsulation enabled. A port can be a single port or can belong to an MLT.

The following figure shows a basic private VLAN topology with private VLAN configured on five switches. All ports connecting to other switches are trunk type ports and all other ports are either promiscuous or isolated ports. On the secondary VLAN, spokes can communicate with hubs, and hubs can communicate with all spokes in the same private VLAN using the primary VLAN, however, spokes cannot communicate with other spokes.

**Figure 242: Private VLAN Topology**

### *E-Tree*

The E-Tree allows private VLANs to traverse the Shortest Path Bridging MAC (SPBM) network.

For more information about E-Tree and SPBM configuration, see [E-Tree and Private VLAN topology](#) on page 750.

### *Routing on Private VLANs*

You can route traffic out of a private VLAN (PVLAN) by applying an IP address to a PVLAN. IP routing is supported on private VLANs for edge switches. With PVLAN packet routing, two hosts located in different private VLANs can communicate over the network.

Packets can be routed over the network between the following:

- regular VLAN and a private VLAN
- different private VLANs
- different I-SIDs (E-tree)

The number of private VLANs that you configure with an IP address influences the IPv4 Egress ACE count. For information about scaling information, see [Fabric Engine Release Notes](#). Limits are not enforced; either number of private VLANs or number of private VLAN trunk ports can go beyond the

recommended values. As a best practice, use the **show io resources filter** command to monitor allocated resources.

#### Note

You cannot enable IP Multicast on a private VLAN interface. **ip spb-multicast enable** and **ip pim enable** commands are not available on a private VLAN.

### Private VLAN Configuration Rules

The following are private VLAN rules for the switch:

- Use private VLANs for Layer 2 and Layer 3 services.
- You cannot configure IP Source Guard (IPSG) on ports that are members of private VLANs.
- Do not use the *untag-port default vlan* parameter on private VLAN interfaces that are operating as trunk ports, because it impacts the private VLAN functionality.

## Policy-based VLANs

Received frames are classified into a policy-based VLAN based on certain fields of the frame that matches the associated VLAN policy.

### Port membership types

In a policy-based VLAN, a port can be designated as a potential member, a static member, or one not allowed to be a member of the VLAN.

If a port is designated as a potential member of the VLAN, and the incoming traffic matches the policy, the system dynamically adds the port to the active port list of the VLAN, making the port an active member of the VLAN. After the system adds a port to the active list, it can remove the port from the active list due to time-out. Potential member ports that join the VLAN are removed (timed out) from the active port list of the VLAN after the timeout (aging time) period expires.

All members of the Spanning Tree Group associated with a protocol-based VLAN are automatically considered potential members of the VLAN. In addition, all tagged ports (trunk ports) become static ports. If you do not want all the tagged ports to be static members of a protocol-based VLAN, put the port in the disallowed list.

Static port members are always members of the VLAN. Static port members are not aged out due to inactivity and they are not removed from the active list. If a server or router connects to a port, designate that port as a static member of a VLAN. If a server connects to a port that is only a potential member and the server sends very little traffic, a client fails to reach the server if the server port is timed out of the VLAN. As a best practice, make these ports static members of the VLAN.

A disallowed port can never become a member of the VLAN until you add it as a port-member. After you remove a port from the VLAN, the system adds the port to the disallowed list.

On any single spanning-tree instance, an access (untagged) port can belong to one port-based VLAN and many policy-based VLANs. A trunk (tagged) port can belong to many port-based and policy-based VLANs.

The following table describes port membership types for policy-based VLANs.

**Table 256: Port membership types for policy-based VLANs**

| Membership type                      | Description                                                                                                                                                                                 |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Potential                            | Potential members of a VLAN become active members upon receiving data matching the policy defined for the VLAN (a packet tagged with that VLAN, or an untagged packet matching the policy). |
| Static (always a member)             | Static members are always active members of the VLAN after you configure them as belonging to that VLAN.                                                                                    |
| Not allowed to join (never a member) | Ports of this type cannot join the VLAN.                                                                                                                                                    |

The following table lists supported policy-based VLANs.

**Table 257: Supported policy-based VLAN types**

| VLAN type      | Support   |
|----------------|-----------|
| Protocol-based | supported |

#### *Protocol-based VLANs*

Protocol-based VLANs are an effective way to segment your network into broadcast domains according to the network protocols in use.

A port member of a port-based VLAN can belong to multiple protocol-based VLANs. Port tagging is not required for a port to be a member of multiple protocol-based VLANs.

The switch supports IPv6 protocol-based VLAN only.

## SPBM B-VLAN

Each SPBM network instance is associated with at least one backbone VLAN (B-VLAN) in the core SPBM network.

This VLAN is used for both control plane traffic and dataplane traffic.

#### Note

Always configure two B-VLANs in the core to allow load distribution over both B-VLANs.

SPBM alters the behavior of the VLAN. When a B-VLAN is associated with an SPBM network the following VLAN attributes and behaviors are modified for the B-VLAN:

- Flooding is disabled
- Broadcasting is disabled
- Source MAC address learning is disabled
- Unknown MAC discard is enabled

Ports cannot be added to a B-VLAN manually, IS-IS takes care of adding ports to the B-VLAN.

Essentially the B-MAC addresses are programmed into the B-VLAN Forwarding Information Bases (FIBs) by IS-IS instead of the traditional VLANs flooding and learning approach.

Modification of the VLAN behavior is necessary to ensure proper control over the SPBM traffic.

## VLAN tagging and port types

The switch supports the IEEE 802.1Q specification for tagging frames and coordinating VLANs across multiple switches.

Figure 243 shows how an additional four octet (tag) header is inserted in a frame after the source address and before the frame type. The tag contains the VLAN ID associated with the frame.

**Figure 243: VLAN tag insertion**

### *802.1Q tagged ports*

Tagging a frame adds four octets to a frame, possibly making it bigger than the traditional maximum frame size. If a device does not support IEEE 802.1Q tagging, it can have problems interpreting tagged frames that it receives.

Whether tagged frames are sent depends on what you configure at the port level. Tagging is configured as true or false for the port, and is applied to all VLANs on that port.

A port with tagging enabled applies the VLAN ID tag to all packets sent on the port. Tagged ports are typically used to multiplex traffic belonging to multiple VLANs to other IEEE 802.1Q-compliant devices.

If you disable tagging on a port, it does not send tagged frames. A nontagged port connects a switch to devices that do not support IEEE 802.1Q tagging. If a tagged frame is forwarded to a port with tagging configured to false, the switch removes the tag from the frame before sending it to the port.

### *Treatment of tagged and untagged frames*

The switch associates a frame with a VLAN based on the data content of the frame and the configuration of the receiving port. The treatment of the frame depends on whether the frame is tagged or untagged.

If a tagged frame is received on a port, if the port is a static or potential member of the VLAN ID specified in the tag, the switch directs it to that VLAN. If the port is not a member of the VLAN that is identified by the tag in the packet, the switch discards the packet. If a port is untagged, you can configure it to discard tagged frames received on the port. In this case the tagged frame is discarded.

For untagged frames, VLAN membership is implied from the content of the frame itself. You can configure a tagged port to accept or discard untagged frames received on the port.

The default VLAN of a port is the VLAN to which untagged frames are classified if they do not match the criteria of any policy-based VLAN of which the port is a member. The default VLAN of the port can be any port-based VLAN a port belongs to, or the unassigned VLAN (1). Frames classified to the unassigned VLAN are discarded.

The frame is forwarded based on the VLAN on which the frame is received, and on the forwarding options available for that VLAN. The switch tries to associate untagged frames with a VLAN in the following order:

- Does the frame belong to a protocol-based VLAN?
- What is the default VLAN for the receiving port?
- Is the default VLAN for the port not the unassigned VLAN?

If the frame meets none of these criteria, it is discarded.

#### *Untagging default VLAN on a tagged port feature*

This feature provides the ability to connect two devices such as an IP phone and a PC to a single port of the switch. Most IP phones ship with an embedded three port switch, and traffic coming from the phone is generally tagged (VLAN ID configured statically or remotely). However, the traffic originating from a PC is usually untagged traffic and must be separated from the IP phone traffic. This separation ensures that broadcast traffic from the PC does not impact voice quality.

After an IP phone is attached to an untagged port, it can fail to register with a remote Internet Telephony Gateway (or equivalent device) dependent on the netmask of the destination IP address (Call Server subnet).

For more information about the Network with IP phone and PC, see the following figure.

**Figure 244: Network with IP phone and PC**

IP phones and PCs coexist on the same port due to the use of an embedded IP Phone Layer 2 switch. In this scenario if you configure the port as untagged, the egress traffic on this port is untagged and no separation exists between the traffic to the IP phone and the PC. To avoid this condition, the port that connects to the IP phone must be tagged. If the port is tagged, the traffic for the PC is tagged with the default VLAN ID for the port. This configuration creates a problem because the PC does not expect tagged packets. Untag the default VLAN on a tagged port (in this example, port 1/1 that connects to the IP phone) to ensure that the traffic to the PC is sent untagged.

## VLAN router interfaces

When you configure routing on a VLAN, you assign an IP address to the VLAN, which acts as a virtual router interface address for the VLAN. This IP address is not associated with a physical port. You can reach the VLAN IP address through any of the VLAN port members. Frames are routed to another VLAN IP address within the device. A port can belong to multiple VLANs; some, all, or none can perform routing.

## IP routing and VLANs

The switch supports IP routing on the following types of VLANs:

- Port-based VLANs
- IP protocol-based VLANs

## VLAN implementation

This section describes how to implement VLANs and describes default VLANs, the unassigned (NULL) VLAN, and brouter ports. This section also summarizes the defaults and rules regarding VLAN creation on the switch.

- [Default VLAN](#) on page 3303
- [NULL VLAN](#) on page 3303
- [Brouter ports](#) on page 3303

### *Default VLAN*

Devices are factory-configured so that all ports are in a port-based VLAN called the default VLAN. Because all ports are in the default VLAN, the device behaves like a Layer 2 device. The VLAN ID of this default VLAN is always 1, and it is always a port-based VLAN. You cannot delete the default VLAN.

### *NULL VLAN*

Internally, the switch creates a special port-based VLAN called NULL VLAN or unassigned VLAN. This is a place holder VLAN for ports that are not members of any port-based VLAN. When a port is removed from all port-based VLANs, it is added to the NULL VLAN as a port member. Ports can belong to policy-based VLANs as well as to the NULL VLAN. If a frame does not meet the policy criteria and no underlying port-based VLAN exists, the port belongs to the NULL VLAN and the frame is dropped.

Because it is an internal construct, the NULL VLAN cannot be deleted.

### *Brouter ports*

A brouter port is actually a one-port VLAN with an IP interface. The difference between a brouter port and a standard IP protocol-based VLAN configured to perform routing is that the routing interface of the brouter port is not subject to the spanning tree state of the port. A brouter port can be in the blocking state for nonroutable traffic and still route IP traffic. Because a brouter port is a single-port VLAN, it uses one VLAN ID. Each brouter port decreases the number of available VLANs by one.

## VLAN configuration rules

The following are VLAN rules for the switch:

- The switch supports configurable VLANs in the range of 1 to 4059. VLAN 0 is invalid. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. VLAN IDs on the switch range from 2 to 4094 but, by default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.
- A tagged port can belong to multiple VLANs in multiple Spanning Tree Groups.
- Under the default configuration, the default Spanning Tree Group is number 1 if the chassis configuration permits multiple STGs.
- An untagged port can belong to only one port-based VLAN.
- You can configure only one protocol-based VLAN for a given protocol.
- The VLAN membership of a frame is determined by the following order of precedence, if applicable:
  1. IEEE 802.1Q tagged VLAN ID
  2. protocol-based VLAN

3. port-based VLAN default VLAN of the receiving port
- You cannot configure a VLAN name that uses all numbers, for example, 222.

## VLAN Feature Support

The following table summarizes supported features.

For the latest scalability information, see [Fabric Engine Release Notes](#).

**Table 258: VLAN support**

| Feature                                                                                                                                              | Description |
|------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| Number of VLANs                                                                                                                                      | 4059        |
| Port-based VLANs                                                                                                                                     | Supported   |
| Policy-based VLANs <ul style="list-style-type: none"> <li>• Protocol-based</li> <li>• SPBM-based</li> </ul>                                          | Supported   |
| IEEE 802.1Q tagging                                                                                                                                  | Supported   |
| IP routing and VLANs                                                                                                                                 | Supported   |
| Special VLANs <ul style="list-style-type: none"> <li>• Default VLAN</li> <li>• Null VLAN</li> <li>• Brouter ports</li> <li>• Private VLAN</li> </ul> | Supported   |

## Network Load Balancing

**Table 259: Network Load Balancing product support**

| Feature                                            | Product     | Release introduced |
|----------------------------------------------------|-------------|--------------------|
| Network Load Balancing (NLB) - multicast operation | 5320 Series | Not Supported      |
|                                                    | 5420 Series | Not Supported      |
|                                                    | 5520 Series | VOSS 8.2.5         |
| Network Load Balancing (NLB) - unicast operation   | 5320 Series | Not Supported      |
|                                                    | 5420 Series | Not Supported      |
|                                                    | 5520 Series | VOSS 8.2.5         |

Microsoft Network Load Balancing (NLB) is a clustering technology available with the Microsoft Windows 2000, Microsoft Windows 2003, Microsoft Windows 2008, and Microsoft Windows 2012 Server family of operating systems. You can use NLB to share the workload among multiple clustering

servers. NLB uses a distributed algorithm to load balance TCP/IP network traffic across a number of hosts, enhancing the scalability and availability of the following mission critical, IP-based services:

- web
- VPN
- Streaming media
- Firewalls

NLB also provides high availability by detecting host failures and automatically redistributing traffic to remaining operational hosts.

### *NLB Considerations and Restrictions*

Although the switch interoperates with NLB clusters that operate in Unicast mode and Multicast mode, the following restrictions apply:

- The software does not support true egress mirroring because packets are mirrored prior to the completion of packet processing, so egress mirrored packets can differ from the packets egressing the port.

#### **Note**

To mirror the egress traffic, you can use the NEXT-hop device ingress mirroring to capture the egress packets of the switch.

- Inter-VRF routing is not supported between an NLB client and an NLB cluster VLAN in Unicast mode or Multicast mode.
- You must configure NLB to use the same mode as the NLB Server.
- Static ARP entries are not supported for NLB Unicast or NLB Multicast.
- For interoperability with NLB, the switch provides configuration options at the VLAN level.
- ARP entries for NLB server IP addresses do not age out when there is still client traffic coming to the NLB servers, even after the NLB servers are no longer reachable.

### *NLB Clustering in Unicast Mode*

When the cluster is running in NLB unicast mode, all servers in the cluster share a common virtual MAC address, which is 02-bf-x-x-x-x (where x-x-x-x is the cluster IP address in hexadecimal form). All traffic destined to this MAC address is sent to all the servers in the cluster. The virtual MAC address is specified in the Sender MAC Address field of the Address Resolution Protocol (ARP) reply from the cluster to the switch. ARP responses from the switch are sent to the virtual MAC address (rather than to the hardware MAC address).

You can configure the switch for NLB unicast mode support. After you enable the NLB unicast option, the switch floods traffic destined to the cluster IP address to all ports on the VLAN. Unicast mode supports connectivity to a secondary virtual IP address. For information about software scaling capabilities in unicast mode, see [Fabric Engine Release Notes](#).

### *NLB Clustering in Multicast Mode*

When the cluster is running in NLB multicast mode, a multicast virtual MAC address with the format 03-bf-x-x-x-x (where x-x-x-x is the cluster IP address in hexadecimal form) is bound to all cluster hosts but the real MAC address of the network adapter is retained. The multicast MAC address is used for client-

to-cluster traffic, and the real MAC address of the adapter is used for network traffic specific to the host server.

You can configure the switch for NLB multicast mode support. When you enable NLB multicast mode on a VLAN, the routed traffic destined to the NLB cluster is flooded by default on all ports of the VLAN. All VLANs support multiple cluster IPs by default. You can connect up to 200 NLB clusters to a single VLAN. For information about software scaling capabilities, see [Fabric Engine Release Notes](#).

#### Note

Shortest Path Bridging MAC (SPBM) supports NLB Unicast and Multicast modes. For more information on SPBM, see [Fabric Basics and Layer 2 Services](#) on page 743.

### Supported NLB Topologies

The switch supports Network Load Balancing (NLB) in the following topologies.

#### Supported NLB topology-example 1

The switch supports NLB when the NLB Cluster connections use a different physical port on the switch than the NLB clients.

The following figure illustrates this configuration where the NLB Server and the NLB Client workstations connect to different aggregation switches, which connect to the switch using different VLANs and different ports.

Figure 245: Supported NLB topology-example 1

### Supported NLB topology–example 2

The switch also supports the following topology where the NLB Server and the NLB Client workstations connect to the same aggregation switch and then connect to the switch using the same port.

#### Note

The switch supports Layer 3 routing between an NLB-enabled VLAN and another VLAN on the same port.

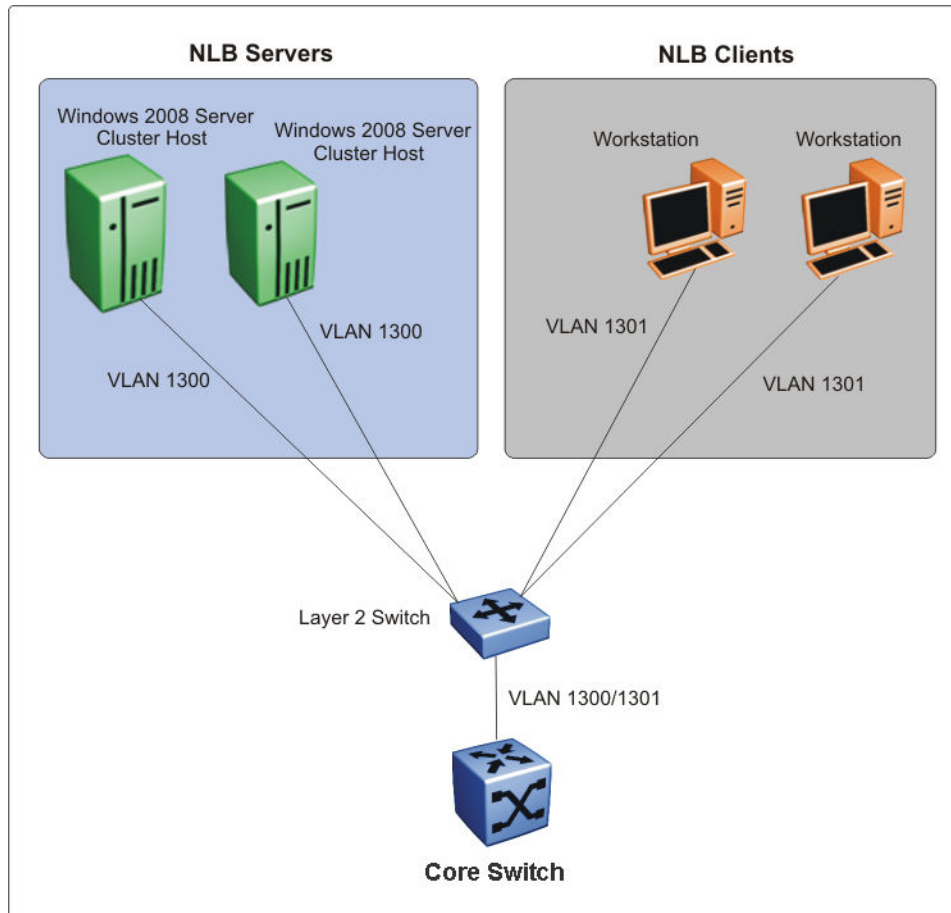

Figure 246: Supported NLB topology–example 2

#### Other supported NLB topologies

The switch supports NLB in the following other topologies:

- NLB cluster hosts and clients are connected to Layer 2 Ethernet switches that are SMLT connected to the SMLT cluster.
- NLB cluster hosts are directly connected and distributed between the switches and the clients are connected to Layer 2 Ethernet switch that is SMLT connected to the SMLT cluster.

- NLB cluster hosts and clients are directly connected and distributed between the switches in the SMLT cluster.
- NLB cluster hosts and clients are connected to Layer 2 Ethernet switches that are SMLT connected to the SMLT cluster core.

#### Note

For more information on the above topologies, see *Technical Configuration Guide for Microsoft Network Load Balancing*.

## NLB and Directed Broadcast Resource Limits

NLB and Directed Broadcast consume resources from the same pool of 200 resources. When you configure either NLB or Directed Broadcast, the switch uses one resource. If you configure both NLB and Directed Broadcast, the switch uses two resources.

To avoid a situation where there is a lack of resources, adhere to the following limits:

- The number of NLB cluster IP interfaces multiplied by the number of configured clusters must be equal to, or less than, 200. The number of NLB cluster IP interfaces is the key, not the number of VLANs. You can configure 1 VLAN with up to 200 NLB cluster IP interfaces or configure up to 200 VLANs with 1 NLB cluster IP interface per VLAN.

For example: 1 NLB cluster IP interface x 200 clusters = 200 or 2 NLB cluster IP interfaces x 100 clusters = 200

- If you configure VLANs with Directed Broadcast only, you can scale up to 200 VLANs.
- If you configure VLANs with both **NLB** and **Directed Broadcast**, you can only scale up to 100 VLANs assuming there is only 1 NLB cluster IP interface per VLAN.

For information on Directed Broadcast, see [Denial-of-Service Attack Prevention](#) on page 2584.

## VLAN MAC-layer Filtering Database and MAC Security

**Table 260: FDB Protected by Port product support**

| Feature                                             | Product     | Release introduced |
|-----------------------------------------------------|-------------|--------------------|
| FDB protected by port (MAC security limit-learning) | 5320 Series | Fabric Engine 8.6  |
|                                                     | 5420 Series | VOSS 8.4           |
|                                                     | 5520 Series | VOSS 8.3           |

To perform MAC-layer bridging, the device must know the destination MAC-layer address of each device on each attached network to forward packets to the appropriate destination. The system stores MAC-layer addresses in the bridge forwarding database (FDB) table, and can forward packet traffic based on the destination MAC-layer address information.

### MAC security

Use MAC security to control traffic from specific number of MAC addresses. You can also limit the number of allowed MAC addresses. You can enable this feature at the port level.

Port-level security applies to traffic for all VLANs received on that port.

Port-level MAC security provides limit—learning option:

- limit-learning: This option protects the FDB from traffic from too many MAC addresses, which fill the FDB table.

This option limits the number of MAC addresses a port learns. You can specify a maximum number of addresses. After the number of addresses reaches the maximum, learning stops. The port disables packet forwarding and drops packets from new source MAC address. MAC address learning resumes after enough existing addresses age out and there is room to learn new MAC addresses.

#### Note

If you configure a limit on a port that has already learned more than the new limit, packet forwarding for those additional MAC addresses continues to work until the port flaps, you flush the MAC address, or the MAC address disappears.

#### Restrictions

The following list identifies restrictions to MAC security limit-learning:

- This feature is not supported on:
  - MLT ports members
  - NNI ports
  - Transparent Port UNI or Switched UNI
- The switch supports MAC learning only in the VLAN domain; it is not supported in the I-SID domain.
- The port MAC limit does not count static MAC addresses.
- The switch supports the maximum number of MAC addresses a port can learn for non-SPBM configurations.

## Prevention of IP Spoofing within a VLAN

### *VLAN IP as the default gateway*

You can prevent VLAN logical IP spoofing by blocking the external use of the device IP address. A configurable option is provided, for each port, which detects a duplicate IP address (that is, an address that is the same as the device VLAN IP address) and blocks all packets with a source or destination address equal to that address.

If an ARP packet is received that has the same source IP address as the logical VLAN IP address of the receiving port, all traffic coming to that port (with this MAC address as source/destination address) is discarded by the hardware. After detecting a duplicate IP address, the device sends a gratuitous ARP packet to inform devices on the VLAN about the correct MAC address for that IP address. You can specify a time on a configurable global timer after which the MAC discard record is deleted, and the device resumes accepting packets from that MAC address.

### *VRRP IP as the default gateway*

Similarly, you can prevent VRRP IP spoofing by blocking the external use of the virtual IP address. A configurable option is provided, for each port, which detects a duplicate IP address (that is, an address

that is the same as the device virtual IP address) and blocks all packets with a source or destination address equal to that address.

If an ARP packet is received that has the same source IP address as the virtual IP address of the receiving port, all traffic coming to that port (with this MAC address as source/destination address) is discarded by the hardware. After detecting a duplicate IP address, the device sends a gratuitous ARP packet to inform devices on the VRRP subnet about the correct virtual router MAC address for that IP address. You can specify a time on a configurable global timer after which the MAC discard record is deleted, and the device resumes accepting packets from that MAC address.

### *Packet spoofing*

You can stop spoofed IP packets by configuring the switch to forward only IP packets that contain the correct source IP address of your network. By denying all invalid source IP addresses, you minimize the chance that your network is the source of a spoofed DoS attack.

A spoofed packet is one that comes from the Internet into your network with a source address equal to one of the subnet addresses on your network. The source address belongs to one of the address blocks or subnets on your network. To provide spoofing protection, you can use a filter that examines the source address of all outside packets. If that address belongs to an internal network or a firewall, the packet is dropped.

To prevent DoS attack packets that come from your network with valid source addresses, you need to know the IP network blocks in use. You can create a generic filter that:

- Permits valid source addresses
- Denies all other source addresses

To do so, configure an ingress filter that drops all traffic based on the source address that belongs to your network.

If you do not know the address space completely, it is important that you at least deny private (see RFC1918) and reserved source IP addresses. The following table lists the source addresses to filter.

**Table 261: Source addresses to filter**

| Address        | Description                                                                                                                                                   |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0.0.0.0/8      | Historical broadcast. High Secure mode blocks addresses 0.0.0.0/8 and 255.255.255.255/16. If you enable this mode, you do not need to filter these addresses. |
| 10.0.0.0/8     | RFC1918 private network                                                                                                                                       |
| 127.0.0.0/8    | Loopback                                                                                                                                                      |
| 169.254.0.0/16 | Link-local networks                                                                                                                                           |
| 172.16.0.0/12  | RFC1918 private network                                                                                                                                       |
| 192.0.2.0/24   | TEST-NET                                                                                                                                                      |
| 192.168.0.0/16 | RFC1918 private network                                                                                                                                       |
| 224.0.0.0/4    | Class D multicast                                                                                                                                             |
| 240.0.0.0/5    | Class E reserved                                                                                                                                              |

**Table 261: Source addresses to filter (continued)**

| Address            | Description |
|--------------------|-------------|
| 248.0.0.0/5        | Unallocated |
| 255.255.255.255/32 | Broadcast1  |

You can also enable the spoof-detect feature on a port.

## VLAN loop prevention

**Table 262: Simple Loop Prevention Protocol product support**

| Feature                                | Product     | Release introduced |
|----------------------------------------|-------------|--------------------|
| Simple Loop Prevention Protocol (SLPP) | 5320 Series | Fabric Engine 8.6  |
|                                        | 5420 Series | VOSS 8.4           |
|                                        | 5520 Series | VOSS 8.2.5         |

### *Loop prevention*

Under certain conditions, such as incorrect configurations or cabling, loops can form. This is true mainly for layer 2 bridged domains, such as VLANs.

Simple Loop Prevention Protocol (SLPP) provides active protection against Layer 2 network loops on a per-VLAN basis. SLPP uses a lightweight hello packet mechanism to detect network loops. Sending hello packets on a per VLAN basis allows SLPP to detect VLAN based network loops for untagged as well as tagged IEEE 802.1Q VLAN link configurations. After SLPP detects a loop, the port is shutdown.

#### **Note**

If SLPP is used in a vIST environment, it must be enabled on both the vIST peers. Because, when an SLPP packet of a vIST peer is looped through UNI ports to the other device, that device will shut down its UNI port due to receiving SLPP packets from its peer. A device's own SLPP packets will go over a vIST connection but will not be forwarded by its vIST peer back onto its UNI ports.

Configure the SLPP functionality with the following criteria:

- **SLPP TX Process** – You decide on which VLANs a switch can send SLPP hello packets. The packets are then replicated out all ports which are members of the SLPP-enabled VLAN. As a best practice, enable SLPP on all VLANs.
- **SLPP RX Process** – You decide on which ports the switch can act when receiving an SLPP packet that is sent by the same switch or by its SMLT peer. You must enable this process only on Access SMLT ports. You can enable this process only when the design permits on SMLT CORE ports in the case of a square/full mesh core design.
- **SLPP Action** – The action operationally disables the ports receiving the SLPP packet. You can also tune the network failure behavior. You can choose how many SLPP packets a port needs to receives before a switch takes an action. You need to stagger these values to avoid edge switch isolation – see the best practices at the end of this section.

Loops can be introduced into the network in many ways. One way is through the loss of an MLT/link aggregation configuration caused by user error or malfunctioning equipment. This scenario does not always introduce a broadcast storm, but because all MAC addresses are learned through the looping ports, does significantly impact Layer 2 MAC learning. Spanning Tree cannot in all cases detect such a configuration issue, whereas SLPP reacts and disables the malfunctioning links and limits network impact to a minimum.

The desire is to prevent a loop from causing network problems, while also attempting not to isolate totally the edge where the loop was detected. Total edge closet isolation is the last resort to protect the rest of the network from the loop. With this in mind, some administrators adopt the concept of an SLPP primary switch and SLPP secondary switch. These are strictly design terms and are not configuration parameters. The Rx thresholds are staggered between the primary and secondary switch. Therefore, the primary switch disables an uplink immediately upon a loop occurring. If this resolves the loop issue, then the edge closet still has connectivity back through the SLPP secondary switch. If the loop is not resolved, then the SLPP secondary switch disables the uplink and isolates the closet to protect the rest of the network from the loop.

As the number of VLANs running SLPP scale off of a specific uplink port, the Rx-threshold value may need to be increased to prevent complete isolation of the offending edge. The primary goal of SLPP is to protect the core at all costs. In certain loop conditions, what can occur is the secondary switch also detects the loop and SLPP Rx-threshold of the secondary switch is reached before the primary can stop the loop by taking its port down. Therefore, both switches eventually take their ports down and the edge is isolated. The larger the number of VLANs associated with the port, the more likely this can occur, especially for loop conditions that affect all VLANs.

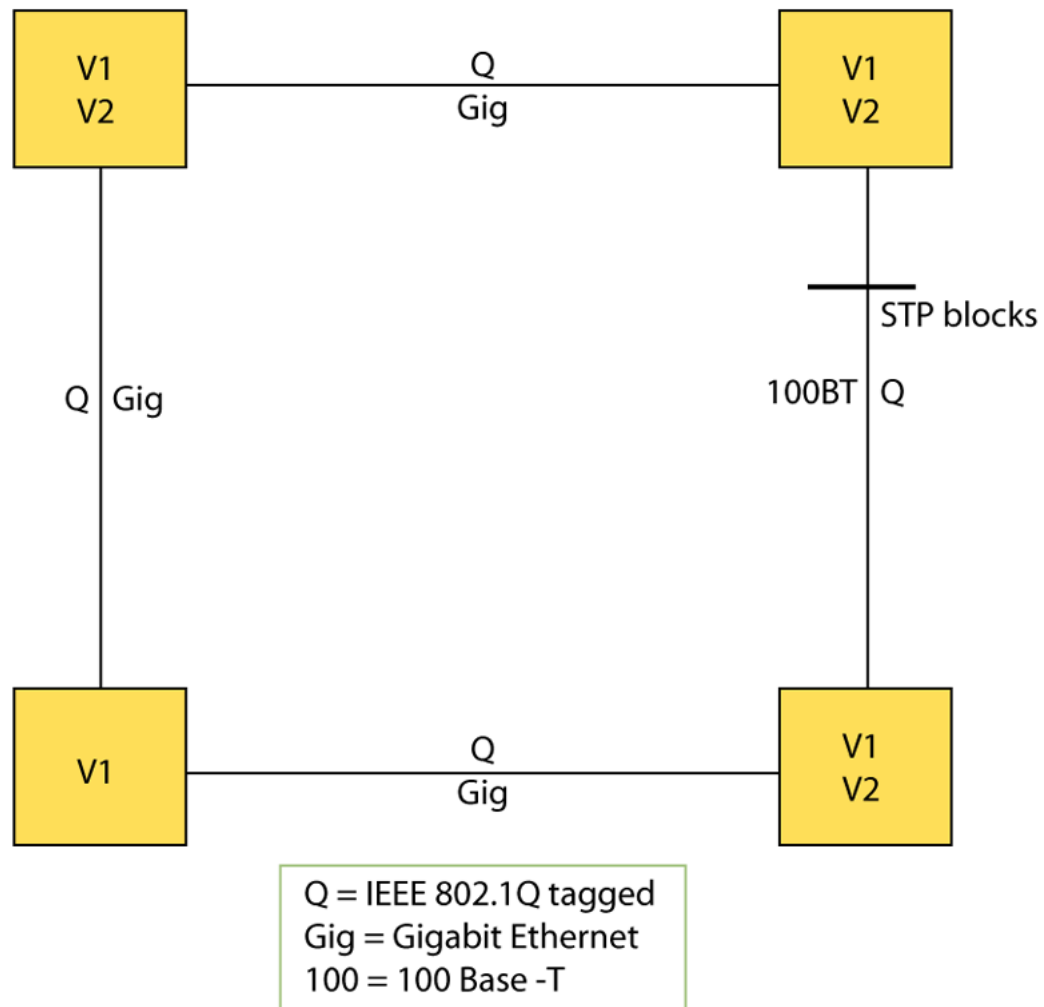

The loop detection functionality of the device must not be used under normal operating conditions. Only use it if directed by the technical support personnel.

You cannot configure the EtherType for SLPP. The switch uses an EtherType of 0x8102 .

## Spanning Tree and Protection against Isolated VLANs

Virtual Local Area Network (VLAN) isolation disrupts packet forwarding. The following figure illustrates the problem. Two VLANs (V1 and V2) connect four devices, and both VLANs are in the same spanning tree group. V2 includes three of the four devices, whereas V1 includes all four devices. After a spanning tree protocol detects a loop, it blocks the link with the highest link cost. In this case, the 100 Mbps link is blocked, which isolates a device in V2. To avoid this problem, either configure V2 on all four devices or use MSTP with a different Multiple Spanning Tree Instance (MSTI) for each VLAN.

**Figure 247: VLAN isolation**

## IGMP Layer 2 Querier

In a Layer 2 multicast network, you can enable Layer 2 querier on one of the switches in the VLAN. IGMP Layer 2 querier provides the IGMP querier function so that the switch can provide the recurring queries that maintain IGMP groups when you do not use multicast routing for multicast traffic.

### *IGMP Layer 2 Querier Overview*

In a multicast network, if you only need to use Layer 2 switching for the multicast traffic, you do not need multicast routing. However, you must have an IGMP querier on the network for multicast traffic to flow from sources to receivers. A multicast router provides the IGMP querier function. You can also use the IGMP Layer 2 Querier feature to provide a querier on a Layer 2 network without a multicast router.

The Layer 2 querier function originates queries for multicast receivers, and processes the responses accordingly. On the connected Layer 2 VLANs, IGMP snoop continues to provide services as normal. IGMP snoop responds to queries and identifies receivers for the multicast traffic.

You must enable Layer 2 querier and configure an IP address for the querier before it can originate IGMP query messages. If a multicast router exists on the network, the switch automatically disables the Layer 2 querier.

In a Layer 2 multicast network, enable Layer 2 querier on only one of the switches in the VLAN. A Layer 2 multicast domain supports only one Layer 2 querier. No querier election exists.

### *IGMP Snooping*

IGMP Snooping enables Layer 2 switches in the network to examine IGMP control protocol packets exchanged between downstream hosts and upstream routers.

When Layer 2 switches examine the IGMP control protocol packets, they:

### *IGMP Layer 2 Querier and IGMP Interaction*

IGMP Layer 2 Querier uses IGMP to learn which groups have members on each of the attached physical networks, and it maintains a list of multicast group memberships for each attached network and a timer for each membership. In this case, multicast group memberships means the presence of at least one member of a multicast group on a given attached network, not a list of all of the members.

IGMP Layer 2 Querier can assume one of two roles for each of the attached networks:

- Querier
- Non-Querier

After you enable IGMP Layer 2 Querier, the system assumes it is a multicast router, so it sends the General Query, Group Specific/Group, and Source Specific Query when Leave/BLOCK messages are received. IGMP queries are required to maintain an IGMP group.

For more information about how to configure IGMP Layer 2 Querier, see [IP Multicast](#) on page 1139.

## Switched UNI Layer 3

Create a platform VLAN using the command **vlan create <vlan-id> type port-mstprsp <msti-instance>**. Enable Layer 3 services on the platform VLAN and is associated with the Switched UNI (S-UNI) Service Instance Identifier (I-SID). All S-UNI ports are added to the platform VLAN.

You must associate the S-UNI I-SID to the platform VLAN. After you associate the platform VLAN with the I-SID, it becomes a CVLAN.

The switch performs MAC and ARP learning on the platform VLAN.

### Note

You cannot add S-UNI ports or MLT to the S-UNI platform VLANs directly. Add the ports to the I-SID and assign the I-SID to the platform VLAN.

You can associate only port based VLAN with S-UNI I-SID.

## VLAN Configuration Using CLI

## Create a VLAN

Create a VLAN by port, protocol, or SPBM. Optionally, you can choose to assign the VLAN a name and color.

Assign an IP address to the VLAN. You can also assign a MAC-offset value that allows you to manually change the default MAC address.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Create a VLAN by specifying one of the following VLAN types:
  - a. Create a VLAN by port:
 

```
vlan create <2-4059> [name WORD<0-64>] type port-mstprstp <0-63>
[color <0-32>]
```
  - b. Create a VLAN using a user-defined protocol and specify the frame encapsulation header type:
 

```
vlan create <2-4059> [name WORD<0-64>] type protocol-mstprstp <0-63>
ipv6 [color <0-32>]
```
  - c. Create an SPBM B-VLAN:
 

```
vlan create <2-4059> [name WORD<0-64>] type spbm-bvlan [color <0-
32>]
```
3. (Optional) Associate a CVLAN I-SID to the platform VLAN.
 

```
vlan i-sid <1-4059> <1-16777215> [force]
```
4. Log on to the VLAN Interface Configuration mode for the VLAN ID:
 

```
interface VLAN <1-4059>
```
5. Assign an IP address to a VLAN:
 

```
ip address {<A.B.C.D/X>|<A.B.C.D> <A.B.C.D>} [dvr-one-ip]
```
6. (Optional) Specify the MAC-offset value:
 

```
ip address <A.B.C.D/X>|<A.B.C.D> <A.B.C.D> dvr-one-ip <MAC-offset>
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#vlan create 2 type port-mstprstp 0 color 4
Switch:1(config)#vlan i-sid 2 100
Switch:1(config)#interface vlan 2
Switch:1(config-if)#ip address 192.0.2.0/24 dvr-one-ip
```

### Variable Definitions

The following table defines parameters for the **vlan create** command.

| Variable                                                 | Value                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <2-4059>                                                 | Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. |
| <i>name WORD</i> <0-64>                                  | Specifies the VLAN name. The name attribute is optional.                                                                                                                                                                                                                                                                                                                           |
| <i>type port-mstprstp</i> <0-63> [ <i>color</i> <0-32>]  | Creates a VLAN by port: <ul style="list-style-type: none"> <li>&lt;0-63&gt; is the STP instance ID from 0 to 63.</li> <li><i>color</i> &lt;0-32&gt; is the color of the VLAN in the range of 0 to 32.</li> </ul> <b>Note:</b><br>MSTI instance 62 is reserved for SPBM if SPBM is enabled on the switch.                                                                           |
| <i>type pvlan-mstprstp</i> <0-63> [ <i>color</i> <0-32>] | Creates a private VLAN by port: <ul style="list-style-type: none"> <li>&lt;0-63&gt; is the STP instance ID from 0 to 63.</li> <li><i>color</i> &lt;0-32&gt; is the color of the VLAN in the range of 0 to 32.</li> </ul>                                                                                                                                                           |
| <i>type protocol-mstprstp</i> <0-63> ipv6                | Creates a VLAN by protocol: <ul style="list-style-type: none"> <li>&lt;0-63&gt; is the STP instance ID.</li> <li><i>color</i> &lt;0-32&gt; is the color of the VLAN in the range of 0 to 32.</li> </ul>                                                                                                                                                                            |
| <i>type spbm-bvlan</i>                                   | Creates a SPBM B-VLAN.                                                                                                                                                                                                                                                                                                                                                             |

The following table defines parameters for the **ip address** command.

| Variable                        | Value                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <A.B.C.D/X> <A.B.C.D> <A.B.C.D> | Specifies the IP address and subnet mask in the format A.B.C.D/X or A.B.C.D A.B.C.D.                                                                                                                                                                                                                                                                                     |
| <i>dvr-one-ip</i>               | Specifies that the IP address will be used as the DvR gateway IP address and will be used by all other DvR Controllers for the DvR VLAN subnet.                                                                                                                                                                                                                          |
| <MAC-offset>                    | Specifies a number by which to offset the MAC address from the chassis MAC address. This ensures that each IP address has a different MAC address. If you omit this variable, a unique MAC offset is automatically generated. Different hardware platforms support different ranges. To see which range is available on the switch, use the CLI command completion Help. |

The following table defines parameters for the **vlan i-sid** command.

| Variable                        | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;1-4059&gt;</code>     | Specifies the VLAN ID.<br>Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <code>&lt;0-16777215&gt;</code> | Specifies the service instance identifier (I-SID). You cannot use I-SID 0x00ffffff. The system reserves this I-SID to advertise the virtual BMAC in an SMLT dual-homing environment.<br>This value is the same for the primary and secondary VLANs.                                                                                                                                                                                                  |
| <code>force</code>              | Specifies the software must replace the existing VLAN-to-I-SID mapping, if one exists.                                                                                                                                                                                                                                                                                                                                                               |

## Create a Private VLAN

### About This Task

You can create a private VLAN and set the port type. The primary and secondary VLAN IDs are associated with the same MTSI, the secondary VLAN inherits the primary VLAN configuration. You cannot create another VLAN with the same VLAN ID as the secondary VLAN. The secondary VLAN cannot be any other type of VLAN other than a secondary VLAN.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Create a private VLAN:
 

```
vlan create <2-4059> type pvlan-mstprstp secondary <2-4059>
```
3. Specify a name for the VLAN:
 

```
vlan create <2-4059> name
```
4. Enter GigabitEthernet Interface Configuration mode:
 

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

5. Set the port type:

```
private-vlan <isolated|promiscuous|trunk>
```

**Note**

If the port is a member of an MLT, the port inherits the private VLAN port type of the MLT.

6. Exit to Global Configuration mode:

```
exit
```

7. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

8. Add ports to the primary VLAN:

```
vlan members add <1-4059> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

**Example**

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

```
Switch:1(config)# vlan create 2 type pvlan-mstprstp 6 secondary 5
```

```
Switch:1(config)# interface gigabitethernet 1/36
```

```
Switch:1(config-if)# private-vlan isolated
```

```
Switch:1(config-if)# exit
```

```
Switch:1(config)# interface vlan 2
```

```
Switch:1(config-if)# vlan members add 2 1/36
```

*Variable Definitions*

Use the data in the following table to use the **vlan create** command.

| Variable                                      | Value                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;2-4059&gt;</code>                   | Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. |
| <code>name WORD&lt;0-64&gt;</code>            | Specifies the VLAN name. The name attribute is optional.                                                                                                                                                                                                                                                                                                                           |
| <code>type pvlan-mstprstp &lt;0-63&gt;</code> | Creates a private VLAN by port. The variable <code>&lt;0-63&gt;</code> is the STP instance ID from 0 to 63.<br><br><b>Note:</b><br>MSTI instance 62 is reserved for SPBM if SPBM is enabled on the switch.                                                                                                                                                                         |
| <code>secondary&lt;2-4059&gt;</code>          | Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. |

Use the data in the following table to use the `private vlan port type` command.

| Variable                                        | Value                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;isolated promiscuous trunk&gt;</code> | Specifies the port type. If not specified, the port type defaults to None. <ul style="list-style-type: none"> <li>Isolated: An Isolated port can belong only to one private VLAN</li> <li>Promiscuous: A Promiscuous port can belong to many private VLANs</li> <li>Trunk: A Trunk port can belong to many private VLANs, is tagged, and can also belong to non-private VLANs</li> </ul> |
| <code>no private-vlan</code>                    | Port defaults to type None.                                                                                                                                                                                                                                                                                                                                                              |
| <code>default private-vlan</code>               | Port defaults to type None.                                                                                                                                                                                                                                                                                                                                                              |

#### Note

If there are other non-private VLANs using the defined port, the following message is displayed: All non private VLANs using this interface will be removed once this port becomes a member of a private VLAN. Ports with private-vlan type of isolated or promiscuous may only contain private VLANs. Do you wish to continue (y/n) ?

Use the data in the following table to use the `interface vlan` and `vlan members add` commands.

| Variable                    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;1-4059&gt;</code> | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <code>vrf-scaling</code> and <code>spbm-config-mode</code> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |

## Assign an IP Address to a VLAN

Assign an IP address to a VLAN so that it supports routing operations.

### Before You Begin

- You must create the VLAN.
- Activate IP forwarding globally.

### About This Task

If an IP interface is configured without specifying the VRF instance, it maps to VRF 0 by default.

Use the `vrf` parameter to associate the VLAN with a VRF instance.

#### Important

The VRRP virtual IP address cannot be same as the local IP address of the port or VLAN on which VRRP is enabled.

### Procedure

- Enter VLAN Interface Configuration mode:
 

```
enable

configure terminal

interface vlan <1-4059>
```
- Assign an IP address to a VLAN:
 

```
ip address {<A.B.C.D/X>|<A.B.C.D> <A.B.C.D>} [dvr-one-ip] [name WORD
<0-64>]
```
- (Optional) If required, associate the VLAN with a VRF:
 

```
vrf WORD<1-16>
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface vlan 2
Switch:1(config-if)#ip address 192.0.2.5 255.255.255.0 dvr-one-ip name Boston
```

### Variable Definitions

The following table defines parameters for the **ip address** command.

| Variable                                                       | Value                                                                                                                                           |
|----------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;A.B.C.D/X&gt; &lt;A.B.C.D&gt; &lt;A.B.C.D&gt;</code> | Specifies the IP address and subnet mask in the format A.B.C.D/X or A.B.C.D A.B.C.D.                                                            |
| <code>dvr-one-ip</code>                                        | Specifies that the IP address will be used as the DvR gateway IP address and will be used by all other DvR Controllers for the DvR VLAN subnet. |
| <code>name WORD &lt;0-64&gt;</code>                            | Specifies the name associated with the IP address on a VLAN.<br>This parameter does not apply to all hardware platforms.                        |

The following table defines parameters for the **vrf** command.

| Variable                      | Value                          |
|-------------------------------|--------------------------------|
| <code>WORD&lt;0-16&gt;</code> | Specifies the VRF of the VLAN. |

## Performing a general VLAN action

Perform a general VLAN action to initiate a specific function on a VLAN, such as clearing learned MAC addresses or ARP entries from the forwarding database by performing this procedure.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Perform a general VLAN action:

```
vlan action <1-4059> {none|flushMacFdb|flushArp|flushIp|flushDynMemb|
triggerRipUpdate|all}
```

### Example

Perform a general VLAN action:

```
Switch(config)# vlan action 1 none
```

```
Switch(config)# vlan action 1 flushMacFdb
```

```
Switch(config)# vlan action 1 flushIp
```

```
Switch(config)# vlan action 1 flushDynMemb
```

*Variable Definitions*

Use the data in the following table to use the **vlan action** command.

| Variable                | Value                                                                                                                                                                                                                     |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>none</i>             | Configures action to none. This action performs no updates.                                                                                                                                                               |
| <i>flushMacFdb</i>      | Configures action to flushMacFdb. This action removes the learned MAC addresses from the forwarding database for the selected VLAN.                                                                                       |
| <i>flushArp</i>         | Configures action to flushArp. This action removes the ARP entries from the address table for the selected VLAN.                                                                                                          |
| <i>flushIp</i>          | Configures action to flushIp. This action removes the learned IP addresses from the forwarding table for the selected VLAN.                                                                                               |
| <i>flushDynMemb</i>     | Configures action to flushDynMemb. This action removes port members not configured as static from the list of active port members of a policy-based VLAN, and removes MAC addresses learned on those ports for this VLAN. |
| <i>flushDynMemb</i>     | Configures action to flushDynMemb. This action removes port members not configured as static from the list of active port members of a policy-based VLAN, and removes MAC addresses learned on those ports for this VLAN. |
| <i>triggerRipUpdate</i> | Configures action to triggerRipUpdate.                                                                                                                                                                                    |
| <i>all</i>              | Configures action to all and performs all preceding actions.                                                                                                                                                              |

## Configuring static MAC addresses for a VLAN

Configure the static MAC address parameters.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure a static MAC address of a VLAN:

```
vlan mac-address-static <1-4059> <0x00:0x00:0x00:0x00:0x00:0x00>
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

### Example

Configure a static MAC address of a VLAN:

```
Switch(config)# vlan mac-address-static 1 0x00:0x00:0x00:0x00:0x00:0x01
1/1
```

### Variable Definitions

Use the data in the following table to use the `vlan mac-address-static` command.

| Variable                                               | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059>                                               | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <0x00:0x00:0x00:0x00:0x00:0x00>                        | Indicates the MAC address.                                                                                                                                                                                                                                                                                                                                                                                                 |
| {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |

## Limit MAC Address Learning

Configure the MAC security feature to control traffic from specific number of MAC addresses. The total number of MAC addresses that you can configure are fixed. The switch help text shows the maximum MAC addresses a port can learn in non-SPBM configurations. In an SPBM configuration, the maximum value is reduced by half.

### About This Task

This feature limits the number of forwarding database (FDB) entries learned on a particular port to a user-specified value. After the number of learned forwarding database entries reaches the maximum limit, MAC learning stops on that port.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[, ...]} or interface mlt <1-512>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Protect the FDB from hits by too many MAC addresses:

```
mac-security [port {slot/port[/sub-port] [-slot/port[/sub-port]]
[, ...]] limit-learning enable [max-addr <max-addr>]
```

**Example**

Protect the FDB from hits by too many MAC addresses:

```
Switch:1(config)#interface gigabitethernet 1/1
Switch:1(config-if)#mac-security limit-learning enable
Switch:1(config-if)#mac-security limit-learning max-addr 5000
```

*Variable Definitions*

Use the data in the following table to use the **mac-security limit-learning** command.

| Variable                                                                                                                                                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>enable</i>                                                                                                                                           | Limits the MAC learning for the port. After the number of addresses reaches the maximum, the port disables packet forwarding and drops packets. If you enable <i>limit-learning</i> , the FDB entry for each port is limited to the number you specify in <i>max-addr</i> s.                                                                                                                                                                       |
| <i>max-addr</i> s<br>< <i>max-addr</i> s>                                                                                                               | Specifies the maximum number of MAC addresses to learn. After the number of addresses reaches the maximum, the port disables packet forwarding and drops packets. The default is 1024. Depending on the hardware platform, the parameter range can vary. Use the CLI Help to see the available range for the switch.                                                                                                                               |
| <i>port</i> { <i>slot</i> /<br><i>port</i> [/ <i>sub</i> -<br><i>port</i> ]}[- <i>slot</i> /<br><i>port</i> [/ <i>sub</i> -<br><i>port</i> ]]<br>[,...] | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. Use this parameter to apply the change to multiple ports without changing CLI modes. |

**Configuring the forwarding database timeout globally**

Use the following procedure to configure the aging time globally for the forwarding database.

**Procedure**

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Enter the following command:
 

```
mac-address-table aging-time <10-1000000>
```

*Variable Definitions*

Use the data in the following table to use the **mac-address-table** command.

| Variable              | Value                                                                                                     |
|-----------------------|-----------------------------------------------------------------------------------------------------------|
| <i>aging-time</i>     | Specifies the timeout period for dynamically learned mac addresses on the vlan. The default value is 300. |
| < <i>10-1000000</i> > | Specifies the range for the aging time.                                                                   |

## Adding or removing ports in a VLAN

Add or remove the ports in a VLAN to configure the ports in the VLAN.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Add ports in a VLAN:

```
vlan members add <1-4059> {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} [{portmember|static|notallowed}]
```

3. Remove ports in a VLAN:

```
vlan members remove <1-4059> {slot/port[/sub-port] [-slot/port[/sub-
port]][,...]} [{portmember|static|notallowed}]
```

### Example

Add ports in a VLAN:

```
Switch(config-if)# vlan members add 1 1/2 static
```

Remove ports in a VLAN:

```
Switch(config-if)# vlan members remove 1 1/2 notallowed
```

### Variable Definitions

Use the data in the following table to use the **vlan members add** and **vlan members remove** commands.

| Variable                                               | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059>                                               | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |
| portmember                                             | Configures the port type as port member.                                                                                                                                                                                                                                                                                                                                                                                   |

## Adding or removing source MAC addresses for a VLAN

Add or remove a VLAN source MAC addresses to configure the source MAC address for a source MAC-based VLAN.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Add a VLAN source MAC address:
 

```
vlan srcmac <1-4059> <0x00:0x00:0x00:0x00:0x00:0x00>
```
3. Remove a VLAN source MAC address:
 

```
no vlan srcmac <1-4059> <0x00:0x00:0x00:0x00:0x00:0x00>
```

### Example

Add a VLAN source MAC address:

```
Switch(config)# vlan create 10 type srcmac-mstprstp 0

Switch(config)# vlan srcmac 10 0x00:0x00:0x00:0x00:0x00:0x11
```

## Configure NLB support

Use Microsoft Network Load Balancing (NLB) to share the workload among multiple clustering servers. For information about software scaling capabilities, see [Fabric Engine Release Notes](#).

### Before You Begin

- For all modes, configure an IP address on the VLAN enabled with NLB.
- To switch between Unicast NLB and Multicast NLB, you must first disable the NLB support.

### About This Task

Use the following procedure to configure NLB support on an IP interface to enable or disable NLB support.

The default value is NLB support disabled.

#### Note

SPBM supports Network Load Balancing (NLB) Unicast and Multicast modes.

### Procedure

1. Enter VLAN Interface Configuration mode:

```
enable

configure terminal

interface vlan <1-4059>
```

2. Enable NLB support on an interface:

```
nlb-mode unicast
```

Or,

```
nlb-mode multicast
```

To switch from one nlb-mode to another, you must first disable the NLB support, and then enter the new nlb-mode.

3. (Optional) Disable NLB support on an interface:

```
no nlb-mode
```

### Example

Configure unicast mode for VLAN 2, and then switch to multicast mode.

```
Switch:1(config)#interface vlan 2
Switch:1(config-if)#nlb-mode unicast
Switch:1(config-if)#no nlb-mode
Switch:1(config-if)#nlb-mode multicast
```

## Configuring a tagged port to discard untagged frames

Configure a tagged port to discard all untagged packets so that the frame is not classified into the default VLAN for the port.

**Procedure**

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure a tagged port to discard untagged frames:

```
untagged-frames-discard [port {slot/port[/sub-port] [-slot/port[/sub-
port]] [,...]}
```

3. Discard a tagged frame on an untagged port:

```
tagged-frames-discard [port {slot/port[/sub-port] [-slot/port[/sub-
port]] [,...]}] enable
```

4. Untag the default VLAN on a tagged port:

```
untag-port-default-vlan [port {slot/port[/sub-port] [-slot/port[/sub-
port]] [,...]}] enable
```

**Example**

Configure a tagged port to discard untagged frames:

```
Switch(config-if)#untagged-frames-discard port 1/1
```

Discard a tagged frame on an untagged port:

```
Switch(config-if)#tagged-frames-discard port 1/1 enable
```

Untag the default VLAN on a tagged port:

```
Switch(config-if)#untag-port-default-vlan port 1/2 enable
```

*Variable Definitions*

Use the data in the following table to use optional parameters with the **untagged-frames-discard** command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Configuring SLPP

Enable the Simple Loop Prevention Protocol (SLPP) globally and for a VLAN to detect a loop and automatically stop it. The VLAN configuration controls the boundary of SLPP-PDU transmission.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Enable SLPP:  
`slpp enable`
3. Configure the transmission interval:  
`slpp tx-interval <500-5000>`
4. Add a VLAN to the transmission list:  
`slpp vid <1-4059>`

### Example

Enable SLPP:

```
Switch(config)# slpp enable
```

Configure the transmission interval to 5000 milliseconds:

```
Switch(config)# slpp tx-interval 5000
```

Add a VLAN, with the VLAN ID 2, to the transmission list:

```
Switch(config)# slpp vid 1
```

*Variable Definitions*

Use the data in the following table to use the **slpp** command.

| Variable              | Value                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>enable</i>         | Enables or disables the SLPP operation. You must enable the SLPP operation to enable the SLPP packet transmit and receive process. If you disable the SLPP operation, the system sends no SLPP packets and discards received SLPP packets. To set this option to the default value, use the <b>default</b> operator with the command. The default is disabled. |
| <i>500-5000</i>       | Configures the SLPP packet transmit interval, expressed in milliseconds in a range from 500-5000. The default value is 500. To set this option to the default value, use the <b>default</b> operator with the command.                                                                                                                                         |
| <i>&lt;1-4059&gt;</i> | Adds a VLAN, by VLAN ID, to a SLPP transmission list. Use the <b>no</b> operator to remove this configuration.                                                                                                                                                                                                                                                 |

*Job aid*

The following table provides SLPP values.

**Table 263: SLPP values**

| Enable SLPP           | Setting                         |
|-----------------------|---------------------------------|
| Access SMLT           | Yes                             |
| Core SMLT             | No                              |
| Primary switch        |                                 |
| Packet Rx threshold   | 5                               |
| Transmission interval | 500 milliseconds (ms) (default) |
| Secondary switch      |                                 |
| Packet Rx threshold   | 50                              |
| Transmission interval | 500 ms (default)                |

## Configuring SLPP packet-rx on a port

Enable SLPP by port to detect a loop and automatically stop it.

### Important

To provide protection against broadcast and multicast storms, as a best practice, enable Rate Limiting for broadcast traffic and multicast traffic.

**Procedure**

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure SLPP on a port:

```
slpp port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} packet-
rx [packet-rx-threshold <1-500>]
```

**Example**

```
Switch(config-if)# slpp port 1/1 packet-rx-threshold 5
```

*Variable Definitions*

Use the data in the following table to use the **slpp port** command.

| Variable                                              | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-500>                                               | <p>Specifies the SLPP reception threshold on the ports, expressed as an integer. The packet reception threshold specifies how many SLPP packets the port receives before it is administratively disabled. To set this option to the default value, use the <b>default</b> operator with the command. The default value is 1.</p> <p><b>Note:</b><br/>As a best practice, configure the rx-threshold above 50 slpp packets only on lightly loaded switches. If you configure the rx-threshold to a value greater than 50 on a heavily loaded switch and a loop occurs, the system can experience high CPU utilization.</p> |
| {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | <p>Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.</p>                                                                                                                                                                                                                                                      |

*Job aid*

The following table provides the SLPP values.

**Table 264: SLPP values**

| Enable SLPP           | Setting                         |
|-----------------------|---------------------------------|
| Access SMLT           | Yes                             |
| Core SMLT             | No                              |
| Primary switch        |                                 |
| Packet Rx threshold   | 5                               |
| Transmission interval | 500 milliseconds (ms) (default) |
| Secondary switch      |                                 |
| Packet Rx threshold   | 50                              |
| Transmission interval | 500 ms (default)                |

## Configuring SLPP packet-tx on a VLAN

Enable SLPP by VLAN to detect a loop and automatically stop it. This configuration controls the boundary of SLPP-PDU transmission.

### Important

To provide protection against broadcast and multicast storms, as a best practice, enable Rate Limiting for broadcast traffic and multicast traffic.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable SLPP:

```
slpp enable
```

3. Configure the transmission interval:

```
slpp tx-interval <500-5000>
```

4. Add a VLAN to the transmission list:

```
slpp vid <1-4059>
```

**Example**

Log on to the VLAN Interface Configuration mode:

```
Switch(config)# interface vlan 2
```

Enable SLPP:

```
Switch(config-if)# slpp enable
```

Configure the transmission interval to 500 milliseconds:

```
Switch(config-if)# slpp tx-interval 500
```

Add a VLAN, with the VLAN ID of 2, to the transmission list:

```
Switch(config-if)# slpp vid 2
```

*Variable Definitions*

Use the data in the following table to use the **slpp** command.

| Variable              | Value                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>enable</i>         | Activates or disables the SLPP operation. You must enable the SLPP operation to enable the SLPP packet transmit and receive process. If you disable the SLPP operation, the system sends no SLPP packets and discards received SLPP packets. To set this option to the default value, use the <b>default</b> operator with the command. The default is disabled. |
| <i>500-5000</i>       | Configures the SLPP packet transmit interval, expressed in milliseconds in a range from 500-5000. The default value is 500. To set this option to the default value, use the <b>default</b> operator with the command.                                                                                                                                           |
| <i>&lt;1-4059&gt;</i> | Adds a VLAN, by VLAN ID, to a SLPP transmission list. Use the <b>no</b> operator to remove this configuration.                                                                                                                                                                                                                                                   |

**Viewing SLPP information**

Use SLPP information to view loop information.

**Procedure**

1. Enter Privileged EXEC mode:  
enable
2. View SLPP information:  
show slpp

**Example**

```
Switch# show slpp
```

```

=====
 SLPP Info
=====
 operation : enabled
 tx-interval : 500
 vlan : 2
=====

```

**Viewing SLPP information for a port**

Show SLPP information for a port so that you can view the loop information for a port.

**Procedure**

1. Enter Privileged EXEC mode:  
enable
2. View SLPP information for a port:  
show slpp interface GigabitEthernet [{slot/port[/sub-port]}[-slot/port[/sub-port]}[,...]]
3. Clear SLPP packet RX counters:  
clear slpp stats port [{slot/port[/sub-port]}[-slot/port[/sub-port]}[,...]]

**Example**

```
Switch# show slpp interface GigabitEthernet 1/7
```

```

=====
 Port Interface
=====
PORT PKT-RX PKT-RX INCOMING SLPP PDU
NUM COUNT THRESHOLD VLAN ID ORIGINATOR

1/7 enabled 5

PORT PKT-RX TIME LEFT
NUM COUNT TO CLEAR RX COUNT

1/7 29 21600

```

### Variable Definitions

Use the data in the following table to use the **show slpp interface GigabitEthernet** command.

| Variable                                                            | Value                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Configuring spoof detection

Configure spoof detection to prevent IP spoofing.

For more information about this feature, see [Prevention of IP Spoofing within a VLAN](#) on page 3309.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[, ...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable or disable spoof detection:

```
spoof-detect [port {slot/port[-slot/port]}] [enable]
```

```
no spoof-detect [port {slot/port[-slot/port]}] [enable]
```

3. Enable or disable auto-recovery on a port:

```
auto-recover-port [port {slot/port[-slot/port]}] [enable]
```

```
no auto-recover-port [port {slot/port[-slot/port]}] [enable]
```

### Example

Enable spoof detection:

```
Switch(config-if)# spoof-detect port 1/1 enable
```

Enable autorecovery on a port:

```
Switch(config-if)# auto-recover-port port 1/1 enable
```

## Viewing VLAN information

View the VLAN information to display the basic configuration for all VLANs or a specified VLAN.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View VLAN information:  

```
show vlan basic <1-4059>
```
3. View advanced parameters:  

```
show vlan advance <1-4059>
```

### Example

View VLAN information for VLAN 2:

```
Switch:1> show vlan basic 2
```

```
=====
 Vlan Basic
=====
```

| VLAN ID | NAME   | TYPE   | INST ID | PROTOCOLID | SUBNETADDR | SUBNETMASK | VRFLD |
|---------|--------|--------|---------|------------|------------|------------|-------|
| 2       | VLAN-2 | byPort | 0       | none       | N/A        | N/A        | 0     |

View VLAN information:

```
Switch:1> show vlan basic
```

```
=====
 Vlan Basic
=====
```

| VLAN ID | NAME      | TYPE       | INST ID | PROTOCOLID | SUBNETADDR | SUBNETMASK | VRFLD |
|---------|-----------|------------|---------|------------|------------|------------|-------|
| 1       | Default   | byPort     | 0       | none       | N/A        | N/A        | 0     |
| 2       | abc       | byPort     | 0       | none       | N/A        | N/A        | 0     |
| 3       | VLAN-VRRP | byPort     | 0       | none       | N/A        | N/A        | 0     |
| 4       | VLAN-6    | byPort     | 0       | none       | N/A        | N/A        | 1     |
| 5       | VLAN-7    | byPort     | 0       | none       | N/A        | N/A        | 1     |
| 6       | VLAN-8    | byPort     | 0       | none       | N/A        | N/A        | 1     |
| 19      | VLAN-9    | byPort     | 0       | none       | N/A        | N/A        | 0     |
| 10      | VLAN-10   | byPort     | 0       | none       | N/A        | N/A        | 0     |
| 11      | VLAN-11   | byPort     | 0       | none       | N/A        | N/A        | 0     |
| 12      | VLAN-12   | byPort     | 0       | none       | N/A        | N/A        | 0     |
| 13      | VLAN-13   | spbm-bvlan | 62      | none       | N/A        | N/A        | 0     |

```

14 VLAN-14 spbm-bvlan 62 none N/A N/A 0
15 VLAN-15 byPort 1 none N/A N/A 0
--More-- (q = quit)

```

View advanced parameters:

```
Switch:1> show vlan advance
```

```

```

### Variable Definitions

Use the data in the following table to use optional parameters with the **show vlan basic** and **show vlan advance** commands.

| Variable | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059> | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |

## View Private VLAN Information

You can view the private VLAN information to display the primary and secondary VLANs and I-SIDs, and also view the private VLAN port types.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View private VLAN information:  
show vlan private-vlan <1-4059>
3. View private VLAN port information:  
show interfaces gigabitethernet private-vlan

### Example

View VLAN information for private VLAN :

```
Switch:1(config)# show vlan private-vlan
```

```
=====
 PRIVATE VLAN
=====
```

| Primary<br>VLAN | Primary<br>ISID | Secondary<br>VLAN | Secondary<br>ISID |
|-----------------|-----------------|-------------------|-------------------|
| 3               | 75              | 5                 | 75                |
| 10              | 22              | 15                | 22                |

```

All 2 out of 2 Total Num of Private Vlans displayed
```

View port information for private VLAN:

```
Switch:1(config)#show interfaces gigabitethernet private-vlan
```

```
=====
 Port Private Vlans
=====
```

| PORT<br>NUM | TAGGING | ORIGIN | PVLAN  | PVLAN TYPE  | VID<br>TYPE | VID |
|-------------|---------|--------|--------|-------------|-------------|-----|
| 2/2         | enable  | CONFIG | enable | promiscuous | -           | -   |

```

All 1 out of 1 Total Num displayed
```

## Viewing router port information

View the router port information to display the router port VLAN information for all VLANs on the device or for the specified VLAN.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View router port information:

```
show vlan router-port
```

### Example

View router port information:

```
Switch:1> show vlan router-port
```

```
=====
```

| Vlan Id | Port | VrfId |
|---------|------|-------|
| 2202    | 1/11 | 0     |

```
=====
All 1 out of 1 Total Num of Vlan Router Port Entries displayed
```

## Viewing VLAN port member status

View the VLAN port member status to display the port member status for all VLANs on the device or for the specified VLAN.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. View VLAN port member status:  

```
show vlan members [<1-4059>][null-vlan][port {slot/port[/sub-port]}[-
slot/port[/sub-port]][, ...]]
```

**Example**

View VLAN port member status:

```
Switch:1> show vlan members port 1/2
```

| Vlan Port |                                                       |                                                       |               |                  |
|-----------|-------------------------------------------------------|-------------------------------------------------------|---------------|------------------|
| VLAN ID   | PORT MEMBER                                           | ACTIVE MEMBER                                         | STATIC MEMBER | NOT_ALLOW MEMBER |
| 2         | 1/2,1/5-1/8,1/11,<br>1/14,1/26,1/38                   | 1/2,1/5-1/8,1/11,<br>1/14,1/26,1/38                   |               |                  |
| 3         | 1/2,1/5-1/8,1/14,<br>1/26,1/38                        | 1/2,1/5-1/8,1/14,<br>1/26,1/38                        |               |                  |
| 4         | 1/1-1/2,1/5-1/8,<br>1/13-1/14,1/25-<br>1/26,1/37-1/38 | 1/1-1/2,1/5-1/8,<br>1/13-1/14,1/25-<br>1/26,1/37-1/38 |               |                  |
| 100       | 1/2,1/14,1/23-<br>1/24,1/26-1/28,<br>1/38             | 1/2,1/14,1/23-<br>1/24,1/26-1/28,<br>1/38             |               |                  |
| 300       | 1/2,1/5-1/8,1/14,<br>1/26,1/38                        | 1/2,1/5-1/8,1/14,<br>1/26,1/38                        |               |                  |

*Variable definitions*

Use the data in the following table to use optional parameters with the **show vlan members** command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>null-vlan</code>                                             | Displays port members of the NULL VLAN. This is a place holder VLAN for ports that are not members of any port-based VLAN. When a port is removed from all port-based VLANs, it is added to the NULL VLAN as a port member. The NULL VLAN is an internal construct and cannot be deleted.                                                                                                                                                                                                                                                                                                                                                              |
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]][, ...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. If you do not specify a port, the command shows information for all the ports.                                                                                                                                                                                                           |
| <code>&lt;1-4059&gt;</code>                                        | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.<br><br><b>Note:</b><br>Entering a VLAN ID is optional. If you enter a VLAN ID the command shows information for the specified VLAN or port. Without the VLAN ID the command shows information for all the configured VLANs. |

**Viewing VLAN source MAC addresses**

View the VLAN source MAC addresses to display the source MAC address for a source MAC-based VLAN on the device or for the specified VLAN.

**Procedure**

View VLAN source MAC addresses:

```
show vlan src-mac [<1-4059>]
```

**Example**

View VLAN source MAC addresses:

```
Switch(config)# show vlan src-mac
```

```
=====
 Vlan Srcmac
=====
VLAN_ID MAC_ADDRESS

10 00:00:00:00:00:11

All 1 out of 1 Total Num of Vlan Srcmac Entries displayed
```

## Viewing VLAN forwarding database information

Use this procedure to display the MAC addresses that are learned or statically configured for a VLAN. In order to learn you have to be connected to another switch or host and receive some traffic.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View VLAN forwarding database information:

```
show vlan mac-address-entry [<1-4059>]
```

### Example

View VLAN forwarding database information:

```
Switch:1> show vlan mac-address-entry
```

```
=====
 Vlan Fdb
=====
VLAN MAC SMLT
ID STATUS ADDRESS INTERFACE REMOTE TUNNEL

1 learned f8:15:47:e1:80:0c Port-1/2 false -
2 learned 32:20:d3:81:00:77 Port-1/9 false -
4 learned b4:a9:5a:2b:78:31 Port-2/1 false -

3 out of 3 entries in all fdb(s) displayed.
```

View where entries are learned. The TUNNEL column indicates where in the SPBM network an entry is learned.

```
Switch:1> show vlan mac-address-entry spbm-tunnel-as-mac
```

```
=====
 Vlan Fdb
=====
VLAN MAC SMLT
ID STATUS ADDRESS INTERFACE REMOTE TUNNEL

1 learned f8:15:47:e1:80:0c Port-1/2 false -
2 learned 32:20:d3:81:00:77 Port-1/9 false -
4 learned b4:a9:5a:2b:78:31 Port-2/1 false -

3 out of 3 entries in all fdb(s) displayed.
```

### Variable Definitions

Use the data in the following table to use optional parameters with the **show vlan mac-address-entry** command.

| Variable                            | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059>                            | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| mac <0x00:0x00:0x00:0x00:0x00:0x00> | Specifies the MAC address.                                                                                                                                                                                                                                                                                                                                                                                                 |
| port {slot/port[-slot/port][,...]}  | Specifies the port or port list.                                                                                                                                                                                                                                                                                                                                                                                           |
| spbm-tunnel-as-mac                  | Displays where entries are learned. The TUNNEL column indicates where in the SPBM network an entry is learned.                                                                                                                                                                                                                                                                                                             |

## Viewing manual edit MAC addresses

Use the procedure to view the list of manual edit MAC addresses and the associated ports configured as allow-mac for MAC security.

### Procedure

View manual edit MAC addresses:  

```
show vlan manual-edit-mac
```

### Example

View manual edit MAC addresses:

```
Switch(config)# show vlan manual-edit-mac
```

```

=====
 Manual Edit Mac
=====
MAC ADDRESS PORTS

00:00:00:00:00:55 1/3
00:00:00:00:00:66 1/3

All 2 out of 2 Total Num of Manual Edit Mac Entries displayed

```

## View Port-Level MAC Security

View port-level MAC security to review the configuration.

**Procedure**

1. Enter Privileged EXEC mode:

```
enable
```

2. View port-level MAC security for limit-learning:

```
show interfaces gigabitethernet limit-fdb-learning [{slot/port[-slot/
port][,...]]
```

**Example**

View port-level MAC security for limit-learning:

```
Switch:1# show interfaces gigabitethernet limit-fdb-learning 1/4-1/5
```

```

=====
 Port limit-fdb-learning
=====
PORT FDB MAXMAC MINMAC PORT CURMAC MAC
NUM PROTECT COUNT COUNT DOWN COUNT LEARN

1/5 ena 5000 3000 dis 0 true
=====

```

## View NLB-Mode Information

View Network Load Balancing-mode (NLB-mode) information.

**Procedure**

1. Enter Privileged EXEC mode:

```
enable
```

2. View NLB port information:

```
show interface vlan nlb-mode [<1-4059>]
```

**Example**

View NLB-mode information.

```

Switch:1#show interface vlan nlb-mode
=====
 Vlan Nlb
=====

## Enable DvR on a Layer 2 VSN (VLAN)

**Before You Begin**

- Ensure that the VLAN on which to enable DvR exists and is associated with an I-SID.

## About This Task

On a Controller, DvR must be manually enabled at the Layer 2 VSN (VLAN) level.

Use this procedure to configure a gateway IPv4 address for a Layer 2 VSN (VLAN) subnet and then enable DvR on it. This address is pushed, along with other Layer 3 configuration information, from the Controllers to the Leaf nodes within the domain, so that the Leaf nodes can create a gateway IP service for each DvR-enabled Layer 2 VSN.

### Note

Optionally, you can now use a single IP address in the subnet for every Controller by configuring the DvR VLAN IP to be the same as the DvR GW IP.

## Procedure

1. Enter VLAN Interface Configuration mode:
 

```
enable

configure terminal

interface vlan <1-4059>
```
2. Configure a gateway IPv4 address for the VLAN.
 

```
dvr gw-ipv4 {A.B.C.D}
```

### Important

Ensure that you configure the same gateway IPv4 address on all Controllers in the domain that belong to a Layer 2 VSN (VLAN).

3. Enable DvR.
 

```
dvr enable
```

By default, DvR is disabled.

## Example

Enable DvR on the Global Router VLAN.

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config-if)#vlan create 200 type port-mstprstp 0
Switch:1(config-if)#vlan i-sid 200 20200
Switch:1(config-if)#interface vlan 200
Switch:1(config-if)#dvr gw-ipv4 192.0.2.1
Switch:1(config-if)#dvr enable
Switch:1(config-if)#ip address 192.0.2.2 255.255.0.0
```

Enable DvR on a VLAN associated to a VRF:

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config-if)#vlan create 400 type port-mstprstp 0
Switch:1(config-if)#vlan i-sid 400 20200
Switch:1(config-if)#interface vlan 400
Switch:1(config-if)#vrf vrf500
```

```
Switch:1(config-if)#dvr gw-ipv4 198.51.100.1
Switch:1(config-if)#dvr enable
Switch:1(config-if)#ip address 198.51.100.2 255.255.0.0
```

### Variable definitions

Use the data in the following table to use the **dvr gw-ipv4** command.

| Variable  | Value                                            |
|-----------|--------------------------------------------------|
| {A.B.C.D} | Specifies the gateway IPv4 address for the VLAN. |

## Configure a Single IP Address for All DvR Controllers on a VLAN Subnet

### Before You Begin

- Ensure that the VLAN on which to enable DvR exists and is associated with an I-SID.

### About This Task

On a Controller, DvR must be manually enabled at the Layer 2 VSN (VLAN) level.

Use this procedure to configure a single IP address to be used for both the DvR GW IP and the VLAN IP in the DvR VLAN. This IP address represents the DvR GW IP address used by all DvR Controllers for the same DvR VLAN. When you configure a DvR VLAN in this way, the Controllers no longer have a unique VLAN IP address.

#### Note

Optionally, you can use two different IP address for the DvR VLAN and the DvR GW IP.

### Procedure

- Enter VLAN Interface Configuration mode:
 

```
enable

configure terminal

interface vlan <1-4059>
```
- Configure a single IP address for both the DvR GW IP and the VLAN IP in the DvR VLAN.
 

```
ip address {<A.B.C.D/X>|<A.B.C.D> <A.B.C.D>} dvr-one-ip
```
- Enable DvR.
 

```
dvr enable
```

By default, DvR is disabled.

### Example

Enable DvR.

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config-if)#vlan create 200 type port-mstprstp 0
Switch:1(config-if)#vlan i-sid 200 20200
```

```
Switch:1(config-if)#interface vlan 200
Switch:1(config-if)#ip address 192.0.2.1 255.255.0.0 dvr-one-ip
Switch:1(config-if)#dvr enable
```

### Variable Definitions

The following table defines parameters for the **ip address** command.

| Variable                          | Value                                                                                         |
|-----------------------------------|-----------------------------------------------------------------------------------------------|
| <A.B.C.D/X>   <A.B.C.D> <A.B.C.D> | Specifies the IP address and subnet mask in the format A.B.C.D/X or A.B.C.D A.B.C.D.          |
| <i>dvr-one-ip</i>                 | Specifies the IP address used for the DvR gateway IP address and the VLAN IP in the DvR VLAN. |

## VLAN Configuration using EDM

This section describes how to configure and manage Virtual Local Area Networks (VLAN) using Enterprise Device Manager (EDM).

### Configure a VLAN on a Port

Configure a VLAN on a port.

#### Procedure

1. In the Device Physical View tab, select a port or multiple ports.
2. In the Navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **VLAN** tab.
5. To perform tagging, select **PerformTagging**.
6. To discard tagged frames, select **DiscardTaggedFrames**.
7. To discard untagged frames, select **DiscardUntaggedFrames**.
8. To use the Untag Default VLAN feature, select **UntagDefaultVlan**.

#### Important

Enable tagging on the port before you configure UntagDefaultVlans.

9. Enter a default VLAN ID.
10. To enable spoof detect, select **SpoofDetect**.
11. In the Classification area, select the types of VLAN to enable.
12. In the **Classification** area, select the Private VLAN port type.  
See [Creating a Private VLAN](#) on page 3350 for more information.
13. Select **Apply**.
14. Select **Close**.

**VLAN** field descriptions

Use the data in the following table to use the **VLAN** tab.

| Name                         | Description                                                                                                                                                                                                                                                                                                 |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PerformTagging</b>        | If checked, this port is a tagged (Trunk) Port. It can belong to multiple port-based VLANs and a VLAN tag is inserted in every frame it transmits. If it is not checked, the port is an untagged (Access) port. The default is disabled.                                                                    |
| <b>VlanIdList</b>            | Identifies which VLANs this port is assigned.                                                                                                                                                                                                                                                               |
| <b>DiscardTaggedFrames</b>   | If selected, and the port is untagged (an access port), tagged frames received on the port are discarded by the forwarding process. If clear, tagged frames are processed normally. The default is disabled.                                                                                                |
| <b>DiscardUntaggedFrames</b> | If selected and the port is tagged (a trunk port), untagged frames received on the port are discarded by the forwarding process. If clear, untagged frames are processed normally. The default is disabled.                                                                                                 |
| <b>UntagDefaultVLAN</b>      | If selected, even if the port is tagged (a trunk port), frames forwarded to the default VLAN for the port are not tagged. The default is disabled.                                                                                                                                                          |
| <b>UntaggedVlanIds</b>       | Identifies which VLANs this port is associated with as untagged.                                                                                                                                                                                                                                            |
| <b>DefaultVlanId</b>         | Specifies the VLAN ID assigned to untagged frames received on this trunk port that match no policy-based VLAN to which the port belongs.                                                                                                                                                                    |
| <b>SpoofDetect</b>           | Enables or disables spoof detection on the specified port.                                                                                                                                                                                                                                                  |
| <b>Protocol</b>              | Enables protocol-based VLAN on the port. This feature is always enabled.                                                                                                                                                                                                                                    |
| <b>PrivateVlanPortType</b>   | Specifies the port type. If not specified, the port type defaults to None. <ul style="list-style-type: none"> <li>Isolated: Only private VLANs are permitted on isolated ports.</li> <li>Promiscuous: Only private VLANs are permitted on promiscuous ports.</li> <li>Trunk: The port is tagged.</li> </ul> |
| <b>Origin</b>                | Specifies the origin of VLAN configuration on the port, either manually configured through CLI or EDM, or dynamically configured through Auto-sense.                                                                                                                                                        |

## Viewing existing VLANs

Display existing VLANs to view all defined VLANs, their configurations, and the current status.

**Procedure**

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **VLANs**.
3. View the configured VLANs in the **Basic** tab.
4. View the configured private VLANs in the **Private VLAN** tab.

**Create a Port-Based VLAN**

Create a port-based VLAN to add a new VLAN. To create a different type of VLAN, see one of the following procedures:

- [Creating a protocol-based VLAN](#) on page 3354
- [Creating a SPBM B-VLAN](#) on page 3356

**Procedure**

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Select **VLANs**.
3. In the **Basic** tab, click **Insert**.
4. In the **Id** box, enter an unused VLAN ID, or use the ID provided.
5. In the **Name** box, type the VLAN name, or use the name provided.
6. In the **Color Identifier** box, click the down arrow and choose a color from the list, or use the color provided.
7. In the **MstInstance** box, click the down arrow and choose an msti instance from the list.
8. In the **Type** box, select **byPort**.
9. In the **PortMembers** box, click the **(...)** button.
10. Click on the ports to add as member ports.

The ports that are selected are recessed, while the nonselected ports are not recessed. Port numbers that are dimmed cannot be selected as VLAN port members.

11. Click **OK**.
12. Click **Insert**.

**Basic Field Descriptions**

Use the data in the following table to use the **Basic** tab.

| Name           | Description                                                                                                                                                                                                                                                                                                                                                                        |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>      | Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. |
| <b>Name</b>    | Specifies the name of the VLAN.                                                                                                                                                                                                                                                                                                                                                    |
| <b>IfIndex</b> | Specifies the logical interface index assigned to the VLAN.                                                                                                                                                                                                                                                                                                                        |

| Name                    | Description                                                                                                                                                                                                                |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Color Identifier</b> | Specifies a proprietary color scheme to associate a color with the VLAN. Color does not affect how frames are forwarded.                                                                                                   |
| <b>Type</b>             | Specifies the type of VLAN: <ul style="list-style-type: none"> <li>• byPort</li> <li>• byProtocolId</li> <li>• spbm-bvlan</li> <li>• private</li> </ul>                                                                    |
| <b>MstpInstance</b>     | Identifies the MSTP instance.                                                                                                                                                                                              |
| <b>VrfId</b>            | Indicates the Virtual Router to which the VLAN belongs.                                                                                                                                                                    |
| <b>VrfName</b>          | Indicates the name of the Virtual Router to which the VLAN belongs.                                                                                                                                                        |
| <b>PortMembers</b>      | Specifies the slot/port of each VLAN member. The system displays the sub-port only for channelized ports.                                                                                                                  |
| <b>ActiveMembers</b>    | Specifies the slot/port of each VLAN member. The system displays the sub-port only for channelized ports.                                                                                                                  |
| <b>StaticMembers</b>    | Specifies the slot/port of each static member of a policy-based VLAN. The system displays the sub-port only for channelized ports.                                                                                         |
| <b>NotAllowToJoin</b>   | Specifies the slot/ports that are never allowed to become a member of the policy-based VLAN. The system displays the sub-port only for channelized ports.                                                                  |
| <b>ProtocolId</b>       | Specifies the network protocol for protocol-based VLANs. This value is taken from the Assigned Numbers of remote function call (RFC). If the VLAN type is port-based, none is displayed in the Basic tab ProtocolId field. |
| <b>AgingTime</b>        | Specifies the timeout period, in seconds, to age out dynamic members of this VLAN. This field only applies to policy-based VLANs. The default is 600.                                                                      |

#### Note

If you or another user changes the name of an existing VLAN using the VLAN **Basic** tab (or using CLI), the system does not display the new name initially in EDM. To display the updated name, perform one of the following actions:

- Refresh your browser to reload EDM.
- Log out of EDM and log in again to restart EDM.
- Click **Refresh** in the VLAN **Basic** tab toolbar. If the system displays the old VLAN name in other tabs, click **Refresh** on those tabs as well.

## Creating a Private VLAN

### Before You Begin

- To create a private VLAN, you must set the VLAN type to private and set the private VLAN port type.
- The ports you add to a private VLAN must have a port type of isolated, promiscuous, or trunk.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > VLAN**.
2. Click **VLANS**.
3. In the **Basic** tab, click **Insert**.
4. In the **Id** box, enter an unused VLAN ID, or use the ID provided.
5. In the **Name** box, type the VLAN name, or use the name provided.
6. In the **Color Identifier** box, click the down arrow and choose a color from the list, or use the color provided.
7. In the **MstpInstance** box, click the down arrow and choose an msti instance from the list.
8. In the **Type** box, select **private**.
9. In the **PortMembers** box, click the **(...)** button.
10. Click on the ports to add as member ports.

The ports that are selected are recessed, while the non-selected ports are not recessed. Port numbers that are dimmed cannot be selected as VLAN port members.

11. Click **OK**.
12. In the **Secondary Vlan** box, enter an unused VLAN ID.
13. Click **Insert**.
14. Collapse the **VLANS** tab.

The VLAN is added to the **Basic** tab.

To set the port type for the private VLAN:

15. In the navigation pane, expand the following folders: **Configuration > VLAN**.
16. Click **VLANS**.
17. In the Classification area, select the **PrivateVlanPortType**.
18. Click **Apply**.
19. Click **Close**.

**Basic** Field Descriptions

Use the data in the following table to use the **Basic** tab.

| Name                    | Description                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>               | Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. |
| <b>Name</b>             | Specifies the name of the VLAN.                                                                                                                                                                                                                                                                                                                                                    |
| <b>IfIndex</b>          | Specifies the logical interface index assigned to the VLAN.                                                                                                                                                                                                                                                                                                                        |
| <b>Color Identifier</b> | Specifies a proprietary color scheme to associate a color with the VLAN. Color does not affect how frames are forwarded.                                                                                                                                                                                                                                                           |
| <b>Type</b>             | Specifies the type of VLAN: <ul style="list-style-type: none"> <li>• byPort</li> <li>• byProtocolId</li> <li>• spbm-bvlan</li> <li>• private</li> </ul>                                                                                                                                                                                                                            |
| <b>MstpInstance</b>     | Identifies the MSTP instance.                                                                                                                                                                                                                                                                                                                                                      |
| <b>VrfId</b>            | Indicates the Virtual Router to which the VLAN belongs.                                                                                                                                                                                                                                                                                                                            |
| <b>VrfName</b>          | Indicates the name of the Virtual Router to which the VLAN belongs.                                                                                                                                                                                                                                                                                                                |
| <b>PortMembers</b>      | Specifies the slot/port of each VLAN member. The system displays the sub-port only for channelized ports.                                                                                                                                                                                                                                                                          |
| <b>ActiveMembers</b>    | Specifies the slot/port of each VLAN member. The system displays the sub-port only for channelized ports.                                                                                                                                                                                                                                                                          |
| <b>StaticMembers</b>    | Specifies the slot/port of each static member of a policy-based VLAN. The system displays the sub-port only for channelized ports.                                                                                                                                                                                                                                                 |
| <b>NotAllowToJoin</b>   | Specifies the slot/ports that are never allowed to become a member of the policy-based VLAN. The system displays the sub-port only for channelized ports.                                                                                                                                                                                                                          |

| Name              | Description                                                                                                                                                                                                                   |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ProtocolId</b> | Specifies the network protocol for protocol-based VLANs. This value is taken from the Assigned Numbers of remote function call (RFC).<br>If the VLAN type is port-based, none is displayed in the Basic tab ProtocolId field. |
| <b>AgingTime</b>  | Specifies the timeout period, in seconds, to age out dynamic members of this VLAN. This field only applies to policy-based VLANs.<br>The default is 600.                                                                      |

#### Note

If you or another user changes the name of an existing VLAN using the VLAN **Basic** tab (or using CLI), the system does not display the new name initially in EDM. To display the updated name, perform one of the following actions:

- Refresh your browser to reload EDM.
- Log out of EDM and log in again to restart EDM.
- Click **Refresh** in the VLAN **Basic** tab toolbar. If the system displays the old VLAN name in other tabs, click **Refresh** on those tabs as well.

### **VLAN** Field Descriptions

Use the data in the following table to use the **VLAN** tab.

| Name                       | Description                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PrivateVlanPortType</b> | Specifies the port type. If not specified, the port type defaults to None. <ul style="list-style-type: none"> <li>• Isolated: An Isolated port can belong only to one private VLAN</li> <li>• Promiscuous: A Promiscuous port can belong to many private VLANs.</li> <li>• Trunk: A Trunk port can belong to many private VLANs, is tagged, and can also belong to non-private VLANs.</li> </ul> |

## Viewing Private VLAN information

You can view the private VLAN information to display the primary and secondary VLANs and I-SIDs, and also view the private VLAN port types.

### Procedure

1. In the navigation pane, expand the **Configuration > VLAN** folders.
2. Click **VLANs**.
3. Click **Private VLAN**.

*Private VLAN field descriptions*

Use the data in the following table to use the **Private VLAN** tab.

| Name                             | Description                               |
|----------------------------------|-------------------------------------------|
| <b>Primary Vlan</b>              | Shows the VLAN ID for the primary VLAN.   |
| <b>Secondary Vlan</b>            | Shows the VLAN ID for the secondary VLAN. |
| <b>Primary / Secondary I-sid</b> | Shows the I-SID for the VLAN.             |

## Configure an IP address for a VLAN

Assign an IP address to a VLAN to enable routing on the VLAN.

### Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. In the **Basic** tab, select the VLAN for which you are configuring an IP address.
4. Select **IP**.
5. Select **Insert**.
6. Configure the required parameters.
7. Select **Insert**.

*IP Address field descriptions*

Use the data in the following table to use the **IP Address** tab.

| Name                   | Description                                                                                                                                                                                      |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>       | Shows the interface to which this entry applies.                                                                                                                                                 |
| <b>Ip Address</b>      | Specifies the IP address to associate with the VLAN.                                                                                                                                             |
| <b>Net Mask</b>        | Specifies the subnet mask associated with the IP address of this entry. The value of the mask is an IP address with all the network bits configured to 1 and all the hosts bits configured to 0. |
| <b>BcastAddrFormat</b> | Shows the IP broadcast address format on this interface.                                                                                                                                         |
| <b>ReasmMaxSize</b>    | Shows the size of the largest IP datagram which this entity can reassemble from incoming IP fragmented datagrams received on this interface.                                                     |

| Name               | Description                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VlanId</b>      | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <b>BrouterPort</b> | Indicates whether this entry corresponds to a brouter port, as oppose to a routable VLAN.                                                                                                                                                                                                                                                                                                                                  |
| <b>MacOffset</b>   | Specifies the MAC offset value. Routable VLANS are assigned MAC addresses arbitrarily or by offset. Their MAC addresses are: <ul style="list-style-type: none"> <li>• 24 bits: Vendor ID</li> <li>• 12 bits: Chassis ID</li> <li>• 12 bits: 0xA00-0xFFFF</li> </ul> If you enter the MAC offset, the lowest 12 bits are 0xA00 plus the offset. If not, they are arbitrary.                                                 |
| <b>Vrfid</b>       | Associates the VLAN or brouter port with a VRF. VRF ID 0 is reserved for the administrative VRF.                                                                                                                                                                                                                                                                                                                           |

## Changing VLAN port membership

Modify VLAN port members to control access to the VLAN.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **VLANS**.
3. Double-click the **PortMembers** number for the VLAN for which you want to modify port membership.
4. Click the port members you wish to add or remove.
5. Click **Ok**.
6. Click **Apply**.

The VLAN port membership is changed.

## Creating a protocol-based VLAN

Use a protocol-based VLAN so that the VLAN only carries certain traffic types.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **VLANS**.
3. In the **Basic** tab, click **Insert**.
4. In the **Id** box, type the unique VLAN ID or use the ID provided.

5. In the **Name** box, type the VLAN name or use the name provided.
6. In the **Color Identifier** box, select the color or use the color provided.  
This color is used to visually distinguish the VLANs in a network.
7. In the **MstpInstance** box, click the down arrow and choose an MSTI instance from the list.
8. In the **Type** box, select **byProtocolId**.  
This activates additional fields needed to configure protocol-based VLANs.
9. To specify the VLAN port membership, click the button (...) for one of the following fields:

**Port Members**

OR

**StaticMembers**

OR

**NotAllowToJoin**

10. Click each port button to choose the desired membership color.  
Yellow: Potential members—dynamic (potential members are treated as always members)

OR

Green: Always members—static

OR

Red: Never members—not allowed to join

**Important**

In a protocol-based VLAN, a potential member becomes an active member of the VLAN after a frame of the specified protocol is received.

11. Click **Insert**.

## Configure Source MAC Addresses for a Source MAC-Based VLAN

Create a source MAC address for an existing source MAC VLAN.

**Before You Begin**

- Configure the VLAN.

**Procedure**

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Select **VLANs**.
3. In the **Basic** tab, select a source MAC address-based VLAN.
4. Select **Mac**.
5. To manually insert a MAC address, select **Insert**, and then enter it in the form nn:nn:nn:nn:nn:nn.  
OR
6. To add a MAC address from a file, select **File, Add From File**.

7. Use the selection box to browse for the file location.
8. To save a MAC address to a file, select it, select **File, Save to File**, and then use the selection box to browse for a save location.
9. To delete a MAC address, select it, and then select **Delete Members On Device**.
10. Select **Yes**.
11. Select **Close**.

### **VLAN MAC** field descriptions

Use the data in the following table to use the **VLAN MAC** tab.

| Name           | Description                                            |
|----------------|--------------------------------------------------------|
| <b>MacAddr</b> | Specifies the MAC addresses associated with this VLAN. |

## Creating a SPBM B-VLAN

Create a Shortest Path Bridging MAC (SPBM) Backbone VLAN (B-VLAN). Each SPBM network instance is associated with at least one backbone VLAN (B-VLAN) in the core SPBM network. This VLAN is used for both control plane traffic and dataplane traffic.

### Note

As a best practice, configure two B-VLANs in an SPBM dual-homing environment.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **VLANs**.
3. In the **Basic** tab, click **Insert**.
4. In the **Id** box, enter an unused VLAN ID, or use the ID provided.
5. In the **Name** box, type the VLAN name, or use the name provided.
6. In the **Color Identifier** box, click the down arrow and choose a color from the list, or use the color provided.
7. In the **Type** box, select **spbm-bvlan**.
8. Click **Insert**.
9. Collapse the **VLANs** tab.

The VLAN is added to the **Basic** tab.

## Configure Advanced VLAN Features

Use advanced VLAN features to configure the VLAN name, aging time, VLAN operation action, and QoS level. The VLAN Operation Action parameter can be useful for troubleshooting.

You can also configure a DvR Gateway IPv4 address on a VLAN, and enable DvR on it.

### Procedure

1. In the navigation pane, expand **Configuration > VLAN**.

2. Select **VLANs**.
3. Select the **Advanced** tab.
4. Configure the parameters as required by double-clicking fields to make changes.  
You cannot make changes to fields that are dim.
5. Select **Apply**.

### **Advanced** Field Descriptions

Use the data in the following table to use the **Advanced** tab.

| Name                                                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>                                                                                | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <b>Name</b>                                                                              | Specifies the name of the VLAN.                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Ifindex</b>                                                                           | Specifies the logical interface index assigned to the VLAN.                                                                                                                                                                                                                                                                                                                                                                |
| <b>Type</b>                                                                              | Specifies the type of VLAN: <ul style="list-style-type: none"> <li>• byPort</li> <li>• byProtocolId</li> <li>• spbm-bvlan</li> <li>• private</li> </ul>                                                                                                                                                                                                                                                                    |
| <b>Isid</b>                                                                              | Specifies the I-SID number assigned to a customer VLAN (C-VLAN). The range is 0 - 16777215. The default value is 0, which indicates that no I-SID is assigned.                                                                                                                                                                                                                                                             |
| <b>Isid Name</b><br><b>Note:</b><br>This field does not apply to all hardware platforms. | Specifies the name of the I-SID.                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>ProtocolId</b>                                                                        | Specifies the network protocol for protocol-based VLANs.<br>If the VLAN type is not protocol-based, None is displayed in the Basic tab ProtocolId field.                                                                                                                                                                                                                                                                   |
| <b>AgingTime</b>                                                                         | Specifies the timeout period for dynamic VLAN membership. A potential VLAN port is made ACTIVE after it receives a packet that matches the VLAN; if no such packet is received for AgingTime seconds, the port is no longer active. The default is 600.                                                                                                                                                                    |

| Name                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>MacAddress</b>                | Specifies the MAC address assigned to the virtual router interface for this VLAN. This field is relevant only after the VLAN is configured for routing. This MAC address is used as the Source MAC in routed frames and ARP replies.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Vlan Operation Action</b>     | <p>Performs an operation on the VLAN. The values are:</p> <ul style="list-style-type: none"> <li>• none</li> <li>• flushMacFdb: Configures action to flushMacFdb. This action removes the learned MAC addresses from the forwarding database for the selected VLAN.</li> <li>• flushArp: Configures action to flushArp. This action removes the ARP entries from the address table for the selected VLAN.</li> <li>• flushIp: Configures action to flushIp. This action removes the learned IP addresses from the forwarding table for the selected VLAN.</li> <li>• flushDynMemb: Configures action to flushDynMemb. This action removes port members not configured as static from the list of active port members of a policy-based VLAN and removes MAC addresses learned on those ports.</li> <li>• all: Configures action to all. This action performs all the supported actions; it does not perform the Snoop-related actions.</li> </ul> <p>The default is none.</p> |
| <b>Result</b>                    | Specifies the result code after you perform an action.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>NlbMode</b>                   | Enables or disables Microsoft Network Load Balancing (NLB) operations on the VLAN. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SpbMulticast</b>              | Enables or disables Multicast over Fabric Connect. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SpbPimGatewayMulticast</b>    | Enables or disables SPB-PIM Gateway Multicast on a VLAN. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>RmonEnable</b>                | Enables or disables Remote Monitoring (RMON) on the interface. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Ipv6FhsSnoopDhcpEnable</b>    | Enables or disables IPv6 dhcp snooping on a VLAN. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Ipv6FhsNDInspectionEnable</b> | Enables or disables neighbor discovery (ND) inspection on a VLAN. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Name                  | Description                                                                                                                                                                                           |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DvrEnable</b>      | Enables or disables DvR on a VLAN that is configured on the DvR Controller. The default is disabled.<br><br><b>Note:</b><br>You must enable DvR on every VLAN that is configured on a DvR Controller. |
| <b>DvrGwIpv4Addr</b>  | Specifies the DvR gateway IPv4 address for a VLAN.<br><br><b>Important:</b><br>Ensure that you configure the same gateway IPv4 address on all Controllers in the DvR domain that belong to a VLAN.    |
| <b>DvrGwIpv4Onelp</b> | Enables or disables the DvR One IP for a VLAN. The default is disabled (false).                                                                                                                       |

## Configure NLB Support

Use Microsoft Network Load Balancing (NLB) to share the workload among multiple clustering servers. For more information about software scaling capabilities, see [Fabric Engine Release Notes](#).

### Before You Begin

Ensure that the VLAN exists and has an associated IP address.

### About This Task

Use the following procedure to configure NLB support on an IP interface to enable or disable NLB support. The default value is NLB support disabled.

#### Note

- SPBM supports Network Load Balancing (NLB) Unicast and Multicast modes.
- Static multicast ARP entries are not supported for NLB Unicast or NLB Multicast.
- Multicast MAC flooding is not supported for NLB.
- ARP entries for NLB server IP addresses do not age out when there is still client traffic coming to the NLB servers, even after the NLB servers are no longer reachable.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **VLAN**.
2. Select **VLANs**.
3. Select the **Advanced** tab.
4. In the row for the VLAN, double-click the value in the **NlbMode** column.
5. Select the appropriate value.
6. Select **Apply**.

## Configuring a port to accept tagged or untagged frames

Configure a port to accept tagged or untagged frames.

### Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation tree, expand the following folders: **Configuration > Edit > Port**.
3. Click **General**.
4. Click the **VLAN** tab.
5. To configure tagging on the port, select the **PerformTagging** check box.

This setting applies to all VLANs associated with the port.

### Note

If the check box is selected, tagging is enabled. All frames sent from this port are tagged. If the check box is cleared, tagging is disabled. The port does not send tagged frames. The switch removes the tag before sending the frame out of the port.

6. To discard tagged frames on a port for which tagging is disabled, select **DiscardTaggedFrames**.
7. To discard untagged frames on a port for which tagging is enabled, select **DiscardUntaggedFrames**.
8. To designate a default VLAN to associate with a packet that does not match a policy-based VLAN, enter a VLAN ID in the **DefaultVLANId** box or use the default VLAN 1.
9. Click **Apply**.
10. Click **Close**.

## Configuring untagging default VLAN on a tagged port

Configure an untagged default VLAN on a tagged port to separate untagged packets originating from a PC from the tagged packets originating from an IP phone.

### Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation tree, expand the following folders: **Configuration > Edit > Port**.
3. Click **General**.
4. Click the **VLAN** tab.
5. Select **UntagDefaultVlan**.
6. In the **DefaultVlanId**, enter a default VLAN ID.
7. Click **Apply**.
8. Click **Close**.

## Configuring SLPP globally

Enable the Simple Loop Prevention Protocol (SLPP) to detect a loop and automatically stop it.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **SLPP**.

3. Click the **Global** tab.
4. Select **GlobalEnable**.
5. In the **TransmissionInterval** box, type a value for the time interval for loop detection.
6. Click **Apply**.

### **Global** field descriptions

Use the data in the following table to use the **Global** tab.

| Name                        | Description                                                                                                                                            |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GlobalEnable</b>         | Activates or disables SLPP globally. The default is disabled.                                                                                          |
| <b>TransmissionInterval</b> | Configures the interval for which loop detection occurs. The interval is expressed in milliseconds in a range from 500–5000. The default value is 500. |

### *Job aid*

The following table provides the SLPP values.

**Table 265: SLPP values**

| Enable SLPP           | Setting                         |
|-----------------------|---------------------------------|
| Access SMLT           | Yes                             |
| Core SMLT             | No                              |
| Primary switch        |                                 |
| Packet Rx threshold   | 5                               |
| Transmission interval | 500 milliseconds (ms) (default) |
| Secondary switch      |                                 |
| Packet Rx threshold   | 50                              |
| Transmission interval | 500 ms (default)                |

## Configuring the SLPP by VLAN

Activate SLPP on a VLAN to enable forwarding of the SLPP packet over the VLAN. This configuration controls the boundary of SLPP-PDU transmission.

### **Before You Begin**

- Enable SLPP globally before you configure it on a VLAN.

### **Procedure**

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **SLPP**.
3. Click the **VLANS** tab.
4. Click **Insert**.
5. Click the **VlanId** ellipses (...).

6. Select the desired VLAN ID.
7. Click **Ok**.
8. Select **SlppEnable**.
9. Click **Insert**.

### **Insert VLANs** Field Descriptions

Use the data in the following table to use the **Insert VLANs** dialog box.

| Name              | Description                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VlanId</b>     | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <b>SlppEnable</b> | Activates SLPP on the selected VLAN. The SLPP packet transmission and reception process is active only if you enable the SLPP operation. If you disable the SLPP operation, the following occurs: <ul style="list-style-type: none"> <li>• the system sends no SLPP packets</li> <li>• the system discards received SLPP packets</li> </ul> The default is enabled.                                                        |

## Configuring the SLPP by port

Use SLPP on a port to avoid traffic loops on the port.

### Note

To provide protection against broadcast and multicast storms, as a best practice, enable Rate Limiting for broadcast traffic and multicast traffic.

### Before You Begin

- Enable SLPP globally before you configure it on a port.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **SLPP**.
3. Click the **Ports** tab.
4. Double-click the **PktRxThreshold** box for the desired port to edit the threshold value for packet reception.
5. Double-click the **SlppEnable** box for the desired port.
6. Select **true** to enable SLPP.
7. Click **Apply**.

**Ports** field descriptions

Use the data in the following table to use the **Ports** tab.

| Name                                | Description                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>                      | Specifies the interface index number for a port.                                                                                                                                                                                                                                                                                                            |
| <b>PktRxThreshold</b>               | Specifies the threshold for packet reception. Configure the SLPP packet receive threshold to a value (1- 500) that represents the number of received SLPP-PDUs to shut down the port. This variable is a port-level parameter, therefore if the port is tagged, SLPP-PDUs from the various VLANs increment this single threshold counter. The default is 1. |
| <b>SlppEnable</b>                   | Activates SLPP on the selected interface. The default is disabled.                                                                                                                                                                                                                                                                                          |
| <b>IncomingVlanId</b>               | Shows the VLAN ID of the classified packet on a port disabled by SLPP.                                                                                                                                                                                                                                                                                      |
| <b>SrcNodeType</b>                  | Specifies the source node type of the received SLPP packet.                                                                                                                                                                                                                                                                                                 |
| <b>PktRxCount</b>                   | Shows the total number of SLPP packets the port received.                                                                                                                                                                                                                                                                                                   |
| <b>TimeToClrPktRxCount</b>          | Specifies the timer to clear the SLPP receive counter. After you enable SLPP and the port receives SLPP PDUs, the timer starts. After the timer exceeds the configured value, the system resets the count to zero. The default is 21,600 seconds.                                                                                                           |
| <b>RemainingTimeToClrPktRxCount</b> | Shows the time remaining before the SLPP receive counter is reset to zero.                                                                                                                                                                                                                                                                                  |

*Job aid*

The following table provides the SLPP values.

**Table 266: SLPP values**

| Enable SLPP           | Setting                         |
|-----------------------|---------------------------------|
| Access SMLT           | Yes                             |
| Core SMLT             | No                              |
| Primary switch        |                                 |
| Packet Rx threshold   | 5                               |
| Transmission interval | 500 milliseconds (ms) (default) |
| Secondary switch      |                                 |
| Packet Rx threshold   | 50                              |
| Transmission interval | 500 ms (default)                |

## Configuring the forwarding database timeout globally

Configure the forwarding database global timeout to age out dynamically learned forwarding information.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**
2. Click **VLANS**.
3. Click the **FdbAging** tab.
4. Type an interval, in seconds, for aging out dynamically learned forwarding information, or keep the default.
5. Click **Apply**.

### **FDB Aging** field descriptions

Use the data in the following table to use the **FDB Aging** tab.

| Name            | Description                                                                                               |
|-----------------|-----------------------------------------------------------------------------------------------------------|
| <b>FdbAging</b> | Specifies the timeout period for dynamically learned mac addresses on the vlan. The default value is 300. |

## Viewing VLAN forwarding database information

Perform this procedure to view forwarding database entries for all VLANs on the device.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **VLANS**.
3. In the VLANS tab, click the **Forwarding** tab.

### **Forwarding** Field Descriptions

Use the data in the following table to use the **Forwarding** tab.

| Name           | Description                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VlanId</b>  | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <b>Address</b> | Specifies a unicast MAC address for which the VLAN has forwarding or filtering information.                                                                                                                                                                                                                                                                                                                                |

| Name          | Description                                                                                                                                                                                  |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Status</b> | Specifies the status of the VLAN. The values are: <ul style="list-style-type: none"> <li>• other</li> <li>• invalid</li> <li>• learned</li> <li>• self</li> <li>• mgmt</li> </ul>            |
| <b>Port</b>   | Specifies either a value of zero (0) or the port number of the port on which a frame having the specified MAC address was seen. A value of <b>cpp</b> indicates a self-assigned MAC address. |
| <b>BMac</b>   | Shows the backbone MAC address if the entry is learned from a Shortest Path Bridging MAC (SPBM) network.                                                                                     |
| <b>Cvid</b>   | Specifies the customer VID.                                                                                                                                                                  |

## Viewing the Forwarding Database for a Specific VLAN

Use the forwarding database for VLANs to determine how the system forwards a received frame.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**
2. Click **VLANs**.
3. Select a VLAN.
4. Click **Bridge**.
5. Click the **Forwarding** tab and the VLAN forwarding database information is displayed.

### **Forwarding** Field Descriptions

Use the data in the following table to use the **Forwarding** tab.

| Name           | Description                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VlanId</b>  | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <b>Address</b> | Specifies a unicast MAC address for which the bridge has forwarding or filtering information.                                                                                                                                                                                                                                                                                                                              |
| <b>Status</b>  | Specifies the status. Values include the following: <ul style="list-style-type: none"> <li>• self—one of the bridge addresses</li> <li>• learned—a learned entry that is being used</li> <li>• mgmt—a static entry</li> </ul>                                                                                                                                                                                              |

| Name        | Description                                                                                                                                                                                  |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Port</b> | Specifies either a value of zero (0) or the port number of the port on which a frame having the specified MAC address was seen. A value of <b>cpp</b> indicates a self-assigned MAC address. |
| <b>Cvid</b> | Identifies the customer VID for this interface.                                                                                                                                              |

## Clearing learned MAC addresses by VLAN

Use the clear learned MAC addresses feature to flush the bridge forwarding database.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **VLANS**.
3. Click the **Advanced** tab.
4. Double-click in the **VLAN Operation Action** field.
5. Choose **FlushMacFdb** from the list.
6. Click **Apply**.

## Clearing learned MAC addresses for all VLANs by port

Use the following procedure to clear all the forwarding database (FDB) for VLANs associated with this port.

### Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation tree, expand the following folders: **Configuration > Edit > Port**.
3. Click **General**.
4. In the Interface tab **Action** box, select **FlushMacFdb**.
5. Click **Apply**.

All learned MAC addresses are cleared from the forwarding database (FDB) for VLANs associated with this port.

6. Click **Close**.

## Configuring static forwarding

Configure static forwarding to specify the group of ports that are allowed to forward frames.

### Important

Entries are valid for unicast and for group/broadcast addresses.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **VLANS**.

3. Select the **Basic** tab.
4. Select a VLAN.
5. Click **Bridge**.
6. In the Bridge, VLAN tab, click the **Static** tab.
7. Click **Insert**.
8. In the **MacAddress** box, enter a forwarding destination MAC address.
9. In the **Port** box, click the ellipsis button (...).
10. Select the port on which the frame is received.
11. Click **Ok**.
12. Click **Insert**.

### **Static** field descriptions

Use the data in the following table to use the **Static** tab.

| Name              | Description                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MacAddress</b> | Specifies the destination MAC address in a frame to which the forwarding information for this entry applies. This object can take the value of a unicast address.                                                                                                                                                                                                                                                          |
| <b>Port</b>       | Specifies the port number of the port on which the frame is received.                                                                                                                                                                                                                                                                                                                                                      |
| <b>VlanId</b>     | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <b>Status</b>     | Specifies the status of the VLAN.                                                                                                                                                                                                                                                                                                                                                                                          |

## Configure Limit Learning

Limit MAC address learning to limit the number of forwarding database (FDB) entries learned on a particular port to a user-specified value. After the number of learned forwarding database entries reaches the maximum limit, MAC learning stops at that port.

### **Procedure**

1. On the Device Physical View tab, select one or more ports.
2. In the navigation pane, expand the **Configuration > Edit > Port** folders.
3. Select **General**.
4. Select the **Limit-Learning** tab.
5. Configure the parameters as required.
6. Select **Apply**.

**Limit Learning** field descriptions

Use the data in the following table to use the **Limit-Learning** tab.

| Name                   | Description                                                                                                       |
|------------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>PortNum</b>         | Shows the slot and port number to configure.                                                                      |
| <b>MaxMacCount</b>     | Configures the number of entries in the MAC table for the port that causes learning to stop. The default is 1024. |
| <b>CurrentMacCount</b> | Shows the number of entries currently in the MAC table for the port.                                              |
| <b>Enable</b>          | Enables or disables limit learning for the port. The default is disable.                                          |
| <b>MacLearning</b>     | Shows if MAC learning is enabled or disabled for the port.                                                        |

VRF Lite provides secure customer data isolation.

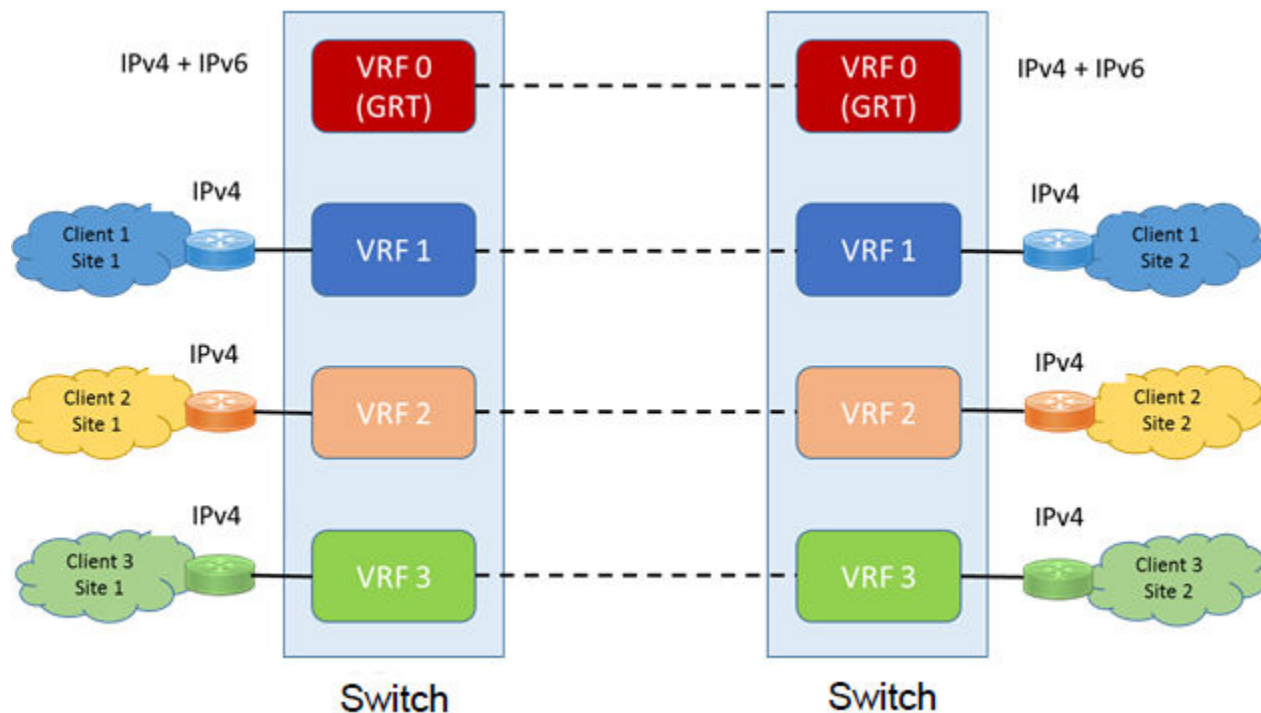

## VRF Lite Fundamentals

The switch supports what is termed as VRF Lite. Lite conveys the fact that the switch does not use Multiprotocol Label Switching (MPLS) for VRF; VRF Lite is a device virtualization feature, not a network-wide virtualization feature.

Use VRF Lite to offer networking capabilities and traffic isolation to customers that operate over the same node (router). Each virtual router emulates the behavior of a dedicated hardware router; the network treats each virtual router as a separate physical router. In effect, you can perform the functions of many routers using a single platform that runs VRF Lite. The result is a substantial reduction in the cost associated with providing routing and traffic isolation for multiple clients.

With multicast virtualization for IPv4, the switch can function as multiple virtual multicast routers.

The following figure shows one platform acting as multiple virtual routers, each serving a different customer network.

**Figure 248: Multiple virtual routers in one system**

A switch can support many virtual routers. Each virtual router instance is called a VRF instance. A VRF represents a single instance of a virtual router. Each instance maintains its own routing table. The term Multiple Virtual Router (MVR) is sometimes used to represent a router that contains many VRF instances.

The IPv6 Virtualization functionality adds IPv6 support on VRFs and Layer 3 VSNs. Each VRF instance has its own IPv6 interfaces, IPv6 address space, IPv6 routing table, and IPv6 global parameters. For more information on Layer 3 VSN, see [Layer 3 VSN Configuration](#) on page 1099.

The Global Router, VRF 0, is the first instance of the router. When the system starts, it creates VRF 0 by default. VRF 0 provides all non-virtual and traditional routing services. You cannot delete this instance. You can create and configure other VRF instances, if required.

VRF 0 is the only VRF that you can log into through CLI. CLI requires you to specify the VRF when you enter commands.

You can associate one VRF instance with many IPv4 or IPv6 interfaces. These interfaces are unique for each VRF instance. An interface is an entity with an IPv4 or IPv6 address that has the following characteristics:

- A unique association with a VLAN.
- A unique association with a brouter, if not associated with a VLAN
- A unique association with a circuit

A VLAN can only be associated with a single VRF instance.

#### Note

- You cannot associate a VLAN or port and a VRF instance if the VLAN or port has an IPv4 or IPv6 address. You must first associate the port and VRF instance and then you can configure the IPv4 or IPv6 address.
- Use the **boot config flag vrf-scaling** command, on supported switches, to increase the total number of supported VRFs. For more information on route scaling, see [Fabric Engine Release Notes](#).

## VRF Lite Capability and Functionality

VRF Lite supports virtualization of the following IPv4 and IPv6 protocols and features.

- IPv4 protocols or features:
  - ARP
  - BGP
  - Circuitless IP
  - DHCP
  - IGMP
  - RIP
  - Route policies
  - Route preferences
  - Router Discovery
  - Static routes
  - User Datagram Protocol (UDP)
  - VLAN
  - VRRP
- IPv6 protocols or features:
  - BGP
  - IPv6 Interfaces and IPv6 Static Routes
  - ECMP and Alternative Route
  - OSPF
  - Route redistribution for static and direct routes
  - VRRPv3
  - DHCP Relay
  - IPv6 Reverse Path Forwarding
  - ICMP Ping & Traceroute
  - ISIS Accept Policies

The switch uses VRF Lite to perform the following actions:

- Partition traffic and data and represent an independent router in the network
- Provide virtual routers that are transparent to end-users

- Support addresses that are not restricted to the assigned address space provided by host Internet Service Providers (ISP)
- Support overlapping IP address spaces in separate VRF instances

#### Note

If you enable multicast route redistribution between two VRFs, the switch does not support IP addresses that overlap within the two VRFs. The device does not generate an error if addresses overlap. You must avoid this situation.

VRF Lite interoperates with RFC 4364, Layer 3 VPNs. Split MultiLink Trunking (SMLT) and Routed SMLT (RSMLT) are also supported for VRF instances.

Although customer data separation into Layer 3 virtual routing domains is usually a requirement, sometimes customers must access a common network infrastructure. For example, they want to access the Internet, data storage, Voice over IP (VoIP)-public switched telephone network (PSTN), or call signaling services. To interconnect VRF instances, you can use an external firewall that supports virtualization, or use inter-VRF forwarding for specific services. With the inter-VRF solution, you can use routing policies and static routes to inject IP subnets from one VRF instance to another, and you can use filters to restrict access to certain protocols. The following figure depicts inter-VRF forwarding by the switch.

**Figure 249: Inter-VRF forwarding**

For more information about the latest VRF Lite scalability, see [Fabric Engine Release Notes](#).

For configuration information about multicast virtualization, see [IP Multicast](#) on page 1139.

## VRF Lite and inter-VRF route redistribution

The switch supports three route redistribution functions:

- Intra-VRF inter-protocol route redistribution (redistribution within the same VRF instance), for example, redistribute RIP to OSPF.
- Inter-VRF inter-protocol redistribution (redistribution between two VRF instances), for example, redistribute RIP in VRF 2 to OSPF in VRF 4.
- Inter-VRF static routes (for example, a static route in a given VRF instance) configured as a typical static route but with the added parameter of a next-hop-vrf (the next-hop IP address is found in the next-hop-vrf instance).

With inter-VRF route redistribution, a user in one VRF instance can access route data in other VRF instances. You can redistribute routes within a VRF instance or between VRF instances; for example, one VRF instance can redistribute routes to all other VRF instances. You can redistribute Local, static, OSPF, RIP, and BGP routes and both dynamic (OSPF, BGP, and RIP) and static route redistribution is supported.

More than one routing protocol can be present in each VRF instance. Route redistribution can occur either between different protocol types, or between the same protocol types on different VRF instances.

An interface uses redistribution to announce routes that are learned by other protocols (OSPF or BGP, for example). Control route redistribution by using route policies. When you associate routing policies with route redistribution, the policy is checked before the target protocol is updated. Across VRF instances, the policy is checked at the source VRF instance, so only qualified routes are added to the routing table.

You can use static route commands to inject one specific route (including a default route) from one VRF instance to another. The route is added to the target VRF instance, while the next hop is resolved by the next-hop VRF instance.

Static routes are used to direct packets from a given source using a next-hop IP address. The next-hop-vrf option in a static route permits this path to proceed from one VRF to another. Overlapping IP addresses are supported within VRFs, thus it is possible for two VRFs to have identical IP addresses.

The following list describes interVRF route redistribution:

- Redistributed routes are added to the target VRF instance, and their next hop remains in the source VRF instance.
- If either the source or destination VRF instance is deleted, the redistribution configuration is automatically deleted.
- Redistributed routes are not further redistributed to another VRF instance.
- Route redistribution is unidirectional. You must configure route redistribution for the reverse direction if you require it. You can configure different route policies for each direction.
- After you configure interVRF route redistribution between two VRF instances, you must avoid using overlapping IP addresses between these two VRF instances.

Avoid overlapping addresses; the device does not generate an error if addresses overlap.

- Intra-VRF routes take precedence over inter-VRF routes.
- You can physically connect two VRF instances to distribute route across VRF instances (in this case, you do not need to configure route redistribution).

### *Route Redistribution Operation*

To perform redistribution, the device maintains a route change list. The change list contains all the best routes that are either added to or deleted from the forwarding table. When a best route is added to or deleted from the forwarding table, the change list is updated to reflect the change and notify registered protocols. The registered protocols pick up the change from the change list when it becomes available.

An example scenario of interVRF redistribution follows. To redistribute OSPF routes in VRF 1 to RIP in VRF 0:

- Create, enable, and apply a RIP redistribution instance. The source protocol is OSPF and the VRF source is VRF 1.
- When an OSPF route is added in VRF 1, the Routing Table Manager (RTM) in VRF 1 puts the new route into the change list.
- The device notifies RIP in VRF 0, because RIP is registered with the RTM of VRF 1 for OSPF route changes.
- To send OSPF routes from VRF 1 through the RIP interface in VRF 0, the interface uses a route policy with match VRF criterion of VRF 1.

The switch also supports inter-domain multicast routing. For more information, see [IP Multicast](#) on page 1139.

## Port parameters and VRF Lite management

You can configure each VRF instance as a separate router, this means that you can configure different routing protocols and associated parameters for each instance. You can associate non0 VRF instances with ports.

The port parameters that you can edit for a VRF instance depend on whether the port belongs to only one, or more than one, VRF instance. For example, if a port belongs to only one VRF, you can edit the port parameters of the VRF. If a port belongs to more than one VRF instance, you cannot edit the port parameters of that port unless you are accessing the port through the Global Router with read-write-all access. If you do not have read-write-all access, you can only edit the GlobalRouter port parameters. If a port belongs to a single non0 VRF, the port parameters can be changed by this VRF. If a port belongs to multiple VRF instances, only a user with read-write-all access who is accessing the port through the Global Router can change this port configuration.

## VRF Lite Configuration Rules

You must select the VRF for global IPv4 or IPv6 options before entering commands; not all Global Router parameters are configurable on other VRF instances.

Layer 1 and Layer 2 information (including VLAN information) is global and is not maintained for each VRF instance. However, you can associate a set of VLANs with a VRF instance.

A VLAN cannot belong to more than one VRF instance at a time. When you create a VLAN, more than one physical port can belong to it. You can associate a VRF instance with more than one IPv4 or IPv6 interface (a physical Ethernet port or a VLAN).

Perform physical port assignment at the VLAN and brouter port level. A VRF instance inherits all the ports assigned to its VLANs and brouter ports. You cannot directly assign a physical port to a VRF instance, but it is implicitly assigned when you associate the VRF with VLANs or brouter ports.

For IPv4, after you configure interVRF route redistribution between two VRF instances, avoid overlapping IP addresses between these two VRF instances.

When you configure VRF Lite, remember the following rules:

- You can connect two VRFs from the same system with an external cable.
- An IPv4 or IPv6 routable VLAN can become a member of a VRF.
- An IPv4 or IPv6 interface can belong to only one VRF.
- A VRF can exist even if no interfaces are assigned to it.
- Routing policies apply to VRFs on an individual basis.
- Multiple VRFs on the same node can function in different autonomous systems.

Following rules apply to IPv4 interfaces specifically:

- If you configure an IPv4 interface without specifying the VRF instance, it is mapped to VRF 0 by default.
- VRF Lite supports SMLT and RSMLT.
- VRF Lite supports RIP in and out policies.
- VRF Lite supports OSPF in and out (accept and redistribute) policies.
- Before you delete a VRF instance, disable OSPF. Deleting a VRF instance deletes the OSPF instance if OSPF is disabled.
- When you create a VRF instance, an OSPF instance is not automatically created. To activate OSPF on a VRF instance, first create an OSPF instance, and then enable OSPF.
- You can configure a VRF so it can have IP interfaces with OSPF, RIP, static routes, and policies simultaneously.
- Every IPv4 interface is a member of VRF 0 unless explicitly defined to belong to another VRF.

### *5320 Series VRF Support*

For the 5320 Series, only 5320-48P-8XE and 5320-48T-8XE support more than one VRF with IP configuration.

The 16- and 24-port 5320 Series models support a single active VRF with IP configuration; the VRF can be the Global Routing Table (GRT) or a non-default VRF:

- The GRT becomes the active VRF if you attach an IP interface to a VLAN. Otherwise, the first non-default VRF you create becomes the active VRF.
- If the GRT is the active VRF, you cannot create a second VRF.
- You cannot create more than one non-default VRF.
- You cannot configure IP interfaces in the GRT if the active VRF is a non-default VRF.

- To transition the active VRF from the GRT to a non-default VRF, remove all IP interfaces and then create the non-default VRF.
- To transition the active VRF from a non-default VRF to the GRT, first remove all router, ARP, and IP interfaces. Delete the VRF, and then add IP interfaces to the GRT.

Support for a single active VRF affects other features that rely on VRFs with IP configuration:

- Fabric Extend - on platforms that support multiple VRFs with IP configuration, you cannot configure the tunnel source address (**ip-tunnel-source-address** command) if the address belongs to a VRF with an attached I-SID, which presents an issue for single VRF platforms. On platforms with only one active VRF, you can use an *overlay* parameter to bypass this restriction.
- Fabric Extend — you must configure a route-map policy to suppress IS-IS redistribution of the FE tunnel subnet:
  - Configure route-maps to not permit redistribution of the local route used as the tunnel source address (**ip-tunnel-source-address** command).
  - Configure an accept policy to deny IS-IS routes that overlap with the destination tunnel IP address.
- IP Shortcuts and Layer 3 VSN - You cannot configure the IP source address (**ip-source-address** command) as an IP address in the GRT if the active VRF is a non-default VRF.

## VRF Lite configuration using the CLI

---

Use Virtual Router and Forwarding (VRF) Lite to provide many virtual routers using one switch.

This section shows you how to configure a VRF instance and how to associate ports and VLANs with VRF instances.

The following task flow shows you the sequence of procedures you perform to configure VRF Lite.

Figure 250: VRF Lite configuration procedures

## Create a VRF Instance

### About This Task

Create a VRF instance to provide a virtual routing interface for a user.

For more information on route scaling, see [Fabric Engine Release Notes](#).

### Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Create a VRF instance and specify a VRF name:  
`ip vrf WORD<1-16>`

3. Configure the maximum number of routes:

- For IPv4:

```
ip vrf WORD<1-16> max-routes <max-routes>
```

- For IPv6:

```
ip vrf WORD<1-16> ipv6-max-routes <max-routes>
```

4. Enable max-routes traps:

- For IPv4:

```
ip vrf WORD<1-16> max-routes-trap enable
```

- For IPv6:

```
ip vrf WORD<1-16> ipv6-max-routes-trap enable
```

**Note**

The maximum number of IPv6 routes for the Global Router are fixed and cannot be changed.

5. Enter VRF Router Configuration mode:

```
router vrf WORD<1-16>
```

6. Configure the IP routing protocol triggers for the VRF:

Use one of the following commands on your switch:

- `ip bgp`

`ip bgp` creates both ipv4 and ipv6 instances.

- `ip ospf`

Use `ipv6 ospf` to create an OSPFv3 instance.

- `ip rip`

RIPng is not virtualized, hence the IPv6 configuration does not apply here.

**Note**

You cannot configure BGP, OSPF, or RIP on a VRF instance unless you first configure the routing protocol trigger.

7. Ensure that the instance is configured correctly:

```
show ip vrf [WORD<1-16>]
```

*Examples*

Create a VRF instance:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip vrf vrfRED
```

Configure the maximum number of IPv4 routes and enable max-routes traps.

```
Switch:1(config)#ip vrf vrfRED max-routes 12000
Switch:1(config)#ip vrf vrfRED max-routes-trap enable
```

Enter Router Configuration mode and configure the routing protocol triggers for the VRF:

```
Switch:1(config)#router vrf vrfRED
Switch:1(router-vrf)#ip bgp
Switch:1(router-vrf)#ip ospf
Switch:1(router-vrf)#ip rip
```

To Configure OSPFv3 instance for the VRF:

```
Switch:1(config)#router vrf vrfRED
Switch:1(router-vrf)#ipv6 ospf
```

Exit to Global configuration mode:

```
Switch:1(router-vrf)#exit
```

Configure the maximum number of IPv6 routes and enable IPv6 max-routes traps.

```
Switch:1(config)#ip vrf vrfRED ipv6-max-routes 7700
Switch:1(config)#ip vrf vrfRED ipv6-max-routes-trap enable
```

Ensure that the instance is configured correctly:

```
Switch:1#show ip vrf vrfRED

## Associating a VLAN or port with a VRF instance

You can assign a VRF instance to a port or VLAN. You cannot associate a VLAN or port and a VRF instance if the VLAN or port has an IP address. You can configure the IP address after you associate the port and VRF instance.

### Before You Begin

- Ensure the VRF is already configured.

**Procedure**

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Associate the port or VLAN with a VRF instance:

```
vrf WORD<1-16>
```

**Example**

```
Switch:1> enable
Switch:1# configure terminal
```

Create a VRF named Two:

```
Switch:1(config-if)# ip vrf Two
```

Create a VLAN of type byport:

```
Switch:1(config-if)# vlan create 33 name vlan-30 type port-mstprstp 0
```

Enter VLAN Interface Configuration mode:

```
Switch:1(config-if)# interface vlan 33
```

Assign the VLAN to VRF Two:

```
Switch:1(config-if)# vrf Two
```

Give the VLAN an IP address:

```
Switch:1(config-if)# ip address 192.0.2.1 255.255.255.0
```

Enter VRF configuration mode:

```
Switch:1(config-if)# router vrf Two
```

*Variable Definitions*

Use the data in the following table to use the **vrf** command.

| Variable                          | Value                               |
|-----------------------------------|-------------------------------------|
| <code>vrf WORD&lt;1-16&gt;</code> | Specifies the VRF instance by name. |

## Create an IP VPN Instance on a VRF

Create an IP VPN instance to advertise IP routes from one VRF to another across a Shortest Path Bridging MAC (SPBM) network.

### Before You Begin

- The VRF must exist.

### Procedure

- Enter VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

router vrf WORD<1-16>
```

- Create an IP VPN instance on the VRF:

```
ipvpn
```

- Assign a service instance identifier (I-SID) to the IP VPN:

```
i-sid <0-16777215>
```

- Enable IP VPN on the VRF:

```
ipvpn enable
```

By default, a new IP VPN instance is disabled.

- Display all IP VPNs:

```
show ip ipvpn [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

### Example

From Global Configuration mode, log on to Router VRF Configuration mode:

```
Switch:1(config)# router vrf red
```

Create the IP VPN instance:

```
Switch:1(router-vrf)# ipvpn
```

Enable IP VPN:

```
Switch:1(router-vrf)# i-sid 100
```

Enable IP VPN:

```
Switch:1(router-vrf)#ipvpn enable
```

```
=====
 IPv4 IPVPN
=====
VRF Name VRF ID IPv4 IPVPN IPv6 IPVPN I-SID I-SID Name

red 1 enabled disabled 100 ISID-1
=====
```

```
1 out of 1 Total active IPv4 L3 VSN displayed, including 0 active IPv6 L3 VSN.
```

*Variable definitions*

Use the data in the following table to use the **show ip ipvpn** command.

| Variable                              | Value                   |
|---------------------------------------|-------------------------|
| <code>vrf WORD&lt;1-16&gt;</code>     | Specifies the VRF name. |
| <code>vrfids WORD&lt;0-512&gt;</code> | Specifies the VRF ID.   |

Use the data in the following table to use the **i-sid** command.

| Variable                              | Value                                                                                                                      |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <code>i-sid &lt;0-16777215&gt;</code> | Assigns an I-SID to the VRF to configure. Use the no or default option to remove the I-SID to VRF allocation for this VRF. |

## Create an IPv6 VPN Instance

### Before You Begin

The VRF must exist.

### About This Task

Create an IPv6 VPN instance to advertise IPv6 routes from a VRF to Shortest Path Bridging MAC (SPBM) network. For more information about Layer 3 Virtual Services Networks (VSNs) and SPBM, see [Layer 3 VSN Configuration](#) on page 1099.

### Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:
 

```
enable

configure terminal

router vrf WORD<1-16>
```
2. Create an IPv6 VPN instance:
 

```
ipv6 ipvpn
```
3. Assign a service instance identifier (I-SID) to the IPv6 VPN:
 

```
i-sid <0-16777215>
```
4. Enable IPv6 VPN:
 

```
ipv6 ipvpn enable
```
5. Display all IPv6 VPNs:
 

```
show ipv6 ipvpn [vrf WORD<1-16> | vrfids WORD<0-512>]
```

### Example

Create and enable IPv6 VPN instance:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf vrfred
```

```

Switch:1(router-vrf)#ipv6 ipvpn
Switch:1(router-vrf)#i-sid 100
Switch:1(router-vrf)#ipv6 ipvpn enable
Switch:1(router-vrf)#show ipv6 ipvpn
=====
 IPv6 IPVPN
=====
VRF Name VRF ID IPv6 IPVPN IPv4 IPVPN I-SID I-SID Name

vrfred 2 enabled disabled 5555 ISID-5555

1 out of 1 Total IPv6 L3 VSN, 1 active IPv6 and 0 active IPv4 displayed.

```

### Variable definitions

Use the data in the following table to configure the **ipv6 ipvpn** command.

| Variable      | Value                                        |
|---------------|----------------------------------------------|
| <i>enable</i> | Enables IPv6 IPVPN. The default is disabled. |

Use the data in the following table to configure the **i-sid** command.

| Variable                  | Value                                         |
|---------------------------|-----------------------------------------------|
| <i>&lt;0-16777215&gt;</i> | Assigns an I-SID to the VRF being configured. |

Use the data in the following table to configure the **show ipv6 ipvpn** command.

| Variable                        | Value                   |
|---------------------------------|-------------------------|
| <i>vrf WORD&lt;1-16&gt;</i>     | Specifies the VRF name. |
| <i>vrfids WORD&lt;0-512&gt;</i> | Specifies the VRF ID.   |

## Configure the Maximum Number of VRFs

Perform this procedure to change the maximum number of VRFs and Layer 3 VSNs that the switch supports. Increasing the number of VRFs or Layer 3 VSNs can be useful in a WAN scenario or other large network.

The maximum number of supported VRFs and Layer 3 VSNs differs depending on the hardware platform. For more information about maximum scaling numbers, see [Fabric Engine Release Notes](#).

### About This Task

#### Important

If you enable this boot config flag, and the switch operates in SPBM mode (default configuration), the switch reduces the number of configurable VLANs. In such a configuration, the switch reserves VLANs 3500 to 3998 for internal use. You cannot use these VLANs as either platform VLANs or B-VLANs. You can still use the reserved VLAN range for customer VLANs (C-VLAN) on Flex UNI and B-VLANs on FE-VID.

**Before You Begin**

- If the switch operates in SPBM mode, before you enable the boot config flag, perform the following actions:
  - Check in-VLAN filters. If a filter references a VLAN in the 3500 to 3998 range, you must delete the filter or the filter configuration fails when you restart the switch.
  - Delete VLANs in the 3500 to 3998 range.

**Procedure**

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Increase the maximum number of VRFs and Layer 3 VSNs:
 

```
boot config flag vrf-scaling
```

OR
3. Verify the configuration:
 

```
show boot config flags
```
4. Save the configuration:
 

```
save config
```
5. Restart the switch for the change to take effect:
 

```
reset
```

*Examples*

Enable the boot config flag to increase the maximum number of VRFs and Layer 3 VSNs. In the following example, the switch operates in SPBM mode and reserves the VLAN ID range of 3500 to 3999. If the switch does not operate in SPBM mode, the system does not display the VLAN warning message when you enable VRF scaling.

```
Switch:1>en
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#boot config flag vrf-scaling
Warning: Vlan 3500 to 3999 will be reserved for internal use.

Warning: Please save the configuration and reboot the switch
 for this configuration to take effect.
```

**Note**

Flag support can vary across hardware models.

```
Switch:1#show boot config flags
flags advanced-feature-bandwidth-reservation low
flags block-snmp false
flags debug-config false
flags debugmode false
flags dvr-leaf-mode false
flags enhancedsecure-mode false
flags factorydefaults false
flags flow-control-mode true
flags ftpd true
flags hsecure false
```

```

flags ipv6-egress-filter true
flags ipv6-mode false
flags logging true
flags macsec false
flags nni-mstp false
flags reboot true
flags spanning-tree-mode mstp
flags spbm-config-mode true
flags spbm-node-scaling true
flags sshd true
flags syslog-rfc5424-format true
flags telnetd true
flags tftpd true
flags trace-logging false
flags urpf-mode true
flags verify-config true
flags vrf-scaling true

```

The following example shows the message that the system displays if you try to enable the boot config flag and configured VLANs use IDs between 3500 and 3999.

```

Switch:1>en
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#boot config flag vrf-scaling

Error: Delete all configured platform vlans between 3500 and 3999 to enable vrf-scaling.

```

## Enabling IPv6 trap notifications

### About This Task

Perform this procedure to enable SNMP traps when maximum number of IPv6 routes are reached.

#### Note

Different hardware platforms support different parameter ranges. Use the CLI Help to see the available range.

### Procedure

1. Enter Global Configuration mode:
 

```
enable
```

```
configure terminal
```
2. Enable max-routes trap:
 

```
ip vrf WORD<1-16> ipv6-max-routes-trap enable
```

### Example

```

Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip vrf vrfRED ipv6-max-routes-trap enable

```

Variable definitions

Use the data in the following table to use the **ipv6-max-routes-trap** command.

| Variable      | Value                                                                                                       |
|---------------|-------------------------------------------------------------------------------------------------------------|
| <i>enable</i> | Enables SNMP trap generation based on the configured number of maximum IPv6 routes. The default is enabled. |

## Displaying IPv6 max-routes information

### About This Task

Perform this procedure to display the maximum IPv6 routes configured.

### Procedure

1. Enter Privileged EXEC mode:  

```
enable
```
2. Display max-routes information:  

```
show ip vrf ipv6-max-routes [vrfids WORD<0-512> | WORD<1-16>]
```

### Example

```
Switch:1#show ip vrf ipv6-max-routes

=====
==
 VRF Specific Configuration
=====
==
VRF-ID VRF-NAME CONTEXT-NAME IPV6-MAX-ROUTES IPV6-MAX-ROUTES-TRAP VRF-TRAP

--

 2 vrfblue vrf2 5000 enable enable

3 out of 3 Total Num of VRF Entries displayed.
```

## VRF Lite configuration using Enterprise Device Manager

Use VRF Lite to provide many virtual routers using a single switch.

## Configuring a VRF instance

### About This Task

Configure a VRF instance to provide a virtual routing interface for a user.

#### Note

The maximum routes of IPv4 and IPv6 for Global Router (GRT) are non-configurable and fixed at the system limits.

Maximum route traps are not generated on GRT. For non-default VRFs, the permitted maximum routes can be lower than system limits and traps generate when the limit is exceeded.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VRF**.
2. Click **VRF**.
3. Click the **VRF** tab.
4. Click **Insert**.
5. Specify the VRF ID.
6. Name the VRF instance.
7. Configure VRF Lite-related traps.
8. Configure the other parameters as required.
9. Click **Insert**.

### *VRF field descriptions*

Use the data in the following table to help you use the **VRF** tab.

| Name                                                                                                                          | Description                                                                                                                                                                                                                                                                              |
|-------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>                                                                                                                     | Specifies the ID number of the VRF instance. VRF ID 0 is reserved for the GlobalRouter.                                                                                                                                                                                                  |
| <b>Name</b>                                                                                                                   | Names the VRF instance.                                                                                                                                                                                                                                                                  |
| <b>ContextName</b>                                                                                                            | Identifies the VRF. The SNMPv2 Community String or SNMPv3 contextName denotes the VRF context and is used to logically separate the MIB port management.                                                                                                                                 |
| <b>TrapEnable</b>                                                                                                             | Enables the VRF to send VRF Lite-related traps (VrfUp and VrfDown). The default is enabled.                                                                                                                                                                                              |
| <b>MaxRoutes</b><br><b>Note:</b><br>Exception: not supported on 5320-16P-4XE, 5320-16P-4XE-DC, 5320-24P-8XE, or 5320-24T-8XE. | Configures the maximum number of routes allowed for the VRF, which varies depending on the hardware. For scaling information, see <a href="#">Fabric Engine Release Notes</a> . The default value varies for the GlobalRouter and non-default VRFs, depending on your hardware platform. |
| <b>RpTrigger</b>                                                                                                              | Specifies the Routing Protocol (RP) triggers for the VRF. The triggers are used to initiate or shutdown routing protocols on a VRF. You can act upon multiple RPs simultaneously. You can also use this option to bring individual RPs up in steps.                                      |

| Name                                                                                                                              | Description                                                                                                                                                                                                                                                                                   |
|-----------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MaxRoutesTrapEnable</b>                                                                                                        | Enables the generation of the VRF Max Routes Exceeded traps. The default is enabled.                                                                                                                                                                                                          |
| <b>Ipv6MaxRoutes</b><br><b>Note:</b><br>Exception: not supported on 5320-16P-4XE, 5320-16P-4XE-DC, 5320-24P-8XE, or 5320-24T-8XE. | Configures the maximum number of IPv6 routes allowed for the VRF, which varies depending on the hardware. For scaling information, see <a href="#">Fabric Engine Release Notes</a> . The default value varies for the GlobalRouter and non-default VRFs, depending on your hardware platform. |
| <b>Ipv6MaxRoutesTrapEnable</b>                                                                                                    | Enables SNMP trap generation after the maximum number of IPv6 routes are reached. The default is enabled.                                                                                                                                                                                     |
| <b>Active</b>                                                                                                                     | Displays if the VRF is active (true). The 16- and 24-port 5320 Series models support a single active VRF with IP configuration; the VRF can be the GlobalRouter (GRT) or a non-default VRF:                                                                                                   |

## Associating a port to a VRF instance

### About This Task

Associate a port to a Virtual Router Forwarding (VRF) instance so that the port becomes a member of the VRF instance.

You can assign a VRF instance to a port after you configure the VRF. The system assigns ports to the GlobalRouter, VRF 0, by default.

### Procedure

1. In the **Device Physical** View tab, select a port.
2. In the navigation pane, expand the **Configuration > Edit > Port** folders.
3. Click **General**.
4. Click the **VRF** tab.
5. To the right of the **BrouterVrfId** box, click the ellipsis (...) button.
6. In the **BrouterVrfId** dialog box, select the required VRF.
7. Click **OK**.
8. Click **Apply**.

### VRF field descriptions

Use the data in the following table to use the **VRF** tab.

| Name            | Description                                               |
|-----------------|-----------------------------------------------------------|
| <b>VrfIds</b>   | Shows the VRF ID.                                         |
| <b>VrfNames</b> | Shows the VRF name.                                       |
| <b>VrfCount</b> | Shows the number of VRFs to which the port is associated. |

| Name                  | Description                              |
|-----------------------|------------------------------------------|
| <b>BrouterVrflid</b>  | Specifies the VRF ID for a brouter port. |
| <b>BrouterVrfName</b> | Shows the VRF name for a brouter port.   |

## Configuring interVRF route redistribution policies

Configure interVRF route redistribution so that a VRF interface can announce routes that other protocols learn, for example, OSPF, RIP, or BGP. Use a route policy to control the redistribution of routes.

### Before You Begin

- Ensure VRF instances exist.
- Configure route policies, if required.
- Change the VRF instance as required.

### About This Task

#### Procedure

1. In the navigation tree, expand **Configuration > IP**.
2. Select **Policy**.
3. Select the **Route Redistribution** tab.
4. Select **Insert**.
5. Select the ellipsis (...) button near the **DstVrflid** box to select the source and destination VRF IDs.
6. Select the ellipsis (...) button near the **SrcVrflid** box to select the source and destination VRF IDs.
7. In the **Protocol** option box, select the protocol.
8. In the **RouteSource** option box, select the route source.
9. Select **Enable**.
10. Choose the route policy to apply to the redistributed routes.
11. Configure other parameters as required.
12. Select **Insert**.
13. Select the **Applying Policy** tab.
14. Select **RedistributeApply**.
15. Select **Apply**.

### **Route Redistribution** field descriptions

Use the data in the following table to use the **Route Redistribution** tab.

| Name             | Description                                                                         |
|------------------|-------------------------------------------------------------------------------------|
| <b>DstVrflid</b> | Specifies the destination VRF ID to use in the redistribution.                      |
| <b>Protocol</b>  | Specifies the protocols for which you want to receive external routing information. |
| <b>SrcVrflid</b> | Specifies the source VRF ID to use in the redistribution.                           |

| Name               | Description                                                                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RouteSource</b> | Indicates if the protocol receives notification about the routes this source learns. The route source is equivalent to the owner in the routing table.                                                                                                                                                                             |
| <b>Enable</b>      | Enables or disables route redistribution. The default is disabled.                                                                                                                                                                                                                                                                 |
| <b>RoutePolicy</b> | Specifies the route policies to apply to the redistributed routes from the source VRF. Use the route policy to determine whether the system advertises a specific route to the specified protocol.                                                                                                                                 |
| <b>Metric</b>      | Specifies the metric announced in advertisements. The default is 0.                                                                                                                                                                                                                                                                |
| <b>MetricType</b>  | Specifies the metric type (applies to OSPF and BGP only). Specifies a type 1 or a type 2 metric. For metric type 1, the cost of the external routes is equal to the sum of all internal costs and the external cost. For metric type 2, the cost of the external routes is equal to the external cost alone. The default is type2. |
| <b>Subnets</b>     | Indicates that all the subnets must be advertised individually. The values are allow(1), and suppress(2). The default value is allow. This variable applies to OSPF only.                                                                                                                                                          |

## Viewing router port and VRF associations

### About This Task

You can view each port and associated VRFs. You can also change the VRFs associated with the port if the port has no IP address.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VRF**.
2. Click **VRF**.
3. Click the **VRF-Ports** tab.
4. To display the VRF names associated with a port, click a cell in one of the table rows and, on the toolbar, click the **ShowVRFNames** button.
5. To change the VRF, double-click the **BrouterVrflid** field for the port.

#### Tip

You can associate a port with more than one VRF.

6. Choose the required VRFs, and then click **Ok**.
7. Click **Apply**.

### **VRF-Ports** field descriptions

Use the data in the following table to use the **VRF-Ports** tab.

| Name         | Description                  |
|--------------|------------------------------|
| <b>Index</b> | Specifies the slot and port. |
| <b>Type</b>  | Specifies the port type.     |

| Name                  | Description                                                                               |
|-----------------------|-------------------------------------------------------------------------------------------|
| <b>VrflDs</b>         | Identifies the set of VRF IDs to which this port belongs.                                 |
| <b>VrfCount</b>       | Shows the number of VRF instances associated with this port.                              |
| <b>BrouterVrflD</b>   | Shows the VRF ID for this brouter port.                                                   |
| <b>BrouterVrfName</b> | Shows the VRF name for this brouter port.                                                 |
| <b>Show VrfNames</b>  | You can use this toolbar button to identify the set of VRF names to which a port belongs. |

Use the data in the following table to use the **Show VrfNames** button.

| Name            | Description                               |
|-----------------|-------------------------------------------|
| <b>Index</b>    | Specifies the slot and port.              |
| <b>VrfNames</b> | Shows the VRF name for this brouter port. |

## Viewing global VRF status information

### About This Task

View global VRF status information to determine the number of VRFs that are configured and active.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VRF**.
2. Click **VRF**.
3. Click the **Global Status** tab.

### *Global Status* field descriptions

Use the data in the following table to use the **Global Status** tab.

| Name                            | Description                                                                                                         |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------|
| <b>ConfigNextAvailableVrflD</b> | Specifies the number of the next available Virtual Router ID (index).                                               |
| <b>ConfiguredVRFs</b>           | Specifies the number of VRFs configured on this network element.                                                    |
| <b>ActiveVRFs</b>               | Specifies the number of VRFs that are active on the network element. These are VRFs for which the OperStatus is up. |

## Viewing VRF instance statistics and status information

### About This Task

View VRF instance status information to determine the operational status of each VRF, as well as other operational parameters.

**Procedure**

1. In the navigation tree, expand the following folders: **Configuration > VRF** .
2. Click **VRF**.
3. Click the **VRF Stats** tab.

**VRF Stats** field descriptions

Use the data in the following table to use the **VRF Stats** tab.

| Name                     | Description                                                                                                                                                   |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>                | Specifies the ID number of the VRF instance.                                                                                                                  |
| <b>StatRouteEntries</b>  | Specifies the total number of routes for this VRF.                                                                                                            |
| <b>StatFIBEntries</b>    | Specifies the total number of Forwarding Information Base (FIB) entries for this VRF.                                                                         |
| <b>StatUpTime</b>        | Specifies the time in (in hundredths of a second) since this VRF entry has been operational.                                                                  |
| <b>OperStatus</b>        | Shows the operational status of the Virtual Router.                                                                                                           |
| <b>RouterAddressType</b> | Specifies the router address type of this VRF.                                                                                                                |
| <b>Router Address</b>    | Specifies the router address of this VRF, derived from one of the interfaces. If a loopback interface is present, you can use the loopback interface address. |

## Viewing Statistics for a VRF

**About This Task**

View VRF statistics to ensure the instance is performing as expected.

**Procedure**

1. In the navigation pane, expand the **Configuration > VRF** folders.
2. Click **VRF**.
3. Click the **VRF** tab.
4. Select a VRF.
5. Click the **Stats** button.

**Stats** Field Descriptions

Use the data in the following table to use the **Stats** tab.

| Name                    | Description                                                                     |
|-------------------------|---------------------------------------------------------------------------------|
| <b>StatRouteEntries</b> | Specifies the number of routes for this VRF.                                    |
| <b>StatFIBEntries</b>   | Specifies the number of Forwarding Information Base (FIB) entries for this VRF. |

## Select and Launch a VRF Context View

Use this procedure to open a VRF context view when you use EDM. GlobalRouter is the default view at log in. If you launch a VRF context view, EDM displays the VRF navigation in a new tab.

### About This Task

#### Important

If you log out from the GRT view, the system generates a warning: all tabs close and your session terminates. If you close a VRF view tab, you close only that view.

#### Note

The Set VRF Context view function is not available to users in a service provider deployment where only a tenant VRF view is assigned.

You can configure both Global Router (GRT) and Virtual Routing and Forwarding (VRF) instances when you launch a VRF context view. You can open five tabs for each EDM session.

### Procedure

1. In the navigation pane, expand **Configuration > VRF Context View**.
2. Select **Set VRF Context View**.
3. Select the **VRF** tab.
4. Select a context to view.
5. Select **Launch VRF Context view**.

A new browser tab opens containing the selected VRF view

### *VRF field descriptions*

Use the descriptions in the following table to use the **VRF** tab.

| Name               | Description                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------|
| <b>Id</b>          | Shows the unique VRF ID.                                                                                    |
| <b>Name</b>        | Shows the name of the virtual router.                                                                       |
| <b>ContextName</b> | Shows the SNMPv3 context name that denotes the VRF context and logically separates the MIB port management. |

## Create an IP VPN Instance on a VRF

Create an IP VPN instance to advertise IP routes from one VRF to another across a Shortest Path Bridging MAC (SPBM) network.

### Before You Begin

- You must configure the required SPBM IS-IS infrastructure.
- The VRF must exist.

### Procedure

1. In the navigation tree, expand **Configuration > IP**.

2. Select **IP-VPN**.
3. Select the **VPN** tab.
4. Select **Insert**.
5. Select **[...]**, and then select a VRF from the list.
6. Select **OK**.
7. Select **Insert**.  
By default, the new IP VPN instance is disabled.
8. In the **Isid Number** column, double-click the **0** value, and then enter the service instance identifier (I-SID) to assign to the IP-VPN.
9. In the **Enable** column, double-click the **disable** value.
10. Select the arrow to view a list of choices, and then choose **enable**.
11. Select **Apply**.

### *VPN Field Descriptions*

Use the data in the following table to use the **VPN** tab.

| Name                                                                                     | Description                                                                      |
|------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------|
| <b>Vrfid</b>                                                                             | Specifies the ID of the VRF to configure.                                        |
| <b>Enable</b>                                                                            | Enables or disables the IP VPN instance on the VRF. The default is disabled.     |
| <b>Isid Number</b>                                                                       | Specifies the I-SID to associate with the VPN. By default, no I-SID is assigned. |
| <b>Isid Name</b><br><b>Note:</b><br>This field does not apply to all hardware platforms. | Specifies the name of the I-SID associated with the VPN.                         |

## Create an IPv6 VPN Instance on a VRF

Create an IPv6 VPN instance to advertise IPv6 routes from a VRF to Shortest Path Bridging MAC (SPBM) network.

### **Before You Begin**

- You must configure the required SPBM IS-IS infrastructure.
- The VRF must exist.

### **Procedure**

1. In the navigation tree, expand **Configuration > IPv6**.
2. Select **IPv6-VPN**.
3. Select the **VPN** tab.
4. Select **Insert**.
5. Select **[...]**, and then select a VRF from the list.
6. Select **OK**.
7. Select **Insert**.

8. In the **IsidNumber** column, double-click the **0** value, and then enter the service instance identifier (I-SID) to assign to the IPv6-VPN.
9. In the **Enable** column, double-click the value and select **true** or **false** from the drop-down list.
10. Select **Apply**.

### VPN Field Descriptions

Use the data in the following table to use the **VPN** tab.

| Name                                                                                          | Description                                                                           |
|-----------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------|
| <b>Vrflid</b>                                                                                 | Specifies the ID of the VRF to configure.                                             |
| <b>Enable</b>                                                                                 | Enables or disables the IPv6 VPN instance on the VRF. The default is disabled.        |
| <b>IsidNumber</b>                                                                             | Specifies the I-SID to associate with the IPv6 VPN. By default, no I-SID is assigned. |
| <b>IsidName</b><br><br><b>Note:</b><br>This field is not supported on all hardware platforms. | Specifies the name of the I-SID.                                                      |

## Configure the Maximum Number of VRFs

Perform this procedure to change the maximum number of VRFs and Layer 3 VSNs that the switch supports. By default, the switch supports 24 VRFs and Layer 3 VSNs. Increasing the number of VRFs or Layer 3 VSNs can be useful in a WAN scenario or other large network.

The maximum number of supported VRFs and Layer 3 VSNs differs depending on the hardware platform. For more information about maximum scaling numbers, see [Fabric Engine Release Notes](#).

### About This Task

#### Important

If you enable this boot config flag, and the switch operates in SPBM mode (default configuration), the switch reduces the number of configurable VLANs. In such a configuration, the switch reserves VLANs 3500 to 3998 for internal use. You cannot use these VLANs as either platform VLANs or B-VLANs. You can still use the reserved VLAN range for customer VLANs (C-VLAN) on Flex UNI and B-VLANs on FE-VID.

Enabling the boot config flag to use more than 24 VRFs requires a Premier or Premier + MACsec license.

### Before You Begin

- If the switch operates in SPBM mode, before you enable this boot config flag, perform the following actions:
  - Check in-VLAN filters. If a filter references a VLAN in the 3500 to 3998 range, you must delete the filter or the filter configuration fails when you restart the switch.
  - Delete VLANs in the 3500 to 3998 range.

- Before you disable this boot config flag, delete additional VRFs if more than 24 exist.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Chassis**.
3. Select the **Boot Config** tab.
4. Perform one of the following actions:
  - a. To enable VRF scaling, select the **EnablevrfScaling** check box.
  - b. To disable VRF scaling, clear the **EnablevrfScaling** check box.

#### Note

This field does not apply to all hardware platforms.

5. Select **Apply**.
6. Restart the switch for the change to take effect.

## VRRP Fundamentals

---

Because end stations often use a static default gateway IP address, a loss of the default gateway router causes a loss of connectivity to the remote networks.

The Virtual Router Redundancy Protocol (VRRP) (RFC 2338) eliminates the single point of failure that can occur when the single static default gateway router for an end station is lost. VRRP introduces a virtual IP address (transparent to users) shared between two or more routers that connect the common subnet to the enterprise network. With the virtual IP address as the default gateway on end hosts, VRRP provides dynamic default gateway redundancy in the event of failover.

The VRRP router that controls the IP addresses associated with a virtual router is the primary router and it forwards packets to these IP addresses. The election process provides a dynamic transition of forwarding responsibility if the primary router becomes unavailable.

#### Note

The VRRP virtual IP address cannot be same as the local IP address of the port or VLAN on which VRRP is enabled.

In the following figure, the first three hosts install a default route to the R1 (virtual router 1) IP address and the other three hosts install a default route to the R2 (virtual router 2) IP address.

This configuration not only shares the load of the outgoing traffic, but it also provides full redundancy. If either router fails, the other router assumes responsibility for both addresses.

**Figure 251: Virtual Router Redundancy Protocol configuration**

For information about the number of supported VRRP interfaces, see the scaling information in [Fabric Engine Release Notes](#).

The following terms are specific to VRRP:

#### VRRP router

a router running the VRRP protocol

#### Virtual router

an abstract object acting as the default router for one or more hosts, consisting of a virtual router ID and a set of addresses

**Primary IP address**

an IP address selected from the real addresses and used as the source address of packets sent from the router interface (The virtual primary router sends VRRP advertisements using this IP address as the source.)

**Virtual primary router**

the router that assumes responsibility to forward packets sent to the IP address associated with the virtual router and answer ARP requests for these IP addresses

**Virtual router backup**

the virtual router that becomes the primary router if the current primary router fails

When a VRRP router is initialized it sends a VRRP advertisement. The VRRP router also broadcasts a gratuitous ARP request that contains the virtual router MAC address for each IP address associated with the virtual router. The VRRP router then transitions to the controlling state.

In the controlling state, the VRRP router functions as the forwarding router for the IP addresses associated with the virtual router. The VRRP router responds to ARP requests for these IP addresses, forwards packets with a destination MAC address equal to the virtual router MAC address, and accepts only packets addressed to IP addresses associated with the virtual router, the router transitions to the backup state to ensure that all Layer 2 switches in the downstream path relearn the new origin of the VRRP MAC addresses.

In the backup state, a VRRP router monitors the availability and state of the primary router. The backup router does not respond to ARP requests and must discard packets with a MAC address equal to the virtual router MAC address. The backup router does not accept packets addressed to IP addresses associated with the virtual router. If a shutdown occurs, the backup router transitions back to the initialize state. If the primary router goes down, the backup router sends the VRRP advertisement and ARP request described in the preceding paragraph and transitions to the controlling state.

If an advertisement timer becomes active, the router sends an advertisement. If an advertisement is received with a 0 priority, the router sends an advertisement. The router transitions to the backup state in the following situations:

- If the priority is greater than the local priority
- If the priority is the same as the local priority and the primary IP address of the sender is greater than the local primary IP address

Otherwise, the router discards the advertisement. If a shutdown occurs, the primary router sends a VRRP advertisement with a priority of 0 and transitions to the initialize state.

## Critical IP Address

Within a VRRP VLAN, one link can go down while the remaining links in the VLAN remain operational. Because the VRRP VLAN continues to function, a virtual router associated with that VLAN does not register a master router failure.

As a result, if the local router IP interface connecting the virtual router to the external network fails, this does not automatically trigger a master router failover.

**Note**

In this context, local implies an address from the same VRF as the IP interface where VRRP is being configured.

The critical IP address resolves this issue. If the critical IP address fails, it triggers a failover of the master router.

You can specify the local router IP interface uplink from the VRRP router to the network as the critical IP address. This ensures that, if the local uplink interface fails, VRRP initiates a master router failover to one of the backup routers.

In VRRP, the local network uplink interface on router 1 is shown as the critical IP address for router 1. As well, the same network uplink is shown as the critical IP address for router 2. Router 2 also requires a critical IP address for cases in which it assumes the role of the master router.

With the support of VRRP and the critical IP interface linked to VRRP, you can build reliable small core networks that provide support for converged applications, such as voice and multimedia.

**Note**

A Brouter port with a VLACP Critical IP address in a VRRP is supported.

## VRRP and SMLT

The standard implementation of VRRP supports only one active master device for each IP subnet. All other VRRP interfaces in a network are in backup mode.

A deficiency occurs when VRRP-enabled switches use Split MultiLink Trunking (SMLT). If VRRP switches are aggregated into two Split MultiLink Trunk switches, the end host traffic is load-shared on all uplinks to the aggregation switches (based on the Multilink Trunk traffic distribution algorithm).

However, VRRP usually has only one active routing interface enabled. All other VRRP routers are in backup mode. Therefore, all traffic that reaches the backup VRRP router is forwarded over the vIST towards the master VRRP router. In this case, the vIST does not have enough bandwidth to carry all the aggregated traffic.

To resolve this issue, assign the backup router as the backup master router. The backup master router can actively load-share the routing traffic with a master router.

When the backup master router is enabled, the incoming host traffic is forwarded over the SMLT links as usual. When the backup master router is configured along with the critical IP interface and the critical IP interface goes down, the VRRP router transitions to be the backup router with the backup master state down. In this state, the VRRP router does not forward traffic.

## VRRP Fast Hello Timers

You can configure the advertisement time interval (in seconds) between sending advertisement messages. This interval permits fast network convergence with standardized VRRP failover. However,

losing connections to servers for more than a second can result in missing critical failures. Customer network uptime in many cases requires faster network convergence, which means network problems must be detected within hundreds of milliseconds. Fast Advertisement Enable and Fast Advertisement Interval meet these requirements

Fast Advertisement Enable acts like a toggle device for the Advertisement Interval and the Fast Advertisement Interval. When Fast Advertisement Enable is enabled, the Fast Advertisement Interval is used instead of the Advertisement Interval.

The Fast Advertisement Interval is similar to the Advertisement Interval parameter except for the unit of measure and the range. The Fast Advertisement Interval is expressed in milliseconds and the range is from 200 to 1000 milliseconds. This unit of measure must be in multiples of 200 milliseconds, otherwise the system displays an error.

When you enable the fast advertisement interval, VRRP can communicate with other switch ports and networking products that have the same configuration.

## Handling of IPv4 Layer 2 Unicast Packets at VRRP Backup Master

Only the VRRP Master handles IPv4 Layer 2 unicast packets, for example, ARO Request and Reply, with the destination MAC as the VRRP MAC.

The Backup-Master forwards all IPv4 Layer 2 unicast packets to the Master and the Master VRRP sends an ARP reply only.

Processing of IP unicast packets (for example, ICMP packets to VRRP IP) or IPv4 routed packets (with destination MAC as VRRP MAC) on VRRP Backup-Master stays the same. For example, the VRRP Backup-Master replies to ICMP requests and routes Layer 3 routed packets to the destination and does not forward these packets to the Master when they arrive at the Backup-Master.

To reflect the above changes, the VRRP MAC entry on the Backup-Master now points to the Master instead of itself, and the ARP entry for VRRP IP on the backup-master points to local.

## VRRP Guidelines

### *VRRP Guidelines*

VRRP provides another layer of resiliency to your network design by providing default gateway redundancy for end users. If a VRRP-enabled router that connects to the default gateway fails, failover to the VRRP backup router ensures no interruption for end users who attempt to route from their local subnet.

Only the VRRP Master router forwards traffic for a given subnet. The backup VRRP router does not route traffic destined for the default gateway.

To enable both VRRP switches to route traffic, the switch software has an extension to VRRP, the BackupMaster, that creates an active-active environment for routing. If you enable BackupMaster on the backup router, the backup router no longer switches traffic to the VRRP Master. Instead the

BackupMaster routes all traffic received on the BackupMaster IP interface according to the switch routing table.

### Figure 252: VRRP with BackupMaster

Stagger VRRP instances on a network or subnet basis. The following figure shows the VRRP Masters and BackupMasters for two subnets. For more information about how to configure VRRP using the Command Line Interface (CLI) and Enterprise Device Manager (EDM), see [VRRP Configuration Using the CLI](#) on page 3412 and [VRRP configuration using EDM](#) on page 3437.

### Figure 253: VRRP network configuration

The VRRP BackupMaster uses the VRRP standardized backup switch state machine. Thus, VRRP BackupMaster is compatible with standard VRRP.

Use the following best practices to implement VRRP:

- Do not configure the virtual address as a physical interface that is used on the routing switches. Instead, use a third address, for example:
  - Interface IP address of VLAN A on Switch 1 = x.x.x.2
  - Interface IP address of VLAN A on Switch 2 = x.x.x.3
  - Virtual IP address of VLAN A = x.x.x.1

#### Note

The switch software does not support a VRRP virtual IP address that is the same as the local physical address of the device.

- Configure the VRRP holddown timer with enough time that the Interior Gateway Protocol (IGP) routing protocol has time to update the routing table. In some cases, configuring the VRRP holddown timer to a minimum of 1.5 times the IGP convergence time is sufficient. For OSPF, as a best practice, use a value of 90 seconds if you use the default OSPF timers.

- Implement VRRP BackupMaster for an active-active configuration (BackupMaster works across multiple switches that participate in the same VRRP domain).
- Configure VRRP priority as 200 to configure VRRP Master.
- Stagger VRRP Masters between switches in the core to balance the load between switches.
- If you implement VRRP Fast, you create additional control traffic on the network and also create a greater load on the CPU. To reduce the convergence time of VRRP, the VRRP Fast feature allows the modification of VRRP timers to achieve subsecond failover of VRRP. Without VRRP Fast, normal convergence time is approximately 3 seconds.
- Do not use VRRP BackupMaster and critical IP at the same time. Use one or the other.

### *VRRP and spanning tree*

The switch can use one of two spanning tree protocols: Rapid Spanning Tree Protocol (RSTP) and Multiple Spanning Tree Protocol (MSTP).

VRRP protects clients and servers from link or aggregation switch failures. Configure the network to limit the amount of time a link is out of service during VRRP convergence. The following figure shows two possible configurations of VRRP and spanning tree; configuration A is optimal and configuration B is not.

**Figure 254: VRRP and STG configurations**

In this figure, configuration A is optimal because VRRP convergence occurs within 2 to 3 seconds. In configuration A, three spanning tree instances exist and VRRP runs on the link between the two routers. Spanning tree instance 2 exists on the link between the two routers, which separates the link between the two routers from the spanning tree instances found on the other devices. All uplinks are active.

In configuration B, VRRP convergence takes between 30 and 45 seconds because it depends on spanning tree convergence. After initial convergence, spanning tree blocks one link (an uplink), so only one uplink is used. If an error occurs on the uplink, spanning tree reconverges, which can take up to 45 seconds. After spanning tree reconvergence, VRRP can take a few more seconds to fail over.

## VRRP for IPv6

---

For IPv6 hosts on a LAN to learn about one or more default routers, IPv6-enabled routers send router advertisements using the IPv6 ND protocol. The routers multicast these router advertisements every few minutes.

The ND protocol uses a mechanism called neighbor unreachability detection to detect the failure of a neighbor node (router or host) or the failure of the forwarding path to a neighbor. Nodes can monitor the health of a forwarding path by sending unicast ND neighbor solicitation messages to the neighbor node. To reduce traffic, nodes only send neighbor solicitations to neighbors to which they actively send traffic and only after the node receives no positive indication that the neighbors are up for a period of time. A host takes a minimum of 5 seconds to learn that a router is unreachable before it switches to another default router, but this minimum value increases ND traffic. This delay can cause service disruption.

VRRP for IPv6 provides a faster switchover to an alternate default router than is possible using the ND protocol. With VRRP for IPv6, a backup router can take over for a failed default router in approximately three seconds (using default parameters). The switchover is accomplished without interaction with the hosts and with a minimum amount of VRRP traffic.

The IPv6 VRRP implementation is similar to the existing IPv4 VRRP operation, including support for holddown timer, critical IP, fast advertisements, and backup master. With backup master enabled, the backup switch routes all traffic according to its routing table. The backup master switch does not perform Layer 2 switching for the traffic to the VRRP master.

You must specify a link-local address to associate with the virtual router. Optionally, you can also assign global unicast IPv6 addresses to associate with the virtual router. Network prefixes for the virtual router are derived from the global IPv6 addresses assigned to the virtual router.

One active master switch exists for each IPv6 network prefix. All other VRRP interfaces in a network are in backup mode.

## VRRP for IPv6 operation

VRRP uses a virtual IP address shared between two or more routers connecting the common network prefix to the enterprise network. With the virtual IP address as the default gateway on end hosts, VRRP provides dynamic default gateway redundancy in the event of failover.

The VRRP router with higher priority is called the master router. In case of equal priority the router with higher link-local address becomes the master router. The master router forwards packets sent to the virtual router IP addresses.

The following figure shows the minimum VRRP topology.

**Figure 255: VRRP network topology**

Traffic flows between users A and users B.

Router A uses VRRP global addresses as next hops for users B, and Router B for users A.

The VRRP master forwards the traffic and sends VRRP advertisements in the VLAN to announce to the backups that it is the master. If the master is no longer available, the backup takes over and becomes master. The only change occurs to the state of VRRP.

The VRRP router then transitions to the controlling state.

**Note**

The VRRP virtual IP address cannot be same as the local IP address of the port or VLAN on which VRRP is enabled.

In the controlling state, the VRRP router functions as the forwarding router for the IP addresses associated with the virtual router. The router responds to ND neighbor solicitation and ND router solicitation messages for these IP addresses, forwards packets with a destination MAC address equal to the virtual router MAC address, and accepts packets addressed to IP addresses associated with the virtual router.

If you initialize the VRRP router and the priority is not 255, the router transitions to the backup state to ensure that all Layer 2 switches in the downstream path relearn the new origin of the VRRP MAC addresses.

In the backup state, a VRRP router monitors the availability and state of the master router. The backup does not respond to ND neighbor solicitation and ND router solicitation messages for virtual router IP addresses and discards packets with a MAC address equal to the virtual router MAC address. The backup does not accept packets addressed to IP addresses associated with the virtual router. If a shutdown occurs, it transitions back to the initialize state. If the master router goes down, the backup router sends the VRRP advertisement and unsolicited ND neighbor advertisements and ND router advertisements described in the preceding paragraphs and transitions to the controlling state.

## VRRP advertisements and master router failover

When you initialize a VRRP router, the master router continues to send advertisement messages at the advertisement interval period.

### Note

The VRRP virtual IP address cannot be same as the local IP address of the port or VLAN on which VRRP is enabled.

The other VRRP routers transition to the backup state in the following situations:

- if the priority in the received advertisement is greater than the local priority
- if the priority in the received advertisement is the same as the local priority and the primary IP address of the sender is greater than the local primary IP address

The backup routers use the advertisements from the master router as a keepalive to monitor the health of the master router. If the backup router does not receive an advertisement during the master downtime interval, calculated as  $3 * \text{advertisement interval}$ , then the master router is declared down.

If a shutdown occurs, the master router sends a VRRP advertisement with a priority of 0 and transitions to the initialize state

The priority value 0 indicates that the master router has stopped participating in VRRP. This value triggers the backup router to transition to the master state without waiting for the current master to time out.

## Critical IPv6 address and holddown timer

The critical IPv6 address is an interface that has primary impact on VRRP. If you enable critical IPv6 and the status of the critical IP changes, the master and backup relationship also changes.

If you configure and enable critical IPv6 address, the master transitions to backup if the critical IPv6 is down, and the backup becomes the master. After the critical IPv6 address of the original master resumes, if the hold-down timer is configured to 0, it becomes the master immediately. Otherwise, the original master transitions to the master state after the hold-down timer time out.

You can specify the local router IP interface uplink from the VRRP router to the network as the critical IP address. This ensures that, if the local uplink interface fails, VRRP initiates a master router failover to one of the backup routers.

The critical address can be one of the global unicast IPv6 addresses assigned to any local IPv6 interfaces.

The holddown timer is a proprietary enhancement to VRRP.

After a master transitions to backup by critical IP changing, one of the backup routers will be elected as the master router. After the critical IPv6 of the original master is restored, the original master remains in the backup state for a period of time that you configure by using the **holddown-timer** parameter.

The router becomes the master immediately if you use the command **ipv6 vrrp <1-255> action preempt**.

The holddown timer allows the master router enough time to detect and update the dynamic routes. The timer delays the preemption of the master over the backup, when the master becomes available. If the hold-timer is configured to 0, it becomes the master router immediately. Otherwise, it transitions to the master state only after the holddown timer times out.

The holddown timer does not apply during failovers caused by VRRP router priority change. The holddown timer applies only to failovers caused by a critical IP failure.

Configure all of your routers to use identical values for the holddown timer.

**Important**

Do not use VRRP backup master and critical IP at the same time. Use one or the other. The critical IP address must be a local address.

## VRRP backup master with triangular SMLT

The standard implementation of VRRP supports one active master switch for each IPv6 subnet. All other VRRP interfaces in a network are in backup mode.

A deficiency occurs when VRRP-enabled switches use SMLT. If VRRP switches are aggregated into two SMLT switches, the end host traffic is load-shared on all uplinks to the aggregation switches (based on the Multilink Trunk [MLT] traffic distribution algorithm).

However, VRRP usually has only one active routing interface enabled. All other VRRP routers are in backup mode. Therefore, all traffic that reaches the backup VRRP router is forwarded over Virtual Inter-Switch Trunk (vIST) toward the master VRRP router. In this case, vIST potentially does not have enough bandwidth to carry all the aggregated traffic.

To resolve this issue, assign the backup router as the backup master router. The backup master router can actively load-share the routing traffic with a master router.

Because the two VRRP peer nodes exchange MAC address tables, the VRRP backup master can forward traffic directly, on behalf of the master router. The switch in the backup master state routes all traffic received on the backup master IP interface according to its routing table. The backup master switch does not perform Layer 2 switching for the traffic to the VRRP master.

If you enable SMLT on the backup master router, the incoming host traffic is forwarded over the SMLT links as usual.

**Important**

Do not use VRRP backup master and critical IP at the same time. Use one or the other.

## Fast advertisement

You can configure the advertisement time interval (in seconds) between sending advertisement messages. This interval permits fast network convergence with standardized VRRP failover. However, losing connections to servers for more than a second can result in missing critical failures. Customer network uptime in many cases requires faster network convergence, which means network problems must be detected within hundreds of milliseconds.

To meet these requirements, the fast advertisement interval are provided.

The fast advertisement interval is similar to the advertisement interval parameter except for the unit of measure and the range. The fast advertisement interval is expressed in milliseconds and the range is from 200 to 1,000 milliseconds. This unit of measure must be in multiples of 200 milliseconds.

To configure fast advertisement, you must specify a fast advertisement interval and explicitly enable the fast advertisement option. After you enable fast advertisement, the fast advertisement interval is used instead of the advertisement interval.

If you enable fast advertisement, VRRP can only communicate with other products that have the same configuration.

## Accept-mode

When you configure VRRP for IPv6 on an interface you can configure the `accept-mode` parameter, which controls whether the VRRP master or backup master accepts packets destined for the IPv6 address associated with the virtual router.

By default, `accept-mode` is disabled. The `accept-mode` parameter does not affect the Neighbor Discovery packets. The master router forwards packets with a destination link-layer MAC address that matches the virtual MAC address, and accepts packets forwarded over the virtual interswitch trunk (vIST) toward the master router, if `accept-mode` is enabled. If you disable `accept-mode`, you cannot ping the virtual IPv6 address. If you enable `accept-mode`, the master router accepts packets addressed to the IPv6 address that is associated with the virtual router.

When you configure VRRP for IPv6 on an interface, you can configure the `accept-mode` parameter. By default, `accept-mode` is disabled. If you disable `accept-mode`, the master router does not drop neighbor solicitations or neighbor advertisements. The master router forwards packets with a destination link-layer MAC address that matches the virtual MAC address. If you disable `accept-mode`, you cannot ping the virtual IPv6 address.

### Note

The VRRP virtual IP address cannot be same as the local IP address of the port or VLAN on which VRRP is enabled.

## VRRPv3

VRRPv3 is a combined protocol for both IPv4 and IPv6. It specifies an election protocol that dynamically assigns responsibility for a virtual router to one of the VRRP routers on a LAN. The VRRP router that controls the IPv4 or IPv6 addresses associated with a virtual router is called the Master, and it forwards packets sent to these IPv4 or IPv6 addresses. VRRP Backups wait for a Master and take ownership when the Master is no longer detected.

The election protocol provides dynamic failover in the forwarding responsibility when the Master is unavailable. VRRP for IPv4 gains a higher-availability default path without configuring dynamic routing

or router discovery protocols on every end-host. VRRP for IPv6 gains a quick switch-over to Backup routers compared to the standard IPv6 Neighbor Discovery mechanisms.

#### Note

The VRRP IPv6 link-local address must be the same for all VRRP routers sharing the same link and the same virtual router ID, that is, the same VRRP instance. It is the address the VRRP advertisements are sent from. Also, the Router Advertisement packets from the VRRP interface are transmitted using this address, so, when IPv6 Stateless Address Autoconfiguration is used, this address is added to host Default Router List and is used as a gateway.

The software supports VRRPv3 for IPv4 and VRRPv3 for IPv6. VRRPv3 for IPv6 is compliant to RFC 5798. The software also supports VRRPv2 for IPv4.

## VRRPv3 guidelines

The switch also supports VRRPv2 for IPv4. If you configure VRRP IPv6 on an interface, it runs independently of the IPv4 version. Configure the version of the VRRP IPv4 on the interface before you configure any other IPv4 VRRP attributes. By default, the version is not configured to a particular value. However, when sourcing older configuration files that do not have the version saved, the router configures the version to VRRPv2 by default. If you change the version, all IPv4 configuration under that interface is automatically removed, and you are prompted for a confirmation before this operation.

Perform the CLI configuration through **ip vrrp** or **ipv6 vrrp** nodes; CLI commands for IPv4 are common for version 2 and version 3.

The following list identifies the features that make both IPv4 and IPv6 VRRPv3 features compliant to RFC 5798:

- Advertisement vs Fast-advertisement — Prior to RFC 5798, the minimum advertisement interval was 1 second, with Fast-advertisement a sub-second interval could be configured. When this feature is enabled, the VRRP ADVERTISEMENT packets are sent with type 7 instead of 1. With RFC 5798 the sub-second interval is standardised, and the switch sends all packets for VRRPv3 with type 1. The use of Fast-advertisement remains the same. VRRPv2 packets send with type 7, if Fast-advertisement is enabled.
- Add Master-advertisement-interval — Prior to RFC 5798 compliance, all virtual routers on the same VLAN had the same Advertisement-Interval configured. RFC 5798 states that you can use different Advertisement Intervals on the Master and Backup. On the Master, the Master-advertisement-interval and the Advertisement-Interval have the same value. On the Backup, the Master-advertisement-interval is used to calculate the timers, and the locally configured Advertisement-Interval is ignored until the Backup transitions to Master. The Master-advertisement-interval value is put in the advertisement packet type sent by the Master
- Transition to master as specified in RFC 5798 — Prior to RFC 5798, if a Backup receives an advertisement with a lower priority (or same priority but lower IP), it immediately sends its own advertisement and transitions to Master. However, RFC 5798 states that such packets must be discarded, which means it will transition to Master after the Master\_Down\_Timer expires
- Add skew-time — RFC 5798 states that skew-time is calculated depending on the priority, and Master-advertisement-interval assures that the Backup with highest priority sends the first advertisement when the Master goes down

Skew time is calculated using the formula:  $((256 - \text{priority}) * \text{Master\_Adver\_Interval}) / 256$ .

- Add preempt-mode — Preempt-mode is different from the **ipv6 vrrp <vrid> action preempt** command, which is an operational command issued when you want to stop the hold-down timer. RFC 5798 states that preempt-mode should be set to false when you do not want a higher priority Backup to transition to Master. By default, it is set to true

#### Note

Accept-mode is not fully implemented for IPv4 VRRPv3. You can only ping the virtual IP address, the same way as it is for IPv4 VRRPv2.

## VRRP Configuration Using the CLI

---

One active master switch exists for each IP subnet. All other VRRP interfaces in a network are in backup mode.

Virtual Router Redundancy Protocol (VRRP) eliminates the single point of failure that can occur after the single static default gateway router for an end station is lost. VRRP introduces the concept of a virtual IP address shared between two or more routers connecting the common subnet to the enterprise network.

#### Note

The VRRP virtual IP address cannot be same as the local IP address of the port or VLAN on which VRRP is enabled.

#### Important

The switch, when it acts as a VRRP master, does not reply to Simple Network Management Protocol (SNMP) Get requests to the VRRP virtual interface address. However, if the switch acts as a VRRP master, and receives SNMP Get requests to its physical IP address, then it does respond.

The Simple Network Management Protocol (SNMP) provides facilities to manage and monitor network resources. An SNMP manager and agent communicate through the SNMP protocol. The manager sends queries and the agent responds. An SNMP Get request is a message that requests the values of one or more objects.

#### Note

The VRRP IP address responds only to ICMP-based traceroute requests. It does not respond to UDP-based traceroute requests.

When you use the fast advertisement interval option to configure a master and backup device, you must enable the fast advertisement interval option on both systems for VRRP to work correctly. If you configure one device with the regular advertisement interval, and the other device with the fast advertisement interval, it causes an unstable state and drops advertisements.

## Configuring VRRP on a port or a VLAN

## About This Task

Configure VRRP on a port or a VLAN to forward packets to the virtual IP addresses associated with the virtual router and customize the VRRP configuration.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure a backup VRRP address:

```
ip vrrp address <1-255> <A.B.C.D>
```

3. Configure VRRP on a port:

```
ip vrrp <1-255> enable
```

4. Show the global VRRP configuration:

```
show ip vrrp
```

## Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface gigabitethernet 1/2
```

Configure a backup VRRP address:

```
Switch:1(config-if)# ip vrrp address 28 192.0.2.1
```

Configure VRRP on a port:

```
Switch:1(config-if)# ip vrrp 28 enable
```

Show the global VRRP configuration:

```
Switch:1(config-if)# show ip vrrp
```

## Variable definitions

Use the data in the following table to use the **ip vrrp** command.

| Variable                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>1-255</code>                                 | Specifies the number of the VRRP to create or modify.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>action {none preempt}</code>                 | <p>Causes the virtual router to disregard the timer and transition to Master state immediately, provided the hold-down timer is running.</p> <p><b>Note:</b><br/>You can use this parameter only if the hold-down timer is active.</p> <p>To set this option to the default value, use the <b>default</b> operator with this command.</p>                                                                                                                                                                                       |
| <code>action {none preempt}</code>                 | <p>Enables the choice option to manually override the hold-down timer and force preemption.</p> <p>You can configure <code>none preempt</code> to preempt the timer or configure it as <code>none</code> to allow the timer to keep working.</p> <p>To configure this option to the default value, use the default operator with this command.</p>                                                                                                                                                                              |
| <code>address &lt;1-255&gt; &lt;A.B.C.D&gt;</code> | <p>Configures the IP address of the VRRP physical interface that forwards packets to the virtual IP addresses associated with the virtual router.</p> <p><code>A.B.C.D</code> is the IP address of the master VRRP.</p> <p>Use the <b>no</b> operator to remove the IP address of the VRRP physical interface: <code>no ip vrrp address &lt;1-255&gt; &lt;A.B.C.D&gt;</code>. To configure this option to the default value, use the <b>default</b> operator with this command.</p>                                             |
| <code>adver-int &lt;1-255&gt;</code>               | <p>Configures the the time interval between sending VRRP advertisement messages. The range is between 1 and 255 seconds. This value must be the same on all participating routers. The default is 1.</p> <p>To configure this option to the default value, use the <b>default</b> operator with this command.</p>                                                                                                                                                                                                               |
| <code>backup-master enable</code>                  | <p>Enables the VRRP backup master.</p> <p>Use the <b>no</b> operator to disable the VRRP backup master: <code>no ip vrrp &lt;1-255&gt; backup-master enable</code>. To configure this option to the default value, use the <b>default</b> operator with this command.</p> <p>When backup master functionality is enabled, the VRRP router will IP-forward packets destined to the VRRP MAC even when the router is not the VRRP Master.</p> <p><b>Important:</b><br/>Do not enable backup master if you enable critical IP.</p> |

| Variable                             | Value                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>critical-ip-addr</i><br><A.B.C.D> | Configures the critical IP address for VRRP.<br>A.B.C.D is the IP address on the local router, which is configured so that a change in its state causes a role switch in the virtual router (for example, from master to backup) in case the interface stops responding.<br><br><b>Note:</b><br>In this context, <i>local</i> implies an address from the same VRF as the IP interface where VRRP is being configured. |
| <i>critical-ip enable</i>            | Enables the critical IP address option.<br>Use the <b>no</b> operator to disable the critical IP address option: <code>no ip vrrp &lt;1-255&gt; critical-ip enable</code> . To configure this option to the default value, use the <b>default</b> operator with this command.<br><br><b>Important:</b><br>Do not enable Critical IP if backup master is enabled.                                                       |
| <i>enable</i>                        | Enables VRRP on the port.<br>Use the <b>no</b> operator to disable VRRP on the port: <code>no ip vrrp &lt;1-255&gt; enable</code> . To configure this option to the default value, use the <b>default</b> operator with this command.                                                                                                                                                                                  |
| <i>fast-adv enable</i>               | Enables the Fast Advertisement Interval. The default is disabled.<br>Use the <b>no</b> operator to disable VRRP on the port: <code>no ip vrrp &lt;1-255&gt; fast-adv enable</code> . To configure this option to the default value, use the <b>default</b> operator with this command.                                                                                                                                 |
| <i>fast-adv-int</i> <200-1000>       | Configures the Fast Advertisement Interval, the time interval between sending VRRP advertisement messages.<br>200-1000 is the range in milliseconds, and must be the same on all participating routers. The default is 200. You must enter values in multiples of 200 milliseconds.<br>To configure this option to the default value, use the <b>default</b> operator with this command.                               |

| Variable                                    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>holddown-timer &lt;0-21600&gt;</code> | <p>Specifies the time interval (in seconds) for which the transition of virtual router to Master state is delayed in case of the following conditions:</p> <ul style="list-style-type: none"> <li>The VRRP hold-down timer runs only when the VRRP virtual router transitions from initialization to backup to master. This occurs only on a system startup.</li> <li>The VRRP hold-down timer does not run if the amount of time passed since VRRP virtual router initialization is greater than preset hold-down time. In such a case, VRRP virtual router transitions to Master happens irrespective of the hold-down timer.</li> <li>The VRRP hold-down timer also applies to the VRRP BackupMaster feature.</li> </ul> <p><code>0-21600</code> is the time interval range (in seconds). To configure this option to the default value, use the <b>default</b> operator with this command. The default value for hold-down timer is 0, that is, the timer is disabled by default.</p> |
| <code>priority &lt;1-255&gt;</code>         | <p>Configures the port VRRP priority.</p> <p><code>1-255</code> is the value used by the VRRP router. The default is 100. Assign the value 255 to the router that owns the IP address associated with the virtual router.</p> <p>To configure this option to the default value, use the <b>default</b> operator with this command.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Showing VRRP information

### About This Task

Show VRRP port or VLAN information to view configuration details and operational status.

### Procedure

- Enter Privileged EXEC mode:  
`enable`
- Display basic VRRP configuration information about the specified port, all ports, or the VLAN:  
`show ip vrrp address [vrid <1-255>] [addr <A.B.C.D>] [vrf WORD<1-16>] [vrfids WORD<0-512>]`
- Displaying the VRRPv3 configuration:  
`show ip vrrp address version <2-3>`
- Displaying version based VRRP configuration for the specified VRF:  
`show ip vrrp address vrf WORD<1-16> version <2-3>`
- Displaying version based VRRP configuration for the specified VRF ID:  
`show ip vrrp address vrfids WORD<0-512> version <2-3>`

### Example

```
Switch:1#show ip vrrp address
```

```
=====
```

```

### Variable definitions

Use the data in the following table to use the **show ip vrrp address** command.

| Variable                  | Value                                                                                                                                                                        |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>addr</i> <A.B.C.D>     | Specifies the physical local address of the master VRRP.                                                                                                                     |
| <i>vrf</i> WORD<1-16>     | Specifies the name of the VRF.                                                                                                                                               |
| <i>vrid</i> <1-255>       | Specifies a unique integer value that represents the virtual router ID in the range 1–255. The virtual router acts as the default router for one or more assigned addresses. |
| <i>vrfids</i> WORD<0-512> | Specifies the ID of the VRF and is an integer in the range of 0–512.                                                                                                         |
| <i>version</i> <2-3>      | Specifies the VRRP version (2 or 3) to be shown.                                                                                                                             |

Use the data in the following table to interpret the **show ip vrrp address** command output.

**Table 270: Field descriptions**

| Name                | Description                                                                                                                                     |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| ADV                 | Indicates the Advertisement Interval, in seconds, between sending advertisement messages.                                                       |
| BACKUP MASTER       | Indicates if the Backup-Master feature is disabled or enabled.                                                                                  |
| BACKUP MASTER STATE | Indicates if the Backup-Master is up. If the switch is in Master state but Backup-Master is enabled, then the BACKUP MASTER STATE will be down. |

**Table 270: Field descriptions (continued)**

| Name                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CONTROL               | Indicates the virtual router function. Configure the value to enabled to transition the state of the router from initialize to backup. Configure the value to disabled to transition the router from master or backup to initialize.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| CRITICAL IP           | Indicates the IP address of the interface that is critical to VRRP. If that IP interface is down, the VRRP state will transition to Backup, even if it has higher priority.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| CRITICAL IP (ENABLED) | Indicates if the critical IP feature is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| FAST ADV              | Indicates the Fast Advertisement Interval, in milliseconds, between sending advertisement messages. When the Fast Advertisement Interval is enabled, the Fast Advertisement Interval is used instead of the regular advertisement interval.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| FAST ADV (ENABLED)    | Indicates the state of fast advertisement.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| HLD DWN               | Specifies the time interval (in seconds) the Hold-down timer has until it expires. If the value is 0, it means the Hold-down timer is not running. This timer will delay the transition from Backup to Master only on a system startup (the VRRP comes from INIT to Backup and determines it should become Master). <ul style="list-style-type: none"> <li>• The VRRP hold-down timer runs when the system transitions from initialization to backup to master. This occurs only on a system startup</li> <li>• The VRRP hold-down timer does not run under the following condition: In a nonstartup condition, the backup system becomes master after the Master Downtime Interval (3 * hello interval), if the master virtual router goes down</li> <li>• The VRRP hold-down timer also applies to the VRRP BackupMaster feature</li> </ul> |
| IP                    | Indicates the assigned IP addresses that a virtual router backs up.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| MAC                   | Indicates the virtual MAC address of the virtual router in the format 00-00-5E-00-01-<vrrpid>, where the first three octets consist of the IANA OUI; the next two octets indicate the address block of the VRRP protocol; and the remaining octets consist of the vrrpid.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| MASTER                | Indicates the master router real (primary) IP address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| PRIO                  | Indicates the priority for the virtual router with respect to other virtual routers that are backing up one or more associated IP addresses. Higher values indicate higher priority. A priority of 255 cannot be configured and it is set for the VRRP router that has the same IP as the physical IP addresses (is Address Owner).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| P/V                   | Indicates the P(ort)/V(lan) on which the VRRP was configured.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| STATE                 | Indicates the current state of the virtual router.<br>initialize—waiting for a startup event<br>backup—monitoring the state or availability of the master router<br>master—forwarding IP addresses associated with this virtual router.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| UP TIME               | Indicates the time interval since this virtual router exited the INIT state.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**Table 270: Field descriptions (continued)**

| Name    | Description                                       |
|---------|---------------------------------------------------|
| VRRP ID | Indicates the virtual router ID on a VRRP router. |
| VERSION | Indicates the VRRP version.                       |

## Showing extended VLAN VRRP

Perform this procedure to display the extended VRRP configuration for all VLANs or a specified VLAN on the device.

### Procedure

1. Enter Privileged EXEC mode:  

```
enable
```
2. Show the extended VRRP configuration for all VLANs on the device or for the specified VLAN:  

```
show ip vrrp interface vlan [<1-4059>] [portList] verbose [vrf WORD<1-16>] [vrffids WORD<0-512>]
```

### Example

```
Switch:1#show ip vrrp interface vlan
=====
 Vlan Vrrp
=====
VLAN VRF VRRP IP VIRTUAL
ID NAME ID ADDRESS MAC ADDRESS

200 GlobalRouter 17 9.9.9.42 00:00:5e:00:01:11

All 1 out of 1 Total Num of Vlan Vrrp displayed
```

### Variable definitions

Use the data in the following table to use the **show ip vrrp interface vlan** command.

| Variable        | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059>        | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <i>portList</i> | Specifies the slot or port number of a range of ports.                                                                                                                                                                                                                                                                                                                                                                     |

| Variable                              | Value                                                                |
|---------------------------------------|----------------------------------------------------------------------|
| <code>vrf WORD&lt;1-16&gt;</code>     | Specifies the name of the VRF.                                       |
| <code>vrfids WORD&lt;0-512&gt;</code> | Specifies the ID of the VRF and is an integer in the range of 0-512. |

Use the data in the following table to use the **show ip vrrp interface vlan [<1-4059>] [portList] verbose [vrf WORD<1-16>] [vrfids WORD<0-512>]** command output.

| Variable            | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VLAN ID             | Indicates the VLAN ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| STATE               | Indicates the current state of the virtual router. <ul style="list-style-type: none"> <li>initialize—waiting for a startup event</li> <li>backup—monitoring the state or availability of the master router</li> <li>master—forwarding IP addresses associated with this virtual router</li> </ul>                                                                                                                                                                        |
| CONTROL             | Indicates the virtual router function. Configure the value to enabled to transition the state of the router from initialize to backup. Configure the value to disabled to transition the router from master or backup to initialize.                                                                                                                                                                                                                                     |
| PRIORITY            | Indicates the priority for the virtual router (for example, master election) with respect to other virtual routers that are backing up one or more associated IP addresses. Higher values indicate higher priority. A priority of 0, which you cannot configure, indicates that this router ceased to participate in VRRP and a backup virtual router transitions to become a new master.<br>Use a priority of 255 for the router that owns the associated IP addresses. |
| MASTER IPADDR       | Indicates the master router real (primary) IP address. The master IP address is listed as the source in the VRRP advertisement last received by this virtual router.                                                                                                                                                                                                                                                                                                     |
| ADVERTISE INTERVAL  | Indicates the time interval, in seconds, between sending advertisement messages. Only the master router sends VRRP advertisements.                                                                                                                                                                                                                                                                                                                                       |
| CRITICAL IPADDR     | Indicates the IP address of the interface that causes a shutdown event.                                                                                                                                                                                                                                                                                                                                                                                                  |
| HOLDDOWN_TIME       | Indicates the configured time (in seconds) that the system waits before it preempts the current VRRP master.                                                                                                                                                                                                                                                                                                                                                             |
| ACTION              | Indicates the trigger for an action on this VRRP interface. Options include none and preemptHoldDownTimer.                                                                                                                                                                                                                                                                                                                                                               |
| CRITICAL IP ENABLE  | Indicates that a user-defined critical IP address is enabled. No indicates the use of the default IP address (0.0.0.0).                                                                                                                                                                                                                                                                                                                                                  |
| BACKUP MASTER       | Indicates the state of designating a backup master router.                                                                                                                                                                                                                                                                                                                                                                                                               |
| BACKUP MASTER STATE | Indicates the state of the backup master router.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| FAST ADV INTERVAL   | Indicates the time interval, in milliseconds, between sending Fast Advertisement messages. When the Fast Advertisement Interval is enabled, the Fast Advertisement Interval is used instead of the regular advertisement interval.                                                                                                                                                                                                                                       |
| FAST ADV ENABLE     | Indicates the Fast Advertisement Interval status.                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Showing VRRP interface information

### About This Task

If you enter a virtual router ID or an IP address when showing VRRP interface information, the system displays the information only for that virtual router ID or for that interface.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display VRRPv3 information about the specified interface:  
show ip vrrp interface version <2-3>
3. Display additional VRRPv3 information about the specified interface:  
show ip vrrp interface verbose version <2-3>
4. Display VRRPv3 information for the specified VRF:  
show ip vrrp interface vrf WORD<1-16> version <2-3>
5. Display VRRPv3 information for the specified virtual router:  
show ip vrrp interface vrfids WORD<0-512> [version <2-3>]

### Example

```
Switch:1#show ip vrrp interface

=====
 Vlan Vrrp
=====
VLAN VRF VRRP IP VIRTUAL VERSION
ID NAME ID ADDRESS MAC ADDRESS

3 GlobalRouter 3 30.30.30.99 00:00:5e:00:01:03 2

All 1 out of 1 Total Num of Vlan Vrrp displayed

=====

Variable definitions

Use the data in the following table to use the **show ip vrrp interface** command.

| Variable                                             | Value                                                                                                                                                                        |
|------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>gigabitethernet {slot/port[-slot/port]}[,...]</i> | Specifies to show the VRRP information of which interface.                                                                                                                   |
| <i>verbose</i>                                       | Specifies to show all available information about the VRRP interfaces.                                                                                                       |
| <i>vlan</i>                                          | Specifies the VLAN that contains the VRRP.                                                                                                                                   |
| <i>vrf WORD&lt;1-16&gt;</i>                          | Specifies the name of the VRF.                                                                                                                                               |
| <i>vrid &lt;1-255&gt;</i>                            | Specifies a unique integer value that represents the virtual router ID in the range 1-255. The virtual router acts as the default router for one or more assigned addresses. |

| Variable                              | Value                                                                |
|---------------------------------------|----------------------------------------------------------------------|
| <code>vrfids WORD&lt;0-512&gt;</code> | Specifies the ID of the VRF and is an integer in the range of 0-512. |
| <code>version&lt;2-3&gt;</code>       | Specifies the VRRP version (2 or 3) configured.                      |

## Viewing IP VRRPv3 Statistics

Use the following procedure to view IP VRRPv3 statistics to monitor network performance.

### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. Enter the following command to view VRRP statistics:  
`show ip vrrp statistics version <2-3>`
3. Enter the following command to view VRRP statistics for the specified VRF:  
`show ip vrrp statistics vrf WORD<1-16> version <2-3>`
4. Enter the following command to view VRRP statistics for the specified virtual router:  
`show ip vrrp statistics vrfids WORD<0-512> version <2-3>`

### Example

View IP VRRPv3 statistics:

```
Switch:1#show ip vrrp statistics

=====
VRRP Global Stats - GlobalRouter
=====

CHK_SUM_ERR VERSION_ERR VRID_ERR VRRP_VERSION

0 0 0 2
0 0 0 3

```

| VRRP ID | P/V | AUTHTYPE_ERR | PACKLEN_ERR | VERSION |
|---------|-----|--------------|-------------|---------|
| 3       | 3   | 0            | 0           | 2       |
| 2       | 1/1 | 0            | 0           | 3       |

### Variable Definitions

Use the data in the following table to use the **ip vrrp version** command.

| Variable                        | Value                                                                               |
|---------------------------------|-------------------------------------------------------------------------------------|
| <i>version</i>                  | Configures the VRRP version on the specified interface.                             |
| <2-3>                           | Specifies the version of VRRP (2 or 3) to be configured on the specified interface. |
| <i>vrf WORD&lt;1-16&gt;</i>     | Specifies the name of the VRF.                                                      |
| <i>vrfids WORD&lt;0-512&gt;</i> | Specifies the ID of the VRF, and is an integer in the range of 0-512.               |

## Enable Ping to a Virtual IP Address

Use the following procedure to enable ping to a virtual IP address. The default is enabled.

### Procedure

- Enter VRRP Router Configuration mode:
 

```
enable

configure terminal

router vrrp
```
- Enable ping to a virtual IP address:
 

```
ping-virtual-address enable [vrf WORD<1-16>]

default ping-virtual-address enable [vrf WORD<1-16>]
```
- Display the configuration:
 

```
show ip vrrp [vrf WORD<1-16>]
```

### Variable definitions

Use the data in the following table to use the `ping-virtual-address enable` and `show ip vrrp` commands.

| Variable                    | Value                                 |
|-----------------------------|---------------------------------------|
| <i>enable</i>               | Enables ping to a virtual IP address. |
| <i>vrf WORD&lt;1-16&gt;</i> | Specifies the VRF.                    |

## Configure VRRP Notification Control

Use the following procedure to enable VRRP notification control. The generation of SNMP traps for VRRP events is enabled, by default.

### About This Task

You can configure traps by creating SNMPv3 trap notifications, creating a target address to send the notifications, and specify target parameters. For more information about how to configure trap notifications, see [Logs and Traps](#) on page 1900.

### Procedure

1. Enter VRRP Router Configuration mode:
 

```
enable

configure terminal

router vrrp
```
2. Enable a trap for VRRP events:
 

```
send-trap enable [vrf WORD<1-16>]
```
3. Disable a trap for VRRP events:
 

```
no send-trap enable [vrf WORD<1-16>]
```
4. Configure a trap for VRRP events to the default:
 

```
default send-trap enable [vrf WORD<1-16>]
```
5. Display the configuration:
 

```
show ip vrrp [vrf WORD<1-16>]
```

#### Variable definitions

Use the data in the following table to use the **send-trap** and **show ip vrrp** commands.

| Variable                    | Value                                          |
|-----------------------------|------------------------------------------------|
| <i>enable</i>               | Enables generation of SNMP traps.              |
| <i>vrf WORD&lt;1-16&gt;</i> | Configures the send-trap for a particular VRF. |

## Configuring VRRP version on an interface

### About This Task

Use the following command to configure the VRRP version on an interface.

**Procedure**

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Use the following command to configure the VRRP version:

```
ip vrrp version <2-3>
```

3. Use the following command to set the VRRP version to default:

```
default ip vrrp version
```

**Example**

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface gigabitethernet 1/2
```

Configure VRRP version for the specified interface:

```
Switch:1(config-if)# ip vrrp version 3
```

*Variable definitions*

Use the data in the following table to use the **ip vrrp version** command.

| Variable                         | Value                                                           |
|----------------------------------|-----------------------------------------------------------------|
| <code>version &lt;2-3&gt;</code> | Configures the VRRP version (2 or 3) on the specified interface |

**Enabling IPv4 VRRP preempt-mode**

You can configure VRRP to preempt the existing router. If a new VRRP router is added to the network with a higher priority than the existing routers, then the new router becomes the master. If preempt-mode is disabled, then the new router does not become a master, it transitions to master only when the current master is down, that is when it does not receive any advertisement packets from the current master. By default, preempt-mode is enabled.

**Procedure**

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enter the following command:

```
ip vrrp <vrid> preempt-mode enable
```

3. Use the following command to set the preempt-mode to its default value:

```
default ip vrrp <vrid> preempt-mode
```

4. Use the following command to disable the preempt-mode:

```
no ip vrrp <vrid> preempt-mode enable
```

**Example**

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface gigabitethernet 1/2
```

Enabling preempt-mode on interface 1/2:

```
Switch:1(config-if)# ip vrrp 1 preempt-mode enable
```

*Variable definitions*

Use the data in the following table to use the **ip vrrp <vrid>** command.

| Variable                                           | Value                                                    |
|----------------------------------------------------|----------------------------------------------------------|
| <i>preempt-mode enable</i>                         | Enables preempt-mode for VRRPv3 for IPv4.                |
| <i>default ip vrrp &lt;vrid&gt; preempt-mode</i>   | Sets the default preempt-mode value for VRRPv3 for IPv4. |
| <i>no ip vrrp &lt;vrid&gt; preempt-mode enable</i> | Disables preempt-mode for VRRPv3 for IPv4.               |

**IPv6 VRRP Configuration using CLI****Configuring the VRRP interface**

Configure VRRP to provide fast failover of a default router for IPv6 LAN hosts, in order to create a VRRP instance.

### Before You Begin

- Assign an IPv6 address to the interface.
- Enable routing globally.
- Do not configure RSMLT on the VLAN.
- You must specify a link-local address to associate with the virtual router.

### About This Task

VRRP supports a virtual IPv6 address shared between two or more routers that connect the common subnet to the enterprise network.

VRRP for IPv6 provides a faster switchover to an alternate default router than is possible using the ND protocol.

Perform this procedure to also configure the additional addresses for which the virtual router acts as a backup.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Associate an address with the virtual router for either link-local or global:

- `ipv6 vrrp address <1-255> link-local WORD <0-127>`
- `ipv6 vrrp address <1-255> global WORD <0-255>`

#### Note

You must configure the link-local address before you configure the global address.

3. Enable VRRP for the interface:

```
ipv6 vrrp <1-255> enable
```

### Example

Associate a link-local address with the virtual router ID 12:

```
Switch:1(config-if)#ipv6 vrrp address 12 link-local fe80::1234
```

Associate a global address with the virtual router ID 12

```
Switch:1(config-if)#ipv6 vrrp address 12 global 3333::1234/64
```

Enable VRRP for the interface:

```
Switch:1(config-if)#ipv6 vrrp 12 enable
```

### Variable Definitions

Use the data in the following table to use the **ipv6 vrrp address** command.

| Variable                       | Value                                                                                                                |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------|
| <1-255>                        | Specifies the virtual router ID. The virtual router acts as the default router for one or more associated addresses. |
| <i>enable</i>                  | Enables IPv6 VRRP. The default is disabled.                                                                          |
| global WORD <0-255>            | Specifies a global IPv6 address and mask to associate with the virtual router.                                       |
| <i>link-local</i> WORD <0-127> | Specifies a link-local IPv6 address to associate with the virtual router.                                            |

Use the data in the following table to use the **interface** command.

| Variable                                                                                  | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059>                                                                                  | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| { <i>slot/port</i> [/ <i>sub-port</i> ] [- <i>slot/port</i> [/ <i>sub-port</i> ]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |

## View VRRP Information

Display VRRP port or VLAN information to verify your configuration. Show VRRP information by IPv6 address or virtual router ID. If you enter a virtual router ID or an IPv6 address when you view VRRP information, the information applies only to that virtual router ID or for that interface.

### Procedure

1. Enter Privileged EXEC mode:
 

```
enable
```
2. View the configuration information for all interfaces:
 

```
show ipv6 vrrp interface [verbose] [vrf WORD<1-16> | vrfids WORD<0-512>]
```
3. View the configuration information for one or more ports:
 

```
show ipv6 vrrp interface gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} [verbose] [vrf WORD<1-16> | vrfids WORD<0-512>]
```

4. View the configuration information for one or more VLANs:

```
show ipv6 vrrp interface vlan [<1-4059>] [verbose] [vrf WORD<1-16> |
vrfids WORD<0-512>]
```

5. View the configuration information for one or more virtual router IDs:

```
show ipv6 vrrp interface vrid <1-255> [verbose] [vrf WORD<1-16> |
vrfids WORD<0-512>]
```

6. View VRRP address information:

```
show ipv6 vrrp address [vrf WORD<1-16> | vrfids WORD<0-512>]
```

7. View VRRP address information for a link-local address:

```
show ipv6 vrrp address link-local WORD<0-127> [verbose] [vrf WORD<1-
16> | vrfids WORD<0-512>]
```

8. View VRRP address information for a virtual router ID:

```
show ipv6 vrrp address vrid <1-255> [vrf WORD<1-16> | vrfids WORD<0-
512>]
```

### Example

```
Switch:1>show ipv6 vrrp address
```

```

### Variable Definitions

Use the data in the following table to use the **show ipv6 vrrp** commands.

| Variable                                                            | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |
| <code>link-local WORD&lt;0-127&gt;</code>                           | Displays information by link-local IPv6 address.                                                                                                                                                                                                                                                                                                                                                                           |
| <code>verbose</code>                                                | Displays extended information.                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>vlan [&lt;1-4059&gt;]</code>                                  | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <code>vrid &lt;1-255&gt;</code>                                     | Displays information by virtual router ID.                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>vrf WORD&lt;1-16&gt;</code>                                   | Specifies the VRF name.                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>vrfids WORD&lt;0-512&gt;</code>                               | Specifies the VRF ID.                                                                                                                                                                                                                                                                                                                                                                                                      |

## Configuring VRRP notification control

Perform this procedure to configure VRRP notification control.

### Before You Begin

- Assign an IPv6 address to the interface.
- Enable routing globally.

### About This Task

By default, generation of SNMP traps for VRRP events is enabled.

### Procedure

1. Enter VRRP Router Configuration mode:
 

```
enable
configure terminal
router vrrp
```
2. Enable the VRRP-router to generate SNMP traps for events:
 

```
ipv6 send-trap enable
```

### Example

Disable generation of SNMP traps for VRRP events:

```
Switch:1(config-vrrp)#no ipv6 send-trap enable
```

## Configuring additional VRRP parameters for an interface

Configure VRRP to provide fast failover of a default router for IPv6 LAN hosts. VRRP supports a virtual IPv6 address shared between two or more routers that connect the common subnet to the enterprise network. VRRP for IPv6 provides a faster switchover to an alternate default router than is possible using the ND protocol.

Configure the parameters in this procedure if the default values do not meet your requirements.

### Before You Begin

- Assign an IPv6 address to the interface.
- Enable routing globally.
- Do not configure RSMLT on the VLAN.

### About This Task

A switch that acts as a VRRP master does not reply to SNMP get requests to the VRRP virtual interface address. The switch will, however, respond to SNMP get requests to the physical IP address.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the accept mode of the master router:

```
ipv6 vrrp <1-255> accept-mode enable
```

3. Determine if the router overrides the holddown timer:

```
ipv6 vrrp <1-255> action <none|preempt>
```

4. Configure the interval between advertisement messages:

```
ipv6 vrrp <1-255> adver-int <1-40>
```

5. Enable the backup VRRP switch for traffic forwarding:

```
ipv6 vrrp <1-255> backup-master enable
```

6. Configure the IP interface on the local router:

```
ipv6 vrrp <1-255> critical-ipv6-addr WORD<0-46> [critical-ipv6 enable]
```

7. Configure the fast advertisement interval:

```
ipv6 vrrp <1-255> fast-adv enable [fast-adv-int <200-1000>]
```

8. Configure the holddown timer:

```
ipv6 vrrp <1-255> holddown-timer <0-21600>
```

9. Configure the priority for the VRRP router:

```
ipv6 vrrp <1-255> priority <1-255>
```

### Example

Configure the fast advertisement interval:

```
Switch:1(config-if)#ipv6 vrrp 12 fast-adv enable fast-adv-int 400
```

Configure the holddown timer:

```
Switch:1(config-if)#ipv6 vrrp 12 holddown-timer 30
```

### Variable Definitions

Use the data in the following table to use the **ipv6 vrrp** command.

| Variable                                   | Value                                                                                                                                                                                                                                                                           |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-255>                                    | Specifies a number that uniquely identifies a virtual router on a VRRP router. The virtual router acts as the default router for one or more assigned addresses.                                                                                                                |
| <i>accept-mode enable</i>                  | Controls whether the VRRP master or backup master accepts packets (other than neighbor discovery packets) destined to the IPv6 address associated with the virtual router. The default value is disable.                                                                        |
| <i>action &lt;none preempt&gt;</i>         | Lists options to override the holddown timer manually and force preemption: <ul style="list-style-type: none"> <li><i>none</i> does not override the timer.</li> <li><i>preempt</i> preempts the timer.</li> </ul> This parameter applies only if the holddown timer is active. |
| <i>adver-int &lt;1-40&gt;</i>              | Specifies the time interval, in seconds, between sending advertisement messages. The default is 1 second. Only the master router sends advertisements.                                                                                                                          |
| <i>backup-master enable</i>                | Uses the backup VRRP switch for traffic forwarding. This option reduces the traffic on the v1ST. The default is disabled.                                                                                                                                                       |
| <i>critical-ipv6 enable</i>                | Enables or disables the use of critical IP. When disabled, the VRRP ignores the availability of the address configured as critical IP. This address must be a local address. The default is disabled.                                                                           |
| <i>critical-ipv6-addr WORD&lt;0-46&gt;</i> | Specifies an IP interface on the local router configured so that a change in its state causes a role switch in the virtual router (for example, from master to backup) in case the interface stops responding.                                                                  |
| <i>fast-adv enable</i>                     | Enables or disables the fast advertisement interval. When disabled, the regular advertisement interval is used. The default is disable.                                                                                                                                         |
| <i>fast-adv-int &lt;200-1000&gt;</i>       | Configures the interval between VRRP advertisement messages. You must configure the same value on all participating routers. This unit of measure must be in multiples of 200 milliseconds. The default is 200.                                                                 |

| Variable                           | Value                                                                                                                                                                              |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>holddown-timer</i><br><0-21600> | Configures the amount of time, in seconds, to wait before preempting the current VRRP master. The default is 0.                                                                    |
| <i>priority</i> <1-255>            | Specifies the priority value used by this VRRP router. The value 255 is reserved for the router that owns the IP addresses associated with the virtual router. The default is 100. |

## Viewing IPv6 VRRP Statistics

View IPv6 VRRP statistics to monitor network performance

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View statistics for the device and for all interfaces:

```
show ipv6 vrrp statistics [link-local WORD<0-127>]] [vrid <1-255>]
```

### Example

View IPv6 VRRP statistics for VRID 1.

```
Switch:1(config)#show ipv6 vrrp statistics vrid 1

=====
 VRRP Interface Stats - GlobalRouter

```

### Variable Definitions

Use the data in the following table to use the **show ipv6 vrrp statistics** command.

| Variable                      | Value                                               |
|-------------------------------|-----------------------------------------------------|
| <i>link-local</i> WORD<0-127> | Shows statistics for a specific link-local address. |
| <i>vrid</i> <1-255>           | Shows statistics for a specific VRID.               |

## Enabling IPv6 VRRP preempt-mode

You can configure IPv6 VRRP to preempt the existing router. If a new VRRP router is added to the network with a higher priority than the existing routers, then the new router becomes the master. If preempt-mode is disabled, then the new router does not become a master, it transitions to master only when the current master is down. By default, preempt-mode is enabled.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enter the following command:

```
ipv6 vrrp <vrid> preempt-mode enable
```

3. Use the following command to set the IPv6 VRRP preempt-mode to its default value:

```
default ipv6 vrrp <vrid> preempt-mode
```

4. Use the following command to disable the IPv6 VRRP preempt-mode:

```
no ipv6 <vrid> preempt-mode enable
```

### Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface gigabitethernet 1/2
```

Enabling IPv6 VRRP preempt-mode for interface 1/2

```
Switch:1(config-if)# ipv6 vrrp 1 preempt-mode enable
```

### Variable definitions

Use the data in the following table to use the `ipv6 vrrp <vrid>` command.

| Variable     | Value                                     |
|--------------|-------------------------------------------|
| enable       | Enables preempt-mode for VRRPv3 for IPv6. |
| vrid <1-255> | Specifies the virtual router ID.          |

## VRRP configuration using EDM

One active master switch exists for each IP subnet. All other VRRP interfaces in a network are in backup mode.

If you have VRRP and IP routing protocols configured on the same IP physical interface, you cannot select the interface address as the VRRP virtual IP address (logical IP address). Use a separate dedicated IP address for VRRP.

To modify the behavior of the VRRP failover mechanism, use the hold-down timer to allow the router enough time to detect and update routes. The timer delays the preemption of the master over the backup, when the master becomes available. The hold-down timer has a default value of 0 seconds. Configure all of your routers to the identical number of seconds for the hold-down timer. In addition, you can manually force the preemption of the master over the backup before the delay timer expires.

#### Note

The VRRP virtual IP address cannot be the same as the local IP address of the port or VLAN on which VRRP is enabled.

#### Important

The switch, when it acts as a VRRP master, does not reply to Simple Network Management Protocol (SNMP) Get requests to the VRRP virtual interface address. However, if the switch acts as a VRRP master, and receives SNMP Get requests to its physical IP address, then it does respond.

The Simple Network Management Protocol (SNMP) provides facilities to manage and monitor network resources. An SNMP manager and agent communicate through the SNMP protocol. The manager sends queries and the agent responds. An SNMP Get request is a message that requests the values of one or more objects.

#### Note

The VRRP IP address responds only to ICMP-based traceroute requests. It does not respond to UDP-based traceroute requests.

### Before You Begin

- Assign an IP address to the interface.
- Enable VRRP globally.

## Enabling VRRP global variables

### About This Task

Enable VRRP global variables to enable the VRRP function.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **VRRP**.
3. Click the **Globals** tab.
4. Configure the required features.
5. Click **Apply**.

### *Globals* field descriptions

Use the data in the following table to use the **Globals** tab.

| Name                         | Description                                                                                                                                                                                                                        |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NotificationCntl</b>      | Indicates whether the VRRP-enabled router generates SNMP traps for events. <ul style="list-style-type: none"> <li>• enabled—SNMP traps are generated</li> <li>• disabled—no SNMP traps are sent</li> </ul> The default is enabled. |
| <b>PingVirtualAddrEnable</b> | Configures whether this device responds to pings directed to a virtual router IP address. The default is enabled.                                                                                                                  |

## Modifying VRRP parameters for an interface

### Before You Begin

- You must enable VRRP on a brouter port or VLAN.

### About This Task

You can manage and configure VRRP parameters for the routing interface.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **VRRP**.
3. Click the **Interface** tab.
4. Double-click the **HoldDownTimer** field, and enter the number of seconds for the timer.
 

The **HoldDownState** field displays active when the hold-down timer is counting down and preemption occurs. The field displays dormant when preemption is not pending. When the hold-down timer is active, the **HoldDownTimeRemaining** field displays the seconds remaining before preemption.
5. In the **Action** check box, select an option.
6. Click **Apply**.

**Interface** field descriptions

Use the data in the following table to use the **Interface** tab.

| Name                         | Description                                                                                                                                                                                                                                                                                                          |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>               | Specifies the index value that uniquely identifies the interface to which this entry is applicable.                                                                                                                                                                                                                  |
| <b>VrId</b>                  | Specifies a number that uniquely identifies a virtual router on a VRRP router. The virtual router acts as the default router for one or more assigned addresses (1 to 255).                                                                                                                                          |
| <b>IpAddr</b>                | Specifies the assigned IP addresses that a virtual router is responsible for backing up.                                                                                                                                                                                                                             |
| <b>VirtualMacAddr</b>        | Specifies the MAC address of the virtual router interface.                                                                                                                                                                                                                                                           |
| <b>State</b>                 | Specifies the state of the virtual router interface: <ul style="list-style-type: none"> <li>• Initialize—waiting for a startup event</li> <li>• Backup—monitoring availability and state of the master router</li> <li>• Master—functioning as the forwarding router for the virtual router IP addresses.</li> </ul> |
| <b>Control</b>               | Specifies whether VRRP is enabled or disabled for the port (or VLAN). The default is enabled.                                                                                                                                                                                                                        |
| <b>Priority</b>              | Specifies the priority value used by this VRRP router. Set a value from 1 to 255, where 255 is reserved for the router that owns the IP addresses associated with the virtual router. The default is 100.                                                                                                            |
| <b>AdvertisementInterval</b> | Specifies the time interval (in seconds) between sending advertisement messages. The range is 1 to 255 seconds with a default of 1 second. Only the master router sends advertisements. The default is 1.                                                                                                            |
| <b>MasterIpAddr</b>          | Specifies the IP address of the physical interface of the master virtual router that forwards packets sent to the virtual IP addresses associated with the virtual router.                                                                                                                                           |
| <b>VirtualRouterUpTime</b>   | Specifies the time interval (in hundredths of a second) since the virtual router was initialized.                                                                                                                                                                                                                    |
| <b>Action</b>                | Lists options to override the delay timer manually and force preemption: <ul style="list-style-type: none"> <li>• <b>none</b> does not override the timer</li> <li>• <b>preemptHoldDownTimer</b> preempts the timer</li> </ul>                                                                                       |
| <b>HoldDownTimer</b>         | Configures the amount of time (in seconds) to wait before preempting the current VRRP master.                                                                                                                                                                                                                        |

| Name                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>HoldDownState</b>           | Indicates the hold-down state of this VRRP interface. If the hold-down timer is operational, this variable is set to active; otherwise, this variable is set to dormant.                                                                                                                                                                                                                                                         |
| <b>HoldDownTimeRemaining</b>   | Indicates the amount of time (in seconds) left before the HoldDownTimer expires.                                                                                                                                                                                                                                                                                                                                                 |
| <b>CriticalIpAddr</b>          | Configures the critical IP address for VRRP. This command specifies an IP interface on the local router, which is configured so that a change in its state causes a role switch in the virtual router (for example, from master to backup) in case the interface stops responding.<br><br><b>Note:</b><br>In this context, <i>local</i> implies an address from the same VRF as the IP interface where VRRP is being configured. |
| <b>CriticalIpAddrEnable</b>    | Configures the IP interface on the local router to enable or disable the backup. The default is disabled.                                                                                                                                                                                                                                                                                                                        |
| <b>BackUpMaster</b>            | Enables the backup VRRP system traffic forwarding. The default is disabled.                                                                                                                                                                                                                                                                                                                                                      |
| <b>BackUpMasterState</b>       | Indicates whether the backup VRRP system traffic forwarding is enabled or disabled. The default is disabled.                                                                                                                                                                                                                                                                                                                     |
| <b>FasterAdvInterval</b>       | Configures the Fast Advertisement Interval between sending VRRP advertisement messages. The interval is between 200 and 1000 milliseconds, and you must enter the same value on all participating routers. The default is 200. You must enter the values in multiples of 200 milliseconds.                                                                                                                                       |
| <b>FasterAdvIntervalEnable</b> | Enables or disables the Fast Advertisement Interval. When disabled, the regular advertisement interval is used. The default is disable.                                                                                                                                                                                                                                                                                          |

## Configuring VRRP on a V3 interface

Perform this procedure to configure VRRP on a V3 interface on either a brouter port or a VLAN.

### Before You Begin

- Assign an IPv4 address to the interface
- Enable routing globally
- Do not configure RSMLT on the VLAN

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **VRRP**.

3. Click the **V3 Interface** tab.
4. Click **Insert**.
5. Beside the **IfIndex** field, click **Port** or **VLAN**.
6. Select a port or VLAN.
7. Click **OK**.
8. Type the virtual router ID.
9. Type the primary IP address.
10. Type the advertisement interval.
11. Click **Insert**.

### **Interface** field descriptions

Use the data in the following table to use the **Interface** tab.

| Name                  | Description                                                                                                                                                                                                                                                                                                                             |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>        | Shows the index value that uniquely identifies the interface to which this entry applies.                                                                                                                                                                                                                                               |
| <b>InetAddrType</b>   | Specifies the source network INET Address Type.                                                                                                                                                                                                                                                                                         |
| <b>VrId</b>           | Specifies a number that uniquely identifies a virtual router on a VRRP router.                                                                                                                                                                                                                                                          |
| <b>PrimaryIpAddr</b>  | Specifies the virtual address assigned to the VRRP.                                                                                                                                                                                                                                                                                     |
| <b>VirtualMacAddr</b> | Specifies the MAC address of the virtual router interface.                                                                                                                                                                                                                                                                              |
| <b>State</b>          | Shows the state of the virtual router interface. The possible states are <ul style="list-style-type: none"> <li>• initialize—waiting for a startup event</li> <li>• backup—monitoring availability and state of the master router</li> <li>• master—functioning as the forwarding router for the virtual router IP addresses</li> </ul> |
| <b>Control</b>        | Displays whether VRRP is enabled or disabled for the port or VLAN.                                                                                                                                                                                                                                                                      |
| <b>Priority</b>       | Specifies the priority value used by this VRRP router. The value 255 is reserved for the router that owns the IP addresses associated with the virtual router. The default is 100.                                                                                                                                                      |
| <b>AdvInterval</b>    | Specifies the time interval, in seconds, between sending advertisement messages. The default is 1 second.                                                                                                                                                                                                                               |
| <b>MasterIpAddr</b>   | Specifies the IP address of the physical interface of the Master's virtual router.                                                                                                                                                                                                                                                      |
| <b>UpTime</b>         | Indicates the time interval since this virtual router exited the INIT state.                                                                                                                                                                                                                                                            |
| <b>CriticalIpAddr</b> | Indicates the IP address of the interface that is critical to VRRP. If that IP interface is down, the VRRP state will transition to Backup, even if it has higher priority.                                                                                                                                                             |

| Name                            | Description                                                                                                                                                                                                                                                                                       |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CriticalIpAddrEnabled</b>    | Enables or disables the use of critical IP. When disabled, the VRRP ignores the availability of the address configured as critical IP. This address must be a local address. The default is disabled.                                                                                             |
| <b>BackUpMaster</b>             | Uses the backup VRRP switch for traffic forwarding. This option reduces the traffic on the v1ST. The default is disabled.                                                                                                                                                                         |
| <b>BackUpMasterState</b>        | Indicates if the Backup-Master is operational up. If the switch is in Master state but the Backup-Master is enabled, then the BACKUP MASTER STATE will be down.                                                                                                                                   |
| <b>FasterAdvIntervalEnabled</b> | Enables or disables the fast advertisement interval. When disabled, the regular advertisement interval is used. The default is disable.                                                                                                                                                           |
| <b>FasterAdvInterval</b>        | Configures the interval between VRRP advertisement messages. The default is 200. Enter the values in multiples of 200 milliseconds.                                                                                                                                                               |
| <b>PreemptMode</b>              | Issued to preempt the existing router. If a new router is added to the network with its priority higher than the existing routers, then the new router becomes the master. The default is enabled.                                                                                                |
| <b>Action</b>                   | Lists options to override the hold-down timer manually and force preemption: <ul style="list-style-type: none"> <li>• <b>none</b> does not override the timer.</li> <li>• <b>preemptHoldDownTimer</b> preempts the timer.</li> </ul> This parameter applies only if the holddown timer is active. |
| <b>HoldDownTimer</b>            | Configures the amount of time, in seconds, to wait before preempting the current VRRP master. The default is 0.                                                                                                                                                                                   |
| <b>HoldDownTimeRemaining</b>    | Indicates the amount of time, in seconds, left before the HoldDownTimer expires.                                                                                                                                                                                                                  |
| <b>MasterAdvInterval</b>        | On the VRRPv3 master, the master advertisement interval is same as the advertisement interval. On the VRRPv3 Backup, the master advertisement interval is set to the Advertisement configured on the Master (received in the packet).                                                             |

## Configuring VRRPv3 Checksum

Perform this procedure to configure VRRPv3 checksum on either a brouter port or a VLAN.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **VRRP**.
3. Click the **V3 Checksum** tab.

4. Click **Insert**.
5. In the **Interface** field, click **Port** or **Vlan**.
6. Select a type of checksum computation.
7. Select a VRRP version.
8. Click **Insert**.

### **V3 Checksum** field descriptions

Use the data in the following table to use the **V3 Checksum** tab.

| Name                     | Description                                                                               |
|--------------------------|-------------------------------------------------------------------------------------------|
| <b>Interface</b>         | Shows VRRPv3 information about a specified interface.                                     |
| <b>rclpConflfIndex</b>   | Shows the index value that uniquely identifies the interface to which this entry applies. |
| <b>ChkSumComputation</b> | Specifies the type of checksum computation, with Pseudo Header or without Pseudo Header.  |
| <b>VrrpVersion</b>       | Specifies the VRRP version as unspecified, v2, or v3.                                     |

## Configuring Fast Advertisement Interval on a port or a VRF instance

### About This Task

Configure the Fast Advertisement Interval to send VRRP advertisement messages. The interval can be between 200 and 1000 milliseconds, and it must be the same on all participating routers. The default is 200. Enter the values in multiples of 200 milliseconds.

### Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand the following folders: **Configuration > Edit > Port**.
3. Click **IP**.
4. Click the **VRRP** tab.
5. Click **Insert**.
6. In the **Insert VRRP** dialog box, enable **FasterAdvIntervalEnable**.
7. In the **FasterAdvInterval** field, enter a value. You must set this value using multiples of 200 milliseconds.
8. Click **Insert**.

## Configuring Fast Advertisement Interval on a VLAN or a VRF instance

### About This Task

Configure the Fast Advertisement Interval to send VRRP advertisement messages. The interval can be between 200 and 1000 milliseconds, and it must be the same on all participating routers. The default is 200. Enter the values in multiples of 200 milliseconds.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > VLAN**.
2. Click **VLANs > Basic**.
3. Select a VLAN.
4. Click **IP**.
5. Click the **VRRP** tab.
6. Click **Insert**.
7. In the IP, VLAN, Insert VRRP dialog box, click the **FasterAdvIntervalEnable** enable option.
8. In the **FasterAdvInterval**, box, enter a value. You must set the value using multiples of 200 milliseconds.
9. Click **Insert**.

## Viewing VRRP Statistics

### About This Task

View VRRP statistics to monitor network performance.

### Procedure

1. In the navigation pane, expand the **Configuration > IP** folders.
2. Click **VRRP**.
3. Select the **Stats** tab.

### *Stats* Field Descriptions

The following table describes parameters on the VRRP statistics tab.

| Name                  | Description                                                                                  |
|-----------------------|----------------------------------------------------------------------------------------------|
| <b>ChecksumErrors</b> | Specifies the number of VRRP packets received with an invalid VRRP checksum value.           |
| <b>VersionErrors</b>  | Specifies the number of VRRP packets received with an unknown or unsupported version number. |
| <b>VrIDErrors</b>     | Specifies the number of VRRP packets received with an invalid VrID for this virtual router.  |

## Viewing VRRP Interface Statistics

### About This Task

View VRRP statistics to manage network performance.

**Procedure**

1. In the navigation pane, expand the **Configuration > IP** folders.
2. Click **VRRP**.
3. Select the **Interface** tab.
4. Select an interface.
5. Click **Graph**.

*Interface Field Descriptions*

The following table describes parameters on the **Interface** tab.

| Name                           | Description                                                                                                                            |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdvertiseRcvd</b>           | Specifies the number of VRRP advertisements received by this virtual router.                                                           |
| <b>AdvertiseIntervalErrors</b> | Specifies the number of received VRRP advertisement packets with a different interval is than configured for the local virtual router. |
| <b>IPtTlErrors</b>             | Specifies the number of VRRP packets received by the virtual router with IP TTL (Time-To-Live) not equal to 255.                       |
| <b>PriorityZeroPktsRcvd</b>    | Specifies the number of VRRP packets received by the virtual router with a priority of 0.                                              |
| <b>PriorityZeroPktsSent</b>    | Specifies the number of VRRP packets sent by the virtual router with a priority of 0.                                                  |
| <b>InvalidTypePktsRcvd</b>     | Specifies the number of VRRP packets received by the virtual router with an invalid value in the 'type' field.                         |
| <b>AddressListErrors</b>       | Specifies the packets received address list the address list does not match the locally configured list for the virtual router.        |
| <b>AuthTypeMismatch</b>        | Specifies the count of authentication type mismatch messages.                                                                          |
| <b>PacketLengthErrors</b>      | Specifies the count of packet length errors.                                                                                           |
| <b>AuthFailures</b>            | Specifies the count of authentication failure messages.                                                                                |

## Viewing IP VRRPv3 Statistics

**About This Task**

Use the following procedure to view IPv6 VRRPv3 statistics for monitoring the network performance.

**Procedure**

1. In the navigation pane, expand the **Configuration --> IP** folders.
2. Click **VRRP**.
3. Click the **V3 Stats** tab.

**V3 Stats** Field Descriptions

Use the data in the following table to interpret the **V3 Stats** tab.

| Name                  | Description                                                                                        |
|-----------------------|----------------------------------------------------------------------------------------------------|
| <b>InetAddrType</b>   | Shows that the address type of the statistical entry is IPv4.                                      |
| <b>ChecksumErrors</b> | Specifies the total number of VRRP packets received with an invalid VRRP checksum value.           |
| <b>VersionErrors</b>  | Specifies the total number of VRRP packets received with an unknown or unsupported version number. |
| <b>VrIdErrors</b>     | Specifies the total number of VRRP packets received with an invalid VRID for the virtual router.   |

## Graphing IP VRRPv3 Statistics

**About This Task**

Use the following procedure to view and graph IP VRRPv3 statistics for monitoring the network performance.

**Procedure**

1. In the navigation pane, expand the **Configuration** --> **IP** folders.
2. Click **VRRP**.
3. Click the **V3 Interface** tab.
4. Select an interface, and click **Graph**.
5. Select one or more values.
6. Select a graph type, click one of the icons in the upper-left corner of the menu bar. Your choices are:
  - Line Chart
  - Area Chart
  - Bar Chart
  - Pie Chart

**V3 Interface** Field Descriptions

Use the data in the following table to use the **V3 Interface** tab.

| Name                  | Description                                                                               |
|-----------------------|-------------------------------------------------------------------------------------------|
| <b>IfIndex</b>        | Shows the index value that uniquely identifies the interface to which this entry applies. |
| <b>VrId</b>           | Specifies a number that uniquely identifies a virtual router on a VRRP router.            |
| <b>PrimaryIpAddr</b>  | Specifies the virtual address assigned to the VRRP.                                       |
| <b>VirtualMacAddr</b> | Specifies the MAC address of the virtual router interface.                                |

| Name                            | Description                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>State</b>                    | Specifies the state of the virtual router interface: <ul style="list-style-type: none"> <li>• Initialize—waiting for a startup event</li> <li>• Backup—monitoring availability and state of the master router</li> <li>• Master—functioning as the forwarding router for the virtual router IP addresses.</li> </ul>                                                         |
| <b>Control</b>                  | Specifies whether VRRP is enabled or disabled for the port (or VLAN). The default is enabled.                                                                                                                                                                                                                                                                                |
| <b>Priority</b>                 | Specifies the priority value used by this VRRP router. Set a value from 1 to 255, where 255 is reserved for the router that owns the IP addresses associated with the virtual router. The default is 100.                                                                                                                                                                    |
| <b>AdvInterval</b>              | Specifies the time interval (in seconds) between sending advertisement messages. The range is 1 to 255 seconds with a default of 1 second. Only the master router sends advertisements. The default is 1.                                                                                                                                                                    |
| <b>UpTime</b>                   | Specifies the time interval (in hundredths of a second) since the virtual router was initialized.                                                                                                                                                                                                                                                                            |
| <b>CriticalIpAddr</b>           | This command specifies an IP interface on the local router, which is configured so that a change in its state causes a role switch in the virtual router (for example, from master to backup) in case the interface stops responding.<br><br><b>Note:</b><br>In this context, local implies an address from the same VRF as the IP interface where VRRP is being configured. |
| <b>CriticalIpAddrEnabled</b>    | Configures the IP interface on the local router to enable or disable the backup. The default is disabled.                                                                                                                                                                                                                                                                    |
| <b>BackUpMaster</b>             | Enables the backup VRRP system traffic forwarding. The default is disabled.                                                                                                                                                                                                                                                                                                  |
| <b>BackUpMasterState</b>        | Indicates whether the backup VRRP system traffic forwarding is enabled or disabled. The default is disabled.                                                                                                                                                                                                                                                                 |
| <b>FasterAdvIntervalEnabled</b> | Enables or disables the Fast Advertisement Interval. When disabled, the regular advertisement interval is used. The default is disabled.                                                                                                                                                                                                                                     |
| <b>FasterAdvInterval</b>        | Configures the Fast Advertisement Interval between sending VRRP advertisement messages. The interval is between 200 and 1000 milliseconds, and you must enter the same value on all participating routers. The default is 200. You must enter the values in multiples of 200 milliseconds.                                                                                   |

| Name                         | Description                                                                                                                                                                                                                           |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PreemptMode</b>           | Issued to preempt the existing router. If a new router is added to the network with its priority higher than the existing routers, then the new router becomes the master.                                                            |
| <b>Action</b>                | Lists options to override the delay timer manually and force preemption: <ul style="list-style-type: none"> <li>• <b>none</b> does not override the timer</li> <li>• <b>preemptHoldDownTimer</b> preempts the timer</li> </ul>        |
| <b>HoldDownTimer</b>         | Indicates the hold-down state of this VRRP interface. If the hold-down timer is operational, this variable is set to active; otherwise, this variable is set to dormant.                                                              |
| <b>HoldDownTimeRemaining</b> | Indicates the amount of time (in seconds) left before the HoldDownTimer expires.                                                                                                                                                      |
| <b>MasterAdvInterval</b>     | On the VRRPv3 master, the master advertisement interval is same as the advertisement interval. On the VRRPv3 Backup, the master advertisement interval is set to the Advertisement configured on the Master (received in the packet). |

## IPv6 VRRP Configuration using EDM

### Configure VRRP for an Interface

Configure VRRP to provide fast failover of a default router for IPv6 LAN hosts. VRRP supports a virtual IPv6 address shared between two or more routers that connect the common subnet to the enterprise network. VRRP for IPv6 provides a faster switchover to an alternate default router than is possible using the ND protocol.

Perform this procedure to configure VRRP on either a brouter port or a VLAN.

#### Before You Begin

- Assign an IPv6 address to the interface.
- Enable routing globally.
- Do not configure RSMLT on the VLAN.
- Change the VRF instance as required to configure a VRRP for an interface on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

#### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Select **VRRP**.
3. Select **V3 Interface**.
4. Select **Insert**.
5. Beside the **IfIndex** field, click **Port** or **VLAN**.
6. In the dialog box that opens, select a port or VLAN.

7. Select **OK**.
8. Type the virtual router ID.
9. To control the packets sent to the IPv6 address associated to the virtual router, select the **AcceptMode** check box.
10. Type the primary IP address.
11. Select **Insert**.

### **V3 Interface** or **Interface** Field Descriptions

Use the data in the following table to use the **V3 Interface** tab.

| Name                  | Description                                                                                                                                                                                                                                                                                                                             |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>        | Shows the index value that uniquely identifies the interface to which this entry applies.                                                                                                                                                                                                                                               |
| <b>InetAddrType</b>   | Specifies the address type for the VRRP interface.                                                                                                                                                                                                                                                                                      |
| <b>VrId</b>           | Specifies a number that uniquely identifies a virtual router on a VRRP router.                                                                                                                                                                                                                                                          |
| <b>PrimaryIpAddr</b>  | Specifies the link-local address assigned to the VRRP.                                                                                                                                                                                                                                                                                  |
| <b>VirtualMacAddr</b> | Specifies the MAC address of the virtual router interface.                                                                                                                                                                                                                                                                              |
| <b>State</b>          | Shows the state of the virtual router interface. The possible states are <ul style="list-style-type: none"> <li>• initialize—waiting for a startup event</li> <li>• backup—monitoring availability and state of the master router</li> <li>• master—functioning as the forwarding router for the virtual router IP addresses</li> </ul> |
| <b>Control</b>        | Displays whether VRRP is enabled or disabled for the port or VLAN.                                                                                                                                                                                                                                                                      |
| <b>Priority</b>       | Specifies the priority value used by this VRRP router. The value 255 is reserved for the router that owns the IP addresses associated with the virtual router. The default is 100.                                                                                                                                                      |
| <b>AdvInterval</b>    | Specifies the time interval, in seconds, between sending advertisement messages. The default is 1 second.                                                                                                                                                                                                                               |
| <b>MasterIpAddr</b>   | Specifies the IP address of the physical interface of the Master's virtual router.                                                                                                                                                                                                                                                      |
| <b>UpTime</b>         | Indicates the time interval since this virtual router exited the INIT state.                                                                                                                                                                                                                                                            |
| <b>CriticalIpAddr</b> | Indicates the IP address of the interface that is critical to VRRP. If that IP interface is down, the VRRP state will transition to Backup, even if it has higher priority.                                                                                                                                                             |

| Name                            | Description                                                                                                                                                                                                                                                                                       |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CriticalIpAddrEnabled</b>    | Enables or disables the use of critical IP. When disabled, the VRRP ignores the availability of the address configured as critical IP. This address must be a local address. The default is disabled.                                                                                             |
| <b>BackUpMaster</b>             | Uses the backup VRRP switch for traffic forwarding. This option reduces the traffic on the vIST. The default is disabled.                                                                                                                                                                         |
| <b>BackUpMasterState</b>        | Indicates if the Backup-Master is up. If the switch is in Master state, but Backup-Master is enabled, then the BACKUP MASTER STATE will be down.                                                                                                                                                  |
| <b>FasterAdvIntervalEnabled</b> | Enables or disables the fast advertisement interval. When disabled, the regular advertisement interval is used. The default is disable.                                                                                                                                                           |
| <b>FasterAdvInterval</b>        | Configures the interval between VRRP advertisement messages. The default is 200. Enter the values in multiples of 200 milliseconds.                                                                                                                                                               |
| <b>AcceptMode</b>               | Controls whether the VRRP master or backup master accepts packets (other than neighbor discovery packets) destined to the IPv6 address associated with the virtual router. The default value is disable.                                                                                          |
| <b>PreemptMode</b>              | Issued to preempt the existing router. If a new router is added to the network with its priority higher than the existing routers, then the new router becomes the master. The default is enabled.                                                                                                |
| <b>Action</b>                   | Lists options to override the hold-down timer manually and force preemption: <ul style="list-style-type: none"> <li>• <b>none</b> does not override the timer.</li> <li>• <b>preemptHoldDownTimer</b> preempts the timer.</li> </ul> This parameter applies only if the holddown timer is active. |
| <b>HoldDownTimer</b>            | Configures the amount of time, in seconds, to wait before preempting the current VRRP master. The default is 0.                                                                                                                                                                                   |
| <b>HoldDownTimeRemaining</b>    | Indicates the amount of time, in seconds, left before the HoldDownTimer expires.                                                                                                                                                                                                                  |
| <b>MasterAdvInterval</b>        | On the VRRP master, the master advertisement interval is same as the advertisement interval. On the VRRPv3 Backup, the master advertisement interval is set to the Advertisement configured on the Master (received in the packet).                                                               |

## Configuring VRRP notification control

Perform this procedure to configure VRRP notification control.

**Before You Begin**

- Assign an IPv6 address to the interface.
- Enable routing globally.
- Change the VRF instance as required to configure VRRP notification control on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

**Procedure**

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **VRRP**.
3. Click the **Globals** tab.
4. Select **enabled**.
5. Click **Apply**.

**Globals** field descriptions

Use the data in the following table to use the **Globals** tab.

| Name                     | Description                                                                                                                                                                                                                                         |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NotificationCntrl</b> | Indicates whether the VRRP-enabled router generates SNMP traps for events. <ul style="list-style-type: none"> <li>• <b>enabled</b>: Generate SNMP traps.</li> <li>• <b>disabled</b>: Do not generate SNMP traps.</li> </ul> The default is enabled. |

**View IPv6 VRRP Statistics**

View IPv6 VRRP statistics to monitor network performance.

**Procedure**

1. In the navigation pane, expand **Configuration > IPv6**.
2. Select **VRRP**.
3. Select the **Stats** tab.

**Stats** Field Descriptions

Use the data in the following table to use the **Stats** tab.

| Name                  | Description                                                                              |
|-----------------------|------------------------------------------------------------------------------------------|
| <b>InetAddrType</b>   | Shows the type of IP address (IPv4 or IPv6).                                             |
| <b>ChecksumErrors</b> | Shows the number of VRRP packets received with an invalid VRRP checksum value.           |
| <b>VersionErrors</b>  | Shows the number of VRRP packets received with an unknown or unsupported version number. |
| <b>VrIdErrors</b>     | Shows the number of VRRP packets received with an invalid VrID for this virtual router.  |

## Viewing IPv6 VRRP Statistics for an Interface

View IPv6 VRRP statistics for a VLAN or port.

### Procedure

1. In the navigation pane, expand the **Configuration > IPv6** folders.
2. Click **VRRP**.
3. Click the **Interface** tab.
4. Select an interface.
5. Click **Statistics**.

### **Statistics** Field Descriptions

Use the data in the following table to use the **Statistics** tab.

| Name                      | Description                                                                                                                                                                                                                                                                                                                                    |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MasterTransitions</b>  | Shows the total number of times that the state of this virtual router has transitioned to master. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.                                                                     |
| <b>RcdAdvertisements</b>  | Shows the total number of VRRP advertisements received by this virtual router. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.                                                                                        |
| <b>AdvIntervalErrors</b>  | Shows the total number of VRRP advertisement packets received for which the advertisement interval is different than the one configured for the local virtual router. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime. |
| <b>IpTtlErrors</b>        | Shows the total number of VRRP packets received by the virtual router with IPv4 TTL (for VRRP over IPv4) or IPv6 Hop Limit (for VRRP over IPv6) not equal to 255. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.     |
| <b>RcvdPriZeroPackets</b> | Shows the total number of VRRP packets received by the virtual router with a priority of 0. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.                                                                           |

| Name                              | Description                                                                                                                                                                                                                                                                                                      |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SentPriZeroPackets</b>         | Shows the total number of VRRP packets sent by the virtual router with a priority of 0. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.                                                 |
| <b>RcvdInvalidTypePkts</b>        | Shows the number of VRRP packets received by the virtual router with an invalid value in the 'type' field. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.                              |
| <b>AddressListErrors</b>          | Shows the total number of packets received for which the address list does not match the locally configured list for the virtual router. Discontinuities in the value of this counter can occur at reinitialization of the management system, and at other times as indicated by the value of DiscontinuityTime. |
| <b>PacketLengthErrors</b>         | Shows the total number of packets received with a packet length less than the length of the VRRP header. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.                                |
| <b>RcvdInvalidAuthentications</b> | Shows the total number of packets received with an unknown authentication type.                                                                                                                                                                                                                                  |

## Configure IPv6 VRRP Statistics

View IPv6 VRRP statistics for a VLAN or port.

### Before You Begin

Change the VRF instance as required to view IPv6 VRRP statistics on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > Port**.
2. Select **IPv6**.
3. Select the **VRRP** tab.
4. Select an interface.
5. Select **Statistics**.

## Graphing IPv6 VRRP Statistics

### About This Task

Use the following procedure to graph IPv6 VRRPv3 statistics for monitoring the network performance.

**Procedure**

1. In the navigation pane, expand the **Configuration --> IPv6** folders.
2. Click **VRRP**.
3. Click the **Stats** tab.
4. Select an interface, and click **Graph**.
5. Select one or more values.
6. Select a graph type, click one of the icons in the upper-left corner of the menu bar. Your choices are:
  - Line Chart
  - Area Chart
  - Bar Chart
  - Pie Chart

**Stats Field Descriptions**

Use the data in the following table to use the **Stats** tab.

| Name                  | Description                                                                              |
|-----------------------|------------------------------------------------------------------------------------------|
| <b>InetAddrType</b>   | Shows the type of IP address (IPv4 or IPv6).                                             |
| <b>ChecksumErrors</b> | Shows the number of VRRP packets received with an invalid VRRP checksum value.           |
| <b>VersionErrors</b>  | Shows the number of VRRP packets received with an unknown or unsupported version number. |
| <b>VrldErrors</b>     | Shows the number of VRRP packets received with an invalid VrID for this virtual router.  |

**Configuring additional addresses on the VRRP brouter port**

Perform this procedure to configure the additional addresses for which the virtual router acts as a back up.

**Before You Begin**

- Assign an IPv6 address to the interface.
- Enable routing globally.

**Procedure**

1. In the navigation pane, expand the following folders: **Configuration > Edit > Port**.
2. Click **IPv6**.
3. Click the **VRRP** tab.
4. Click **AssociatedIPAddr**.
5. Click **Insert**.
6. Type the address.
7. Type the prefix length.
8. Click **Insert**.

## Configuring additional addresses on the VRRP interface

Perform this procedure to configure the additional addresses for which the virtual router acts as a back up.

### Before You Begin

- Assign an IPv6 address to the interface.
- Enable routing globally.
- Do not configure RSMLT on the VLAN.
- Change the VRF instance as required to configure additional addresses on the VRRP interface on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IPv6**.
2. Click **VRRP**.
3. Click the **Interface** tab.
4. Select an interface.
5. Click **AssociatedIPAddr**.
6. Click **Insert**.
7. Type the address.
8. Type the prefix length.
9. Click **Insert**.

### **Address List** field descriptions

Use the data in the following table to use the **Address List** tab.

| Name                      | Description                                                                                                                                                                     |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IpAddr</b>             | Specifies an IP address that is associated with a virtual router. The number of rows on this tab equals the number of IP addresses associated (backed up) by the virtual router |
| <b>IpAddrPrefixLength</b> | Specifies the length of the prefix in bits.                                                                                                                                     |

# Port Numbering and MAC Address Assignment Reference

[Port Numbering](#) on page 3456

[Interface Indexes](#) on page 3472

[MAC Address Assignment](#) on page 3474

This section provides information about the port numbering and Media Access Control (MAC) address assignment used on the switch.

## Port Numbering

A port number includes the slot location of the port in the chassis, as well as the port position. For example, the first port in the first slot is structured as 1/1. The number of slots and ports varies depending on the hardware platform. For more information about hardware, see the hardware documentation for your platform.

### 5320 Series

The following diagrams illustrate the components on the front panels of the 5320 Series switches.

#### *5320-16P-4XE and 5320-16P-4XE-DC*

The following diagram illustrates the components of the front panel of the 5320-16P-4XE and 5320-16P-4XE-DC switches. The only difference between these switches is the power source. All ports are in slot 1.

**Figure 256: 5320-16P-4XE Front Panel**

**Figure 257: 5320-16P-4XE-DC Front Panel**

1. RJ-45 serial console port
2. USB Type-A port
3. USB Micro-B console port
4. 10/100/1000BASE-T ports — These ports support 802.3af Type 1 PoE and 802.3at Type 2 PoE+.
5. 1/10Gb SFP+ uplink ports
6. 1/10Gb SFP+ Universal Ports

The back panel (not shown) includes:

- Grounding lug
- 1 AC or DC power inlet connector

*5320-24P-8XE and 5320-24T-8XE*

The following diagram illustrates the components of the front panel of the 5320-24P-8XE and 5320-24T-8XE switches. All ports are in slot 1.

**Figure 258: 5320-24P-8XE Front Panel**

**Figure 259: 5320-24T-8XE Front Panel**

1. RJ-45 serial console port
2. USB Type-A port
3. USB Micro-B console port
4. 10/100/1000BASE-T ports — These ports support 802.3af Type 1 PoE and 802.3at Type 2 PoE+ on 5320-24P-8XE.
5. 1/10Gb SFP+ uplink ports
6. 1/10Gb SFP+ Universal Ports

The back panel (not shown) includes:

- Grounding lug

- 1 AC power inlet connector

### 5320-48P-8XE and 5320-48T-8XE

The following diagram illustrates the components of the front panel of the 5320-48P-8XE and 5320-48T-8XE switches. All ports are in slot 1.

**Figure 260: 5320-48P-8XE Front Panel**

**Figure 261: 5320-48T-8XE Front Panel**

1. RJ-45 serial console port
2. USB Type-A port
3. USB Micro-B console port
4. 10/100/1000BASE-T ports — These ports support 802.3af Type 1 PoE and 802.3at Type 2 PoE+ on 5320-48P-8XE.
5. 1/10Gb SFP+ uplink ports
6. 1/10Gb SFP+ Universal Ports

The back panel (not shown) includes:

- Grounding lug
- 1 AC power inlet connector

## 5420 Series

In addition to the regular fixed ports, all 5420 Series switches have two SFP-DD Universal Ethernet ports that are reserved for advanced features (factory default). You can also use these ports as regular ports if you do not require the advanced features. For more information about using the advanced-feature-bandwidth-reservation boot flag to configure the functionality of these ports, see [advanced-feature-bandwidth-reservation Boot Flag](#) on page 119.

When advanced features are disabled on these SFP-DD Universal Ethernet ports, they can function as regular Ethernet ports, supporting data rates of either 10Gb using SFP+ optics or 20Gb using SFP-DD

optics. 5420M switch models support two 10Gb channels on each SFP-DD port. 5420F switch models support one 10Gb channel on each SFP-DD port when the ports are used as Ethernet ports.

**Note**

25 SFP28 direct attach cables (DAC) handling in SFP28 and SFP+ ports can be used for 25Gb and 10Gb by setting speed or Custom Auto-Negotiation Advertisement (CANA) at both ends.

Front panel ports 1/1-1/28, 1/29/1, 1/29/2, 1/30/1, and 1/30/2 can be used for traffic on the following switches:

- 5420F-8W-16P-4XE
- 5420F-24P-4XE
- 5420F-24S-4XE
- 5420F-24T-4XE
- 5420M-24W-4YE
- 5420M-24T-4YE

Front panel ports 1/1-1/52, 1/53/2, 1/53/1, 1/53/2, 1/54/1, and 1/54/2 can be used for traffic on the following switches:

- 5420F-16W-32P-4XE
- 5420F-48P-4XE
- 5420F-48P-4XL
- 5420F-48T-4XE
- 5420M-16MW-32P-4YE
- 5420M-48T-4YE
- 5420M-48W-4YE

On the following switches, you can create two 10Gb channels on each SFP-DD port:

- 5420M-24W-4YE
- 5420M-24T-4YE
- 5420M-16MW-32P-4YE
- 5420M-48T-4YE
- 5420M-48W-4YE

*5420F-8W-16P-4XE*

The following diagram illustrates the components of the front panel of the 5420F-8W-16P-4XE switch.

**Figure 262: 5420F-8W-16P-4XE Front Panel**

The front panel of the 5420F-8W-16P-4XE switch includes:

1. 8 10/100/1000BASE-T full-duplex (FDX), half-duplex (HDX) 802.3bt Type 4 PoE+ MACsec-capable ports, 16 1000BASE-T FDX/HDX Type 2 PoE+ MACsec-capable ports.
2. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK, and BT). Switch LEDs for system power (P1, P2), fan (FAN), and System Locator LED (LOC).

#### Note

The software only supports SYS and SPD LED mode indicators. STK and BT LED indicators remain off.

3. 1 Micro-B USB console port
4. 1 RJ-45 management port
5. 1 RJ-45 serial console port
6. 2 Type-A USB ports
7. 2 SFP-DD Universal Ethernet ports (labeled U1 and U2)
8. 4 1/10 Gbps SFP+ ports

The back panel (not shown) includes two fixed fan modules, an AC power inlet connector, a power supply slot, and a grounding lug.

#### 5420F-24P-4XE

The following diagram illustrates the components of the front panel of the 5420F-24P-4XE switch.

**Figure 263: 5420F-24P-4XE Front Panel**

The front panel of the 5420F-24P-4XE switch includes:

1. 24 10/100/1000BASE-T FDX/HDX 802.3bt Type 2 PoE+ MACsec-capable ports.
2. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2), fan (FAN), and System Locator LED (LOC).

#### Note

The software only supports SYS and SPD LED mode indicators. STK and BT LED indicators remain off.

3. 1 Micro-B USB console port
4. 1 RJ-45 out of band (OOB) management port
5. 1 RJ-45 serial console port
6. 2 Type-A USB ports
7. 2 SFP-DD Universal Ethernet ports (labeled U1 and U2)
8. 4 1/10 Gbps SFP+ ports

The back panel (not shown) includes 2 fixed fan modules, an AC power inlet connector, a power supply slot, and a grounding lug.

### 5420F-24S-4XE

The following diagram illustrates the components of the front panel of the 5420F-24S-4XE switch.

**Figure 264: 5420F-24S-4XE Front Panel**

The front panel of the 5420F-24S-4XE switch includes:

1. 24 1000BASE-X SFP MACsec-capable ports.
2. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2), fan (FAN), and System Locator LED (LOC).

**Note**

The software only supports SYS and SPD LED mode indicators. STK and BT LED indicators remain off.

3. 1 Micro-B USB console port
4. 1 RJ-45 out of band (OOB) management port
5. 1 RJ-45 serial console port
6. 2 Type-A USB ports
7. 2 SFP-DD Universal Ethernet ports (labeled U1 and U2)
8. 4 10 Gbps SFP+ ports

The back panel (not shown) includes 2 fixed fan modules, an AC power inlet connector, a power supply slot, and a grounding lug.

### 5420F-24T-4XE

The following diagram illustrates the components of the front panel of the 5420F-24T-4XE switch.

**Figure 265: 5420F-24T-4XE Front Panel**

The front panel of the 5420F-24T-4XE switch includes:

1. 24 10/100/1000BASE-T FDX/HDX MACsec-capable ports.
2. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2), fan (FAN), and System Locator LED (LOC).

**Note**

The software only supports SYS and SPD LED mode indicators. STK and BT LED indicators remain off.

3. 1 Micro-B USB console port
4. 1 RJ-45 out of band (OOB) management port
5. 1 RJ-45 serial console port
6. 2 Type-A USB ports
7. 2 SFP-DD Universal Ethernet ports (labeled U1 and U2)
8. 4 1/10 Gbps SFP+ ports

The back panel (not shown) includes 2 fixed fan modules, an AC power inlet connector, a power supply slot, and a grounding lug.

*5420F-16MW-32P-4XE*

The following diagram illustrates the components of the front panel of the 5420F-16MW-32P-4XE switch.

**Figure 266: 5420F-16MW-32P-4XE Front Panel**

The front panel of the 5420F-16MW-32P-4XE switch includes:

1. 16 100Mb/1GB/2.5GB 802.3bt Type 4 PoE ports.
2. 32 10/100/1000BASE-T FDX/HDX Type 2 PoE+ MACsec-capable ports.
3. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2), fan (FAN), and System Locator LED (LOC).

**Note**

The software only supports SYS and SPD LED mode indicators. STK and BT LED indicators remain off.

4. 1 Micro-B USB console port
5. 1 RJ-45 out of band (OOB) management port
6. 1 RJ-45 serial console port
7. 2 Type-A USB ports
8. 2 SFP-DD Universal Ethernet ports (labeled U1 and U2)
9. 4 1/10 Gbps SFP+ ports

The back panel (not shown) includes three fixed fan modules, a power supply slot, an AC power inlet connector, and a grounding lug.

*5420F-16W-32P-4XE*

The following diagram illustrates the components of the front panel of the 5420F-16W-32P-4XE switch.

**Figure 267: 5420F-16W-32P-4XE Front Panel**

The front panel of the 5420F-16W-32P-4XE switch includes:

1. 16 10/100/1000BASE-T FDX/HDX 802.3bt Type 4 PoE MACsec-capable ports.
2. 32 10/100/1000BASE-T FDX/HDX Type 2 PoE+ MACsec-capable ports.
3. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2), fan (FAN), and System Locator LED (LOC).

**Note**

The software only supports SYS and SPD LED mode indicators. STK and BT LED indicators remain off.

4. 1 Micro-B USB console port
5. 1 RJ-45 out of band (OOB) management port
6. 1 RJ-45 serial console port
7. 2 Type-A USB ports
8. 2 SFP-DD Universal Ethernet ports (labeled U1 and U2)
9. 4 1/10 Gbps SFP+ ports

The back panel (not shown) includes three fixed fan modules, a power supply slot, an AC power inlet connector, and a grounding lug.

*5420F-48P-4XE*

The following diagram illustrates the components of the front panel of the 5420F-48P-4XE switch.

**Figure 268: 5420F-48P-4XE Front Panel**

The front panel of the 5420F-48P-4XE switch includes:

1. 48 10/100/1000BASE-T FDX/HDX Type 2 PoE+ MACsec-capable ports.
2. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2), fan (FAN), and System Locator LED (LOC).

**Note**

The software only supports SYS and SPD LED mode indicators. STK and BT LED indicators remain off.

3. 1 Micro-B USB console port
4. 1 RJ-45 out of band (OOB) management port
5. 1 RJ-45 serial console port
6. 2 Type-A USB ports
7. 2 SFP-DD Universal Ethernet ports (labeled U1 and U2)
8. 4 1/10 Gbps SFP+ ports

The back panel (not shown) includes three fixed fan modules, a power supply slot, an AC power inlet connector, and a grounding lug.

#### 5420F-48P-4XL

The following diagram illustrates the components of the front panel of the 5420F-48P-4XL switch.

**Figure 269: 5420F-48P-4XL Front Panel**

The front panel of the 5420F-48P-4XL switch includes:

1. 48 10/100/1000BASE-T FDX/HDX Type 2 PoE+ MACsec-capable ports.
2. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2), fan (FAN), and System Locator LED (LOC).

**Note**

The software only supports SYS and SPD LED mode indicators. STK and BT LED indicators remain off.

3. 1 Micro-B USB console port
4. 1 RJ-45 out of band (OOB) management port
5. 1 RJ-45 serial console port
6. 2 Type-A USB ports
7. 2 SFP-DD Universal Ethernet ports (labeled U1 and U2)
8. 4 1/10 Gbps LRM/MACsec-capable SFP+ ports

The back panel (not shown) includes three fixed fan modules, a power supply slot, an AC power inlet connector, and a grounding lug.

### 5420F-48T-4XE

The following diagram illustrates the components of the front panel of the 5420F-48T-4XE switch.

**Figure 270: 5420F-48T-4XE Front Panel**

The front panel of the 5420F-48T-4XE switch includes:

1. 48 10/100/1000BASE-T FDX/HDX MACsec-capable ports.
2. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2), fan (FAN), and System Locator LED (LOC).

**Note**

The software only supports SYS and SPD LED mode indicators. STK and BT LED indicators remain off.

3. 1 Micro-B USB console port
4. 1 RJ-45 out of band (OOB) management port
5. 1 RJ-45 serial console port
6. 2 Type-A USB ports
7. 2 SFP-DD Universal Ethernet ports (labeled U1 and U2)
8. 4 1/10 Gbps SFP+ ports

The back panel (not shown) includes two fixed fan modules, a power supply slot, an AC power inlet connector, and a grounding lug.

### 5420M-24T-4YE

The following diagram illustrates the components of the front panel of the 5420M-24T-4YE switch.

**Figure 271: 5420M-24T-4YE Front Panel**

The front panel of the 5420M-24T-4YE switch includes:

1. 24 10/100/1000BASE-T FDX/HDX Type 2 MACsec-capable ports.
2. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2), fan (FAN), and System Locator LED (LOC).

**Note**

The software only supports SYS and SPD LED mode indicators. STK and BT LED indicators remain off.

3. 1 Micro-B USB console port
4. 1 RJ-45 out of band (OOB) management port
5. 1 RJ-45 serial console port
6. 2 Type-A USB ports
7. 2 SFP-DD Universal Ethernet ports (labeled U1 and U2)
8. 4 1/10/25 Gbps SFP28 ports

The back panel (not shown) includes a removable fan module, two power supply slots, and a grounding lug.

*5420M-24W-4YE*

The following diagram illustrates the components of the front panel of the 5420M-24W-4YE switch.

**Figure 272: 5420M-24W-4YE Front Panel**

The front panel of the 5420M-24W-4YE switch includes:

1. 24 10/100/1000BASE-T FDX/HDX 802.3bt Type 4 PoE MACsec-capable ports.
2. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2), fan (FAN), and System Locator LED (LOC).

**Note**

The software only supports SYS and SPD LED mode indicators. STK and BT LED indicators remain off.

3. 1 Micro-B USB console port
4. 1 RJ-45 out of band (OOB) management port
5. 1 RJ-45 serial console port
6. 2 Type-A USB ports
7. 2 SFP-DD Universal Ethernet ports (labeled U1 and U2)
8. 4 1/10/25 Gbps SFP28 ports

The back panel (not shown) includes a removable fan module, two power supply slots, and a grounding lug.

*5420M-16MW-32P-4YE*

The following diagram illustrates the components of the front panel of the 5420M-16MW-32P-4YE switch.

**Figure 273: 5420M-16MW-32P-4YE Front Panel**

The front panel of the 5420M-16MW-32P-4YE switch includes:

1. 16 100Mb/1Gb/2/5Gb 802.3bt Type 4 PoE ports.
2. 32 10/100/1000BASE-T FDX/HDX Type 2 PoE+ MACsec-capable ports.
3. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2), fan (FAN), and System Locator LED (LOC).

**Note**

The software only supports SYS and SPD LED mode indicators. STK and BT LED indicators remain off.

4. 1 Micro-B USB console port
5. 1 RJ-45 out of band (OOB) management port
6. 1 RJ-45 serial console port
7. 2 Type-A USB ports
8. 2 SFP-DD Universal Ethernet ports (labeled U1 and U2)
9. 4 1/10/25 Gbps SFP28 ports

The back panel (not shown) includes a removable fan module, two power supply slots, and a grounding lug.

*5420M-48T-4YE*

The following diagram illustrates the components of the front panel of the 5420M-48T-4YE switch.

**Figure 274: 5420M-48T-4YE Front Panel**

The front panel of the 5420M-48T-4YE switch includes:

1. 48 10/100/1000BASE-T FDX/HDX MACsec-capable ports.
2. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2), fan (FAN), and System Locator LED (LOC).

**Note**

The software only supports SYS and SPD LED mode indicators. STK and BT LED indicators remain off.

3. 1 Micro-B USB console port
4. 1 RJ-45 out of band (OOB) management port
5. 1 RJ-45 serial console port
6. 2 Type-A USB ports
7. 2 SFP-DD Universal Ethernet ports (labeled U1 and U2)
8. 4 1/10/25 Gbps SFP28 ports

The back panel (not shown) includes a removable fan module, two power supply slots, and a grounding lug.

*5420M-48W-4YE*

The following diagram illustrates the components of the front panel of the 5420M-48W-4YE switch.

**Figure 275: 5420M-48W-4YE Front Panel**

The front panel of the 5420M-48W-4YE switch includes:

1. 48 10/100/1000BASE-T FDX/HDX 802.3bt Type 4 PoE ports MACsec-capable ports.
2. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2), fan (FAN), and System Locator LED (LOC).

**Note**

The software only supports SYS and SPD LED mode indicators. STK and BT LED indicators remain off.

3. 1 Micro-B USB console port
4. 1 RJ-45 out of band (OOB) management port
5. 1 RJ-45 serial console port
6. 2 Type-A USB ports
7. 2 SFP-DD Universal Ethernet ports (labeled U1 and U2)
8. 4 1/10/25 Gbps SFP28 ports

The back panel (not shown) includes a removable fan module, two power supply slots, and a grounding lug.

## 5520 Series

The following diagrams illustrate the components on the front panels of the 5520 Series switches.

### Note

In addition to the regular fixed ports, all 5520 Series switches have two QSFP28/QSFP+ Universal Ethernet ports and a Versatile Interface Module (VIM) slot. If you install a VIM, the switch reserves the Universal Ethernet ports for advanced features. If you do not install a VIM, the switch reserves two internal VIM ports for advanced features and you can use the Universal Ethernet ports as regular ports. If you do not require advanced features, you can use the Universal Ethernet ports as regular ports. For more information about using the advanced-feature-bandwidth-reservation boot flag to configure the functionality of these ports, see [advanced-feature-bandwidth-reservation Boot Flag](#) on page 119.

When used as regular ports, the port speed is 40 Gbps as a single channel port. Although the maximum supported single channel port speed is 40 Gbps, the ports can be channelized to operate as four 10 or 25 Gbps channels.

For information about supported VIM modules, see [ExtremeSwitching 5520 Series Hardware Installation Guide](#).

### 5520-24T

The following diagram illustrates the components of the front panel of the 5520-24T switch. Slot 1 is used for the 24 copper ports and the two QSFP28/QSFP+ ports, and slot 2 is used for Versatile Interface Module (VIM) ports, if a VIM is installed in the VIM slot.

**Figure 276: 5520-24T**

1. 24 10/100/1000BASE-T full-duplex (FDX), half-duplex (HDX), MACsec-capable ports
2. 1 USB A port
3. 1 USB micro B management port
4. 2 Universal Ethernet QSFP28 ports
5. VIM slot (shown with VIM covered). Port numbering depends on the type of VIM installed in the slot.

The back panel (not shown) includes an RJ-45 out of band (OOB) management port, an RJ-45 console port, a USB A port, locator LED, two PSU slots, and hot-swappable fan units.

### 5520-24W

The following diagram illustrates the components of the front panel of the 5520-24W switch. Slot 1 is used for the 24 copper ports and the two QSFP28/QSFP+ ports, and slot 2 is used for Versatile Interface Module (VIM) ports, if a VIM is installed in the VIM slot.

**Figure 277: 5520-24W**

1. 24 10/100/1000BASE-T FDX/HDX 802.3bt Type 4 PoE MACsec-capable ports
2. 1 USB A port
3. 1 USB micro B management port
4. 2 Universal Ethernet QSFP28 ports
5. VIM slot (shown with VIM covered). Port numbering depends on the type of VIM installed in the slot.

The back panel (not shown) includes an RJ-45 out of band (OOB) management port, an RJ-45 console port, a USB A port, locator LED, two PSU slots, and hot-swappable fan units.

#### 5520-48T

The following diagram illustrates the components of the front panel of the 5520-48T switch. Slot 1 is used for the 48 copper ports and the two QSFP28/QSFP+ ports, and slot 2 is used for Versatile Interface Module (VIM) ports, if a VIM is installed in the VIM slot.

**Figure 278: 5520-48T**

1. 48 10/100/1000BASE-T FDX/HDX MACsec-capable ports
2. 1 USB A port
3. 1 USB micro B management port
4. 2 Universal Ethernet QSFP28 ports
5. VIM slot (shown with VIM covered). Port numbering depends on the type of VIM installed in the slot.

The back panel (not shown) includes an RJ-45 out of band (OOB) management port, an RJ-45 console port, a USB A port, locator LED, two PSU slots, and hot-swappable fan units.

#### 5520-48W

The following diagram illustrates the components of the front panel of the 5520-48W switch. Slot 1 is used for the 48 copper ports and the two QSFP28/QSFP+ ports, and slot 2 is used for Versatile Interface Module (VIM) ports, if a VIM is installed in the VIM slot.

**Figure 279: 5520-48W**

1. 48 10/100/1000BASE-T FDX/HDX 802.3bt Type 4 PoE MACsec-capable ports
2. 1 USB A port
3. 1 USB micro B management port
4. 2 Universal Ethernet QSFP28 ports
5. VIM slot (shown with VIM covered). Port numbering depends on the type of VIM installed in the slot.

The back panel (not shown) includes an RJ-45 out of band (OOB) management port, an RJ-45 console port, a USB A port, locator LED, two PSU slots, and hot-swappable fan units.

#### 5520-12MW-36W

The following diagram illustrates the components of the front panel of the 5520-12MW-36W switch. Slot 1 is used for the 48 copper ports and the two QSFP28/QSFP+ ports, and slot 2 is used for Versatile Interface Module (VIM) ports, if a VIM is installed in the VIM slot.

**Figure 280: 5520-12MW-36W**

1. 36 10/100/1000BASE-T FDX/HDX 802.3bt Type 4 PoE MACsec-capable ports
2. 1 USB A port
3. 1 USB micro B management port
4. 2 Universal Ethernet QSFP28 ports
5. VIM slot (shown with VIM covered). Port numbering depends on the type of VIM installed in the slot.
6. 12 100 Mbps/1 Gbps/2.5 Gbps/5 Gbps 802.3bt Type 4 PoE MACsec-capable ports

The back panel (not shown) includes an RJ-45 out of band (OOB) management port, an RJ-45 console port, a USB A port, locator LED, two PSU slots, and hot-swappable fan units.

#### 5520-24X

The following diagram illustrates the components of the front panel of the 5520-24X switch. Slot 1 is used for the 24 SFP+ ports and the two QSFP28/QSFP+ ports, and slot 2 is used for Versatile Interface Module (VIM) ports, if a VIM is installed in the VIM slot.

**Figure 281: 5520-24X**

1. 24 100/1000BASE-X/10GBASE-X SFP+ ports
2. 1 USB A port
3. 1 USB micro B management port
4. 2 Universal Ethernet QSFP28 ports
5. VIM slot (shown with VIM covered). Port numbering depends on the type of VIM installed in the slot.

The back panel (not shown) includes an RJ-45 out of band (OOB) management port, an RJ-45 console port, a USB A port, locator LED, two PSU slots, and hot-swappable fan units.

#### 5520-48SE

The following diagram illustrates the components of the front panel of the 5520-48SE switch. Slot 1 is used for the 48 SFP ports and the two QSFP28/QSFP+ ports, and slot 2 is used for Versatile Interface Module (VIM) ports, if a VIM is installed in the VIM slot.

**Figure 282: 5520-48SE**

1. 48 100/1000BASE-X MACsec-capable SFP ports
2. 1 USB A port
3. 1 USB micro B management port
4. 2 Universal Ethernet QSFP28 ports
5. VIM slot (shown with VIM covered). Port numbering depends on the type of VIM installed in the slot.

The back panel (not shown) includes an RJ-45 out of band (OOB) management port, an RJ-45 console port, a USB A port, locator LED, two PSU slots, and hot-swappable fan units.

## Interface Indexes

The Simple Network Management Protocol (SNMP) uses interface indexes to identify ports, Virtual Local Area Networks (VLAN), and Multilink Trunking (MLT).

## Port Interface Index

To determine the interface index (IfIndex), you can calculate it, or use the CLI command provided in this section.

As a result of channelization support, the IfIndex of each channelization-capable port increases by 4. The number is reserved for the 3 sub-ports when channelization is enabled.

### 5320 Series, 5420 Series, and 5520 Series

For switches that include channelization-capable ports, use the following equations to determine the IfIndex of a port:

- If the port does not support channelization, use  $(64 \times \text{slot number}) + 128 + (\text{port number} - 1)$ .
- If the port supports channelization, use the following equations:
  - for the port in question:  $(64 \times \text{slot number}) + 128$
  - for subsequent ports:  $(64 \times \text{slot number}) + 128 + ((\text{port number} - 1) * 4)$

This equation reserves space for the creation of the 3 sub-ports on the previous port, if or when you enable channelization.

The slot number is 1 for the 5320 Series.

The slot numbers are 1-2 for the 5420 Series.

The slot numbers are 1-2 for the 5520 Series.

### CLI command

To determine the port interface index through the CLI, use the following command:

```
show interfaces gigabitEthernet
```

The following example shows output for this command:

```
Switch:1(config)#show interfaces gigabitEthernet

```

## VLAN interface index

The interface index of a VLAN is computed using the following formula:

Because the default VLAN always uses an MGID value of 1, its interface index is always 2049.

$$\text{ifIndex} = 2048 + \text{VLAN multicast group ID (MGID)}$$

## MLT interface index

The interface index of a multilink trunk (MLT) is computed using the following formula:

$$\text{ifIndex} = 6143 + \text{MLT ID number}$$

## MAC Address Assignment

You must understand MAC addresses assignment if you perform one of the following actions:

- Define static Address Resolution Protocol (ARP) entries for IP addresses in the switch
- Use a network analyzer to decode network traffic

Each chassis is assigned a base number of MAC addresses with a number reserved for ports and other internal purposes, and the remainder assigned to routable VLANs. The following table identifies the numbers provided by product.

| Product     | Base assignment | Reserved  | Assigned to routable VLANs |
|-------------|-----------------|-----------|----------------------------|
| 5320 Series | 1,024           | First 256 | remaining 768              |
| 5420 Series | 1,024           | First 256 | remaining 768              |
| 5520 Series | 1,024           | First 256 | remaining 768              |

## Virtual MAC Addresses

Virtual MAC addresses are the addresses assigned to VLANs. The system assigns a virtual MAC address to a VLAN when it creates the VLAN. The MAC address for a VLAN IP address is the virtual MAC address assigned to the VLAN.

| 802.3x                                            | Full Duplex & Flow Control                                                                                                                                 |
| 802.3z                                            | 1000 Mbps Operation, implemented as 1000BASE-X SFP                                                                                                         |
| ANSI/TIA-1057                                     | LLDP-MED                                                                                                                                                   |

## Supported RFCs

The following table and sections list the RFCs that the switch supports.

**Table 272: Supported request for comments**

| Request for comment       | Description                                                            |
|---------------------------|------------------------------------------------------------------------|
| draft-grant-tacacs-02.txt | TACACS+ Protocol                                                       |
| RFC 768                   | UDP Protocol                                                           |
| RFC 783                   | Trivial File Transfer Protocol (TFTP)                                  |
| RFC 791                   | Internet Protocol (IP)                                                 |
| RFC 792                   | Internet Control Message Protocol (ICMP)                               |
| RFC 793                   | Transmission Control Protocol (TCP)                                    |
| RFC 815                   | IP Datagram Reassembly Algorithm                                       |
| RFC 826                   | Address Resolution Protocol (ARP)                                      |
| RFC 854                   | Telnet protocol                                                        |
| RFC 894                   | A standard for the Transmission of IP Datagrams over Ethernet Networks |
| RFC 896                   | Congestion control in IP/TCP internetworks                             |
| RFC 906                   | Bootstrap loading using TFTP                                           |
| RFC 950                   | Internet Standard Subnetting Procedure                                 |

**Table 272: Supported request for comments (continued)**

| Request for comment                                                                     | Description                                                                                                                                        |
|-----------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|

| RFC1930             | Guidelines for creation, selection, and registration of an Autonomous System (AS)            |
| RFC2428             | FTP Extensions for IPv6                                                                      |
| RFC2541             | DNS Security Operational Considerations                                                      |
| RFC2572             | Message Processing and Dispatching for the Simple Network Management Protocol (SNMP)         |
| RFC2573             | SNMP Applications                                                                            |
| RFC2574             | User-based Security Model (USM) for v3 of the Simple Network Management Protocol (SNMPv3)    |
| RFC2575             | View-based Access Control Model (VACM) for the Simple Network Management Protocol (SNMP)     |
| RFC2576             | Coexistence between v1, v2, & v3 of the Internet standard Network Management Framework       |
| RFC2616             | IPv6 HTTP server                                                                             |
| RFC2819             | Remote Network Monitoring Management Information Base                                        |
| RFC 3411            | Architecture for describing SNMP Management Frameworks                                       |
| RFC4292             | IP Forwarding Table MIB                                                                      |

## MIBs

**Table 275: Supported request for comments**

| Request for comment | Description                                                                                          |
|---------------------|------------------------------------------------------------------------------------------------------|
| RFC1156             | MIB for network management of TCP/IP                                                                 |
| RFC1212             | Concise MIB definitions                                                                              |
| RFC1213             | TCP/IP Management Information Base                                                                   |
| RFC1398             | Ethernet MIB                                                                                         |
| RFC1442             | Structure of Management Information for version 2 of the Simple Network Management Protocol (SNMPv2) |
| RFC1450             | Management Information Base for v2 of the Simple Network Management Protocol (SNMPv2)                |
| RFC1573             | Interface MIB                                                                                        |

**Table 275: Supported request for comments (continued)**

| Request for comment | Description                                                                     |
|---------------------|---------------------------------------------------------------------------------|
| RFC1650             | Definitions of Managed Objects for the Ethernet-like Interface Types            |
| RFC1657             | BGP-4 MIB using SMIv2                                                           |
| RFC2021             | RMON MIB using SMIv2                                                            |
| RFC2452             | IPv6 MIB: TCP MIB                                                               |
| RFC2454             | IPv6 MIB: UDP MIB                                                               |
| RFC2466             | IPv6 MIB: ICMPv6 Group                                                          |
| RFC2578             | Structure of Management Information v2 (SMIv2)                                  |
| RFC2787             | Definitions of Managed Objects for the Virtual Router Redundancy Protocol       |
| RFC2863             | Interface Group MIB                                                             |
| RFC2925             | Remote Ping, Traceroute & Lookup Operations MIB                                 |
| RFC3416             | v2 of the Protocol Operations for the Simple Network Management Protocol (SNMP) |
| RFC4022             | Management Information Base for the Transmission Control Protocol (TCP)         |
| RFC4113             | Management Information Base for the User Datagram Protocol (UDP)                |
| RFC4292             | IP Forwarding Table MIB                                                         |
| RFC4363             | Bridges with Traffic MIB                                                        |
| RFC4673             | RADIUS Dynamic Authorization Server MIB                                         |

## Standard MIBs

The following table details the standard MIBs that the switch supports.

**Table 276: Supported MIBs**

| Standard MIB name                                                                   | Institute of Electrical and Electronics Engineers/Request for Comments (IEEE/RFC) | File name        |
|-------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|------------------|
| STDMIB2— Link Aggregation Control Protocol (LACP) (802.3ad)                         | 802.3ad                                                                           | ieee802-lag.mib  |
| STDMIB3—Exensible Authentication Protocol Over Local Area Networks (EAPoL) (802.1x) | 802.1x                                                                            | ieee8021x.mib    |
| STDMIB4—Internet Assigned Numbers Authority (IANA) Interface Type                   | —                                                                                 | iana_if_type.mib |

**Table 276: Supported MIBs (continued)**

| Standard MIB name                                                                                                        | Institute of Electrical and Electronics Engineers/Request for Comments (IEEE/RFC) | File name   |
|--------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|-------------|
| STD MIB5—Structure of Management Information (SMI)                                                                       | RFC1155                                                                           | rfc1155.mib |
| STD MIB6—Simple Network Management Protocol (SNMP)                                                                       | RFC1157                                                                           | rfc1157.mib |
| STD MIB7—MIB for network management of Transfer Control Protocol/Internet Protocol (TCP/IP) based Internet MIB2          | RFC1213                                                                           | rfc1213.mib |
| STD MIB8—A convention for defining traps for use with SNMP                                                               | RFC1215                                                                           | rfc1215.mib |
| STD MIB10—Definitions of Managed Objects for Bridges                                                                     | RFC1493                                                                           | rfc1493.mib |
| STD MIB11—Evolution of the Interface Groups for MIB2                                                                     | RFC2863                                                                           | rfc2863.mib |
| STD MIB12—Definitions of Managed Objects for the Ethernet-like Interface Types                                           | RFC1643                                                                           | rfc1643.mib |
| STD MIB15—Remote Network Monitoring (RMON)                                                                               | RFC2819                                                                           | rfc2819.mib |
| STD MIB17—Management Information Base of the Simple Network Management Protocol version 2 (SNMPv2)                       | RFC1907                                                                           | rfc1907.mib |
| STD MIB21—Interfaces Group MIB using SMIv2                                                                               | RFC2233                                                                           | rfc2233.mib |
| STD MIB26b—Message Processing and Dispatching for the SNMP                                                               | RFC2572                                                                           | rfc2572.mib |
| STD MIB26c—SNMP Applications                                                                                             | RFC2573                                                                           | rfc2573.mib |
| STD MIB26d—User-based Security Model (USM) for version 3 of the SNMP                                                     | RFC2574                                                                           | rfc2574.mib |
| STD MIB26e—View-based Access Control Model (VACM) for the SNMP                                                           | RFC2575                                                                           | rfc2575.mib |
| STD MIB26f—Coexistence between Version 1, Version 2, and Version 3 of the Internet-standard Network Management Framework | RFC2576                                                                           | rfc2576.mib |
| STD MIB29—Definitions of Managed Objects for the Virtual Router Redundancy Protocol                                      | RFC2787                                                                           | rfc2787.mib |

**Table 276: Supported MIBs (continued)**

| Standard MIB name                                                                                      | Institute of Electrical and Electronics Engineers/Request for Comments (IEEE/RFC) | File name                                          |
|--------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|----------------------------------------------------|
| STDMIB31—Textual Conventions for Internet Network Addresses                                            | RFC2851                                                                           | rfc2851.mib                                        |
| STDMIB32—The Interface Group MIB                                                                       | RFC2863                                                                           | rfc2863.mib                                        |
| STDMIB33—Definitions of Managed Objects for Remote Ping, Traceroute, and Lookup Operations             | RFC2925                                                                           | rfc2925.mib                                        |
| STDMIB35—Internet Group Management Protocol MIB                                                        | RFC2933                                                                           | rfc2933.mib                                        |
| STDMIB36—Protocol Independent Multicast MIB for IPv4                                                   | RFC2934                                                                           | rfc2934.mib                                        |
| STDMIB38—SNMPv3 These Request For Comments (RFC) make some previously named RFCs obsolete              | RFC3411, RFC3412, RFC3413, RFC3414, RFC3415                                       | rfc2572.mib, rfc2573.mib, rfc2574.mib, rfc2575.mib |
| STDMIB39—Entity Sensor Management Information Base                                                     | RFC3433                                                                           |                                                    |
| STDMIB40—The Advanced Encryption Standard (AES) Cipher Algorithm in the SNMP User-based Security Model | RFC3826                                                                           | rfc3826.mib                                        |
| STDMIB41—Management Information Base for the Transmission Control protocol (TCP)                       | RFC4022                                                                           | rfc4022.mib                                        |
| STDMIB43—Management Information Base for the User Datagram Protocol (UDP)                              | RFC4113                                                                           | rfc4113.mib                                        |
| Q-BRIDGE-MIB —Management Information Base for managing Virtual Bridged LANs                            | RFC4363                                                                           | q-bridge.mib                                       |
| LLDP-EXT-MED-MIB — LLDP-MED                                                                            | ANSI/TIA-1057                                                                     | lldpExtMed.mib                                     |

## Proprietary MIBs

The following table details the proprietary MIBs that the switch supports.

**Table 277: Proprietary MIBs**

| Proprietary MIB name                                                                                                                         | File name                     |
|----------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------|
| Extreme Networks Energy Saver MIB                                                                                                            | bayStackNes.mib               |
| Extreme Networks Link-state tracking (LST) MIB                                                                                               | bayStackLinkStateTracking.mib |
| Extreme Networks IGMP MIB                                                                                                                    | rfc_igmp.mib                  |
| Extreme Networks IP Multicast MIB                                                                                                            | ipmroute_rcc.mib              |
| Extreme Networks MIB definitions                                                                                                             | wf_com.mib                    |
| Extreme Networks PIM MIB                                                                                                                     | pim-rcc.mib                   |
| Extreme Networks RSTP/MSTP proprietary MIBs                                                                                                  | nnrst000.mib, nnmst000.mib    |
| Extreme Networks SLA Monitor Agent MIB                                                                                                       | slamon.mib                    |
| Other SynOptics definitions                                                                                                                  | s5114roo.mib                  |
| Other SynOptics definitions                                                                                                                  | s5emt103.mib                  |
| Other SynOptics definitions                                                                                                                  | s5tcs112.mib                  |
| Other SynOptics definition for Combo Ports                                                                                                   | s5ifx.mib                     |
| Other SynOptics definition for PoE                                                                                                           | bayStackPethExt.mib           |
| Rapid City MIB<br><br><b>Note:</b><br>The MACsec tables, namely, rcMACSecCAtable and rcMACSecIfConfigTable are a part of the Rapid City MIB. | rapid_city.mib                |
| SynOptics Root MIB                                                                                                                           | synro.mib                     |

## ICMPv6 Type and Code

The Internet Control Message Protocol (ICMPv6) uses many messages identified by a type and code field (see RFC 4443). Error messages use message types 0 to 127. Informational messages use message types 128 to 255. The following table provides the type and code reference.

**Table 278: ICMPv6 type and code details**

| Type | Name                      | Code                                                                                                                                                         | Reference |
|------|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| 1    | Destination Unreachable   | 0—no route to destination<br>1—communication with destination administratively prohibited<br>2—(not assigned)<br>3—address unreachable<br>4—port unreachable | RFC 4443  |
| 2    | Packet Too Big            | N/A                                                                                                                                                          | RFC 4443  |
| 3    | Time Exceeded             | 0—hop limit exceeded in transit<br>1—fragment reassembly time exceeded                                                                                       | RFC 4443  |
| 4    | Parameter Problem         | 0—erroneous header field encountered<br>1—unrecognized Next Header type encountered<br>2—unrecognized IPv6 option encountered                                | RFC 4443  |
| 128  | Echo Request              | N/A                                                                                                                                                          | RFC 4443  |
| 129  | Echo Reply                | N/A                                                                                                                                                          | RFC 4443  |
| 130  | Multicast Listener Query  | N/A                                                                                                                                                          |           |
| 131  | Multicast Listener Report | N/A                                                                                                                                                          |           |
| 132  | Multicast Listener Done   | N/A                                                                                                                                                          |           |
| 133  | Router Solicitation       | N/A                                                                                                                                                          | RFC 4861  |
| 134  | Router Advertisement      | N/A                                                                                                                                                          | RFC 4861  |
| 135  | Neighbor Solicitation     | N/A                                                                                                                                                          | RFC 4861  |
| 136  | Neighbor Advertisement    | N/A                                                                                                                                                          | RFC 4861  |

**Table 278: ICMPv6 type and code details (continued)**

| Type | Name                                             | Code                                                                                     | Reference |
|------|--------------------------------------------------|------------------------------------------------------------------------------------------|-----------|
| 137  | Redirect Message                                 | N/A                                                                                      | RFC 4861  |
| 138  | Router Renumbering                               | 0—router renumbering command<br>1—router renumbering result<br>255—sequence number reset |           |
| 139  | ICMP Node Information Query                      | N/A                                                                                      |           |
| 140  | ICMP Node Information Response                   | N/A                                                                                      |           |
| 141  | Inverse neighbor discovery Solicitation Message  | N/A                                                                                      | RFC 3122  |
| 142  | Inverse neighbor discovery Advertisement Message | N/A                                                                                      | RFC 3122  |
| 143  | Version 2 Multicast Listener Report              | N/A                                                                                      | RFC 3810  |
| 144  | Home Agent Address Discovery Request Message     | N/A                                                                                      | RFC 3775  |
| 145  | Home Agent Address Discovery Reply Message       | N/A                                                                                      | RFC 3775  |
| 146  | Mobile Prefix Solicitation                       | N/A                                                                                      | RFC 3775  |
| 147  | Mobile Prefix Advertisement                      | N/A                                                                                      | RFC 3775  |
