Fabric Engine User Guide

For Fabric Engine Release 8.7

9037374-00 Rev AB
August 2022

Legal Notice

Extreme Networks, Inc. reserves the right to make changes in specifications and other information contained in this document and its website without prior notice. The reader should in all cases consult representatives of Extreme Networks to determine whether any such changes have been made.

The hardware, firmware, software or any specifications described or referred to in this document are subject to change without notice.

Trademarks

Extreme Networks and the Extreme Networks logo are trademarks or registered trademarks of Extreme Networks, Inc. in the United States and/or other countries.

All other names (including any product names) mentioned in this document are the property of their respective owners and may be trademarks or registered trademarks of their respective companies/owners.

For additional information on Extreme Networks trademarks, see: www.extremenetworks.com/company/legal/trademarks

Open Source Declarations

Some software files have been licensed under certain open source or third-party licenses. End-user license agreements and open source declarations can be found at: https://www.extremenetworks.com/support/policies/open-source-declaration/

About this Document

The topics in this section discuss the purpose of this document, the conventions used, ways to provide feedback, additional help, and information regarding other Extreme Networks publications.

Purpose

This document provides information on features in Extreme Networks Fabric Engine™. Fabric Engine runs on the following product families:

- ExtremeSwitching 5320 Series
- ExtremeSwitching 5420 Series
- ExtremeSwitching 5520 Series
- ExtremeSwitching 5720 Series

Note

Prior to Fabric Engine 8.6, 5520 Series and 5420 Series platforms ran VOSS. VOSS support ends for these platforms with VOSS 8.5.x.

Conventions

To help you better understand the information presented in this guide, the following topics describe the formatting conventions used for notes, text, and other elements.

Text Conventions

The following tables list text conventions that can be used throughout this document.

Table 1: Notes and warnings

Icon	Notice type	Alerts you to...
	Tip	Helpful tips and notices for using the product.
	Note	Useful information or instructions.
	Important	Important features or instructions.
	Caution	Risk of personal injury, system damage, or loss of data.
	Warning	Risk of severe personal injury.

Documentation and Training

Find Extreme Networks product information at the following locations:

Current Product Documentation

Release Notes

Hardware and software compatibility for Extreme Networks products

Extreme Optics Compatibility

Other resources such as white papers, data sheets, and case studies

Extreme Networks offers product training courses, both online and in person, as well as specialized certifications. For details, visit www.extremenetworks.com/education/.

Help and Support

If you require assistance, contact Extreme Networks using one of the following methods:

Extreme Portal

Search the GTAC (Global Technical Assistance Center) knowledge base; manage support cases and service contracts; download software; and obtain product licensing, training, and certifications.

The Hub

A forum for Extreme Networks customers to connect with one another, answer questions, and share ideas and feedback. This community is monitored by Extreme Networks employees, but is not intended to replace specific guidance from GTAC.

Call GTAC

For immediate support: (800) 998 2408 (toll-free in U.S. and Canada) or 1 (408) 579 2826. For the support phone number in your country, visit: www.extremenetworks.com/support/contact

Before contacting Extreme Networks for technical support, have the following information ready:

- Your Extreme Networks service contract number, or serial numbers for all involved Extreme Networks products
- A description of the failure
- A description of any actions already taken to resolve the problem
- A description of your network environment (such as layout, cable type, other relevant environmental information)
- Network load at the time of trouble (if known)
- The device history (for example, if you have returned the device before, or if this is a recurring problem)
- Any related RMA (Return Material Authorization) numbers

Subscribe to Product Announcements

You can subscribe to email notifications for product and software release announcements, Field Notices, and Vulnerability Notices.

1. Go to The Hub.
2. In the list of categories, expand the **Product Announcements** list.
3. Select a product for which you would like to receive notifications.
4. Select **Subscribe**.
5. To select additional products, return to the **Product Announcements** list and repeat steps 3 and 4.

You can modify your product selections or unsubscribe at any time.

Send Feedback

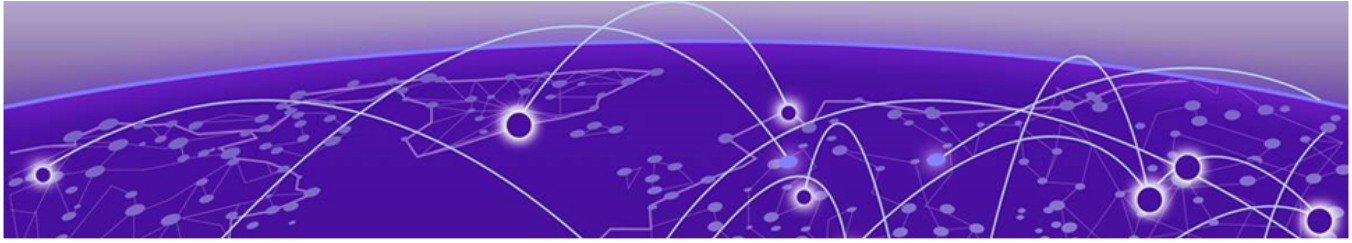
The Information Development team at Extreme Networks has made every effort to ensure that this document is accurate, complete, and easy to use. We strive to improve our documentation to help you in your work, so we want to hear from you. We welcome all feedback, but we especially want to know about:

- Content errors, or confusing or conflicting information.
- Improvements that would help you find relevant information.
- Broken links or usability issues.

To send feedback, do either of the following:

- Access the feedback form at https://www.extremenetworks.com/documentation-feedback/.
- Email us at documentation@extremenetworks.com.

Provide the publication title, part number, and as much detail as possible, including the topic heading and page number if applicable, as well as your suggestions for improvement.



New in this Document

Notice about Feature Support on page 9

The following sections detail what is new in this document.

5720 Series

ExtremeSwitching 5720 Series is a family of high-performance, feature-rich edge and aggregation switches designed for the next generation digital enterprise. As a universal hardware platform, the 5720 Series provides end-to-end secure network segmentation, in addition to advanced policy capabilities, and offers a user-selectable choice of Extreme's flagship switch operating systems.

Fabric Engine 8.7 supports the following new switching models:

5720-24MW

- 24 100M/1/2.5/5GbaseT full-duplex (FDX), MACsec-capable ports with 802.3bt PoE (90W)

5720-48MW

- 48 100M/1/2.5/5GbaseT full-duplex (FDX), MACsec-capable ports with 802.3bt PoE (90W)

5720-24MXW

- 24 100M/1/2.5/5/10GbaseT full-duplex (FDX), MACsec-capable ports with 802.3bt PoE (90W)

5720-48MXW

- 48 100M/1/2.5/5/10GbaseT full-duplex (FDX), MACsec-capable ports with 802.3bt PoE (90W)

In addition to the fixed ports, all models provide two QSFP28 Universal Ethernet ports, console interface ports (one micro Type B USB and one RJ-45), one RJ 45 out-of-band (OOB) management port (10/100/1000), two USB Type A ports for removable storage, one VIM slot, and hot-swappable, redundant power supplies and fan units.

Each model provides one Versatile Interface Module (VIM) slot. You can install any one of the following VIMs in the VIM slot to provide flexible linkage to other switches or devices over a range of media:

- 5720-VIM-2CE: Two 100-GbE (QSFP28) MACsec-capable ports.
- 5720-VIM-6YE: Six 25-GbE (SFP28) MACsec-capable ports.

For optics compatibility, see the Extreme Optics website.

For high-level feature support information, see *Fabric Engine Feature Support Matrix*.

IPv4 ACL Architecture Enhancements

This release introduces a change to the ACL architecture for Fabric Engine switches.

In earlier releases, ACL ACE rules were defined as:

- Security: ACE ID range 1-1000
- QoS: ACE ID range 1001-2000

Security ACEs were used to perform permit or deny actions on a match. QoS ACEs were used to perform remarking actions on a match. The switch performed a parallel search on both Security and QoS ACE lists, which resulted in distinct and non-conflicting actions.

Now, ACL ACE rules can be defined as:

- Primary Bank: ACE ID range 1-1000
- Secondary Bank: ACE ID range 1001-2000

You can use both Primary and Secondary Banks for Security and QoS ACEs. The switch performs a parallel search on both ACE lists. If actions do not conflict, both actions apply. If actions conflict, the action from the Primary Bank has precedence.

Note

As a best practice, apply deny actions to Primary Bank ACEs in configurations where ACEs in Primary and Secondary Banks with deny and permit actions applied can match the same flow.

For more information, see Traffic Filtering on page 3063.

Extreme Integrated Application Hosting

This release introduces Extreme Integrated Application Hosting support for 5720-24MXW and 5720-48MXW, providing high-performance and flexible visibility applications using dedicated resources.

For more information, see Extreme Integrated Application Hosting on page 770.

In this release, the Third Party Virtual Machine (TPVM) version is based on Ubuntu 20.04.04 TLS.

Increase the Number of SPB Nodes per Area using EDM

This release introduces EDM support to modify the spbm-node scaling boot config flag. This is only applicable to, and supported on, 5320 Series and 5420 Series.

For more information, see Configure Boot Flags on page 542.

OSPFv2 Point-to-Point Interfaces

You can now configure OSPFv2 point-to-point network interface type, which provides a single connection between two specific points or OSPF routers. In earlier releases, you could only configure broadcast, non-broadcast multiple access, and passive OSPFv2 network interface types.

For more information, see the following sections:

- OSPF Interfaces on page 2178
- Configure an OSPF area on a VLAN or port on page 2211
- Configure OSPF for a Port or VLAN on page 2200
- Configure OSPF on a Port on page 2272
- Configure OSPF on a VLAN on page 2277

Reauthentication on Ports through RADIUS

Prior to this release, you could only enable reauthentication on ports manually through CLI. Now you can enable reauthentication dynamically through RADIUS VSA Extreme-Dynamic-Config. To identify the origin of configuration, the origin displays as either CONFIG or RADIUS.

For more information, see Extreme-Dynamic-Config on page 2482.

Support for Concurrent 4-Port and 8-Port 10 Gbps Licenses on 5320 Series

Prior to this release, you could not apply two 10 Gbps Port Licenses to the same switch nor could you move to an 8-port license without revoking the 4-port license first, which caused the SFP+ ports on the switch to revert to operating at 1 Gbps. You can now apply a 4-port and an 8-port 10 Gbps Port License to the switch concurrently. You can also move from one license to another license without a loss in connectivity.

In this release, you can use Enterprise Device Manager (EDM) to revoke either the 4-port 10 Gbps or the 8-port 10 Gbps port license.

For more information, see the following sections:

- Feature Licensing for Universal Hardware on page 1891
- Revoke a License on page 1900

Support for Microsoft Internet Explorer is Removed

In this release, support for Microsoft Internet Explorer to access Enterprise Device Manager (EDM) is removed.

For a list of supported browsers, see Supported Browsers on page 232.

Support for VLAN ID 0

Prior to this release, packets tagged with VLAN ID 0 were dropped. This release provides support for processing and forwarding packets with VLAN ID 0.

Third Party Virtual Machine Version

In this release, the Third Party Virtual Machine (TPVM) version is based on Ubuntu 20.04.04 LTS.

View the Fan Speed in RPM

In this release, you can use CLI and EDM to view the current operational speed of the chassis fan in rotations per minute (RPM).

For more information, see the following sections:

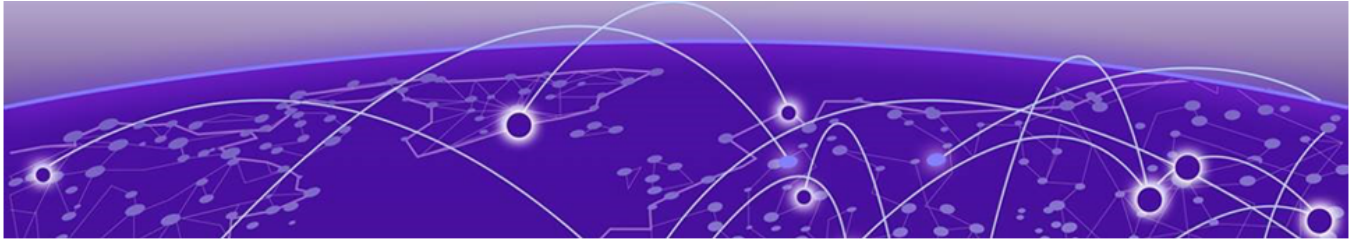
- View Fan Information on page 516 - CLI
- View Fan Information on page 556 - EDM

Notice about Feature Support

This document includes content for multiple hardware platforms across different software releases. As a result, the content can include features not supported by your hardware in the current software release.

If a documented command, parameter, tab, or field does not display on your hardware, it is not supported.

For information about physical hardware restrictions, see your hardware documentation.



Installation and Commissioning Documentation

Use installation and commissioning documentation to install the product hardware and software, and perform the initial configuration.

Table 2: Installation and commissioning documents

Read Me First – Universal Hardware	This document provides important information about how to use ExtremeCloud™ IQ to select a Network Operating System (NOS) personality for universal hardware products.

Zero Touch Capabilities

The switch supports the following zero touch capabilities:

- Auto-sense support for the following features:
  - Fabric Attach (FA)
  - Extensible Authentication Protocol (EAP) and non-EAPoL (NEAP)
  - IP Phones
- Zero Touch Deployment
- Zero Touch Provisioning Plus (ZTP+)
- Zero Touch Fabric Configuration including Auto-sense for network-to-network interface (NNI)

Note

For bridged or routed reachability of the management servers (DHCP, RADIUS, ExtremeCloud IQ - Site Engine, or ExtremeCloud IQ) the onboarding I-SID must be manually mapped to the management segment on at least one Backbone Edge Bridge (BEB) in the network prior to zero touch deployments of new switches. Additionally, you must enable a Dynamic Nickname server on at least one node. For more information, see *Fabric Engine Release Notes*.

Auto-sense

Table 3: Auto-sense product support

Feature	Product	Release introduced
Auto-sense	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.3
	5720 Series	Fabric Engine 8.7
Auto-sense ports can apply Fabric Attach (FA)-specific configuration	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4.2
	5520 Series	VOSS 8.4.2
	5720 Series	Fabric Engine 8.7

Auto-sense is a port-based functionality that supports zero touch capabilities on the switch. Auto-sense dynamically configures the port to act as an IS-IS network-to-network interface (NNI), Fabric UNI (Flex-UNI), Fabric Attach (FA), or voice (IP phone) interface, based on the Link Layer Discovery Protocol (LLDP) events. Auto-sense provides global configuration options for IS-IS authentication, FA authentication, and voice configuration for IP phones, on the switch. For more information about IP Phone Support, see IP Phone Support on page 43.

When a switch boots in Zero Touch Fabric Configuration mode, all ports on the switch automatically operate in Auto-sense mode, unless you manually change the port configuration. For more information on Zero Touch Fabric Configuration, see Zero Touch Fabric Configuration on page 57.

With Auto-sense functionality, ports on a switch can detect whether they connect to a Shortest Path Bridging (SPB) device, an FA client, FA Proxy, Voice IP devices, or an undefined host:

- If a port connects to an SPB device or an FA client, then the system establishes Fabric architecture.
- If a port connects to any undefined host, then the system moves all untagged traffic on the port to an onboarding service network, also known as the onboarding I-SID.
- If a port operates in Auto-sense mode, Extensible Authentication Protocol (EAP) is enabled globally with a RADIUS configuration, and the Auto-sense port does not detect an SPB or Fabric Attach proxy neighbor, then the system automatically activates EAP and Non-EAP (NEAP) authentication on them, for untagged traffic.

When you manually disable Auto-sense on a specific port, the switch removes the dynamic configuration on that port unless you use an optional parameter to convert the dynamic configuration to a manual configuration. If you do not use the optional parameter, the software removes all Auto-sense state configuration and reverts the port to the default configuration.

If you enable Auto-sense on a port with a conflicting feature configuration, the software automatically deletes the conflicting configuration from the port. Conflicting configurations include the following commands or features:

- **`access-diffserv`** command
- **`flex-uni enable`** command
- **`mac-security limit-learning`** command

- **qos 802.1p-override enable** command
- Other feature configurations on the port:
  - brouter port
  - port tagging (encapsulation) - If a port has encapsulation enabled and you enable Auto-sense, the port remains with encapsulation enabled. Disabling Auto-sense transitions the encapsulation value to disabled. If a port has encapsulation disabled and you enable Auto-sense, port encapsulation is enabled.
  - Extensible Authentication Protocol over LAN (EAPoL)
  - FA
  - IS-IS interface
  - Link Aggregation Control Protocol (LACP) and Virtual Link Aggregation Control Protocol (VLACP)
  - LLDP enable
  - LLDP MED network policies
  - private VLAN
  - MLT member
  - Switched UNI (S-UNI) or Transparent Port UNI (T-UNI) interface
  - VLAN member

Implementation on Upgraded Switches with Existing Configuration

If the switch does not boot in Zero Touch Fabric Configuration mode and you want to use Auto-sense functionality with an existing switch configuration, you must:

- Enable Auto-sense on the applicable port or ports.
- Create a new VLAN 4048. If the existing configuration uses VLAN 4048, you must configure a new VLAN for those original purposes.
- Configure I-SID 15999999 as the Auto-sense onboarding I-SID.
- Assign onboarding I-SID 15999999 to private VLAN 4048.

Auto-Sense Data I-SID

Auto-sense supports global configuration of a data I-SID on the switch, which applies to all Auto-sense enabled ports. You can also configure Auto-sense data I-SID on each port to separate the data traffic into individual port specific data I-SIDs. For example, if device A and device B connect to different Auto-sense enabled ports and you configure an Auto-sense data I-SID on each port, the switch separates the data traffic of device A from the data traffic of device B. A port-level data I-SID and the global data I-SID can use the same value. The system prioritizes the I-SIDs in the following order:

1. Untagged I-SID assigned per client by EAP/NEAP MHMV
2. Untagged voice I-SID
3. Port data I-SID
4. Global data I-SID
5. Onboarding I-SID

The **show running-config** output includes the configured Auto-sense data I-SID for the port module only if you enable Auto-sense on the port. If you disable Auto-sense on the port, the

configuration remains on the switch even though the command output does not include it. If you disable Auto-sense on the port and use the **convert-to-config** parameter, the port remains in the I-SID until you manually remove the data I-SID configuration from the port. If you re-enable Auto-sense on the port, you must reconfigure the data I-SID on the port.

If you remove the Auto-sense data I-SID from a port, then the port uses either the global Auto-sense data I-SID, if one exists, or the Auto-sense onboarding I-SID.

IS-IS Authentication

Auto-sense supports global configuration of IS-IS authentication key on the switch. All ports operating in Auto-sense mode and transitioned to the NNI state, use the global IS-IS authentication key that you configure using the **auto-sense isis hello-auth type** command. For more information, see Configure Auto-sense IS-IS Authentication on page 21.

FA Configuration

Depending on the device that the Auto-sense port detects, the software can apply different FA-specific configurations that you define:

- You can configure an I-SID for FA clients such as FA wap-type 1, FA camera, and FA open-virtual-switch (OVS). The software prefers the FA I-SID over the onboarding I-SID.
- You can configure a specific I-SID and customer VLAN ID to use as the management I-SID when the port is in the Auto-sense FA PROXY state. If you do not configure a management I-SID, the port uses the onboarding I-SID for untagged traffic.
- You can disable EAPoL authentication requirements for specific FA client types (wap-type1, camera, and ovs).

FA Authentication

Auto-sense supports FA message authentication on switches. You can enable FA message authentication globally on a switch. All ports operating in Auto-sense mode use the global authentication key. A preconfigured authentication key exists on the switch, by default, which you can change. For more information, see Configure Auto-sense Fabric Attach (FA) Authentication on page 27.

Auto-sense Voice Capabilities

Auto-sense voice capabilities are based on the events when the switch detects an IP phone in the network. For more information, see Auto-sense Voice on page 44.

Loop Prevention

Auto-sense ports between two switches that have transitioned to NNI state are not prone to loops. Any connection can be wired and SPB establishes the shortest path connections. On Auto-sense NNI links BVID information, as well as IS-IS area information, is exchanged enabling Zero Touch Fabric functionality.

Auto-sense ports that connect to non-SPB switches operate in UNI mode, or FA Proxy mode in the case of ERS, EXOS, and Switch Engine switches. In UNI mode, Fabric Engine devices send Spanning Tree BPDU packets emulating root bridge behavior ensuring that any potential UNI loop is broken by the attached spanning tree enabled devices. For universal hardware switches that transition from Switch Engine to Fabric Engine, there can be scenarios where certain links are spanning tree blocked.

For more information on the port states, see Auto-sense Port States on page 15.

Running Configuration

If you view the running configuration, the global Auto-sense configuration displays under the port module. Use the command **`show running-config module port`**.

Auto-sense Port States

The system uses a per-interface state to adapt to all Auto-sense events. Each state transition determines background configuration on the port. The system does not display these configurations in the output of the **`show running-config`** command or in the saved configuration file but if you disable Auto-sense on the port and use the *`convert-to-config`* parameter, the dynamic configuration becomes a manual configuration and is visible in the **`show running-config`** output. Use **`show auto-sense`** commands to monitor the running states of each port.

For flowcharts that describe the system logic for Auto-sense port state detection, see Auto-sense Logical Flowcharts on page 38.

Port Down State

If you run the **`auto-sense enable`** command on a port that is disabled or has an inactive link, the port transitions to the Auto-sense Port Down state. This state transitions to the Auto-sense Wait state after the port becomes operational or the link becomes active.

Wait State

The port modifies outgoing LLDP packets to represent the enhanced properties of the port and analyzes incoming LLDP packets for possible transitions to advanced states like network-to-network interface (NNI), Fabric Attach (FA), or VOICE. If the port does not receive LLDP packets, the port transitions to the UNI state.

UNI State

This state grants onboarding and data connectivity to the port if you configure the onboarding I-SID, or a data I-SID in the global Auto-sense configuration or at the port level. The system also applies the trusted and untrusted Auto-sense global configuration. As with the Wait state, the port continues to monitor received LLDP packets for transitions to other states.

Network Access Control (NAC) support, through EAP/NEAP, is enabled by default on each Auto-sense port, but disabled globally. If you require EAP/NEAP operation on Auto-sense ports, you must globally enable EAP and configure a RADIUS server.

The system performs the following background configurations on port x:

```
flex-uni enable
eapol status auto
eapol multihost radius-non-eap-enable
eapol multihost eap-oper-mode mhmv
[qos 802.1p-override enable]
[access-diffserv enable]
on port X interface, if onboarding I-SID Y is configured without data I-SID:
eapol guest i-sid Y
on onboarding I-SID interface, if it is configured without data I-SID:
untagged-traffic port X
on data I-SID interface, if it is configured:
untagged-traffic port X
```

An Auto-sense port in the UNI state remains in PVLAN isolated mode when any additional untagged I-SID is applied to the port. Auto-sense ports support multiple VLAN/I-SIDs and PVLAN/I-SIDs on the same port at any time concurrently. Typically, this operational mode is required when you configure NAC support with Multiple Host Multiple VLAN (MHMV). The software then assigns clients to their VLAN/I-SIDs based on their NAC authentication results.

NNI States

The NNI states are as follows:

- NNI
- NNI onboarding
- NNI IS-IS
- NNI pending

If, while in the Wait state, the port receives a Fabric Connect LLDP packet, the port transitions to the NNI state and adds the IS-IS SPBM instance on the interface. The system tries to establish an IS-IS adjacency and, if successful, transitions the port to the NNI IS-IS state. The port remains in the NNI IS-IS state until the adjacency fails, at which time it returns to the NNI state.

The system performs the following background configurations on port x:

```
isis
isis spbm 1
isis enable
[isis hello-auth …] inherited from global configuration
```

If the system cannot establish the adjacency, it transitions the port to the NNI onboarding state. The system creates a Switched UNI (S-UNI) with the onboarding I-SID.

The system performs the following background configurations:

```
flex-uni enable
isis
isis spbm 1
isis enable
[isis hello-auth …] inherited from global configuration
on onboarding i-sid interface, if it exists:
untagged-traffic port X
```

Fabric Attach (FA) States

The FA states are as follows:

- FA - this state is used for FA capable wireless access points, Camera or OVS devices
- FA PROXY - this state is used for interaction with ERS, EXOS, and Switch Engine switches, which are capable of FA proxy function
- FA PROXY NOAUTH - this state is used for interaction with ERS, EXOS, and Switch Engine switches, which are capable of FA proxy function

LLDP uses the FA TLV to detect FA-capable neighbors.

The port enters the FA state after LLDP detects an access point, an FA client that is not another switch.

The system performs the following background configurations on port x:

```
flex-uni enable
eapol status auto
eapol multihost radius-non-eap-enable
eapol multihost eap-oper-mode mhmv
eapol guest i-sid X
fa enable
 on onboarding i-sid interface, if it exists:
untagged-traffic port X
```

If LLDP detects an FA proxy switch such as an ERS, EXOS, or Switch Engine switch that uses FA message authentication, the port transitions to the FA PROXY state.

The system performs the following background configurations on port x:

```
flex-uni enable
fa enable
fa message-authentication
fa management-isid
```

Note

By default, the FA PROXY state uses the onboarding I-SID as the management I-SID but you can override this with a specific I-SID and customer VLAN ID combination.

If the FA proxy switch does not use FA message authentication, the port transitions to the FA PROXY NOAUTH state.

The system performs the following background configurations on port x:

```
flex-uni enable
fa enable
on onboarding i-sid interface, if it exists:
untagged-traffic port X
```

Depending on the device that the Auto-sense port detects, the switch can apply different FA-specific configurations that you define. For more information, see Auto-sense on page 12.

When a port is in the FA state, the system uses the following priority for untagged traffic:

1. EAP/NEAP assigned I-SID
2. WAP, camera, or open virtual switch (OVS) I-SID

3. Onboarding I-SID
4. Drop

Voice State

If the port detects an LLDP packet from a phone, the port transitions to the VOICE state. A global Auto-sense voice configuration is not required to transition to the VOICE state except a specific voice VLAN shall be signaled to the phone.

For more information on Auto-sense voice, see Auto-sense Voice on page 44.

DHCP Port Snooping

For zero touch onboarding, if a port answers Dynamic Host Configuration Protocol (DHCP) requests sent by the switch and the port is in the Auto-sense UNI state, the system automatically changes the port's Private VLAN configuration from isolated mode to promiscuous mode.

Without this port type change on the Private VLAN, the other devices in the network cannot receive an IP address through the DHCP server if they are in the Zero Touch Fabric Configuration mode unless you disable Auto-sense on the port and manually change the port from isolated mode to promiscuous mode.

Auto-sense Configuration using CLI

To change the Auto-sense configuration on a port using EDM, see Configure Basic Port Parameters on page 529.

Enable Auto-sense on Port(s)

About This Task

Perform this procedure to manually enable Auto-sense on a specific port.

Note

After a switch boots without a configuration file, Auto-sense is enabled on all ports, by default.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable Auto-sense on the port:

   ```
   auto-sense enable
   ```

Example

Enabling Auto-sense on port 1/2:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#auto-sense enable
 Warning: Enabling Auto-Sense will default port configurations.
```

Disable Auto-sense on Port(s)

About This Task

Perform this procedure to disable Auto-sense on a specific port. You also have the option to disable Auto-sense on the port but retain the configuration that the system applied dynamically.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Disable Auto-sense on the port:

   ```
   no auto-sense enable [convert-to-config]
   ```

Example

Disable Auto-sense on port 1/2 but retain the configuration. The dynamic configuration becomes a manual configuration and is visible in the **show running-config** output and can be saved to the configuration file using the **save config** command.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface interface gigabitEthernet 1/2
Switch:1(config-if)#no auto-sense enable convert-to-config
Switch:1(config-if)#save config
```

Variable Definitions

The following table defines parameters for the **no auto-sense enable** command.

Variable	Value
convert-to-config	Retains the Auto-sense configuration that the system applies dynamically on the specific port. The dynamic configuration becomes a manual configuration and is visible in the **show running-config** output. If you run the "no auto-sense enable" command without the "convert-to-config" option, then the configuration will be removed from the port and the port returns to the default state where VLAN 1 is assigned.

Configure the Auto-sense Wait Interval

About This Task

Perform this task to configure the time, in seconds, for Auto-sense to wait for a Link Layer Discovery Protocol (LLDP) neighbor to be detected in the Auto-sense wait state before transitioning to the Auto-sense onboarding state.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the Auto-sense wait interval:

   ```
   auto-sense wait-interval <10-120>
   ```

3. Verify the Auto-sense wait interval information:

   ```
   show auto-sense wait-interval
   ```

Examples

Configure the Auto-sense wait interval as 50 seconds:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#auto-sense wait-interval 50
```

Verify the Auto-sense wait-interval information:

```
Switch:1>show auto-sense wait-interval
================================================================================
                                AUTO-SENSE GLOBAL Config
================================================================================
WAIT
INTERVAL
--------------------------------------------------------------------------------
50
--------------------------------------------------------------------------------

--------------------------------------------------------------------------------
0 out of 0 Total Num of AUTO-SENSE entries displayed
--------------------------------------------------------------------------------
```

Variable Definitions

The following table defines parameters for the **auto-sense wait-interval** command.

Variable	Value
<10–120>	Specifies the wait interval, in seconds, for Auto-sense ports. The default value is 35.

Configure Auto-sense IS-IS Authentication

Before You Begin

Enable IS-IS globally.

About This Task

Perform this procedure to configure a global IS-IS authentication key for ports that are operating in Auto-sense mode.

Note
If the IS-IS authentication keys on auto-sense ports between two switches do not match, then the auto-sense port state will be auto-sense UNI onboarding, until the keys are matching, then an IS-IS adjacency will be established.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the authentication type for IS-IS hello packets on Auto-sense ports:

   ```
   auto-sense isis hello-auth type {none|simple|hmac-md5|hmac-sha-256}
   [key WORD<1-16>] [key-id <1-255>]
   ```

Example

Configuring simple authentication for IS-IS hello packets on Auto-sense ports:

```
Switch:1>enable
Switch:1#configure terminal
```

```
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#auto-sense isis hello-auth type simple key Secure
```

Variable Definitions

The following table defines parameters for the **auto-sense isis hello-auth type** command.

Variable	Value
{none|simple|hmac-md5|hmac-sha-256}	Specifies the authentication type for IS-IS hello packets on Auto-sense ports: • none • simple - simple password authentication uses a text password in the transmitted packet. The receiving router uses an authentication key (password) to verify the packet. • hmac-md5 - MD5 authentication creates an encoded checksum in the transmitted packet. The receiving router uses an authentication key (password) to verify the MD5 checksum of the packet. • hmac-sha–256 - with SHA-256 authentication, the switch adds an hmac-sha–256 digest to each Hello packet. The switch that receives the Hello packet computes the digest of the packet and compares it with the received digest. Note: Secure Hashing Algorithm 256 bits (SHA-256) is a cipher and a cryptographic hash function of SHA2 authentication. You can use SHA-256 to authenticate ISIS Hello messages. This authentication method uses the SHA-256 hash function and a secret key to establish a secure connection between switches that share the same key. This feature is in full compliance with RFC 5310. The default authentication type is none.
key WORD<1–16>	Specifies the authentication key (password) used by the receiving router to verify the packet.
key-id <1–255>	Specifies the key ID.

Configure Auto-sense Access Ports

About This Task

Perform this procedure to configure ports operating in Auto-sense mode to determine the Layer 3 Quality of Service (QoS) actions the switch performs. The Auto-sense access ports override the Differentiated Services Code Point (DSCP) markings.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure Auto-sense access ports:

   ```
   auto-sense access-diffserv [enable]
   ```

Example

Configure the Auto-sense access ports:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)#auto-sense access-diffserv enable
```

Variable Definitions

The following table defines parameters for the **auto-sense access-diffserv** command.

Variable	Value
enable	Configures the ports operating in Auto-sense mode to determine the Layer 3 Quality of Service (QoS) actions the switch performs. The Auto-sense access ports override the Differentiated Services Code Point (DSCP) markings. The default configuration is enabled.

Disable Auto-sense DHCP Server Detection

About This Task

Perform this procedure to disable Dynamic Host configuration Protocol (DHCP) server detection in Auto-sense mode.

Note
By default Auto-sense DHCP server detection is enabled. This ensures automatic detection of the DHCP uplink ports in Zero Touch Deployment.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Disable DHCP server detection:

   ```
   no auto-sense dhcp-detection
   ```

Example

Enable DHCP server detection:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#no auto-sense dhcp-detection
```

Configure the Auto-sense Onboarding I-SID on the Switch

About This Task

Perform this procedure to configure the onboarding I-SID for ports that are operating in Auto-sense mode. The onboarding I-SID is typically used to onboard networking devices such as switches and non FA capable access points. By default, the onboarding I-SID provides automatic reachability when switches are booted from factory without a configuration file. For security reasons, the onboarding I-SID forms an isolated PVLAN/ETREE to block any unwanted port to port cross talk.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the onboarding I-SID:

   ```
   auto-sense onboarding i-sid <1-15999999>
   ```

Example

Configuring the Auto-sense onboarding I-SID:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#auto-sense onboarding i-sid 15000000
```

Variable Definitions

The following table defines parameters for the **`auto-sense onboarding`** command.

Variable	Value
`i-sid<1-15999999>`	Specifies the service instance identifier (I-SID). The default onboarding I-SID value is 15999999.

Configure a Auto-sense Global Data I-SID

Before You Begin

- Enable Auto-sense on the port.
- Associate a VLAN with the I-SID before you configure it as the global data I-SID.

About This Task

Perform this task to configure Auto-sense data traffic information for ports that are operating in Auto-sense mode.

Note
This option applies to the auto-sense UNI and voice states only, it replaces the onboarding I-SID and places an (untagged) client device into a pre-defined global data I-SID.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the data service instance identifier (I-SID):

   ```
   auto-sense data i-sid <1-15999999>
   ```

Example

Configuring the Auto-sense data I-SID:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#auto-sense data i-sid 1000
```

Variable Definitions

The following table defines parameters for the **auto-sense data** command.

Variable	Value
i-sid <1-15999999>	Specifies the service instance identifier (I-SID).

Configure an Auto-sense Port Data I-SID

Before You Begin

- Enable Auto-sense on the port.
- Associate a VLAN with the I-SID before you configure it as the data I-SID on the port. This does not apply to a DvR leaf.

About This Task

Perform this procedure to configure a data I-SID on a port.

Note

This option applies to the Auto-sense UNI and voice states only, it replaces the onboarding I-SID and places an (untagged) client device into a pre-defined port specific data I-SID.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the Auto-sense port data I-SID:

   ```
   auto-sense data i-sid <1-15999999>
   ```

Example

Configuring the Auto-sense data I-SID for ports 1/1 to 1/5:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/1-1/5
Switch:1(config-if)#auto-sense data i-sid 15000000
```

Variable Definitions

The following table defines parameters for the **auto-sense data** command.

Variable	Value
i-sid <1-15999999>	Specifies the service instance identifier (I-SID).

Configure Layer 2 Trusted Auto-sense Ports

About This Task

Perform this procedure to override incoming 802.1p bits on ports that operate in Auto-sense UNI or voice mode.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure Auto-sense ports as Layer 2 untrusted:

   ```
   auto-sense qos 802.1p-override
   ```

Example

Configure Auto-sense ports as Layer 2 trusted:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#auto-sense qos 802.1p-override
```

Configure EAPoL Authentication Requirements for Auto-sense Fabric Attach Clients

You can disable EAPoL authentication for specific Fabric Attach (FA) client types.

About This Task

By default, authentication is required before the connection is authorized.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure EAPoL authentication requirements from the following choices:
   - For auto-sensed cameras: `auto-sense fa camera eapol status {authorized | auto}`
   - For auto-sensed virtual switches: `auto-sense fa ovs eapol status {authorized | auto}`
   - For auto-sensed wireless access points (WAP): `auto-sense fa wap-type1 eapol status {authorized | auto}`

Variable Definitions

The following table defines parameters for the **`auto-sense`** commands related to EAPoL authentication for Fabric Attach (FA).

Variable	Value
`{authorized | auto}`	Configures the EAPoL authentication requirement for the specific client type. Choose from the following options: • *`authorized`* — the port skips EAPoL authentication and authorizes the connection. • *`auto`* — authorization depends on the result of EAPoL authentication. By default, authentication is required before the connection is authorized.

Configure Auto-sense Fabric Attach (FA) Authentication

About This Task

Perform this procedure to configure FA authentication for ports that are operating in Auto-sense mode.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the FA authentication key:

   ```
   auto-sense fa authentication-key WORD<0-32>
   ```

3. Enable FA message authentication:

   ```
   auto-sense fa message-authentication
   ```

Example

Configuring FA message authentication globally:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#auto-sense fa message-authentication
```

Variable Definitions

The following table defines parameters for the **`auto-sense fa`** command.

Variable	Value
`authentication-key WORD<0-32>`	Specifies the authentication key value.
`message-authentication`	Enables Fabric Attach (FA) message authentication globally, for ports that operate in Auto-sense mode.

Configure an I-SID for Auto-sense Fabric Attach Clients

For Zero Touch Deployment and assignments of dedicated I-SIDs for FA capable cameras, Wireless Access Points, FA proxy switches and Open Virtual Switches (OVS), configure a specific I-SID to use instead of the onboarding I-SID when a port is in an Auto-sense Fabric Attach (FA) state and detects an FA client.

Before You Begin

- Create the I-SID.
- Associate the I-SID with either a platform or private VLAN; this association is not required on a DvR Leaf.

About This Task

You can create only one I-SID of each type.

The FA I-SID can be the same as the voice I-SID because they are used by different Auto-sense port states.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the FA I-SID from the following choices:
   - For auto-sensed cameras: `auto-sense fa camera i-sid <1-15999999>`
   - For auto-sensed FA client switches that do not use FA message authentication, like EXOS or Switch Engine: `auto-sense fa proxy-no-auth i-sid <1-15999999>`
   - For auto-sensed virtual switches: `auto-sense fa ovs i-sid <1-15999999>`
   - For auto-sensed wireless access points (WAP): `auto-sense fa wap-type1 i-sid <1-15999999>`

Variable Definitions

The following table defines parameters for the **`auto-sense`** commands related to Fabric Attach (FA) I-SIDs.

Variable	Value
`i-sid <1-15999999>`	Specifies the service instance identifier (I-SID).

Configure a Management I-SID for Auto-sense Fabric Attach Proxy Switches

Configure a specific I-SID and customer VLAN ID to use as the management I-SID when a port is in the Auto-sense FA PROXY state.

About This Task

The switch creates this I-SID dynamically and uses it instead of the onboarding I-SID.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the management I-SID:

   ```
   auto-sense fa proxy management i-sid <1-15999999> c-vid <1-4094>
   ```

Variable Definitions

The following table defines parameters for the **`auto-sense fa proxy management`** command.

Variable	Value
`c-vid <1-4094>`	Specifies the customer VLAN ID.
`i-sid <1-15999999>`	Specifies the service instance identifier (I-SID).

Display Auto-sense Configuration on the Switch

About This Task

Perform this procedure to display the Auto-sense configuration on the switch.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the Auto-sense configuration:

   ```
   show auto-sense [access-differv] [data] [dhcp-detection] [eapol] [fa]
   [isis] [onboarding] [qos] [voice] [wait-interval]
   ```

3. Display the Auto-sense status and state on a port:

   ```
   show interfaces gigabitEthernet auto-sense [{slot/port[/sub-port][-
   slot/port[/sub-port]][,...]}]
   ```

Examples

Display the Auto-sense configuration related to voice:

```
Switch:1>show auto-sense voice
================================================================================
                              AUTO-SENSE VOICE Config
================================================================================
TYPE   LDDP-AUTH ENABLE I-SID      C-VID      DSCP       PRIORITY
--------------------------------------------------------------------------------
phone  FALSE            2000       2000       46         6
--------------------------------------------------------------------------------
1 out of 1 Total Num of AUTO-SENSE entries displayed
--------------------------------------------------------------------------------
```

Display the Auto-sense status and state on a range of ports:

```
Switch:1>show interfaces gigabitethernet auto-sense 1/1-1/5
================================================================================
                                Port Auto-sense
================================================================================
--------------------------------------------------------------------------------
PORT     AUTO-SENSE   AUTO-SENSE            AUTO-SENSE
NUM      STATUS       STATE                 PORT-DATA-ISID
--------------------------------------------------------------------------------
1/1      Enable       UNI-ONBOARDING        500
1/2      Disable      OFF
1/3      Disable      OFF
1/4      Disable      OFF
1/5      Disable      OFF
```

Display the Auto-sense status for Fabric Attach (FA):

```
Switch:1>show auto-sense fa
================================================================================
                                  AUTO-SENSE FA Config
================================================================================
MSG-AUTH                      MSG-AUTH-KEY
--------------------------------------------------------------------------------
enabled                       ****
--------------------------------------------------------------------------------

================================================================================
                           AUTO-SENSE FA Client specific config
```

```
================================================================================
TYPE                EAPOL STATUS    I-SID   VLANID  C-VID  MGMT I-SID MGMT C-VID

```

Auto-sense Configuration using EDM

The following sections provide procedural information to configure Auto-sense on the switch using Enterprise Device Manager (EDM). Auto-sense configuration can include both global- and port-level configuration.

- Auto-sense Global Configuration using EDM on page 31
- Auto-sense Port Configuration using EDM on page 37

Auto-sense Global Configuration using EDM

Perform the procedures in this section to configure Auto-sense globally using Enterprise Device Manager (EDM).

Enable LLDP Authentication of IP Phones

Before You Begin

You must enable EAPoL globally.

About This Task

Perform this procedure to enable Link Layer Discovery Protocol (LLDP) authentication of IP phones. The switch authenticates the phone after it receives LLDP packets from the phone.

Auto-sense LLDP authentication applies to Auto-sense ports in the VOICE state. Auto-sense LLDP authentication does not require a global Auto-sense voice configuration.

The system removes the LLDP session for the following reasons:

- You disable EAPoL globally.

- You disable Auto-sense on the port.
- The LLDP neighbor is removed.

If the LLDP authentication configuration exists and one of the following situations occur, the LLDP session is recreated:

- You renable EAPoL globally.
- You renable Auto-sense on the port.
- The LLDP neighbor is recreated.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **AutoSense**.
3. Select the **Globals** tab.
4. Select **EapolVoiceLldpAuthEnable**, to enable the EAPoL LLDP authorization for voice Auto-sense ports.
5. Select **Apply**.

Configure Auto-sense Voice Information for IP Phones

The switch applies the Auto-sense voice configuration on specific port(s), after it discovers IP phones on the port through LLDP packets.

Before You Begin

If you boot the switch with a configuration file, and not through Zero Touch Fabric Configuration, you must manually enable Auto-sense on specific port(s).

About This Task

Perform this procedure to configure Auto-sense voice information for IP phones. A global Auto-sense voice configuration does not require LAuto-senseLDP authentication.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **AutoSense**.
3. Select the **Globals** tab.
4. For **VoiceIsid**, type the I-SID value.
5. For **VoiceCvid**, type the CVID value associated with the voice I-SID.
6. Select **Apply**.

Disable Auto-sense DHCP Server Detection

About This Task

Perform this procedure to disable DHCP server detection in Auto-sense mode.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **AutoSense**.

3. Select the **Globals** tab.
4. Select **DhcpDetection** to disable DHCP detection.
5. Select **Apply**.

Configure Auto-sense Onboarding I-SID Globally

About This Task

Perform this procedure to configure the onboarding I-SID for ports that are operating in Auto-sense mode.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **AutoSense**.
3. Select the **Globals** tab.
4. For **OnboardingIsid**, type I-SID value for the Auto-sense ports.
5. Select **Apply**.

Configure Auto-sense Data I-SID Globally

Before You Begin

- Enable Auto-sense on the port.
- Associate a VLAN with the I-SID before you configure it as the global data I-SID.

About This Task

Perform this task to configure Auto-sense data traffic information for ports that are operating in Auto-sense mode.

Note
This option applies to the Auto-sense UNI and voice states only; it replaces the onboarding I-SID and places an (untagged) client device into a pre-defined global data I-SID.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **AutoSense**.
3. Select the **Globals** tab.
4. For **DataIsid**, type the data I-SID value used by the Auto-sense ports.
5. Select **Apply**.

Configure Layer 2 Trusted Auto-sense Ports

About This Task

Perform this procedure to override incoming 802.1p bits on ports that operate in Auto-sense mode.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **AutoSense**.

3. Select the **Globals** tab.
4. Select **Qos8021pOverrideEnable** to override incoming 802.1p bits on ports that operate in Auto-sense mode.
5. Select **Apply**.

Configure Auto-sense IS-IS Authentication

About This Task

Perform this procedure to configure a global IS-IS authentication key for ports that are operating in Auto-sense mode.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **AutoSense**.
3. Select the **Globals** tab.
4. For **IsisHelloAuthType**, select a type of IS-IS hello authentication.
5. For **IsisHelloAuthKeyId**, type the key ID for IS-IS authentication for the Auto-sense ports.
6. For **IsisHelloAuthKey**, type the key for IS-IS authentication for the Auto-sense ports.
7. Select **Apply**.

Configure Auto-sense Access Ports

About This Task

Perform this procedure to configure ports operating in Auto-sense mode to determine the Layer 3 QoS actions the switch performs. The Auto-sense access ports override the Differentiated Services Code Point (DSCP) markings.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **AutoSense**.
3. Select the **Globals** tab.
4. Select **AccessDiffservEnable** to enable differentiated serve type as access for Auto-sense ports.
5. Select **Apply**.

Configure Auto-sense for Fabric Attach

Perform this procedure for the following purposes:

- Configure Fabric Attach (FA) authentication for ports that are operating in Auto-sense mode.
- For Zero Touch Deployment and assignments of dedicated I-SIDs for FA capable cameras, Wireless Access Points, FA proxy switches and Open Virtual Switches (OVS), you can configure a specific I-SID to use instead of the onboarding I-SID when a port is in an Auto-sense Fabric Attach (FA) state and detects an FA client.
- Configure a specific I-SID and customer VLAN ID to use as the management I-SID when a port is in the Auto-sense FA PROXY state.

Before You Begin

- Create the I-SID.

- Associate the I-SID with either a platform or private VLAN; this association is not required on a DvR Leaf.

About This Task

You can create only one I-SID of each type.

The FA I-SID can be the same as the voice I-SID because they are used by different Auto-sense port states.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **AutoSense**.
3. Select the **Globals** tab.
4. Configure Fabric Attach authentication:
   a. Select **FaMsgAuthEnable**, to enable FA message authentication.
   b. For **FaAuthenticationKey**, type the key for FA authentication for the Auto-sense ports.
5. Configure a specific I-SID to use instead of the onboarding I-SID:
   a. For auto-sensed cameras, type the I-SID in **FaCameraIsid**.
   b. For auto-sensed FA client switches that do not use FA message authentication, like EXOS or Switch Engine, type the I-SID in **FaProxyNoAuthIsid**.
   c. For auto-sensed virtual switches, type the I-SID in **FaVirtualSwitchIsid**.
   d. For auto-sensed wireless access points (WAP), type the I-SID in **FaWapType1Isid**.
6. Configure a specific I-SID and customer VLAN ID to use as the management I-SID:
   a. In **FaProxyMgmtIsid**, type the I-SID.
   b. In **FaProxyMgmtCvid**, type the customer VLAN ID.
7. Select **Apply**.

Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
AccessDiffservEnable	Enables or disables the differentiated service type as access for Auto-sense ports. The default is enabled.
DataIsid	Specifies the data I-SID used by the Auto-sense ports.
EapolVoiceLldpAuthEnable	Enables the EAPoL LLDP authentication for Auto-sense voice ports. The default is disabled.
FaMsgAuthEnable	Enables or disables the FA message authentication for Auto-sense ports. The default is enabled.
FaAuthenticationKey	Specifies the FA authentication key for Auto-sense ports.

Name	Description
IsisHelloAuthType	Specifies the authentication type for IS-IS hello packets on Auto-sense ports: • None • simple - simple password authentication uses a text password in the transmitted packet. The receiving router uses an authentication key (password) to verify the packet. • hmac-md5 - MD5 authentication creates an encoded checksum in the transmitted packet. The receiving router uses an authentication key (password) to verify the MD5 checksum of the packet. • hmac-sha256 - with SHA-256 authentication, the switch adds an hmac-sha–256 digest to each Hello packet. The switch that receives the Hello packet computes the digest of the packet and compares it with the received digest. Note: Note: Secure Hashing Algorithm 256 bits (SHA-256) is a cipher and a cryptographic hash function of SHA2 authentication. You can use SHA-256 to authenticate ISIS Hello messages. This authentication method uses the SHA-256 hash function and a secret key to establish a secure connection between switches that share the same key. This feature is in full compliance with RFC 5310. The default authentication type is none.
IsisHelloAuthKeyId	Specifies the IS-IS hello authentication number key id for the Auto-sense ports.
IsisHelloAuthKey	Specifies the IS-IS hello authentication number key for the Auto-sense ports. You must configure the IS-IS hello authentication key along with the IS-IS hello authentication type.
OnboardingIsid	Specifies the onboarding I-SID used by the Auto-sense ports.
Qos8021pOverrideEnable	Overrides the incoming 802.1p bits on ports that operate in Auto-sense mode. The default is enabled.
VoiceIsid	Specifies the voice I-SID used by Auto-sense ports.
VoiceCvid	Specifies the customer VLAN ID associated with the voice I-SID used by Auto-sense ports. Voice C-Vid is configured for tagged voice traffic only. You must configure the Auto-sense voice customer VLAN ID along with the auto-sense voice I-SID.
DhcpDetection	Enables or disables the DHCP detection in Auto-sense mode. The default is enabled.
FaCameraIsid	Specifies the FA camera I-SID used by auto-sense ports.
FaProxyMgmtIsid	Specifies the FA proxy management I-SID used by auto-sense ports.
FaProxyMgmtCvid	Specifies the FA proxy management Client-VLAN ID (c-vid) used by auto-sense ports.
FaProxyNoAuthIsid	Specifies the FA proxy no-auth I-SID used by auto-sense ports.
FaVirtualSwitchIsid	Specifies the FA virtual-switch I-SID used by auto-sense ports.
FaWapType1Isid	Specifies the FA WAP type-1 I-SID used by auto-sense ports.
FaCameraEapolStatus	Specifies the FA EAPOL status for Camera I-SID used by auto-sense ports.

Name	Description
FaEapolOVSStatus	Specifies the FA EAPOL status for OVS (Open-Virtual-Switch) I-SID used by auto-sense ports.
FaEapolWap1Status	Specifies the FA EAPOL status for Wap-type-1 I-SID used by auto-sense ports.
WaitInterval	Specifies the wait interval in seconds for the 'WAIT' state of auto-sense's finite state machine.

Auto-sense Port Configuration using EDM

Perform the procedures in this section to configure Auto-sense on specific ports using Enterprise Device Manager (EDM).

Enable Auto-sense on Port(s)

About This Task

Perform this procedure to enable Auto-sense on one or more ports.

If you select more than one port, the format of the tab changes to a table-based tab.

Note

- After a switch boots without a configuration file, Auto-sense is enabled on all ports, by default.
- Auto-sense is disabled by default for existing configurations but enabled for new Zero Touch Fabric Configuration deployments.

Procedure

1. In the **Device Physical View** tab, select one or more ports.
2. In the navigation pane, expand **Configuration** > **Edit** > **Port**.
3. Select **General**.
4. Select the **Interface** tab.
5. For **AutoSense**, select enable.
6. Select **Apply**.

Disable Auto-sense on Port(s)

About This Task

Perform this procedure to disable Auto-sense on one or more ports. You also have the option to disable Auto-sense on the port but retain the configuration that the system applied dynamically. The dynamic configuration becomes a manual configuration and is visible in the **`show running-config`** output.

If you select more than one port, the format of the tab changes to a table-based tab.

Procedure

1. In the **Device Physical View** tab, select one or more ports.
2. In the navigation pane, expand **Configuration** > **Edit** > **Port**.

3. Select **General**.
4. Select the **Interface** tab.
5. For **AutoSense**, select disable.
6. (Optional) Select **AutoSenseKeepAutoConfig** to retain the configuration that the system applies dynamically.
7. Select **Apply**.

Configure an Auto-sense Data I-SID on a Port

About This Task

Perform this procedure to configure an Auto-sense Data I-SID on a port.

Procedure

1. In the **Device Physical View** tab, select a port.
2. In the navigation pane, expand **Configuration** > **Edit** > **Port**.
3. Select **General**.
4. Select the **Interface** tab.
5. For **AutoSenseDataIsid**, type the data I-SID value. The range is 0 to 15999999.
6. Select **Apply**.

Auto-sense Logical Flowcharts

The system uses a per-interface state to adapt to all Auto-sense events. Each state transition determines background configuration on the port. The system does not display Auto-sense port configurations in the **`show running-config`** command or in the saved configuration file; instead use the **`show auto-sense`** commands to show global and port specific Auto-sense information..

The following flowcharts describe the system logic for Auto-sense port state detection, how the system configurations change the logic path, and the Auto-sense configuration results.

Note
The **`vlan create`** CLI command examples do not apply to DvR leaf switch configurations. DvR leaf switches create VLANs automatically.

Auto-sense Fabric NNI

Detection of a Fabric network-to-network interface (NNI) results in tagged Backbone VLAN IDs (B-VID) with IS-IS NNI enabled.

Figure 1: Auto-sense Fabric NNI

Auto-sense UNI Client without NAC

Detection of a user-to-network interface (UNI) client without network access control (NAC) results in untagged data configuration based on system configuration.

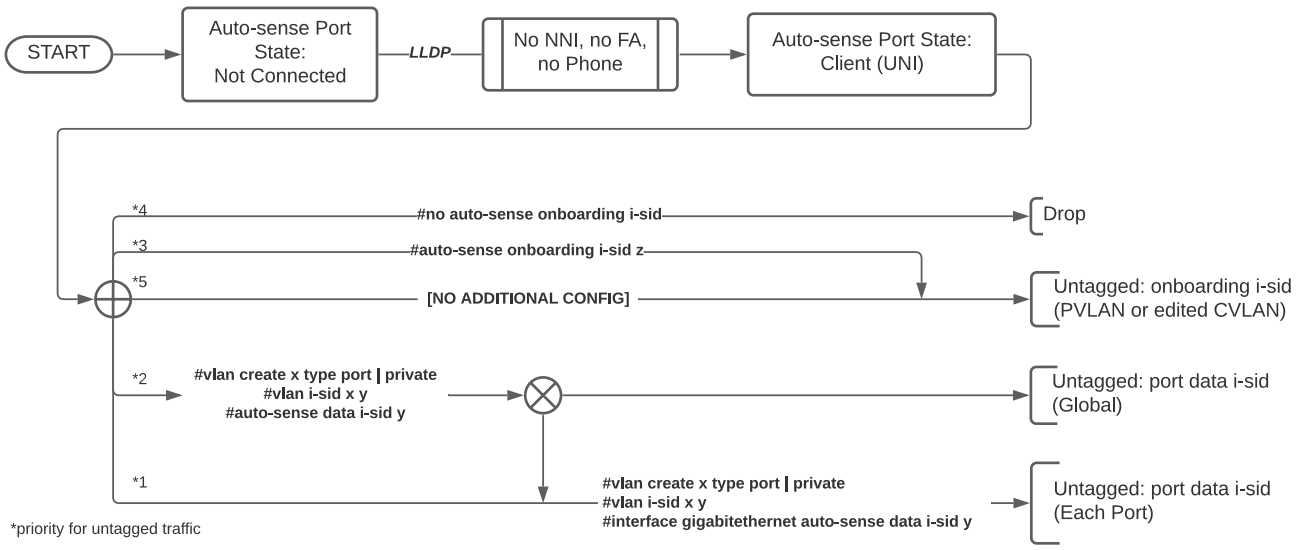

Figure 2: Auto-sense UNI client without NAC

Auto-sense UNI Client with NAC

Detection of a user-to-network interface (UNI) client with network access control (NAC) results in untagged, tagged, or dropped data configuration based on system configuration.

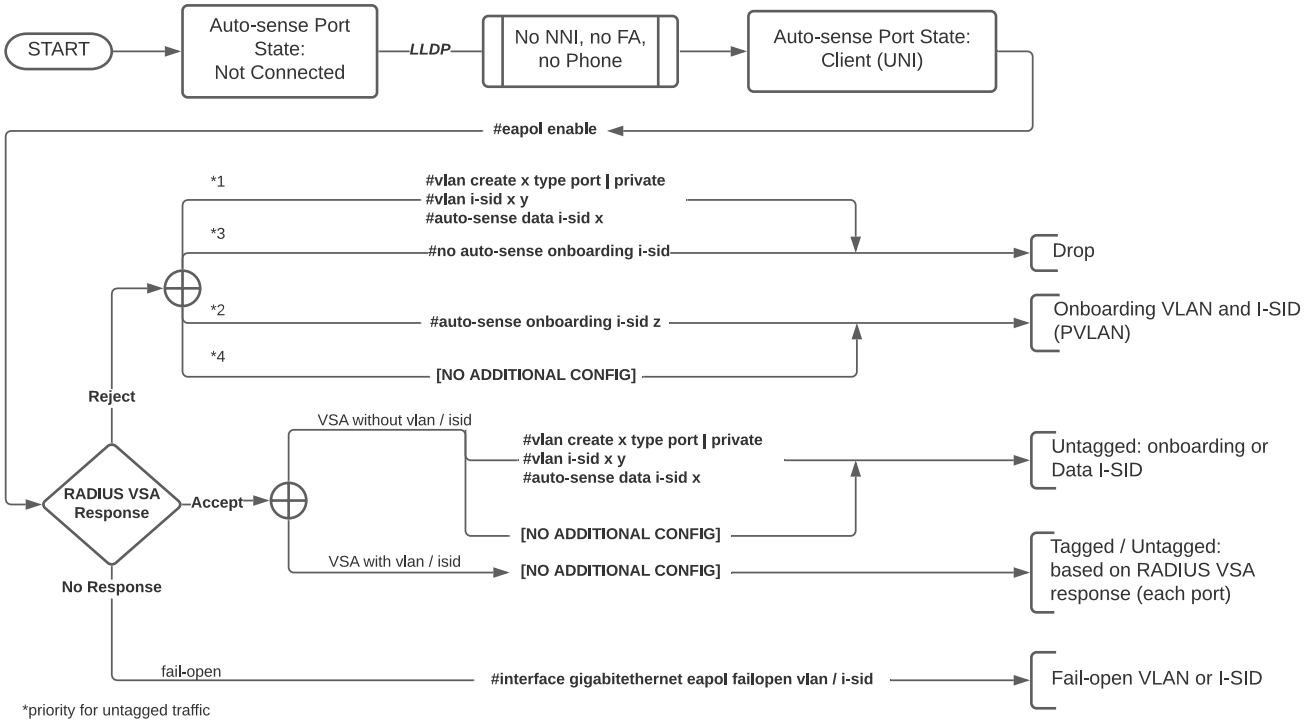

Figure 3: Auto-sense UNI client with NAC

Auto-sense Voice without NAC

Detection of voice without network access control (NAC) results in untagged, tagged, or dropped data based on system configuration.

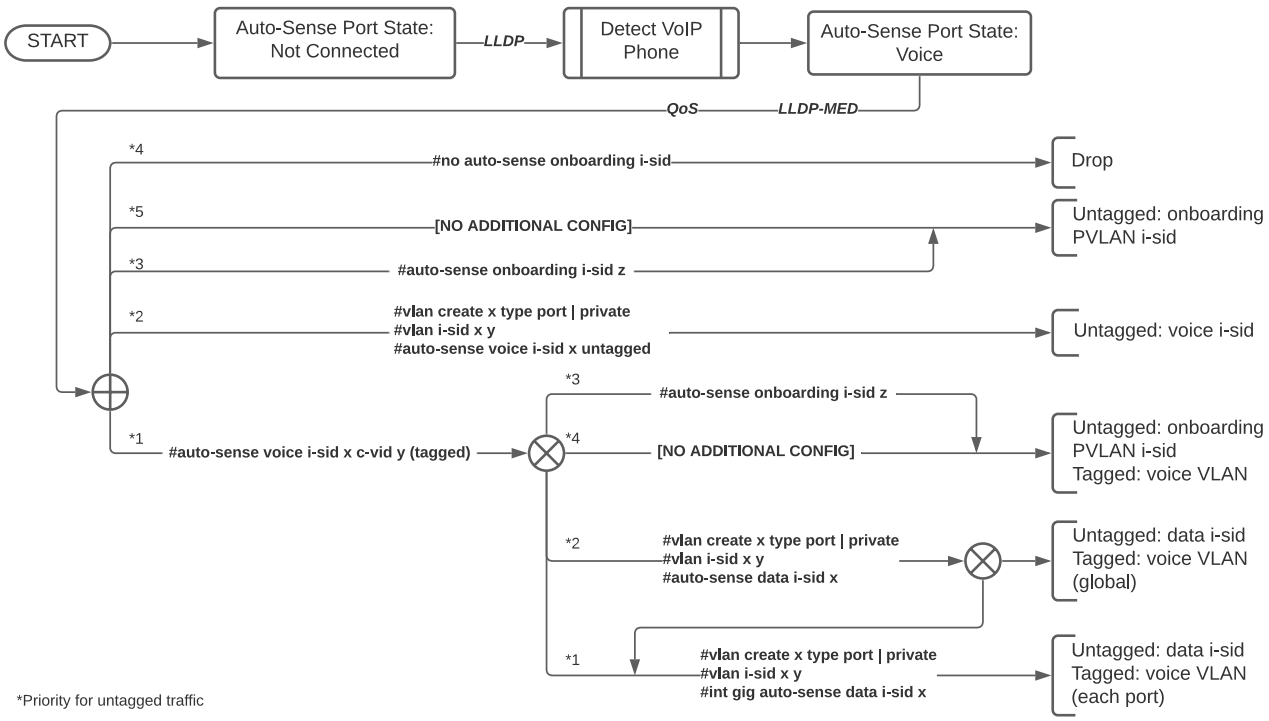

Figure 4: Auto-sense voice without NAC

Auto-sense Voice with NAC

Detection of voice with network access control (NAC) results in untagged, tagged, or dropped data based on system configuration.

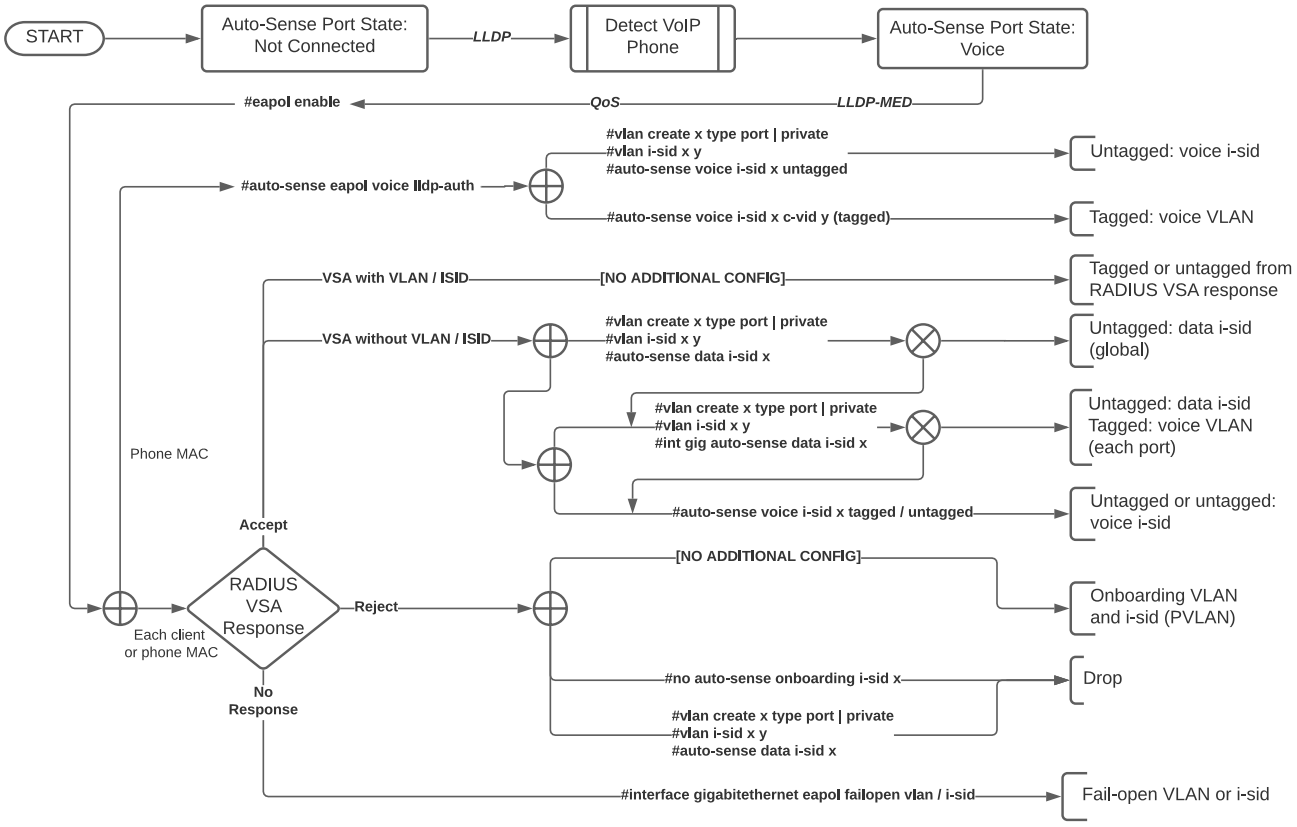

Figure 5: Auto-sense voice with NAC

Auto-sense FA Proxy Switch

Detection of a Fabric Attach (FA) proxy switch results in untagged or tagged data based on system configuration.

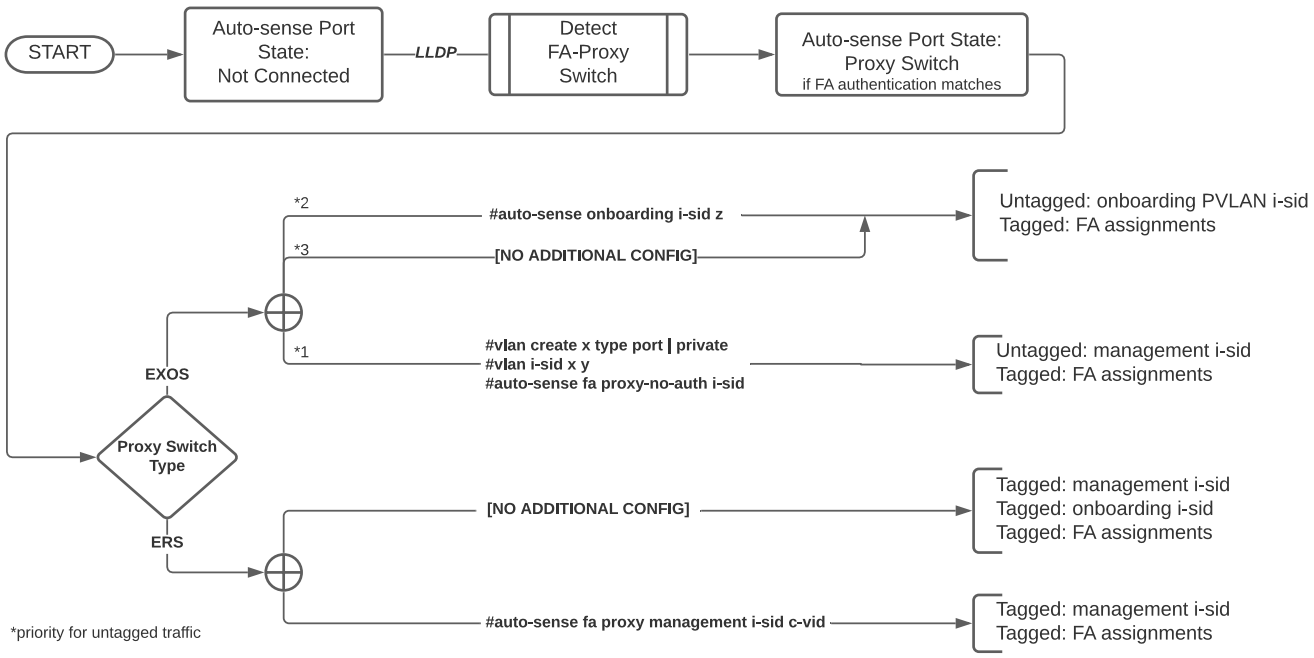

Figure 6: Auto-sense FA proxy switch

Auto-sense FA WAP, Camera, or OVS without NAC

Detection of a Fabric Attach (FA) wireless access point (WAP), camera, or open virtual switch (OVS) without network access control (NAC) results in untagged or tagged data based on system configuration.

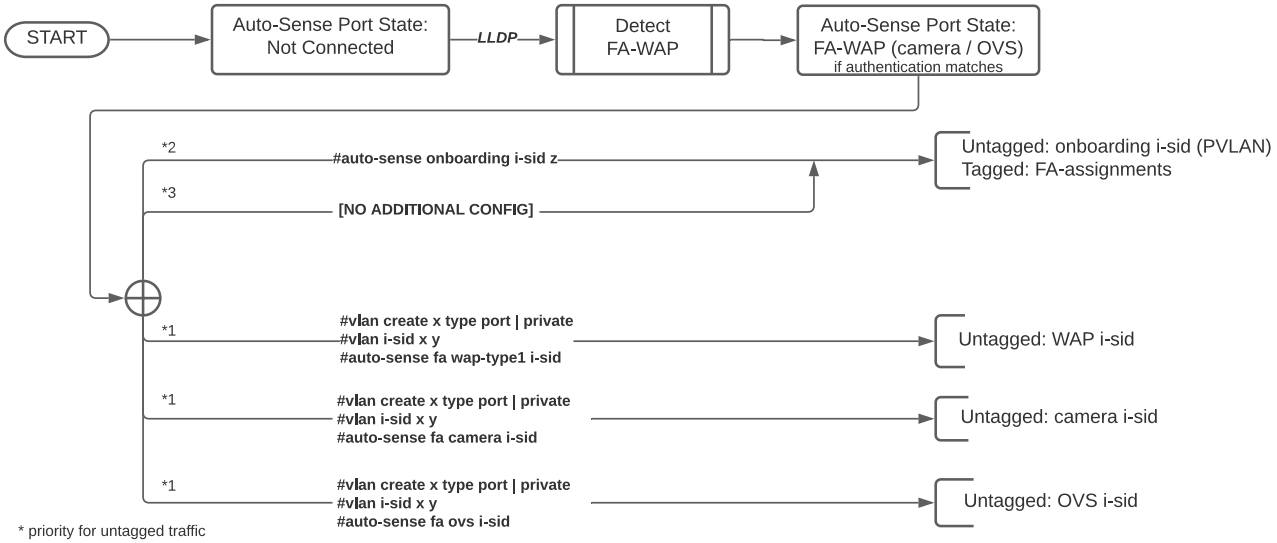

Figure 7: Auto-sense FA WAP / camera / OVS without NAC

Auto-sense FA WAP, Camera, or OVS with NAC

Detection of a Fabric Attach (FA) wireless access point (WAP), camera, or open virtual switch (OVS) with network access control (NAC) results in untagged or tagged data based on system configuration.

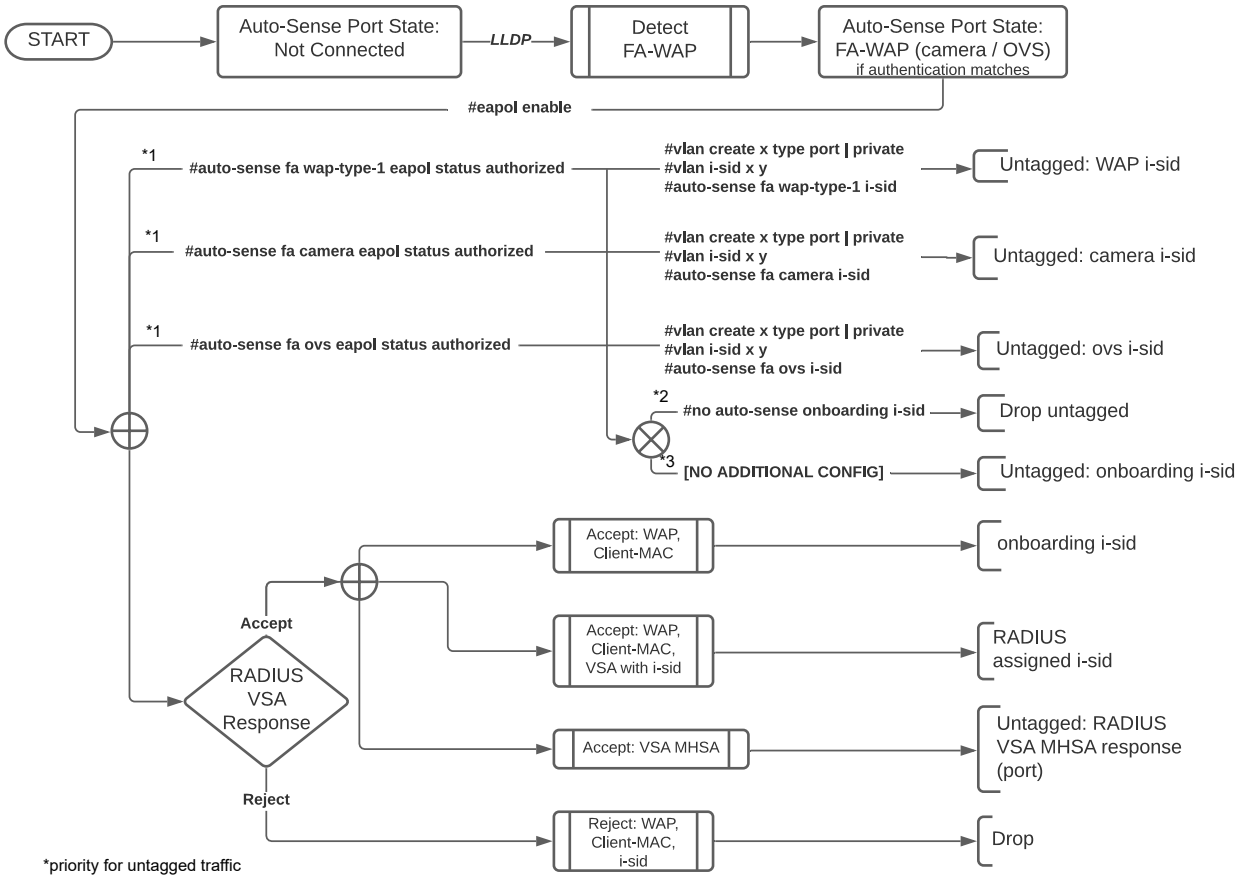

Figure 8: Auto-sense FA WAP / camera / OVS with NAC

IP Phone Support

Table 4: IP Phone product support

Feature	Product	Release introduced
IP Phone Support	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.3
	5720 Series	Fabric Engine 8.7

The IP phone support feature focusses on the following key points:

- Works only on the Flex UNI-enabled and Auto-sense ports.

- For Avaya phones, you can choose to configure and send call server and file server Link Layer Discovery Protocol (LLDP) Type-Length-Value (TLV) options through the **`lldp vendor-specific`** CLI command.
- To reduce configuration overhead, this feature includes the Auto-sense voice mechanism to detect IP phones from LLDP signalling. After the switch detects the phone, this mechanism manages the following tasks:
  - Provides the voice VLAN to the phone, tagging, Differentiated Services Code Point (DSCP), and priority parameters through the LLDP Media Endpoint Discovery (MED) signaling options.
  - Configures a switched UNI for phone traffic and sends it to the Service Instance Identifier (I-SID) that is associated with the voice VLAN.
  - Handles the configuration, whether “trusted” or “untrusted” on the port and priority re-markings.
  - Integrates with the Auto-sense functionality. For more information on Auto-sense, see Auto-sense on page 12.

Note

This feature does not support auto-creation of voice VLAN and MultiLink Trunking (MLT) or Split Multi-Link Trunking (SMLT).

This feature has the following connectivity models:

- Standalone IP phone, which connects to a switch port.
- IP Phone with PC behind it, where the IP Phone has a small inbuilt bridge, and a PC connects to that bridge port.

Note

Phone traffic is tagged with the voice VLAN whereas the PC traffic is untagged. However, you can configure the phone to send the traffic as untagged.

The IP phone connectivity supports the following scenarios:

- Call server and file Server LLDP TLV options—These TLVs are Avaya proprietary. Use them only with the Avaya IP phones to detect the IP addresses of a Call server and File Server.
- Phone detection through LLDP messaging—Use the Capabilities and Enabled Capabilities field in the LLDP packet to detect a phone. A “T” capability identifies a phone.
- Auto-sense voice option, without Network Access Control (NAC)—Use this functionality to specify the voice VLAN and voice I-SID in a single CLI command.
- Auto-ISID-Offset—Use this functionality if the voice VLAN is received without an I-SID from a Radius response. The Auto-ISID-Offset functionality determines an I-SID automatically to send the data traffic.
- Auto-sense voice, LLDP authentication, and Non- EAP (NEAP) (MAC authentication) connectivity—If you have enabled NEAP, it authorizes all the MAC addresses received on the port and IP phone. With the LLDP authentication option, a device, such as phone, is trusted and does not require a Remote Authentication Dial-in User (RADIUS) authentication. For this authentication, the Extensible Authentication Protocol (EAP) is notified after a phone is detected and the port is in the Auto-sense voice state. Then, the MAC address of the phone is added to EAP or NEAP host table.

Auto-sense Voice

The Auto-sense voice feature is an addition to the Auto-sense module. Based on the events of the phone discovery in the network, you can use this feature to configure phone devices without manual intervention.

After the switch discovers a Link Layer Discovery Protocol (LLDP) packet with phone capabilities, the port transitions to the "voice" state. The port receives a message on the voice event details.

With the Auto-sense voice feature, you can configure the voice I-SID and the voice VLAN. If you configure the I-SID as untagged, the phone receives VLAN as zero. When you configure Auto-sense voice, switched UNI is configured in VOICE I-SID for each port that is in "voice" state. The switch adds the Link Layer Discovery Protocol-Media Endpoint Discovery (LLDP-MED) policies for voice and voice-signaling Type-Length-Value (TLVs) to the LLDP packet and sends LLDP packets to the phone. It uses the configured voice VLAN and default values for Differentiated Services Code Point (DSCP) (46) and priority (6). After you run the **auto-sense voice** command, a filter is installed to prioritize the traffic that passes through the configured I-SID. The filter applies to traffic that reaches the VOICE I-SID, which implies the voice traffic.

Note

To change the Auto-sense voice configuration on the switch, delete the earlier configured voice I-SID and VLAN entry.

After you configure auto-sense voice, following tasks take place:

- The I-SID <I-SID value> and C-VID <C-VID value> are saved in the control plane.
- The voice I-SID is created.
- The ports that are in the "voice" state process the voice configuration message and begin the dynamic configuration. This configuration includes the following tasks:
  - Creation of voice Switched UNI (S-UNI).
  - Deletion of onboarding and data I-SID, or S-UNI, if you configured auto-sense as "untagged".
  - Addition of LLDP-MED voice and voice-signaling TLVs to the LLDP packet and sending of LLDP packets to the phone.
- The voice filter is updated. After you run the **auto-sense voice** command, a filter is installed to prioritize the traffic that passes through the configured I-SID. The filter applies to the traffic in Voice

I-SID. The traffic that passes through this I-SID is internally prioritized with level 6 and forwarded with a dot1p value of 6, for tagged packets. For the IP packets, the DSCP value of 46 is forwarded.

Note

- To disable Auto-sense on the port but keep the dynamic configurations made by Auto-sense, use the command **no auto-sense enable convert-to-config**. The voice S-UNI loses its Auto-sense origin and has a config origin instead. The LLDP-MED policies installed by Auto-sense are preserved.
- If you use the **no auto-sense voice** command, the system removes the voice S-UNI and the LLDP-MED policies. The voice I-SID is removed if it was installed by using the **auto-sense voice** command. If the I-SID existed before you used the **auto-sense voice** command, the system does not remove the I-SID but the I-SID does lose its Auto-sense origin.
- A port exits the voice state in one of the following scenarios:
  - If the port is down
  - If the LLDP session fails between the switch and the phone
  - If Auto-sense is disabled on the port that connects to the IP phone

  After a port exits the voice state, the Switched UNI (S-UNI), LLDP voice and voice-signaling are deleted.

IP Phone Configuration using CLI

Configure Auto-sense Voice Information for IP Phones

The switch applies the voice configuration on Auto-sense-enabled ports, after it discovers IP phones on the port through Link Layer Discovery Protocol (LLDP) packets.

Before You Begin

If you boot the switch with a configuration file, and not through Zero Touch Fabric Configuration, you must manually enable Auto-sense on specific ports.

About This Task

Perform this procedure to configure Auto-sense voice information for IP phones.

A global Auto-sense voice configuration does not require Auto-sense LLDP authentication based on the following cases.

- In a non NAC, a phone is classified based on the phones LLDP signaling.
- In a NAC, a phone is authenticated based on EAP/NEAP radius authenticated, or if configured, it is LLDP authenticated

Procedure

1. Enter Global Configuration mode:
   ```
   enable

   configure terminal
   ```

2. Configure the customer VLAN ID:

   ```
   auto-sense voice i-sid <1-15999999> c-vid <c-vid>
   ```

3. Configure the traffic as untagged:

   ```
   auto-sense voice i-sid <1-15999999> untagged
   ```

Note

The phone receives VLAN ID as 0 and the tagging is configured as "untagged".

Example

Configure VLAN tagging as untagged:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#auto-sense voice i-sid 1234 untagged
```

Variable Definitions

The following table defines parameters for the **auto-sense voice** command.

Variable	Value
i-sid<1-15999999>	Specifies the service instance identifier (I-SID).
c-vid<c-vid>	Specifies the customer VLAN ID. Different hardware platforms support different customer VLAN ID ranges. Use the CLI Help to see the available range for the switch.
untagged	Specifies the VLAN tagging type as untagged. Note: The phone receives VLAN ID as 0 and the tagging is configured as "untagged".

Enable Auto-sense LLDP Authentication of IP Phones

Before You Begin

- You must enable Extensible Authentication Protocol over LAN (EAPoL) globally.

About This Task

Perform this procedure to enable Link Layer Discovery Protocol (LLDP) authentication of IP phones. The switch authenticates the phone after it receives LLDP packets from the phone if EAP/NEAP is enabled.

Auto-sense LLDP authentication applies to Auto-sense ports in the VOICE state. Auto-sense LLDP authentication does not require a global Auto-sense voice configuration.

The **no auto-sense eapol voice lldp-auth** command removes all Auto-sense LLDP sessions and removes the Auto-sense LLDP authentication configuration.

The system removes the LLDP session for the following reasons:

- You disable EAPoL globally.

- You disable Auto-sense on the port.
- The LLDP neighbor is removed.

If the LLDP authentication configuration exists and one of the following situations occur, the LLDP session is recreated:

- You renable EAPoL globally.
- You renable Auto-sense on the port.
- The LLDP neighbor is recreated.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable LLDP authentication:

   ```
   auto-sense eapol voice lldp-auth
   ```

Example

Enabling LLDP authentication on the switch:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#auto-sense eapol voice lldp-auth
```

Variable Definitions

The following table defines parameters for the **auto-sense eapol voice** command.

Variable	Value
lldp-auth	Enables Link Layer Discovery Protocol (LLDP) authentication of IP phones. By default, LLDP authentication of IP phones is disabled on the switch.

Configure LLDP Vendor Specific Information

About This Task

Use this procedure to configure the Link Layer Discovery Protocol (LLDP) vendor-specific information on a call server or a file server.

Note

After you configure LLDP vendor specific call server information, the SIP Proxy of the phone is configured as transport type Transport Layer Security (TLS) port 5061. This option is available depending on the operating system of the call server.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. To configure LLDP vendor-specific information for a call server server, enter:

   ```
   lldp vendor-specific call-server <1-8> <A.B.C.D>
   ```

3. To configure LLDP vendor-specific information for a file server, enter

   ```
   lldp vendor-specific file-server <1-4> <A.B.C.D>
   ```

Example

Configure the LLDP vendor-specific information on a call server:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#lldp vendor-specific call-server 1 192.0.2.0
```

Variable Definitions

The following table defines parameters for the **`lldp vendor-specific`** command.

Variable	Value
`call-server <1-8> <A.B.C.D>`	Specifies the Link Layer Discovery Protocol (LLDP) vendor specific information on the call server number and the IP address.
`file-server <1-4> <A.B.C.D>`	Specifies an LLDP vendor specific information on the file server number and the IP address.

View LLDP Vendor Specific Information

About This Task

Use this procedure to view the Link Layer Discovery Protocol (LLDP) vendor-specific information on a call server or a file server.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. To view LLDP vendor-specific information for a call server, enter:

   ```
   show lldp vendor-specific call-server
   ```

3. To configure LLDP vendor-specific information for a file server, enter

   ```
   show lldp vendor-specific file-server
   ```

Example

Display the LLDP vendor-specific information on a call server:

```
Switch:1>enable
Switch:1#show lldp vendor-specific call-server
=======================================================
```

```
                      LLDP Call-Server
============================================================
NUM          IP
------------------------------------------------------------
1            192.0.2.0
2            198.51.100.0
------------------------------------------------------------
All 2 out of 2 Total Num of call-server entries displayed
```

View LLDP Neighbor Vendor Specific Information

About This Task

Use this procedure to view the remote Link Layer Discovery Protocol (LLDP) vendor-specific information on a call server or a file server.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. To view remote LLDP vendor-specific information for a call server, enter:

   ```
   show lldp neighbor vendor-specific call-server
   ```

3. To view remote LLDP vendor-specific information for a file server, enter:

   ```
   show lldp neighbor vendor-specific file-server
   ```

Example

Display remote LLDP vendor-specific information on a file server:

```
Switch:1>enable
Switch:1#show lldp neighbor vendor-specific file-server
====================================================================
           Remote LLDP File-Server IP Addresses
====================================================================
PORT       IP
--------------------------------------------------------------------
203        192.0.2.0, 198.51.100.0, 203.0.113.0
--------------------------------------------------------------------
All 3 out of 3 Total Num of remote file-server entries displayed
```

Enable LLDP Voice Authentication on a Specific Port

About This Task

Perform this procedure to enable Link Layer Discovery Protocol (LLDP) voice authentication of IP phones on a port.

You cannot manually enable LLDP voice authentication on an Auto-sense-enabled port. If the system detects a phone on an Auto-sense port, then “eapol voice lldp-auth” configuration is automatically applied on the port that connects to the phone. This procedure applies to ports with Auto-sense disabled.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable LLDP voice authentication on a specific port:

   ```
   eapol voice lldp-auth
   ```

Example

Enabling LLDP voice authentication on a specific port:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#eapol voice lldp-auth
```

Variable Definitions

The following table defines parameters for the **`eapol voice`** command.

Variable	Value
`lldp-auth`	Enables Link Layer Discovery Protocol (LLDP) voice authentication of IP phones on the selected port. By default, LLDP authentication of IP phones is disabled on the switch.

IP Phone Configuration using EDM

View Vendor Specific Call Server Information

About This Task

Perform this procedure to view inventory attributes for vendor-specific call server information.

Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability** > **Diagnostics** > **802_1ab**.
2. Select **Vendor Specific**.
3. Select the **Call Server** tab.

Vendor Specific Call Server Field Descriptions

Use the data in the following table to use the **Call Server** tab.

Name	Description
CallServerNum	Specifies the call server ID.
CallServerAddressType	Specifies the IP address type of the call server.
CallServerAddress	Specifies the IP address of the call server.

View Vendor Specific File Server Information

About This Task

Perform this procedure to view inventory attributes for vendor-specific file server information.

Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability** > **Diagnostics** > **802_1ab**.
2. Select **Vendor Specific**.
3. Select the **File Server** tab.

Vendor Specific File Server Field Descriptions

Use the data in the following table to use the **File Server** tab.

Name	Description
FileServerNum	Specifies the file server ID.
FileServerAddressType	Specifies the IP address type of the file server.
FileServerAddress	Specifies the IP address of the file server.

Zero Touch Deployment

Table 5: Zero Touch Deployment product support

Feature	Product	Release introduced
Zero Touch Deployment	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

For the most current information on switches supported by ExtremeCloud™ IQ, see ExtremeCloud™ IQ Learning What's New.

Zero Touch Deployment enables a switch to be deployed automatically with ExtremeCloud IQ but you still need to onboard the switch on the ExtremeCloud IQ side. When the switch powers on, the Dynamic Host Configuration Protocol (DHCP) Client obtains the IP address and gateway from a DHCP Server, and discovers the Domain Name Server, connecting the switch automatically to ExtremeCloud IQ - Site Engine or to ExtremeCloud IQ cloud management application.

The switch integrates with ExtremeCloud IQ using IQAgent.

Zero Touch Provisioning Plus (ZTP+) provides ExtremeCloud IQ - Site Engine connectivity to the switch.

For more information about ExtremeCloud IQ Agent, see ExtremeCloud IQ Agent on page 760. For more information about ZTP+, see Zero Touch Provisioning Plus on page 54 .

To use zero touch functionality, your switch must be in a Zero Touch Deployment-ready configuration mode, which means the switch cannot have existing primary or secondary configuration files loaded. Factory shipped switches are Zero Touch Deployment ready because they deploy without configuration files. However, existing switches require manual preparation before Zero Touch Deployment can function.

To prepare an existing switch for Zero Touch Deployment, the switch must boot without a configuration file. Perform one of the following actions:

- Rename existing primary and secondary configuration files. Use the **mv** command to rename the existing configuration files. For example, **mv config.cfg config.cfg.backup**.

  This is the preferred option as it ensures that the primary and secondary files are removed while making a backup of them at the same time. This option also ensures that the switch uses the default config.cfg file for the final configuration after it has successfully onboarded.
- Boot from non-existent configuration files. Use the **boot config choice** command to configure the primary and backup configuration files to reference files that do not exist on the switch:

  ```
  boot config choice primary config-file nonexistent1.cfg

  boot config choice primary backup-config-file nonexistent2.cfg
  ```

  This option also works, however, after the switch has successfully onboarded, it does not use the default config.cfg file but uses the alternative configuration file name provided instead, which might not be desired.
- Delete the existing primary and secondary configuration files. Create a backup of these files before you delete them.

Configuration Considerations

The switch configuration depends on whether you use factory default mode or Zero Touch Deployment.

Zero Touch Deployment Configuration

With Zero Touch Deployment, the switch configuration consists of the following:

- The ssh and sshd boot configuration flags are enabled by default.
- All ports are Private VLAN isolated ports.
- VLAN 4048 is created as an *onboarding-vlan* for host-only connectivity for In Band management. All front panel ports are members of VLAN 4048.
- In Band management is enabled.
- Dynamic Host Configuration Protocol (DHCP) client requests are cycled between In Band and Out of Band ports, except on the 5320 Series. 5320 Series supports In Band management only.
- If the switch resets after the IP address is obtained from the DHCP Server, the entire DHCP process does not need to be repeated. Instead, the switch can directly send the DHCP Request to the DHCP Server for the IP stored in the /intflash/dhcp/dhclient.leases file.

- Out of Band management is enabled, except on the 5320 Series. 5320 Series supports In Band management only.
- All ports are administratively enabled.
- IQAgent is enabled by default.
- Zero Touch Provisioning Plus (ZTP+) for ExtremeCloud IQ - Site Engine onboarding is enabled by default.
- Initiates Zero Touch Fabric Configuration.
- After the Zero Touch Fabric establishes successfully, the onboarding VLAN 4048 is automatically assigned to onboarding I-SID 15999999.

For information about IQAgent, see ExtremeCloud IQ Agent on page 760.

Factory Default Mode

The switch continues to support the boot configuration flag **`boot config flags factorydefaults`** to return an existing switch to factory default configuration.

Note

Zero Touch Deployment does not run on a switch returned to factory default configuration in this manner.

For more information, see Boot Sequence on page 128.

Zero Touch Provisioning Plus

Table 6: Zero Touch Provisioning Plus product support

Feature	Product	Release introduced
Zero Touch Provisioning Plus	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

With zero touch functionality, switches are automatically discovered on the network within minutes of when they are connected.

Zero Touch Provisioning Plus (ZTP+) enables you to deploy and configure switches in ExtremeCloud IQ - Site Engine with minimal server configuration and intervention. ZTP+ enabled switches send information, such as the serial number, software version, MAC, management IP, and port information to ExtremeCloud IQ - Site Engine automatically.

When the switch powers on, the DHCP Client obtains the IP address and gateway from the DHCP server, discovers the Domain Name Server, and connects the switch to ExtremeCloud IQ - Site Engine.

ZTP+ uses HTTPS for communication between the switch and the ExtremeCloud IQ - Site Engine server. The switch discovers theExtremeCloud IQ - Site Engine server by resolving the DNS name *extremecontrol.<domain-name>*.

Important

This feature requires a Zero Touch Deployment-ready configuration. For more information, see Zero Touch Deployment on page 52.

ZTP+ Phases of Operation

Zero Touch Provisioning Plus (ZTP+) auto-provisioning occurs in phases after you connect the switch to the network, if the switch is in factory ship state with no valid configuration saved on the device.

Connect

The Connect phase is the first phase of ZTP+ during which the switch connects to the ExtremeCloud IQ - Site Engine server on the network. The ExtremeCloud IQ - Site Engine server is discovered by resolving the DNS name *extremecontrol.<domain-name>*.

If the attempt is successful, the ExtremeCloud IQ - Site Engine server responds with an Accept message. When connectivity is established, the switch communicates with the ExtremeCloud IQ - Site Engine server securely and transmits information, such as its serial number, model number. The switch then progresses to the next phase of ZTP+.

Upgrade

After a successful connect to the ExtremeCloud IQ - Site Engine server, the next phase of ZTP+ is the Upgrade phase. This phase verifies that the switch is running the image file version that is currently selected as the reference version on the ExtremeCloud IQ - Site Engine server.

Image file validation is initiated by the switch. After a successful connect, the switch sends an image file upgrade request to the ExtremeCloud IQ - Site Engine server with details on the current image file version. If the image file versions on the switch and the ExtremeCloud IQ - Site Engine server match, no upgrade is initiated, and the switch moves to the next phase of ZTP+. If the ExtremeCloud IQ - Site Engine server detects a different image file version, ZTP+ initiates the .tgz image file download from a specified URL location.

After a successful image upgrade, the switch reboots and reconnects to the ExtremeCloud IQ - Site Engine server. If there are errors in the image upgrade process, an event is added to the server log. The switch then retries the image upgrade.

Configuration

The next phase after the image upgrade is ZTP+ Configuration phase. During this phase, the switch queries the ExtremeCloud IQ - Site Engine server for configuration updates, and initiates auto-provisioning by transmitting information, such as the image version, model name, and serial number. The switch then attempts to apply the configuration that is pushed from the ExtremeCloud IQ - Site Engine server.

If the switch can still communicate with the ExtremeCloud IQ - Site Engine server after the configuration is applied, the new configuration is automatically saved on the switch. The switch can be managed through the ExtremeCloud IQ - Site Engine using Simple Network Management Protocol (SNMP).

However, if the configuration that is pushed from the ExtremeCloud IQ - Site Engine server breaks switch connectivity to the ExtremeCloud IQ - Site Engine server, the switch reboots without saving the configuration. After the switch reboots, the ZTP+ onboarding restarts.

Any configurations pushed from the ExtremeCloud IQ - Site Engine server to devices using the initial ZTP+ configuration push are not displayed in the **`show log file detail`** command output. The logs associated with the Cloud connector are logged internally to state_machine.txt and ztp_plus.txt files located in `/intflash/cc/cc_logs/`.

ExtremeCloud IQ - Site Engine uses ZTP+ to configure the following items:

- Link Layer Discovery Protocol (LLDP) neighbor discovery

  Note
  Based on the LLDP discovery, port templates can be used on the ExtremeCloud IQ - Site Engine server. Enabling or disabling LLDP is not supported.

- Login
- Network Time Protocol (NTP)
- Ports configuration
- SNMP
- VLANs

  Note
  ZTP+ cannot manage VLAN port membership. With ZTP+, new VLANs are created with no ports. Ports cannot be removed from the onboarding VLAN. Ports cannot be added to another VLAN. VLAN port membership is managed through Auto-sense functionality or through manual configuration after initial onboarding is complete.

ZTP+ Considerations

The following considerations apply to Zero Touch Provisioning Plus (ZTP+) :

- Fabric configurations are not supported with ZTP+. After ZTP+ is configured, ExtremeCloud IQ - Site Engine server can use Simple Network Management Protocol (SNMP) to remotely configure Fabric-related configurations on the switch using SNMP MIBs.
- Only the Out-of-Band (OOB) port or the Management VLAN interface are used to connect the ExtremeCloud IQ - Site Engine server.

  Note
  ZTP+ cannot change the Management VLAN interface. If onboarding started on the Management onboarding VLAN, this cannot be changed while using ZTP+.

Configuring ZTP+ using the CLI

This section provides procedures to configure and manage Zero Touch Provisioning Plus (ZTP+) using the Command Line Interface (CLI).

After your device is onboarded, you have access to ExtremeCloud IQ - Site Engine.

Note

You must configure a Segmented Management Instance to use ZTP+. For more information, see Segmented Management Instance Configuration using the CLI on page 75.

For information about onboarding switches, see https://www.extremenetworks.com/support.

View ZTP+ Status

About This Task

Use this procedure to verify the status of Zero Touch Provisioning Plus (ZTP+) on the switch.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Verify that ZTP+ is enabled:

   ```
   show application auto-provision
   ```

Example

The following is an example output of the **`show application auto-provision`** command:

```
Switch:1>show application auto-provision

Admin state          : Enabled
Operational state    : Running
```

Zero Touch Fabric Configuration

Table 7: Zero Touch Fabric Configuration product support

Feature	Product	Release introduced
Zero Touch Fabric Configuration	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
LLDP Fabric Connect TLV	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

You can use Zero Touch Fabric Configuration to deploy Fabric-capable switches in a plug and play manner with no initial configuration. The switches form a new Fabric automatically or they can connect to an existing Fabric that is Auto-sense-capable, obtain an IP address and Domain Name System (DNS) information from a Dynamic Host Configuration Protocol (DHCP) server using the onboarding I-SID/VLAN, which then permits the system to automatically onboard to the management servers, such as

ExtremeCloud IQ or ExtremeCloud IQ - Site Engine, to conduct actual provisioning deployment of the switch. For more information about Auto-sense, see Auto-sense on page 12.

Zero Touch Fabric Configuration automatically configures Shortest Path Bridging MAC (SPBM) and IS-IS without user intervention if you boot the switch in Zero Touch Deployment-ready configuration mode, meaning you boot without a configuration file. Zero Touch Fabric Configuration uses LLDP to signal Fabric capability and exchanges SPB backbone VLAN IDs information to ensure seamless joining to any existing fabric deployment. The switches use the chassis MAC addresses as their system ID. To ensure participation in the correct area, newly joining ZTF switches listen to IS-IS update packets for area information. A unique nick-name is as assigned by a pre-configured nick-name server switch. For more information, see Zero Touch Deployment on page 52.

Important

To add new Zero Touch Fabric Configuration devices or implement Zero Touch Fabric Configuration on existing devices, the network requires a nickname server and reachability to the DHCP server. How you implement this depends on if the network is a new deployment or an existing Fabric network that you upgrade. In a new deployment, you can meet the network requirements with one node, known as a seed node. In an existing network, functions may already exist on different nodes. For more information, see *Fabric Engine Release Notes*.

Zero Touch Fabric Configuration uses the port-based Auto-sense features, that enables all ports on the switch, by default, and all ports operate in Auto-sense mode. With the support of Auto-sense, Zero Touch Fabric Configuration onboards all ports on the switch to an existing network, without having to manually enable each port. Auto-sense automatically detects neighbor capabilities and performs the configuration on the port to reach the desired connectivity with the neighbor without user invention.

With Auto-sense functionality, ports on a switch can detect whether they connect to a Shortest Path Bridging (SPB) device, a Fabric Attach (FA) client, FA Proxy, Voice IP devices, or an undefined host, and then make the necessary configuration. For more information about Auto-sense, see Auto-sense on page 12.

If you start two nodes in a network without an existing configuration file, then Zero Touch Fabric Configuration, through Auto-sense, dynamically establishes an IS-IS adjacency between them. For more information, see Establishing IS-IS Adjacencies on page 59.

Default IS-IS Parameters

Zero Touch Fabric Configuration automatically configures the Shortest Path Bridging (SPB) and Intermediate System-to-Intermediate System (IS-IS) infrastructure to enable Fabric architecture on a switch. The system initializes the following items after you start the switch in Zero Touch Fabric Configuration mode:

- Enables Shortest Path Bridging MAC (SPBM).
- Creates a private VLAN 4048.
- Creates the Auto-sense onboarding I-SID 15999999.

- Assigns the Auto-sense onboarding I-SID 15999999 to private VLAN 4048 and also includes the management VLAN.

  Note

  As a best practice, use the onboarding I-SID for onboarding purposes and, whenever possible, configure a management VLAN or management CLIP on a different I-SID after the onboarding procedures have been successfully completed.

- Enables Auto-sense on all ports.
- Configures Auto-sense access ports and layer 2 trusted Auto-sense ports.
- Creates an SPBM instance.
- Enables IS-IS globally.

Parameter	Default value
SPBM instance	1
Primary B-VLAN	4051
Secondary B-VLAN	4052
Manual area	Initialize to 00.1515.fee1.900d.1515.fee1.900d **Note:** You can change the manual area dynamically, without disabling IS-IS, only when the area is the Zero Touch Fabric Configuration area. When IS-IS is enabled, you cannot delete the last manual area.
Auto-sense onboarding I-SID	15999999

Establishing IS-IS Adjacencies

Zero Touch Fabric Configuration automatically triggers when the switch boots without a configuration file, the platform enables Intermediate System-to-Intermediate System (IS-IS) without a configured nickname or manual area. The system creates default backbone VLANs (B-VLAN) (4051 and 4052) and IS-IS manual area values. As a result, if you start two nodes in a network without an existing configuration file, then Zero Touch Fabric Configuration dynamically establishes an IS-IS adjacency between them.

The switch uses the Auto-sense functionality with the Zero Touch Fabric Configuration feature to establish the adjacency between two nodes. For more information about how and when the system tries to establish the adjacency, see Auto-sense Port States on page 15 .

- If you manually configure an SPBM instance on a node, then the system removes the SPBM instance that is dynamically created by Zero Touch Fabric Configuration. The system uses the LLDP Fabric Connect TLV to send user-defined B-VLANs to other nodes in the network. Only the first pair of B-VLANs is learned. If the switch already learned the B-VLANs from neighbor_A, the switch ignores the B-VLANs received from neighbor_B, if those are different.

- If a switch operating in Zero Touch Fabric Configuration mode in the network receives B-VLANs from a neighboring switch, which do not match the default B-VLANs configured through Zero Touch Fabric Configuration, then the switch will perform the following actions:
  - Disables ISIS.
  - Deletes its VLANs.
  - Unassigns the B-VLANs.
  - Assigns the values received through LLDP Fabric Connect TLV.
  - Creates the corresponding VLANs.
  - Re enables ISIS and log a message on the console.

LLDP Fabric Connect TLV

The system uses the Link Layer Discovery Protocol (LLDP) Fabric Connect Type-Length-Value (TLV) to communicate B-VLANs and system IDs between nodes in the SPB cloud. For more information about LLDP and its interaction with Fabric Attach, see Link Layer Discovery Protocol (802.1AB) Fundamentals on page 1940.

Table 8: LLDP Fabric Connect TLV Format

TLV Type	TLV Length	OUI	Subtype	Fabric Connect Capability	B-VLANs Number	B-VLAN-1	B-VLAN-2	System ID Length	System ID
7 bits	9 bits	3 octets	1 byte	1 byte	1 byte	2 bytes	2 bytes	1 byte	6 bytes

Table 9: LLDP Fabric Connect TLV Field Descriptions

TLV Field	Description
OUI	Specifies the Extreme OID value (0xd88466).
Fabric Connect capability	Fabric Connect capability is enabled on all nodes that support Zero Touch Fabric Configuration. The value is 0 if the LLDP Fabric Connect TLV is not carrying any information in it. By default, the value is set to 1 on all ports.
B-VLANs number	Specifies the number of B-VLANs that the TLV can carry. The LLDP Fabric Connect TLV supports an unlimited number of B-VLANs, but Zero Touch Fabric Configuration sends two B-VLANs through the TLV. The value is 0 if the node is sending default B-VLAN values.
B-VLANs	Specifies the B-VLAN that is user-configured or dynamically learned from a neighbor node in the network.
System ID Length	Specifies the length (in bytes) of the System ID.
System ID	Specifies the IS-IS system ID.

Configuration Example to Create an IS-IS Adjacency between the VSP 8600 Series and Auto-sense Switches

Link Layer Discovery Protocol (LLDP) stations that connect to a local area network (LAN) advertise the station capabilities to each other, allowing the discovery of physical topology information for network management. When the system enables a switch as a Fabric Attach (FA) server in the Shortest Path Bridging (SPB) network, it receives LLDP messages from the FA Client and the FA Proxy devices using the LLDP Fabric Connect Type-Length-Value (TLV). For more information, see LLDP Fabric Connect TLV on page 60.

Following are the steps to create an Intermediate-System-to-Intermediate-System (IS-IS) adjacency between the VSP 8600 Series and Auto-sense switches.

On the VSP 8600 Series switch:

1. Disable the High Availability-CPU mode.
2. Enable the Shortest path bridging MAC (SPBM) mode.
3. Create an SPBM instance.
4. Create an SPBM B-VLAN.
5. Configure the port that links to the Fabric Engine switch.

On the Fabric Engine switch:

1. Enable the Shortest path bridging MAC (SPBM) mode.
2. Enable Auto-sense on the port that links to the VSP 8600 Series switch.

Example

Create an IS-IS adjacency:

On the VSP 8600 Series switch:

```
enable
configure terminal
no boot config flags ha-cpu
boot config flags spbm-config-mode
spbm
router isis
spbm 1
spbm 1 b-vid 100,101 primary 100
spbm 1 nick-name 1.44.66
manual-area c1
exit
vlan create 100 type spbm-bvlan
vlan create 101 type spbm-bvlan
vlan members remove 1 1/3
interface gigabitEthernet 1/3
isis
isis spbm 1
isis enable
router isis enable
```

On the Fabric Engine switch:

```
enable
configure terminal
boot config flags spbm-config-mode
interface gigabitEthernet 1/3
auto-sense enable
1 YYYY-MM-DD HH:MM:SS.622Z Switch - 0x00374589 - 00000000 GlobalRouter FA INFO Fabric Attach Assignments will
be rejected since ISIS is disabled.
1 YYYY-MM-DD HH:MM:SS.779Z Switch - 0x001dc703 - 00000000 GlobalRouter ISIS INFO B-VLANs (100,101) dynamically
learnt through LLDP. ISIS Restarted
1 YYYY-MM-DD HH:MM:SS.779Z Switch - 0x002d0609 - 00000000 GlobalRouter LLDP INFO New LLDP Neighbor Discovered
```

```
on interface 1/3
1 YYYY-MM-DD HH:MM:SS.954Z Switch - 0x00004727 - 00000000 GlobalRouter SNMP INFO SPBM detected adj INIT on
Port1/3, neighbor f873.a201.03df
1 YYYY-MM-DD HH:MM:SS.984Z Switch - 0x00004727 - 00000000 GlobalRouter SNMP INFO SPBM detected adj UP on

Table 10: Segmented Management Instance product support (continued)

Feature	Product	Release introduced
Segmented Management Instance — DHCP Client for Management Interface OOB or Management Interface VLAN	5320 Series	Fabric Engine 8.6 OOB not supported
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

A Management Instance is required to provide access to specific management applications.

With Segmented Management, the Management plane (management protocols) is separated from the Control Plane (routing plane) from a process and data-path perspective. Segmented Management is the only method to manage switches. One or a combination of the following management interface/management instance types can be used:

- Out-of-Band (OOB) management IP address (IPv4 and IPv6)
- In-band Loopback/circuitless IP (CLIP) management IP address (IPv4 and IPv6)
- In-band management VLAN IP address (IPv4 and IPv6)

Important

The Segmented Management Instance provides support for management interfaces that transmit and receive packets directly to and from the system native Linux IP stack. Unlike a traditional management interface, for example, a CLIP in the GRT that is part of the OS networking IP stack, Segmented Management Instance interfaces do not route packets through the OS networking IP stack.

Segmented Management provides better security because you cannot reach the management instance from outside the VRF (in case of CLIP) or outside VLAN/I-SID (in case of management VLAN), and because it has a built-in firewall for the management plane. There is also more predictability with symmetric traffic flows for management traffic originating from and terminating on the switch, for instance:

- Sessions originated from switch (client mode) - Source IP of packets is determined based on Management IP stack routing table weights (configurable).
- Sessions connecting to switch (server mode) - Source IP is derived from session connection and reply will go out on management interface packet.

Migration to Segmented Management Instance

Segmented Management Instance Migration

You have two command options to change attributes of a Management Instance:

- **`convert`** command
- **`migrate-to-mgmt`** command

As a best practice, use the **`convert`** command.

With the **convert** command, you can dynamically change the attributes of a Management Instance while you actively manage the switch over that same Management Instance without requiring the switch to reboot. This option also has rollback functionality to recover from unwanted changes.

For more information, see the following sections:

- Dynamic Change Options for Segmented Management Instance Attributes on page 74
- Change Management Instance Attributes on page 88

You can use the **migrate-to-mgmt** command to move a management VLAN to a different VLAN ID, or a management CLIP to a different VRF. However, if you use this option, you must reboot your switch after you save the configuration changes.

The following is an outline of the steps required for management migration using the **migrate-to-mgmt** command:

1. Configure a new or existing VLAN or CLIP management interface using Interface Configuration mode in the CLI (**interface vlan <vlan_id>** or **interface loopback <clip_id>**) or EDM.

   

   Important
   The IP interface and all routing protocols attached to the original VLAN are deleted post migration.

2. Add required routes to reach management services and subnets from the new interface.
3. Test connectivity to the new interface using ping and traceroute, and from the switch to management stations and servers.
4. Use the **migrate-to-mgmt** command from the new interface CLI mode.
5. Save the configuration and reboot.

   

   Note
   During boot, the migrate-to-mgmt settings are parsed and override the existing management interface with the new interface.

6. Access and manage the switch from the new interface.

For more information see, Migrate a VLAN or CLIP IP address to the Segmented Management Instance on page 75 (using CLI) or Migrate an IP Address to a Segmented Management Instance on page 103 (using EDM).

Interface Types

The Management Instance supports the following interface types:

- CLIP on page 66
- OOB on page 67
- VLAN on page 67

You can configure a maximum of three Management Instance interfaces, one of each type.

You can configure the route priority for the Segmented Management Instance. The Source IP default route priority is management CLIP (weight 100), then management VLAN (weight 200), then

management OOB interface (weight 300). You can route packets through a different management interface than the default configuration, but you must add a specific static route or change the default weight of the management interface.

Note

If you change the default route weight, the management interface with the lowest weight value becomes the default route for all segmented management interface traffic.

You can configure the default topology IP for LLDP and SONMP advertisements. Both LLDP and SONMP advertise the same topology IP. SONMP supports only IPv4 addresses. If multiple IPv4 addresses are configured on an OOB or VLAN management interface, the advertised IP priority is static IP address, then DHCP IP address, then link-local IP address.

IPSec is not supported on Segmented Management Instance management interfaces.

CLIP

You can use this interface type for CLIP management network routing in a Fabric network or Layer 3 routing network.

Important

A CLIP Management Instance is not a management CLIP created in the GRT. You must create the CLIP Management Instance using the Segmented Management Instance configuration.

The following list defines the abilities of this interface type:

- You can assign a circuitless management IP (CLIP) address bound to a VRF.
- You can associate only one VRF ID with a CLIP Management Instance IP address.

  

  Note

  For the 5320-24P-8XE, 5320-24T-8XE, 5320-16P-4XE, and 5320-16P-4XE-DC switches, the VRF must be the active VRF. For more information about VRF support on these models, see VRF Lite on page 3478.

- The IP address is not bound to a physical network; it does not transmit nor receive IPv4 Address Resolution Protocol (ARP) or IPv6 Neighbor Discovery (ND) messages.
- You do not need to configure a default or static route. This interface type uses all routing information learned by protocols attached to the associated VRF.
- Packets can ingress on any port or VLAN that belongs to the VRF associated with the CLIP Management Instance.
- You must configure accept policies or configure inter-VRF route redistribution to access the CLIP Management Instance from a different VRF. Inter-VRF access is not permitted with traditional IP routing using OSPF, BGP, or RIP. Packets ingressing the switch from a VLAN that belongs to a different VRF without a configured accept policy will not reach the CLIP Management Instance IP address. For more information, see Redistribution of CLIP Segmented Management Instance Examples on page 100.

- If you migrate the current IS-IS IP source address to the CLIP Management Instance, after the upgrade the IS-IS source IP address moves to the CLIP Management Instance. You must configure a new GRT CLIP using a different IP address and assign that as the new IS-IS source IP.
- Advertisement of the IPv4 or IPv6 address for the CLIP Management Instance to IS-IS in the GRT occurs automatically. Advertisement of the IPv4 or IPv6 address in the VRF Layer 3 VSN bound to the CLIP Management Instance occurs automatically. You must configure route redistribution to advertise the CLIP Management Instance to different protocols. For more information, see Redistribution of CLIP Segmented Management Instance Examples on page 100.

OOB

You can use this interface type for OOB management network routing, as an alternative to in-band network routing management.

Note

The OOB Segmented Management Instance is not supported on 5320 Series.

The following list defines the abilities of this interface type:

- You can assign a management IP address bound to the Out-of-Band (OOB) interface.
- You can associate only one OOB interface with an OOB Management Instance IP address.
- The Dynamic Host Configuration Protocol (DHCP) Client can request an IPv4 address for the OOB Management Instance interface.
- You must configure a default or static route to reach the next-hop gateway; no routing protocol information is used to access off-link networks.
- You can configure only Layer 3 networking parameters in the Management Instance Configuration mode (**`mgmt OOB`**) in CLI.
- You can configure only Layer 1 and Layer 2 networking parameters in the mgmtEthernet Interface Configuration mode (**`interface mgmtEthernet mgmt`**) in CLI.

VLAN

You can use this interface type for management of Layer 2 switches or for Zero-Touch onboarding of newly deployed devices.

For more information on Zero-Touch onboarding, see Zero Touch Capabilities on page 11.

You can configure a Management Instance VLAN on a DvR Leaf node by specifying the I-SID. For more information, see Management I-SID Assignment to DvR Leaf on page 634.

The following list defines the abilities of this interface type:

- You can assign a Management Instance IP address to an inband VLAN.
- You can associate only one VLAN ID with a VLAN Management Instance IP address.
- The DHCP Client can request an IPv4 address for the VLAN Management Instance interface.
- The interface resides on the physical VLAN segment, behaving as a host for sending and receiving IPv4 ARP and IPv6 ND messages.

- You must configure a default or static route to reach the next-hop gateway; no routing protocol information is used to access off-link (other subnets) networks.
- For the VLAN Management Instance to take route priority when used in conjunction with the CLIP Management Instance, you must configure a default route for the VLAN Management Instance with a value lower than 100, or configure static routes for direct communication over the VLAN Management Instance and management networks.
- No internal routing occurs between the VLAN Management Instance and other non Management Instance VLANs. The VLAN Management Instance does not route to or from the GRT. Packets must ingress on one of the ports in the VLAN Management Instance.

  Packets sent to the VLAN Management Instance IP address must ingress the switch from a VLAN or network-to-network interface (NNI) port (or contain the VLAN ID) associated with the VLAN Management Instance. The system does not route packets between the network operating system (NOS) routing VLAN and the VLAN Management Instance.

  If you configure the same VLAN ID for NOS routing and for the VLAN Management Instance, the NOS routing stack transmits and receives all ARP, ND, and ICMP packets. In this scenario, the packets are only counted and shown in the NOS routing KHI port statistics. The management statistics and KHI management statistics do not count or show the packets.
- You can bind the VLAN Management Instance to an I-SID, which bridges all management traffic to a single I-SID in a Fabric network. Also, other normal VLAN related operations such as VLAN port member changes are valid.
- Bridged management traffic must ingress on the VLAN or I-SID.
- The VLAN Management Instance can be routed by upstream routers.

Coexistence Restrictions

IPv4 and IPv6 address coexistence for both a NOS routing VLAN and VLAN Management Instance is supported, however you must manually match both IP address configurations between the VLANs.

If you configure the VLAN Management Instance with a manual IPv4 address and a DHCP IPv4 address first, you cannot add a IPv4 address to a NOS routing VLAN.

If you configure the VLAN Management Instance with an IPv6 address first, you can only add one IPv6 global address to a NOS routing VLAN.

The following restrictions apply when a VLAN Management Instance coexists with a port-based VLAN or with a brouter port:

- If you want a dual stack IPv4 and IPv6 coexistence between a NOS VLAN and VLAN Management Instance, you must configure the same IPv4 and IPv6 addresses on the VLAN Management Instance and on the NOS VLAN.

  You cannot configure the VLAN Management Instance with both IPv4 and IPv6 and configure the NOS VLAN with IPv4 or IPv6 only.
- If you disable NOS routing for IPv4, then you must disable routing for IPv6, and vice versa.

For the 5320-24P-8XE, 5320-24T-8XE, 5320-16P-4XE, and 5320-16P-4XE-DC switches, the management VLAN must be part of the active VRF. For more information about VRF support on these models, see VRF Lite on page 3478.

Configuration Example - Coexistence with Port-Based VLAN

The following example shows how the VLAN Management Instance can be configured to share the same IP address as a routing port-based VLAN.

You can configure the NOS VLAN first, and then configure the VLAN Management Instance, or in reverse order. You can remove or add the coexistence at any time.

Note

With the coexistence between NOS routing stack and the VLAN Management Instance, packets sent to the VLAN Management Instance IP address must ingress the switch from a VLAN port (or contain the VLAN ID) associated with the VLAN Management Instance. The system does not route packets between the NOS routing VLAN and the VLAN Management Instance.

IPv4

```
vlan create 10 type port-mstprstp 0
vlan members add 10 1/1
interface vlan 10
ip address 192.0.2.0/24
exit
mgmt vlan 10
ip address 192.0.2.0/24
ip route 0.0.0.0/0 next-hop 192.0.2.1
enable
```

IPv6

```
vlan create 10 type port-mstprstp 0
vlan members add 10 1/1
interface vlan 10
ipv6 interface address 2001:DB8::/32
ipv6 interface enable
exit
mgmt vlan 10
ipv6 address 2001:DB8::/32
ipv6 route 0::0/0 next-hop 2001::1
enable
```

Configuration Example - Coexistence with Brouter Port

The following example shows how the VLAN Management Instance can be configured to share the same IP address as a brouter interface.

You must configure the brouter interface before you enable the VLAN Management Instance. When the VLAN Management Instance is enabled, you must disable the VLAN Management Instance before you disable the brouter port.

IPv4

```
interface GigabitEthernet 1/1
no shutdown
brouter port 1/1 vlan 10 subnet 192.0.2.0/24
mgmt vlan 10
ip address 192.0.2.0/24
enable
```

IPv6

```
interface GigabitEthernet 1/1
no shutdown
ipv6 interface vlan 10
ipv6 interface address 2001:DB8::/32
ipv6 interface enable
mgmt vlan 10
ipv6 address 2001:DB8::/32
enable
```

Management Applications

The Segmented Management Instance provides support for management interfaces that transmit and receive packets directly to and from the system native Linux IP stack. Unlike a traditional management interface, for example, a CLIP in the GRT that is part of the networking IP stack, Segmented Management Instance interfaces do not route packets through the networking IP stack.

The following management applications use the Segmented Management Instance directly to transmit or receive packets with segmented management interfaces and addresses.

Segmented Management Instance Applications and Protocols	Client	Server	IPv4	IPv6
Digital Certificates	Yes		Yes	
DHCP Client	Yes		Yes	
DNS	Yes		Yes	Yes
FTP	Yes	Yes	Yes	Yes
HTTP/HTTPS		Yes	Yes	Yes
IQAgent	Yes		Yes	
NTPv4	Yes	Yes	Yes	Yes

Segmented Management Instance Applications and Protocols	Client	Server	IPv4	IPv6
TFTP	Yes	Yes	Yes	Yes
Traceroute	Yes	Yes	Yes	Yes

The following management applications do not use the Segmented Management Instance directly to transmit or receive packets, but can integrate with segmented management interfaces and addresses.

Applications and Protocols	IPv4	IPv6
Link Layer Discovery Protocol (LLDP)	Yes	Yes
SynOptics Network Management Protocol (SONMP)	Yes	
Sampled Flow (sFlow)	Yes	
Remote Network Monitoring version 2 (RMON2)	Yes	

Operational Notes for UDP Management Applications

Management applications that use UDP, such as TFTP, RADIUS dynamic server, or SNMP can have restrictions when multiple Segmented Management Instances are configured with overlapping or asymmetrical routing.

Note

The restrictions listed do not apply to TCP applications or if a single Management Instance is configured.

Asymmetrical routing can occur in any of the following scenarios. For the first two scenarios you can use the OOB or VLAN Management Instance IP address instead of the CLIP Management Instance IP address. Also, use FTP or SCP file transfer as an alternative because those protocols are TCP based.

In the third scenario, you can configure more specific static routes for networks originating UDP client communication to the OOB or VLAN Management Instance IP address if the CLIP Management Instance is also configured.

1. Client communication to the CLIP Management Instance IP address is from the same subnet as the VLAN Management Instance.
2. Client communication to the CLIP Management Instance IP address when specific static routes or default route with higher preference back to the client network exist on OOB Management Instance or VLAN Management Instance.

3. Client communication to the OOB Management Instance IP address or VLAN Management Instance IP address that relies on a default route with a lower preference than the internal default route used by the CLIP Management Instance.
4. Client communication to the CLIP Management Instance IP address is from the same subnet as the OOB Management Instance (even if the OOB port is down).

DHCP Client for Segmented Management Instance

To support Zero Touch Deployment, a DHCP Client is used for the Segmented Management Instance VLAN management interface or Out-of-Band (OOB) management interface. The DHCP Client configuration supports a VLAN mode, OOB mode, and a cycle mode. DHCP Client cycle mode alternates IP address requests between the VLAN management interface and OOB management interface until an IP address is obtained on one of the interfaces. Priority is given to the OOB management interface.

You can also manually configure the DHCP Client to request an IPv4 address from a DHCP server for the In-band VLAN management interface, or the OOB management interface, or to cycle requests until an IP address is obtained on a VLAN or OOB management interface. The DHCP Client supports IPv4 addresses only, and cannot be enabled on multiple management interfaces simultaneously.

Note

If a default route is configured on an OOB or VLAN management interface, and then you configure DHCP so that it replaces the default route, the original default route is restored if you disable DHCP.

However, if the DHCP default route is updated or deleted after it is created by DHCP, the default route will not be replaced by the original route when DHCP is disabled.

DHCP Client Restrictions

DHCP Client for the Segmented Management Instance supports IPv4 addresses only, and cannot be enabled on multiple management interfaces simultaneously. The DHCP Client only supports the in-band VLAN management interface, or the OOB management interface, or to cycle requests on the the VLAN then OOB management interface until an IP address is obtained on one of the interfaces.

Note

The DHCP Client is disabled by default on previously configured or upgraded switches.

The DHCP Client is enabled by default in cycle mode when:

- The switch ships directly from manufacturing with Fabric Engine Release 8.6 or later.
- The primary and secondary configuration file is not on the switch.
- The primary and secondary configuration file fail to load on the switch.

The DHCP Client is not available if RMON2 is configured on a Management Instance, and RMON2 is not available if the DHCP Client is configured on a Management Instance.

When DHCP is enabled on a Management Instance interface, the DHCP Client initial broadcast discovery packet and initial response from the DHCP server are not counted or shown in KHI management statistics for the management interface. Only the packets after the DHCP IP address assignment

completes are counted and shown. After an IP address is assigned, a UDP socket opens and packets are counted on the interface.

If you change the DHCP Client configuration between management VLAN, OOB, or cycle, the default route provided by the DHCP server might delete and add with a different nexthop or network. DHCP Client configuration changes can cause interruptions to existing management connections.

DHCP static routes are not saved in the configuration file or displayed in **show running-config**. You can view DHCP static routes with **show mgmt ip route static**. If the DHCP Client adds a default route to an interface, the previous default route is deleted. If you modify a default route created by the DHCP Client, the route type output of **show mgmt ip route static** changes from DHCP to STATIC. You can save the modified to static default route to the configuration file, but on reboot the DHCP Client deletes the modified default route and restores the default static route the DHCP server specifies.

DHCP Option 43

DHCP option 43 requests specific vendor options from the DHCP server. Only sub-option 226 (EXTREME.cloudiq-ip) is supported to change the value of the ExtremeCloud IQ server IP address on the switch.

With the support of DHCP option 43, DHCP can dynamically configure the IP address of a private/non-public ExtremeCloud IQ server for zero touch deployments when the default ExtremeCloud IQ server (hac.extremecloudiq.com) is not desired.

For information about configuring the switch to support ExtremeCloud IQ, see ExtremeCloud IQ Agent on page 760.

DHCP Option 43 Configuration Examples

This section provides examples to configure DHCP Option 43 on a Linux server and on Windows Server.

ISC DHCP Server configuration on Linux:

```
/etc/dhcp/dhcpd.conf
default-lease-time 60;
max-lease-time 7200;
option space EXTREME;
option EXTREME.cloudiq-ip code 226 = ip-address;

class "Edge-without-POE" {
      match if (option vendor-class-identifier = "EXTREME");
      vendor-option-space EXTREME;
      option EXTREME.cloudiq-ip 10.16.231.131;
}

subnet 30.30.30.0 netmask 255.255.255.0 {
        pool {
                range 30.30.30.10 30.30.30.20;
                allow members of "Edge-without-POE";
        }
        option domain-name-servers 10.1.10.1;
        option domain-name "labs.extremenetworks.com";
        option routers 30.30.30.250;
```

```
        default-lease-time 3600;
}
```

Windows Server configuration:

1. Go to scope options for defined DHCP pool.
2. Enter the following for Option 43: e2 04 0a 10 e7 83

Value	Description
e2 04	vendor ID prefix (e2 is the hexadecimal value of the code 226 used to identify sub-option EXTREME.cloudiq-ip and 04 the hexadecimal value of the length of an IP address in bytes)
0a 10 e7 83	IP address 10.16.231.131 converted to hexadecimal

Dynamic Change Options for Segmented Management Instance Attributes

You can now dynamically change the attributes of a Management Instance while you actively manage the switch over that same Management Instance without requiring the switch to reboot. For example, if your switch onboards using VLAN 4048, you can change that Management Instance VLAN to a new VLAN.

You can change the following attributes for the Management Instance:

- Management Instance VLAN:
  - VLAN ID
  - IPv4 address
  - default gateway
  - I-SID (on a DvR Leaf)
  - ports-tagged
  - ports-untagged
- Management Instance CLIP
  - IPv4 address
  - vrf
- Management Instance Out-of-Band (OOB)
  - IPv4 address
  - default gateway

Operational Considerations

The following are operational considerations when you change Management Instance attributes using the **convert** command:

- IPv6 is not supported and is removed during conversion, if an IPv6 address exists.
- You cannot change parameters for more than one Management Instance operation at a time. You must issue the **mgmt convert-commit** command before you use the **convert** command for either the same or a different Management Instance.
- If you attempt to change attributes for an existing Management Instance VLAN, you cannot configure ports-tagged, ports-untagged, and I-SID parameters. Make configuration changes to the

existing Management InstanceVLAN first before you use the **convert** command. If you change your switch to a DvR leaf node, you can change the I-SID parameter.

- If you attempt to change attributes for a Management Instance VLAN and the VLAN does not exist, a VLAN is automatically created in the background. You can specify ports-tagged, ports-untagged, and I-SID parameters to be associated with this new VLAN. The new VLAN is assigned to the default Spanning Tree Group, which is 0.
- If you attempt to change attributes for a Management Instance VLAN and the VLAN does not exist, and you do not specify ports-tagged, ports-untagged, or I-SID parameters, then this is a special case. If any untagged ports in the old VLAN have dynamic Address Resolution Protocol (ARP) entries then these ports automatically move from the old VLAN to the new VLAN. For example, VLAN 200 has port members 1/1, 1/2, and 1/3. ARP entries are configured on ports 1/1 and 1/2. VLAN 300 is created in the background and only ports 1/1 and 1/2 automatically move to this new VLAN.

  If an MLT ID is associated with the old VLAN, the association is removed and re-added to the new Management Instance VLAN ID.
- If you attempt to change the vrf attribute for a Management Instance CLIP but the vrf does not exist, a vrf is automatically created in the background. In order for this vrf to function properly, you must configure either SPBM Layer 3 VSN or IP interfaces and routing protocols.

  The best practice is to configure and test vrf connectivity before you use the **convert** command.
- The following applies when you change static routes attributes on a Management Instance VLAN or Management Instance OOB interface:
  - If you provide the static route next-hop gateway, all next-hop gateway direct to the new gateway.
  - If you do not provide the static route next-hop gateway and the new subnet is the same as the old subnet, all routes are re-added as is.
  - If you do not provide a gateway and the new subnet is different, routes are discarded.
- Dynamic routes added by DHCP convert to static routes.

Segmented Management Instance Configuration using the CLI

This section provides procedures to configure segmented management instance using the command line interface (CLI).

Migrate a VLAN or CLIP IP address to the Segmented Management Instance

Perform this procedure to migrate a new routing VLAN with a new IP address or a new loopback IP address under a different VRF to the Segmented Management Instance. Alternatively, you can also use the **convert** command. For more information, see Change Management Instance Attributes on page 88.

Important

Choose a VLAN that does not have an IP interface on it. The upgrade process removes the IP configuration and network connectivity will be impacted.

About This Task

Note

Do not migrate interfaces used for routing purposes, for example, where you configure Layer 3 routing protocols.

This command does not apply to the OOB or mgmtEthernet interface. Releases that support this migration procedure automatically move the IP address on the mgmtEthernet interface from the routing stack to the Segmented Management Instance during the upgrade to this release.

Procedure

1. Enter Interface Configuration mode for either a VLAN or loopback interface:

   ```
   enable

   configure terminal

   interface vlan <1-4059> or interface loopback <1-256>
   ```

2. Select the interface address for migration:

   ```
   migrate-to-mgmt
   ```

3. View the designated interface addresses selected for migration:

   ```
   show mgmt migration
   ```

4. Save the configuration selected for migration:

   ```
   save config
   ```

Example

Identify an IP address currently assigned to an inband VLAN to migrate to the Management VLAN. The example assumes you already identified a CLIP address. The VRF column in **show mgmt migration** indicates where the interface is being moved from.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#interface vlan 20
Switch:1(config-if)#migrate-to-mgmt
Switch:1(config-if)#show mgmt migration

================================================================================
                                  Mgmt Migration Information

```

Configure a Segmented Management Instance Using quick-config-mgmt Utility

Use the following procedure to run the quick-config-mgmt utility script to ease the transition to the Segmented Management Instance.

Note

5320 Series does not support the OOB Management Instance.

The quick-config-mgmt utility recognizes existing configuration. For the OOB Management Instance, you can overwrite the existing configuration only. However, for the VLAN Management Instance, you can overwrite the existing configuration, or you can migrate the existing configuration to a coexistence of IP on both the routing VLAN and the management VLAN.

The quick-config-mgmt utility supports the following:

- IPv4 only
- only one interface at one time
- Out-of-Band mangagement and In-Band VLAN management

About This Task

You can use this procedure to help you transition to a new Segmented Management Instance. You can configure IPv4, static routes, and DHCP support for the Out-of-Band (OOB) Management Instance or for the In-Band VLAN Management Instance. If configuration exists for the interface type you selected, you are prompted to replace the configured interface or to quit the utility.

Important

If you configure DHCP, any other running DHCP instance is stopped and a new DHCP instance is created on the interface. This might cause loss of connectivity.

The default values are given in square brackets. You can input your values at the prompt or you can press `Enter` to accept the default values.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enter the following command to start the utility:

   ```
   quick-config-mgmt
   ```

   Important

   If DHCP mode cycle is enabled, the following warning message displays to inform you that DHCP client will be disabled, if you continue.

   ```
   Continuing will disable dhcp and may affect your connectivity
   to the DUT. Do you want to continue? y/n [n]:
   ```

Examples

The following examples show outputs from the **`quick-config-mgmt`** utility.

Configure the OOB Management Instance:

```
Switch:1(config)#quick-config-mgmt
Welcome to the management interface setup utility.
You will be requested for information to initially configure the switch.
When finished the information will be applied and stored as a part of the
configuration.

 Once the basic parameters are configured, additional configuration can proceed using
other management interfaces.
 Press q to abort at any time.
 Management interface types:
    1 - Out of band management port
    3 - In-band port-based VLAN
 Please enter management interface type or "q" to quit. [1]:
 Please enter the Management Address IPv4 address, "d" for DHCP configuration or "q" to
quit [192.0.2.2]:
 Please enter the Management Address Mask IPv4 address or "q" to quit [255.255.255.0]:
 Please enter the Default Gateway Address IPv4 address, 0.0.0.0 for no default gateway,
or "q" to quit [192.0.2.5] :
 Management interface created successfully
```

Replace an existing OOB Management Instance configuration:

```
Switch:1(config)#quick-config-mgmt
Welcome to the management interface setup utility.
You will be requested for information to initially configure the switch.
When finished the information will be applied and stored as a part of the
configuration.

 Once the basic parameters are configured, additional configuration can proceed using
other management interfaces.
 Press q to abort at any time.
 Management interface types:
    1 - Out of band management port
    3 - In-band port-based VLAN
 Please enter management interface type or "q" to quit. [1]:
 MGMT OOB is already configured.
 Continuing may remove parts or all of current config.
 Do you want to continue? y/n [y]:
 Please enter management interface type or "q" to quit. [1]:
 Please enter the Management Address IPv4 address, "d" for DHCP configuration or "q" to
quit [192.0.2.2]:
 Please enter the Management Address Mask IPv4 address or "q" to quit [255.255.255.0]:
 Please enter the Default Gateway Address IPv4 address, 0.0.0.0 for no default gateway,
or "q" to quit [192.0.2.5] :
 Management interface created successfully
```

Configure the In-band port-based VLAN Management Instance by removing parts of or all of the existing VLAN configuration:

```
Switch:1(config)#quick-config-mgmt
Welcome to the management interface setup utility.
You will be requested for information to initially configure the switch.
When finished the information will be applied and stored as a part of the
configuration.

 Once the basic parameters are configured, additional configuration can proceed using
other management interfaces.
 Press q to abort at any time.
 Management interface types:
    1 - Out of band management port
    3 - In-band port-based VLAN
 Please enter management interface type or "q" to quit. [1]: 3
```

```
 MGMT VLAN is already configured.
 Continuing may remove parts or all of current config.
 Do you want to continue? y/n [n]: y
 Please enter VLAN ID (2-4059) or "q" to quit [4059]: 2
 VLAN 2 is already in use.
 Do you want to re-use existing vlan configuration? y/n/q: [n]
 This option will remove all current config on VLAN 2.
 Please enter port to be added to the in-band management VLAN or "q" to quit [1/1]:
 Please enter the Management Address Mask IPv4 address or "q" to quit [255.255.255.0]:
 Please enter the Default Gateway Address IPv4 address, 0.0.0.0 for no default gateway,
or "q" to quit [192.0.2.5] :
 Management interface created successfully
```

Configure the In-band port-based VLAN Management Instance by reusing the existing VLAN configuration:

```
Switch:1(config)#quick-config-mgmt
Welcome to the management interface setup utility.
You will be requested for information to initially configure the switch.
When finished the information will be applied and stored as a part of the
configuration.

 Once the basic parameters are configured, additional configuration can proceed using
other management interfaces.
 Press q to abort at any time.
 Management interface types:
    1 - Out of band management port
    3 - In-band port-based VLAN
 Please enter management interface type or "q" to quit. [1]: 3
 MGMT VLAN is already configured.
 Continuing may remove parts or all of current config.
 Do you want to continue? y/n [n]: y
 Please enter VLAN ID (2-4059) or "q" to quit [4059]: 2
 VLAN 2 is already in use.
 Do you want to re-use existing vlan configuration? y/n/q: [y]
 Please enter port to be appended to the in-band management VLAN or leave empty
 to keep currently configured ports or "q" to quit []: 1/1
 Please enter the Management Address IPv4 address, "d" for DHCP configuration or "q" to
quit [192.0.2.2]:
 Please enter the Management Address Mask IPv4 address or "q" to quit [255.255.255.0]:
 Please enter the Default Gateway Address IPv4 address, 0.0.0.0 for no default gateway,
or "q" to quit [192.0.2.5] :
 Management interface created successfully
```

Configure the In-band port-based VLAN Management Instance by reusing the existing VLAN configuration when IP address is configured and coexistance of mgmt and routing on same VLAN is desired:

```
Switch:1(config)#quick-config-mgmt
Welcome to the management interface setup utility.
You will be requested for information to initially configure the switch.
When finished the information will be applied and stored as a part of the
configuration.

 Once the basic parameters are configured, additional configuration can proceed using
other management interfaces.
 Press q to abort at any time.
 Management interface types:
    1 - Out of band management port
    3 - In-band port-based VLAN
 Please enter management interface type or "q" to quit. [1]: 3
 MGMT VLAN is already configured.
 Continuing may remove parts or all of current config.
```

```
 Do you want to continue? y/n [n]: y
 Please enter VLAN ID (2-4059) or "q" to quit [4059]: 2
 VLAN 2 is already in use.
 Do you want to re-use existing vlan configuration? y/n/q: [y]
 Please enter port to be appended to the in-band management VLAN or leave empty
 to keep currently configured ports or "q" to quit []: 1/1
 IP address is already configured on VLAN 2.
 Do you want to configure coexistence of mgmt and routing on the same vlan? y/n/q: [y]
 Please enter the Management Address IPv4 address, "d" for DHCP configuration or "q" to
quit [192.0.2.2]:
 Please enter the Management Address Mask IPv4 address or "q" to quit [255.255.255.0]:
 Please enter the Default Gateway Address IPv4 address, 0.0.0.0 for no default gateway,
or "q" to quit [192.0.2.5] :
 Management interface created successfully
```

Configure the In-band port-based VLAN Management Instance by reusing the existing VLAN configuration when IP address is configured but coexistance of mgmt and routing on same VLAN is not desired:

```
Switch:1(config)#quick-config-mgmt
Welcome to the management interface setup utility.
You will be requested for information to initially configure the switch.
When finished the information will be applied and stored as a part of the
configuration.

 Once the basic parameters are configured, additional configuration can proceed using
other management interfaces.
 Press q to abort at any time.
 Management interface types:
    1 - Out of band management port
    3 - In-band port-based VLAN
 Please enter management interface type or "q" to quit. [1]: 3
 MGMT VLAN is already configured.
 Continuing may remove parts or all of current config.
 Do you want to continue? y/n [n]: y
 Please enter VLAN ID (2-4059) or "q" to quit [4059]: 2
 VLAN 2 is already in use.
 Do you want to re-use existing vlan configuration? y/n/q: [y]
 Please enter port to be appended to the in-band management VLAN or leave empty
 to keep currently configured ports or "q" to quit []: 1/1
 IP address is already configured on VLAN 2.
 Do you want to configure coexistence of mgmt and routing on the same vlan? y/n/q: [n]
 Management interface created successfully
```

Create a Segmented Management Instance

You must create a Management Instance to gain access to specific management applications. After you create the Management Instance, you can add an IP address to it and configure route redistribution to advertise reachability of the Management Instance to the rest of the network.

About This Task

The Management Instance supports different management interface types. When you create the Management Instance, you specify the interface type and the switch automatically creates the appropriate instance ID for that type.

A management VLAN is used for Layer 2 deployments. In a Layer 3 routing or Fabric deployment, use a management CLIP. For Out-of-band Management, use a management OOB.

Each Management Instance supports a IPv4 and IPv6 (global scope) management address for use by management applications.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Create the Management Instance required for your deployment:

   a. To create a management CLIP:

      ```
      mgmt clip [vrf WORD<1-16>]
      ```

      

      Note

      If you do not specify a VRF, the management CLIP uses the GRT.

      OR

   b. To create a management OOB:

      ```
      mgmt oob
      ```

      OR

   c. To create a management VLAN and associate it with an existing port-based VLAN:

      ```
      mgmt vlan <2-4059>
      ```

3. Enable the Management Instance:

   ```
   enable
   ```

Example

Create and enable a Management CLIP:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#mgmt clip
Switch:1(mgmt:clip)#enable
```

Create and enable a Management OOB:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#mgmt oob
Switch:1(mgmt:oob)#enable
```

Create and enable a Management VLAN:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#mgmt vlan 20
Switch:1(mgmt:vlan)#enable
```

Delete a Segmented Management Instance

Use this task to delete a Management Instance. Deleting the Management Instance removes the IP address, and changes the associated VRF for a management CLIP.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Delete the Management Instance:

   ```
   no mgmt {clip | oob | vlan}
   ```

Configure the DHCP Client for a Segmented Management Instance

Use this task to configure the DHCP Client to obtain an IPv4 address for the Management Instance VLAN interface or Out-of-Band interface.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable and configure the DHCP Client for a management interface:

   ```
   mgmt dhcp-client {cycle | oob | vlan}
   ```

Example

The following example configures the DHCP Client to cycle IPv4 requests for the management OOB interface, and then the In-Band management VLAN interface; priority is given to the OOB interface. The system cycles attempts until one management interface receives an IP address from the DHCP server:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#mgmt dhcp-client cycle
```

Variable Definitions

The following table defines parameters for the **mgmt dhcp-client** command.

Variable	Value
cycle Note: Exception: not supported on 5320 Series	DHCP Client cycles IP requests for in-band VLAN and Out-of-Band management interfaces.
oob Note: Exception: not supported on 5320 Series	DHCP Client requests an IP address for the Out-of-Band management interface.
vlan	DHCP Client requests an IP address for the VLAN management interface.

Configure an IP Address for a Segmented Management Instance

Use this task to add an IPv4 or IPv6 address to a Management Instance.

Before You Begin

- Ensure the IP address you plan to assign is not in use by an existing VLAN or CLIP IP subnet configured on the switch.
- If the DHCP client is configured for a Segmented Management Instance, you must manually disable the client. Configuring an IP address does not automatically disable the DHCP client.

Procedure

1. Enter Global Configuration mode:
   ```
   enable

   configure terminal
   ```
2. Enter the configuration mode for the Management Instance:
   ```
   mgmt {clip | oob | vlan}
   ```
3. Add an IPv4 address:
   ```
   ip address {A.B.C.D [A.B.C.D] | A.B.C.D/X}
   ```
4. Add an IPv6 address:
   ```
   ipv6 address WORD<0-255>
   ```

Example

Add an IPv4 address to the VLAN Management Instance:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#ip address 192.0.2.12/24
```

Add an IPv4 address to the OOB Management Instance:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#mgmt oob
Switch:1(mgmt:oob)#ip address 192.0.2.12 255.255.255.0
```

Add an IPv6 address to the CLIP Management Instance:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#mgmt clip
Switch:1(mgmt:clip)#ipv6 address 2001:DB8::1/128
```

Configure a Segmented Management Instance Interface as Default Topology IP

Use this task to configure a Management Instance with a default topology IP.

Note

You can only configure one Management Instance interface as the default topology IP.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enter the configuration mode for the Management Instance:

   ```
   mgmt {clip | oob | vlan}
   ```

3. Configure the Management Instance as the default topology IP.

   ```
   force-topology-ip
   ```

Example

The following example configures the Segmented Management Instance VLAN as the default topology IP:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#force-topology-ip
```

Configure Static Routes for a Management Instance

Use this task to configure static routes for Management Instances.

About This Task

For the Management Instance CLIP, you do not need to configure a default or static route. This interface type uses all routing information learned by protocols attached to the VRF. For more information about how to associate a VRF with the CLIP interface, see Create a Segmented Management Instance on page 80.

For the Management Instance OOB and VLAN, you must configure a default or static route to reach the next-hop gateway; no routing protocol information is used to access off-link networks.

You can configure up to 100 IPv4 and IPv6 static routes.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enter the configuration mode for the Management Instance:

   ```
   mgmt {clip | oob | vlan}
   ```

3. Configure a static route:

   ```
   ip route <A.B.C.D A.B.C.D | A.B.C.D/X> next-hop <A.B.C.D> [weight <1-65535>]
   ```

   OR

   ```
   ipv6 route WORD<0-255> [next-hop WORD<0-255>] [weight <1-65535>]
   ```

Example

Add a static route to configure routing for a Management Instance:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#ip route 192.0.2.2/24 next-hop 198.51.100.1
```

Variable definitions

The following table defines parameters for the **`ip route`** and **`ipv6 route`** commands.

Variable	Value
<A.B.C.D A.B.C.D | A.B.C.D/X>	Specifies the IP address and mask in one of the following formats: • A.B.C.D A.B.C.D • A.B.C.D/X
next-hop <A.B.C.D> or *next-hop WORD<0-255>*	Specifies the next hop address for the static route. Use an IP in the same subnet as the management VLAN IP address.
weight <1-65535>	Specifies the static route cost. The default is 100 for CLIP, 200 for VLAN, and 300 for OOB. The management CLIP uses an internal static route with a weight of 100. If you use both CLIP and VLAN and need to force all default traffic out the management VLAN interface, configure a default static route with a weight lower than 100.
WORD<0-255>	Specifies the IPv6 address.

Configure Fragmented ICMP Packet Filtering on a Segmented Management Instance

About This Task

Use this task to enable fragmented ICMP packet filtering on a Segmented Management Instance.

Procedure

1. Enter Global Configuration mode:

   ```
   enable
   ```

   ```
   configure terminal
   ```
2. Enter the configuration mode for the Management Instance:

   ```
   mgmt {clip | oob | vlan}
   ```
3. Enable fragmented ICMP packet filtering:
   - For IPv4:

     ```
     ip icmp drop-fragments
     ```
   - For IPv6:

     ```
     ipv6 icmp drop-fragments
     ```

View Fragmented ICMP packet filtering Statistics on a Segmented Management Instance

About This Task

Use this task to view Fragmented ICMP packet filtering details on a Management Instance.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View Fragmented ICMP packet filtering:
   - For IPv4:

     ```
     show mgmt ip icmp [clip | oob | vlan]
     ```
   - For IPv6:

     ```
     show mgmt ipv6 icmp [clip | oob | vlan]
     ```

Variable Definitions

The following table defines parameters for the **show mgmt ip icmp** command.

Variable	Value
clip	Displays the IPv4 or IPv6 ICMP information specific to the management CLIP.
oob	Displays the IPv4 or IPv6 ICMP information specific to the management OOB.
vlan	Displays the IPv4 or IPv6 ICMP information specific to the management VLAN.

Configure MAC-offset for a Management VLAN Instance

Use this task to configure MAC-offset for a Management VLAN instance.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enter the MAC-offset for a Management VLAN instance:

   ```
   mgmt vlan mac-offset <MAC-offset>
   ```

   Note
   Different hardware platforms support different ranges.

Example

Configure the MAC-offset for the Management VLAN instance:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#mac-offset <0-511>
```

Variable Definitions

The following table defines parameters for the **mgmt vlan** interface.

Variable	Value
mac-offset <MAC-offset>	Specifies a number by which to offset the MAC address from the chassis MAC address. This ensures that each IP address has a different MAC address. If you omit this variable, a unique MAC offset is automatically generated. Different hardware platforms support different ranges. To see which range is available on the switch, use the CLI command completion Help.

Change Management Instance Attributes

Use this task to change the IP address, VLAN, VRF, or default gateway for a Management Instance while you actively manage the switch over the same instance.

Important

Change the parameters in the following order:

1. VLAN or VRF
2. ports-tagged, ports-untagged-, or I-SID
3. IP address or default gateway

About This Task

You cannot change parameters for more than one Management Instance operation at a time.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enter the configuration mode for the Management Instance:

   ```
   mgmt {clip | oob | vlan}
   ```

3. Use one of the following Management Instances interfaces to configure the new values:

   a. Configure new Management Instance VLAN parameters:

   ```
   convert [vlan <1-4059>] [i-sid <1-16777215>] [ports-tagged {slot/
   port[/sub-port][-slot/port[/sub-port]][,...]}] [ports-untagged{slot/
   port[/sub-port][-slot/port[/sub-port]][,...]}] [ip {<A.B.C.D/X>|
   <A.B.C.D> <A.B.C.D>}] [gateway <A.B.C.D>] [rollback <0-3600>]
   ```

   

   Important

   After you configure the new values, the existing Management Instance VLAN is deleted and connectivity to the switch can be lost. You must reconnect to the switch before you can issue the `mgmt convert-commit` command.

   b. Configure new Management Instance OOB parameters:

   ```
   convert [ip {<A.B.C.D/X>|<A.B.C.D> <A.B.C.D>}] [gateway <A.B.C.D>]
   [rollback <0-3600>]
   ```

   c. Configure new Management Instance CLIP parameters:

   ```
   convert [vrf WORD <1-16>] [ip {<A.B.C.D/X>|<A.B.C.D> <A.B.C.D>}]
   [rollback <0-3600>]
   ```

   

   Note

   If the VRF does not exist before you issue the **`convert`** command, the VRF is automatically created in the background. For this VRF to function properly, you must configure either SPBM Layer 3 VSN or IP interfaces and routing protocols.

4. Log on to Global Configuration mode to commit the parameter changes:

   ```
   mgmt convert-commit
   ```

   Note
   Commit the change within 120 seconds (default) of issuing the `mgmt convert-commit` command. Otherwise, the configuration changes automatically roll back to the previous configuration.

Examples

The following examples show the change options attributes for a Management Instance VLAN:

Convert a management VLAN to a new VLAN ID:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#convert vlan 300
```

```
Switch1:(mgmt:vlan)#1 2021-09-24T21:41:54.627Z 4902 CP1 - 0x003c8677 -
00000000 GlobalRouter NLS_BASE INFO Mgmt convert: Dynamically moved the following ports
from vlan 10 to
new mgmt vlan 300  that had ARP entries: 1/1,

Mgmt convert: new mgmt
vlan instance created successfully with IP address 100.1.1.66/24
1 2021-09-24T21:41:54.719Z 4902 CP1 - 0x003c867e - 00000000 GlobalRouter NLS_BASE INFO
Convert on mgmt vlan
instance: Mgmt convert executed successfully

.
<reconnect to switch…>
Login: rwa
Password: ***

Mgmt convert: Please issue 'mgmt convert commit' before 120 seconds rollback timer
expires otherwise mgmt vlan
config change will be reverted
```

Convert a management VLAN to new IP address in the same subnet and in the same VLAN:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#convert ip 10.10.10.30/24
```

Convert a management VLAN to new IP address in a different subnet.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#convert ip 11.11.11.30/24 gateway 11.11.11.1
```

Convert a management VLAN to new VLAN ID with specified port or ports:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#convert vlan 300 ports-untagged 1/2 ports-tagged 1/4
```

Convert a management VLAN to new VLAN ID with a specified I-SID:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#convert vlan 300 i-sid 4300
```

Convert a management VLAN to new VLAN ID with a new IP address and default Gateway:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#convert vlan 300 ip 11.11.11.30/24 gateway 11.11.11.1
```

Convert a management VLAN with all options:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#convert vlan 300 ports-untagged 1/2 ports-tagged 1/4 i-sid 43000
ip 11.11.11.30/24 gateway 11.11.11.1
```

Convert a management VLAN to new I-SID (DvR Leaf only):

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#convert i-sid 4000
```

Convert a management VLAN with a faster rollback option (default is 120 seconds):

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#convert vlan 300 rollback 60
```

Convert a management VLAN with no rollback option:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#convert vlan 300 rollback 0
```

The following examples show the change options attributes for Management Instance CLIP.

Convert a management CLIP from one VRF to another VRF. The IP address is the same:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt clip
Switch:1(mgmt:clip)#convert vrf blue
```

```
WARNING: the specified vrf does not exist - connectivity to the mgmt clip will be lost
until l3vsn or
ip interfaces for the given vrf are provisioned.
Continue with this operation (y/n) ? n
```

Note

If the VRF does not exist before you issue the **convert** command, the VRF is automatically created in the background. In order for this VRF to function properly, you must configure either SPBM Layer 3 VSN or IP interfaces and routing protocols.

Convert a management CLIP to a new IP address. The VRF is the same:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt clip
Switch:1(mgmt:vlan)#convert ip 30.30.30.100/32
```

Convert a management CLIP to new IP address and VRF:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt clip
Switch:1(mgmt:vlan)#convert vrf blue ip 30.30.30.100/32
```

The following examples show the change options attributes for Management Instance Out-Of-Band (OOB):

Convert a management OOB to a new IP address in the same subnet:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt oob
Switch:1(mgmt:vlan)#convert ip 20.20.20.100/24
```

Convert a management OOB IP address to a different subnet:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt oob
Switch:1(mgmt:vlan)#convert ip 21.21.21.100/24 gateway 21.21.21.1
```

Variable Definitions

The following table defines parameters for the **convert** command.

Variable	Value
<A.B.C.D A.B.C.D | A.B.C.D/X>	Specifies the IP address and subnet mask. This parameter applies to the following Management Instance interface types: • CLIP • OOB • VLAN
<A.B.C.D>	Specifies the gateway IP address. This parameter applies to the following Management Instance interface types: • OOB • VLAN
<1-16777215>	Specifies the service instance identifier (I-SID). This parameter applies to the Management Instance VLAN interface type. Note: You can specify the I-SID for a switch not configured as a DvR Leaf node.
{slot/port[/sub-port][-slot/port[/sub-port]][,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<0-3600>	Specifies the time in seconds between when the command is issued and when the command changes automatically roll back to the previous configuration. The default is 120 seconds. To disable the rollback, enter 0.
<2-4059>	Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. This parameter applies to the Management Instance VLAN interface type only.
WORD<0-16>	Specifies the vrf name. This parameter applies to the Management Instance CLIP interface type only.

View Segmented Management Instance Information

Use this task to view Management Instance information.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View general configuration information:

   ```
   show mgmt interface [clip | oob | vlan]
   ```

3. View operational routes for the Management Instance:

   ```
   show mgmt ip route [clip | oob | vlan]
   ```

   OR

   ```
   show mgmt ipv6 route [clip | oob | vlan]
   ```

   

   Note
   Routes with a type of LOCAL have a metric equal to 1.

4. View configured static routes for the Management Instance:

   ```
   show mgmt ip route static [vlan | oob | clip]
   ```

   OR

   ```
   show mgmt ipv6 route static [vlan | oob | clip]
   ```

   

   Note
   Routes with a type of LOCAL have a metric equal to 256.

5. View the ARP or Neighbor Discovery cache information for the Management Instance:

   ```
   show mgmt ip arp [clip | oob | vlan]
   ```

   OR

   ```
   show mgmt ipv6 neighbor [clip | oob | vlan]
   ```

Example

```
Switch:1>show mgmt interface vlan

```

View Segmented Management Instance Statistics

Use this task to view Management Instance statistics.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View general Segmented Management Instance statistics:

   ```
   show mgmt statistics [clip | oob | vlan]
   ```
3. View ICMP statistics for the Management Instance:

   ```
   show mgmt ip icmp-statistics
   ```

   OR

   ```
   show mgmt ipv6 icmp-statistics
   ```
4. View IP statistics for the Management Instance:

   ```
   show mgmt ip ip-statistics
   ```

   OR

   ```
   show mgmt ipv6 ip-statistics
   ```
5. View the TCP connections for the Management Instance:

   ```
   show mgmt ip tcp-connections
   ```

   OR

   ```
   show mgmt ipv6 tcp-connections
   ```

6. View the TCP statistics for the Management Instance:
   ```
   show mgmt ip tcp-statistics
   ```
   OR
   ```
   show mgmt ipv6 tcp-statistics
   ```
7. View the UDP endpoints for the Management Instance:
   ```
   show mgmt ip udp-endpoints
   ```
   OR
   ```
   show mgmt ipv6 udp-endpoints
   ```
8. View the UDP statistics for the Management Instance:
   ```
   show mgmt ip udp-statistics
   ```
   OR
   ```
   show mgmt ipv6 udp-statistics
   ```
9. Enter Privileged EXEC mode:
   ```
   enable
   ```
10. (Optional) Clear all of the statistics for the Management Instance:
    ```
    clear mgmt statistics
    ```

Examples

```
Switch:1>show mgmt statistics

================================================================================================================================
                                        Mgmt Interface Stats Information
================================================================================================================================

Redistribution of CLIP Segmented Management Instance Examples

The CLIP Management Instance is added as a LOCAL route in the Control Processor Route Table Manager table and change list infrastructure. Existing route redistribution mechanisms redistribute local routes into the desired routing protocols within the associated VRF or across VRF instances.

Redistribute IPv4 CLIP Management Instance to OSPF in GRT

```
router ospf
redistribute direct
redistribute direct enable
exit
ip ospf apply redistribute direct
```

Redistribute IPv6 CLIP Management Instance to OSPF in GRT

```
router ospf
ipv6 redistribute direct
ipv6 redistribute direct enable
ipv6 ospf apply redistribute direct
```

Redistribute IPv4 CLIP Management Instance to OSPF in VRF

```
router vrf red
ip ospf redistribute direct
ip ospf redistribute direct enable
exit
ip ospf apply redistribute direct vrf red
```

Redistribute IPv6 CLIP Management Instance to OSPF in VRF

```
router vrf red
ipv6 ospf redistribute direct
ipv6 ospf redistribute direct enable
exit
ipv6 ospf apply redistribute direct vrf red
```

Redistribute IPv4 CLIP Management Instance to BGP in GRT

```
router bgp
redistribute direct
redistribute direct enable
ip bgp apply redistribute direct
```

Redistribute IPv6 CLIP Management Instance to BGP in GRT

```
router vrf
redistribute ipv6-direct
redistribute ipv6-direct enable
ipv6 bgp apply redistribute direct
```

Redistribute IPv4 CLIP Management Instance to BGP in VRF

```
router vrf red
ip bgp redistribute direct
ip bgp redistribute direct enable
exit
ip bgp apply redistribute direct vrf red
```

Redistribute IPv6 CLIP Management Instance to BGP in VRF

```
router vrf red
ip bgp redistribute ipv6-direct
ip bgp redistribute ipv6-direct enable
exit
ipv6 bgp apply redistribute direct vrf red
```

Accept Policy for IPv4 CLIP Management Instance in GRT to VRF Red (I-SID 200)

```
#grt-->vrf
router vrf red
isis accept i-sid 0
isis accept i-sid 0 enable
isis redistribute direct
isis redistribute direct enable
exit
isis apply accept vrf red
isis apply redistribute direct vrf red

#vrf-->grt
router isis
accept i-sid 200
accept i-sid 200 enable
exit
isis apply accept
```

Accept Policy for IPv6 CLIP Management Instance in GRT to VRF Red (I-SID 200)

```
#grt-->vrf
router vrf red
ipv6 isis accept i-sid 0
```

```
ipv6 isis accept i-sid 0 enable
ipv6 isis redistribute direct
ipv6 isis redistribute direct enable
exit
ipv6 isis apply accept vrf red
ipv6 isis apply redistribute direct vrf red

#vrf-->grt
router isis
ipv6 accept i-sid 200
ipv6 accept i-sid 200 enable
exit
ipv6 isis apply accept
```

Accept Policy for IPv4 CLIP Management Instance in VRF Blue (I-SID 300) to GRT

```
#vrf --> grt
router isis
accept i-sid 300
accept i-sid 300 enable
redistribute direct
redistribute direct enable
exit
isis apply accept
isis apply redistribute direct

#grt --> vrf
router vrf blue
isis accept i-sid 0
isis accept i-sid 0 enable
exit
isis apply accept vrf blue
```

Accept Policy for IPv6 CLIP Management Instance in VRF Blue (I-SID 300) to GRT

```
#vrf --> grt
router isis
ipv6 accept i-sid 300
ipv6 accept i-sid 300 enable
ipv6 redistribute direct
ipv6 redistribute direct enable
exit
ipv6 isis apply accept
ipv6 isis apply redistribute direct

#grt --> vrf
router vrf blue
ipv6 isis accept i-sid 0
ipv6 isis accept i-sid 0 enable
exit
ipv6 isis apply accept vrf blue
```

Segmented Management Instance Configuration for Fabric Engine using EDM

This section provides procedures to configure segmented management instance using the EDM.

Migrate an IP Address to a Segmented Management Instance

Perform this procedure to migrate a new routing VLAN with a new IP address or a new loopback IP address under a different VRF to the Segmented Management Instance. Alternatively, you can also use the **convert** command.

Important

Choose a VLAN that does not have an IP interface on it. The upgrade process removes the IP configuration and network connectivity will be impacted.

About This Task

You cannot migrate interfaces used for routing purposes, for example, where you configure Layer 3 routing protocols.

This command does not apply to the OOB or mgmtEthernet interface. Releases that support this migration procedure automatically move the IP address on the mgmtEthernet interface from the routing stack to the Segmented Management Instance.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **Migrate** tab.
5. Select **Insert**.
6. Select the instance type, either **clip** or **vlan**.
7. Specify the existing VLAN or loopback ID.
8. Select **Insert**.

Migrate field descriptions

Use the data in the following table to use the **Migrate** tab.

Name	Description
InstanceId	Specifies the interface instance to migrate.
InterfaceIndex	Shows the interface index of the identified interface.
InterfaceType	Shows the interface type.
Description	Shows the interface description.
VlanId	Specifies the VLAN ID for a port-based VLAN.
LoopbackId	Specifies the loopback ID.
VrfName	Shows the VRF associated with the loopback interface.
IpAddress	Shows the IPv4 address to migrate.
IpMask	Shows the subnet mask for the IPv4 address.

Name	Description
Ipv6Address	Shows the IPv6 address to migrate.
Ipv6PrefixLength	Shows the prefix length for the IPv6 address.

Configure a Segmented Management Instance

You must create a Management Instance to gain access to specific management applications.

About This Task

The Management Instance supports different management interface types. When you create the Management Instance, you specify the interface type and the switch automatically creates the appropriate instance ID for that type.

In a Layer 2 routing deployment, use a management VLAN. In a Layer 3 routing or Fabric deployment, use a management CLIP. To separate management network from Layer 2 and Layer 3, use a management OOB.

Each Management Instance supports a IPv4 and IPv6 (global scope) management address for use by management applications.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Expand **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **Interface** tab.
5. Select **Insert**.
6. In the **InstanceId** field, select the type of Management Instance to create.
7. (Optional) For a CLIP Management Instance, in the **VrfName** field, type the VRF name to associate with the CLIP instance.

   Note

   If you want to associate the GRT with the CLIP instance, type **GlobalRouter** in the **VrfName** field.

8. For a VLAN Management Instance, in the **VlanId** field, type the VLAN ID to associate the management VLAN with an existing port-based VLAN.
9. For an OOB Management Instance, in the **OOBIfindex** field, select the interface port number to associate for Out-of-Band management.
10. Select the **State** check box to enable the instance.
11. To specify the interface as the default topology IP for LLDP advertisements, select **InterfaceTopologyIpFlag**.
12. To administratively enable RMON for the interface, select **RmonAdminEnable**.
13. For a DvR Leaf node, in the **Isid** field, type the I-SID value to associate with the Management Instance VLAN.
14. Select **Insert**.

Interface *Field Descriptions*

Use the data in the following table to use the **Interface** tab.

Name	Description
InstanceId	Indicates the Management Instance type associated with this entry.
InterfaceType	Indicates the interface type.
VlanId	Specifies the VLAN ID to associate with the management VLAN.
OOBIfindex	Specifies the interface ID to associate with the management OOB.
VrfName	Specifies the VRF name to associate with the management CLIP .
State	Indicates if the interface is enabled for this instance. The default is disabled.
InterfaceMacAddr	Indicates the MAC address for the interface.
InterfaceName	Indicates the interface name.
InterfaceTopologyIpFlag	Specifies if the interface is the default topology source IP.
ZtpOn	Identifies the Zero Touch Provisioning status for the interface.
RmonAdminEnable	Specifies if RMON is administrative enabled for the interface.
RmonOperEnable	Indicates the RMON operational status for the interface.
RmonIpAddress	Indicates the RMON IP address for the interface.
MacOffset	Translates the IP address into a MAC address.
DropIcmpFragEnable	Enables IPv4 Fragmented ICMP packet filtering on the Management Instance. The default is disabled.
DropIcmpv6FragEnable	Enables IPv6 Fragmented ICMP packet filtering on the Management Instance. The default is disabled.
Isid	Specifies the I-SID number that associated with the Management Instance VLAN for the DvR Leaf node. For non DvR node, the default I-SID value is 0 and this value cannot be edited.

Configure DHCP Client for a Segmented Management Instance

Use this task to configure a DHCP Client on a management interface.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit** > **Mgmt Instance**.
2. Select **Mgmt**.
3. Select the **Dhcp** tab.
4. In the **Client** field, select an option to configure the DHCP Client.
5. Select **Apply**.

Dhcp Field Descriptions

Use the data in the following table to use the **Dhcp** tab.

Name	Description
Client Note: Exception: **oob** and **cycle** not supported on 5320 Series	Specifies the DHCP client configuration: • **oob** - DHCP Client on the Out-of-Band management interface. • **vlan** - DHCP Client on the VLAN management interface. • **cycle** - DHCP Client cycles between in-band and Out-of-Band management interfaces until an IP address is obtained on one management interface. • **disable** - DHCP Client is disabled.
ClientPreferredInterface	Shows the DHCP Client preferred management interface when in cycle mode. On reboot, the system first attempts to aquire a DHCP IP address on the preferred interface.

View IPv4 ARP Information for a Segmented Management Instance

Use this task to view IPv4 Address Resolution Protocol (ARP) information.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Expand **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **IpArp** tab.

IpArp Field Descriptions

Use the data in the following table to use the **IpArp** tab.

Name	Description
Address	Shows the IPv4 address of the ARP entry.
Instance	Shows the Management Instance ID.
IntfName	Shows the Management Instance interface name for the ARP entry.
MacAddr	Shows the MAC address for the ARP entry.
State	Shows the state of the ARP entry. The state can be one of the following: • reachable • stale • permanent • failed • delay

View IPv6 ND Information for a Segmented Management Instance

Use this task to view IPv6 Neighbor Discovery (ND) information.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Expand **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **Ipv6Neighbor** tab.

Ipv6Neighbor Field Descriptions

Use the data in the following table to use the **Ipv6Neighbor** tab.

Name	Description
Addr	Shows the IPv6 address of the neighbor entry.
Instance	Shows the Management Instance ID.
IntfName	Shows the Management Instance interface name for the neighbor entry.
MacAddr	Shows the MAC address for the neighbor entry.
State	Shows the state of the neighbor entry. The state can be one of the following: • reachable • stale • permanent • failed • delay

Configure IPv4 Static Routes for a Management Instance

Use this task to configure IPv4 static routes for Management Instances.

About This Task

For the Management Instance CLIP, you do not need to configure a default or static route. This interface type uses all routing information learned by protocols attached to the VRF. For more information about how to associate a VRF with the CLIP interface, see Configure a Segmented Management Instance on page 104.

For the Management Instance OOB and VLAN, you must configure a default or static route to reach the next-hop gateway; no routing protocol information is used to access off-link networks.

You can configure up to 100 IPv4 and IPv6 static routes.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Expand **Mgmt Instance**.
3. Select **Mgmt**.

4. Select the **IpStaticRoute** tab.
5. Select **Insert**.
6. For the **Instance**, select the type of Management Instance interface.
7. Type the destination IP address and mask.
8. Type the next hop IP address.
9. Type a metric value.
10. Select **Insert**.

IpStaticRoute *Field Descriptions*

Use the data in the following table to use the **IpStaticRoute** tab.

Name	Description
Instance	Specifies the Management Instance.
DestAddr	Specifies the destination IP address.
DestMask	Specifies the destination mask.
NextHop	Specifies the next hop address for the static route. Use an IP address in the same subnet as the management VLAN IP address.
IntfName	Specifies the Management Instance interface name for the route entry.
Metric	Specifies the static route cost. The default is 200. The management CLIP uses an internal static route with a weight of 100. If you use both CLIP and VLAN and need to force all default traffic out the management VLAN interface, configure a default static route with a weight lower than 100.
State	Shows if the route is active or inactive.

Configure IPv6 Static Routes for a Management Instance

Use this task to configure IPv6 static routes for Management Instances.

About This Task

For the Management Instance CLIP, you do not need to configure a default or static route. This interface type uses all routing information learned by protocols attached to the VRF. For more information about how to associate a VRF with the CLIP interface, see Configure a Segmented Management Instance on page 104.

For the Management Instance OOB and VLAN, you must configure a default or static route to reach the next-hop gateway; no routing protocol information is used to access off-link networks.

You can configure up to 100 IPv4 and IPv6 static routes.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Expand **Mgmt Instance**.

3. Select **Mgmt**.
4. Select the **Ipv6StaticRoute** tab.
5. Select **Insert**.
6. For the **Instance**, select elect the type of Management Instance interface.
7. Type the destination IPv6 address and prefix length.
8. Type the next hop IPv6 address.
9. Type a metric value.
10. Select **Insert**.

Ipv6StaticRoute Field Descriptions

Use the data in the following table to use the **Ipv6StaticRoute** tab.

Name	Description
Instance	Specifies the Management Instance.
DestAddr	Specifies the destination IP address.
DestPrefixLen	Specifies the destination prefix length.
NextHop	Specifies the next hop address for the static route. Use an IP address in the same subnet as the management VLAN IP address.
IntfName	Specifies the Management Instance interface name for the route entry.
Metric	Specifies the static route cost. The default is 200. The management CLIP uses an internal static route with a weight of 100. If you use both CLIP and VLAN and need to force all default traffic out the management VLAN interface, configure a default static route with a weight lower than 100.
State	Shows if the route is active or inactive.

View IPv4 Operational Routes for a Segmented Management Instance

Use this task to view IPv4 operational routes.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **IpRoute** tab.

IpRoute Field Descriptions

Use the data in the following table to use the **IpRoute** tab.

Name	Description
DestAddr	Shows the destination address of the route entry.
DestMask	Shows the destination mask of the route entry.
Metric	Shows the metric, or cost, assigned to the route entry. If multiple entries exist to the same destination, the metric determines which route is used. Routes with a type of LOCAL have a metric equal to 1.
Instance	Shows the Management Instance ID.
NextHop	Shows the next hop for the route entry.
IntfName	Shows the Management Instance interface name for the route entry.
Type	Shows the type of route entry.

View IPv6 Operational Routes for a Segmented Management Instance

Use this task to view IPv6 operational routes.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **Ipv6Route** tab.

Ipv6Route Field Descriptions

Use the data in the following table to use the **Ipv6Route** tab.

Name	Description
DestAddr	Shows the destination address of the route entry.
PrefixLen	Shows the destination prefix length of the route entry.
Metric	Shows the metric, or cost, assigned to the route entry. If multiple entries exist to the same destination, the metric determines which route is used. Routes with a type of LOCAL have a metric equal to 256.
Instance	Shows the Management Instance ID.
NextHop	Shows the next hop for the route entry.
IntfName	Shows the Management Instance interface name for the route entry.
Type	Shows the type of route entry.

View Topology IP for a Segmented Management Instance

Use this task to view the default topology IP address for a Segmented Management Instance.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **TopologyIp** tab.

TopologyIp Field Descriptions

Use the data in the following table to use the **TopologyIp** tab.

Name	Description
AddrType	Shows the IP address type for the topology IP.
Addr	Shows the IP address for the topology IP.
InterfaceName	Shows the interface name of the identified interface for the topology IP.
InstanceId	Specifies the interface instance for the topology IP.

Configure an IP Address for a Segmented Management Instance

Use this task to configure and view IPv4 address information for a Segmented Management Instance.

Before You Begin

- Ensure the IP address you plan to assign is not in use by an existing VLAN or CLIP IP subnet configured on the switch.
- If the DHCP client is configured for a Segmented Management Instance, you must manually disable the client. Configuring an IP address does not automatically disable the DHCP client.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **IpAddress** tab.
5. Select **Insert**.
6. Select the Segmented Management Instance interface type.
7. Type the address information.
8. Select **Insert**.

IpAddress *Field Descriptions*

Use the data in the following table to use the **IpAddress** tab.

Name	Description
InstanceId	Specifies the interface instance.
Address	Specifies IPv4 address for the interface instance. Ensure that the management CLIP IP address does not fall into the range of a configured VLAN IP address range as this is not allowed.
Mask	Specifies the subnet mask of the IP address.
AddrOrigin	Shows the IP address origin.
IntfName	Shows the interface name.

Configure an IPv6 Address for a Segmented Management Instance

Use this task to configure or view IPv6 address information for a Segmented Management Instance.

Before You Begin

- Ensure the IP address you plan to assign is not in use by an existing VLAN or CLIP IP subnet configured on the switch.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **Ipv6Address** tab.
5. Select **Insert**.
6. Select the Segmented Management Instance interface type.
7. Type the address information.
8. Select **Insert**.

Ipv6Address *Field Descriptions*

Use the data in the following table to use the **Ipv6Address** tab.

Name	Description
InstanceId	Specifies the interface instance.
Address	Specifies the IPv6 address for the interface instance. Ensure that the management CLIP IP address does not fall into the range of a configured VLAN IP address range as this is not allowed.
PrefixLength	Specifies the prefix length for the IPv6 address.
AddrOrigin	Shows the IPv6 address origin.
IntfName	Shows the interface name.
DadStatus	Shows the IPv6 DAD status of the address.

View Segmented Management Instance Statistics

View operational statistics for the Management Instance.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **Interface** tab.
5. Select a Management Instance by placing the cursor in a cell within the applicable row.
6. Select **Graph**.

Interface Counters Field Descriptions

Use the data in the following table to use the **Interface Counters** tab.

Name	Description
RxPkts	Counts the packets received on the Segmented Management Instance.
RxError	Counts the packets received with errors on the Segmented Management Instance.
RxDrop	Counts the packets received and dropped on the Segmented Management Instance.
TxPkts	Counts the packets transmitted on the Segmented Management Instance.
TxError	Counts the packets transmitted with errors on the Segmented Management Instance.
TxDrop	Counts the packets dropped before transmission on the Segmented Management Instance.

View IP Address Statistics for a Segmented Management Instance

Use this task to view IP address statistics for a Segmented Management Instance.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Mgmt Instance**.
3. Select **Stats**.
4. Select the **IP** tab.
5. To clear IP statistics, select **Clear Stats**.
6. To clear IP counters, select **Clear Counters**.

IP Field Descriptions

Use the data in the following table to use the **IP** tab.

Name	Description
InReceives	Shows the inbound packet statistics.
InHdrErrors	Shows the inbound packets with header errors statistics.
InAddrErrors	Shows the inbound packets with address errors statistics.
InUnknownProtos	Shows the inbound packets with unknown protocols statistics.
InDiscards	Shows the inbound packets discarded statistics.
InDelivers	Shows the inbound packets delivered statistics.
OutRequests	Shows the outbound packet requests statistics.
OutDiscards	Shows the outbound packets discarded statistics.
OutNotRoutes	Shows the outbound packets with no routes statistics.
ForwDatagrams	Shows the forwarded datagram packets statistics.
ReasmTimeout	Shows the packet reassembly timeouts statistics.
ReasmReqds	Shows the packet reassembly requests statistics.
ReasmOKs	Shows the successfully reassembled packets statistics.
ReasmFails	Shows the failed reassembled packets statistics.
FragOKs	Shows the successfully fragmented packets statistics.
FragFails	Shows the failed fragmented packets statistics.
FragCreates	Shows the fragments created statistics.

View IPv6 Address Statistics for a Segmented Management Instance

Use this task to view IPv6 address statistics for a Segmented Management Instance.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Mgmt Instance**.
3. Select **Stats**.
4. Select the **IPv6** tab.
5. To clear IP statistics, select **Clear Stats**.
6. To clear IP counters, select **Clear Counters**.

IPv6 Field Descriptions

Use the data in the following table to use the **IPv6** tab.

Name	Description
InReceives	Shows the inbound packet statistics.
InHdrErrors	Shows the inbound packets with header errors statistics.
InAddrErrors	Shows the inbound packets with address errors statistics.
InUnknownProtos	Shows the inbound packets with unknown protocols statistics.
InDiscards	Shows the inbound packets discarded statistics.
InDelivers	Shows the inbound packets delivered statistics.
InTooBigErrors	Shows the inboud packets too big errors statistics.
InNoRoutes	Shows the inbound packets with no routes statistics.
InTruncatedPkts	Shows the inbound packets truncated statistics.
InMcastPkts	Shows the inbound multicast packets statistics.
InOctets	Shows the inbound octets statistics.
InMcastOctets	Shows the inbound multicast octets statistics.
InBcastOctets	Shows the inbound broadcast octets statistics
InNoECTPkts	Shows the inbound packets with no Explicit Congestion Notification (ECN) statistics.
InECT1Pkts	Shows the inbound packets with ECT(1) statistics.
InECT0Pkts	Shows the inbound packets with ECT(0) statistics.
InCEPkts	Shows the inbound packets with Congestion Ecountered (CE) statistics.
OutRequests	Shows the outbound packet requests statistics.
OutDiscards	Shows the outbound packets discarded statistics.
OutNoRoutes	Shows the outbound packets with no routes statistics.
OutForwDatagrams	Shows the forwarded datagram packets statistics.
OutMcastPkts	Shows the outbound multicast packets statistics.
OutOctets	Shows the outbound octets statistics.
OutMcastOctets	Shows the outbound multicast octets statistics.
OutBcastOctets	Shows the outpound broadcast octets statistics.
ReasmTimeout	Shows the packet reassembly timeouts statistics.
ReasmReqds	Shows the packet reassembly requests statistics.
ReasmOKs	Shows the successfully reassembled packets statistics.
ReasmFails	Shows the failed reassembled packets statistics.
FragOKs	Shows the successfully fragmented packets statistics.

Name	Description
FragFails	Shows the failed fragmented packets statistics.
FragCreates	Shows the fragments created statistics.

View IP ICMP Statistics for a Segmented Management Instance

Use this task to view IP ICMP statistics for a Segmented Management Instance.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Mgmt Instance**.
3. Select **Stats**.
4. Select the **IP-ICMP** tab.
5. To clear IP statistics, select **Clear Stats**.
6. To clear IP counters, select **Clear Counters**.

IP-ICMP Field Descriptions

Use the data in the following table to use the **IP-ICMP** tab.

Name	Description
InMsgs	Shows the inbound messages statistics.
InErrors	Shows the inbound errors statistics.
InCsumErrors	Shows the inbound checksum errors statistics.
InDestUnreachs	Shows the inbound destination unreachable statistics.
InTimeExcds	Shows the inbound time exceeded statistics.
InParmProbs	Shows the inbound parameter problems statistics.
InSrcQuenchs	Shows the inbound source quenchs statistics.
InRedirects	Shows the inbound redirects statistics.
InEchos	Shows the inbound echos statistics.
InEchoReps	Shows the inbound echo replies statistics.
InTimestamps	Shows the inbound timestamps statistics.
InTimestampsReps	Shows the inbound timestamp replies statistics.
InAddrMasks	Shows the inbound address masks statistics.
InAddrMaskReps	Shows the inbound address mask replies statistics.
OutMsgs	Shows the outbound messages statistics.
OutErrors	Shows the outbound errors statistics.
OutDestUnreachs	Shows the outbound destination unreachable statistics.
OutTimeExcds	Shows the outbound time exceeded statistics.

Name	Description
OutParmProbs	Shows the outbound parameter problems statistics.
OutSrcQuenchs	Shows the outbound source quenchs statistics.
OutRedirects	Shows the outbound redirects statistics.
OutEchos	Shows the outbound echos statistics.
OutEchoReps	Shows the outbound echo replies statistics.
OutTimestamps	Shows the outbound timestamps statistics.
OutTimestampReps	Shows the outbound timestamps replies statistics.
OutAddrMasks	Shows the outbound address masks statistics.
MsgInType0	Shows the inbound Type0 messages statistics.
MsgOutType8	Shows the outbound Type8 messages statistics.

View IPv6 ICMP Statistics for a Segmented Management Instance

Use this task to view IPv6 ICMP statistics for a Segmented Management Instance.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Mgmt Instance**.
3. Select **Stats**.
4. Select the **IPv6-ICMP** tab.
5. To clear IP statistics, select **Clear Stats**.
6. To clear IP counters, select **Clear Counters**.

IPv6-ICMP Field Descriptions

Use the data in the following table to use the **IPv6-ICMP** tab.

Name	Description
InMsgs	Shows the inbound messages statistics.
InErrors	Shows the inbound errors statistics.
InCsumErrors	Shows the inbound checksum errors statistics.
InDestUnreachs	Shows the inbound destination unreachable statistics.
InTimeExcds	Shows the inbound time exceeded statistics.
InParmProbs	Shows the inbound parameter problems statistics.
InPktTooBigs	Shows the inbound packets too big statistics.
InRedirects	Shows the inbound redirects statistics.
InEchos	Shows the inbound echos statistics.
InEchoReplies	Shows the inbound echo replies statistics.

Name	Description
InGroupMembQueries	Shows the inbound group member queries statistics.
InGroupMembResponses	Shows the inbound group member responses statistics.
InGroupMembReductions	Shows the inbound group member reductions statistics.
InRouterSolicits	Shows the inbound router solicits statistics.
InRouterAdvertisements	Shows the inbound router advertisements statistics.
InNeighborSolicits	Shows the inbound neighbor solicits statistics.
InNeighborAdvertisements	SHows the inbound neighbor advertisements statistics.
InMLDv2Reports	Shows the inbound MLDv2 reports statistics.
InType134	Shows the inbound type134 statistics.
InType136	Shows the inbound type136 statistics.
OutMsgs	Shows the outbound messages statistics.
OutErrors	Shows the outbound errors statistics.
OutDestUnreachs	Shows the outbound destination unreachable statistics.
OutTimeExcds	Shows the outbound time exceeded statistics.
OutParmProbs	Shows the outbound parameter problems statistics.
OutPktTooBigs	Shows the outbound packets too big statistics.
OutRedirects	Shows the outbound redirects statistics.
OutEchos	Shows the outbound echos statistics.
OutEchoReps	Shows the outbound echo replies statistics.
OutGroupMembQueries	Shows the outbound group member queries statistics.
OutGroupMembResponses	Shows the outbound group member responses statistics.
OutGroupMembReductions	Shows the outbound group member reductions statistics.
OutRouterStatistics	Shows the outbound router statistics
OutRouterAdvertisements	Shows the outbound router advertisements statistics.
OutNeighborSolicits	Shows the outbound neighbor solicits statistics.
OutNeighborAdvertisements	Shows the outbound neighbor advertisements statistics.
OutMLDv2Reports	Shows the outbound MLDv2 reports statistics.
OutType133	Shows the outbound Type133 statistics.

Name	Description
OutType135	Shows the outbound Type135 statistics.
OutType143	Shows the outbound Type143 statistics.

View UDP Statistics for a Segmented Management Instance

Use this task to view UDP statistics for a Segmented Management Instance.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Mgmt Instance**.
3. Select **Stats**.
4. Select the **IP/IPv6 UDP** tab.

IP/IPv6 UDP *Field Descriptions*

Use the data in the following table to use the **IP/IPv6 UDP** tab.

Name	Description
IPVersion	Shows the IP address version as ipv4 or ipv6.
InDatagrams	Shows the input datagram statistics.
NoPorts	Shows the number of ports statistics.
InErrors	Shows the input errors statistics.
OutDatagrams	Shows the output datagram statistics.
IgnoredMulti	Show the ignored multiport statistics.
RcvbufErrors	Shows the received buffer errors statistics.
SndbufErrors	Shows the send buffer errors statistics.
InCsumErrors	Shows the input checksum errors statistics.
Clear	Specifies to clear the statistics. Default is false.

View TCP Statistics for a Segmented Management Instance

Use this task to view TCP statistics for a Segmented Management Instance.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Mgmt Instance**.
3. Select **Stats**.
4. Select the **IP/IPv6 TCP** tab.

IP/IPv6 TCP *Field Descriptions*

Use the data in the following table to use the **IP/IPv6 TCP** tab.

Name	Description
IPVersion	Shows the IP address version as ipv4 or ipv6.
ActiveOpens	Shows the active open TCP connections statistics.
PassiveOpens	Shows the passive open TCP connections statistics.
AttemptFails	Shows the TCP connection attempt failures statistics.
EstabResets	Shows the TCP connection esablished resets statistics.
InSegs	Shows the input segments statistics.
OutSegs	Shows the output segments statistics.
RetransSegs	Shows the retransmit segments statistics.
InErrs	Shows the input checksum errors statistics.
OutRsts	Shows the output resets statistics.
InCsumErrors	Shows the input checksum errors statistics.
Clear	Specifies to clear the statistics. Default is false.

View TCP Connections and UDP Endpoints Statistics for a Segmented Management Instance

Use this task to view TCP connections and UDP endpoints statistics for a Segmented Management Instance.

Procedure

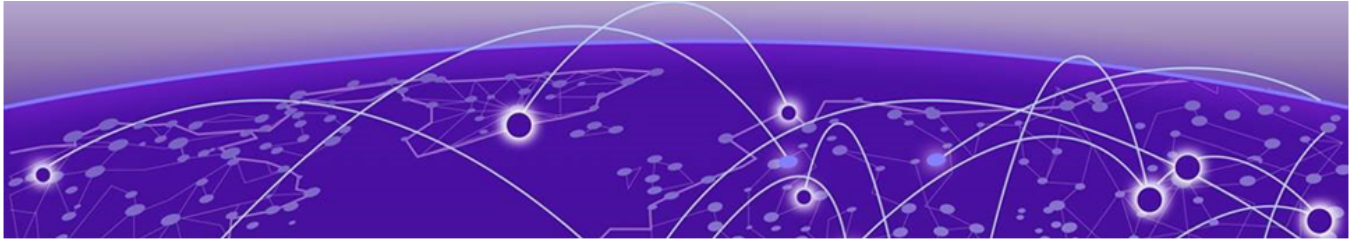
1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Mgmt Instance**.
3. Select **Stats**.
4. Select the **IP/IPv6 Socket (TCP/UDP)** tab.

IP/IPv6 Socket (TCP/UDP) *Field Descriptions*

Use the data in the following table to use the **IP/IPv6 Socket (TCP/UDP)** tab.

Name	Description
IPVersion	Shows the IP address version as ipv4 or ipv6.
Type	Shows the connection type as tcp or udp.
Index	Shows the index ID for the connection.
State	Shows the link state for the connection.
RecvQ	Shows the connection received quanitity.
SendQ	Shows the connection sent quantity.

Name	Description
LocalAddressAndPort	Shows the local IP address and port.
PeerAddressAndPort	Shows the peer IP address and port.



Basic Administration

The following topics provide instructions to perform basic configuration of, and administrative tasks for, the switch and software.

Examples and network illustrations may illustrate only one of the supported platforms. Unless otherwise noted, the concept illustrated applies to all supported platforms.

Fundamentals

This section includes the minimum, but essential, configuration steps to:

- provide a default, starting point configuration
- establish basic security on the node

For more information about hardware specifications and installation procedures, see the following documents:

- *ExtremeSwitching 5320 Series Hardware Installation Guide*
- *ExtremeSwitching 5420 Series Hardware Installation Guide*
- *ExtremeSwitching 5520 Series Hardware Installation Guide*
- *ExtremeSwitching 5720 Series Hardware Installation Guide*

advanced-feature-bandwidth-reservation Boot Flag

Table 11: Advanced Feature Bandwidth Reservation product support

Feature	Product	Release introduced
Advanced Feature Bandwidth Reservation Note: If your switch does not have this boot flag, it is because the hardware reserves the bandwidth automatically with no user interaction.	5320 Series	Fabric Engine 8.6 5320-24P-8XE, 5320-24T-8XE, 5320-48P-8XE, and 5320-48T-8XE only
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

The switch enables the **boot config flags advanced-feature-bandwidth-reservation** command by default to use advanced features on the switch. If you disable the **boot config flags advanced-feature-bandwidth-reservation** command and attempt to enable an advanced feature, the switch displays an error message to explain why the advanced feature failed to start, and to remind you that you must enable this boot configuration flag for that advanced feature.

Important

If you change the configuration, you must save the configuration, and then reboot the switch for the change to take effect.

If you disable this feature and save the configuration, any configuration for advanced features remains saved in the configuration file but is not used.

By default, this boot configuration flag is enabled with the following options:

- low level option for 5320 Series and 5420 Series switches.
- vim level option for 5520 Series switches (if vim port is available and VIM is not installed, else low level option is enabled).
- vim level option for 5720 Series switches (if vim port is available and VIM is not installed, else high level option is enabled).

When disabled, you can use all ports for Layer 2 or Layer 3 forwarding of standard unicast and multicast features. Use this mode if you are not configuring advanced features. The syntax for disabling this boot configuration flag is **no boot config flags advanced-feature-bandwidth-reservation**.

When enabled, also known as Full Feature mode, the switch supports advanced features by reassigning some of the front panel ports to be loopback ports. The following advanced features require loopback ports:

- Fabric Extend
- SPB
- SMLT
- vIST
- Fabric RSPAN (Mirror to I-SID)

- Application Telemetry
- IS-IS Accept Policies
- Segmented Management Instance CLIP interface

Note
Full Feature mode does not support PIM.

The syntax for enabling the boot flag for this mode is **boot config flags advanced-feature-bandwidth-reservation [low | high | vim].**

The *low* level parameter means that the switch reserves less bandwidth to support minimum functionality for advanced features.

The *high* level parameter means that the switch reserves the maximum bandwidth for the advanced features.

The *vim* level parameter means that the switch uses Versatile Interface Module (VIM) ports as loopback ports.

The following table shows the supported parameters and ports reserved as loopback ports on each platform:

Platform	Parameter		
	low	*high*	*vim*
5320-24P-8XE 5320-24T-8XE	Reserved loopback ports: 1/25-1/27		
5320-48P-8XE 5320-48T-8XE	Reserved loopback ports: 1/49-1/51		
• 5420F-24T-4XE • 5420F-8W-16P-4XE • 5420F-24P-4XE • 5420F-24S-4XE • 5420M-24T-4YE • 5420M-24W-4YE	Reserved loopback ports: Universal Ethernet ports 1/29 and 1/30 Note: To understand restrictions on using reserved loopback ports as front panel ports, see 5420 Series on page 3568.		

Platform	Parameter		
	low	*high*	*vim*
• 5420F-48T-4XE • 5420F-16MW-32P-4XE • 5420F-16W-32P-4XE • 5420F-48P-4XE • 5420F-48P-4XL • 5420M-48T-4YE • 5420M-48W-4YE • 5420M-16MW-32P-4YE	Reserved loopback ports: Universal Ethernet ports 1/53 and 1/54 **Note:** To understand restrictions on using reserved loopback ports as front panel ports, see 5420 Series on page 3568.		
• 5520-24T • 5520-24W • 5520-24X	Reserved loopback ports: Universal Ethernet ports 1/25 and 1/26		Reserved internal Versatile Interface Module ports
• 5520-12MW-36W • 5520-48SE • 5520-48T • 5520-48W	Reserved loopback ports: Universal Ethernet ports 1/49 and 1/50		Reserved internal Versatile Interface Module ports
• 5720-24MW • 5720-24MXW			Reserved internal Versatile Interface Module ports
• 5720-48MW • 5720-48MXW		Reserved loopback ports: Universal Ethernet ports 1/49 and 1/50	Reserved internal Versatile Interface Module ports

Note

To understand restrictions on using reserved loopback ports as front panel ports on the 5420 Series, see 5420 Series on page 3568.

After the switch reserves the appropriate ports to become loopback ports, the ports are no longer visible in the output when you enter **`show interfaces gigabitEthernet`**.

By default, for the 5520 Series and 5720 Series switches, if you do not install a VIM in the switch, the switch uses the vim parameter. In this configuration, the VIM ports are used as loopback ports and the Universal Ethernet ports are used as regular uplink ports. When used as regular uplink ports, the port speed for the Universal Ethernet ports is 40 Gbps as a single channel port. Although the maximum supported single channel port speed is 40 Gbps, the ports can be channelized to operate as four 10 or 25 Gbps channels.

If a VIM is already installed in the 5520 Series, the switch uses the low parameter that uses Universal Ethernet ports as loopback ports and VIM ports as regular uplink ports. For the 5720 Series, the switch

uses the high parameter that uses Universal Ethernet ports as loopback ports and VIM ports as regular uplink ports.

Important

If you change the configuration, you must save the configuration, and then reboot the switch for the change to take effect.

If you disable this feature and save the configuration, any configuration for advanced features remains saved in the configuration file but is not used.

Important

You must ensure your configuration does not include reserved ports before you enable this feature. If the configuration includes reserved ports, after you enable this feature and restart the switch, the switch stops loading the configuration.

spbm-config-mode boot flag

Table 12: spbm-config-mode product support

Feature	Product	Release introduced
spbm-config-mode (**boot config flags spbm-config-mode**)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine

Shortest Path Bridging (SPB) and Protocol Independent Multicast (PIM) cannot interoperate with each other on the switch at the same time. To ensure that SPB and PIM stay mutually exclusive, the software uses a boot flag called **boot config flags spbm-config-mode**.

- The **boot config flags spbm-config-mode** flag is enabled by default. This enables you to configure SPB and IS-IS, but you cannot configure PIM and IGMP either globally or on an interface.
- If you disable the boot flag, save the configuration, and then reboot with the saved configuration. When the flag is disabled, you can configure PIM and IGMP Snooping, but you cannot configure SPB or IS-IS.

Important

After you change the **boot config flags spbm-config-mode** flag, you must save the configuration, and then reboot the switch for the change to take effect.

For more information about this boot flag and Simplified vIST, see IP Multicast on page 1230.

nni-mstp boot config flag

Table 13: nni-mstp boot flag product support

Feature	Product	Release introduced
nni-mstp boot flag (**boot config flags nni-mstp**)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

The nni-mstp boot flag changes the default behavior of the MSTP on SPBM network-to-network interface (NNI) ports. The Common and Internal Spanning Tree (CIST) is disabled automatically on the NNI, and the NNI ports can only be members of backbone VLANs (B-VLAN).

- During startup, if you have non-B-VLAN on SPBM NNI ports in your configuration file, the system sets the nni-mstp flag to true (if it was not already set to true) and enables MTSP on SPBM NNI ports, and all other configurations remain the same. Save your configuration file. If you do not save your configuration, you continue to see the following message on reboot:

```
Warning
Detected brouter and/or vlans other than BVLANs on NNI ports. Setting the boot config
flag nni-mstp to true. Saving configuration avoids repetition of this warning on
reboot.
```

Note

When the nni-mstp flag is set to true, only MSTI 62 is disabled on the SPBM NNI ports. You can add the SPBM NNI ports to any VLAN.

- If you configure the nni-mstp boot configuration flag to false (default), the system checks to make sure that the SPBM NNI ports do not have brouter (IPv4 or IPv6) or non-SPBM VLANs configured. The nni-mstp flag is then set to false. Save your configuration file, and reboot the switch for the configuration change to take effect.

Note

Ensure that all SPBM NNI ports in non-B-VLAN are removed prior to setting the nni-mstp flag to false.

Example: Configuring nni-mstp to true

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#boot config flags nni-mstp
Warning: Please save the configuration and reboot the switch for this configuration to
take effect.
Switch:1(config)#
```

System Connections

Connect the serial console interface (an RJ–45 jack) to a PC or terminal to monitor and configure the switch. The port uses a RJ–45 connector that operates as data terminal equipment (DTE). Some

switches also provide a USB port or micro USB port for serial console interface connectivity. See your hardware documentation for available ports.

The default communication protocol settings for the console port are:

- Baud rate:
  - 5320 Series — 115200
  - 5420 Series — 115200
  - 5520 Series — 115200
  - 5720 Series — 115200
- 8 data bits
- 1 stop bit
- No parity
- No flow control.

To use the console port, you need a terminal or teletypewriter (TTY)-compatible terminal, or a portable computer with a serial port and terminal-emulation software.

Boot Sequence

Table 14: Linux kernel version product support

Feature	Product	Release introduced
Linux kernel version	5320 Series	5.4 as of Fabric Engine 8.6
	5420 Series	5.4 as of Fabric Engine 8.6
	5520 Series	5.4 as of Fabric Engine 8.6
	5720 Series	5.4 as of Fabric Engine 8.7

The switch goes through a boot sequence before it becomes fully operational. After you turn on power to the switch, the system starts.

The boot sequence consists of the following stages:

- Loading Linux on page 129
- Loading the Primary Release on page 130
- Deploying Zero Touch on page 130 or Loading the Configuration File on page 130

Note

Extreme Networks offers universal hardware products that support more than one Network Operating System (NOS) personality. The first time you start a universal hardware product, the boot sequence can be different from what is documented in this section. The boot sequence documented in this section assumes a NOS selection of Fabric Engine is already established. For more information on NOS personalities, see Network Operating System Personalities on page 2144.

The following figure shows a summary of the boot sequence.

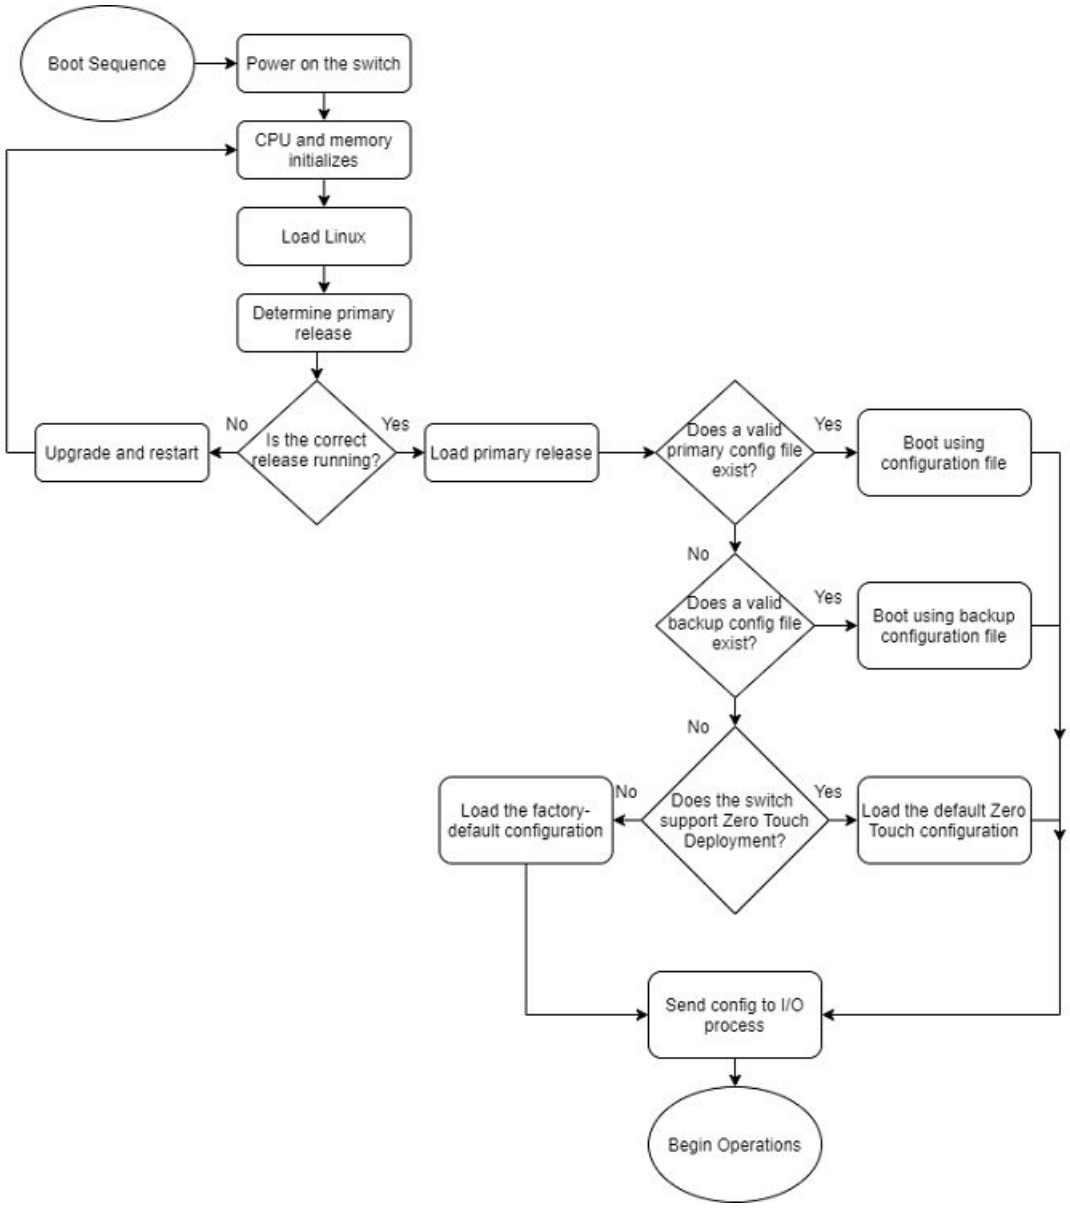


Figure 9: Boot Sequence

Loading Linux

Depending on the Linux kernel used, the boot image is stored either in a boot flash partition, Secure Digital (SD), or Solid State Drive (SSD) flash card. The boot image includes the boot loader, and the Linux kernel and applications.

The boot location contains two versions of the boot image: a committed version (the primary release) and a backup version. A committed version is one that is marked as good (if you can start the system using that version). The system automatically uses the backup version if the system fails the first time you start with a new version.

Loading the Primary Release

You can store up to six software releases on the 5520 Series and 5720 Series. If you have six releases already stored on the switch, you are prompted to remove one release before you can proceed to add and activate a new software release. You can store a maximum of two software releases on the 5320 Series and 5420 Series. If you attempt to add a third software release, the software displays a confirmation to overwrite the non-primary release. You can also use the **`software add <filename> -y`** to bypass the confirmation question and automatically overwrite the non-primary release.

The system saves software image files to the `/intflash/release/` directory.

After loading the primary release, the CPU and basic system devices, such as the console port, initializes. At this stage, the I/O ports are not available; the system does not initialize the I/O ports until the port sends configuration data.

Deploying Zero Touch

Important
Zero Touch Deployment does not function if primary or secondary configuration files exist.

After the system loads the primary release and the switch is in a Zero Touch Deployment-ready configuration mode, the switch automatically deploys without intervention.

For more information, see Zero Touch Deployment on page 52.

Loading the Configuration File

After the system loads the primary release, it identifies the location and file name of the primary configuration file. You can save this file in internal flash.

If the primary configuration file does not exist, the system looks for the backup configuration file, as identified by version.cfg. If this file does not exist, the system initiates Zero Touch functionality on the switch that enables Zero Touch Fabric Configuration. For more information, see Zero Touch Fabric Configuration on page 57.

The switch configuration consists of higher-level functionality, including:

- Chassis configuration
- Port configuration
- Virtual LAN (VLAN) configuration
- Routing configuration
- IP address assignments
- Remote monitoring (RMON) configuration

The default switch configuration in Zero Touch Fabric Configuration mode includes the following:

- Shortest Path Bridging MAC (SPBM) instance is created.
- Intermediate System-to-Intermediate System (IS-IS) is enabled.

- All ports are enabled and operating in Auto-sense mode.
- The switch issues DHCP requests on the out-of-band (OOB) management port and the management VLAN.

The default switch configuration in factory default mode includes the following:

- A single, port-based default VLAN with a VLAN identification number of 1
- No interface assigned IP addresses
- Traffic priority for all ports configured to normal priority
- All ports as untagged ports
- Default communication protocol settings for the console port. For more information about these protocol settings, see System Connections on page 127.

Configuration File Statements

In the configuration file, statements preceded by both the number sign (#) and exclamation point (!) load prior to the general configuration parameters. Statements preceded by only the number sign are comments meant to add clarity to the configuration; they do not load configuration parameters. The following table illustrates the difference between these two statement formats.

Table 15: Configuration file statements

Sample statement	Action
# software version : 8.6.0.0	Adds clarity to the configuration by identifying the software version.
#!no boot config flags sshd	Configures the flag to the false condition, prior to loading the general configuration.

Boot Sequence Modification

You can change the boot sequence in the following ways:

- Change the primary designations for file sources.
- Change the file names from the default values. You can store several versions of the configuration file and specify a particular one by file name. The specified configuration file only gets loaded when the chassis starts. To load a new configuration file, you need to restart the system.
- Start the system without loading an existing configuration file so that the system uses the factory default configuration. You can do this by running the **`boot config flags factorydefaults`** command.

  The factorydefaults boot flag removes the runtime, primary, and backup configuration files, resets all local default user account passwords, and removes all digital certificates. The Radsec, IPsec, IKE, OSPF, SNMP, SSL, SSH, and NTP files are also removed. The CLI displays a warning that the configurations, passwords, and files will be reset, and the system logs an informational message. The configuration and file removals occur during the next boot sequence when the factorydefaults boot flag is enabled. After the switch reboots, the security mode setting is retained. To enable Zero Touch Onboarding after a factorydefaults boot, reboot the switch again without saving a configuration.
- Start the system in Zero Touch Deployment mode, which includes Zero Touch Fabric Configuration. For more information, see Zero Touch Deployment on page 52.

Runtime

After the switch is operational, you can use the runtime commands to perform configuration and management functions necessary to manage the system. These functions include the following

- Resetting or restarting the switch
- Adding, deleting, and displaying address resolution protocol (ARP) table entries
- Pinging another network device
- Viewing and configuring variables for the entire system and for individual ports
- Configuring and displaying MultiLink Trunking (MLT) parameters
- Creating and managing port-based VLANs or policy-based VLANs

To access the runtime environment you need a connection from a PC or terminal to the switch. You can use a direct connection to the switch through the console port or remotely through Telnet or Secure Shell (SSH) sessions.

Important

Before you attempt to access the switch using one of the preceding methods, ensure you first enable the corresponding daemon flags.

System logon

After the platform boot sequence is complete, the system opens the logon prompt. The following table shows the default values for logon and password for console and Telnet sessions.

Note

With enhanced secure mode enabled, the person in the role-based authentication level of administrator configures the login and password values for the other role-based authentication levels. The administrator initially logs on to the switch using the default login of `admin` and the default password of `admin`. After the initial login, the switch prompts the administrator to create a new password.

Table 16: Access levels and default logon values

Access level	Description	Default logon	Default password
Read-only	Permits view-only configuration and status information. Is equivalent to Simple Network Management Protocol (SNMP) read-only community access.	ro	ro
Layer 1 read/write	View most switch configuration and status information and change physical port settings.	l1	l1
Layer 2 read/write	View and change configuration and status information for Layer 2 (bridging and switching) functions.	l2	l2
Layer 3 read/write	View and change configuration and status information for Layer 2 and Layer 3 (routing) functions.	l3	l3

Table 16: Access levels and default logon values (continued)

Access level	Description	Default logon	Default password
Read/write	View and change configuration and status information across the switch. You cannot change security and password settings. This access level is equivalent to SNMP read/write community access.	rw	rw
Read/write/all	Permits all the rights of read/write access and the ability to change security settings, including CLI and web-based management user names and passwords and the SNMP community strings.	rwa	rwa

System flags

After you enable or disable certain modes and functions, you need to save the configuration and restart the switch for your change to take effect. This section lists parameters and indicates if they require a switch restart.

The following table lists parameters you configure in the CLI using the **`boot config flags`** command. For information on system flags and their configuration, see Configure Boot Flags on page 190.

Note

Flag support can vary across hardware models.

Table 17: Boot config flags

CLI flag	Restart
advanced-feature-bandwidth-reservation	Yes
block-snmp	No
debug-config	Yes
debugmode	Yes
dvr-leaf-mode	No
enhancedsecure-mode	Yes
factorydefaults	Yes
flow-control-mode	Yes
ftpd	No
hsecure	Yes
ipv6-egress-filter	Yes
ipv6-mode	Yes

Table 17: Boot config flags (continued)

CLI flag	Restart
logging	No
macsec Note: Exception: Only required on 5320 Series and 5420 Series.	Yes
nni-mstp	Yes
reboot	No
spanning-tree-mode	Yes
spbm-config-mode	Yes
spbm-node-scaling Note: Exception: does not apply to 5520 Series.	Yes
sshd	No
telnetd	No
tftpd	No
trace-logging	No
urpf-mode	Yes
verify-config	Yes
vrf-scaling	Yes

Secure and Nonsecure Protocols

The following table describes the secure and nonsecure protocols that the switch supports.

Table 18: Secure and nonsecure protocols for IPv4 and IPv6

Nonsecure protocols	Default status	Equivalent secure protocols	Default status
FTP and Trivial FTP	Disabled	Secure Copy (SCP) and Secure File Transfer Protocol (SFTP)	Disabled
Note: File Transfer Protocol (FTP) and Trivial File Transfer Protocol (TFTP) support both IPv4 and IPv6 addresses, with no difference in functionality or configuration.			
Telnet	Disabled	Secure Shell version 2 (SSHv2)	Disabled

Table 18: Secure and nonsecure protocols for IPv4 and IPv6 (continued)

Nonsecure protocols	Default status	Equivalent secure protocols	Default status
SNMPv1, SNMPv2	Enabled	SNMPv3	Enabled
HTTP	Disabled	HTTPS Important: Take the appropriate security precautions within the network if you use HTTP. You must use the **`web-server enable`** command in CLI before you can access EDM.	Enabled

Client and Server Support

Table 19: Client and Server product support

Feature	Product	Release introduced
File Transfer Protocol (FTP) server and client (IPv4)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
File Transfer Protocol (FTP) server and client (IPv6)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
Hypertext Transfer Protocol (HTTP) and Hypertext Transfer Protocol Secure (HTTPS) (IPv4)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
Hypertext Transfer Protocol (HTTP) and Hypertext Transfer Protocol Secure (HTTPS) (IPv6)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
Remote Login (Rlogin) server/ client (IPv4)	5320 Series	Not Supported
	5420 Series	Not Supported
	5520 Series	Not Supported
	5720 Series	Not Supported

Table 19: Client and Server product support (continued)

Feature	Product	Release introduced
Rlogin server (IPv6)	5320 Series	Not Supported
	5420 Series	Not Supported
	5520 Series	Not Supported
	5720 Series	Not Supported
Rlogin client (IPv6)	5320 Series	Not Supported

SSH rekey	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

The client-server model partitions tasks between servers that provide a service and clients that request a service.

For active CLI clients, users initiate a client connection from the switch to another device.

Note

Both FTP and TFTP clients are supported by the switch. The switch does not launch FTP and TFTP clients explicitly as a separate command; you can launch them through the CLI **copy** command. If you have configured the username through the **boot config host** command, the FTP client is used to transfer files to and from the switch using the CLI **copy** command; If you have not configured the username, the TFTP client is used to transfer files to and from the switch using the CLI **copy** command.

Configuring the `boot config flags ftpd` or `boot config flags tftpd` enables the FTP or TFTP Servers on the switch.

For non-active clients, the client exists on the switch and the switch console initiates the request, with no intervention from users after the initial setup. For instance, Network Time Protocol (NTP) is a non active client. The switch initiates the client request to the central server to obtain the up-to-date time.

Password encryption

The platform stores passwords in encrypted format and not in the configuration file.

Important

For security reasons, configure the passwords to values other than the factory defaults.

Enterprise Device Manager

The switch includes Enterprise Device Manager (EDM), an embedded graphical user interface (GUI) that you can use to manage and monitor the platform through web-based access without additional installations.

For more information about EDM, see Enterprise Device Manager on page 232.

Enterprise Device Manager access

To access EDM, enter one of the following addresses in your web browser:

- http://<A.B.C.D>
- https://<A.B.C.D>

Where <A.B.C.D> is the device IP address.

Ensure you use a supported browser version. For more information about supported browsers, see Supported Browsers on page 232.

Important

- You must enable the web server from CLI to enable HTTP access to the EDM. If you want HTTP access to the device, you must also disable the web server secure-only option. The web server secure-only option, allowing for HTTPS access to the device, is enabled by default. Take the appropriate security precautions within the network if you use HTTP.
- EDM access is available to read-write users only.

If you experience any issues while connecting to the EDM, check the proxy settings. Proxy settings may affect EDM connectivity to the switch. Clear the browser cache and do not use proxy when connecting to the device. This should resolve the issue.

Default user name and password

The following table contains the default user name and password that you can use to log on to the switch using EDM. For more information about changing the passwords, see Change Passwords on page 2751.

Table 21: EDM default username and password

Username	Password
admin	password

Important

The default passwords and community strings are documented and well known. As a best practice, change the default passwords and community strings immediately after you first log on. For more information about changing user names and passwords, see Change Passwords on page 2751.

TLS server for secure HTTPS

Table 22: TLS server for secure HTTPS product support

Feature	Product	Release introduced
TLS server for secure HTTPS	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

This feature enhances communications security by implementing Mocana NanoSSL to secure HTTPS server using Transport Layer Security (TLS) cryptographic protocol.

The following are the key properties of Secure web server with TLS:

- This feature can be implemented on a maximum of only 10 concurrent client connections.
- The switch supports version TLS 1.2 and above by default. You can explicitly configure TLS 1.0 and TLS 1.1 version support using CLI or EDM.
- This feature replaces SSL 3.0 with TLS. SSL 3.0 is not supported.
- TLS server does not support RC4, DES, TDES, and MD5 based cipher suites.
- The minimum password length for the web server is 8 characters, by default. You can change this using CLI or EDM.

For information about the certificate order priority when the Transport Layer Security (TLS) server and switch connect, see Certificate Order Priority on page 2700.

Basic Configuration

Connect a Terminal

Before You Begin

- To use the console port, you need the following equipment:
  - A terminal or Teletypewriter (TTY)-compatible terminal, or a portable computer with a serial port and terminal-emulation software.
  - A specific cable with an RJ–45 or USB connector for the console port on the switch. The other end of the cable must use a connector appropriate to the serial port on the computer or terminal.
- To comply with emissions regulations and requirements, you must shield the cable that connects to the console port.

Note

If you are using the USB console port with a terminal running Windows 10, you must install the CP210x USB to UART Bridge Virtual COM Port (VCP) driver from Silicon Labs before you connect to the terminal.

About This Task

Connect a terminal to the serial console interface to monitor and configure the system directly.

Procedure

1. Configure the terminal protocol as follows:
   - 115200 baud
   - 8 data bits
   - 1 stop bit
   - No parity
   - No flow control
2. Connect the RJ–45 or USB cable to the console port on the switch.
3. Connect the other end of the cable to the terminal or computer serial port.
4. Turn on the terminal.
5. Log on to the switch.

Changing passwords

Configure new passwords for each access level, or change the logon or password for the different access levels of the switch. After you receive the switch, use default passwords to initially access CLI. If you use Simple Network Management Protocol version 3 (SNMPv3), you can change encrypted passwords.

If you enable the hsecure flag, after the aging time expires, the system prompts you to change your password. If you do not configure the aging time, the default is 90 days.

If you enable enhanced secure mode with the **`boot config flags enhancedsecure-mode`** command, you enable new access levels, along with stronger password complexity, length, and

minimum change intervals. For more information on system access fundamentals and configuration, see System access fundamentals on page 2988.

Before You Begin

- You must use an account with read-write-all privileges to change passwords. For security, the switch saves passwords to a hidden file.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Change a password:

   ```
   cli password WORD<1-20> {layer1|layer2|layer3|read-only|read-write|
   read-write-all}
   ```

3. Enter the old password.
4. Enter the new password.
5. Re-enter the new password.
6. Configure password options:

   ```
   password [access-level WORD<2-8>] [aging-time day <1-365>] [default-
   lockout-time <60-65000>] [lockout WORD<0-46> time <60-65000>] [min-
   passwd-len <10-20>] [password-history <3-32>]
   ```

Example

```
Switch:1> enable

Switch:1# configure terminal
```

Change a password:

```
Switch:1(config)# cli password rwa read-write-all
```

Enter the old password: ***

Enter the new password: ***

Re-enter the new password: ***

Set password to an access level of read-write-all and the expiration period for the password to 60 days:

```
Switch:1(config)# password access-level rwa aging-time 60
```

Variable Definitions

Use the data in the following table to use the **cli password** command.

Variable	Value
layer1|layer2|layer3|read-only|read-write|read-write-all	Changes the password for the specific access level.
WORD<1-20>	Specifies the user logon name.

Use the data in the following table to use the **password** command.

Variable	Value
access-level WORD<2-8>	Permits or blocks this access level. The available access level values are as follows: • layer1 • layer2 • layer3 • read-only • read-write • read-write-all
aging-time day <1-365>	Configures the expiration period for passwords in days, from 1–365. The default is 90 days.
default-lockout-time <60-65000>	Changes the default lockout time after three invalid attempts. Configures the lockout time, in seconds, and is in the 60–65000 range. The default is 60 seconds. To configure this option to the default value, use the **default** operator with the command.
lockout WORD<0-46> time <60-65000>	Configures the host lockout time. • *WORD<0-46>* is the host IPv4 or IPv6 address. • *<60-65000>* is the lockout-out time, in seconds, in the 60–65000 range. The default is 60 seconds.
min-passwd-len <10-20>	Configures the minimum length for passwords in high-secure mode. The default is 10 characters. To configure this option to the default value, use the **default** operator with the command.
password-history <3-32>	Specifies the number of previous passwords the switch stores. You cannot reuse a password that is stored in the password history. The default is 3. To configure this option to the default value, use the **default** operator with the command.

Configuring system identification

Configure system identification to specify the system name, contact person, and location of the switch.

Procedure

1. Log on as rwa.

2. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

3. Change the system name:

   ```
   sys name WORD<0-255>
   ```

4. Configure the system contact:

   ```
   snmp-server contact WORD<0-255>
   ```

5. Configure the system location:

   ```
   snmp-server location WORD<0-255>
   ```

Example

Change the system name, configure the system contact, and configure the system location:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#sys name Floor3Lab2
Floor3Lab2:1(config)#snmp-server contact http://companyname.com
Floor3Lab2:1(config)#snmp-server location "12 Street, City, State, Zip"
```

Variable Definitions

Use the data in the following table to use the system-level commands.

Variable	Value
contact WORD<0-255>	Identifies the contact person who manages the node. To include blank spaces in the contact, use quotation marks (") around the text.
location WORD<0-255>	Identifies the physical location of the node. To include blank spaces in the location, use quotation marks (") around the text.
name WORD<0-255>	Configures the system or root level prompt name for the switch. *WORD<0-255>* is an ASCII string from 1–255 characters (for example, LabSC7 or Closet4).

Configuring the CLI Banner

Configure the logon banner to display a message to users before authentication and configure a system login message-of-the-day in the form of a text banner that displays after each successful logon.

About This Task

You can use the custom logon banner to display company information, such as company name and contact information. For security, you can change the default logon banner of the switch, which contains specific system information, including platform type and software release.

Use the custom message-of-the-day to update users on a configuration change, a system update or maintenance schedule. For security purposes, you can also create a message-of-the-day with a warning message to users that, “Unauthorized access to the system is forbidden.”

Procedure

1. Enter Global Configuration mode:
   ```
   enable
   ```
   ```
   configure terminal
   ```
2. Configure the switch to use a custom banner or use the default banner:
   ```
   banner <custom|static>
   ```
3. Create a custom banner:
   ```
   banner WORD<1-80>
   ```

   

   Note

   To enter multiple lines for a message, use the **banner** command before each new line of the message. To provide a string with spaces, include the text in quotation marks.

4. Create the message-of-the-day:
   ```
   banner motd WORD<1-1516>
   ```

   

   Note

   To enter multiple lines for a message, use the **banner motd** command before each new line of the message. To provide a string with spaces, include the text in quotation marks.

5. Enable the custom message-of-the-day:
   ```
   banner displaymotd
   ```
6. Save the configuration:
   ```
   save config
   ```
7. Display the banner information:
   ```
   show banner
   ```
8. Logon again to verify the configuration.
9. (Optional) Disable the banner:
   ```
   no banner [displaymotd][motd]
   ```

Example

Configure the custom banner to “Company, www.Companyname.com.” and configure the message of the day to “Unauthorized access to this system is forbidden. Please logout now.”

```
Switch:1> enable
Switch:1#configure terminal
Switch:1(config)# banner custom
Switch:1(config)# banner Company
Switch:1(config)# banner www.Companyname.com
Switch:1(config)# banner motd "Unauthorized access to this system is forbidden"
Switch:1(config)# banner motd "Please logout now"
Switch:1(config)#banner displaymotd
Switch:1(config)#show banner
Company
www.company.com
               defaultbanner : false
               custom banner :
```

```
                displaymotd : true
                custom motd :
Unauthorized access to this system is forbidden
Please logout now
```

Variable definitions

Use the data in the following table to use the **banner** command.

Variable	Value
custom	Disables the use of the default banner.
static	Activates the use of the default banner.
WORD <1-80>	Adds lines of text to the CLI logon banner.
motd WORD<1-1516>	Create the message of the day. To provide a string with spaces, include the text in quotation marks (“).
displaymotd	Enable the custom message of the day.

Configure the Date

Configure the calendar time in the form of month, day, year, hour, minute, and second.

About This Task

Log on as rwa to perform this procedure.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Configure the date:

   ```
   clock set <MMddyyyyhhmmss>
   ```
3. Verify the configuration:

   ```
   show clock
   ```

Example

Configure the date and time, and then verify the configuration.

```
Switch:1>enable
Switch:1#clock set 19042014063030
Switch:1#show clock
Wed Mar 19 06:30:32 2014 EDT
```

Variable Definitions

Use the data in the following table to use the **clock set** command.

Variable	Value
MMddyyyyhhmmss	Specifies the date and time in the format month, day, year, hour, minute, and second.

Enable Remote Access Services

About This Task

Enable the remote access service to provide multiple methods of remote access.

File Transfer Protocol (FTP), Trivial File Transfer Protocol (TFTP) and Telnet server support both IPv4 and IPv6 addresses, with no difference in functionality or configuration.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable the access service:

   ```
   boot config flags {ftpd | sshd | telnetd | tftpd}
   ```

3. Repeat as necessary to activate the desired services.
4. Save the configuration.

Example

Enable the access service for Telnet:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#boot config flags telnetd
```

Variable Definitions

The following table defines parameters for the **boot config flags** command.

Variable	Value
advanced-feature-bandwidth-reservation [low | high | vim] Note: Exception: vim is only supported on 5520 Series and 5720 Series. Exception: high is only supported on 5720 Series. Exception: low is not supported on 5720 Series.	Enables the switch to support advanced features by reserving ports as loopback ports. When disabled, you can use all ports on the switch, but advanced features do not work. The default varies depending on the platform: • The default for 5320 Series and 5420 Series is enabled with low level. • The default for 5520 Series is enabled with vim level if Versatile Interface Module (VIM) is not installed, else low level is enabled. • The default for 5720 Series is enabled with vim level if Versatile Interface Module (VIM) is not installed, else high level is enabled. • The low level means that the switch reserves less bandwidth to support minimum functionality for advanced features. • The vim level means that the switch uses VIM ports as loopback ports and the Universal Ethernet ports for uplinks. • The high level parameter means that the switch reserves the maximum bandwidth for the advanced features. If you change this parameter, you must restart the switch.
block-snmp	Activates or disables Simple Network Management Protocol management. The default value is false (disabled), which permits SNMP access.

Variable	Value
debug-config [console] | [file]	Enables you to debug the configuration file during loading configuration at system boot up. The default is disabled. You do not have to restart the switch after you enable debug-config, unless you want to immediately debug the configuration. After you enable debug-config and save the configuration, the debug output either displays on the console or logs to an output file the next time the switch reboots. The options are: • debug-config [console]—Displays the line-by-line configuration file processing and result of the execution on the console while the device loads the configuration file. • debug-config [file]— Logs the line-by-line configuration file processing and result of the execution to the debug file while the device loads the configuration file. The system logs the debug config output to /intflash/debugconfig_primary.txt for the primary configuration file. The system logs the debug config output to /intflash/debugconfig_backup.txt for the backup configuration, if the backup configuration file loads.
debugmode	Enables a TRACE on any port by prompting the selection on the console during boot up. This allows the user start trace for debugging earlier on specified port. Works on console connection only. The default is disabled. **Important:** Do not change this parameter unless directed by technical support.
dvr-leaf-mode	Enables an SPB node to be configured as a DvR Leaf. A node that has this flag set cannot be configured as a DvR Controller. The boot flag is disabled by default.

Variable	Value
enhancedsecure-mode {jitc | non-jitc}	Enables enhanced secure mode in either the Joint Interoperability Test Command (JITC) or non-JITC sub-modes. Note: As a best practice, enable the enhanced secure mode in the non-JITC sub-mode, because the JITC sub-mode is more restrictive and prevents the use of some CLI commands that are commonly used for troubleshooting. When you enable enhanced secure mode in either the JITC or non-JITC sub-modes, the switch provides role-based access levels, stronger password requirements, and stronger rules on password length, password complexity, password change intervals, password reuse, and password maximum age use.
factorydefaults	Specifies whether the switch uses the factory default settings at startup. The default value is disabled. This flag is automatically reset to the default setting after the CPU restarts. If you change this parameter, you must restart the switch. Note: The factorydefaults flag deletes the runtime, primary and backup configuration files, local password files, authentication keys, and certificates. After a factory default, you must change the password on first login.
flow-control-mode	Enables or disables flow control globally. When disabled, the system does not generate nor configure the transmission of flow control messages. The system always honors received flow control messages regardless of the flow control mode status. You must enable this mode before you configure an interface to send pause frames. The default is disabled.
ftpd	Activates or disables the FTP server on the switch. The default value is disabled. To enable FTP, ensure that the *tftpd* flag is disabled.

Variable	Value
hsecure	Activates or disables High Secure mode. The hsecure command provides the following password behavior: • 10 character enforcement • The password must contain a minimum of 2 uppercase characters, 2 lowercase characters, 2 numbers, and 2 special characters. • Aging time • Failed login attempt limitation The default value is disabled. If you enable High Secure mode, you must restart the switch to enforce secure passwords. If you operate the switch in High Secure mode, the switch prompts a password change if you enter invalid-length passwords.
ipv6-egress-filter	Enables IPv6 egress filters. The default is disabled. If you change this parameter, you must restart the switch. For 5320 Series and 5420 Series platforms, the **boot config flags ipv6-egress-filter** and **boot config flags macsec** commands are mutually exclusive.
ipv6-mode	Enables IPv6 mode on the switch.
logging	Activates or disable system logging. The default value is enabled. The system names log files according to the following: • The system displays the file names in 8.3 (log.xxxxxxxx.sss) format. • The first 6 characters of the file name contain the last three bytes of the chassis base MAC address. • The next two characters in the file name specify the slot number of the CPU that generated the logs. • The last three characters in the file name are the sequence number of the log file. The system generates multiple sequence numbers for the same chassis and same slot if the system reaches the maximum log file size.
macsec Exception: only required for 5320 Series and 5420 Series.	Enables Media Access Control Security (MACsec) globally. The **boot config flags ipv6-egress-filter** and **boot config flags macsec** commands are mutually exclusive.

Variable	Value
nni-mstp	Enables MSTP and VLAN configuration on network-to-network interface (NNI) ports. The default is disabled. Note: Spanning Tree is disabled on all NNIs. You cannot add an SPBM NNI port or MLT port to any non SPBM B-VLAN. You cannot add additional C-VLANs to a brouter port.
reboot	Activates or disables automatic reboot on a fatal error. The default value is activated. Important: Do not change this parameter unless directed by technical support.
spanning-tree-mode <mstp|rstp>	Specifies the Multiple Spanning Tree Protocol or Rapid Spanning Tree Protocol mode. If you do not specify a protocol, the switch uses the default mode. The default mode is mstp. If you change the spanning tree mode, you must save the current configuration and restart the switch.
spbm-config-mode	Enables you to configure SPB and IS-IS, but you cannot configure PIM and IGMP either globally or on an interface. Use the **no** operator so that you can configure PIM and IGMP. The boot flag is enabled by default. To set this flag to the default value, use the **default** operator with the command.
spbm-node-scaling Note: Exception: Only supported on 5320 Series and 5420 Series.	Increases the number of supported SPB nodes per area that the switch supports. The default is 350 nodes per area. This flag is disabled by default. Important: If you enable this boot config flag, it impacts the following features: • the switch does not support more than 250 SPB nodes per area and sending multicast steams while the local Backbone Edge Bridges (BEB) receives. • the number of SPB nodes is also reduced for other features such as Switched UNI (S-UNI) endpoints, Layer 2 and Layer 3 I-SIDs, IP Multicast over Fabric Connect local streams, and Private VLANs. For more information about scaling numbers, see *Fabric Engine Release Notes*.

Variable	Value
sshd	Activates or disables the SSHv2 server service. The default value is disabled.
syslog-rfc5424-format	Controls the format of the syslog output and logging. By default, the switch uses the RFC5424 format. If the RFC based format is disabled, the older format is used.
telnetd	Activates or disables the Telnet server service. The default is disabled.
tftpd	Activates or disables Trivial File Transfer Protocol server service. The default value is disabled.
trace-logging	Activates or disables the creation of trace logs. The default value is disabled. Important: Do not change this parameter unless directed by technical support.
urpf-mode	Enables Unicast Reverse Path Forwarding (uRPF) globally. You must enable uRPF globally before you configure it on a port or VLAN. The default is disabled.

Variable	Value
verify-config	Activates syntax checking of the configuration file. The default is enabled. • Primary config behavior: When the verifyconfig flag is enabled, the primary config file is pre-checked for syntax errors. If the system finds an error, the primary config file is not loaded, instead the system loads the backup config file. If the verify-config flag is disabled, the system does not pre-check syntax errors. When the verify-config flag is disabled, the system ignores any lines with errors during loading of the primary config file. If the primary config file is not present or cannot be found, the system tries to load the backup file. • Backup config behavior: If the system loads the backup config file, the system does not check the backup file for syntax errors. It does not matter if the verify-config flag is disabled or enabled. With the backup config file, the system ignores any lines with errors during the loading of the backup config file. If no backup config file exists, the system defaults to factory defaults. As a best practice, disable the verify-config flag.
vrf-scaling	Increases the maximum number of VRFs and Layer 3 VSNs that the switch supports. This flag is disabled by default. Important: If you enable both this flag and the spbmconfig-mode flag, the switch reduces the number of configurable VLANs. For more information about maximum scaling numbers, see *Fabric Engine Release Notes*.

Using Telnet to Log on to the Device

About This Task

Use Telnet to log on to the device and remotely manage the switch.

Procedure

1. From a PC or terminal, start a Telnet session:

   ```
   telnet <ipv4 or ipv6 address>
   ```

2. Enter the logon and password when prompted.

Example

```
C:\Users\jsmith>telnet 192.0.2.40
Connecting to 192.0.2.40.....
Login:rwa
Password:rwa
```

Enable the Web Management Interface

About This Task

Enable the web management interface to provide management access to the switch using a web browser.

HTTP and HTTPS, and FTP support both IPv4 and IPv6 addresses, with no difference in functionality or configuration.

Important

To enable HTTP access to the device, you must disable the web server secure-only option. To enable HTTPS access to the device, the web server secure-only option is enabled by default. The TFTP server supports both IPv4 and IPv6 TFTP clients.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable the web server:

   ```
   web-server enable
   ```

3. To enable the secure-only option (for HTTPS access), enter:

   ```
   web-server secure-only
   ```

4. (Optional) To disable the secure-only option (for HTTP access), enter:

   ```
   no web-server secure-only
   ```

5. Configure the username and the access password:

   ```
   web-server password rwa WORD<1-20>
   ```

   

   Important

   The default passwords and community strings are documented and well known. Change the default passwords and community strings immediately after you first log on.

6. Enter and confirm your password.
7. Enable read-only user:

   ```
   web-server read-only-user enable
   ```

8. Save the configuration:

   ```
   save config
   ```

9. Display the web server status:

   ```
   show web-server
   ```

Example

Enable the secure-only web-server.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#web-server enable
Switch:1(config)#web-server secure-only
Switch:1(config)#web-server read-only-user enable
Switch:1(config)#web-server password rwa smith2
Enter the New password : ********
Re-enter the New password : ********
Password changed.
Switch:1(config)#web-server password ro jones6
Enter the New password : ********
Re-enter the New password : ********
Password changed.

Switch:1(config)#show web-server
Web Server Info :

TLS_RSA_WITH_AES_256_CBC_SHA
                                    TLS_RSA_WITH_AES_128_CBC_SHA256
TLS_RSA_WITH_AES_128_CBC_SHA
```

Variable Definitions

Use the data in the following table to use the **web-server** command.

Variable	Value
def-display-rows <10-100>	Configures the number of rows each page displays, between 10 and 100.
enable	Enables the web interface. To disable the web server, use the **no** form of this command: `no web-server [enable]`
help-tftp <WORD/0-256>	Configures the TFTP or FTP directory for Help files, in one of the following formats: a.b.c.d:/| peer:/ [<dir>]. The path can use 0–256 characters. The following example paths illustrate the correct format: • 192.0.2.1:/help • 192.0.2.1:/
http-port <80-49151>	Configures the web server HTTP port. The default port is 80.
https-port <443-49151>	Configure the web server HTTPS port. The default port is 443.
inactivity-timeout<30-65535>	Configures the web-server session inactivity timeout. The default is 900 seconds (15 minutes).
password {ro | rwa} WORD<1-20>	Configures the logon and password for the web interface.
password min-passwd-len<1-32>	Configures the minimum password length. By default, the minimum password length is 8 characters.
read-only-user	Enables read-only user for the web server. Note: **read-only-user enable** is available for demonstration purposes on some products. For more information, see *Fabric Engine Feature Support Matrix*.
secure-only	Enables secure-only access for the web server.
tls-min-ver<tlsv10|tlsv11|tlsv12>	Configures the minimum version of the TLS protocol supported by the web-server. You can select among the following: • tlsv10 – Configures the version to TLS 1.0. Note: tlsv10 is not supported in enhanced secure mode. • tlsv11 – Configures the version to TLS 1.1. • tlsv12 – Configures the version to TLS 1.2 The default is tlsv12.

Enable the Web Server RO User

About This Task

Perform this procedure to enable the web server RO user, which is disabled by default after a software upgrade.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable the read-only user:

   ```
   web-server read-only-user enable
   ```

Example

```
Switch:1>enable
Switch:1#configure terminal
```

Enable the default ro username:

```
Switch1:(config)#web-server read-only-user enable
```

Display the output of the **`show web-server command`** with the ro username enabled:

```
Switch:1(config)#show web-server
Web Server Info :

        Status                    : on
        Secure-only               : enabled
        TLS-minimum-version       : tlsv12
        RO Username Status        : enabled
        RO Username               : jones6
        RO Password               : ********
        RWA Username              : smith2
        RWA Password              : ********
        Def-display-rows          : 30
        Inactivity timeout        : 900 sec
        Html help tftp source-dir :
        HttpPort                  : 80
        HttpsPort                 : 443
        NumHits                   : 87
        NumAccessChecks           : 4
        NumAccessBlocks           : 0
        NumRxErrors               : 73
        NumTxErrors               : 0
        NumSetRequest             : 0
        Minimum password length   : 8
        Last Host Access Blocked  : 0.0.0.0
        In use certificate        : Self signed
```

Configure the TLS Protocol Version

The switch by default supports version TLS 1.2 and above. You can explicitly configure TLS 1.0 and TLS 1.1 version support using CLI.

Note

In enhanced secure mode, TLS 1.0 is available on 5520 Series and 5420 Series only.

About This Task

Disable the web server before changing the TLS version. By disabling the web server, other existing users with a connection to the web server are not affected from changing to a different version after you run the **`tls-min-ver`** command.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Disable the web server:

   ```
   no web-server enable
   ```

3. Set the TLS protocol version:

   ```
   web-server tls-min-ver [tlsv10 | tlsv11 | tlsv12]
   ```

4. Enable the web server:

   ```
   web-server enable
   ```

5. Verify the protocol version:

   ```
   show web-server
   ```

Example

```
Switch> enable
Switch# configure terminal
Switch(config)# web-server tls-min-ver tlsv12
```

Verify the protocol version.

```
Switch:1(config)#show web-server
Web Server Info :

                                    TLS_RSA_WITH_AES_256_CBC_SHA256
TLS_RSA_WITH_AES_256_CBC_SHA
                                    TLS_RSA_WITH_AES_128_CBC_SHA256
TLS_RSA_WITH_AES_128_CBC_SHA
```

Variable Definitions

Use the data in the following table to use the **web-server** command.

Variable	Value
def-display-rows <10-100>	Configures the number of rows each page displays, between 10 and 100.
enable	Enables the web interface. To disable the web server, use the **no** form of this command: `no web-server [enable]`
help-tftp <WORD/0-256>	Configures the TFTP or FTP directory for Help files, in one of the following formats: a.b.c.d:/| peer:/ [<dir>]. The path can use 0–256 characters. The following example paths illustrate the correct format: • 192.0.2.1:/help • 192.0.2.1:/
http-port <80-49151>	Configures the web server HTTP port. The default port is 80.
https-port <443-49151>	Configure the web server HTTPS port. The default port is 443.
inactivity-timeout<30-65535>	Configures the web-server session inactivity timeout. The default is 900 seconds (15 minutes).
password {ro | rwa} WORD<1-20>	Configures the logon and password for the web interface.
password min-passwd-len<1-32>	Configures the minimum password length. By default, the minimum password length is 8 characters.

Variable	Value
read-only-user	Enables read-only user for the web server. Note: **read-only-user enable** is available for demonstration purposes on some products. For more information, see *Fabric Engine Feature Support Matrix*.
secure-only	Enables secure-only access for the web server.
tls-min-ver<tlsv10|tlsv11|tlsv12>	Configures the minimum version of the TLS protocol supported by the web-server. You can select among the following: • tlsv10 – Configures the version to TLS 1.0. Note: tlsv10 is not supported in enhanced secure mode. • tlsv11 – Configures the version to TLS 1.1. • tlsv12 – Configures the version to TLS 1.2 The default is tlsv12.

Access the Switch Through the Web Interface

Before You Begin

You must enable the web server using CLI.

About This Task

Monitor the switch through a web browser from anywhere on the network. The web interface uses a 15-minute timeout period. If no activity occurs for 15 minutes, the system logs off the switch web interface, and you must re-enter the password information.

Hypertext Transfer Protocol (HTTP) and Hypertext Transfer Protocol Secure (HTTPS) support both IPv4 and IPv6 addresses, with no difference in functionality or configuration.

Note

By default the web server is configured with the secure-only option, which requires you to use HTTPS to access EDM. To access EDM using HTTP, you must disable the secure-only option. For more information about configuring the secure-only option, see Enable the Web Management Interface on page 155.

Procedure

1. Start your web browser.
2. Type the switch IP address as the URL in the web address field.
3. In the **User Name** box, type `admin` and in the **Password** box, type `password`.
4. Select **Login**.

Configuring the minimum version of the TLS protocol

Use the following procedure to configure the minimum version of the TLS protocol.

Earlier releases used a self-signed certificate generated using the OpenSSL API, and this self-signed certificate was installed in `/inflash/.ssh`. The self-signed certificate is now generated with the Mocana API.

Disable the web server before changing the TLS version. By disabling the web server, other existing users with a connection to the web server are not affected by changing to a different version.

The switch by default supports version TLS 1.2 and above. You can explicitly configure TLS 1.0 and TLS 1.1 version support.

Procedure

1. In the navigation tree, open the following folders: **Configuration** > **Security** > **Control Path**.
2. Select **General** and then select **Web** tab.
3. In the **TlsMinimumVersion** field, select the TLS version you want to configure as the minimum on the system.

Web *Field Descriptions*

Use the data in the following table to use the **Web** tab.

Name	Description
WebRWAUserName	Specifies the RWA username from 1–20 characters. The default is admin.
WebRWAUserPassword	Specifies the password from 1–32 characters. The default is 12345678.
WebROEnable	Enables the web server read-only (RO) user, which is disabled by default after a software upgrade.
WebEncryptionType	Specifies the ciphers for preset version of TLS for the web server.
WebCertSubjectName	Specifies the digital certificate subject Name used as identity certificate in the web server.
WebCertCAName	Specifies the digital certificate CA trustpoint name used for the certificate in the web server.
WebROUserName	Specifies the RO username. The default is user.
WebROUserPassword	Specifies the password from 1–32 characters. The default is password.
MinimumPasswordLength	Configures the minimum password length. By default, the minimum password length is 8 characters.
HttpPort	Specifies the HTTP port for web access. The default value is 80.
HttpsPort	Specifies the HTTPS port for web access. The default value is 443.

Name	Description
SecureOnly	Controls whether the secure-only option is enabled. The default is enabled.
InactivityTimeout	Specifies the idle time (in seconds) to wait before the EDM login session expires. The default value is 900 seconds (15 minutes).
TlsMinimumVersion	Configures the minimum version of the TLS protocol supported by the web-server. You can select from the following options: • tlsv10 – Configures the version to TLS 1.0. • tlsv11 – Configures the version to TLS 1.1. • tlsv12 – Configures the version to TLS 1.2 The default is tlsv12.
InUseCertType	Shows if the certificate is self-signed or user-installed.
HelpTftp/Ftp_SourceDir	Configures the TFTP or FTP directory for Help files, in one of the following formats: a.b.c.d:/| peer:/ [<dir>]. The path can use 0–256 characters. The following example paths illustrate the correct format: • 192.0.2.1:/Help • 192.0.2.1:/
DefaultDisplayRows	Configures the web server display row width between 10–100. The default is 30.
LastChange	Shows the last web-browser initiated configuration change.
NumHits	Shows the number of hits to the web server.
NumAccessChecks	Shows the number of access checks performed by the web server.
NumAccessBlocks	Shows the number of access attempts blocked by the web server.
LastHostAccessBlockedAddressType	Shows the address type, either IPv4 or IPv6, of the last host access blocked by the web server.
LastHostAccessBlockedAddress	Shows the IP address of the last host access blocked by the web server.
NumRxErrors	Shows the number of receive errors the web server encounters.
NumTxErrors	Shows the number of transmit errors the web server encounters.
NumSetRequest	Shows the number of set-requests sent to the web server.

Saving the configuration

Save the configuration to a file to retain the configuration settings.

About This Task

File Transfer Protocol (FTP) and Trivial File Transfer Protocol (TFTP) support both IPv4 and IPv6 addresses, with no difference in functionality or configuration.

Note

If you use File Transfer Protocol (FTP) or Trivial File Transfer Protocol (TFTP), ensure that you enable the FTP or TFTP server.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Save the running configuration:

   ```
   save config [backup WORD<1-99>] [file WORD<1-99>] [verbose]
   ```

Example

```
Switch:1> enable
```

Save the file to the default location:

```
Switch:1# save config
```

Variable Definitions

Use the data in the following table to use the **`save config`** command.

Variable	Value
`backup WORD<1-99>`	Saves the specified file name and identifies the file as a backup file. `WORD` uses one of the following formats: • a.b.c.d:<file> • /intflash/<file> The file name, including the directory structure, can include up to 99 characters.
`file WORD<1-99>`	Specifies the file name in one of the following formats: • a.b.c.d:<file> • /intflash/<file> The file name, including the directory structure, can include up to 99 characters.
`verbose`	Saves the default and current configuration. If you omit this parameter, the command saves only parameters you change.

Backing up configuration files

Before and after you upgrade your switch software, make copies of the configuration files. If an error occurs, use backup configuration files to return the switch to a previous state.

Before You Begin

- If you use File Transfer Protocol (FTP) or Trivial File Transfer Protocol (TFTP), ensure that you enable the FTP or TFTP server. File Transfer Protocol (FTP) and Trivial File Transfer Protocol (TFTP) support both IPv4 and IPv6 addresses, with no difference in functionality or configuration.

About This Task

Keep several copies of backup files.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Determine the configuration file names:

   ```
   show boot config choice
   ```

3. Save the configuration files. Assuming the files use the default file names, enter:

   ```
   save config
   ```

4. Copy the files to a safe place:

   ```
   copy /intflash/config.cfg /intflash/config_backup.cfg

   copy /intflash/config.cfg a.b.c.d:/dir/config_backup.cfg
   ```

Example

Determine the configuration file names, save the configuration files, and copy the files to a safe place.

```
Switch:1>enable
Switch:1#show boot config choice
choice primary config-file "/intflash/config.cfg"
choice primary backup-config-file "/intflash/config.cfg"
Switch:1#save config
Switch:1#copy /intflash/config.cfg 00:11:f9:5b:10:42/dir/config_backup.cfg
Do you want to continue? (y/n)
y
```

Resetting the platform

About This Task

Reset the platform to reload system parameters from the most recently saved configuration file.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Reset the switch:

   ```
   reset [-y]
   ```

Example

Reset the switch:

```
Switch:1>enable
Switch:1#reset
Are you sure you want to reset the switch? (y/n)
y
```

Variable Definitions

Use the data in the following table to use the **reset** command.

Variable	Value
-y	Suppresses the confirmation message before the switch resets. If you omit this parameter, you must confirm the action before the system resets.

Remove a Software Build

Use the following procedure to remove a software build for the switch.

Note

You can store up to 6 software releases on the 5520 Series. When the limit is reached, you are prompted to remove one release before you can proceed with adding and activating a new software release.

You can store a maximum of 2 software releases on the 5320 Series and 5420 Series. When the limit is reached, the software displays a confirmation to overwrite the non-primary release before you can install a new software release.

For more information, see Upgrade the Software on page 255.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Remove the software build:

   ```
   software remove WORD<1-99>
   ```

Example

Remove the software build:

```
Switch:1>enable
Switch:1#software remove w.x.y.z
```

Verification

Verify Boot Configuration Flags

Verify the boot configuration flags to verify boot configuration settings. Boot configuration settings only take effect after you reset the system. Verification of these parameters is essential to minimize system downtime and the resets to change them.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```
2. Verify the flags:
   ```
   show boot config flags
   ```

Example

Note

Flag support can vary across hardware models.

```
Switch:1#show boot config flags
flags advanced-feature-bandwidth-reservation low
flags block-snmp false
flags debug-config false
flags debugmode false
flags dvr-leaf-mode false
flags enhancedsecure-mode false
flags factorydefaults false
flags flow-control-mode true
flags ftpd true
flags hsecure false
flags ipv6-egress-filter true
flags ipv6-mode false
flags logging true
flags macsec false
flags nni-mstp false
flags reboot true
flags spanning-tree-mode mstp
flags spbm-config-mode true
flags spbm-node-scaling true
flags sshd true
flags syslog-rfc5424-format true
flags telnetd true
flags tftpd true
flags trace-logging false
flags urpf-mode true
flags verify-config true
flags vrf-scaling true
```

Verify the Software Release

About This Task

Use CLI to verify your installed software. It is important to verify your software version before you place a device into a production environment.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```

2. Verify the software release:

   ```
   show software detail
   ```

Example

The following is an example of the output of the `show software detail` command.

```
Switch:1>show software detail
================================================================================
                    software releases in /intflash/release/
================================================================================
5420.8.5.0.0.GA (Primary Release) (Signed Release)
  SSIO
    UBOOT                             2.3.2.3
    APP_FS                            5420.8.5.0.0.GA
  AVAILABLE ENCRYPTION MODULES
    3DES
    AES/DES

5420.8.4.0.0.GA (Backup Release) (Unsigned Release)
  SSIO
    UBOOT                             2.3.2.1
    APP_FS                            5420.8.4.0.0.GA
  AVAILABLE ENCRYPTION MODULES
    3DES
    AES/DES
```

Display local alarms

View local alarms to monitor alarm conditions.

Local alarms are raised and cleared by applications running on the switch. Local alarms are an automatic mechanism run by the system that do not require any additional user configuration. The raising and clearing of local alarms also creates a log entry for each event. Check alarms occasionally to ensure no alarms require additional operator attention.

For more information, see Alarm Database on page 3168.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display local alarms:

   ```
   show alarm database
   ```

Example

Display local alarms:

Note

The switches that support SF cards display warning messages when SFIs are down.

```
Switch:1#show alarm database
       ALARM         EVENT          ALARM       ALARM                        CREATION  UPDATED        CLEARED
SLOT   ID            CODE           TYPE        STATUS       SEVERITY  FREQ   TIME      TIME           TIME        REASON

Cold-Start Trap
```

Display log files

Use this procedure to display log files.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display log files:

   ```
   show logging file
   ```

Example

Display log files:

```
Switch:1>show logging file

Basic Administration Procedures using CLI

The following section describes common procedures that you use while you configure and monitor the switch operations using the Command Line Interface (CLI).

Note

Unless otherwise stated, to perform the procedures in this section, you must log on to the Privileged EXEC mode in the CLI. For more information about how to use CLI, see CLI Procedures on page 222.

Restarting the platform

Before You Begin

Note

The command mode is key for this command. If you are logged on to a different command mode, such as Global Configuration mode, rather than Privileged EXEC mode, the system displays different options for this command.

About This Task

Restart the switch to implement configuration changes or recover from a system failure. When you restart the system, you can specify the boot config file name. If you do not specify a boot source and file, the boot command uses the configuration files on the primary boot device defined by the `boot config choice` command.

After the switch restarts normally, it sends a cold trap within 45 seconds after the restart.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Restart the switch:

   ```
   boot [config WORD<1-99>] [-y]
   ```

Important

If you enter the `boot` command with no arguments, you cause the switch to start using the current boot choices defined by the `boot config choice` command.

If you enter a boot command and the configuration file name without the directory, the device uses the configuration file from /intflash/.

Example

```
Switch:1> enable
```

Restart the switch:

```
Switch:1# boot config /intflash/config.cfg

Switch:1# Do you want to continue? (y/n)

Switch:1# Do you want to continue? (y/n) y
```

Variable Definitions

The following table defines parameters for the **boot** command.

Variable	Value
config WORD<1-99>	Specifies the software configuration device and file name in one of the following formats: • /intflash/ <file> The file name, including the directory structure, can include up to 99 characters.
-y	Suppresses the confirmation message before the switch restarts. If you omit this parameter, you must confirm the action before the system restarts.

Resetting the platform

About This Task

Reset the platform to reload system parameters from the most recently saved configuration file.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```
2. Reset the switch:
   ```
   reset [-y]
   ```

Example

```
Switch:1> enable
```

Reset the switch:

```
Switch:1# reset

Are you sure you want to reset the switch? (y/n) y
```

Variable Definitions

The following table defines parameters for the **reset** command.

Variable	Value
-y	Suppresses the confirmation message before the switch resets. If you omit this parameter, you must confirm the action before the system resets.

Shutting Down the System

Use the following procedure to shut down the system.

Caution

Before you unplug the AC power cord, always perform the following shutdown procedure.

This procedure:

- Flushes any pending data to ensure data integrity.
- Ensures the completion of recent configuration save actions, thus preventing the system from inadvertently booting up with incorrect configuration.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```
2. Shut down the system:
   ```
   sys shutdown
   ```
3. Before you unplug the power cord, wait until you see the following message:
   ```
   System Halted, OK to turn off power
   ```

Example

Shut down a running system.

```
Switch:1#sys shutdown
Are you sure you want shutdown the system? Y/N  (y/n) ? y
CP1  [05/08/14 15:47:50.164] 0x00010813 00000000 GlobalRouter HW INFO System shutdown

Configure the Default Ping and Traceroute Context

About This Task

Ping commands and traceroute commands execute in Global Router (GRT) context by default. You can configure ping commands and traceroute commands to execute in management (mgmt) context or in Virtual Router Forwarding (vrf) context.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the default ping command and traceroute command context:

   ```
   sys default-ping-context {grt | mgmt | vrf}
   ```

Variable Definitions

The following table defines parameters for the **`sys default-ping-context`** command.

Variable	Value
grt	Specifies Global Routing Table (grt) context as the default context for ping commands and traceroute commands. The default configuration is grt as the default context.
mgmt	Specifies management (mgmt) context as the default context for ping commands and traceroute commands. The default configuration is grt as the default context.
vrf	Specifies Virtual Router Forwarding (VRF) context as the default context for ping commands and traceroute commands. The default configuration is grt as the default context.

Calculate and Verify the MD5 Checksum for a File on the Switch

Perform this procedure to verify that the software files are downloaded properly to the switch. The MD5 checksum for each release is available on the Extreme Networks Support website.

Before You Begin

- Download the MD5 checksum to an intermediate workstation or server where you can open and view the contents.
- Download the image file to the switch.

About This Task

Calculate and verify the MD5 checksum after you download software files.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View the list of files:

   ```
   ls *.voss
   ```

3. Calculate the MD5 checksum for the file:

   ```
   file-checksum md5 WORD<1-99>
   ```

4. Compare the number generated for the file on the switch with the number that displays in the MD5 checksum on the workstation or server. Ensure that the MD5 checksum of the software suite matches the system output generated from calculating the MD5 checksum from the downloaded file.

Example

View the contents of the MD5 checksum on the workstation or server:

```
9e8e4356ec44661514cd142e933dca59  5420.8.4.0.0_edoc.tar
4602bf5adbc0c31c0e5f5d38209d7b87  5420.8.4.0.0_mib_sup.txt
25be1902e954e3140d1072562c926d4b  5420.8.4.0.0_mib.txt
09d06a9dbbfdaa07cabd2000556d5d2b  5420.8.4.0.0_mib.zip
8e23c6632b5b7a9ec134418348baebea  5420.8.4.0.0_oss-notice.html
d83cd61e0b115c83aca0c52c9dd5eb0e  5420.8.4.0.0.voss
eb86e5991d8ce2a69b21510b993e0727  restconf_yang.tgz
561a5b566c42b68cc4b1fc3b1e71cf70  VOSSv840_HELP_EDM_gzip.zip
```

Calculate the MD5 checksum for the file on the switch:

```
Switch:1>ls *.voss
Listing Directory /intflash:
-rw-r--r--  1 0       0       94195267 Dec 13 14:42  5420.8.4.0.0.voss
Switch:1>file-checksum md5 5420.8.4.0.0.voss
MD5 (5420.8.4.0.0.voss) = d83cd61e0b115c83aca0c52c9dd5eb0e
```

Variable Definitions

The following table defines parameters for the **`file-checksum md5`** command:

Variable	Value
WORD<1-99>	Specifies the file name.

Calculate and Verify the MD5 Checksum for a File on a Client Workstation

Perform this procedure on a Unix or Linux machine to verify that the software files downloaded properly. The MD5 checksum for each release is available on the Extreme Networks Support website.

About This Task

Calculate and verify the MD5 checksum after you download software files.

Procedure

1. Calculate the MD5 checksum of the downloaded file:

   ```
   $ /usr/bin/md5sum <downloaded software-filename>
   ```

   Typically, downloaded software files are in the form of .voss files.
2. Verify the MD5 checksum of the software suite:

   ```
   $ more <md5-checksum output file>
   ```
3. Compare the output that displays on the screen. Ensure that the MD5 checksum of the software suite matches the system output generated from calculating the MD5 checksum from the downloaded file.

Example

Calculate the MD5 checksum of the downloaded file:

```
$ /usr/bin/md5sum 5420.8.4.0.0.voss

d83cd61e0b115c83aca0c52c9dd5eb0e 5420.8.4.0.0.voss
```

View the MD5 checksum of the software suite:

```
$ more 5420.8.4.0.0.md5
9e8e4356ec44661514cd142e933dca59  5420.8.4.0.0_edoc.tar
4602bf5adbc0c31c0e5f5d38209d7b87  5420.8.4.0.0_mib_sup.txt
25be1902e954e3140d1072562c926d4b  5420.8.4.0.0_mib.txt
09d06a9dbbfdaa07cabd2000556d5d2b  5420.8.4.0.0_mib.zip
8e23c6632b5b7a9ec134418348baebea  5420.8.4.0.0_oss-notice.html
d83cd61e0b115c83aca0c52c9dd5eb0e  5420.8.4.0.0.voss
eb86e5991d8ce2a69b21510b993e0727  restconf_yang.tgz
561a5b566c42b68cc4b1fc3b1e71cf70  VOSSv840_HELP_EDM_gzip.zip
```

Calculating the File Checksum

About This Task

Perform the following procedure to calculate or comapre the MD5 or SHA512 digest for a specific file. The **file-checksum** command calculates the MD5 or SHA512 digest for files on the internal flash and either shows the output on screen or stores the output in a file that you specify. The **file-checksum** command compares the calculated MD5 or SHA512 digest with that in a checksum file on flash, and the compared output displays on the screen. By verifying the MD5 or SHA512 checksum, you can verify that the file is transferred properly to the switch.

Important

- If the MD5 key file parameters change, you must remove the old file and create a new file.
- Use the **file-checksum** command with reserved files (for example, a password file) only if you possess sufficient permissions to access these files.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Calculate the file checksum:

   ```
   file-checksum {md5 | sha512} WORD<1-99> [-a] [-c] [-f WORD<1-99>] [-r]
   ```

Example

```
Switch:1>file-checksum md5 password -a -f password.md5
```

Variable Definitions

The following table defines parameters for the **file-checksum** command.

Variable	Value
md5	Calculates or compares the MD5 digest for a specific file.
sha512	Calculates or compares the SHA512 digest for a specific file.
-a	Adds data to the output file instead of overwriting it. You cannot use the *-a* option with the *-c* option.
-c	Compares the checksum of the specified file with the MD5 checksum present in the checksum file name. You can specify the checksum file name using the *-f* option. If the checksum filename is not specified, the file `/intflash/checksum.md5` is used for comparison. If the supplied checksum filename and the default file are not available on flash, the system displays the following error message on the switch: Error: Checksum file *<filename>* not present. The *-c* option also • calculates the checksum of the specified files • compares the checksum with all keys in the checksum file, even if filenames do not match • displays the output of comparison

-f	Stores the result of MD5 checksum to a file on internal flash.
	If the output file specified with the *-f* option is reserved filenames on the switch, the command fails with the error message:
	`Error: Invalid operation.`
	If the output file specified with the *-f* option is files for which to compute MD5 checksum, the command fails with the error message:
	`Switch:1# md5 *.cfg -f config.cfg Error: Invalid operation on file <filename>`
	If the checksum filename specified by the *-f* option exists on the switch (and is not one of the reserved filenames), the system displays the following message on the switch:
	`File exists. Do you wish to overwrite? (y/n)`

Variable	Value
-r	Reverses the output. Use with the *-f* option to store the output to a file. You cannot use the *-r* option with the *-c* option.
WORD<1-99>	Specifies the file name.

Resetting system functions

About This Task

Reset system functions to reset all statistics counters on the console port. Depending on your hardware platform, the console port displays as console or 10101.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```
2. Reset system functions:
   ```
   sys action reset {console|counters}
   ```

Example

```
Switch:1> enable
```

Reset the statistics counters:

```
Switch:1# sys action reset counters

Are you sure you want to reset system counters (y/n)? y
```

Variable Definitions

The following table defines parameters for the **sys action** command.

Variable	Value
reset {console|counters}	Reinitializes the hardware universal asynchronous receiver transmitter (UART) drivers. Use this command only if the console connection does not respond. Resets all the statistics counters in the switch to zero. Resets the console port.

Sourcing a Configuration

Source a configuration to merge a script file into the running configuration or verify the syntax of a configuration file.

About This Task

The **source** cli command is intended for use with a switch that is running with a factory default configuration to quick load a pre-existing configuration from a file. If you source a configuration file to merge that configuration into a running configuration, it can result in operational configuration loss if

the sourced configuration file contains any configuration that has dependencies on or conflicts with the running configuration. Use the source command to merge smaller portions of a configuration into the existing configuration.

Not all CLI commands are included in configuration files. Typical examples include, but are not limited to some operational and security-related commands. Ensure that you understand what configuration options are included or not included in a configuration file, when you use that file to build new configurations.

The operational modes in the boot configuration file must be configured for some features (for example, **spbm-config-mode true/false**). Before sourcing a configuration file, you need to configure the **boot config flag**, save the configuration, and reboot the system. After the reboot, you can source the configuration file without fail.

Important

Do not source a verbose configuration (verbose.cfg) with the *debug stop* option. The sourcing process cannot complete if you use these two options with a verbose configuration.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```
2. Source a configuration:
   ```
   source WORD<1-99> [debug] [stop] [syntax]
   ```

Example

```
Switch:1> enable
```

Debug the script output:

```
Switch:1# source testing.cfg debug
```

Variable Definitions

The following table defines parameters for the **source** command.

Variable	Value
debug	Debugs the script by outputting the configuration commands to the screen.
stop	Stops the sourcing of a configuration if an error occurs.

Variable	Value
syntax	Checks the syntax of the configuration file. This parameter does not load the configuration file; only verifies the syntax. If you use this parameter with the *stop* parameter (**source WORD<1-99> stop syntax**), the output displays on screen and verification stops if it encounters an error. If you use this parameter with the *debug* parameter (**source WORD<1-99> debug syntax**), the output does not stop if it encounters an error; you must review the on-screen output to verify if an error exists. If you use this parameter by itself, it does not output to the screen or stop on error; it shows an error message, `syntax errors in script`, to indicate if errors exist in the configuration file.
WORD<1-99>	Specifies a filename and location in one of the following format: • a.b.c.d:<file> • /intflash/<file> <file> is a string.

Using the USB Device

The following sections describe common procedures that you can use with the USB device.

Save a File to an External USB Device

Use the following procedure to save the configuration file or log file to an external USB device.

Caution

Always use the `usb-stop` command to safely unplug the USB drive from the USB slot.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Save the file to an external USB device:

   a. To save the configuration file to an external USB device, enter:

   ```
   save config file WORD<1-99>
   ```

   b. To save the log file to an external USB device, enter:

   ```
   save log file WORD<1-99>
   ```

Example

```
Switch:1#save config file /usb/test.cfg
CP-1: Save config to file /usb/test.cfg successful.
WARNING: Choice Primary Node Config file is "/intflash/soak.cfg".
```

```
Switch:1#
Switch:1#save log file /usb/test.log

Save log to file /usb/test.log successful.
Save log to file /usb/test.log successful.
Switch:1#
```

Variable definitions

The following table defines parameters for the `save` command.

Variable	Value
`config file` *WORD<1-99>*	Specifies the software configuration device and configuration file name in one of the following formats: • a.b.c.d:<file> • /intflash/<file> • /usb/<file> The file name, including the directory structure, can include up to 99 characters.
`log file` *WORD<1-99>*	Specifies the software configuration device and log file name in one of the following formats: • a.b.c.d:<file> • /intflash/<file> • /usb/<file> The file name, including the directory structure, can include up to 99 characters.

Back Up and Restore the Compact Flash to an External USB Device

Perform this procedure to back up and restore the contents of the internal compact flash to a USB flash device without entering multiple **copy** commands. This procedure is useful if you want to copy the complete compact flash contents to another chassis.

Caution

Always use the `usb-stop` command to safely unplug the USB drive from the USB slot.

Before You Begin

- 

  Important

  Disable logging using the command: `no boot config logging`.

- You must have a USB storage device ready to use that is at least 2 GB. The switch supports USB 1 and 2.

About This Task

The system verifies that the USB flash device has enough available space to perform the backup operation. If the USB flash device does not have enough available space, the system displays an error message. The backup command uses the following filepath on the USB flash device: `/usb/intflash/intflashbackup_yyyymmddhhmmss.tgz`.

The backup action can take up to 10 minutes.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```
2. Backup the internal flash to USB:
   ```
   backup intflash
   ```
3. Restore the data to the internal flash:
   ```
   restore intflash
   ```

Example

```
Switch:1#backup intflash
```

```
Warning: Command will backup all data from /intflash to /usb/intflash.
         It will take a few minutes and may cause high CPU utilization.

         Are you sure you want to continue? (y/n) ? y

For file system /intflash:
          7252475904 total bytes on the filesystem
           990920704 used bytes on the filesystem
          6261555200 free bytes on the filesystem

For file system /usb:
          2021216256 total bytes on the filesystem
            12038144 used bytes on the filesystem
          2009178112 free bytes on the filesystem

cd /intflash ; /bin/tar -czvf /usb/intflash/intflashbackup_20140610074501.tgz *
; /bin/sync

Info: Backup /intflash to filename /usb/intflash/intflashbackup_20140610074501.tgz is
complete!

         Do you want to stop the usb? (y/n) ? n
```

Copy Configuration and Log Files from a USB Device to Intflash

Copy configuration and log files from an external USB device to the internal Flash memory.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```
2. Copy configuration or log files from the USB device to Intflash:
   ```
   copy /usb/<srcfile> /intflash/<destfile>
   ```

Example

```
Switch:1#enable

Switch:1#copy /usb/test.cfg /intflash/test.cfg
```

Variable Definitions

The following table defines parameters for the `copy` command.

Variable	Value
<destfile>	Specifies the name of the configuration or log file when copied to the internal Flash memory. The destination file name must be lower case and have a file extension of .cfg or .log. For example, test.cfg or test.log. The file name, including the directory structure, can include up to 255 characters.
<srcfile>	Specifies the name of the configuration or log file on the USB device. For example, test.cfg or test.log. The file name, including the directory structure, can include up to 255 characters.

Display the Contents of a USB File

Use the following procedure to view content of a USB file.

Caution

Always use the `usb-stop` command to safely unplug the USB drive from the USB slot.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Display content of a USB file:

   ```
   more WORD<1-99>
   ```

Example

```
Switch:1#enable

Switch:1#more /usb/test.cfg
```

Variable definitions

The following table defines parameters for the `more` command.

Variable	Value
WORD<1-99>	Specifies the file name in the following format: • /usb/<file> The file name, including the directory structure, can include up to 99 characters.

Move a File to or from a USB Device

Use the following procedure to move a file from the internal Flash memory (Intflash) to an external USB device, or from a USB device to Intflash.

Caution

Always use the `usb-stop` command to safely unplug the USB drive from the USB slot.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Move a file to a safe location:

   a. To move a file from Intflash to a USB device:

      ```
      mv /intflash/<srcfile> /usb/<destfile>
      ```

   b. To move a file from a USB device to Intflash:

      ```
      mv /usb/<srcfile> /intflash/<destfile>
      ```

Example

```
Switch:1#enable
Switch:1#mv /intflash/test.cfg /usb/test.cfg

Switch:1#enable
Switch:1#mv /usb/test.cfg /intflash/test.cfg
```

Variable Definitions

The following table defines parameters for the `mv` command.

Variable	Value
<destfile>	Specifies the name of the configuration or log file when moved to the USB device. The destination file name must be lower case and have a file extension of .cfg or .log. For example, test.cfg or test.log. The file name, including the directory structure, can include up to 255 characters.
<srcfile>	Specifies the name of the configuration or log file on the internal flash memory. For example, test.cfg or test.log. The file name, including the directory structure, can include up to 255 characters.

Delete a file from a USB Device

Use the following procedure to delete a file from an external USB device.

Caution

Always use the `usb-stop` command to safely unplug the USB drive from the USB slot.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Delete a file from a USB device:

   ```
   delete WORD<1-255>
   ```

Example

```
Switch:1#enable

Switch:1#delete /usb/test.cfg
Are you sure (y/n) ? y
```

Variable Definitions

The following table defines parameters for the `delete` command.

Variable	Value
WORD<1–255>	Specifies the file name in the following format: • /usb/<file>

Back Up Configuration Files to ZIP

Table 23: ExtremeCloud IQ - Site Engine backup configuration ZIP file product support

Feature	Product	Release introduced
ExtremeCloud IQ - Site Engine backup configuration ZIP file For more information, see ExtremeCloud IQ - Site Engine documentation.	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

ExtremeCloud IQ - Site Engine has a configuration backup feature with a requirement to be able to backup configuration related files.

Note

License files are not backed up.

Backing up configuration files to a ZIP file

About This Task

Use this procedure to back up configuration files.

Important

Only the RWA user can use the **backup** command.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Use the backup command:

   ```
   backup configure WORD<1–99>
   ```

Example

```
Switch:1>enable
Switch:1#backup configure /intflash/backup02072018

Successfully backed up config /intflash to /intflash/backup02072018.tgz
```

Restoring configuration files from a ZIP file

About This Task

Use the following procedure to restore previously backed up configuration files.

Before You Begin

- Download the backup file to the /intflash directory.
- If restoring the configuration files on a new switch, you must do one of the following:
  - Disable ISIS on the old switch .
  - Power the old switch down.
  - Remove the old switch from the network.
- If restoring the configuration files on a different switch, use the “isis dup-detection-temp-disable “ command on the new switch to suspend duplicate detection prior to its insertion into the existing SPBM topology.

Important

This must be done after the original unit has been completely removed or isolated from the SPBM topology.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Run the restore command to restore the configuration files.

   ```
   restore configure WORD<1-99>
   ```

Example

```
Switch:1>enable
Switch:1#restore configure /intflash/backup02072018.tgz

Warning: Command will restore your backup setup and access files
  The current files will be overwritten.

    Are you sure you want to continue? (y/n) ?y

 Restore /intflash from /intflash/backup02072018.tgz is complete!
 Reboot is required for the new configuration to be effective
```

Basic administration procedures using EDM

The following section describes common procedures that you use while you configure and monitor the switch operations using Enterprise Device Manager (EDM).

Reset the Platform

Reset the platform to reload system parameters from the most recently saved configuration file. Use the following procedure to reset the device using EDM.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Chassis**.
3. Select the **System** tab.
4. From **ActionGroup1**, select **saveRuntimeConfig**.
5. Select **Apply**.
6. From **ActionGroup4**, select **softReset** .
7. Select **Apply**.

Show the MTU for the System

About This Task

Perform this procedure to show the MTU configured for the system.

Procedure

1. On the Device Physical View, select the Device.
2. In the navigation pane, expand **Configuration** > **Edit**.
3. Click **Chassis**.
4. Click on the **Chassis** tab.
5. Verify the selection for the MTU size.

Save the Configuration

About This Task

After you change the configuration, you must save the changes on the device. Save the configuration to a file to retain the configuration settings.

Note

When you logout of the EDM interface, a dialog box automatically prompts if you want to save the configuration. If you want to save the configuration, click **OK**. If you want to close without saving the configuration, click **Cancel**. If you no longer see the prompt, clear your browser cache, restart your browser and reconnect.

Procedure

1. In the Device Physical View tab, select the Device.
2. In the navigation pane, expand **Configuration** > **Edit**.
3. Click **Chassis**.
4. Click the **System** tab.
5. (Optional) Specify a filename in **ConfigFileName**.

   If you do not specify a filename, the system saves the information to the default file.
6. In **ActionGroup1**, select **saveRuntimeConfig**.
7. Click **Apply**.

View UBoot Version and Status

About This Task

Use this information to verify the integrity of the software and hardware. A representative from Customer Support will instruct you to obtain this information when required.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Chassis**.
3. Select the **UBoot** tab.

UBoot *Field Descriptions*

Use the data in the following table to use the **UBoot** tab.

Name	Description
DefaultVersion	Displays the default UBoot version.
AlternateVersion	Displays the alternate UBoot version.
VersionUsed	Displays the UBoot version in use, either the default or alternate.
TrustedDeliveryStatus	Displays the status of the chain of trust image signature validation steps.

Boot parameter configuration using the CLI

Use the procedures in this section to configure and manage the boot process.

Modify the Boot Sequence

About This Task

Modify the boot sequence to prevent the switch from using the factory default settings or, conversely, to prevent loading a saved configuration file.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Bypass the loading of the switch configuration file and load the factory defaults:

   ```
   boot config flags factorydefaults
   ```

3. Use a configuration file and not the factory defaults:
   ```
   no boot config flags factorydefaults
   ```

Important

If the switch fails to read and load a saved configuration file after it starts, check the log file to see if the log file indicates that the factorydefaults setting was enabled, before you investigate other options.

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#boot config flags factorydefaults
```

Configuring the remote host logon

Before You Begin

- The FTP server must support the FTP passive (PASV) command. If the FTP server does not support the passive command, the file transfer is aborted, and then the system logs an error message that indicates that the FTP server does not support the passive command.

About This Task

Configure the remote host logon to modify parameters for FTP and TFTP access. The defaults enable TFTP transfers. If you want to use FTP as the transfer mechanism, you need to change the password to a non-null value.

Important

tftp-debug should be used exclusively to transfer small files less than 1MB in size. Using it for larger files might cause unwanted behavior, such as transfer failure.

Procedure

1. Enter Global Configuration mode:
   ```
   enable

   configure terminal
   ```
2. Define conditions for the remote host logon:
   ```
   boot config host {ftp-debug|password WORD<0-16>|tftp-debug|tftp-hash|
   tftp-rexmit <1-120>|tftp-timeout <1-120>|user WORD<0-16>}
   ```
3. Save the changed configuration.

Example

```
Switch:1> enable

Switch:1# configure terminal
```

Enable console tftp/tftpd debug messages:

```
Switch:1# boot config host tftp-debug
```

```
Switch:1# save config
```

Changing the primary or secondary boot configuration files

About This Task

Change the primary or secondary boot configuration file to specify which configuration file the system uses to start.

Configure the primary boot choices.

You have a primary configuration file that specifies the full directory path and a secondary configuration file that also contains the full directory path.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Change the primary boot choice:

   ```
   boot config choice primary {backup-config-file|config-file} WORD<0-255>
   ```

3. Save the changed configuration.
4. Restart the switch.

Example

```
Switch:1> enable

Switch:1# configure terminal
```

Specify the configuration file in internal flash memory as the primary boot source:

```
Switch:1(config)# boot config choice primary config-file /intflash/
config.cfg

Switch:1(config)# save config

Switch:1(config)# reset
```

Variable Definitions

The following table defines parameters for the **boot config** command.

Variable	Value
{backup-config-file|config-file}	Specifies that the boot source uses either the configuration file or a backup configuration file.
WORD<0-255>	Identifies the configuration file. *WORD<0-255>* is the device and file name, up to 255 characters including the path, in one of the following format: • a.b.c.d:<file> • /usb/<file> • /intflash/<file> To set this option to the default value, use the **default** operator with the command.

Configure Boot Flags

Before You Begin

- If you enable the hsecure flag, you cannot enable the flags for the web server or SSH password-authentication.

Important

After you change certain configuration parameters using the **boot config flags** command, you must save the changes to the configuration file.

About This Task

Configure the boot flags to enable specific services and functions for the chassis.

Note

Flag support can vary across hardware models.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable boot config flag(s) on the switch using the **boot config flags** command.

   Enable the following flags, as needed:

   - *advanced-feature-bandwidth-reservation [low | vim]*
   - *block-snmp*
   - *debug-config [file*
   - *debugmode*
   - *dvr-leaf-mode*

- *enhancedsecure-mode <jitc|non-jitc>*
- *factorydefaults*
- *flow-control-mode*
- *ftpd*
- *hsecure*
- *ipv6-egress-filter*
- *ipv6-mode*
- *logging*
- *macsec*
- *nni-mstp*
- *reboot*
- *spanning-tree-mode <mstp|rstp>*
- *spbm-config-mode*
- *spbm-node-scaling*
- *sshd*
- *syslog-rfc5424-format*
- *telnetd*
- *tftpd*
- *trace-logging*
- *urpf-mode*
- *verify-config*
- *vrf-scaling*

3. Save the changed configuration.
4. Restart the switch.

Example

Activate High Secure mode:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#boot config flags hsecure
Switch:1(config)#save config
Switch:1(config)#reset
```

Variable Definitions

The following table defines parameters for the **boot config flags** command.

Variable	Value
advanced-feature-bandwidth-reservation [low | high | vim] Note: Exception: vim is only supported on 5520 Series and 5720 Series. Exception: high is only supported on 5720 Series. Exception: low is not supported on 5720 Series.	Enables the switch to support advanced features by reserving ports as loopback ports. When disabled, you can use all ports on the switch, but advanced features do not work. The default varies depending on the platform: • The default for 5320 Series and 5420 Series is enabled with low level. • The default for 5520 Series is enabled with vim level if Versatile Interface Module (VIM) is not installed, else low level is enabled. • The default for 5720 Series is enabled with vim level if Versatile Interface Module (VIM) is not installed, else high level is enabled. • The low level means that the switch reserves less bandwidth to support minimum functionality for advanced features. • The vim level means that the switch uses VIM ports as loopback ports and the Universal Ethernet ports for uplinks. • The high level parameter means that the switch reserves the maximum bandwidth for the advanced features. If you change this parameter, you must restart the switch.
block-snmp	Activates or disables Simple Network Management Protocol management. The default value is false (disabled), which permits SNMP access.

Variable	Value
debug-config [console] | [file]	Enables you to debug the configuration file during loading configuration at system boot up. The default is disabled. You do not have to restart the switch after you enable debug-config, unless you want to immediately debug the configuration. After you enable debug-config and save the configuration, the debug output either displays on the console or logs to an output file the next time the switch reboots. The options are: • debug-config [console]—Displays the line-by-line configuration file processing and result of the execution on the console while the device loads the configuration file. • debug-config [file]— Logs the line-by-line configuration file processing and result of the execution to the debug file while the device loads the configuration file. The system logs the debug config output to /intflash/ debugconfig_primary.txt for the primary configuration file. The system logs the debug config output to /intflash/ debugconfig_backup.txt for the backup configuration, if the backup configuration file loads.
debugmode	Enables a TRACE on any port by prompting the selection on the console during boot up. This allows the user start trace for debugging earlier on specified port. Works on console connection only. The default is disabled. **Important:** Do not change this parameter unless directed by technical support.
dvr-leaf-mode	Enables an SPB node to be configured as a DvR Leaf. A node that has this flag set cannot be configured as a DvR Controller. The boot flag is disabled by default.

Variable	Value
enhancedsecure-mode {jitc | non-jitc}	Enables enhanced secure mode in either the Joint Interoperability Test Command (JITC) or non-JITC sub-modes. Note: As a best practice, enable the enhanced secure mode in the non-JITC sub-mode, because the JITC sub-mode is more restrictive and prevents the use of some CLI commands that are commonly used for troubleshooting. When you enable enhanced secure mode in either the JITC or non-JITC sub-modes, the switch provides role-based access levels, stronger password requirements, and stronger rules on password length, password complexity, password change intervals, password reuse, and password maximum age use.
factorydefaults	Specifies whether the switch uses the factory default settings at startup. The default value is disabled. This flag is automatically reset to the default setting after the CPU restarts. If you change this parameter, you must restart the switch. Note: The factorydefaults flag deletes the runtime, primary and backup configuration files, local password files, authentication keys, and certificates. After a factory default, you must change the password on first login.
flow-control-mode	Enables or disables flow control globally. When disabled, the system does not generate nor configure the transmission of flow control messages. The system always honors received flow control messages regardless of the flow control mode status. You must enable this mode before you configure an interface to send pause frames. The default is disabled.
ftpd	Activates or disables the FTP server on the switch. The default value is disabled. To enable FTP, ensure that the *tftpd* flag is disabled.

Variable	Value
hsecure	Activates or disables High Secure mode. The hsecure command provides the following password behavior: • 10 character enforcement • The password must contain a minimum of 2 uppercase characters, 2 lowercase characters, 2 numbers, and 2 special characters. • Aging time • Failed login attempt limitation The default value is disabled. If you enable High Secure mode, you must restart the switch to enforce secure passwords. If you operate the switch in High Secure mode, the switch prompts a password change if you enter invalid-length passwords.
ipv6-egress-filter	Enables IPv6 egress filters. The default is disabled. If you change this parameter, you must restart the switch. For 5320 Series and 5420 Series platforms, the **boot config flags ipv6-egress-filter** and **boot config flags macsec** commands are mutually exclusive.
ipv6-mode	Enables IPv6 mode on the switch.
logging	Activates or disable system logging. The default value is enabled. The system names log files according to the following: • The system displays the file names in 8.3 (log.xxxxxxxx.sss) format. • The first 6 characters of the file name contain the last three bytes of the chassis base MAC address. • The next two characters in the file name specify the slot number of the CPU that generated the logs. • The last three characters in the file name are the sequence number of the log file. The system generates multiple sequence numbers for the same chassis and same slot if the system reaches the maximum log file size.
macsec Exception: only required for 5320 Series and 5420 Series.	Enables Media Access Control Security (MACsec) globally. The **boot config flags ipv6-egress-filter** and **boot config flags macsec** commands are mutually exclusive.

Variable	Value
nni-mstp	Enables MSTP and VLAN configuration on network-to-network interface (NNI) ports. The default is disabled. Note: Spanning Tree is disabled on all NNIs. You cannot add an SPBM NNI port or MLT port to any non SPBM B-VLAN. You cannot add additional C-VLANs to a brouter port.
reboot	Activates or disables automatic reboot on a fatal error. The default value is activated. Important: Do not change this parameter unless directed by technical support.
spanning-tree-mode <mstp|rstp>	Specifies the Multiple Spanning Tree Protocol or Rapid Spanning Tree Protocol mode. If you do not specify a protocol, the switch uses the default mode. The default mode is mstp. If you change the spanning tree mode, you must save the current configuration and restart the switch.
spbm-config-mode	Enables you to configure SPB and IS-IS, but you cannot configure PIM and IGMP either globally or on an interface. Use the **no** operator so that you can configure PIM and IGMP. The boot flag is enabled by default. To set this flag to the default value, use the **default** operator with the command.
spbm-node-scaling Note: Exception: Only supported on 5320 Series and 5420 Series.	Increases the number of supported SPB nodes per area that the switch supports. The default is 350 nodes per area. This flag is disabled by default. Important: If you enable this boot config flag, it impacts the following features: • the switch does not support more than 250 SPB nodes per area and sending multicast steams while the local Backbone Edge Bridges (BEB) receives. • the number of SPB nodes is also reduced for other features such as Switched UNI (S-UNI) endpoints, Layer 2 and Layer 3 I-SIDs, IP Multicast over Fabric Connect local streams, and Private VLANs. For more information about scaling numbers, see *Fabric Engine Release Notes*.

Variable	Value
sshd	Activates or disables the SSHv2 server service. The default value is disabled.
syslog-rfc5424-format	Controls the format of the syslog output and logging. By default, the switch uses the RFC5424 format. If the RFC based format is disabled, the older format is used.
telnetd	Activates or disables the Telnet server service. The default is disabled.
tftpd	Activates or disables Trivial File Transfer Protocol server service. The default value is disabled.
trace-logging	Activates or disables the creation of trace logs. The default value is disabled. Important: Do not change this parameter unless directed by technical support.
urpf-mode	Enables Unicast Reverse Path Forwarding (uRPF) globally. You must enable uRPF globally before you configure it on a port or VLAN. The default is disabled.

Variable	Value
verify-config	Activates syntax checking of the configuration file. The default is enabled. • Primary config behavior: When the verifyconfig flag is enabled, the primary config file is pre-checked for syntax errors. If the system finds an error, the primary config file is not loaded, instead the system loads the backup config file. If the verify-config flag is disabled, the system does not pre-check syntax errors. When the verify-config flag is disabled, the system ignores any lines with errors during loading of the primary config file. If the primary config file is not present or cannot be found, the system tries to load the backup file. • Backup config behavior: If the system loads the backup config file, the system does not check the backup file for syntax errors. It does not matter if the verify-config flag is disabled or enabled. With the backup config file, the system ignores any lines with errors during the loading of the backup config file. If no backup config file exists, the system defaults to factory defaults. As a best practice, disable the verify-config flag.
vrf-scaling	Increases the maximum number of VRFs and Layer 3 VSNs that the switch supports. This flag is disabled by default. Important: If you enable both this flag and the spbmconfig-mode flag, the switch reduces the number of configurable VLANs. For more information about maximum scaling numbers, see *Fabric Engine Release Notes*.

Reserve Bandwidth for Advanced Features

Use this procedure if you want the switch to support advanced features. When you enable this boot flag, you need to save and reboot with the new configuration.

Before You Begin

You must ensure your configuration does not include reserved ports before you enable this feature. If the configuration includes reserved ports after you enable this feature and restart the switch, the switch stops loading the configuration.

About This Task

The command parameters apply to this procedure as follows:

- high only applies to 5720 Series
- low does not apply to 5720 Series
- vim does not apply to 5320 Series and 5420 Series

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable the boot flag:

   ```
   boot config flags advanced-feature-bandwidth-reservation [low | high | vim]
   ```

3. Save the configuration, and then reboot the switch.

   

   Important

   A change to the advanced-feature-bandwidth-reservation boot flag requires a reboot for the change to take effect.

4. Verify the boot flag configuration:

   ```
   show boot config flags
   ```

5. Verify that the switch reserved the ports as loopback ports. Reserved ports are not visible in the output of the following command:

   ```
   show interfaces gigabitEthernet
   ```

Example

Enable this feature to the low level.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#boot config flags advanced-feature-bandwidth-reservation low
   Warning: Please note that the configuration for the following ports 1/25-1/26
            will be removed from the configuration file.
 Are you sure you want to continue (y/n) ? y
    Warning: Please save the configuration and reboot the switch
             for this to take effect.
             Flag advanced-feature-bandwidth-reservation is changed to enable (low).
```

Display Advanced Feature Bandwidth Reservation Ports

After you configure the **advanced-feature-bandwidth-reservation** boot flag and reboot with the new configuration, you can use the following procedure to verify that the switch reserved ports for configuring advanced features.

Procedure

1. To enter User EXEC mode, log on to the switch.

2. Display the Advanced Feature Bandwidth Reservation mode and reserved ports:

   ```
   show sys-info
   ```

Example

```
Switch#show sys-info

General Info :

SysDescr     : Switch1 (w.x.y.z)   BoxType: Switch1
SysName      : Switch1
.
.
.

Advanced Feature Bandwidth Reservation:
--------------------------------------------------------------------------------

Reservation Mode : low
Port Usage Info  : 1/53 and 1/54 are not available to use
```

Display the Boot Configuration

About This Task

Display the configuration to view current or changed settings for the boot parameters.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. View the configuration:

   ```
   show boot config <choice|flags|general|host|master|running-config
   [verbose]|sio>
   ```

Example

Show the current boot configuration. (If you omit verbose, the system only displays the values that you changed from their default value.):

```
Switch:1>enable

Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.

Switch:1#(config)#show boot config running-config
#
#Mon Feb 13 13:32:58 2017 EST
#
boot config flags debug-config file
boot config flags debugmode
boot config flags ftpd
no boot config flags spbm-config-mode
boot config flags sshd
boot config flags telnetd
boot config flags tftpd
no boot config flags verify-config
```

```
boot config choice primary backup-config-file "/intflash/config.cfg"
#boot config sio console baud 115200
```

Variable Definitions

The following table defines parameters for the **show boot config** command.

Variable	Value
choice	Shows the current boot configuration choices.
flags	Shows the current flag settings.
general	Shows system information.
host	Shows the current host configuration.
master	Shows the master information.
running-config [verbose]	Shows the current boot configuration. If you use *verbose*, the system displays all possible information. If you omit *verbose*, the system displays only the values that you changed from their default value.
sio	Specifies the current configuration of the serial ports.

Configure Serial Port Devices

Configure the serial port devices to define connection settings for the console port. Depending on your hardware platform the console port displays as console or 10101.

Procedure

1. Enter Global Configuration mode:
   ```
   enable

   configure terminal
   ```
2. View the current baud rate configuration:
   ```
   show boot config sio
   ```
3. Change the console baud rate:
   ```
   boot config sio console baud <115200>
   ```
4. Save the changed configuration.
5. Restart the switch.

Variable Definitions

The following table defines parameters for the **boot config sio console** command.

Variable	Value
baud <115200>	Configures the baud rate for the port. The default is 115200 and cannot be modified.

Run-time process management using CLI

Configure and manage the run-time process using the Command Line Interface (CLI).

Configuring the time zone

About This Task

Configure the time zone to use an internal system clock to maintain accurate time. The time zone data in Linux includes daylight changes for all time zones up to the year 2038. You do not need to configure daylight savings.

The default time zone is Coordinated Universal Time (UTC).

Important

In October 2014, the government of Russia moved Moscow from UTC+4 into the UTC+3 time zone with no daylight savings.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the time zone by using the following command:

   ```
   clock time-zone WORD<1-10> WORD<1-20> WORD<1-20>
   ```

3. Save the changed configuration.

Example

Configure the system to use the time zone data file for Vevay:

```
Switch:1(config)# clock time-zone America Indiana Vevay
```

Variable Definitions

The following table defines parameters for the **`clock time-zone`** command.

Variable	Value
WORD<1-10>	Specifies a directory name or a time zone name in /usr/share/zoneinfo, for example, Africa, Australia, Antarctica, or US. To see a list of options, enter `clock time-zone` at the command prompt without variables.
WORD<1-20> WORD<1-20>	The first instance of *WORD<1-20>* is the area within the timezone. The value represents a time zone data file in `/usr/share/zoneinfo/WORD<1-10>/`, for example, Shanghai in Asia. The second instance of *WORD<1-20>*is the subarea. The value represents a time zone data file in `/usr/share/zoneinfo/WORD<1-10>/WORD<1-20>/`, for example, Vevay in America/Indiana. To see a list of options, enter `clock time-zone` at the command prompt without variables.

Configure the Run-time Environment

About This Task

Configure the run-time environment to define generic configuration settings for CLI sessions.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Change the login prompt:

   ```
   login-message WORD<1-1513>
   ```

3. Change the password prompt:

   ```
   passwordprompt WORD<1-1510>
   ```

4. Configure the number of supported inbound Telnet sessions:

   ```
   telnet-access sessions <0-8>
   ```

5. Configure the idle timeout period before automatic logoff for CLI and Telnet sessions:

   ```
   cli timeout <30-65535>
   ```

6. Configure the number of lines in the output display:

   ```
   terminal length <8-64>
   ```

7. Configure scrolling for the output display:

   ```
   terminal more <disable|enable>
   ```

Example

```
Switch:1>enable
Switch:#configure terminal
```

Use the default option to enable use of the default logon string:

```
Switch:(config)#default login-message
```

Use the default option before this parameter to enable use of the default string:

```
Switch:(config)#default passwordprompt
```

Configure the allowable number of inbound Telnet sessions:

```
Switch:(config)#telnet-access sessions 8
```

Configure the timeout value, in seconds, to wait for a Telnet or CLI login session before terminating the connection:

```
Switch:(config)#cli timeout 900
```

Configure the number of lines in the output display for the current session:

```
Switch:(config)#terminal length 30
```

Configure scrolling for the output display:

```
Switch:(config)#terminal more disable
```

Variable Definitions

The following table defines parameters for the **login-message** command.

Variable	Value
WORD<1-1513>	Changes the CLI logon prompt. • *WORD<1-1513>* is an American Standard Code for Information Interchange (ASCII) string from 1–1513 characters. • Use the default option before this parameter, `default login-message`, to enable use of the default logon string. • Use the no operator before this parameter, `no login-message`, to disable the default logon banner and display the new banner.

Use the data in the following table to use the **passwordprompt** command.

Variable	Value
WORD<1-1510>	Changes the CLI password prompt. • *WORD<1-1510>* is an ASCII string from 1–1510 characters. • Use the default option before this parameter, `default passwordprompt`, to enable using the default string. • Use the no operator before this parameter, `no passwordprompt`, to disable the default string.

Use the data in the following table to use the **telnet-access sessions** command.

Variable	Value
<0-8>	Configures the allowable number of inbound Telnet sessions. The default value is 8.

Use the data in the following table to use the **cli time-out** command.

Variable	Value
<30-65535>	Configures the timeout value, in seconds, to wait for a Telnet or CLI login session before terminating the connection.

Use the data in the following table to use the **terminal** command.

Variable	Value
<8–64>	Configures the number of lines in the output display for the current session. To configure this option to the default value, use the**default** operator with the command. The default is value 23.
disable|enable	Configures scrolling for the output display. The default is enabled. Use the **no** operator to remove this configuration. To configure this option to the default value, use the **default** operator with the command. **no**

Configuring CLI logging

About This Task

Use CLI logging to track all CLI commands executed and for fault management purposes. The CLI commands are logged to the system log file as CLILOG module.

Note

The platform logs CLILOG and SNMPLOG as INFO. Normally, if you configure the logging level to WARNING, the system skips all INFO messages. However, if you enable CLILOG and SNMPLOG the system logs CLI Log and SNMP Log information regardless of the logging level you set. This is not the case for other INFO messages.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable CLI logging:

   ```
   clilog enable
   ```

3. Disable CLI logging:

   ```
   no clilog enable
   ```

4. Ensure that the configuration is correct:

   ```
   show clilog
   ```

5. View the CLI log:

   ```
   show logging file module clilog
   ```

6. View the CLI log.

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#clilog enable
```

Variable Definitions

The following table defines parameters for the **clilog** commands.

Variable	Value
enable	Activates CLI logging. To disable, use the `no clilog enable` command.

Configure System Parameters

About This Task

Configure individual system-level switch parameters to configure global options for the switch.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Change the system name:

   ```
   sys name WORD<0-255>
   ```

3. Enable support for Jumbo frames:

   ```
   sys mtu <1522-9600>
   ```

4. Enable the User Datagram Protocol (UDP) checksum calculation:

   ```
   udp checksum
   ```

Example

```
Switch:1> enable

Switch:1# configure terminal
```

Configure the system, or root level, prompt name for the switch:

```
Switch:1(config)# sys name Floor3Lab2
```

Variable Definitions

The following table defines parameters for the **sys** command.

Variable	Value
control tcp-timestamp	Enables or disables TCP Timestamp.
force-msg	Adds forced message control pattern. *WORD<4-4>* Enter force message pattern.
msg-control	Configures system message control feature.
mtu <1522-9600>	Configures Jumbo frame support for the data path. The value can be either 1522, 1950 (default), or 9600 bytes.

Variable	Value
name WORD<0-255>	Configures the system, or root level, prompt name for the switch. *WORD<0-255>* is an ASCII string from 0–255 characters (for example, LabSC7 or Closet4).
power	Enables power to specified slot(s).
security-console	Enables the security console.
software	Configures software configuration.
priv-exec-password	Enables authentication for the Privileged EXEC CLI command mode.

Configuring system message control

About This Task

Configure system message control to suppress duplicate error messages on the console, and to determine the action to take if they occur.

Procedure

1. Enter Global Configuration mode:
   ```
   enable

   configure terminal
   ```
2. Configure system message control action:
   ```
   sys msg-control action <both|send-trap|suppress-msg>
   ```
3. Configure the maximum number of messages:
   ```
   sys msg-control max-msg-num <2-500>
   ```
4. Configure the interval:
   ```
   sys msg-control control-interval <1-30>
   ```
5. Enable message control:
   ```
   sys msg-control
   ```

Example

```
Switch:1> enable

Switch:1# configure terminal
```

Configure system message control to suppress duplicate error messages on the console and send a trap notification:

```
Switch:1(config)# sys msg-control action both
```

Configure the number of occurrences of a message after which the control action occurs:

```
Switch:1(config)# sys msg-control max-msg-num 2
```

Configure the message control interval in minutes:

```
Switch:1(config)# sys msg-control control-interval 3
```

Enable message control:

```
Switch:1(config)# sys msg-control
```

Variable Definitions

The following table defines parameters for the **sys msg-control** command.

Variable	Value
action <both|send-trap|suppress-msg>	Configures the message control action. You can either suppress the message or send a trap notification, or both. The default is suppress.
control-interval <1-30>	Configures the message control interval in minutes. The valid options are 1–30. The default is 5.
max-msg-num <2-500>	Configures the number of occurrences of a message after which the control action occurs. To configure the maximum number of occurrences, enter a value from 2–500. The default is 5.

Extending system message control

About This Task

Use the force message control option to extend the message control feature functionality to the software and hardware log messages.

To enable the message control feature, you must specify an action, control interval, and maximum message number. After you enable the feature, the log messages, which get repeated and cross the maximum message number in the control interval, trigger the force message feature. You can either suppress the message or send a trap notification, or both.

Procedure

1. Enter Global Configuration mode:
   ```
   enable

   configure terminal
   ```
2. Configure the force message control option:
   ```
   sys force-msg WORD<4-4>
   ```

Example

```
Switch:1> enable

Switch:1# configure terminal
```

Configure the force message control option. (If you specify the wildcard pattern (****), then all messages undergo message control:

```
Switch:1(config)# sys force-msg ****
```

Variable Definitions

The following table defines parameters for the **sys force-msg** command.

Variable	Value
WORD<4-4>	Adds a forced message control pattern, where *WORD<4-4>* is a string of 4 characters. You can add a four-byte pattern into the force-msg table. The software and the hardware log messages that use the first four bytes that match one of the patterns in the force-msg table undergo the configured message control action. You can specify up to 32 different patterns in the force-msg table, including a wildcard pattern (****) as well. If you specify the wildcard pattern, all messages undergo message control.

Hardware status using EDM

This section provides methods to check the status of basic hardware in the chassis using Enterprise Device Manager (EDM).

Configure Polling Intervals

About This Task

Enable and configure polling intervals to determine how frequently EDM polls for port and LED status changes or detects the hot swap of installed ports.

Procedure

1. In the navigation pane, expand **Configuration** > **Device**.
2. Click **Preference Setting**.
3. Enable polling or hot swap detection.
4. Configure the frequency to poll the device.
5. Click **Apply**.

Preference Setting *field descriptions*

Use the data in the following table to use the **Preference Setting** tab.

Name	Description
Enable	Enables polling for port and LED status changes. The default is disabled.
Poll Interval	Specifies the polling interval, if enabled. The default is 60 seconds.
Enable	Detects the hot swap of installed ports. The default is disabled.
Detection per Status Poll Intervals	Specifies the number of poll intervals for detection, if enabled. The default is 2 intervals.

View Power Supply Parameters

Perform this procedure to view information about the operating status of the power supplies.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Click **Power Supply**.

Details *Field Descriptions*

Use the data in the following table to use the **Details** tab.

Name	Description
Id	Specifies the ID number.
Type	Describes the type of power used.
Description	Provides a description of the power supply.
SerialNumber	Specifies the power supply serial number.
HardwareRevision	Specifies the hardware revision number.
PartNumber	Specifies the power supply part number.
PowerSupplyOperStatus	Specifies the status of the power supply as one of the following: • on (up) • off (down)
InputLineVoltage	Displays the input line voltage: • low 110v—power supply connected to a 110 Volt source • high 220v—power supply connected to a 220 Volt source • ac110vOr220v—power supply connected to a 110 Volt or 220 Volt source
OutputWatts	Displays the output power of this power supply.
InputOperLineVoltage	Displays the operating input line voltage. If the power supplies in a chassis are not of identical input line voltage values, the operating line voltage shows the low 110v value.
InputPower	Displays the input power of this power supply.

View System Temperature Information

View information about the temperature for each sensor on the device.

The system triggers an alarm when one of the zones exceeds the threshold temperature value.

Procedure

1. In the Device Physical View tab, select the chassis.
2. In the navigation pane, expand **Configuration** > **Edit**.
3. Click **Chassis**.

4. Click the **System Temperature** tab.

System Temperature *field descriptions*

Use the data in the following table to use the **System Temperature** tab.

Name	Description
SensorIndex	Specifies the range of sensors on the device.
SensorDescription	Specifies the name of the sensor.
Temperature (degrees celsius)	Specifies the sensor temperature measured in Celsius degrees.
WarningThreshold	Specifies the temperature value of the warning threshold for the sensor. When the temperature crosses the warning threshold a warning message is generated.
CriticalThreshold	Species the temperature value of the critical threshold for the sensor. When the temperature crosses the critical threshold, a critical message is generated or the system shuts down, depending on hardware capability.
Status	Specifies the current temperature status based on the warning and critical thresholds.

Command Line Interface

Table 24: Command Line Interface product support

Feature	Product	Release introduced
Command Line Interface (CLI)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

For information about specific commands, see *Fabric Engine CLI Commands Reference*.

Command Line Interface Fundamentals

This section describes the Command Line Interface (CLI).

CLI is an industry standard command line interface that you can use for single-device management.

CLI Command Modes

CLI command modes provide specific sets of CLI commands. When you log onto the switch, you are in User EXEC mode with limited commands. While in a higher mode, you can access most commands from lower modes, except if they conflict with commands of your current mode.

There are two categories of CLI commands: show commands and configuration commands. You can use show commands from multiple command modes with the same results; they show the same configuration information regardless of the command mode. Configuration command results, however, might be dependent on the command mode from which a configuration command is used. For example, an **enable** command used in Global Configuration mode will enable a feature globally for all devices, and the same command used from one of the interface command modes will enable a feature for a specific interface only.

The following figure illustrates the navigation paths for the various command modes:

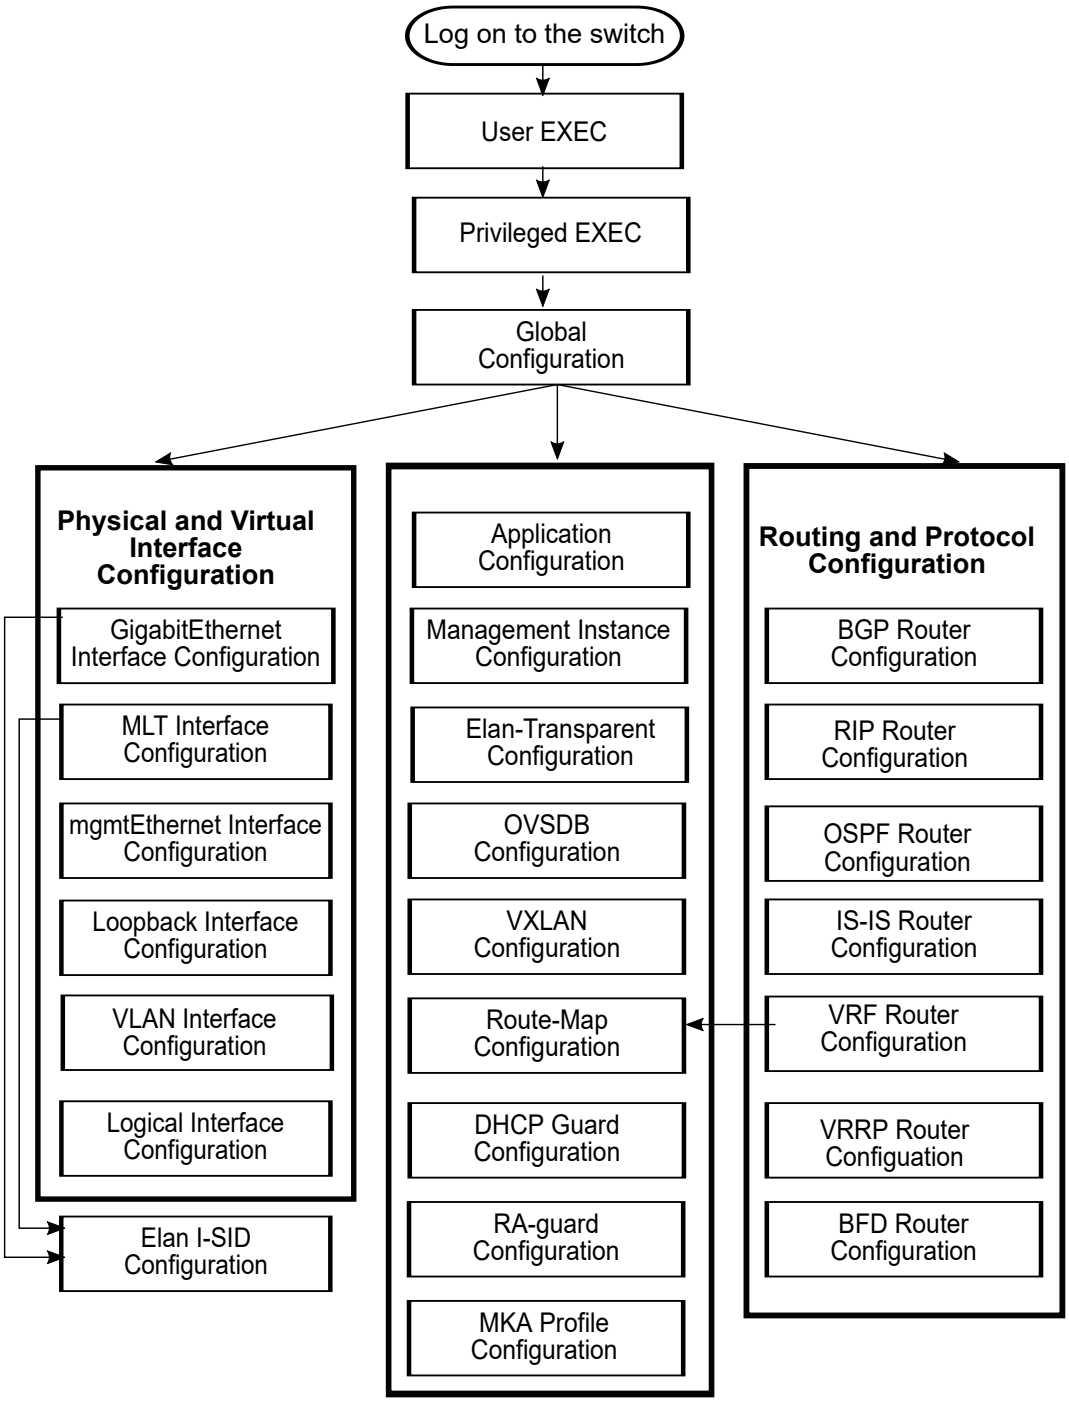

Figure 10: CLI Command Mode Navigation

Your user authorization credentials determine what commands are available to you in Privileged EXEC mode and all higher-level modes. See System Access on page 2988 for more information.

To navigate from higher-level modes to lower-level modes, use the following commands:

- **exit** to navigate from a higher-level mode to a lower-level mode, down to Privileged EXEC mode
- **end** to navigate from any command mode directly to Privileged EXEC mode
- **disable** to navigate from Privileged EXEC mode to User EXEC mode
- **logout** to terminate the CLI session from any command mode

The following table describes the various command modes, including the CLI command to access each mode, the command prompt that displays in each mode, and a description of the purpose of the mode.

Note

Some command modes are hardware dependent. If any of the following commands modes do not display on your hardware, they are not supported or applicable.

Table 25: CLI Command Mode Summary

Command mode	Command to access mode	Prompt displayed in mode	Description
User EXEC	None required; default mode	>	View configuration settings and connection status.
Privileged EXEC	`enable`	#	Configure limited device-wide settings.
	Note: Depending on feature configuration, you can be prompted to enter a username and password to access Privileged EXEC mode. For more information, see Authentication for Privileged EXEC Command Mode on page 222.		
Global Configuration	`configure {terminal|network}`	`(config)#`	From a terminal or TFTP server, configure device-wide global parameters on a running configuration, or specify the filename of a configuration file.
GigabitEthernet Interface Configuration	`interface GigabitEthernet {slot/port[/sub-port][-slot/port[/subport]][,...]}`	`(config-if)#`	Configure chassis operations and features on a physical port.
MLT Interface Configuration	`interface mlt <1-512>`	`(config-mlt)#`	Configure an MLT interface.
mgmtEthernet Interface Configuration	`interface mgmtEthernet <mgmt|mgmt2>`	`(config-if)#`	Configure a dedicated physical management port (if supported on your hardware).

Table 25: CLI Command Mode Summary (continued)

Command mode	Command to access mode	Prompt displayed in mode	Description
Loopback Interface Configuration	`interface loopback <1-256>`	`(config-if)#`	Configure a loopback CLIP interface.
VLAN Interface Configuration	`interface vlan <1-4059>`	`(config-if)#`	Configure port-based, policy-based, private, or SPBM B-VLANs
Logical Interface Configuration	`logical-intf isis <1-255>`	Layer 2: `(config-isis-<1-255>)#` Layer 3: `(config-isis-<1-255>-<A.B.C.D>)#`	Configure a logical Layer 2 or Layer 3 interface.
BGP Router Configuration	`router bgp`	`(router-bgp)#`	Configure device-wide BGP routing protocol settings.
RIP Router Configuration	`router rip`	`(config-rip)#`	Configure device-wide RIP routing protocol settings.
OSPF Router Configuration	`router ospf`	`(config-ospf)#`	Configure device-wide OSPF routing protocol settings.
IS-IS Router Configuration	`router isis`	`(config-isis)#`	Configure device-wide IS-IS routing protocol settings.
VRF Router Configuration	`router vrf WORD<1-16>`	`(router-vrf)#`	Configure a VRF instance.
VRRP Router Configuration	`router vrrp`	`(config-vrrp)#`	Configure device-wide VRRP protocol settings.
Application Configuration	`application`	`(config-app)#`	Configure custom applications, such as SLA Monitor or RESTCONF.
Management Instance Configuration	`mgmt <clip | oob | vlan>`	`(mgmt:clip)#` or `(mgmt:oob)#` or `(mgmt:vlan)#`	Configure a segmented management CLIP, Out-of-Band (OOB), or VLAN instance.
Elan I-SID Configuration	`i-sid <1-16777215> [elan]`	`(elan:<1-16777215>)#`	Add ports and traffic to a Switched UNI I-SID on a GigabitEthernet or MLT interface.
Elan-Transparent Configuration	`i-sid <1-16777215> elan-transparent`	`(elan-tp:<1-16777215>)#`	Add ports and MLT interfaces to an Elan-Transparent based service.

Table 25: CLI Command Mode Summary (continued)

Command mode	Command to access mode	Prompt displayed in mode	Description
Route-Map Configuration	`route-map WORD<1-64> <1-65535>`	`(route-map)#`	Configure device-wide or VRF instance-specific route map policy settings.
DHCP-guard Configuration	`ipv6 fhs dhcp-guard policy WORD<1-64>`	`(config-dhcpguard)#`	Configure DHCPv6 for advertised address-based, prefix-based, and preference-based filtering.
RA-guard Configuration	`ipv6 fhs ra-guard policy WORD<1-64>`	`(config-raguard)#`	Configure RA Guard for advertised IPv6 and MAC address-based, IPv6 prefix-based, preference-based, hop count limit-based, and default router preference-based filtering.
MKA Profile Configuration	`macsec mka profile WORD<1-16>`	`(mka-profile)#`	Configure replay protection and confidentiality offset for an MKA profile.
BFD Router Configuration	`router bfd`	`(router-bfd)#`	Configure device-wide BFD settings.

Default User Names and Passwords for CLI

The following table contains the default user names and passwords that you can use to log on to the switch using the command line interface (CLI). For more information about how to change passwords, see Security on page 2687.

Table 26: CLI default user names and passwords

User name	Password	Description
rwa	rwa	read-write-all
rw	rw	read-write
ro	ro	read-only
l1	l1	layer 1
l2	l2	layer 2
l3	l3	layer 3

You can create up to a maximum of 10 CLI users for each role. For more information, see Multiple CLI Users for Each Role on page 2993.

If you enable enhanced secure mode, the user names and passwords are different than the default values documented in the preceding table. For more information on enhanced secure mode, see Enhanced Secure Mode on page 2994.

Important

The default passwords and community strings are documented and well known. As a best practice, change the default passwords and community strings immediately after you first log on. For more information about how to change user names and passwords, see Security on page 2687.

Documentation convention for the port variable

Commands that require you to enter one or more port numbers on the switch use the parameter *{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}* in the syntax. The following table specifies the rules for using *{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}*.

Syntax	How to use
{slot/port[/sub-port]}	Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. For example, 1/1 indicates the first port on slot 1. 1/41/1 indicates the first channel on slot 1, port 41.
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. For example, 1/1–1/3 indicates ports 1 to 3 on slot 1, or 1/41/1,1/41/3 indicates the first and third channels of slot 1, port 41.

Command completion

The CLI provides potential command completions to the command string. Completions are provided by using a question mark (?) or by using the CLI autocompletion feature.

? command completion

The ? command completion is available for any valid command. By typing a command and using a ? as the last argument in the command, the system returns a list of possible command completions from the point of the ?. A short description is provided with each possible completion.

If you enter the following command:

```
Switch:1(config-isis)#redistribute ?
```

CLI provides a list of completions for the **redistribute ?** command.

```
Switch:1(config-isis)#redistribute ?
    direct     isis redistribute direct command
    ospf        isis redistribute ospf command
    rip          isis redistribute rip command
    static     isis redistribute static command
```

All the parameters listed under redistribute indicate sub-context commands.

You must use one of the available completions, and if necessary, use the command completion help again to find the next completion.

```
Switch:1(config-isis)#redistribute direct ?
  enable       Enable isis redistribute direct command
  metric       Isis route redistribute metric
  metric-type  Set isis redistribute metric type
  route-map    Set isis redistribute direct route-policy
  subnets      Set isis redistribute subnets
<cr>
```

When you see *<cr>* (Carriage Return/Enter Key) in the list with the additional choices, this means that no additional parameters are required to execute the CLI command. However, the additional choices listed could be peer commands or sub-context commands.

For example, the parameters listed under **`redistribute direct ?`** are peer commands. You can enter these peer commands on the same line as the root command, for example **`redistribute direct enable`**. However, the *<cr>* indicates that you can also enter the **`redistribute direct`** command only and this command does not require any additional parameters at this level.

CLI autocompletion

CLI autocompletion is a feature that you can use to automatically fill in the unique parts of a command string rather than typing the entire command. Autcompletion makes the CLI experience easier and prevents mistakes in spelling that force you to re-enter the command.

Autocompletion completes the token in the command as soon as it becomes unique.

The `Tab` key autocompletes the command without executing the command, and places the cursor immediately after the last character. The `Enter` key autocompletes the command and executes it.

To enable redistribution of ISIS direct routes,

```
Switch:1(config-isis)#redistribute direct
```

When you use `redistribute ?`, you see four possible sub-context commands.

```
direct
static
ospf
rip
```

If you type the following without pressing `Enter`:

```
Switch:1(config-isis)#redistribute direct m
```

and press the `Tab` key, the system completes the command to the following point:

```
redistribute direct metric
```

Two possible completions exist. You can type `-t`, and then press `Tab` to finish the command:

```
Switch:1(config-isis)#redistribute direct metric-type
```

default command operator

You can reset the modified configuration of a command to the default configuration by using the default operator. For more information about the default value for each command, see *Fabric Engine CLI Commands Reference*.

Use the ? command completion along with the default keyword in each configuration mode, to view the list of commands that support the default operator. For more information, see Command completion on page 217.

Examples

Configure **csnp-interval** to its default value. The default value of **csnp-interval** is 10 seconds.

```
Switch:1>show isis

virtual-ist      Create virtual-ist on MLT with default value
Switch:1(config-mlt)#default ip ?
Default IP configurations on MLT interface
  arp-inspection   Default arp inspection configuration
  dhcp-snooping    Default dhcp snooping configuration
Switch:1(config-mlt)#default ip arp-inspection ?
  <cr>
```

no command operator

You can use the **no** operator in a command to negate a configuration. Based on the functionality of the command, you can perform negations, such as disable, delete, remove, or reset to the default configuration. For more information about the **no** operator for each command, see *Fabric Engine CLI Commands Reference*.

Use the ? command completion along with the **no** keyword to view the list of commands that support the **no** operator in each configuration mode. For more information, see Command completion on page 217.

Negate the automatic virtual link that provides automatic dynamic backup link for OSPF traffic.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#router ospf
Switch:1(config-ospf)#no auto-vlink
```

Remove an IP address configuration from VLAN.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#interface vlan 3
Switch:1(config-if)#no ip address 192.0.2.4
```

View the commands that can negate a configuration in RIP router configuration mode.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#router rip
Switch:1(config-rip)#no ?
Negate a command or set its defaults
ipv6          Disable ipv6 configurations
network       Disable rip on an ip network
redistribute  To disable/delete redistribute golbally
Switch:1(config-rip)#no network ?
  {A.B.C.D}  Network ip address
Switch:1(config-rip)#no network 192.0.2.4 ?
  <cr>
```

GREP with CLI show command

You can use Global Regular Expression Print (GREP) with **show** commands to filter the output based on match criteria.

Enter the **show** command followed by the pipe (|) character, followed by the GREP filter command. The **show** command output contains only the lines that match the GREP filter pattern.

Note

The **show fulltech** command does not support GREP filters.

The following GREP filter commands are supported.

GREP filter function	Description
begin	Displays the output of a command starting from the first line, which matches the given pattern.
count	Counts the number of lines in the output of a command.
exclude	Displays only the output lines which do not match the given pattern. The lines matching the pattern are discarded.
head	Limits the output of a command to the first few lines. If a number is not specified then only the first 10 lines display.
include	Displays only the output lines which match the given pattern.

GREP filter function	Description
no-more	Temporarily disables pagination for the output of an CLI command. When the lines of output exceed the terminal length, you are not prompted to continue or quit but the entire output of the command continues to be displayed. The effect is similar to setting terminal length 0 but only for the current command.
tail	Limits the output of a command to the last few lines. If a number is not specified then only the last 10 lines display.

Timestamp in show command outputs

The output for all CLI show commands includes a timestamp header to indicate when the command output was generated. This information can be helpful when communicating with Support.

The following command output shows a timestamp example.

```
Switch:1#show alarm statistics
********************************************************************************
                Command Execution Time: Wed Nov 07 19:55:15 2018 UTC
********************************************************************************

================================================================================
                                ALARM STATISTICS
================================================================================
PERSISTENT PERSISTENT PERSISTENT  PERSISTENT  DYNAMIC   DYNAMIC  DYNAMIC DYNAMIC
  ALARM      ACTIVE    CLEARED      WRPRD      ALARM    ACTIVE   CLEARED  WRPRD
    0          0         0            0         11        8        3       0
```

Authentication for Privileged EXEC Command Mode

For enhanced security, you can request user authentication to enter Privileged EXEC command mode. When you configure password authentication, the switch prompts you to enter a username and password to access Privileged EXEC command mode from User EXEC command mode. You use the same username and password used to Telnet or SSH to the switch.

For more information about configuring Privileged EXEC authentication, see Authentication for Privileged EXEC Command Mode on page 2693.

CLI Procedures

This section contains information about common CLI tasks. You can access CLI during runtime to manage the switch.

Logging on to the software

Before You Begin

- The first time you connect to the switch, you must log on to CLI using the direct console port.

About This Task

After you first connect to CLI you can log on to the software using the default user name and password. For more information about the default user names and passwords, see Default User Names and Passwords for CLI on page 216.

Procedure

1. At the login prompt, enter the user name.
2. At the password prompt, enter the password.

View the Configuration

You can view the running configuration using the show command.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```
2. View the running configuration:
   ```
   show running-config
   ```

Example

```
5320-48T-8XE-FabricEngine:1>enable
5320-48T-8XE-FabricEngine:1#show running-config
Preparing to Display Configuration...
#
# Mon Dec 13 23:44:36 2021 EET

--More-- (q = quit)
```

Saving the configuration

After you change the configuration, you must save the changes to the module. Save the configuration to a file to retain the configuration settings.

About This Task

File Transfer Protocol (FTP) and Trivial File Transfer Protocol (TFTP) support both IPv4 and IPv6 addresses, with no difference in functionality or configuration.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Save the running configuration:

   ```
   save config [backup WORD<1-99>] [file WORD<1-99>] [verbose]
   ```

Example

Save the configuration to the default location:

```
Switch:1#save config
```

Identify the file as a backup file and designate a location to save the file:

```
Switch:1#save config backup 198.51.100.1/configs/backup.cfg
```

Variable definitions

Use the data in the following table to use the **save config** command.

Variable	Value
backup WORD<1-99>	Saves the specified file name and identifies the file as a backup file. *WORD<1-99>* uses one of the following formats: • a.b.c.d:<file> • /intflash/<file> The file name, including the directory structure, up to 1 to 99 characters.
file WORD<1-99>	Specifies the file name in one of the following formats: • /intflash/<file> • a.b.c.d:<file> The file name, including the directory structure, up to 1 to 99 characters.
verbose	Saves the default and current configuration. If you omit this parameter, the command saves only parameters you change.
standby WORD<1-99>	Specifies the standby file name in the following format: • /intflash/<file> The file name, including the directory structure, up to 1 to 99 characters.

Configure the Web Server

Perform this procedure to enable and manage the web server using the Command Line Interface (CLI). After you enable the web server, you can connect to EDM.

HTTP and FTP support both IPv4 and IPv6 addresses, with no difference in functionality or configuration. The TFTP server supports both IPv4 and IPv6 addresses. The TFTP client is not supported, only the server.

About This Task

This procedure assumes that you use the default port assignments. You can change the port number used for HTTP and HTTPS.

Important

To enable HTTP access to the device, you must disable the web server secure-only option. To enable HTTPS access to the device, the web server secure-only option is enabled by default.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable the web server:

   ```
   web-server enable
   ```

3. Disable the secure-only option (for HTTP access) :

   ```
   no web-server secure-only
   ```

4. Enable the secure-only option (for HTTPs access) :

   ```
   web-server secure-only
   ```

5. Enable read-only user:

   ```
   web-server read-only-user enable
   ```

6. Display the web server status:

   ```
   show web-server
   ```

Example

```
Switch:1(config)#show web-server
Web Server Info :

        Status                    : off
        Secure-only               : enabled
        TLS-minimum-version       : tlsv12
        RO Username Status        : disabled
        RO Username               : user
        RO Password               : ********
        RWA Username              : admin
        RWA Password              : ********
        Def-display-rows          : 30
        Inactivity timeout        : 900 sec
        Html help tftp source-dir :
        HttpPort                  : 80
        HttpsPort                 : 443
        NumHits                   : 0
        NumAccessChecks           : 0
        NumAccessBlocks           : 0
        NumRxErrors               : 0

        NumTxErrors               : 0
        NumSetRequest             : 0
        Minimum password length   : 8

        Ciphers-Tls               : TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384
TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256
                                    TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384
TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256
                                    TLS_DHE_RSA_WITH_AES_256_CBC_SHA256
TLS_DHE_RSA_WITH_AES_256_CBC_SHA
                                    TLS_DHE_RSA_WITH_AES_128_CBC_SHA256
TLS_DHE_RSA_WITH_AES_128_CBC_SHA
                                    TLS_RSA_WITH_AES_256_CBC_SHA256
```

```
TLS_RSA_WITH_AES_256_CBC_SHA
                                    TLS_RSA_WITH_AES_128_CBC_SHA256
TLS_RSA_WITH_AES_128_CBC_SHA
```

Variable Definitions

Use the data in the following table to use the **web-server** command.

Variable	Value
def-display-rows <10-100>	Configures the number of rows each page displays, between 10 and 100.
enable	Enables the web interface. To disable the web server, use the **no** form of this command: `no web-server [enable]`
help-tftp <WORD/0-256>	Configures the TFTP or FTP directory for Help files, in one of the following formats: a.b.c.d:/| peer:/ [<dir>]. The path can use 0–256 characters. The following example paths illustrate the correct format: • 192.0.2.1:/help • 192.0.2.1:/
http-port <80-49151>	Configures the web server HTTP port. The default port is 80.
https-port <443-49151>	Configure the web server HTTPS port. The default port is 443.
inactivity-timeout<30-65535>	Configures the web-server session inactivity timeout. The default is 900 seconds (15 minutes).
password {ro | rwa} WORD<1-20>	Configures the logon and password for the web interface.
password min-passwd-len<1-32>	Configures the minimum password length. By default, the minimum password length is 8 characters.
read-only-user	Enables read-only user for the web server. Note: **read-only-user enable** is available for demonstration purposes on some products. For more information, see *Fabric Engine Feature Support Matrix*.

Variable	Value
secure-only	Enables secure-only access for the web server.
tls-min-ver<tlsv10|tlsv11|tlsv12>	Configures the minimum version of the TLS protocol supported by the web-server. You can select among the following: • tlsv10 – Configures the version to TLS 1.0. Note: tlsv10 is not supported in enhanced secure mode. • tlsv11 – Configures the version to TLS 1.1. • tlsv12 – Configures the version to TLS 1.2 The default is tlsv12.

Using GREP CLI show command filters

Use the following GREP filters to output only the command lines specified by the filter.

Procedure

1. Count the number of lines in the output:

   ```
   <CLI command> | count
   ```

2. Display the output of a command starting from the first line that matches the given pattern:

   ```
   <CLI command> | begin WORD<0-255> [field <number>] [ignore-case]
   [header <number>]
   ```

3. Display only the output lines that match the given pattern:

   ```
   <CLI command> | include <pattern> [field <number>] [ignore-case]
   [header <number>]
   ```

4. Display only the output lines that do not match the given pattern:

   ```
   <CLI command> | exclude <pattern> [field <number>] [ignore-case]
   [header <number>]
   ```

5. Temporarily disable pagination for the output of a CLI command:

   ```
   <CLI command> | no-more
   ```

   There is no prompt to continue or to quit when the lines of output exceed the terminal length.

6. Limit the output of a command to the first few lines:

   ```
   <CLI command> | head [<number>]
   ```

   If a number is not specified, the first 10 lines display.

7. Limit the output of a command to the last few lines:

   ```
   <CLI command> | tail [<number>] [from-line <number>] [header <number>]
   ```

   If a number is not specified, the last 10 lines display.

Example

```
Switch:1>enable
Siwtch:1#configure terminal
```

Count the number of lines in the output:

```
Switch1:#show vlan basic | count
Count: 17 lines
```

Display only the output lines that match the given pattern:

```
Switch:1(config)#show vlan basic | include byPort field 3 header 6

11    VLAN-11          byPort       11      none         N/A             N/A             0
12    VLAN-12          byPort       12      none         N/A             N/A             0
20    VLAN-20          byPort       0       none         N/A             N/A             0
```

Display only the first few lines of output:

```
Switch:1(config)#show vlan basic | head 9

================================================================================================
                                        Vlan Basic
================================================================================================
VLAN                                MSTP
ID    NAME             TYPE         INST_ID PROTOCOLID   SUBNETADDR      SUBNETMASK      VRFID
------------------------------------------------------------------------------------------------
1     Default          byPort       0       none         N/A             N/A             0
3     VLAN3            byPort       3       none         N/A             N/A             0
```

Display only the last few lines of output:

```
Switch:1(config)#show vlan basic | tail 8 header 6

================================================================================================
                                        Vlan Basic
================================================================================================
VLAN                                MSTP
ID    NAME             TYPE         INST_ID PROTOCOLID   SUBNETADDR      SUBNETMASK      VRFID
8     VLAN-8           byPort       8       none         N/A             N/A             0
9     VLAN-9           byPort       9       none         N/A             N/A             0
11    VLAN-11          byPort       11      none         N/A             N/A             0
```

```
12    VLAN-12          byPort       12      none         N/A            N/A            0
20    VLAN-20          byPort       0       none         N/A            N/A            0

Switch:1(config)#show vlan basic | tail from-line 15 header 6

================================================================================================
                                        Vlan Basic
================================================================================================
VLAN                                MSTP

9     VLAN-9           byPort       9       none         N/A            N/A            0
11    VLAN-11          byPort       11      none         N/A            N/A            0
12    VLAN-12          byPort       12      none         N/A            N/A            0
20    VLAN-20          byPort       0       none         N/A            N/A            0
```

Variable definitions

The GREP filters use the following parameters:

Parameter	Description
field<number>	Specifies the field in each line to match against the pattern. Fields are separated by white spaces and are counted starting with 1 for the left-most field. If the output is formatted as a table, whitespaces are not counted as fields.
from-line <number>	Specifies the remaining output starting with a given line.
head<number>	Specifies the number of lines to keep from the beginning of the output.
header<number>	Specifies a number of lines from the start of the output to display unchanged before trying to match the pattern. This parameter is useful to keep the header of a table intact. This filter skips the header lines.
ignore-case	Specifies letters to match in the pattern regardless of case.
<number>	Specifies the number of lines of output to keep, either from the beginning of the output or from the end of the output.
<pattern>	Specifies the regular expression to match against each line of output. Use quotations if the parameter contains spaces.

Enterprise Device Manager

Table 27: Enterprise Device Manager product support

Feature	Product	Release introduced
Enterprise Device Manager (EDM)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
Read-Only user for EDM	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

Enterprise Device Manager Fundamentals

This section details Enterprise Device Manager (EDM).

EDM is a web-based graphical user interface (GUI) you can use to configure a single switch. EDM runs from the switch and you can access it from a web browser. You do not need to install additional client software, and you can access it with all operating systems.

Supported Browsers

Use the following browser versions to access Enterprise Device Manager (EDM):

- Microsoft Edge 97
- Mozilla Firefox 96
- Google Chrome 97
- Safari 15.3

Important
For optimal performance, use Mozilla Firefox or Google Chrome.

Enterprise Device Manager Access

To access EDM, open *http://<deviceip>/login.html* or *https://<deviceip>/login.html* from Microsoft Edge, Microsoft Internet Explorer, Google Chrome, or Mozilla Firefox. Ensure you use a supported browser version.

Important

You must enable the web server from CLI (see Configure the Web Server on page 225) to enable HTTP access to EDM. For HTTP access to the device, you must also disable the web server secure-only option. The web server secure-only option, allowing for HTTPS access to the device, is enabled by default. As a best practice, take the appropriate security precautions within the network if you use HTTP

If you experience issues while connecting to EDM, check the proxy settings. Proxy settings can affect EDM connectivity to the switch. Clear the browser cache and do not use proxy when connecting to the device.

Default User Name and Password for EDM

The following table contains the default user name and password that you can use to log on to the switch using EDM. For more information about changing the passwords, see Security on page 2687.

Table 28: EDM default username and password

Username	Password
admin	password

For information about creating CLI accounts for each user role on the switch, see Multiple CLI Users for Each Role on page 2993.

Important

The default passwords and community strings are documented and well known. Change the default passwords and community strings immediately after you first log on. For more information about changing user names and passwords, see Security on page 2687.

Device Physical View

After you access EDM, the system displays a real-time physical view of the front panel of the device on the **Device Physical View** tab in the content pane. From the front panel view, you can view fault, configuration, and performance information for the device or a single port.

You can use the device view to determine the operating status of the various ports in your hardware configuration. You can also use the device view to perform management tasks on specific objects. In the device view, you can select a port or the entire chassis. EDM outlines the selected object in yellow.

The conventions on the device view are similar to the actual device appearance. The port LEDs and the ports are color-coded to provide status. Green indicates the module or port is up and running, red indicates the module or port is disabled, dark pink indicates a protocol is down, and amber indicates an

enabled port that is not connected to anything. For information about LED behavior, see your hardware documentation.

EDM Window

The following list identifies the different sections of the EDM window:

- Navigation pane—Located on the left side of the window, the navigation pane displays all the available command tabs in a tree format. A row of buttons at the top of the navigation pane provides a quick method to perform common functions.
- Content pane—Located on the right side of the window, the content pane displays the tabs and dialog boxes where you can view or configure parameters on the switch.
- Menu bar—Located at the top of the content pane, the menu bar shows the most recently accessed primary tabs and their respective secondary tabs.
- Toolbar—Located just below the menu bar, the toolbar provides quick access to the most common operational commands such as Apply, Refresh, and Help.

The following figure shows an example of two tabs open in the content pane of the EDM window.

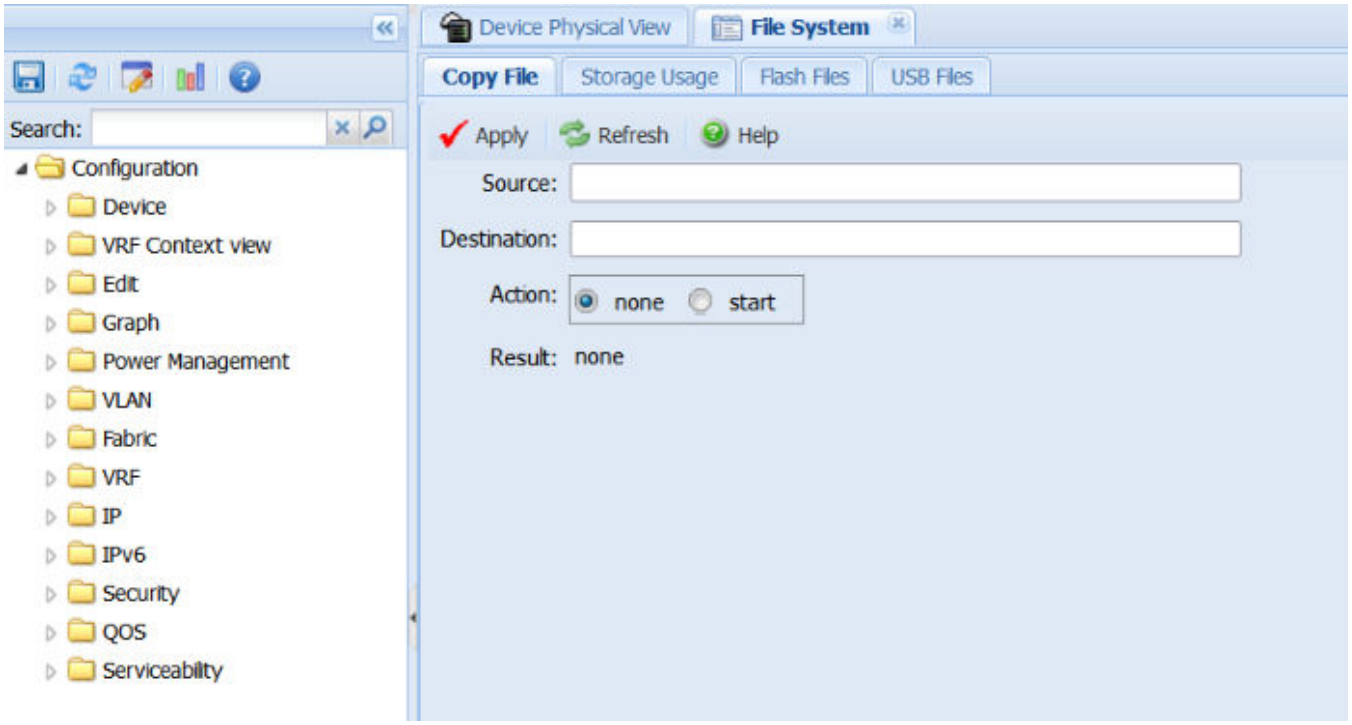

Figure 11: EDM window

Navigation Pane

You can use the navigation pane to see what commands are available and to quickly browse through the command hierarchy. A row of buttons at the top of the navigation pane provides a quick method to perform common functions.

Note

For module-based chassis, menu options related to a specific module are activated only after you install and select the required module.

The following table describes the buttons that display at the top of the navigation pane.

Table 29: Navigation pane buttons

Button	Name	Description
	Save Config	Saves the running configuration.
	Refresh Status	Refreshes the Device Physical View.
	Edit	Edits the selected item in the Device Physical View.
	Graph	Opens the graph options for the selected item in the Device Physical View.
	Help Setup Guide	Opens instructions about how to install the Help files and configure EDM to use the Help files.

Expand a folder by selecting the directional arrow next to the folder name. Some folders have sub-folders such as the Edit folder, which has the Port, NTP, and other sub-folders.

Within each folder and sub-folder, there are numerous options, which provide access to tabs. To open an option, select it. The selected tab displays in the menu bar and opens in the content pane. The following table describes the top-level folders in the navigation pane.

Table 30: Navigation Pane Folders

Menu	Description
Device	Use the Device menu to refresh and update device information or enable polling. • Preference Setting — Enable polling or hot swap detection. Configure the frequency to poll the device. • Refresh Status — Use this option to refresh the device view. • Rediscover Device — Use this to trigger a rediscovery to update all of the device information.
VRF Context view	Use the VRF Context view to switch to another VRF context when you use the embedded EDM. GlobalRouter is the default view at log in. You can configure both Global Router (GRT) and Virtual Routing and Forwarding (VRF) instances when you launch a VRF context view. You can open only five tabs for each EDM session.
Edit	Use the Edit menu to view and configure parameters for the chassis hardware or for the currently selected hardware component, including one or more ports. You can also use the Edit menu to perform the following tasks: • check and configure ports, including the internal Extreme Integrated Application Hosting ports, on the device • change the configuration of many features, including but not limited to, the file system, NTP, OVSDB, SMTP, Link-state tracking, VTEP, Management Instance, Endpoint Tracking, and SNMPv3
Graph	Use the Graph menu to view and configure EDM statistics and to produce graphs of the chassis or port statistics.
Power Management	Use the Power Management menu to view and configure Energy Saver.
VLAN	Use the VLAN menu to view and configure VLANs, spanning tree groups (STG), MultiLink Trunks/ LACP, SMLT, and SLPP.
Fabric	Use the Fabric menu to view and configure IS-IS, Shortest Path Bridging MAC (SPBM), I-SIDs, Fabric Attach, DvR, and statistics.
VRF	Use the VRF menu to view and create VRFs.

Table 30: Navigation Pane Folders (continued)

Menu	Description
IP	Use the IP menu to view and configure IP routing functions for the system, including the following: • IP-VPN • IP-MVPN • IP • TCP/UDP • OSPF • RIP • VRRP • RSMLT • BGP • Multicast • MSDP • IGMP • IPFIX • PIM • SPB-PIM-GW • DHCP Relay • DHCP Snooping • ARP Inspection • Source Guard • UDP Forwarding • IS-IS • Policies • BFD
IPv6	Use the IPv6 menu to view and configure IPv6 routing functions, including the following: • IPv6 • IPv6 - VPN • TCP/UDP • Tunnel • OSPFv3 • VRRP • BGP+ • RSMLT • DHCP Relay • Policy • FHS • IS-IS • RIPng • IPv6 PIM • IPv6 MLD • IPv6 Mroute • IPv6 BFD

Table 30: Navigation Pane Folders (continued)

Menu	Description
Security	Use the Security menu to view and configure access policies, ACL filters, certificates, and features such as RADIUS, RADIUS CoA, SSH, IPSec, TACACS+, and EAPoL.
QOS	Use the QOS menu to view and configure mapping tables, QoS port states, CoS Queue Stats, and Queue Profiles.
Serviceability	Use the Serviceability menu to run diagnostics, and to enable, configure, or view the following: • RMON • sFlow • Application Telemetry • RESTCONF • Virtual services • ExtremeCloud IQ Agent

Menu Bar

The menu bar is above the content pane and consists of two rows of tabs.

- The top row displays the tabs you can open through the navigation pane. The system displays these primary tabs in the sequence in which you open them.
- After you click a primary tab, the secondary tabs associated with it display in the bottom row. Click a secondary tab to display it in the content pane.

In both the top and bottom rows of the menu bar, if the number of tabs exceeds the viewable space, the system displays left- and right-pointing arrows. Click an arrow to scroll to the required tab.

To reduce the number of tabs on the top row, you can click the X on the right corner of a tab to remove it from the row. The following figure shows a sample menu bar.

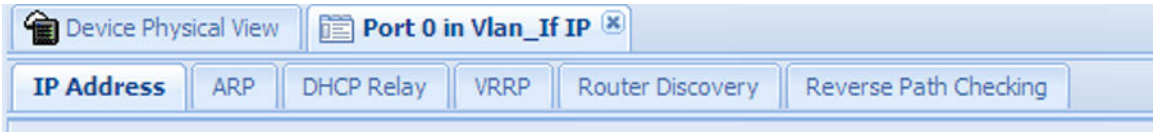

Figure 12: Menu bar

Toolbar

The toolbar buttons provide quick access to commonly used operational commands. The system displays the buttons that vary depending on the tab you select. However, the Apply, Refresh, and Help buttons are on almost every screen. Other common buttons are Insert and Delete. The following list detail the common toolbar buttons.

- Apply—Use this button to execute all edits that you make.
- Refresh—Use this button to refresh all data on the screen.

- Help—Use this button to display online help that is context sensitive to the current dialog box.
- Insert—Use this button to display a secondary dialog box related to the selected tab. After you edit the configurable parameters, click the Insert button in the dialog box. This causes a new entry to display in the dialog box of the selected tab.
- Delete—Use this button to delete a selected entry.

The following figure shows a sample toolbar.

Figure 13: Toolbar

Content Pane

The content pane is the main area on the right side of the window that displays the configuration tabs and dialog boxes. Use the content pane to view or configure parameters on the switch.

Note

You can view valid ranges for all configurable parameters on EDM tabs.

The following figure is a sample that shows the content pane for the Port 1/3 General, Interface tab. If you want to compare the information in two tabs, you can undock one, then open another tab. For more information about undocking a tab, see Undocking and docking tabs on page 245.

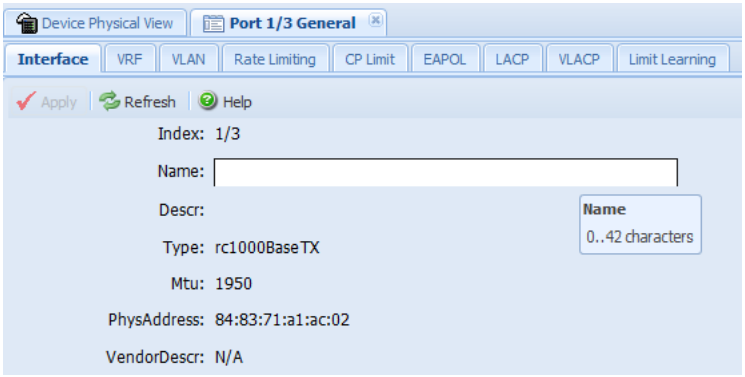

Figure 14: Content pane

EDM user session extension

If the EDM user session remains unused for a duration of ten minutes, the system displays the following message:

```
Your session will expire in about 5 minute(s). Would you like to extend
the session?
```

If you do not respond, EDM automatically ends the session with the following message: `Your session has expired`.

You can log on again if you want to continue to use EDM.

EDM interface procedures

This section contains procedures for starting and using Enterprise Device Manager (EDM). The software is built-in to the switch, and you do not need to install additional software.

Connect to EDM

Before You Begin

- Ensure that the switch is running.
- Note the IP address of the switch.
- Ensure that you use a supported browser version.
- Ensure that you enable the web server using CLI.

About This Task

Perform this procedure to connect to EDM to configure and maintain your network through a graphical user interface.

Procedure

1. In the address field, enter the IP address of the system using the following formats: **https://<IP_address>** (default) or **http://<IP_address>**.

   Note

   By default the web server is configured with the secure-only option, which requires you to use HTTPS to access EDM. To access EDM using HTTP, you must disable the secure-only option.

2. In the **User Name** field, type the user name.

   The default is admin.

3. In the **Password** field, type a password.

   The default is password.

4. Select **Log On**.

Configure the Web Management Interface

Before You Begin

- Enable the web server.

About This Task

Configure the web management interface to change the user names and passwords for management access to the switch using a web browser.

HTTP, FTP, and TFTP server supports both IPv4 and IPv6 addresses, with no difference in functionality or configuration.

You can also use the CLI interface for creating users.

Procedure

1. In the navigation pane, expand **Configuration** > **Security** > **Control Path**.
2. Select **General**.
3. Select the **Web** tab.
4. Complete the **WebRWAUserName** and **WebRWAUserPassword** fields to specify the user name and password for access to the web interface.

   This user will have full permission.
5. To enable the RO user for the web server, select **WebROEnable**.
6. Complete the **WebROUserName** and **WebROUserPassword** fields to specify the user name and password for access to the web interface.

   This user will have read only permission.
7. Select **Apply**.

Web *Field Descriptions*

Use the data in the following table to use the **Web** tab.

Name	Description
WebRWAUserName	Specifies the RWA username from 1–20 characters. The default is admin.
WebRWAUserPassword	Specifies the password from 1–32 characters. The default is 12345678.
WebROEnable	Enables the web server read-only (RO) user, which is disabled by default after a software upgrade.
WebEncryptionType	Specifies the ciphers for preset version of TLS for the web server.
WebCertSubjectName	Specifies the digital certificate subject Name used as identity certificate in the web server.
WebCertCAName	Specifies the digital certificate CA trustpoint name used for the certificate in the web server.
WebROUserName	Specifies the RO username. The default is user.
WebROUserPassword	Specifies the password from 1–32 characters. The default is password.
MinimumPasswordLength	Configures the minimum password length. By default, the minimum password length is 8 characters.
HttpPort	Specifies the HTTP port for web access. The default value is 80.
HttpsPort	Specifies the HTTPS port for web access. The default value is 443.
SecureOnly	Controls whether the secure-only option is enabled. The default is enabled.
InactivityTimeout	Specifies the idle time (in seconds) to wait before the EDM login session expires. The default value is 900 seconds (15 minutes).

Name	Description
TlsMinimumVersion	Configures the minimum version of the TLS protocol supported by the web-server. You can select from the following options: • tlsv10 – Configures the version to TLS 1.0. • tlsv11 – Configures the version to TLS 1.1. • tlsv12 – Configures the version to TLS 1.2 The default is tlsv12.
InUseCertType	Shows if the certificate is self-signed or user-installed.
HelpTftp/Ftp_SourceDir	Configures the TFTP or FTP directory for Help files, in one of the following formats: a.b.c.d:/| peer:/ [<dir>]. The path can use 0–256 characters. The following example paths illustrate the correct format: • 192.0.2.1:/Help • 192.0.2.1:/
DefaultDisplayRows	Configures the web server display row width between 10–100. The default is 30.
LastChange	Shows the last web-browser initiated configuration change.
NumHits	Shows the number of hits to the web server.
NumAccessChecks	Shows the number of access checks performed by the web server.
NumAccessBlocks	Shows the number of access attempts blocked by the web server.
LastHostAccessBlockedAddressType	Shows the address type, either IPv4 or IPv6, of the last host access blocked by the web server.
LastHostAccessBlockedAddress	Shows the IP address of the last host access blocked by the web server.
NumRxErrors	Shows the number of receive errors the web server encounters.
NumTxErrors	Shows the number of transmit errors the web server encounters.
NumSetRequest	Shows the number of set-requests sent to the web server.

Using the chassis shortcut menu

About This Task

Perform the following procedure to display the chassis shortcut menu.

Procedure

1. In the Device Physical View, select the chassis.

2. Right-click the chassis.

Chassis shortcut menu *field descriptions*

Use the data in the following table to use the **Chassis** shortcut menu.

Name	Description
Edit	Edits chassis parameters.
Graph	Graphs chassis statistics.
Refresh Status	Refreshes the status of the chassis and MDAs.
Refresh Port Tooltips	Refreshes the port tooltip data of the system. The port tooltip data contains the following variables: Slot/Port, PortName, and PortOperSpeed.

Using the port shortcut menu

About This Task

Perform this procedure to display the port shortcut menu.

Procedure

1. In the Device Physical View, select a port.
2. Right-click the selected port.

Port shortcut menu *field descriptions*

Use the data in the following table to use the port shortcut menu.

Name	Description
Edit General	Configures the general options for the port.
Edit IP	Configures the IP options for the port.
Edit IPv6	Configures the IPv6 options for the port.
Channelization Enable	Enables channelization for the port.
Channelization Disable	Disables channelization for the port.
Graph	Displays the statistics for the port.
Enable	Enables the port.
Disable	Disables the port.

Using a table-based tab

About This Task

Change an existing configuration using a table-based tab. You cannot edit grey-shaded fields in the table. The following procedure is an illustration on how to use a table-based tab.

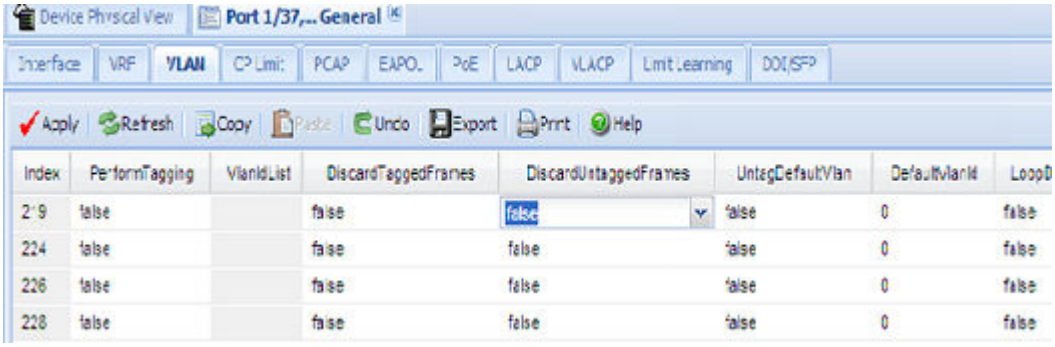
Note

You can expand the appropriate folders for any feature you configure and select a table-based tab.

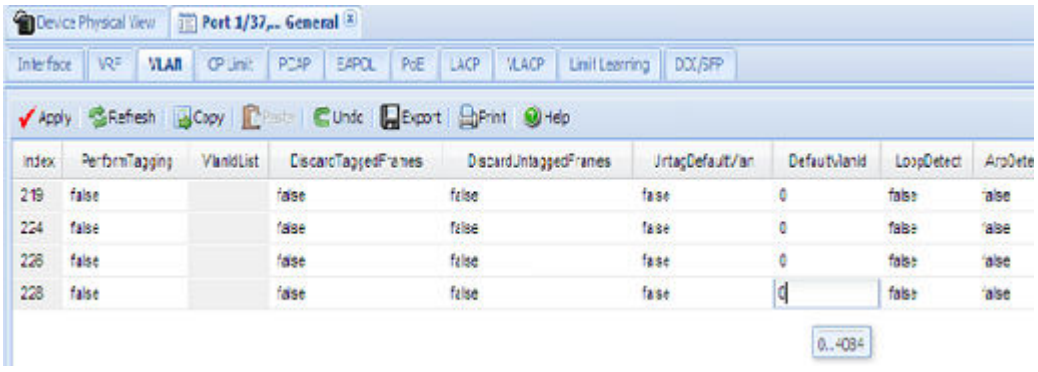
Procedure

1. In the Device Physical View, select multiple ports.
2. In the navigation pane, expand the **Configuration** > **Edit** > **Port** > **General** folders.
3. Click the **VLAN** tab.

   The system displays a table-based tab with the VLAN information.
4. Select a table-based tab.
5. Double-click a white-shaded field to edit the value.
6. Click the arrow in the list field to view the options, and then select the appropriate value.



7. In a text-entry field, double-click, and then edit the value.



8. Click **Apply** to save the configuration changes.

Monitor Multiple Ports and Configuration Support

About This Task

You can monitor or apply the same configuration changes to more than one port by using the multiple port selection function. You can use the standard menu or the shortcut menu to edit the configuration settings for multiple ports.

Tip

A selected port shows a yellow outline around the port.

Procedure

1. Select the **Device Physical View** tab.
2. To select multiple ports, press **Ctrl** (Control), and then select the required ports.

Open Folders and Tabs

About This Task

Perform this procedure to navigate in EDM.

Procedure

1. In the navigation pane, expand the **Configuration** folder.
2. Click a subfolder to expand the subfolder and see the list of menu options, for example, the **VLAN** folder.
3. In a folder or subfolder menu, click an option to open the related tabs.

Undocking and docking tabs

About This Task

Perform this procedure to undock a tab. You can undock tabs to have more than one tab visible at a time.

Procedure

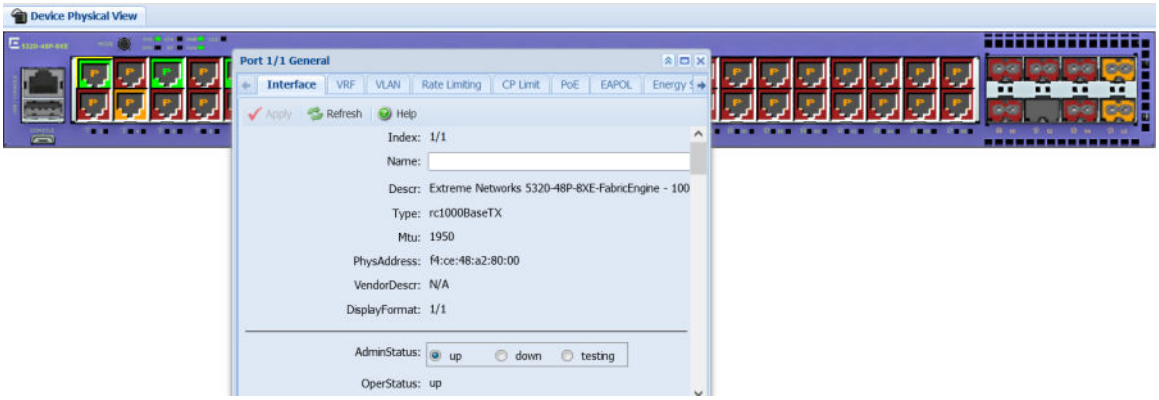
1. In the navigation pane, click a tab.
2. In the menu bar, click and drag a tab to undock it.
3. In the top right corner of the tab, click **pages** to dock the tab.

Example of Undocking and Docking Tabs

Procedure

1. Select the **Device Physical View** tab.
2. In the Device Physical View, select a port. In this example, right-click port 1.
3. In the **Port** shortcut menu, click **Edit General**.

4. Select and drag the **Port 1/1 General** tab wherever you want on the screen as shown in the following figure.



5. To reposition the tab anywhere on the screen, Select and drag the title bar.
6. To manipulate the tab, Select on the buttons in the top-right of the dialog box.

7. Select the up arrowhead to minimize the tab as shown in the following figure.

8. Select the down arrowhead to restore the tab to its original size.
9. Select the pages to dock the tab back into the menu bar.
10. Select the X to close the tab.

Installing EDM help files

While the EDM GUI is bundled with the switch software, the associated EDM help files are not. To access the help files from the EDM GUI, you must install the EDM help files on a TFTP or FTP server in your network.

Use the following procedure to install the EDM help files on a TFTP or FTP server, and configure EDM to use the help files

Before You Begin

If you use an FTP server to store the help files, ensure that you configure the switch with the host user name and password.

Procedure

1. Download the EDM help file.
2. On a TFTP or FTP server reachable from the switch, create a directory called **Help**.

Tip

You can name the directory anything that will help you remember its purpose.

3. Unzip the EDM help zip file into the directory created in the preceding step.
4. In the EDM navigation pane, expand the **Configuration** > **Security** > **Control Path** folders.
5. Click **General**.
6. Click **Web**.
7. In the **HelpTftp/Ftp_SourceDir** field, enter the IP address of the file server and the path to the help files, for example, 192.0.2.15:/home/Help/.

File Management in EDM

This setion contains procedures for managing files with Enterprise Device Manager (EDM).

Use the File System tab to perform the following tasks:

- Copy a file.
- Check the amount of memory used and the number of files stored in the internal flash memory.
- Verify the name, size, and storage date of each file present in the internal flash memory.
- Display USB file information.

Copy a File

About This Task

Copy files on the internal flash.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **File System**.
3. Select the **Copy File** tab.
4. Edit the fields as required.
5. Select **Apply**.

Copy File *Field Descriptions*

Use the data in the following table to use the **Copy File** tab.

Name	Description
Source	Identifies the device and file name to copy. You must specify the full path and filename, for example, `<deviceip-ftp server>:/<filename>` Note: For certain switches in enhanced secure mode, sensitive files and paths are protected.
Destination	Identifies the location to which to copy the source file with the filename, for example, `/intflash/<filename>`. Note: For certain switches in enhanced secure mode, sensitive files and paths are protected.
Action	Starts or stops the copy process.
Result	Specifies the result of the copy process: • none • inProgress • success • fail • invalidSource • invalidDestination • outOfMemory • outOfSpace • fileNotFound

Display Storage Use

About This Task

Display the amount of memory used, memory available, and the number of files for internal flash memory.

Note

5320 Series and 5420 Series support 512 MB of flash memory but only 390 MB is available for use.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **File System**.
3. Select the **Storage usage** tab.

***Storage Usage** Field Descriptions*

Use the data in the following table to use the **Storage Usage** tab.

Name	Description
IntflashBytesUsed	Specifies the number of bytes used in internal flash memory.
IntflashBytesFree	Specifies the number of bytes available for use in internal flash memory.
IntflashNumFiles	Specifies the number of files in internal flash memory.
UsbBytesUsed	Specifies the number of bytes used in USB device.
UsbBytesFree	Specifies the number of bytes available for use in USB device.
UsbNumFiles	Specifies the number of files in USB device.

Display Internal Flash File Information

About This Task

Display information about the files in internal flash memory on this device.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Click **File System**.
3. Click the **Flash Files** tab.

***Flash Files** field descriptions*

Use the data in the following table to use the **Flash Files** tab.

Name	Description
Slot	Specifies the slot number.
Name	Specifies the directory name of the file.
Date	Specifies the creation or modification date of the file.
Size	Specifies the size of the file.

Display USB File Information

About This Task

Display information about the files on a USB device to view general file information.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Click **File System**.
3. Click the **USB Files** tab.

USB Files *field descriptions*

Use the data in the following table to use the **USB Files** tab.

Name	Description
Slot	Specifies the slot number of the device.
Name	Specifies the directory name of the file.
Date	Specifies the creation or modification date of the file.
Size	Specifies the size of the file.

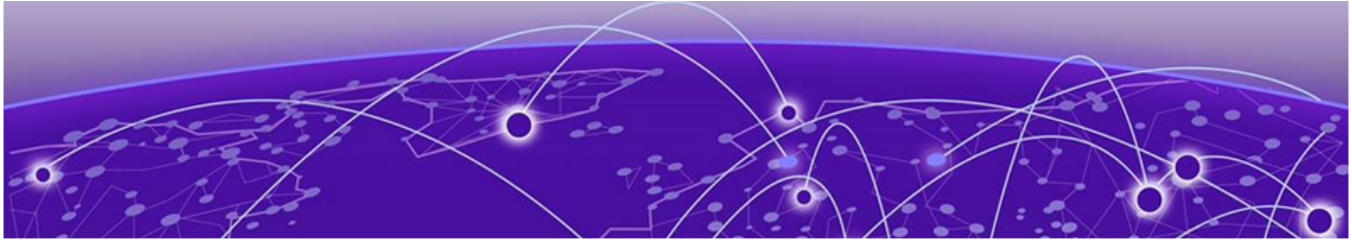


Image Management

This section details what you must know to manage the software image on the switch.

Image Upgrades

Install new software upgrades to add functionality to the switch. Major and minor upgrades are released depending on how many features the upgrade adds or modifies.

Upgrade time requirements

Image upgrades take less than 30 minutes to complete. The switch continues to operate during the image download process. A service interruption occurs during the installation and subsequent reset of the device. The system returns to an operational state after a successful installation of the new software and device reset.

Before you upgrade the software image

Before you upgrade the switch, ensure that you read the entire upgrading procedure.

You must keep a copy of the previous configuration file (config.cfg), in case you need to return to the previous version. The upgrade process automatically converts, but does not save, the existing configuration file to a format that is compatible with the new software release. The new configuration file may not be backward compatible.

Image Naming Conventions

The switch software use a standardized dot notation format.

Software Images

Software image names use the following number formats to identify release and maintenance values:

```
Product Name.Major Release.Minor Release.Maintenance Release.Maintenance
Release Update.voss
```

For example, the image file name `5320.8.6.1.0.voss` denotes a software image for the 5320 Series product with a major release version of 8, a minor release version of 6, a maintenance release version of 1 and a maintenance release update version of 0. VOSS is the file extension.

Firmware Update And Verification With Digital Signed Certificate

VOSS software images are cryptographic signed. Code signing is the process of digitally signing executables and scripts to confirm the software author and guarantee that the code has not been altered or corrupted since it was signed. This process employs the use of a cryptographic hash to validate authenticity and integrity.

The **`show software`** command displays information about the software image:

```
5720-24MW-FabricEngine:1>show software
================================================================================
                    software releases in /intflash/release/
================================================================================
5720.8.7.0.0int01             (Backup Release)              (Signed Release)
5720.8.7.0.0int02             (Primary Release)             (Signed Release)
```

Operational Considerations

The following section describes operational considerations:

- You not required to provide additional input.
- You can use unsigned images; however, this is not recommended. To use an unsigned image, downgrade to a pre-VOSS 8.5 software image then load a debug image.
- You cannot enter Enhanced Secure Mode with an unsigned image. Enhanced Secure Mode requires a signed image.

Interfaces

You can apply upgrades to the switch using the Command Line Interface (CLI).

For more information about CLI, see Command Line Interface on page 212.

File Storage Options

This section details what you must know about the internal boot and system flash memory and Universal Serial Bus (USB) mass-storage device, which you can use to store the files that start and operate the switch.

The switch file system uses long file names.

Internal flash

The switch has two internal flash memory devices: the boot flash memory and the system flash memory. The system flash memory size is 2 gigabytes (GB).

Boot flash memory is split into two banks that each contain a different copy of the boot image files. Only the Image Management feature can make changes to the boot flash.

The system flash memory stores configuration files, runtime images, the system log, and other files. You can access files on the internal flash through the /intflash/ folder.

USB device

The switch can use a USB device for additional storage or configuration files, release images, and other files. The USB device provides a convenient, removable mechanical to copy files between a computer and a switch, or between switches. In cases where network connectivity has not yet been established, or network file transfer is not feasible, you can use a USB device to upgrade the configuration and image files on the switch.

File Transfer Protocol

You can use File Transfer Protocol (FTP) to load the software directly to the switch, or to download the software to the internal flash memory or to an installed USB device.

The switch can act as an FTP server or client. If you enable the FTP daemon (ftpd), you can use a standards-based FTP client to connect to the switch by using the CLI log on parameters. Copy the files from the client to either the internal flash memory or USB device.

Boot Loader Image on Universal Hardware

On universal hardware products, new software activations automatically detect the uboot image, check if it is valid, and then compare the version of the uboot image with the version currently on the system. If the system started with the default uboot image, indicated by `Boot Version Used` in the **`show sys-info uboot`** command output, and the uboot image in the activated software release is newer, image synchronization performs a default uboot upgrade. After the default uboot upgrade is complete, the **`show sys-info uboot`** command output displays the uboot version from the system boot time, so it still shows the previous version, but it also indicates that the default uboot was upgraded and that a system reboot is required.

After you reboot the system for a default uboot upgrade, if a temporary default uboot upgrade file is present on the system, if the system started with the default uboot image, and if the default and alternate uboot versions are not the same, the alternate uboot is upgraded. You must restart the system for the alternate uboot upgrade to take effect.

Before You Upgrade

This section provides important feature impacts you need to understand before you upgrade the switch software.

Important Upgrade Note for Systems using IPv6 Static Neighbors

Due to an issue in VOSS 4.2.1 and later releases, the port number for an IPv6 static neighbor is saved with the wrong value in the configuration file if the port is part of an MLT or SMLT. You can view the incorrect port number by using the **`show running-config`** command.

If performing a named boot (e.g. **`boot config.cfg`**), the configuration loading fails and the switch remains in a default configuration. You can manually source the configuration file (e.g. **`source config.cfg`**) to retrieve/reapply the configuration (minus the IPv6 neighbor configuration with the invalid port value).

If you boot the switch without a specified configuration (e.g.**`reset -y`**), the primary configuration fails to load and the backup configuration file is loaded instead.

Caution

You should never configure an IPv6 static neighbor on a port belonging to an MLT or SMLT.

Saving the Configuration

Save the configuration

- When you make a change to the configuration.
- To create a backup configuration file before you upgrade the software on the switch.

After you change the configuration, you must save the changes on the device. Save the configuration to a file to retain the configuration settings.

Note that not all CLI commands are included in configuration files. Typical examples include, but are not limited to some operational and security-related commands.

Note

When loading large configuration files or large sections of a configuration file, avoid copying and pasting of the files into the console or terminal window as it can lead to the loss of configuration. You must either source the file or boot to the intended configuration file. Sourcing and booting allow for the debug and verification of the configuration file using the boot config flags. For more information about booting, sourcing, and debugging or verification using boot flags, see *Fabric Engine CLI Commands Reference*.

About This Task

File Transfer Protocol (FTP) and Trivial File Transfer Protocol (TFTP) support IPv4 and IPv6 addresses.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Save the running configuration:

   ```
   save config [backup WORD<1-99>] [file WORD<1-99>] [verbose]
   ```

Example

```
Switch:1> enable
```

Save the configuration to the default location:

```
Switch:1# save config
```

Identify the file as a backup file and designate a location to save the file:

```
Switch:1# save config backup /usb/PreUpgradeBackup.cfg
```

Variable Definitions

The following table defines parameters for the **`save config`** command.

Variable	Value
backup WORD<1-99>	Saves the specified file name and identifies the file as a backup file. *WORD<1-99>* uses one of the following format: • a.b.c.d:<file> • /intflash/<file> • /usb/<file> The file name, including the directory structure, can include up to 99 characters.
file WORD<1-99>	Specifies the file name in one of the following format: • a.b.c.d:<file> • /intflash/<file> • /usb/<file> The file name, including the directory structure, can include up to 99 characters.
verbose	Saves the default and current configuration. If you omit this parameter, the command saves only parameters you change.

Upgrade the Software

Important

Upgrades from some releases require release-specific steps. For more information, see *Fabric Engine Release Notes*.

Perform this procedure to upgrade the software on the switch. This procedure shows how to upgrade the software using the internal flash memory as the file storage location.

Use one of the following options to upload the file with the new software to the switch:

- Use FTP or SFTP to transfer the file.
- Download the image file to your computer. Copy the file to a USB device and insert the USB device into the USB port on the switch.

You can store up to six software releases on the 5520 Series and 5720 Series. If you have six releases already stored on the switch, you are prompted to remove one release before you can proceed to add and activate a new software release. You can store a maximum of two software releases on the 5320 Series and 5420 Series. If you attempt to add a third software release, the software displays a confirmation to overwrite the non-primary release. You can also use the **`software add <filename> -y`** to bypass the confirmation question and automatically overwrite the non-primary release.

For information about how to remove a software release, see Remove a Software Build on page 166.

Before You Begin

- To obtain the new software, go to the Extreme Networks support site: http://www.extremenetworks.com/support. You need a valid user or site ID and password.
- Back up the configuration files.
- Use an FTP or SFTP application or USB device to transfer the file with the new software release to the switch.
- Ensure that you have not configured a VLAN above 4059. If you have, you must port all configuration on this VLAN to another VLAN, before you begin the upgrade.

Caution

Only VLAN range 2 to 4059 is supported. All configuration on a higher numbered VLAN from earlier releases will be lost after the upgrade.

Note

Software upgrade configurations are case-sensitive.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. If you are using the USB port to transfer files, go to the next step. If you are using FTP or SFTP to download the files, start the FTP daemon on the switch and enable the ftpd flag for FTP or sshd flag for SFTP:

   

   Note

   Start an FTP session from your computer to the switch using the same username and password used to Telnet or SSH to the switch. Upload or copy the image to the switch.

   ```
   boot config flag <ftpd | sshd>

   end
   ```

3. Download the files to the switch through FTP or SFTP, or transfer them to the switch through the USB port.
4. Enter Privileged EXEC configuration mode by exiting the Global Configuration mode.

   ```
   exit
   ```
5. Extract the release distribution files to the `/intflash/release/` directory:

   ```
   software add WORD<1-99> [-y]
   ```

   Note

   The image file is removed after the **`software add`** command runs.

6. Install the image:

   ```
   software activate WORD<1-99>
   ```
7. Restart the switch:

   ```
   reset
   ```

   Important

   After you restart the system, you have the amount of time configured for the commit timer to verify the upgrade and commit the software to gold. If you do not commit the software to gold and auto-commit is not enabled, the system restarts with the last known working version after the commit timer has expired. This feature ensures you can regain control of the system if an upgrade fails. By default, auto-commit is enabled.

8. After you restart the switch, enter Privileged EXEC configuration mode:

   rwa

   ```
   enable
   ```
9. Confirm the software is upgraded:

   ```
   show software
   ```
10. Commit the software:

    ```
    software commit
    ```

    Important

    If you disable the auto-commit feature, you must run the **`software commit`** command manually before the commit timer expires to commit the new software version, otherwise the system restarts automatically to the previous (committed) version. By default, auto-commit is enabled.

Example

Note

The image file name is switch dependent. See *Fabric Engine Release Notes* for information about file names.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#boot config flags ftpd
```

```
Switch:1(config)#end
Switch:1#copy /usb/5420.8.5.0.0.voss /intflash/5420.8.5.0.0.voss
Switch:1#software add 5420.8.5.0.0.voss -y
Switch:1#software activate 5420.8.5.0.0.GA
Switch:1#reset -y
Switch:1>show software
================================================================================
                    software releases in /intflash/release/
================================================================================
5420.8.5.0.0.GA (Primary Release) (Signed Release)
5420.8.4.0.0.GA (Backup Release) (Unsigned Release)

--------------------------------------------------------------------------------
Auto Commit     : enabled
Commit Timeout  : 10 minutes

Remaining time until software auto-commit is 8 minutes 59 seconds

Switch:1>show software detail
================================================================================
                    software releases in /intflash/release/
================================================================================
5420.8.5.0.0.GA (Primary Release) (Signed Release)
  SSIO
    UBOOT                           2.3.2.3
    APP_FS                          5420.8.5.0.0.GA
  AVAILABLE ENCRYPTION MODULES
    3DES
    AES/DES

5420.8.4.0.0.GA (Backup Release) (Unsigned Release)
  SSIO
    UBOOT                           2.3.2.1
    APP_FS                          5420.8.4.0.0.GA
  AVAILABLE ENCRYPTION MODULES
    3DES
    AES/DES
```

Variable Definitions

The following table defines parameters for the **software** command.

Variable	Value
activate WORD<1-99>	Copies the software version to the boot flash file. When you use the software activate command, the system checks for hardware dependencies and prevents a downgrade if it detects a dependency. For example, if a hardware component has a minimum software version dependency, you cannot downgrade to an incompatible software version or install the hardware component in a chassis that runs an incompatible software version.
add WORD<1-99>	Unpacks a software release <version>.
-y Note: Exception: not supported on 5520 Series.	Suppresses the confirmation message to automatically overwrite the non-primary image. If you omit this parameter, you must confirm the action to overwrite the non-primary image.

Verifying the upgrade

Verify your upgrade to ensure proper switch operation.

Procedure

1. Check for alarms or unexpected errors:

   ```
   show logging file tail
   ```

2. Verify all modules and slots are online:

   ```
   show sys-info
   ```

Commit an upgrade

Perform the following procedure to commit an upgrade.

About This Task

The software commit functionality for software upgrades allows maximum time set by the commit timer (the default is 10 minutes) to ensure that the upgrade is successful. If you enable the auto-commit option, the system automatically commits to the new software version after the commit timer expires.

Procedure

1. Enter Global Configuration mode:

   ```
   enable
   ```

   ```
   configure terminal
   ```

2. (Optional) Configure the timer to activate the software:

   ```
   sys software commit-time <10-60>
   ```

   The default is 10 minutes.
3. **(Optional)** Extend or reduce the time to commit the software:

   software reset-commit-time [<1–60>]
4. Commit the upgrade:

   ```
   software commit
   ```

Important

If you disable the auto-commit feature, you must run the **`software commit`** command manually before the commit timer expires to commit the new software version, otherwise the system restarts automatically to the previous (committed) version. By default, auto-commit is enabled.

Downgrade the Software

Perform this procedure to downgrade the switch from the current trusted version to a previous release.

Important

MACsec connectivity association (CA) configurations fail during downgrade. If you plan to downgrade MACsec to an earlier version, delete the MACsec CA entries, perform the downgrade, and then reconfigure the MACsec CA entries. This applies to both 2AN and 4AN modes.

Before You Begin

Ensure that you have a previous version installed.

About This Task

Note

The image file name is switch dependent. See *Fabric Engine Release Notes* for information about file names.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```
2. Extract the release distribution files to the /intflash/release/ directory:

   ```
   software add WORD<1-99>
   ```
3. Activate a prior version of the software:

   ```
   software activate WORD<1-99>
   ```

4. Restart the switch:

   ```
   reset
   ```

   Important

   After you restart the system, you have the amount of time configured for the commit timer to verify the software change and commit the software to gold. If you do not commit the software to gold and auto-commit is not enabled, the system restarts with the last known working version after the commit timer expires. This feature ensures you can regain control of the system if an upgrade fails. By default, auto-commit is enabled.

5. Commit the software change:

   ```
   software commit
   ```

   Important

   If you disable the auto-commit feature, you must run the **`software commit`** command manually before the commit timer expires to commit the new software version, otherwise the system restarts automatically to the previous (committed) version. By default, auto-commit is enabled.

6. Verify the downgrade:
   - Check for alarms or unexpected errors using the `show logging file tail` command.
   - Verify all modules and slots are online using the `show sys-info` command.
7. (Optional) Remove unused software:

   ```
   software remove WORD<1-99>
   ```

Variable Definitions

The following table defines parameters for the `software` command.

Variable	Value
activate WORD<1-99>	Specifies the name of the software release image.
add WORD<1-99>	Specifies the path and version of the compressed software release archive file.
remove WORD<1-99>	Specifies the path and version of the compressed software release archive file.

Remove a Software Build

Use the following procedure to remove a software build for the switch.

Note

You can store up to 6 software releases on the 5520 Series. When the limit is reached, you are prompted to remove one release before you can proceed with adding and activating a new software release.

You can store a maximum of 2 software releases on the 5320 Series and 5420 Series. When the limit is reached, the software displays a confirmation to overwrite the non-primary release before you can install a new software release.

For more information, see Upgrade the Software on page 255.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Remove the software build:

   ```
   software remove WORD<1-99>
   ```

Example

Remove the software build:

```
Switch:1>enable
Switch:1#software remove w.x.y.z
```

Update the Complex Programmable Logic Device (CPLD) Image

During the device bootup, if an older version of a CPLD module is detected, the system displays a log message to upgrade the CPLD module image.

You can also use **`show sys-info cpld`** command to check the current version of the CPLD module on the device.

Before You Begin

Upgrade the software on the switch to the latest build.

About This Task

The **`cpld-install`** command compares the image version of the modules with the current version on the device:

- If the versions are the same, the command exits.
- If the current version is an earlier version, you must update the image version of the specific module.

The device automatically restarts after sucessful installation of the specific module.

Procedure

1. To enter User EXEC mode, log on to the switch.

2. Update one of the following CPLDs:
   - APP:

     ```
     cpld-install app [WORD<1-99>]
     ```
   - BOOT:

     ```
     cpld-install boot [WORD<1-99>]
     ```
   - Main CPLD module:

     ```
     cpld-install main [WORD<1-99>]
     ```
   - Port:

     ```
     cpld-install port [WORD<1-99>]
     ```
3. When prompted, type `y` to continue with the CPLD update.

Variable Definitions

The following table defines parameters for the **`cpld-install`** command.

Variable	Value
app	Updates the APP module.
boot	Updates the BOOT module.
main	Updates the main CPLD module.
port	Updates the Port module.
WORD<1-99>	Specifies the image filename. Note: This parameter is optional. If you do not specify the filename, the command checks the image file for the image from the running filesystem.

Address Resolution Protocol

Table 31: Address Resolution Protocol product support

Feature	Product	Release introduced
Address Resolution Protocol (ARP) including Proxy ARP and Static ARP	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
Gratuitous ARP filtering	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

Address Resolution Protocol

Network stations using the IP protocol need both a physical address and an IP address to transmit a packet. In situations where the station knows only the network host IP address, the network station uses Address Resolution Protocol (ARP) to determine the physical address for a network host by binding a 32-bit IP address to a 48-bit MAC address. A network station can use ARP across a single network only, and the network hardware must support physical broadcasts.

The network station uses ARP to determine the host physical address as follows:

- The network station broadcasts a special packet, called an ARP request, that asks the host at the specified IP address to respond with its physical address.
- All network hosts receive the broadcast request.
- Only the specified host responds with its hardware address.
- The network station then maps the host IP address to its physical address and saves the results in an address-resolution cache for future use.
- The network station ARP table displays the associations of the known MAC address to IP address.

You can create ARP entries, and you can delete individual ARP entries.

Enable ARP traffic

The switch accepts and processes ARP traffic, spanning tree bridge packet data units (BPDU), and Topology Discovery Protocol packets on port-based VLANs with the default port action of drop. If a filter port action is drop for a packet, ARP packets are also dropped. As a result, ARP entries on that port are cleared and are not relearned when the ARP aging timer expires.

To prevent dropped ARP packets, configure the following options:

- A user-defined protocol-based VLAN for ARP EtherType (byprotocol usrDefined 0x0806).
- Ports as static members to this VLAN with the default port action of drop.
- The port default VLAN ID to the correct port-based VLAN where the ARPs are processed.

You do not need to make configuration changes for the BPDU and Topology Discovery Protocol packets.

Only one user-defined protocol-based VLAN for ARP is allowed for each Spanning Tree Group (STG). If the ports with the default port action of drop are in different STGs, you must create additional user-defined protocol-based VLANs.

Proxy ARP

A network station uses proxy ARP to respond to an ARP request from a locally attached host or end station for a remote destination. The network station sends an ARP response back to the local host with its own MAC address of the network station interface for the subnet on which the ARP request was received. The reply is generated only if the device has an active route to the destination network.

The following figure shows an example of proxy ARP operation. In this example, the system displays host C with mask 24 to be locally attached to host B with mask 16, so host B sends an ARP request for host C. However, the switch is between the two hosts. To enable communication between the two hosts, the switch responds to the ARP request with the IP address of host C but with its own MAC address.

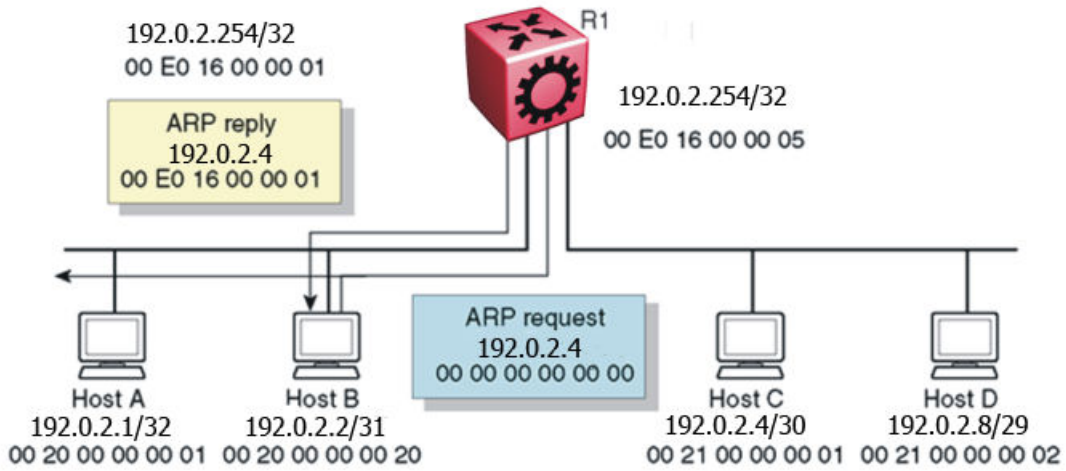

Figure 15: Proxy ARP operation

Loop detection

To prevent cases of ARP looping, configure the ARP loop detection flag to detect this situation. When a loop is detected, the port is shut down.

Flushing router tables

For administrative or troubleshooting purposes, sometimes you must flush the routing tables. Flush routing tables either by VLAN or by port. In a VLAN context, all entries associated with the VLAN are flushed. In a port context, all entries associated with the port are flushed.

Reverse Address Resolution Protocol

Certain devices use the Reverse Address Resolution Protocol (RARP) to obtain an IP address from a RARP server. MAC address information for the port is broadcast on all ports associated with an IP protocol-based or port-based VLAN. To enable a device to request an IP address from a RARP server outside its IP VLAN, you must create a RARP protocol-based VLAN.

RARP has the format of an ARP frame but its own Ethernet type (8035). You can remove RARP from the IP protocol-based VLAN definition and treat it as a separate protocol, thus creating a RARP protocol-based VLAN.

A typical network topology provides desktop switches in wiring closets with one or more trunk ports that extend to one or more data center switches where attached servers provide file, print, and other services. Use RARP functionality to define all ports in a network that require access to a RARP server as potential members of a RARP protocol-based VLAN. You must define all tagged ports and data center RARP servers as static or permanent members of the RARP VLAN. Therefore, a desktop host broadcasts an RARP request to all other members of the RARP VLAN. In normal operation, these members include only the requesting port, tagged ports, and data center RARP server ports. Because all other ports are potential members of this VLAN and RARP is only transmitted at startup, all other port VLAN memberships expire. With this feature, one or more centrally located RARP servers extend RARP services across traditional VLAN boundaries to reach desktops globally.

ARP configuration using the CLI

Network stations that use IP protocol require both a physical address and an IP address to transmit packets. In situations where the station knows only the network host IP address, the Address Resolution Protocol (ARP) lets you use the network station to determine a network host physical address by binding a 32-bit IP address to a 48-bit MAC address.

A network station can use ARP across a single network only, and the network hardware must support physical broadcasts. If a network station wants to send a packet to a host but knows only the host IP address, the network station uses ARP to determine the host physical address.

ARP response is enabled by default.

Enabling ARP on a port or a VLAN

Enable ARP on the device so that it answers local ARP requests.

About This Task

You can enable or disable ARP responses on the device. You can also enable ARP proxy, which lets a router answer a local ARP request for a remote destination.

Procedure

1. Enter Interface Configuration mode:
   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]} or interface vlan <1-4059>
   ```

   

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable ARP on the device:
   ```
   ip arp-response
   ```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 200
Switch:1(config-if)#ip arp-response
```

Enabling ARP proxy

About This Task

Configure an ARP proxy to allow the platform to answer a local ARP request for a remote destination. ARP proxy is disabled by default.

Procedure

1. Enter Interface Configuration mode:
   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]} or interface vlan <1-4059>
   ```

   

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable ARP proxy on the device:
   ```
   ip arp-proxy enable
   ```

   Use the `no` operator to disable ARP proxy: `no ip arp-proxy [enable]`

Example

Enable ARP proxy on VLAN 200:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 200
Switch:1(config-if)#ip arp-proxy enable
```

View ARP Information

The **show ip arp** command displays all of the configured and dynamically learned ARP entries in the ARP table.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display ARP information for a specified port or for all ports:

   ```
   show ip arp interface gigabitethernet [slot/port[/sub-port][-slot/port[/sub-port]][,...]]
   ```
3. Display ARP information for a VLAN:

   ```
   show ip arp interface vlan <1-4059>
   ```

Example

```
Switch:1>show ip arp interface

================================================================================
                                    Port Arp

Variable definitions

Use the data in the following table to use the **show ip arp** command.

Variable	Value
A.B.C.D	Specifies the IP address of a network.
{slot/port[/sub-port][-slot/port[/sub-port]][,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
interface	Displays ARP interface configuration information.
spbm-tunnel-as-mac	Displays the remote host name in the TUNNEL column for the SPBM ARP entry.
-s	Specifies a subnet. You must indicate the IP address followed by the subnet mask expressed as <A.B.C.D> <A.B.C.D>.
vlan <1-4059>	Displays ARP entries for a particular VLAN ID. Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
vrf WORD<1-16>	Specifies a VRF name expressed as text from 1 to 16 characters in length. The total number of ARPs listed in the summary line of the **show ip arp** output represents the total number of ARPs on the chassis, including all VRFs.
vrfids WORD<0-512>	Specifies a range of VRFIDs as text from 0 to 512 characters in length. The total number of ARPs listed in the summary line of the **show ip arp** output represents the total number of ARPs on the chassis, including all VRFs.

Use the data in the following table to help you understand the **show ip arp interface** command output.

Variable	Value
PORT_NUM	Indicates the port number.
DOPROXY	Indicates if ARP proxy responses are enabled or disabled on the specified interface.
DORESP	Indicates if the sending of ARP responses is enabled or disabled on the specified interface.

Use the data in the following table to help you understand the **show ip arp interface vlan** command output.

Variable	Value
VLAN_ID	Indicates the VLAN ID.
DOPROXY	Indicates if ARP proxy responses are enabled or disabled on the specified interface.
DORESP	Indicates if the sending of ARP responses is enabled or disabled on the specified interface.

Configuring IP ARP static entries

About This Task

Configure ARP static entries to modify the ARP parameters on the device. The only way to change a static ARP is to delete the static ARP entry and create a new entry with new information.

Note

Static multicast ARP entries are not supported for NLB Unicast or NLB Multicast operations.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

   ```
   enable

   configure terminal
   ```

   Optional: `router vrf WORD<1-16>`
2. Configure ARP static entries on the device:

   ```
   ip arp <A.B.C.D> 0x00:0x00:0x00:0x00:0x00:0x00 {slot/port[-slot/port]
   [,...]}
   ```

Example

Configure ARP static entries:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip arp 192.0.2.10 00-16-76-7D-80-C2 2/1
```

Variable Definitions

Use the data in the following table to use the **ip arp** command.

Variable	Value
request-threshold <50-1000>	Configures the maximum number of outstanding ARP requests that a device can generate. The range is 50–1000. The default value is 500. To configure this option to the default value, use the **default** operator with this command.
timeout <1-32767>	Configures the length of time in seconds an entry remains in the ARP table before timeout. The range is 1–32767. To configure this option to the default value, use the **default** operator with this command. Note: The aging of ARP records is tied to the aging of MAC records. The ARP record for a given IP address is not removed unless the associated MAC record ages out and the router stops receiving a response to ARP requests for that IP address. In cases where the ARP aging time is set to less than the MAC aging time, the switch waits until the MAC ages out before deleting the ARP for an inactive host.
<A.B.C.D>	Adds ARP entries.

Clearing ARP entries

Use this procedure to clear dynamic ARP table entries associated with the interface or VLAN.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Clear ARP entries:

   ```
   clear ip arp interface <gigabitethernet|vlan> <slot/port[/sub-port][-slot/port[/sub-port]][,...]| <1-4059>>
   ```

Example

Clear ARP entries:

```
Switch:1> enable
Switch:1# clear ip arp interface gigabitethernet 1/16
```

Variable definitions

Use the data in the following table to use the **clear ip arp interface** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
gigabitethernet|vlan	Specifies the interface type.
{slot/port[/sub-port][-slot/port[/sub-port]][,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Showing ARP table information

Show ARP information to view the configuration information in the ARP table.

About This Task

When you use the *interface* parameter with the **show ip arp** command you can display ARP configuration information only for a specific switch.

The **show ip arp** command displays all of the configured and dynamically learned ARP entries in the ARP table.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```
2. Display the ARP table:
   ```
   show ip arp [<A.B.C.D>] [-s <A.B.C.D>] [gigabitEthernet <slot/port[/sub-port]>] [interface <gigabitethernet|vlan>] [nlb] [spbm-tunnel-as-mac][vlan <1-4059>] [vrf WORD<1-16>] [vrfids WORD<0-512>]
   ```

Example

```
Switch:1#show ip arp
================================================================================================
                                IP Arp - GlobalRouter
================================================================================================

8 out of 8 ARP entries displayed

ARPs on TX-NNI: Current = 0, re-ARP count = 0
```

Variable definitions

Use the data in the following table to help you use the **`show ip arp`** command.

Variable	Value
-s	Specifies the subnet for the table.
gigabitEthernet	Displays the entries for a particular brouter port.
interface	Displays ARP interface configuration information. Use the following parameters to display ARP table information specifically for: • gigabitethernet {slot/port[-slot/port][,...]} displays IP ARP gigabitethernet interface information • VLAN *<1-4059>* displays IP ARP VLAN interface information Example: `show ip arp interface vlan 1`
nlb	Displays the Network Load Balancing (NLB) ARP entries on the switch.
spbm-tunnel-as-mac	Displays the remote host name in the TUNNEL column for the SPBM ARP entry.

Variable	Value
vlan	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. Use these parameters to display ARP table information specifically for: • vrf WORD<1–16>—the VLAN VRF name in a range from 1 to 16 characters • vrfids WORD<0–512>—the VLAN VRF ID in a range from 0 to 512 Example: `show ip arp vlan 1 vrf 1`
vrf WORD <1-16>	Specifies the name of the VRF. The total number of ARPs listed in the summary line of the "show ip arp" display represents the total number of ARPs on the chassis including all VRFs.
vrfids WORD <0-512>	Specifies the VRF ID. The total number of ARPs listed in the summary line of the "show ip arp" display represents the total number of ARPs on the chassis including all VRFs.
<A.B.C.D>	Specifies the network IP address for the table.

Use the data in the following table to help you understand the output of the **show ip arp** command.

Parameter	Description
IP_ADDRESS	Indicates the IP address where ARP is configured.
MAC_ADDRESS	Indicates the MAC address where ARP is configured.
VLAN	Indicates the VLAN address where ARP is configured.
PORT	Indicates the port where ARP is configured.
TYPE	Indicates the type of learning (dynamic or local) where ARP is configured.
TTL<10 secs>	Indicates the time to live as tenths of a second where ARP is configured.
TUNNEL	Displays the remote host name in the TUNNEL column for the SPBM ARP entry.
MULTICAST-MAC-FLOODING	Displays whether IP ARP multicast MAC flooding is enabled or disabled. When enabled, the ARP entries for multicast MAC addresses are associated with the VLAN or port interface on which they were learned.

Parameter	Description
AGING (Minutes)	Displays when the ARP aging timer expires.
ARP-THRESHOLD	Displays the maximum number of outstanding ARP requests that a device can generate.

Configuring Gratuitous ARP

Use the following procedure to configure Gratuitous Address Resolution Protocol (ARP). When Gratuitous ARP is enabled the switch allows all Gratuitous ARP request packets. The default is enabled.

If you disable Gratuitous ARP, the switch only allows Gratuitous ARP packets associated with Routed Split Multi-Link Trunking (RSMLT) or Virtual Router Redundancy Protocol (VRRP), and the switch discards all other Gratuitous ARP request packets.

About This Task

ARP translates network layer (layer 3) IP addresses into link layer (layer 2) MAC addresses. A host sends a Gratuitous ARP request packet to inform other hosts of the existence of an interface on the network, so other local hosts can update their ARP tables. If the IP or MAC address changes, or in the event of a failover, a host sends a Gratuitous ARP request packet to inform other hosts to update their ARP tables.

VRRP and RSMLT use gratuitous ARP to update the MAC address tables on switches.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable Gratuitous ARP:

   ```
   ip gratuitous-arp
   ```

3. (Optional) Disable Gratuitous ARP:

   ```
   no ip gratuitous-arp
   ```

4. (Optional) Configure Gratuitous ARP to the default value:

   ```
   default ip gratuitous-arp
   ```

5. Save the changed configuration.

   ```
   save config [backup WORD<1-99>][file WORD<1-99>][verbose]
   ```

ARP configuration using Enterprise Device Manager

Network stations using the IP protocol need both a physical address and an IP address to transmit a packet. In situations where the station knows only the network host IP address, the network station can use Address Resolution Protocol (ARP) to determine a network host physical address by binding a 32-bit IP address to a 48-bit MAC address. A network station can use ARP across a single network only, and the network hardware must support physical broadcasts. If a network station wants to send a packet to a host but knows only the host IP address, the network station uses ARP to determine the host physical address.

Enable or Disable ARP on a Port

After you assign the IP address, you can configure ARP. By default, ARP Response is enabled and Proxy ARP is disabled.

Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504. All parameters might not be available in non-default VRFs.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand: **Configuration** > **Edit** > **Port**.
3. Select **IP**.
4. Select the **ARP** tab.
5. In **DoProxy**, select **enable** to enable the Proxy ARP function.
6. In **DoResp**, select **enable** to configure the system to respond to an ARP. The default is enable.
7. Select **Apply**.

   The ARP function is available only when the port or VLAN is routed; that is, it is assigned an IP address.

***ARP** field descriptions*

Use the data in the following table to use the **ARP** tab fields.

Name	Description
DoProxy	Configures the system to respond to an ARP request from a locally attached host or end station for a remote destination. The default value is disable.
DoResp	Configures the system to send ARP responses for this IP interface address. The default value is enable.

Enable or Disable ARP on a VLAN

Use the following procedure to enable ARP on VLAN level.

Procedure

1. In the navigation pane, expand **Configuration** > **VLAN**.
2. Select **VLANs**.
3. Select the **Basic** tab.
4. Select a VLAN.
5. Select **IP**.
6. Select the **ARP** tab.
7. In **DoProxy**, select **enable** to enable the Proxy ARP function.
8. In **DoResp**, select **enable** to configure the system to respond to an ARP. The default is enable.
9. Select **Apply**.

   The ARP dialog box is available only if the port or VLAN is routed; that is, it is assigned an IP address.

ARP field descriptions

Use the data in the following table to use the **ARP** tab.

Name	Description
DoProxy	Configures the system to respond to an ARP request from a locally attached host or end station for a remote destination. The default value is disable.
DoResp	Configures the system to send ARP responses for this IP interface address. The default value is enable.

View ARP Entries

You can view and manage known MAC address to IP address associations. In addition, you can create or delete individual ARP entries. For information about how to create a static ARP entry, see Create Static ARP Entries on page 278.

Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504. All parameters might not be available in non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Select **IP**.
3. Select the **ARP** tab.

ARP field descriptions

Use the data in the following table to use the **ARP** tab.

Name	Description
NetAddress	Specifies the IP address corresponding to the media-dependent physical address.
IfIndex	Identifies the router interface for this ARP entry: • Brouter interfaces are identified by the slot/port number of the brouter port. • VLAN interfaces are identified by the vlan name.
PhysAddress	Specifies the media-dependent physical address (that is, the Ethernet address).
Type	Specifies the type of ARP entry: • local—a locally configured ARP entry • static—a statically configured ARP entry • dynamic—a learned ARP entry
TimeToLive	Indicates the time to live where the ARP is configured.
DestIfIndex	Indicates the slot/port on which the ARP entry was learned. For brouter interfaces this is the same value as IfIndex, but for VLAN interfaces, it designates the particular port in the VLAN on which the ARP was learned.
DestVlanId	VLAN ID where the ARP is configured.

Name	Description
BMac	Identifies the backbone MAC address if the entry is learned from an SPBM network.
DestCvid	Identifies the customer VLAN ID for a Switched UNI port.

Create Static ARP Entries

Use the following procedure to create a static ARP entry.

Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504. All parameters might not be available in non-default VRFs.

About This Task

Note

Static multicast ARP entries are not supported for NLB Unicast or NLB Multicast operations.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Select **IP**.
3. Select the **ARP** tab.
4. Select **Insert**.
5. In **NetAddress**, type the IP address.
6. Select **Port** or **Port in VLAN**.
7. In the dialog box, select the interface.
8. Select **OK**.
9. In **PhysAddress**, type the MAC address.
10. Select **Insert**.

Configure ARP Proxy

With an ARP proxy, the switch can respond to an ARP request from a locally attached host or end station for a remote destination. Proxy ARP does so by sending an ARP response back to the local host with its own MAC address of the router interface for the subnet on which the ARP request was received. The reply is generated only if the system has an active route to the destination network.

Procedure

1. In the navigation pane, expand **Configuration** > **VLAN**.
2. Select **VLANs**.
3. Select the **Basic** tab.
4. Select a VLAN.
5. Select **IP**.

6. Select the **ARP** tab.
7. For **DoProxy**, select **enable**.
8. Select **Apply**.

Alternative Routes

Table 32: Alternative routes product support

Feature	Product	Release introduced
Alternative routes for IPv4	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine
Alternative routes for IPv6	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

To avoid traffic interruption, you can globally enable the alternative routes feature so the router can use the next-best route, also known as an alternative route, if the best route becomes unavailable.

Routers learn routes to a destination through routing protocols. Routers maintain a routing table of the learned alternative routes sorted in order by route preference, route costs, and route sources. The first route on the list is the best route and the route that the router prefers to use.

The alternative route concept also applies between routing protocols. For example, if an OSPFv3 route becomes unavailable and an alternative RIPng route is available, the system activates the RIPng route without waiting for the update interval to expire.

Route Preference

On the switch, all standard routing protocols have default preference values that determine the routing priority of the protocol. The router uses default preferences to select the best route when a clash exists in preference between the protocols.

You can modify the global preference for a protocol to give the protocol a higher or lower priority than other protocols. If you change the global preference for a static route and all best routes remain best routes, only the local route tables change. However, if the protocol preference change causes best routes to no longer be best routes, the change affects neighboring route tables.

Important

Changing route preferences is a process-intensive operation that can affect system performance and network reach while you perform route preference procedures. As a best practice, if you want to change preferences for static routes or routing protocols, do so when you configure routes or during a maintenance window.

If a router learns a route with the same network mask and cost values from multiple sources, the router uses the route preferences to select the best route to add to the forwarding database.

Note

To modify the preference for a route, you do *not* need to disable a route before you edit the configuration.

Preferences for Static Routes

When you configure a static route on the switch, you can specify a global preference for the route. You can also specify an individual route preference that overrides the global static route preference. The preference value can be between 0 and 255, with 0 reserved for local routes and 255 representing an unreachable route.

Preferences for Dynamic Routes

You can modify the preference value for dynamic routes through route filtering and IP policies, and this value overrides the global preference for the protocol.

The following table shows the default preferences for routing protocols and route types. Use this table to help you modify the global preference value.

Table 33: Routing protocol default preferences

Protocol	Default preference
Local	0
Static	5
SPBM_L1	7
OSPF intra-area	20
OSPF inter-area	25
Exterior BGP	45
RIP/RIPng	100
OSPF external type 1	120
OSPF external type 2	125
IBGP	175

Table 33: Routing protocol default preferences (continued)

Protocol	Default preference
Staticv6	5
OSPFv3 intra-area	20
OSPFv3 inter-area	25
OSPFv3 external type 1	120
OSPFv3 external type 2	125

Alternative Route Configuration using CLI

Enable IPv4 Alternative Routes

About This Task

The default value is enabled. If you disable the alternative-route parameter, all existing alternative routes are removed. After you enable the parameter, all alternative routes are readded.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

   ```
   enable

   configure terminal
   ```

   Optional: `router vrf WORD<1-16>`
2. Activate the alternative route feature globally:

   ```
   ip alternative-route
   ```

Enable IPv6 Alternative Routes

Use this procedure to enable IPv6 alternative routes and view the configuration on the switch.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

   ```
   enable

   configure terminal
   ```

   Optional: `router vrf WORD<1-16>`

2. Enable IPv6 alternative routes:

   ```
   ipv6 alternative-route
   ```

   Note

   IPv6 alternative routes are enabled by default.

3. Verify the configuration of the IPv6 alternative route:

   ```
   show ipv6 global [vrf WORD<1-16> | vrfids WORD<0-512>]

   show ipv6 route alternative [vrf WORD<1-16> | vrfids WORD<0-512>]
   ```

Example:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf globalRouter
Switch:1(router-vrf)#ipv6 alternative-route

Switch:1#show ipv6 global
================================================================================

Alternative Route Configuration using EDM

Enable IPv4 Alternative Routes

Enable alternative routes so that you can subsequently enable it on interfaces.

Before You Begin

- To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504. All parameters might not be available in non-default VRFs.

Procedure

1. In the navigation tree, expand **Configuration** > **IP**.
2. Select **IP**.
3. Select the **Globals** tab.
4. Select **AlternativeEnable**.

   If the **AlternativeEnable** parameter is disabled, all existing alternative routes are removed. After you enable the parameter, all alternative routes are re-added.
5. Select **Apply**.

Enable IPv6 Alternative Routes

To avoid traffic interruption, enable alternative routes on the switch, to replace the best route with the next-best route if the best route becomes unavailable. By default, this feature is enabled.

Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504. All parameters might not be available in non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Select **IPv6**.
3. Select the **Globals** tab.
4. To enable IPv6 alternative routes, select **AlternativeRouteEnable**.
5. Select **Apply**.

IPv6 Alternative Routes Configuration Example

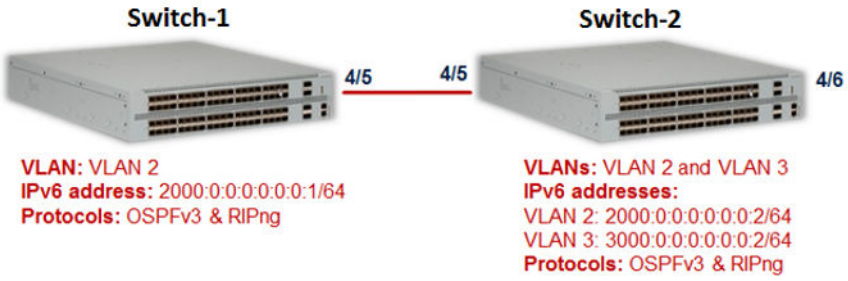
To avoid traffic interruption, you can enable alternative routes globally to replace the best route with the next-best route, if the best route becomes unavailable.

The concept of alternative route applies between routing protocols. For example, if an OSPFv3 route becomes unavailable and an alternative RIPng route is available, the system activates the RIPng route immediately without waiting for an update interval to expire.

By default, the alternative routes feature is globally enabled on the switch.

The following example demonstrates this behavior.

In this example, you configure OSPFv3 and RIPng routes on two switches Switch-1 and Switch-2, as shown in the following figure.



Configuration on Switch-1

VLAN configuration:

On Switch-1, configure VLAN 2 and the IPv6 interface address `2000:0:0:0:0:0:0:1/64`.

```
Switch1:1:1>enable
Switch1:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.

Switch1:1(config)#vlan create 2 type port-mstprstp 0
Switch1:1(config)#vlan members 2 4/5
Switch1:1(config)#interface vlan 2
Switch1:1(config-if)#ipv6 interface address 2000:0:0:0:0:0:0:1/64
Switch1:1(config-if)#ipv6 interface enable
Switch1:1(config-if)#exit
Switch1:1(config)#show vlan basic

Viewing route and alternative route configuration on the switches

On Switch-1 and Switch-2, the route 3000:0:0:0:0:0:0:2/64 is learned using the protocols RIPng and OSPFv3. The OSPFv3 route is learned as the best route because of its route preference value of 20. The RIPng route is added as alternative route as it has the route preference 100, which is greater than the OSPFv3 route preference of 20. On Switch-2, the route 3000:0:0:0:0:0:0:2/64 is a local route.

Viewing route and alternative route configuration on Switch-1:

```
Switch1:1(config)#show ipv6 route alternative

================================================================================================

Changing the route preference on Switch-1

On the switch, default preferences are assigned to all standard routing protocols. You can modify the global preference for a protocol to give it a higher or lower priority than other protocols. When you change the preference for a static route, if all best routes remain best routes, only the local route tables change. However, if changing the protocol preference causes best routes to no longer be best routes, neighboring route tables can be affected.

In the following example scenario, you configure a different routing preference for the RIPng protocol on Switch-1 and observe the learning of best and alternative routes. The existing route preference for RIPng is 100.

```
Switch1:1#show ipv6 route alternative

================================================================================================================
                            IPv6 Routing Table Information - GlobalRouter
================================================================================================================

Configure a different route preference for the RIPng protocol, for example, 19:

```
Switch1:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch1:1(config)#ipv6 route preference protocol ripng 19
Switch1:1(config)#exit
```

Verify the route preference configuration:

```
Switch1:1#show ipv6 route preference

================================================================================================
                              IPv6 Route Preference - GlobalRouter

================================================================================================
PROTOCOL         DEFAULT    CONFIG
------------------------------------------------------------------------------------------------
LOCAL            0          0
STATIC           5          5
SPBM_L1          7          7
OSPFv3_INTRA     20         20
OSPFv3_INTER     25         25

Application Telemetry

Table 34: Application Telemetry product support

Feature	Product	Release introduced
Application Telemetry	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
Application Telemetry Host Monitoring	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

Extreme Networks offers two Analytics solutions that monitor traffic on your network:

- sFlow
- Application Telemetry

Important

You can use either sFlow, or sFlow with Application Telemetry or both at the same time as they can coexist on a switch. Note that to enable Application Telemetry, you must enable sFlow first.

In both solutions, the switch collects flow information and sends it to a central server that processes the information and provides statistical data in the form of reports. Then you can use Extreme Management Center or ExtremeCloud IQ - Site Engine to analyze the reports to give you a full understanding of the applications on your network and learn who is using those applications. Extreme Management Center or ExtremeCloud IQ - Site Engine also provides information such as DoS tracking, security monitoring, and statistics for protocols, ports, and applications.

This section describes how Application Telemetry works and how to configure it. Because there is some commonality between the two features, this section also describes some sFlow features.

For further information about sFlow, see sFlow Fundamentals on page 2767.

For more information about Extreme Management Center or ExtremeCloud IQ - Site Engine, see the documentation on the Extreme Networks Documentation portal (www.extremenetworks.com/documentation/) with special attention to the *Application Analytics User Guide*.

How Application Telemetry Works

Both sFlow and Application Telemetry mirror packets to a server for deep packet inspection, but they collect streams in different ways:

- sFlow samples 1 out of n packets to create flow streams. This methodology achieves scalability and applies to high speed networks, but it provides limited application visibility.
- Application Telemetry does not sample some packets like sFlow; it monitors all traffic and uses policy rules to filter packets for analysis. This pattern matching methodology enables Application Telemetry to monitor all application-level traffic flows at wire speed on all interfaces simultaneously.

The policy rules that Application Telemetry uses are ACL and ACE filters that are pre-configured in a policy configuration file called `sflow.pol`. This policy file is not user configurable. These rules enable the switch to recognize several signatures that represent a combination of the following:

- IP protocol type (TCP/UDP)
- TCP flags
- Layer 4 port numbers
- data patterns (defined as offset/data/mask triplets)

Pattern matching enables Application Telemetry to target very specific, well-defined packets in each flow and not full streams of traffic. Thus, the switch mirrors only a relatively few packets to the Analytics

Engine. It is the Analytics Engine that performs deep packet inspection to create reports of statistical data.

Important

When you enable Application Telemetry, the switch loads the filter rules based on the logic below:

- Application Telemetry uses the `apptelemetry.pol` or the `sflow.pol` file because the filter rules can exist in either file. The `sflow.pol` file is the default file and is included with the image that is loaded on the switch. This file contains the default filter rules. The `apptelemetry.pol` file is the user-defined file, which can be updated by the ExtremeCloud IQ - Site Engine. To use this file, configure Application Telemetry using the ExtremeCloud IQ - Site Engine. When you run the Application Telemetry LiveUpdate script from ExtremeCloud IQ - Site Engine, the updated `apptelemetry.pol` file is placed in `/intflash/`.
- When you enable Application Telemetry, the feature uses the files in the following order:
  - If the user-defined file (`apptelemetry.pol`) exists, then the switch loads the rules from this file.
  - If the `apptelemetry.pol` file does not exist or if there is a problem reading this file, then the switch uses the default `sflow.pol` file.

Common Elements Between sFlow and Application Telemetry

sFlow and Application Telemetry send mirrored packets from a common source to a common destination. sFlow sends samples directly to the destination, while Application Telemetry sends mirrored packets through a GRE tunnel, to the same destination.

The tunnel source is the switch that you want to monitor:

- sFlow sends sampled flows.
- Application Telemetry sends packets that match its policy rules.

Both sFlow and Application Telemetry use an agent to package either the sFlow streams or the Application Telemetry packets. To configure the agent, they both use the **`sflow agent-ip`** command.

Note

The switch sends only one mirrored copy, even if the packet matches two or more policies. For information on which mirrored copies take precedence, see Configuration considerations.

The tunnel destination for the mirrored traffic is a server where software performs a deep packet inspection of the mirrored traffic.

- sFlow sends flow and counter samples as datagrams to the sFlow Collector.
- Application Telemetry sends packets that match the policy rules over a GRE tunnel to the Analytics Engine.

To configure the tunnel destination, they both use the **sflow collector <1–2>** command.

Important

You can configure two Collectors, but Application Telemetry uses Collector 1 only. You must configure Collector 1 before you enable Application Telemetry.

Operational Considerations and Restrictions

The following section describes operational considerations for deploying Application Telemetry, including general considerations, followed by a summary of platform-specific considerations.

General Considerations

The following list describes general Application Telemetry operational considerations:

- When you enable Application Telemetry, it is globally enabled on all ports. You cannot disable the feature on a per-port basis.
- Application Telemetry supports IPv4 and IPv6 packets, although host monitoring is available for IPv4 hosts only.
- Application Telemetry filter rules are not user configurable. However, an updated `app-telemetry.pol` file can be installed through the ExtremeCloud IQ - Site Engine.
- If a user-created filter rule (ACL) conflicts with an Application Telemetry defined filter, the user-created rule always takes precedence.
- There are two configurable sFlow collectors (Collector 1 and Collector 2). However, Application Telemetry uses Collector 1 only and you must configure it before enabling Application Telemetry.

Platform-Specific Considerations

This section provides a summary of operational considerations for different switches.

Table 35: Coexistence with security filters

Attribute	5320 Series 5420 Series	5520 Series 5720 Series
IPv6 security filters or IPv6 source guard	Not supported (consistency checks in place)	Allowed

Configuration Overview

After the optional step of uploading the `apptelemetry.pol` file to flash memory using Extreme Management Center or ExtremeCloud IQ - Site Engine, activate Application Telemetry by configuring the following:

1. Configure the IP address of the egress interface for the GRE tunnel with the **sFlow agent-ip** command.
2. Enable sFlow with the **sflow enable** command.
3. Configure the IP address of the Analytics Engine with the **sFlow collector 1** command.
4. Enable Application Telemetry with the **app-telemetry enable** command.

The following figure shows the Application Telemetry agent on various routers and switches with packets being sent to the Analytics Engine.

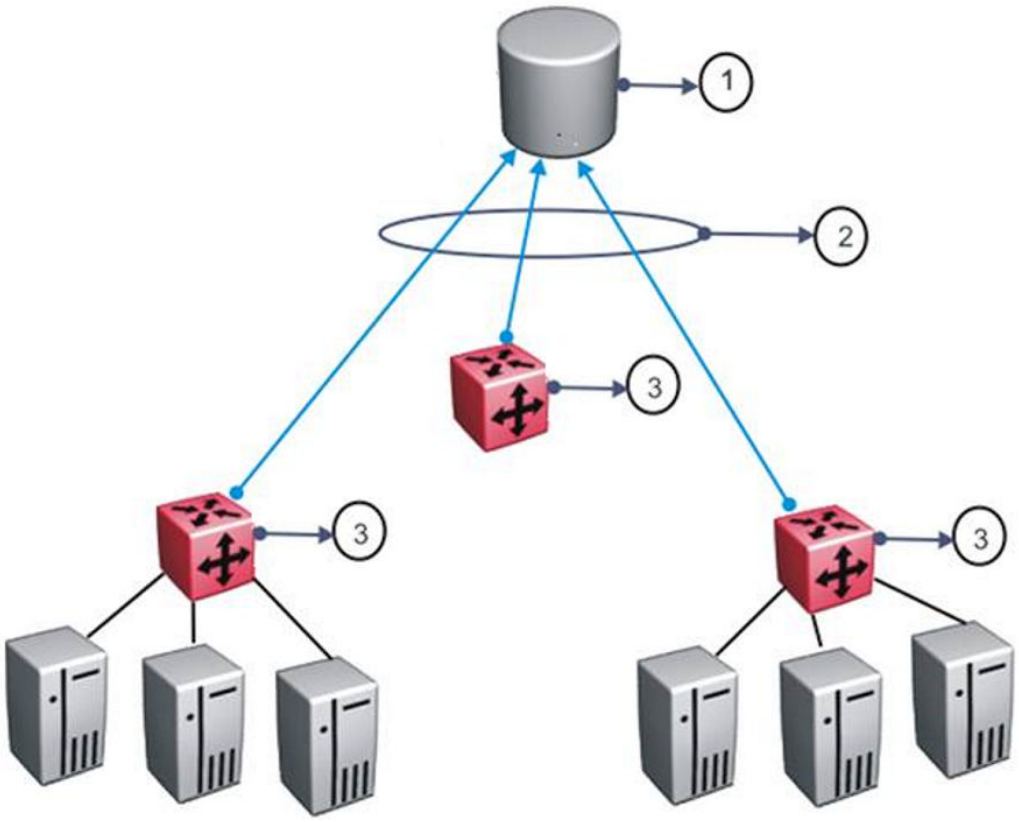

Figure 16: Application Telemetry Overview

Table 36: Application Telemetry Legend

Number	Description
1	Analytics Engine
2	GRE tunnels
3	Application Telemetry agents

Host Monitoring

You can use Application Telemetry to get better visibility for a selected host by performing a timed packet capture for both incoming and outgoing traffic specific to that host. Initiate the packet capture (PCAP) from ExtremeCloud IQ - Site Engine and specify a source or destination IP address to match. ExtremeCloud IQ - Site Engine pushes an additional rule to the Application Telemetry agent on the switch, which captures packets that match this rule and uses the existing ERSPAN GRE session to mirror these packets to Analytics Engine for analysis.

To use this feature, all configuration occurs in ExtremeCloud IQ - Site Engine. The following prerequisites for configuration must be met:

- Application Telemetry is active.
- The Analytics Engine records application flows.
- You can see the flows in ExtremeCloud IQ - Site Engine.

In ExtremeCloud IQ - Site Engine, select a flow and configure packet capture. You can specify the host, either the originating or destination host for the flow, and a monitoring interval. For more information about how to configure packet capture in ExtremeCloud IQ - Site Engine, see the ExtremeCloud IQ - Site Engine documentation.

The following list identifies restrictions specific to host monitoring:

- You cannot configure monitoring of the same host twice.
- Host monitoring shares resources with the filter ACL application. The maximum number of hosts that can be monitored depends on the number of ACEs you configure. If no resources are available, the Resource Manager generates an error for both applications.
- You cannot configure monitoring of the sFlow agent IP address or collector IP address.

Although you use ExtremeCloud IQ - Site Engine to configure the packet capture, the switch logs a message when this feature is activated or deactivated. Configuration of host monitoring is not saved; the monitoring is time-based.

Note

Host monitoring is supported beginning with ExtremeCloud IQ - Site Engine version 8.2.4.

Application Telemetry Configuration Using CLI

Use Application Telemetry to capture traffic statistics to monitor traffic in a data network. This section provides procedures to view and configure this feature using CLI.

Configuring the Agent IP Address

Use this procedure to configure the source of the Application Telemetry packets.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable the agent IPv4 address:

   ```
   sflow agent-ip {A.B.C.D}
   ```

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#sflow agent-ip 192.0.2.27
```

Variable Definitions

Use the data in the following table to use the **sflow agent-ip** command.

Variable	Definition
{A.B.C.D.}	Specifies the agent-ip address (IPv4).

Configuring an Analytics Engine and Enabling Application Telemetry Globally

Use this procedure to enable Application Telemetry and configure the device used as either an sFlow Collector or an Application Telemetry Analytics Engine. This device is where the agent sends sFlow datagrams and Application Telemetry packets for analysis.

sFlow supports up to two collectors for each interface slot in the chassis. However, Application Telemetry supports Collector 1 only.

Note

- You can configure two Collectors, but Application Telemetry uses Collector 1 only. You must configure Collector 1 before you enable Application Telemetry.
- Before you change or remove Collector 1, you must disable Application Telemetry.
- By default, Application Telemetry is globally disabled.

Before You Begin

- You must configure the sFlow agent IP address.
- You must enable sFlow before you can enable Application Telemetry.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the Analytics Engine information using Collector 1:

   ```
   sflow collector 1 address {A.B.C.D} [owner WORD<1-20>] [port
   <1-65535>]
   ```

3. Verify the Analytics Engine configuration:

   ```
   show sflow collector 1
   ```

4. Enable Application Telemetry:

   ```
   app-telemetry enable
   ```

5. Verify the global configuration:

   ```
   show app-telemetry status
   ```

   Note

   The output of this command shows whether Application Telemetry is enabled or not and if the collector is reachable.

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#sflow collector 1 address 192.0.2.26 owner sflow1 port 6343 timeout 497
Switch:1(config)#show sflow collector 1

================================================================================================
                        sFlow Collector Configuration Info

================================================================================================

Switch:1(config)#app-telemetry enable
Switch:1(config)#show app-telemetry status
Application Telemetry is enabled
Collector is reachable via 192.0.2.26
```

Variable Definitions

Use the data in the following table to use the **`sflow collector`** command.

Variable	Value
<1–2>	Specifies the ID of the collector where you want to send packets for analysis. Application Telemetry uses Collector 1 only.
owner WORD<1–20>	Specifies the name of the collector.
Collector-IP {A.B.C.D.}	Specifies the IP address of the collector.
port <1–65535>	Specifies the destination port. The default port is 6343. Note: Application Telemetry does not use this parameter.
timeout <1–65535>	Specifies the time remaining (in seconds) before the collector is released. The default timeout is 0, which means the timeout is not used and the switch sends data forever. Note: Application Telemetry does not use this parameter.

View Application Telemetry Counters

Use the following procedure to view the Application Telemetry status counters. The switch assigns an ID to each counter and displays information about each filter rule by name. The information includes how many packets were transmitted to the Analytics Engine that matched the specified pattern in the rule and the total number of bytes in the packets.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View Application Telemetry counters:

   ```
   show app—telemetry counter [name <WORD<1-32> | id <1-2000>]
   ```

Example

```
Switch:1>show app—telemetry counter

=================================================================
              Application Telemetry Counters
=================================================================
EntryId        Name        Packets        Bytes
-----------------------------------------------------------------
1            ssh         1258           72145
2            sslclient      457            27000
-----------------------------------------------------------------

All 2 out of 2 Total Num of Application Telemetry counters entries displayed
```

Clearing Application Telemetry Counters

Use this procedure to clear the Application Telemetry status counters. You can clear all of the counters or specify just the counters you want to clear by name or ID.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Clear Application Telemetry counters:

   ```
   clear app—telemetry counter [name <WORD<1-32> | id <1-2000>]
   ```

3. Verify that the counters were cleared:

   ```
   show app—telemetry counter [name <WORD<1-32> | id <1-2000>]
   ```

Example

Clear the counters.

```
Switch:1>enable
Switch:1#clear app—telemetry counter
Switch:1>show app—telemetry counter

=================================================================
              Application Telemetry Counters
=================================================================
EntryId            Name                    Packets        Bytes
-----------------------------------------------------------------
1              ssh                         0               0
2              sslclient                   0               0
-----------------------------------------------------------------

All 2 out of 2 Total Num of Application Telemetry counters entries displayed
```

Application Telemetry Configuration Using EDM

Use Application Telemetry to capture traffic statistics to monitor traffic in a data network. This section provides procedures to view and configure this feature using EDM.

sFlow and Application Telemetry send mirrored packets from a common source to a common destination. sFlow sends samples directly to the destination, while Application Telemetry sends mirrored packets through a GRE tunnel, to the same destination.

Both sFlow and Application Telemetry use an agent to package either the sFlow streams or the Application Telemetry packets. To configure the agent, they both use the **Serviceability** > **Sflow** > **Globals** and **Serviceability** > **Sflow** > **Collector** tabs. For more information, see sFlow Configuration Using EDM on page 2778.

Enabling Application Telemetry Globally

Use this procedure to globally enable Application Telemetry so it can send packets to an Analytics Engine. By default, Application Telemetry is globally disabled.

Before You Begin

You must complete the following:

- Configure an agent IP address.
- Enable sFlow.
- Configure Collector 1.

Procedure

1. In the navigation pane, expand the **Configuration** > **Serviceability** folders.
2. Click **Application Telemetry**.
3. Click the **Globals** tab.
4. Select the **AdminEnable** check box.
5. Click **Apply**.

Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
AdminEnable	Shows whether Application Telemetry is enabled. By default, the check box is not enabled.
ClearCounterStats	Clears the Application Telemetry status counters.

Viewing Application Telemetry Counters

Use the following procedure to view the Application Telemetry status counters. The switch assigns an ID to each counter and displays information about each filter rule by name. The information includes how many packets were transmitted to the Analytics Engine that matched the specified pattern in the rule and the total number of bytes in the packets.

Procedure

1. In the navigation pane, expand the **Configuration** > **Serviceability** folders.
2. Click **Application Telemetry**.

3. Click the **Counter** tab.

Counter field descriptions

Use the data in the following table to use the **Counter** tab.

Name	Description
CounterId	Shows the Application Telemetry rule ID.
CounterName	Shows the rule name.
CounterPkts	Shows the number of packets transmitted to the Analytics Engine that matched the specified pattern in the rule.
CounterBytes	Shows the total number of bytes in the packets.

Clearing Application Telemetry Counters

Use this procedure to clear the Application Telemetry status counters. You can clear all of the counters or specify just the counters you want to clear by name or ID.

Procedure

1. In the navigation pane, expand the **Configuration** > **Serviceability** folders.
2. Click **Application Telemetry**.
3. Perform one of the following actions:
   - To clear all the counters, click the **Globals** tab, and then select **ClearCounterStats**.
   - To clear specific counters, click the **Counter** tab, select the counter ID you want to clear, and then click **ClearStats**.
4. Click **Apply**.

Viewing Application Telemetry Status

About This Task

Use this procedure to view the status of the Application Telemetry collector.

Procedure

1. In the navigation pane, expand the **Configuration** > **Serviceability** folders.
2. Click **Application Telemetry**.
3. Click the **Status** tab.

Status field descriptions

Use the data in the following table to use the **Status** tab.

Name	Description
Collector IP Address	Shows the address of the Application Telemetry collector.
IsReachable	Shows whether the Application Telemetry collector is reachable.
NextHop	If the collector is reachable, shows the name or address of the next hop through which the collector is reachable.

Bidirectional Forwarding Detection

Table 37: Bidirectional Forwarding Detection (BFD) product support

Feature	Product	Release introduced
BFD (IPv4)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4

	5720 Series	Fabric Engine 8.7
BFD (IPv6)	5320 Series	Fabric Engine 8.6 demonstration feature
	5420 Series	VOSS 8.4 demonstration feature
	5520 Series	VOSS 8.2.5 demonstration feature
	5720 Series	Fabric Engine 8.7 demonstration feature
BFD over Fabric Extend Tunnels (IPv4)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

Use Bidirectional Forwarding Detection (BFD) to provide a failure detection mechanism between two systems.

The following sections provide information and procedures for BFD.

BFD Fundamentals

The following sections provide fundamentals information about Bidirectional Forwarding Detection (BFD).

BFD Overview

Bidirectional Forwarding Detection (BFD) is a simple Hello protocol used between two peers. In BFD, peer systems periodically transmit BFD packets to each other. If one of the systems does not receive a BFD packet after a certain period of time, the system assumes that the link or other system is not operating.

A path is considered operational when bidirectional communication is established between systems. However, this does not preclude the use of unidirectional links.

BFD provides low-overhead, short-duration failure detection between two systems. BFD also provides a single mechanism for connectivity detection over any media, at any protocol layer.

Because BFD sends rapid failure-detection notifications to the routing protocols that run on the local system, which initiates routing table recalculations, BFD helps reduce network convergence time.

BFD supports IPv4/IPv6 single hop detection for static routes, OSPFv2, OSPFv3, iBGP, iBGPv6. Forwarding path failure detection for Fabric Extend tunnels is supported over an IPv4 network only.

Note

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see *Fabric Engine Feature Support Matrix*.

Note

iBGPv6 is not supported in VRF.

BFD Operation

The switch uses one BFD session for all protocols with the same destination. For example, if a network runs OSPFv2 and BGP across the same link with the same peer, only one BFD session is established, and BFD shares session information with both routing protocols.

You can enable BFD over data paths with specified OSPFv2 and OSPFv3 neighbors, BGP neighbors, static routing next-hop addresses, and Fabric Extend tunnels.

The switch supports BFD asynchronous mode, which sends BFD control packets between two systems to activate and maintain BFD neighbor sessions. To reach an agreement with its neighbor about how rapidly failure detection occurs, each system estimates how quickly it can send and receive BFD packets.

A session begins with the periodic, slow transmission of BFD control packets. When bidirectional communication is achieved, the BFD session comes up.

After the session is up, the transmission rate of Control packets can increase to achieve detection time requirements. If Control packets are not received within the calculated detection time, the session is declared down. After a session is down, Control packet transmission returns to the slow rate.

If a session is declared down, it cannot come back up until the remote end signals that it is down (three-way handshake). A session can be kept administratively down by configuring the state of AdminDown.

In asynchronous mode, detection time is equal to the value of DetectMult received from the remote system multiplied by the agreed transmit interval of the remote system (the greater of RequiredMinRxInterval and DesiredMinTxInterval.) DetectMult is approximately equal to the number of sequential packets that must be missed to declare a session down.

BFD States

A session normally proceeds through three states; two states are used to establish a session (Init and Up) and one state is used to tear down a session (Down). This allows a three-way handshake for both session establishment and session teardown, assuring that both systems are aware of all session state changes. There is a fourth state (AdminDown) that you can use to administratively put a session down indefinitely.

- Down state: Indicates the session is down or has just been created. The session will remain in Down state until the remote system sends a BFD control packet indicating anything other than Up state. If the control packet signals Down state, the session advances to Init state. If the control packet signals Init state, the session advances to Up state.
- Init state: In this state, the host system establishes communications with the remote system and sends a request to move the session to the Up state, but the remote system has not yet recognized the request. A session remains in Init state until it receives a BFD control packet signaling Init or Up state, or until the connectivity timer expires, indicating communication with the remote system is lost.
- Up state: Indicates the BFD session is established and connectivity is working. A session remains in Up state until connectivity fails or until the session is taken down administratively.
- AdminDown state: Indicates the BFD session is being held down administratively. This causes the remote system to enter Down state and remain there until the local system exits AdminDown state.

BFD Configuration

The following sections provide conceptual information about BFD configuration. For detailed procedural information about BFD configuration, see BFD Configuration using CLI on page 314 and BFD Configuration using EDM on page 328.

Enable BFD

To enable Bidirectional Forwarding Detection (BFD) between 2 peers:

- Configure BFD globally.
- Configure BFD on the required interfaces of both peer systems.
- Enable BFD on the required routing protocols.
- Specify the next-hop device with which the switch initiates the BFD session.

Delete a BFD Session

To delete a BFD session, disassociate all applications with the BFD session, then administratively bring down the BFD session.

Note

To successfully delete a BFD session, you must execute the commands in the following order:

1. Disassociate all applications from the BFD session.
2. Disable BFD at the global level or interface level, which transitions the BFD session to AdminDown state.

If you change the above order of operations, the BFD session is not deleted.

BFD Considerations

The following considerations apply to Bidirectional Forwarding Detection (BFD):

- BFD is supported only in asynchronous mode. Demand mode and echo functionalities are not supported.
- You configure BFD parameters on a per session basis, not on a per next-hop basis.
- BFD creates multiple sessions even though a neighbor shares an IP address.
- The granularity of the fault detection interval in BFD is 100 ms, and the minimum multiplier is 2.

  The minimum value for the transmit interval or the receive interval is 100 ms. If you configure the transmit interval or the receive interval as 100 ms, you must configure a value of 4 or greater for the multiplier.

  You can configure a total of 16 BFD sessions. Of the 16 possible BFD sessions, you can configure a maximum of 4 BFD sessions with the minimum value for transmit interval or receive interval. You can configure the remaining BFD sessions with a transmit interval or a receive interval that is greater than or equal to the 200 ms default value.
- BFD is not supported over RSMLT links. This applies to BFD sessions over IPv4 interfaces and IPv6 interfaces.
- Inter-tunnel routing with 6in4 tunnels is not supported. This means that incoming IPv6 packets over a tunnel cannot be forwarded over another tunnel configured on the same switch.
- BFD for Interior Border Gateway Protocol (iBGP) and BGPv6 in VRF is not supported.
- BFD for eBGPv6 in VRF is not supported.
- Session dampening is not supported for BFD.
- The switch supports BFD multihop only at the eBGP application level. For other applications, the switch does not support BFD multihop, as defined by RFC 5883. However, there is no requirement for source and destination IP addresses to be in the same subnet.
- BFD over IPv6 Fabric Extend (FE) tunnels is not supported.
- The minimum value for the transmit interval or the receive interval is 1 second with a fault detection time of 3 seconds for BFD over IPv4 FE tunnels.
- BFD does not support a static route flag.
- BFD is not supported on a Virtual Router Redundancy Protocol (VRRP) interface.

- You can configure a total of 256 BFD and Virtual Link Aggregation Control Protocol (VLACP) sessions.
- BFD packets cannot be mirrored when BFD is configured on the switch.

BFD Configuration using CLI

Use the following procedures to configure Bidirectional Forwarding Detection (BFD) using CLI. BFD provides low-overhead, short-duration failure-detection between two systems.

Enable BFD Globally

Note

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see *Fabric Engine Feature Support Matrix*.

About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable BFD globally.

Note

Enabling BFD globally does not establish a BFD session. To establish a BFD session, you must also configure BFD at the interface level and at the application level.

Procedure

1. Enter BFD Router Configuration mode:

   ```
   enable

   configure terminal

   router bfd
   ```

2. Enable BFD:

   ```
   router bfd enable
   ```

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#router bfd
Switch:1(router-bfd)#router bfd enable
```

Configure BFD on an IPv4 Interface

About This Task

Use the following procedure to enable and to configure Bidirectional Forwarding Detection (BFD) on an IPv4 interface. All interface configuration is performed at the VLAN, GigabitEthernet, or Loopback level.

Note

Enabling BFD on an interface does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the application level.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal
   ```

   followed by one of the following:

   - `interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]}`
   - `interface loopback <1-256>`
   - `interface vlan <1-4059>`

   

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable BFD on an interface:

   ```
   ip bfd enable
   ```

3. (Optional) Configure the transmit interval:

   ```
   ip bfd interval <100-65335>
   ```

4. (Optional) Configure the minimum receive interval:

   ```
   ip bfd min-rx <100-65335>
   ```

5. (Optional) Configure the multiplier:

   ```
   ip bfd multiplier <1-20>
   ```

6. (Optional) In GigabitEthernet Interface Configuration mode, you can configure a value for port:

   ```
   ip bfd port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
   ```

7. (Optional) In VLAN Interface Configuration mode, you can configure a value for VLAN:

   ```
   ip bfd vlan <1-4094>
   ```

8. (Optional) In Loopback Interface Configuration mode, you can configure a value for loopback:

   ```
   ip bfd loopback <1-256>
   ```

Variable Definitions

The following table defines parameters for the **ip bfd** command.

Variable	Value
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
enable	Enable BFD on a port, VLAN, or loopback.
interval <100-65335>	Specifies the transmit interval in milliseconds. The default is 200 ms. Note: The minimum value you can configure for the transmit interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the transmit interval. You can configure any remaining BFD sessions with a transmit interval that is greater than or equal to the 200 ms default value.
min-rx <100-65535>	Specifies the receive interval in milliseconds. The default is 200 ms. Note: The minimum value you can configure for the receive interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the receive interval. You can configure any remaining BFD sessions with a receive interval that is greater than or equal to the 200 ms default value.
multiplier <1-20>	Specifies the multiplier used to calculate the amount of time BFD waits before declaring a receive timeout. The default is 3. Note: If you configure the transmit interval or the receive interval as 100 ms, you must configure a value of 4 or greater for the multiplier.
port *{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}*	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
vlan <1-4094>	Specifies the VLAN ID.
loopback <1-256>	Specifies the Loopback ID.

Configure BFD on an IPv6 Interface

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see *Fabric Engine Feature Support Matrix*.

About This Task

Use the following procedure to enable and to configure BFD on an IPv6 interface. All interface configuration is performed at the VLAN or GigabitEthernet level.

Note

Enabling BFD on an interface does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the application level.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]} or interface vlan <1-4059>
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable BFD on an interface:

   ```
   ipv6 bfd enable
   ```

3. (Optional) Configure the transmit interval:

   ```
   ipv6 bfd interval <100-65335>
   ```

4. (Optional) Configure the minimum receive interval:

   ```
   ipv6 bfd min-rx <100-65335>
   ```

5. (Optional) Configure the multiplier:

   ```
   ipv6 bfd multiplier <1-20>
   ```

6. (Optional) In GigabitEthernet Interface Configuration mode, you can configure a value for port:

   ```
   ipv6 bfd port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
   ```

7. (Optional) In VLAN Interface Configuration mode, you can configure a value for VLAN:

   ```
   ipv6 bfd vlan <1-4094>
   ```

Variable Definitions

The following table defines parameters for the **ip bfd** command.

Variable	Value
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
enable	Enable BFD on a port, VLAN, or loopback.

Variable	Value
interval <100-65335>	Specifies the transmit interval in milliseconds. The default is 200 ms. Note: The minimum value you can configure for the transmit interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the transmit interval. You can configure any remaining BFD sessions with a transmit interval that is greater than or equal to the 200 ms default value.
min-rx <100-65535>	Specifies the receive interval in milliseconds. The default is 200 ms. Note: The minimum value you can configure for the receive interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the receive interval. You can configure any remaining BFD sessions with a receive interval that is greater than or equal to the 200 ms default value.
multiplier <1-20>	Specifies the multiplier used to calculate the amount of time BFD waits before declaring a receive timeout. The default is 3. Note: If you configure the transmit interval or the receive interval as 100 ms, you must configure a value of 4 or greater for the multiplier.
port *{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}*	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
vlan <1-4094>	Specifies the VLAN ID.
loopback <1-256>	Specifies the Loopback ID.

Enable BFD at the BGP Application Level

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see *Fabric Engine Feature Support Matrix*.

About This Task

BFD supports internal Border Gateway Protocol (iBGP) and external Border Gateway Protocol (eBGP) on IPv4 interfaces. You configure BFD on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. BFD does not support BGPv6 for VRF on IPv6 interfaces.

Note

Enabling BFD at the BGP application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

Procedure

1. Enter BGP Router Configuration mode:

   ```
   enable

   configure terminal

   router bgp
   ```

2. Enable BFD for the BGP protocol:

   ```
   neighbor WORD<0-1536> fall-over bfd
   ```

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#router bgp
Switch:1(router-bgp)#neighbor 192.0.2.15 fall-over bfd
```

Variable Definitions

The following table defines parameters for the **neighbor** command.

Variable	Value
WORD<0-1536>	Specifies the peer IP address or the peer group name.

Enable BFD at the OSPF Application Level

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see *Fabric Engine Feature Support Matrix*.

About This Task

BFD supports Open Shortest Path First (OSPF) for IPv4 interfaces and OSPFv3 for IPv6 interfaces.

Use the following procedure to enable BFD at the OSPF application level.

Note

Enabling BFD at the OSPF application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]} or interface vlan <1-4059>
   ```

   Note
   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. (Optional) Enable BFD on an IPv4 interface under the OSPF protocol:

   ```
   ip ospf bfd
   ```

3. Enable BFD on an IPv6 interface under the OSPF protocol:

   ```
   ipv6 ospf bfd
   ```

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#interface gigabitethernet 1/3
Switch:1(config-if)#ip ospf bfd
```

Variable Definitions

The following table defines parameters for the **ip ospf bfd** command.

Variable	Value
{slot/port[/sub-port][-slot/port[/sub-port]][,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.

Configure BFD on an IPv4 Static Route

About This Task

Use the following procedure to configure BFD on an IPv4 static route.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure BFD on an IPv4 static route:

   ```
   ip route bfd {A.B.C.D}
   ```

Variable Definitions

The following table defines parameters for the **`ip route bfd`** command.

Variable	Value
{A.B.C.D}	Specifies the BFD static route IPv4 address.

Configure BFD on an IPv6 Static Route

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see *Fabric Engine Feature Support Matrix*.

About This Task

Use the following procedure to configure BFD on an IPv6 static route.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure BFD on an IPv6 static route:

   ```
   ipv6 route bfd WORD<0-128>
   ```

3. (Optional) Configure an IPv6 static route for a port:

   ```
   ipv6 route bfd WORD<0-128> port {slot/port[/sub-port] [-slot/port[/
   sub-port]] [,...]}
   ```

4. (Optional) Configure an IPv6 static route for a VLAN:

   ```
   ipv6 route bfd WORD<0-128> vlan <1-4094>
   ```

Variable Definitions

The following table defines parameters for the **ipv6 route bfd** command.

Variable	Value
WORD<0-128>	Specifies the BFD static route IPv6 address.
port *{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}*	Specifies the port number for the BFD IPv6 static route.
vlan <1-4094>	Specifies the VLAN ID for the BFD IPv6 static route.

Clear BFD Session Statistics

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see *Fabric Engine Feature Support Matrix*.

About This Task

Use the following procedure to clear local and remote Bidirectional Forwarding Detection (BFD) session statistics for IPv4 or IPv6 interfaces.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```
2. (Optional) Clear BFD session statistics for an IPv4 interface:

   ```
   clear ip bfd stats
   ```
3. Clear BFD session statistics for an IPv6 interface:

   ```
   clear ipv6 bfd stats
   ```

Variable Definitions

The following table defines parameters for the **clear ip bfd stats** command.

Variable	Value
vrf WORD<1-16>	Specifies a VRF instance by VRF name.
vrfids WORD<0-512>	Specifies a VRF or range of VRFs by ID.

Display BFD Global Configuration

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see *Fabric Engine Feature Support Matrix*.

About This Task

Use this procedure to display global configuration information for BFD.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display global BFD configuration information:

   ```
   show ip bfd [vrf WORD<1-16>] [vrfids WORD<0-512>]
   ```

Example

The following example displays global configuration information for BFD on an IPv4 interface.

```
Switch:1>show ip bfd
================================================================================
                          BFD information - GlobalRouter
================================================================================
                       BFD Version :  1
                      Admin Status :  TRUE
                       Trap Enable :  FALSE
--------------------------------------------------------------------------------
   Total session number :  1

    UP: 1, DOWN: 0, AdminDown: 0, Init: 0
--------------------------------------------------------------------------------
```

Variable Definitions

The following table defines parameters for the **show ip bfd** command.

Variable	Value
vrf WORD<1-16>	Specifies a VRF instance by VRF name.
vrfids WORD<0-512>	Specifies a VRF or range of VRFs by ID.

Display BFD Configuration for an IPv4 Interface

About This Task

Use the following procedure to display BFD configuration on an interface.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display BFD on a Gigabit Ethernet interface:

   ```
   show ip bfd interfaces Gigabitethernet [{slot/port[/sub-port][-slot/
   port[/sub-port]][,...]}] [vrf WORD<1-16>] [vrfids WORD<0-512>]
   ```

3. Display BFD on a VLAN interface:

   ```
   show ip bfd interfaces vlan [<1-4059>] [vrf WORD<1-16>] [vrfids
   WORD<0-512>]
   ```

Examples

The following example displays VLAN interface configuration information for BFD.

```
Switch:1>show ip bfd interfaces vlan 11
================================================================================================
                                    Vlan Bfd
```

```
================================================================================================
VLAN       STATUS     MIN_RX     INTERVAL   MULTIPLIER      VRF-ID
------------------------------------------------------------------------------------------------
11         enable     200        200        3               0
```

The following example displays Loopback interface configuration information for BFD:

```
Switch:1>enable
Switch:1#show ip bfd interfaces loopback
================================================================================
                          Circuitless IP Interface Bfd
================================================================================
INTF ID    STATUS     MIN_RX     INTERVAL   MULTIPLIER      VRF-ID
--------------------------------------------------------------------------------
1          enable     200        200        3               0
2          enable     200        200        3               2
```

Variable Definitions

The following table defines parameters for the **`show ip bfd interfaces`** command.

Variable	Value
`{slot/port[/sub-port][-slot/port[/sub-port]][,...]}`	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *`vrf-scaling`* and *`spbm-config-mode`* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
vrf WORD<1-16>	Specifies a VRF instance by VRF name.
vrfids WORD<0-512>	Specifies a VRF or range of VRFs by ID.

Display BFD Configuration for an IPv6 Interface

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see *Fabric Engine Feature Support Matrix*.

About This Task

Use the following procedure to display BFD configuration on an IPv6 interface.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display BFD on a Gigabit Ethernet interface:

   `show ipv6 bfd interfaces Gigabitethernet [{slot/port[/sub-port][-slot/port[/sub-port]][,...]}]`

3. Display BFD on a VLAN interface:

   ```
   show ipv6 bfd interfaces vlan <1-4059>
   ```

Example

The following example displays port configuration information for BFD.

```
Switch:1>show ipv6 bfd interfaces gigabitethernet 1/3

================================================================================================
                                    Port Bfd
================================================================================================
PORT       STATUS     MIN_RX     INTERVAL   MULTIPLIER      VRF-ID
------------------------------------------------------------------------------------------------
1/3        enable     200        200            3           0
```

Variable Definitions

The following table defines parameters for the **show ip bfd interfaces** command.

Variable	Value
{slot/port[/sub-port][-slot/port[/sub-port]][,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
vrf WORD<1-16>	Specifies a VRF instance by VRF name.
vrfids WORD<0-512>	Specifies a VRF or range of VRFs by ID.

Display BFD IPv4 Neighbor Information

About This Task

Use this procedure to display BFD session information for IPv4 neighbors.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display BFD neighbor information:

   ```
   show ip bfd neighbors
   ```

3. (Optional) Display BFD neighbor next-hop information:

   ```
   show ip bfd neighbors next-hop {A.B.C.D}
   ```

4. (Optional) Display BFD neighbor information for a particular VRF:

   ```
   show ip bfd neighbors vrf WORD<1-16>
   ```

5. (Optional) Display BFD neighbor information for a VRF ID or a range of VRF IDs:

   ```
   show ip bfd neighbors vrfids WORD<0-512>
   ```

Example

The following example displays BFD session information for an IPv4 neighbor.

```
Switch:1>show ip bfd neighbors
================================================================================================================================
                                        BFD Session - GlobalRouter
================================================================================================================================

MY_DISC    YOUR_DISC  NEXT_HOP        STATE      MULTI MIN_TX MIN_RX ACT_TX DETECT_TIME REMOTE_STATE APP    RUN

1          0          192.0.2.11      Down       3     200    200    1000   600         Down         O
--------------------------------------------------------------------------------------------------------------------------------
  1 out of 1 BFD session displayed
--------------------------------------------------------------------------------------------------------------------------------
APP and RUN Legend:
        B=BGP, O=OSPF, S=Static Route
--------------------------------------------------------------------------------------------------------------------------------
```

Variable Definitions

The following table defines parameters for the **`show ip bfd neighbors`** command.

Variable	Value
{A.B.C.D}	Specifies the next-hop IP address in the format a.b.c.d.
vrf WORD<1-16>	Specifies a VRF instance by name (the string length ranges from 1–16 characters).
vrfids WORD<0-512>	Specifies a range of VRFs by ID number (the ID ranges from 0–512).

Display BFD IPv6 Neighbor Information

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see *Fabric Engine Feature Support Matrix*.

About This Task

Use this procedure to display information about BFD IPv6 neighbors.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display BFD neighbor information:

   ```
   show ipv6 bfd neighbors
   ```

3. (Optional) Display BFD neighbor next-hop information:

   ```
   show ipv6 bfd neighbors next-hop WORD<0-128>
   ```

4. (Optional) Display BFD neighbor information for a particular VRF:

   ```
   show ipv6 bfd neighbors vrf WORD<1-16>
   ```

5. (Optional) Display BFD neighbor information for a range of VRFs:

   ```
   show ipv6 bfd neighbors vrfids WORD<0-512>
   ```

Example

The following example displays BFD session information for an IPv6 neighbor.

```
Switch:1>show ipv6 bfd neighbors
================================================================================================================================================
                                        BFD Session - GlobalRouter
================================================================================================================================================

MY_DISC    YOUR_DISC  NEXT_HOP                          STATE      MULTI MIN_TX MIN_RX ACT_TX DETECT_TIME REMOTE_STATE APP    RUN

------------------------------------------------------------------------------------------------------------------------------------------------
APP and RUN Legend:
        B=BGP_IPv6, O=OSPFv3, S=IPv6 Static Route
------------------------------------------------------------------------------------------------------------------------------------------------
```

Variable Definitions

The following table defines parameters for the **`show ipv6 bfd neighbors`** command.

Variable	Value
WORD<0-128>	Specifies the next-hop IPv6 address in the format a:b:c:d:e:f:g:h.
vrf WORD<1-16>	Specifies a VRF instance by name (the string length ranges from 1–16 characters).
vrfids WORD<0-512>	Specifies a range of VRFs by ID number (the ID ranges from 0–512).

Display BFD Statistics

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see *Fabric Engine Feature Support Matrix*.

About This Task

Use the following procedure to display BFD statistics for IPv4 or IPv6 interfaces.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display BFD IPv4 statistics:

   ```
   show ip bfd stats [vrf] [vrfids]
   ```
3. Display BFD IPv6 statistics:

   ```
   show ipv6 bfd stats [vrf] [vrfids]
   ```

Example

The following example displays BFD statistics for IPv4 interfaces.

```
Switch:1>show ip bfd stats
================================================================================================================
                            BFD staticstics - GlobalRouter

--------------------------------------------------------------------------------------------------------------------------------
```

Variable Definitions

The following table defines parameters for the **show ip bfd stats** command.

Variable	Value
vrf	Specifies a VRF instance by VRF name.
vrfids	Specifies a VRF or range of VRFs by ID.

BFD Configuration using EDM

Use the following procedures to configure Bidirectional Forwarding Detection (BFD) using EDM. BFD provides low-overhead, short-duration failure-detection between two systems.

Enable BFD Globally

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see *Fabric Engine Feature Support Matrix*.

Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504. All parameters might not be available in non-default VRFs.

About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable BFD globally.

Note
Enabling BFD globally does not establish a BFD session. To establish a BFD session, you must enable BFD at the interface level and at the application level.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **BFD**.
3. Select the **Globals** tab.
4. In **AdminStatus**, select **enabled**.
5. (Optional) Select **TrapEnabled** to send BFD traps.
6. Select **Apply**.

BFD Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
AdminStatus	Specifies whether BFD is enabled.
VersionNumber	Specifies the current version number of the BFD protocol.
TrapEnabled	Specifies whether BFD traps are sent.

Display BFD Sessions

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see *Fabric Engine Feature Support Matrix*.

Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504. All parameters might not be available in non-default VRFs.

About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to display information about BFD sessions. You can optionally display BFD session information for IPv4 or IPv6 interfaces.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **BFD**.
3. Select the **Sessions** tab.
4. (Optional) Select **Filter**.
5. (Optional) Select **AddrType**.
6. (Optional) In **AddrType**, specify a value for address type.

BFD Sessions Field Descriptions

Use the data in the following table to use the **Sessions** tab.

Name	Description
Discriminator	Specifies the local discriminator that uniquely identifies the BFD session.
RemoteDiscr	Specifies the discriminator of the remote system in the BFD session.
UdpPort	Specifies the UDP Port for the BFD session. The default value is the well-known value for the port.
State	Specifies the state of the BFD session. Possible values are Down, Up, Init, and AdminDown.

Name	Description
Addr	Specifies the IP address of the interface associated with the BFD session. A value of unknown (0) indicates the BFD session is not associated with a specific interface.
DesiredMinTxInterval	Specifies the preferred minimum interval for transmitting BFD control packets by the local system.
ReqMinTxInterval	Specifies the minimum interval for transmitting BFD control packets that the local system can support.
DestAddr	Specifies the destination IP address of the interface associated with the BFD session.
OldState	Specifies the old state of the BFD session.
App	Specifies the applications configured on the BFD session.
AppRun	Specifies the applications running on the BFD session.
AddrType	Specifies the IP address type of the interface associated with this BFD session. Possible values are ipv4 and ipv6.

Configure BFD for an IPv4 Interface on a Port

About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable and configure BFD for an IPv4 interface on a port.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit** > **Port**.
2. Select **IP**.
3. Select the **BFD** tab.
4. Select **Enable**.
5. (Optional) In the **MinRxInterval** field, specify the minimum receive interval..
6. (Optional) In the **TxInterval** field, specify the transmit interval.
7. (Optional) In the **Multiplier** field, specify a value for the multiplier used to calculate a receive timeout.

BFD Field Descriptions

Use the data in the following table to use the **BFD** tab.

Name	Description
Enable	Enable BFD on the port.
MinRxInterval	Specifies the minimum interval, in milliseconds, between received BFD control packets that the local system is capable of supporting. The default is 200 ms. Note: The minimum value you can configure for the receive interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the receive interval. You can configure any remaining BFD sessions with a receive interval that is greater than or equal to the 200 ms default value.
TxInterval	Specifies the transmit interval in milliseconds. The default is 200 ms. Note: The minimum value you can configure for the transmit interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the transmit interval. You can configure any remaining BFD sessions with a transmit interval that is greater than or equal to the 200 ms default value.
Multiplier	Specifies a value for the multiplier used to calculate a receive timeout. The default is 3. Note: If you configure the transmit interval or the receive interval as 100 ms, you must configure a value of 4 or greater for the multiplier.

Configure BFD for an IPv6 Interface on a Port

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see *Fabric Engine Feature Support Matrix*.

About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable and configure BFD for an IPv6 interface on a port.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit** > **Port**.
2. Select **IPv6**.
3. Select the **IPv6 BFD Interface** tab.
4. (Optional) In the **MinRxInterval** column, double-click the field and type a value for **MinRxInterval**.
5. (Optional) In the **TxInterval** column, double-click the field and type a value for **TxInterval**.
6. (Optional) In the **Multiplier** column, double-click the field and type a value for **Multiplier**.

BFD Field Descriptions

Use the data in the following table to use the **BFD** tab.

Name	Description
Interface	Specifies the BFD interface.
MinRxInterval	Specifies the minimum interval, in milliseconds, between received BFD control packets that the local system is capable of supporting. The default is 200 ms. Note: The minimum value you can configure for the receive interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the receive interval. You can configure any remaining BFD sessions with a receive interval that is greater than or equal to the 200 ms default value.
TxInterval	Specifies the transmit interval in milliseconds. The default is 200 ms. Note: The minimum value you can configure for the transmit interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the transmit interval. You can configure any remaining BFD sessions with a transmit interval that is greater than or equal to the 200 ms default value.
Multiplier	Specifies a value for the multiplier used to calculate a receive timeout. The default is 3. Note: If you configure the transmit interval or the receive interval as 100 ms, you must configure a value of 4 or greater for the multiplier.

Configure BFD for an IPv4 Interface on a VLAN

About This Task

BFD provides a failure detection-mechanism between two systems. Use the following procedure to enable and configure BFD for an IPv4 interface on a VLAN.

Procedure

1. In the navigation pane, expand **Configuration** > **VLAN**.
2. Select **VLANs**.
3. Select the **Basic** tab.
4. Select the VLAN on which you want to configure BFD.
5. Select **IP**.
6. Select **BFD**.
7. Select **Enable**.
8. (Optional) In the **MinRxInterval** field, specify the minimum receive interval..
9. (Optional) In the **TxInterval** field, specify the transmit interval.

10. (Optional) In the **Multiplier** field, specify a value for the multiplier used to calculate a receive timeout.

IP BFD field descriptions

Use the data in the following table to use the **BFD** tab.

Name	Description
Enable	Enable BFD on the VLAN.
MinRxInterval	Specifies the minimum interval, in milliseconds, between received BFD control packets that the local system is capable of supporting. The default is 200 ms. Note: The minimum value you can configure for the receive interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the receive interval. You can configure any remaining BFD sessions with a receive interval that is greater than or equal to the 200 ms default value.
TxInterval	Specifies the transmit interval in milliseconds. The default is 200 ms. Note: The minimum value you can configure for the transmit interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the transmit interval. You can configure any remaining BFD sessions with a transmit interval that is greater than or equal to the 200 ms default value.
Multiplier	Specifies a value for the multiplier used to calculate a receive timeout. The default is 3. Note: If you configure the transmit interval or the receive interval as 100 ms, you must configure a value of 4 or greater for the multiplier.

Configure BFD for an IPv6 Interface on a VLAN

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see *Fabric Engine Feature Support Matrix*.

About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable and configure BFD for an IPv6 interface on a VLAN.

Procedure

1. In the navigation pane, expand **Configuration** > **VLAN**.
2. Select **VLANs**.
3. Select the **Basic** tab.
4. Select the VLAN on which you want to configure BFD.
5. Select **IPV6**.
6. Select **IPv6 BFD Interface**.

7. (Optional) In the **MinRxInterval** column, double-click the field and type a value for **MinRxInterval**.
8. (Optional) In the **TxInterval** column, double-click the field and type a value for **TxInterval**.
9. (Optional) In the **Multiplier** column, double-click the field and type a value for **Multiplier**.

IPV6 BFD Interface field descriptions

Use the data in the following table to use the **IPv6 BFD Interface** tab.

Name	Description
Interface	Specifies an index value that uniquely identifies the interface.
Enable	Enable BFD on the VLAN.
MinRxInterval	Specifies the minimum interval, in milliseconds, between received BFD control packets that the local system is capable of supporting. The default is 200 ms. Note: The minimum value you can configure for the receive interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the receive interval. You can configure any remaining BFD sessions with a receive interval that is greater than or equal to the 200 ms default value.
TxInterval	Specifies the transmit interval in milliseconds. The default is 200 ms. Note: The minimum value you can configure for the transmit interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the transmit interval. You can configure any remaining BFD sessions with a transmit interval that is greater than or equal to the 200 ms default value.
Multiplier	Specifies a value for the multiplier used to calculate a receive timeout. The default is 3. Note: If you configure the transmit interval or the receive interval as 100 ms, you must configure a value of 4 or greater for the multiplier.

Enable BFD for BGP Peers

Before You Begin

- To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504. All parameters might not be available in non-default VRFs.
- The VRF must have an RP trigger of BGP.

About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable BFD for Border Gateway Protocol (BGP) peers.

Note
Enabling BFD at the application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Select **BGP**.
3. Select the **Peers** tab.
4. Select **Insert**.
5. Select **BfdEnable**.
6. Select **Insert**.

Peers *Field Descriptions*

Use the data in the following table to use the **Peers** tab.

Name	Description
Instance	Specifies the BGP peer instance.
LocalAddrType	Specifies the local IP address type of the entered BGP peer.
LocalAddr	Specifies the local IP address of the entered BGP peer.
RemoteAddrType	Specifies the remote IP address type of the entered BGP peer.
RemoteAddr	Specifies the remote IP address of the entered BGP peer.
AdminStatus	Specifies the administrative status of the BGP peer.
GroupName	Specifies the peer group name to which the peer belongs (optional).
PeerState	Specifies the BGP peer connection state.
RemoteAs	Configures a remote AS number for the peer or peer-group in the range 0–65535.
Enable	Controls whether the peer connection is enabled or disabled. The default is disabled.
EbgpMultiHop	Enables or disables a connection to a BGP peer that is more than one hop away from the local router. The default value is disable.
RoutePolicyIn	Specifies the policy (by name) that applies to all network routes learned from this peer.
RoutePolicyOut	Specifies the policy (by name) that applies to all outgoing route updates.
RemovePrivateAs	Strips (when enabled) private AS numbers when the switch sends an update. The default is enable.
UpdateSourceInterface	Specifies the source IP address to use when the switch sends eBGP packets to this peer or peer group.

Name	Description
ConnectRetryInterval	Specifies the time interval, in seconds, for the connect retry timer. The suggested value for this timer is 120 seconds. The range is 1 to 65535.
HoldTimeConfigured	Specifies the time interval, in seconds, for the hold time for this BGP speaker with this peer. This value is in an open message sent to this peer by this BGP speaker. To determine the hold time with the peer, the switch compares this value with the HoldTime value in an open message received from the peer. The HoldTime must be at least three seconds. If the value is zero, the hold time does not establish with the peer. The suggested value for this timer is 180 seconds. The range is 0 to 65535.
KeepAliveConfigured	Specifies the time interval, in seconds, for the KeepAlive timer configured for this BGP speaker with this peer. KeepAliveConfigured determines the keep alive message frequency relative to HoldTimeConfigured; KeepAlive indicates the actual time interval for the keep alive messages. The maximum value for this timer is one-third of HoldTimeConfigured. If KeepAliveConfigured is zero, no periodic keep alive messages are sent to the peer after the peers establish a BGP connection. Configure a value of 60 seconds. The range is 0 to 21845.
MD5Authentication	Enables and disables MD5 authentication.
AdvertisementInterval	Specifies the time interval, in seconds, that elapses between each transmission of an advertisement from a BGP neighbor. The default value is 30 seconds and the range is 5–120 seconds. The route advertisement interval feature is implemented using the time stamp that indicates when each route is advertised. The time stamp is marked to each route so that the route advertisement interval is compared to the time stamp and BGP is then able to make a decision about whether the route advertisement can be sent or should be delayed when a better route is received. This feature does not work for a withdraw route because the route entry is already removed when the processing route advertisement is sent and the time stamp marked in the route entry cannot be obtained.
DefaultOriginate	When enabled, specifies that the current route originated from the BGP peer. This parameter enables or disables sending the default route information to the specified neighbor or peer. The default value is false.
DefaultOriginateIpv6	When enabled, specifies that the current IPv6 route originated from the BGP peer. This parameter enables or disables sending the default IPv6 route information to the specified neighbor or peer. The default value is false.
Weight	Specifies the peer or peer group weight, or the priority of updates the system can receive from this BGP peer. The default value is 100 and the range is 0–65535.
MaxPrefix	Configures a limit on the number of routes accepted from a neighbor. The default value is 12000 routes and the range is 0–2147483647. A value of 0 means no limit exists.

Name	Description
NextHopSelf	Specifies that the next-hop attribute in an iBGP update is the address of the local router or the router that generates the iBGP update. The default is disable.
RouteReflectorClient	Specifies that this peer is a route reflector client. Note: This parameter only applies to VRF 0.
SoftReconfigurationIn	When enabled, the router relearns routes from the specified neighbor or group of neighbors without restarting the connection after the policy changes in the inbound direction. The default value is disable. Enabling SoftReconfigurationIn stores all BGP routes in local memory (even non-best routes).
DebugMask	Displays the specified debug information for the BGP peer. The default value is none. • None disables all debug messages. • Event enables the display of debug event messages. • State enables display of debug state transition messages. • Update enables display of debug messages related to updates transmission and reception. • Error enables the display of debug error messages. • Trace enables the display of debug trace messages. • Init enables the display of debug initialization messages. • All enables all debug messages. • Packet enables the display of debug packet messages. • Warning enables the display of debug warning messages. • Filter enables the display of debug messages related to filtering.
SendCommunity	Enables or disables sending the community attribute of the update message to the specified peer. The default value is disable.
Vpnv4Address	Specifies the vpnv4 routes.
IpvpnLiteCap	Enable or disable IP VPN-lite capabilitiy on the BGP neighbor peer.
Ipv6Cap	Enable or disable the IPv6 capability on the BGP neighbor peer. The default value is disable.
SooAddress	Specifies the site-of-origin (SoO) address of the BGP peer.
SooAsNumber	Specifies the site-of-origin (SoO) Autonomous System (AS) number of the BGP peer.
SooAssignedNum	Specifies the site-of-origin (SoO) assigned number of the BGP peer.
SooType	Specifies the site-of-origin (SoO) type of the BGP peer.
RouteRefresh	Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates in the database that are eligible for the peer that issues the request. This parameter only applies to VRF 0.

Name	Description
AsOverride Note: This does not apply to 5320 Series switches.	Specifies that the AS Override parameter can be enabled or disabled for the BGP peer. The default is disable.
AllowAsIn Note: This does not apply to 5320 Series switches.	Specifies the number of AS-in allowed for the BGP peer. The range is 1–10.
Ipv6RoutePolicyIn	Specifies the policy (by name) that applies to all network IPv6 routes learned from this peer.
Ipv6RoutePolicyOut	Specifies the policy (by name) that applies to all outgoing IPv6 route updates.
Ipv6MaxPrefix	Configures a limit on the number of IPv6 routes accepted from a neighbor. A value of 0 means no limit exists.
BfdEnable	Enables Bidirectional Forwarding Detection (BFD) for this BGP peer.

Enable BFD for BGP Peer Groups

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see *Fabric Engine Feature Support Matrix*.

Before You Begin

- To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504. All parameters might not be available in non-default VRFs.
- The VRF must have an RP trigger of BGP.

About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable BFD for Border Gateway Protocol (BGP) peer groups.

Note
Enabling BFD at the application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Select **BGP**.
3. Select the **Peer Groups** tab.
4. Select **Insert**.

5. Select **BfdEnable**.
6. Select **Insert**.

Peer Groups *field descriptions*

Use the data in the following table to use the **Peer Groups** tab.

Name	Description
Index	Specifies the index of this peer group.
GroupName	Specifies the peer group to which this neighbor belongs (optional).
Enable	Enables or disables the peer group.
RemoteAs	Configures a remote AS number for the peer-group in the range 0–65535.
DefaultOriginate	When enabled, the BGP speaker (the local router) sends the default route 0.0.0.0 to a group of neighbors for use as a default route. The default is disabled.
DefaultOriginateIpv6	When enabled, the BGP speaker (the local router) sends the default route to a group of neighbors for use as a default route. The default is disabled.
EbgpMultiHop	When enabled, the switch accepts and attempts BGP connections to external peers that reside on networks that do not directly connect. The default is disabled.
AdvertisementInterval	Specifies the time interval, in seconds, that elapses between BGP routing updates. The default value is 30 seconds.
KeepAlive	Specifies the time interval, in seconds, between sent BGP keep alive messages to remote peers. The default value is 60.
HoldTime	Configures the hold time for the group of peers in seconds. Use a value that is three times the value of the KeepAlive time. The default value is 180.
Weight	Assigns an absolute weight to a BGP network. The default value is 100.
MaxPrefix	Limits the number of routes accepted from this group of neighbors. A value of zero indicates no limit The default value is 12,000 routes.
NextHopSelf	Specifies that the switch must set the NextHop attribute to the local router address before sending updates to remote peers.
RoutePolicyIn	Specifies the route policy that applies to all networks learned from this group of peers.
RoutePolicyOut	Specifies the route policy that applies to all outgoing updates to this group of peers.
RouteReflectorClient	Specifies that this peer group is a route reflector client. Note: This parameter only applies to VRF 0.

Name	Description
SoftReconfigurationIn	When enabled, the router relearns routes from the specified neighbor or group of neighbors without restarting the connection after the policy changes in the inbound direction. The default value is enable. Enabling SoftReconfigurationIn stores all BGP routes in local memory (even non-best routes).
MD5Authentication	Enables and disables MD5 authentication. The default is disable.
RemovePrivateAs	Strips (when enabled) private AS numbers when the switch sends an update. The default is enable.
SendCommunity	Enables or disables sending the community attribute of the update message to the specified peer group. The default value is disable.
AfUpdateSourceInterfaceType	Specifies the interface type.
AfUpdateSourceInterface	Specifies the IP address used for circuitless IP (CLIP) for this peer group.
Vpnv4Address	Enables BGP address families for IPv4 (BGP) and Layer 3 VPN (MP-BGP) support. Enable this parameter for VPN/VRF Lite routes.
IpvpnLiteCap	Specifies (when enabled) that IP VPN Lite capability can be enabled or disabled on the BGP neighbor peer. The default is disable.
RouteRefresh	Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates in the database that are eligible for the peer that issues the request. This parameter only applies to VRF 0.
AsOverride	Specifies that the AS Override parameter can be enabled or disabled for the BGP peer group. The default is disable.
AllowedAsIn	Specifies the number of AS-in allowed for the BGP peer group. The range is 1–10.
IPv6Cap	Enable or disable the IPv6 capability on the BGP neighbor peer. The default value is disable.
Ipv6RoutePolicyIn	Specifies the policy (by name) that applies to all network IPv6 routes learned from this peer.
Ipv6RoutePolicyOut	Specifies the policy (by name) that applies to all outgoing IPv6 route updates.
Ipv6MaxPrefix	Configures a limit on the number of IPv6 routes accepted from a neighbor. A value of 0 means no limit exists.
BfdEnable	Enables Bidirectional Forwarding Detection (BFD) for the BGP peer group.

Enable BFD for BGPv6 Peers

About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable BFD for BGPv6 peers.

Note
Enabling BFD at the application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

Note
BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see *Fabric Engine Feature Support Matrix*.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Select **BGP+**.
3. Select the **Peers** tab.
4. Select **Insert**.
5. Select **BfdEnable**.

Peers *Field Descriptions*

Use the data in the following table to use the **Peers** tab.

Name	Description
RemoteAddr	Specifies the remote IPv6 address of the entered BGP+ peer.
GroupName	Specifies the peer group name to which the peer belongs (optional).
PeerState	Specifies the BGPv6 peer connection state.
RemoteAs	Configures a remote AS number for the peer or peer-group in the range 0 to 65535.
Enable	Controls whether the peer connection is enabled or disabled. The default is disabled.
EbgpMultiHop	Enables or disables a connection to a BGPv6 peer that is more than one hop away from the local router. The default value is disable.
RoutePolicyIn	Specifies the policy (by name) that applies to all network routes learned from this peer.
RoutePolicyOut	Specifies the policy (by name) that applies to all outgoing route updates.
RemovePrivateAs	Strips (when enabled) private AS numbers when the switch sends an update. The default is enable.
UpdateSourceInterface	Specifies the source IP address to use when the switch sends eBGP packets to this peer or peer group.

Name	Description
ConnectRetryInterval	Specifies the time interval, in seconds, for the connect retry timer. The suggested value for this timer is 120 seconds. The range is 1 to 65535.
HoldTimeConfigured	Specifies the time interval, in seconds, for the hold time for this BGP speaker with this peer. This value is in an open message sent to this peer by this BGP speaker. To determine the hold time with the peer, the switch compares this value with the HoldTime value in an open message received from the peer. The HoldTime must be at least three seconds. If the value is zero, the hold time does not establish with the peer. The suggested value for this timer is 180 seconds. The range is 0 to 65535.
KeepAliveConfigured	Specifies the time interval, in seconds, for the KeepAlive timer configured for this BGP speaker with this peer. KeepAliveConfigured determines the keep alive message frequency relative to HoldTimeConfigured; KeepAlive indicates the actual time interval for the keep alive messages. The maximum value for this timer is one-third of HoldTimeConfigured. If KeepAliveConfigured is zero, no periodic keep alive messages are sent to the peer after the peers establish a BGP connection. Configure a value of 60 seconds. The range is 0 to 21845.
MD5Authentication	Enables and disables MD5 authentication.
AdvertisementInterval	Specifies the time interval, in seconds, that elapses between each transmission of an advertisement from a BGPv6 neighbor. The default value is 30 seconds and the range is 5 to 120 seconds. The route advertisement interval feature is implemented using the time stamp that indicates when each route is advertised. The time stamp is marked to each route so that the route advertisement interval is compared to the time stamp and BGP is then able to make a decision about whether the route advertisement can be sent or should be delayed when a better route is received. This feature does not work for a withdraw route because the route entry is already removed when the processing route advertisement is sent and the time stamp marked in the route entry cannot be obtained.
DefaultOriginateIpv6	When enabled, specifies that the current IPv6 route originated from the BGP peer. This parameter enables or disables sending the default IPv6 route information to the specified neighbor or peer. The default value is false.
Weight	Specifies the peer or peer group weight, or the priority of updates the system can receive from this BGP peer. The default value is 100 and the range is 0 to 65535.
MaxPrefix	Configures a limit on the number of routes accepted from a neighbor. The default value is 12000 routes and the range is 0 to 2147483647. A value of 0 means no limit exists.
NextHopSelf	Specifies that the next-hop attribute in an iBGP update is the address of the local router or the router that generates the iBGP update. The default is disable.

Name	Description
RouteReflectorClient	Specifies that this peer is a route reflector client. Note: This parameter only applies to VRF 0.
SoftReconfigurationIn	When enabled, the router relearns routes from the specified neighbor or group of neighbors without restarting the connection after the policy changes in the inbound direction. The default value is disable. Enabling SoftReconfigurationIn stores all BGP routes in local memory (even non-best routes).
DebugMask	Displays the specified debug information for the BGP peer. The default value is none. • None disables all debug messages. • Event enables the display of debug event messages. • State enables display of debug state transition messages. • Update enables display of debug messages related to updates transmission and reception. • Error enables the display of debug error messages. • Trace enables the display of debug trace messages. • Init enables the display of debug initialization messages. • All enables all debug messages. • Packet enables the display of debug packet messages. • Warning enables the display of debug warning messages. • Filter enables the display of debug messages related to filtering.
SendCommunity	Enables or disables sending the community attribute of the update message to the specified peer. The default value is disable.
IpvpnLiteCap	Enable or disable IP VPN-lite capabilitiy on the BGP neighbor peer.
Ipv6Cap	Enable or disable the IPv6 capability on the BGP neighbor peer. The default value is disable.
RouteRefresh	Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates in the database that are eligible for the peer that issues the request. This parameter only applies to VRF 0.
AsOverride Note: This field does not apply to 5320 Series switches.	Specifies that the AS Override parameter can be enabled or disabled for the BGP peer. The default is disable.
AllowAsIn Note: This field does not apply to 5320 Series switches.	Specifies the number of AS-in allowed for the BGP peer. The range is 1–10.

Name	Description
Ipv6RoutePolicyIn	Specifies the policy (by name) that applies to all network IPv6 routes learned from this peer.
Ipv6RoutePolicyOut	Specifies the policy (by name) that applies to all outgoing IPv6 route updates.
Ipv6MaxPrefix	Configures a limit on the number of IPv6 routes accepted from a neighbor. A value of 0 means no limit exists.
BfdEnable	Enables Bidirectional Forwarding Detection (BFD) for this peer.

Enable BFD for OSPF on an IPv4 Port Interface

About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable BFD for the OSPF protocol on an IPv4 port interface.

Note
Enabling BFD at the application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration** > **Edit** > **Port**.
3. Select **IP**.
4. Select the **OSPF** tab.
5. Select **BfdEnable**.

OSPF *Field Descriptions*

Use the data in the following table to use the **OSPF** tab.

Name	Description
Enable	Enables or disables OSPF routing on the specified port. The default is false.
HelloInterval	Specifies the length of time, in seconds, between the transmission of hello packets. This value must be the same for all routers attached to a common network. The default is 10 seconds. After you change the hello interval values, you must save the configuration file, and then restart the switch. After the switch restarts, it restores the values and checks for consistency.

Name	Description
RtrDeadInterval	Specifies the interval used by adjacent routers to determine if the router was removed from the network. This interval must be identical on all routers on the subnet, and a minimum of four times the hello interval. To avoid interoperability issues, the RtrDeadInterval value for the OSPF interface needs to match with the RtrDeadInterval value for the OSPF virtual interface. The default is 40 seconds.
DesigRtrPriority	Specifies the priority of this port in multiaccess networks to use in the designated router election algorithm. The value 0 indicates the router is not eligible to become the designated router on this particular network. If a tie occurs, routers use their router ID as a tie breaker. The default is 1.
Metric	Specifies the metric for the type of service (TOS) on this port. The value of the TOS metric is (10^9 / interface speed). The default is 1. • FFFF—No route exists for this TOS. • IPCP links—Defaults to 0. • 0—Use the interface speed as the metric value when the state of the interface is up.
AuthType	Specifies the type of authentication required for the interface. • none—Specifies that no authentication required. • simple password—Specifies that all OSPF updates received by the interface must contain the authentication key specified in the interface AuthKey parameter. • MD5 authentication—Specifies that all OSPF updates received by the interface must contain the MD5 key. • sha1—Specifies secure hash algorithm (SHA-1), which is a cryptographic hash function that produces a 160-bit hash value, usually given in a hexadecimal number, 40 digits long. You can only access and enable the SHA-1 authentication type after you enable enhanced secure mode. • sha-2—Specifies SHA-2, which offers the hash function SHA-256. Note: sha-2, an update of SHA-1, can offer six hash functions that include SHA-224, SHA-256, SHA-384, SHA-512, SHA-512/224, SHA 512/256, with hash values that are 224, 256, 384, or 512 bits. However, the current release supports only SHA-256.
AuthKey	Specifies the key (up to 8 characters) when you specify simple password authentication in the port AuthType variable.
AreaId	Specifies the OSPF area name in dotted-decimal format. The area name is not related to an IP address. You can use a suitable value for the OSPF area name (for example, 1.1.1.1 or 200.200.200.200).

Name	Description
AdvertiseWhenDown	Advertises the network on this port as up, even if the port is down. The default is false. After you configure a port with no link and enable AdvertiseWhenDown, it does not advertise the route until the port is active. Then, OSPF advertises the route even if the link is down. To disable advertising based on link-states, disable AdvertiseWhenDown.
IfType	Specifies the type of OSPF interface (broadcast, NBMA, passive, or p2p). Before you change an OSPF interface type, you must first disable the interface. If the interface is an NBMA interface, you must also delete all configured neighbors.
PollInterval	Specifies the length of time, in seconds, between hello packets sent to an inactive OSPF router. Neighbors must have the same poll interval.
IfMtuIgnore	Specifies whether the interface ignores the global maximum transmission unit (MTU) configuration. To allow the switch to accept OSPF database description (DD) packets with a different MTU size, enable MtuIgnore. The interface drops incoming OSPF DD packets if their MTU is greater than 1500 bytes.
BfdEnable	Enable Bidirectional Forwarding Detection (BFD) for OSPF.

Enable BFD for OSPF on an IPv4 VLAN Interface

About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable OSPF BFD on an IPv4 VLAN interface.

Note
Enabling BFD at the application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

Procedure

1. In the navigation pane, expand **Configuration** > **VLAN**.
2. Select **VLANs**.
3. Select the **Basic** tab.
4. Select the VLAN on which you want to enable BFD for OSPF.
5. Select **IP**.
6. Select **OSPF**.
7. Select **BfdEnable**.

OSPF *Field Descriptions*

Use the data in the following table to use the **OSPF** tab.

Name	Description
Enable	Enables or disables OSPF routing on the specified VLAN. The default is false.
HelloInterval	Specifies the length of time, in seconds, between the transmission of hello packets. This value must be the same for all routers attached to a common network. The default is 10 seconds. After you change the hello interval values, you must save the configuration file, and then restart the switch. After the switch restarts, it restores the values and checks for consistency.
RtrDeadInterval	Specifies the interval used by adjacent routers to determine if the router was removed from the network. This interval must be identical on all routers on the subnet and a minimum of four times the hello interval. To avoid interoperability issues, the RtrDeadInterval value for the OSPF interface needs to match with the RtrDeadInterval value for the OSPF virtual interface. The default is 40 seconds.
DesigRtrPriority	Specifies the priority of this VLAN in multiaccess networks to use in the designated router election algorithm. The value 0 indicates the router is not eligible to become the designated router on this particular network. If a tie occurs, routers use their router ID as a tie breaker. The default is 1.
Metric	Specifies the metric for this TOS on this VLAN. The value of the TOS metric is (10^9 / interface speed). The default is 1. • FFFF—No route exists for this TOS. • IPCP links—Defaults to 0. • 0—Use the interface speed as the metric value when the state of the interface is up.
AuthType	Specifies the type of authentication required for the interface. • none—Specifies that no authentication required. • simple password—Specifies that all OSPF updates received by the interface must contain the authentication key specified in the interface AuthKey parameter. • MD5 authentication—Specifies that all OSPF updates received by the interface must contain the MD5 key. • sha1—Specifies secure hash algorithm 1 (SHA-1), which is a cryptographic hash function that produces a 160-bit hash value, usually given in a hexadecimal number, 40 digits long. You can only access and enable the SHA-1 authentication type after you enable enhanced secure mode. • sha-2—Specifies SHA-2, which offers the hash function SHA-256. Note: sha-2, an update of SHA-1, can offer six hash functions that include SHA-224, SHA-256, SHA-384, SHA-512, SHA-512/224, SHA 512/256, with hash values that are 224, 256, 384, or 512 bits. However, the current release supports only SHA-256.

Name	Description
AuthKey	Specifies the key (up to eight characters) when you specify simple password authentication in the VLAN AuthType variable.
AreaId	Specifies the OSPF area name in dotted-decimal format. The area name is not related to an IP address. You can use a suitable value for the OSPF area name (for example, 1.1.1.1 or 200.200.200.200).
AdvertiseWhenDown	Advertises the network even if the port is down. If true, OSPF advertises the network on this VLAN as up, even if the port is down. The default is false. After you configure a port without a link and enable AdvertiseWhenDown, it does not advertise the route until the port is active. Then, OSPF advertises the route even when the link is down. To disable advertising based on link states, disable AdvertiseWhenDown.
IfType	Specifies the type of OSPF interface (broadcast, NBMA, passive, or p2p). Before you change an OSPF interface type, you must first disable the interface. If the interface is an NBMA interface, you must also delete all configured neighbors.
PollInterval	Specifies the length of time, in seconds, between hello packets sent to an inactive OSPF router. Neighbors must use the same poll interval.
IfMtuIgnore	Specifies whether the VLAN ignores the MTU configuration. To allow the switch to accept OSPF DD packets with a different MTU size, enable MtuIgnore. The interface drops incoming OSPF DD packets if their MTU is greater than 1500 bytes.
BfdEnable	Enables Bidirectional Forwarding Detection (BFD) for OSPF.

Enable BFD for OSPF on an IPv6 Port Interface

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see *Fabric Engine Feature Support Matrix*.

About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable BFD for the OSPF protocol on an IPv6 port interface.

Note
Enabling BFD at the application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration** > **Edit** > **Port**.
3. Select **IPv6**.
4. Select the **IPv6 OSPF Interface** tab.

5. Select **Insert**.
6. Select **BfdEnable**.

IPv6 OSPFv3 Interface *Field Descriptions*

Use the data in the following table to use the **IPv6 OSPFv3 Interface** tab.

Name	Description
Index	Specifies the interface index for the IPv6 interface on which OSPFv3 is configured.
AreaId	Specifies the area ID to which the IPv6 interface connects. Use 0.0.0.0 for the OSPFv3 backbone.
Type	Specifies the OSPFv3 interface type as one of the following: • broadcast • NBMA • point-to-point • point-to-multipoint • passive
AdminStat	Specifies the administrative status for the OSPFv3 interface. If you enable the status, it is advertised as an internal route to some areas. If you disable the status, the interface is external to OSPFv3. The default is enabled.
RtrPriority	Specifies the priority of this interface. Multiaccess networks use the priority in the designated router election. A higher priority value increases the chance the router becomes the designated router. A value of zero (0) indicates the router cannot become the designated router for the network. If more than one router uses the same priority value, the router ID determines the designated router. The default is 1.
TransitDelay	Specifies the estimated number of seconds to transmit a link-state-update packet over this interface. The default is 1.
RetransInterval	Specifies the number of seconds between retransmission of link-state advertisements for the adjacencies that belong to this interface, and for database description and link-state request packets. The default is 5.
HelloInterval	Specifies the number of seconds between the hello packets that the router sends on this interface. You must configure this field to the same value for all routers attached to a common network. The default is 10.

Name	Description
RtrDeadInterval	Specifies the number of seconds after which to declare a router down if no hello packets are received. You must configure this field to the same value for all routers attached to a common network. The default is 40.
PollInterval	Specifies the number of seconds between hello packets sent to an inactive NBMA neighbor. The default is 120.
State	Shows the state of the OSPFv3 interface as one of the following: • down • loopback • waiting • pointToPoint • designatedRouter • backupDesginatedRouter • otherDesignatedRouter
DesignatedRouter	Shows the router ID for the designated router.
BackupDesignatedRouter	Shows the router ID for the backup designated router.
MetricValue	Specifies the cost for the interface. The default value for a brouter port or VLAN is 1. The default value for a tunnel is 100. Note: If you do not specify a cost for the interface, the switch dynamically updates the interface cost with the configured global OSPF default cost. The global OSPF default cost depends on the speed of the interface.
LinkLsaSuppression	Specifies whether Link LSA suppression is enabled.

Enable BFD for OSPF on an IPv6 VLAN Interface

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see *Fabric Engine Feature Support Matrix*.

About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable OSPF BFD on an IPv6 VLAN interface.

Note
Enabling BFD at the application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

Procedure

1. In the navigation pane, expand the **Configuration** > **VLAN** folders.
2. Select **VLANs**.
3. Select the **Basic** tab.
4. Select the VLAN on which you want to enable BFD for OSPF.
5. Select **IPV6**.
6. Select **IPv6 OSPF Interface**.
7. Select **Insert**.
8. Select **BfdEnable**.

IPv6 OSPF Interface *Field Descriptions*

Use the data in the following table to use the **IPv6 OSPF Interface** tab.

Name	Description
Index	Shows the interface index for the IPv6 interface on which OSPFv3 is configured.
AreaId	Specifies the area ID to which the IPv6 interface connects. Use 0.0.0.0 for the OSPFv3 backbone.
Type	Specifies the OSPFv3 interface type as one of the following: • broadcast • NBMA • point-to-point • point-to-multipoint • passive
AdminStat	Specifies the administrative status for the OSPFv3 interface. If you enable the status, it is advertised as an interal route to some areas. If you disable the status, the interface is external to OSPFv3. The default is enabled.
RtrPriority	Specifies the priority of this interface. Multiaccess networks use the priority in the designated router election. A higher priority value increases the chance the router becomes the designated router. A value of zero (0) indicates the router cannot become the designated router for the network. If more than one router uses the same priority value, the router ID determines the designated router. The default is 1.
TransitDelay	Specifies the estimated number of seconds to transmit a link-state-update packet over this interface. The default is 1.
RetransInterval	Specifies the number of seconds between retransmission of link-state advertisements for the adjacencies that belong to this interface, and for database description and link-state request packets. The default is 5.

Name	Description
HelloInterval	Specifies the number of seconds between the hello packets that the router sends on this interface. You must configure this field to the same value for all routers attached to a common network. The default is 10.
RtrDeadInterval	Specifies the number of seconds after which to declare a router down if no hello packets are received. You must configure this field to the same value for all routers attached to a common network. The default is 40.
PollInterval	Specifies the number of seconds between hello packets sent to an inactive NBMA neighbor. The default is 120.
State	Shows the state of the OSPFv3 interface as one of the following: • down • loopback • waiting • pointToPoint • designatedRouter • backupDesginatedRouter • otherDesignatedRouter
DesignatedRouter	Shows the router ID for the designated router.
BackupDesignatedRouter	Shows the router ID for the backup designated router.
MetricValue	Specifies the cost for the interface. The default value for a brouter port or VLAN is 1. The default value for a tunnel is 100. Note: If you do not specify a cost for the interface, the switch dynamically updates the interface cost with the configured global OSPF default cost. The global OSPF default cost depends on the speed of the interface.
LinkLsaSuppression	Specifies whether Link LSA suppression is enabled.
BfdEnable	Enables Bidirectional Forwarding Detection (BFD) for OSPF.

Configure BFD on an IPv4 Static Route

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Select **BFD**.

3. Select **Insert**.
4. In the **NextHop** field, type the IPv4 address of the next hop of the BFD session.
5. (Optional) In the **VrfId** field, type the ID of the VRF associated with the BFD session.

BFD Static Route Field Descriptions

Use the data in the following table to use the **Static Route** tab.

Name	Description
NextHop	Specifies the IPv4 address of the next hop of the BFD session.
VrfId	Specifies the ID of the VRF associated with the BFD session.
VrfName	Specifies the name of the VRF associated with the BFD session.

Configure BFD on an IPv6 Static Route

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see *Fabric Engine Feature Support Matrix*.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Select **IPv6 BFD**.
3. Select **Insert**.
4. In the **Interface** field, select either **Port** or **Vlan** and select an interface.
5. In the **NextHop** field, type the IPv6 address of the next hop of the BFD session.
6. (Optional) In the **VrfId** field, type the ID of the VRF associated with the BFD session.

IPv6 BFD Static Route Field Descriptions

Use the data in the following table to use the **Static Route** tab.

Name	Description
Interface	Specifies either a port or VLAN interface.
NextHop	Specifies the IPv4 address of the next hop of the BFD session.
VrfId	Specifies the ID of the VRF associated with the BFD session.
VrfName	Specifies the name of the VRF associated with the BFD session.

Display BFD Performance Counters

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see *Fabric Engine Feature Support Matrix*.

Procedure

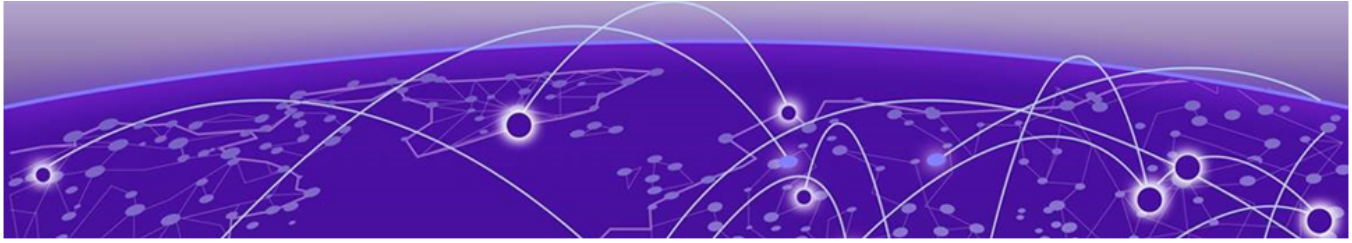
1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **BFD**.

3. Select the **Performance counters** tab.

BFDPerformance Counters Field Descriptions

Use the data in the following table to use the **Performance counters** tab.

Name	Description
PktIn	Specifies the total number of BFD messages received for this BFD session.
PktOut	Specifies the total number of BFD messages sent for this BFD session.



BGP

The following sections provide conceptual information and procedures that you can use to configure Border Gateway Protocol (BGP) services. The following operations are supported by BGP:

- IPv4
- 4-byte AS
- Peer groups
- Redistribution

Examples and network illustrations in these sections illustrate only one of the supported platforms. Unless otherwise noted, the concept illustrated applies to all supported platforms.

BGP fundamentals

Table 38: Border Gateway Protocol product support

Feature	Product	Release introduced
Border Gateway Protocol for IPv4 (BGPv4)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
BGP+ (BGPv4 for IPv6).	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5

BGPv6	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

Table 38: Border Gateway Protocol product support (continued)

Feature	Product	Release introduced
External BGP (eBGP)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
Internal BPG (iBGP)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
Route metric for BGP route redistribution	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
iBGP over user-created VRFs	5320 Series	Fabric Engine 8.6 Only 5320-48P-8XE and 5320-48T-8XE support more than one VRF with IP configuration.
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

Border Gateway Protocol (BGP) is an inter-domain routing protocol that provides loop-free routing between autonomous systems (AS) or within an AS. This section describes the major BGP features.

Autonomous Systems

An Autonomous system (AS) is a group of routers and hosts run by a single technical administrator that has a single, clearly defined routing policy. Each AS uses a unique AS number assigned by the appropriate Internet Registry entity. LANs and WANs that interconnect by IP routers form a group of networks called an internetwork. For administrative purposes, internetworks divide into boundaries known as autonomous systems.

The following figure shows a sample internetwork segmented into three autonomous systems.

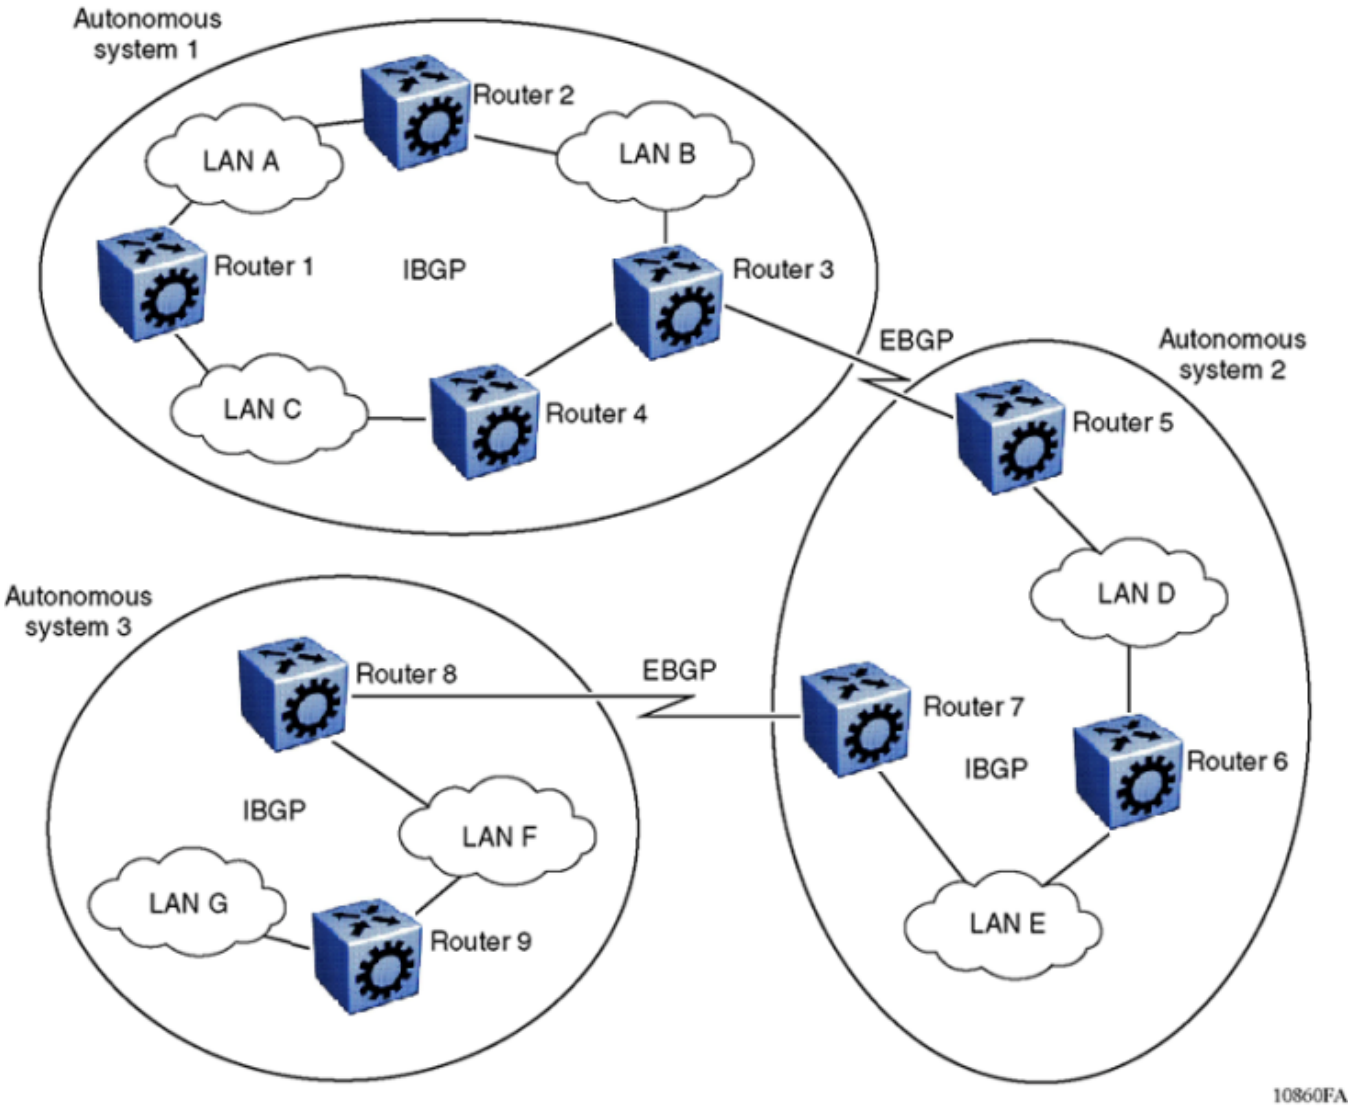

Figure 17: Internetwork segmented into three autonomous systems

BGP exchanges information between autonomous systems as well as between routers within the same AS. As shown in the preceding figure, routers that are members of the same AS and exchange BGP updates run internal BGP (iBGP), and routers that are members of different autonomous systems and exchange BGP updates run external BGP (eBGP).

Internal and external BGP routing

The switch supports both iBGP intra-AS routing and eBGP external-AS routing. With iBGP, each router within an AS runs an interior gateway protocol (IGP), such as Routing Information Protocol (RIP) or Open Shortest Path First (OSPF). The iBGP information, along with the IGP route to the originating BGP border router, determines the next hop to use to exchange information with an external AS. Each router uses iBGP exclusively to determine reachability to external autonomous systems. After a router receives an iBGP update destined for an external AS, it passes the update to IP for inclusion in the routing table only if a viable IGP route to the correct border gateway is available.

BGP speakers in different autonomous systems use eBGP communicate routing information.

BGP speaker

BGP routers employ an entity within the router, referred to as a BGP speaker, which transmits and receives BGP messages and acts upon them. BGP speakers establish a peer-to-peer session with other BGP speakers to communicate.

All BGP speakers within an AS must be fully meshed. The following figure shows a BGP network with fully-meshed BGP speakers.

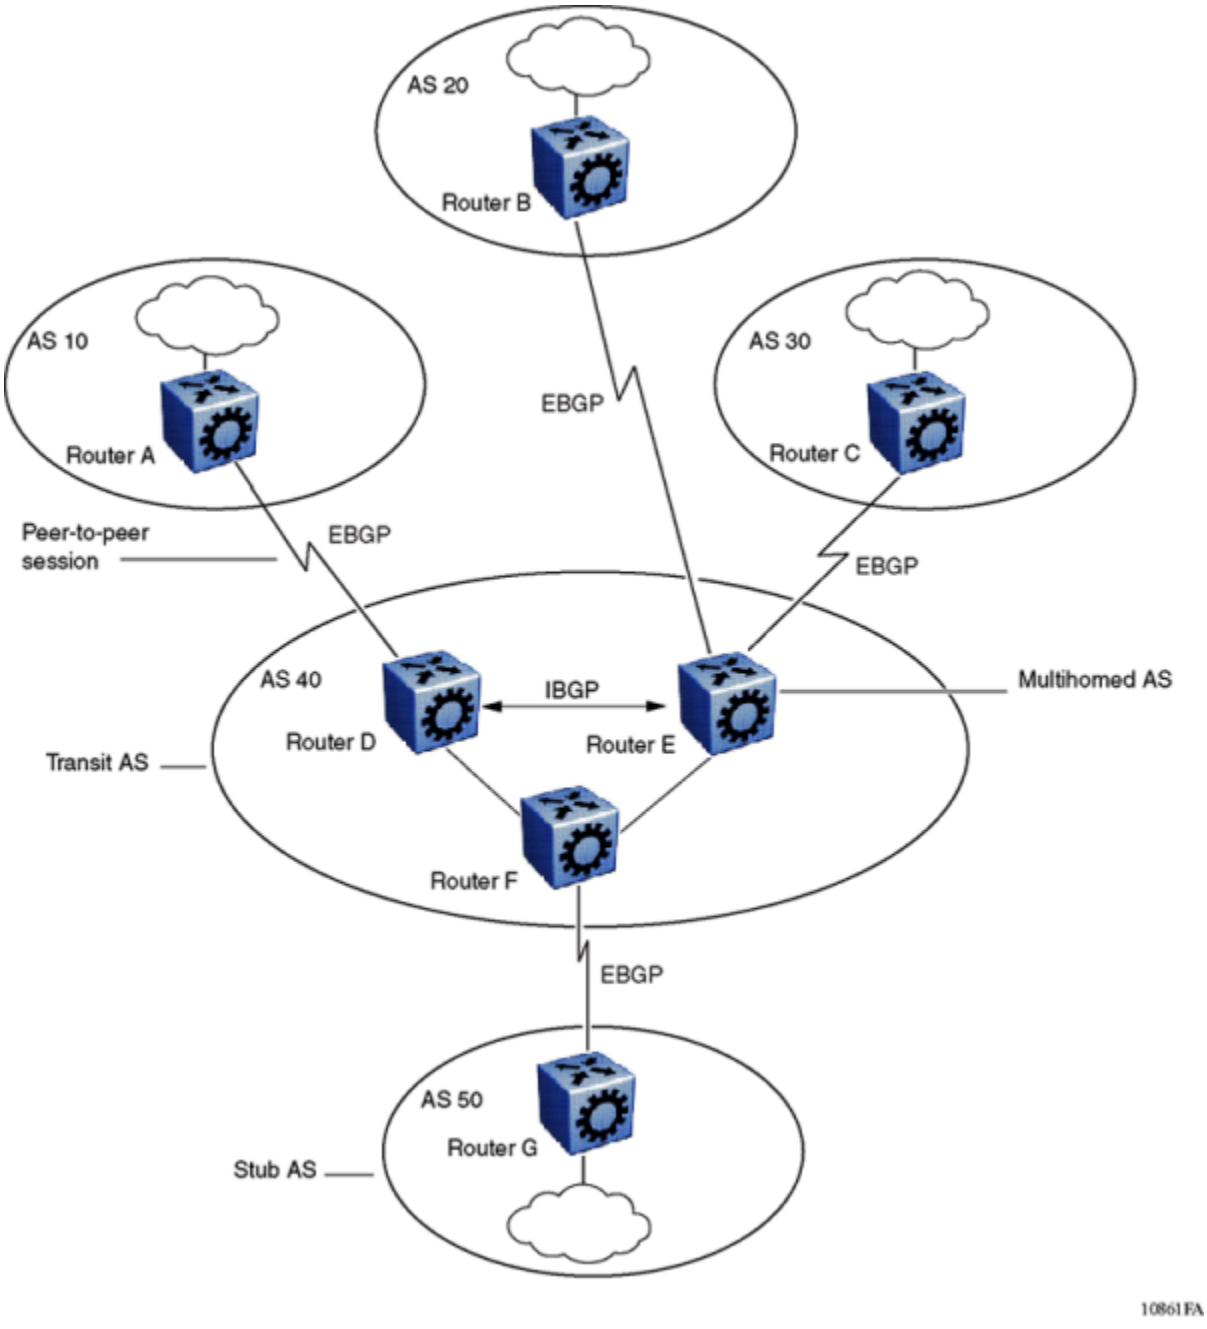

Figure 18: BGP networks

Transit AS

An AS with more than one BGP speaker can use iBGP to provide a transit service for networks located outside the AS. An AS that provides this service is a transit AS. As shown in the preceding figure, BGP networks , AS 40 is the transit AS. AS 40 provides information about the internal networks, as well as transit networks, to the remaining autonomous systems. The iBGP connections between routers D, E, and F provide consistent routing information to the autonomous systems.

Stub and multihomed autonomous systems

As shown in the preceding figure, BGP networks , an AS can include one or more BGP speakers that establish peer-to-peer sessions with BGP speakers in other autonomous systems to provide external route information for the networks within the AS.

A stub AS has a single BGP speaker that establishes a peer-to-peer session with one external BGP speaker. In this case, the BGP speaker provides external route information only for the networks within its own AS.

A multihomed AS has multiple BGP speakers.

Peers

BGP uses Transmission Control Protocol (TCP) as a transport protocol. When two routers open a TCP connection to each other for the purpose of exchanging routing information, they form a peer-to-peer relationship. In the preceding figure, BGP networks, Routers A and D are BGP peers, as are Routers B and E, C and E, F and G, and Routers D, E, and F.

Although Routers A and D run eBGP, Routers D, E, and F within AS 40 run iBGP. The eBGP peers directly connect to each other, while the iBGP peers do not. As long as an IGP operates and allows two neighbors to logically communicate, the iBGP peers do not require a direct connection.

Note

You cannot create the same iBGP peers on two different VRFs, or the same eBGP peers on two different chassis. Only one local autonomous system (AS) can exist for each chassis or VRF.

Because all BGP speakers within an AS must be fully meshed logically, the iBGP mesh can grow to large proportions and become difficult to manage. You can reduce the number of peers within an AS by creating confederations and route reflectors.

BGP peers exchange complete routing information only after the peers establish a connection. Thereafter, BGP peers exchange routing updates. An update message consists of a network number, a list of autonomous systems that the routing information passed through (the AS path), and other path attributes that describe the route to a set of destination networks. When multiple paths exist, BGP compares the path attributes to choose the preferred path. Even if you disable BGP, the system logs all BGP peer connection requests. For more information about update messages, see BGP Updates on page 374.

Supernet advertisements

BGP has no concept of address classes. Each network listed in the network layer reachability information (NLRI) portion of an update message contains a prefix length field, which describes the length of the mask associated with the network. The prefix length field allows for both supernet and

subnet advertisement. The supernet advertisement is what makes classless interdomain routing (CIDR) possible (see CIDR and aggregate addresses on page 363).

Bandwidth and maintenance reduction

BGP provides two features that reduce the high bandwidth and maintenance costs associated with a large full-mesh topology:

- confederations
- route reflectors

Note

Confederations and route reflectors are not supported on iBGP for non-default VRFs.

For information on confederations and route reflectors, see Routing information consolidation on page 363.

BGP 4 Byte AS Support

Each Autonomous System (AS) must have its own unique number. Because the 2-byte AS numbering scheme is unable to meet the increasing demand, the switch supports 4-byte AS numbers. This feature is enabled by supporting RFC 4893, BGP Support for 4-octet AS Number Space.

The switch supports the following three types of peer relationships as a result of 4 byte AS support:

- Old peer to old peer
- Old peer to new peer
- New peer to new peer

An old peer is the one that supports 2–byte AS numbers only and new peer is the one that supports both 2–byte AS numbers and 4–byte AS numbers.

RFC4893 supports two new path attributes:

- AS4_PATH contains the AS path encoded with a 4-octet AS number.
- AS4-AGGR is a new aggregator attribute that carries a 4-octet AS number.

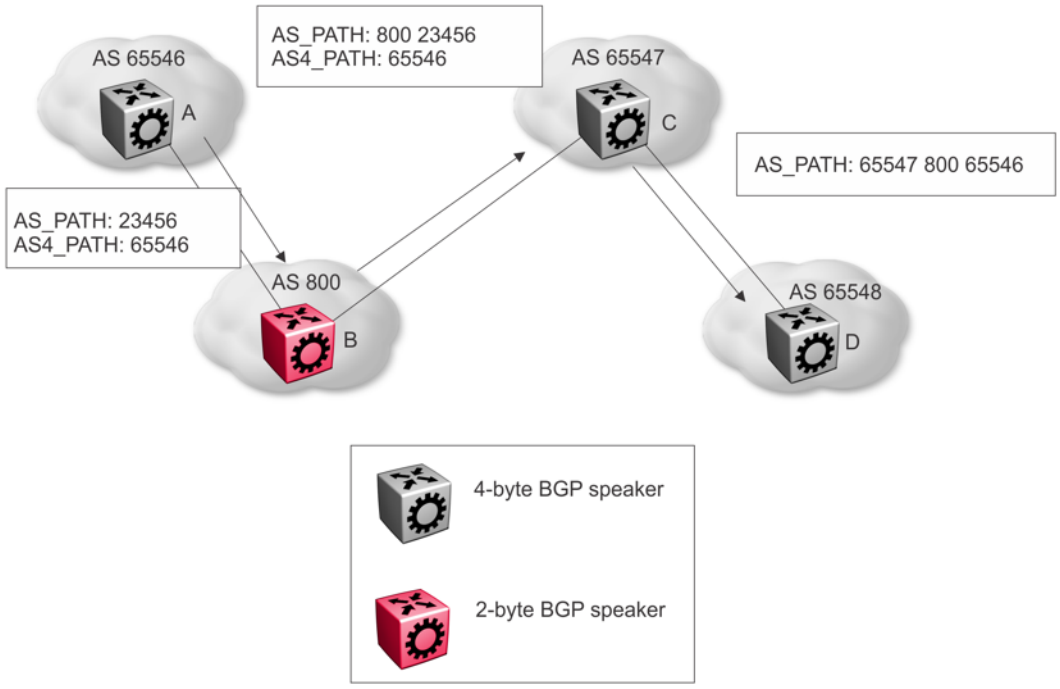

Figure 19: 2-byte and 4-byte Mixed Environment

The preceding figure shows an example of how the switch uses the AS4_PATH attribute in a mixed environment. The figure illustrates how a 2-byte BGP speaker interoperates with a 4-byte BGP speaker.

Router B is a 2-byte BGP speaker. Router A substitutes AS_PATH with the AS_TRANS, a 2-octet AS number defined by RFC4893 for backward compatibility, and encodes the 4-byte AS into AS4_PATH in BGP updates it sends to router B.

Router B does not understand the AS4_PATH but does preserve the information and sends it to router C.

Router C is a 4-byte BGP speaker. Router C merges the information received in AS_PATH and AS4_PATH, and encodes the 4-byte AS when it sends the AS_PATH information to router D.

Old Peer to Old Peer

When the peer relationship between an old peer and another old peer is established, 4 byte AS numbers contained in the AS4_PATH and AS4_AGGREGATOR are transited to other peers.

Important

Do not assign 23456 as an AS number. The Internet Assigned Numbers Authority (IANA) reserved this number for the AS_TRANS attribute and BGP uses it to facilitate communication between peer modes. AS_TRANS uses a 2-byte AS format to represent a 4-byte AS number. The switch interprets the AS_TRANS attribute and propagates it to other peers.

New Peer to New Peer

The new BGP speaker establishes its 4 byte AS support through BGP capability advertisement. A BGP speaker that announces such capability and receives it from its peer, uses 4 byte AS numbers in

AS_PATH and AGGREGATOR attributes and assumes these attributes received from its peer are encoded in 4 byte AS numbers.

The new BGP attributes AS4_PATH and AS4_AGGREGATOR received from the new BGP speaker between the new BGP peers in the update message is discarded.

Old Peer to New Peer

An old BGP speaker and a new BGP speaker can form peering relationship only if the new BGP speaker is assigned a 2 byte AS number. This 2 byte number can be any global unique AS number or AS_TRANS.

New BGP speaker sends AS path information to the old BGP speaker in AS_PATH attribute as well as AS4_PATH attribute. If the entire AS_PATH consists of only 2 byte AS numbers then the new BGP speaker does not send AS4_PATH information.

The 4-byte AS number feature does not in any way restrict the use or change the way you configure 2-byte AS numbers. You can also configure 2-byte AS or 4 byte AS numbers in AS path lists, community lists, and route policies.

BGP 4–byte AS Number Notation

BGP 4–byte AS numbers are represented in two ways: AS Plain and AS dot. The default form of representing the AS numbers is AS Plain while you have an option to configure AS dot. AS Plain form of representation is preferred over AS dot representation as a large amount of network providers find the AS dot notation incompatible with the regular expressions used by them. In case of any issues, troubleshooting and analyzing also gets difficult with AS dot notation.

BGP AS Number Format – AS Plain

Table 39: Default Asplain 4-Byte Autonomous System Number Format

Format	Configuration Format	Show Command Output and Regular Expression Match Format
asplain	2-byte: 1 to 65535 4-byte: 65536 to 4294967295	2-byte: 1 to 65535 4-byte: 65536 to 4294967295
asdot	2-byte: 1 to 65535 4-byte: 1.0 to 65535.65535	2-byte: 1 to 65535 4-byte: 65536 to 4294967295

BGP AS Number Format - ASdot

Table 40: Asdot 4-Byte Autonomous System Number Format

Format	Configuration Format	Show command output and Regular Expression Match Format
asplain	2-byte: 1 to 65535 4-byte: 65536 to 4294967295	2-byte: 1 to 65535 4-byte: 1.0 to 65535.65535
asdot	2-byte: 1 to 65535 4-byte: 1.0 to 65535.65535	2-byte: 1 to 65535 4-byte: 1.0 to 65535.65535

For more information on configuring 4 byte AS numbers, see Configure 4-byte AS numbers on page 395.

Routing information consolidation

Use the information in this section to understand how to reduce the size of routing tables.

CIDR and aggregate addresses

Classless interdomain routing (CIDR) is an addressing scheme (also known as supernetting) that eliminates the concept of classifying networks into class types. Earlier addressing schemes identified five classes of networks: Class A, Class B, Class C, Class D, and Class E. This document does not discuss Classes D (used for multicast) and E (reserved and currently not used).

Network 195.215.0.0, an illegal Class C network number, becomes a legal supernet when represented in CIDR notation as 195.215.0.0/16. The /16 is the prefix length and expresses the explicit mask that CIDR requires. In this case, the addition of the prefix /16 indicates that the subnet mask consists of 16 bits (counting from the left).

Using this method, supernet 195.215.0.0/16 represents 195.215.0.0 255.255.0.0. The following table shows the conversion of prefix length to subnet mask.

Table 41: CIDR conversion

Prefix	Dotted-decimal	Binary	Network class
/1	128.0.0.0	1000 0000 0000 0000 0000 0000 0000 0000	128 Class A
/2	192.0.0.0	1100 0000 0000 0000 0000 0000 0000 0000	64 Class A
/3	224.0.0.0	1110 0000 0000 0000 0000 0000 0000 0000	32 Class A
/4	240.0.0.0	1111 0000 0000 0000 0000 0000 0000 0000	16 Class A
/5	248.0.0.0	1111 1000 0000 0000 0000 0000 0000 0000	8 Class A
/6	252.0.0.0	1111 1100 0000 0000 0000 0000 0000 0000	4 Class A
/7	254.0.0.0	1111 1110 0000 0000 0000 0000 0000 0000	2 Class A
/8	255.0.0.0	1111 1111 0000 0000 0000 0000 0000 0000	1 Class A or 256 Class B
/9	255.128.0.0	1111 1111 1000 0000 0000 0000 0000 0000	128 Class B
/10	255.192.0.0	1111 1111 1100 0000 0000 0000 0000 0000	64 Class B

/23	255.255.254.0	1111 1111 1111 1111 1111 1110 0000 0000	2 Class C
/24	255.255.225.0	1111 1111 1111 1111 1111 1111 0000 0000	1 Class C

Use CIDR to assign network prefixes of arbitrary lengths, as opposed to the obsolete class system, which assigned prefixes as even multiples of an octet.

For example, you can assign a single routing table supernet entry of 195.215.16/21 to represent 8 separate Class C network numbers: 195.215.16.0 through 195.215.23.0.

Supernet addressing

You can create a supernet address that covers an address range.

For example, to create a supernet address that covers an address range of 192.32.0.0 to 192.32.9.255, perform the following steps:

1. Convert the starting and ending address range from dotted-decimal notation to binary notation (see the following figure).

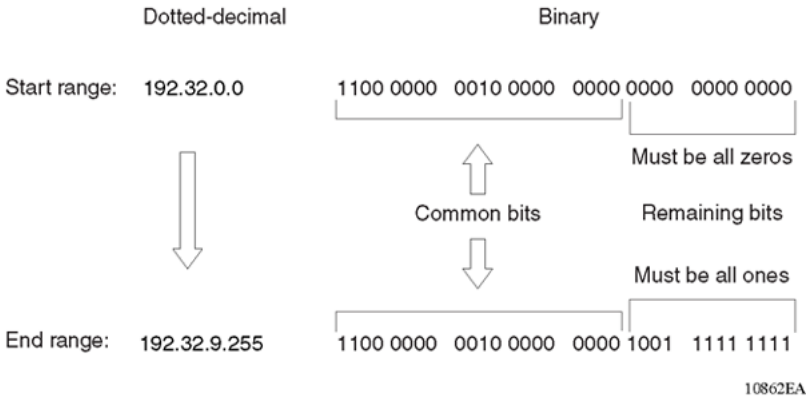

Figure 20: Binary notation conversion

2. Locate the common bits in both ranges. Ensure that the remaining bits in the start range are zeros, and the remaining bits in the end range are all ones. In this example, the remaining bits in the end range are not all ones.
3. If the remaining bits in the end range are not all ones, you must recalculate to find the IP prefix that has only ones in the remaining bits in the end range.
4. Recalculate to find a network prefix that has all ones in the remaining end range bits (see the following figure). In this example, 192.32.7.255 is the closest IP prefix that matches the common bits for the start range.

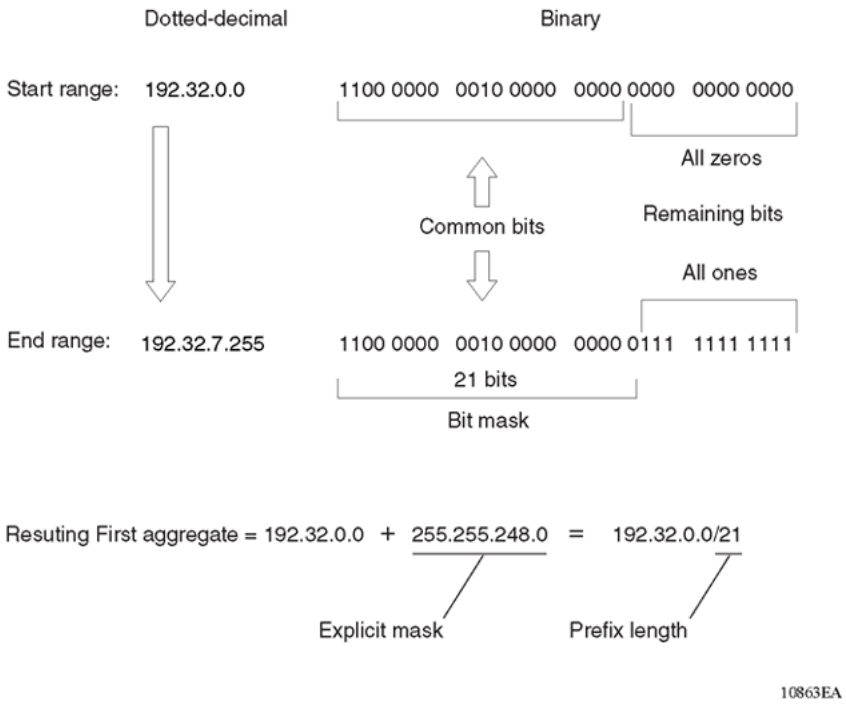

Figure 21: First aggregate and prefix length

5. The 21 bits that match the common bits form the prefix length. The prefix length is the number of binary bits that form the explicit mask (in dotted-decimal notation) for this IP prefix.
6. The remaining aggregate is formed from 192.32.8.0 to the end range, 192.32.9.255.

   As shown in Figure 21, the resulting first aggregate 192.32.0.0/21 represents all of the IP prefixes from 192.32.0.0 to 192.32.7.255.

The following figure shows the results after forming the remaining aggregate from 192.32.9.0 to the end range, 192.32.9.255.

The resulting aggregate 192.32.8.0/23 represents all of the IP prefixes from 192.32.8.0 to 192.32.9.255.

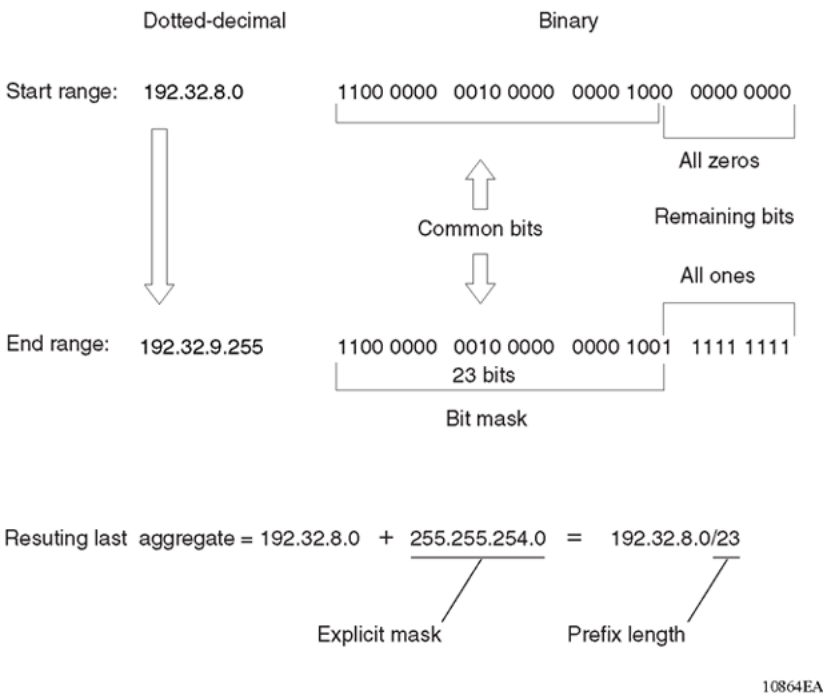

Figure 22: Last aggregate and prefix length

The final result of calculating the supernet address that ranges from 192.32.00 to 192.32.9.255 is as follows:

192.32.0.0 (with mask) 255.255.248.0 = 192.32.0.0/21

192.32.8.0 (with mask) 255.255.254.0 = 192.32.8.0/23

Aggregate routes

Eliminating the idea of network classes provides an easy method to aggregate routes. Rather than advertise a separate route for each destination network in a supernet, BGP uses a supernet address to advertise a single route (called an aggregate route) that represents all the destinations. CIDR also reduces the size of the routing tables used to store advertised IP routes.

The following figure shows an example of route aggregation using CIDR. In this example, a single supernet address 195.215.0.0/16 advertises 256 separate Class C network numbers 195.215.0.0 through 195.215.255.0.

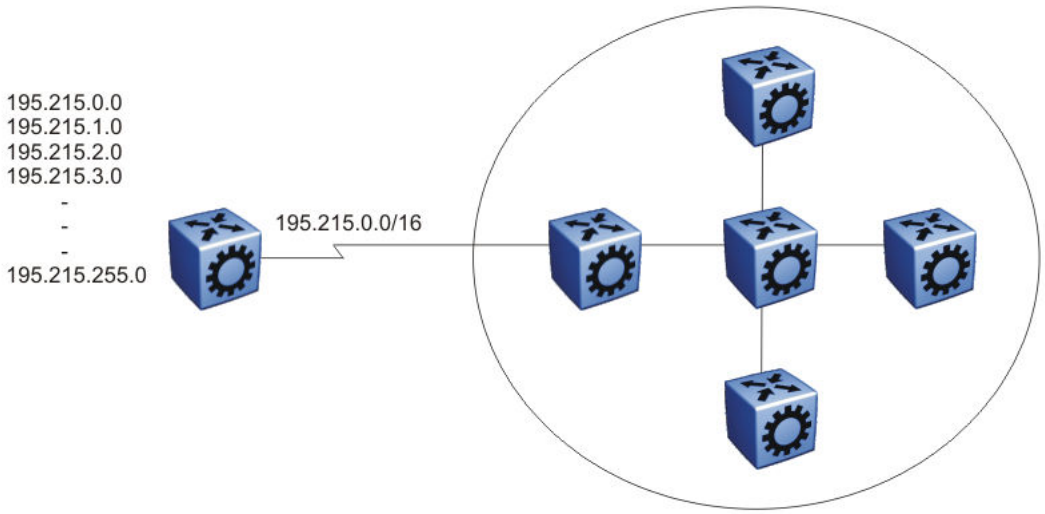

Figure 23: Aggregating routes with CIDR

Confederations

A BGP router configured for iBGP establishes a peer-to-peer session with every other iBGP speaker in the AS. In an AS with a large number of iBGP speakers, this full-mesh topology can result in high bandwidth and maintenance costs.

Note

Confederations are not supported on iBGP for non-default VRFs.

As shown in the following example, a full-mesh topology for an AS with 50 iBGP speakers requires 1225 internal peer-to-peer connections:

Example:

n x (n-1)/2 = n iBGP sessions

where:

50 x (50-1)/2 = 1225 number of unique iBGP sessions

You can reduce the high bandwidth and maintenance costs associated with a large full-mesh topology by dividing the AS into multiple smaller autonomous systems (sub-autonomous systems), and then group them into a single confederation (see the following figure).

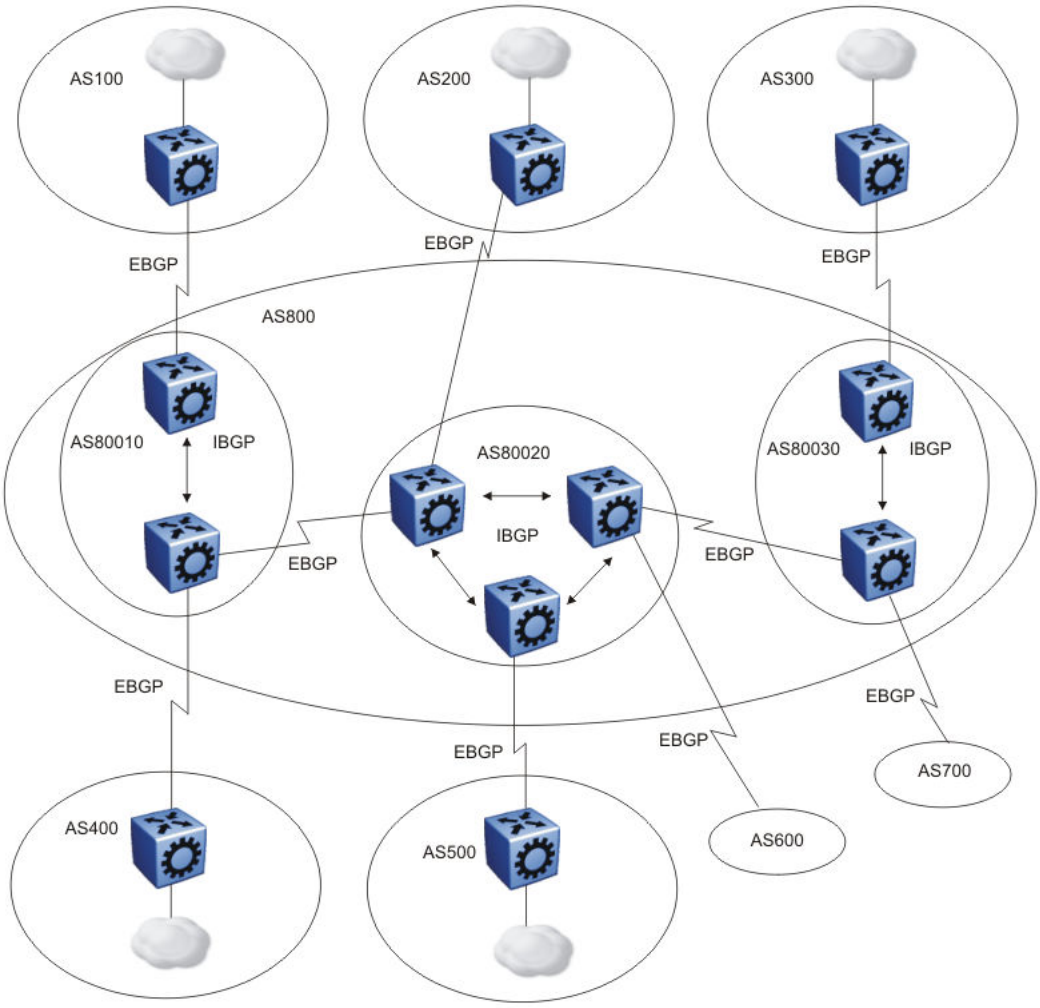

Figure 24: Confederations

As shown in the preceding figure, each sub-AS is fully meshed within itself and has eBGP sessions with other sub-autonomous systems in the same confederation.

Although the peers in different autonomous systems have eBGP sessions with the various sub-AS peers, they preserve the next-hop, Multi-Exit Discriminator (MED), and local preference information and exchange routing updates as if they were iBGP peers. All of the autonomous systems retain a single interior gateway protocol (IGP). When the confederation uses its own confederation identifier, the system displays the group of sub-autonomous systems as a single AS (with the confederation identifier as the AS number).

Route reflectors

Another way to reduce the iBGP mesh inherent in an AS with a large number of iBGP speakers is to configure a route reflector. Using this method, when an iBGP speaker needs to communicate with other

BGP speakers in the AS, the speaker establishes a single peer-to-peer route reflector client session with the iBGP route reflector.

Note

Route reflectors are not supported on iBGP for non-default VRFs.

In an AS, more than one route reflector cluster can exist and more than one route reflector in a cluster. When more than one reflector exists in a cluster, take care to prevent route loops.

The following figure shows a simple iBGP configuration with three iBGP speakers (routers A, B, and C). Without route reflectors, after Router A receives an advertised route from an external neighbor, it must advertise the route to Routers B and C.

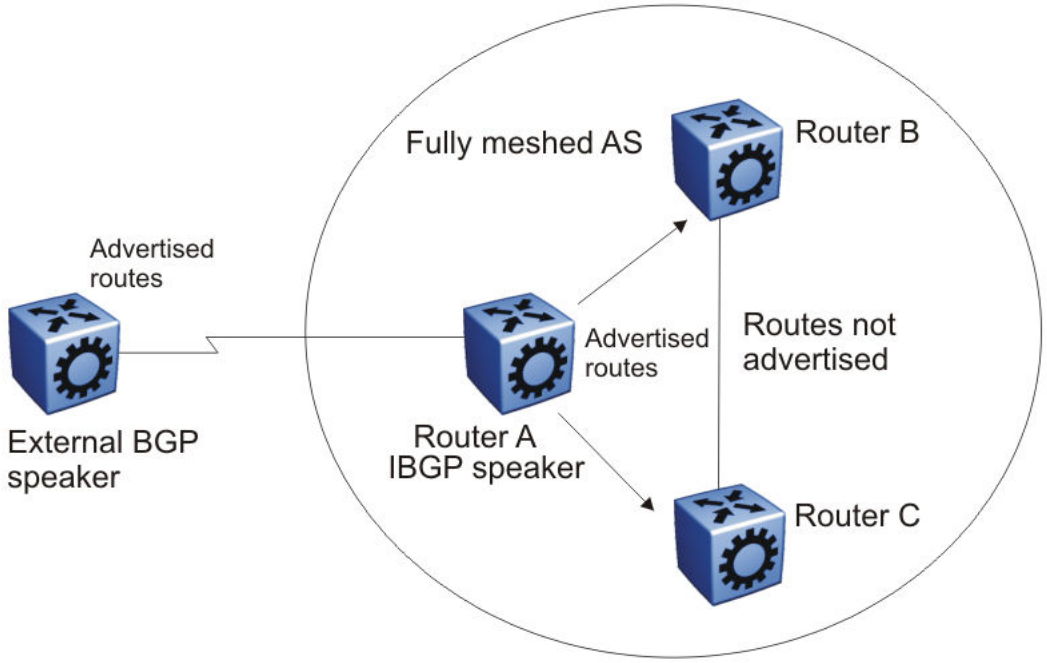

Figure 25: Fully meshed AS with iBGP speakers

Routers B and C do not readvertise the iBGP learned routes to other iBGP speakers. BGP does not allow routers to pass routes learned from internal neighbors on to other internal neighbors, which avoids routing information loops.

As shown in the following figure, when you configure an internal BGP peer (Router B) as a route reflector, all of the iBGP speakers do not need to be fully meshed. In this case, the assigned route reflector passes iBGP learned routes to a set of iBGP neighbors.

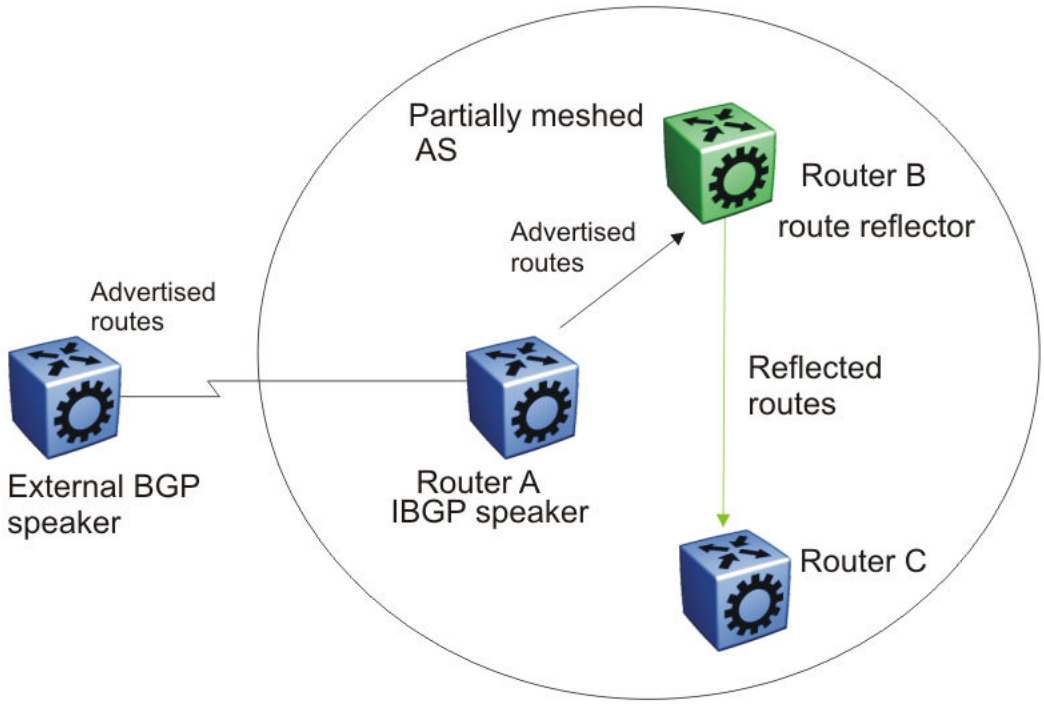

Figure 26: AS with route reflector

After Router B, the route reflector, receives routes from Router A (the iBGP speaker), it advertises them to router C. Conversely, after the route reflector receives routes from internal peers, it advertises those routes to Router A. Routers A and C do not need an iBGP session.

Route reflectors separate internal peers into two groups: client peers and nonclient peers. The route reflector and its clients form a cluster. The client peers in the cluster do not need to be fully meshed, and do not communicate with iBGP speakers outside their cluster. Nonclient peers must be fully meshed with each other.

The following figure shows a cluster, where Router A is the route reflector in a cluster with client routers B, C, and D. Routers E, F, and G are fully meshed, nonclient routers.

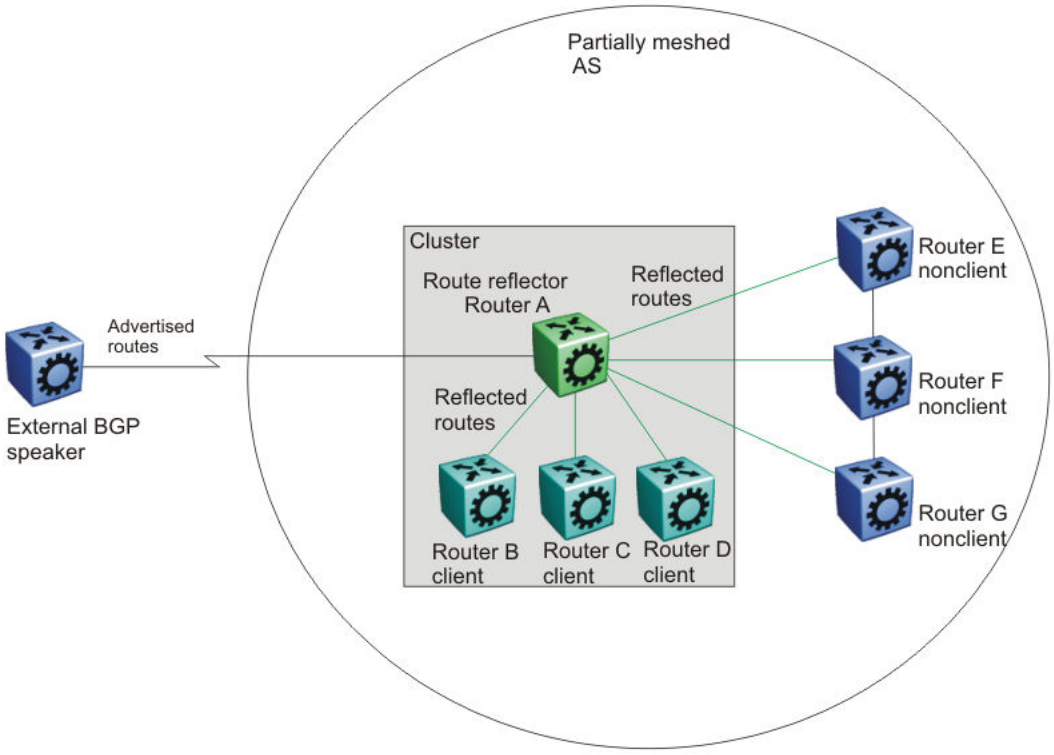

Figure 27: Route reflector with client and nonclient peers

BGP Communities

You can group destinations into communities to simplify policy administration. A community is a group of destinations that share a common administrative property.

Use community control routing policies with respect to destinations. Create communities when you have more than one destination and want to share a common attribute.

The following list identifies specific community types:

- Internet—advertise this route to the Internet community
- no advertise—do not advertise to BGP peers including iBGP peers

You can use a community to control which routing information to accept, prefer, or distribute to other BGP neighbors. If you specify the append option in the route policy, the router adds the specified community value to the existing value of the community attribute. Otherwise, the specified community value replaces a previous community value.

BGP path attributes

You can create policies that control routes, work with default routing, control specific and aggregated routes, and manipulate BGP path attributes.

Four categories of BGP path attributes exist:

- Well-known mandatory attributes must be in every BGP update message.
- Well-known discretionary attributes can be in a BGP update message.
- Optional transitive attributes are accepted and passed to other BGP peers.
- Optional non-transitive attributes can be either accepted or ignored, but must not pass along to other BGP peers.

Border routers that utilize built-in algorithms or manually configured polices to select paths use path attributes. BGP uses the following path attributes to control the path a BGP router chooses:

- origin (well-known mandatory)
- AS_path (well-known mandatory)
- next hop (well-known mandatory)
- MED attribute (optional non-transitive)
- local preference (well-known discretionary)
- atomic aggregate (well-known discretionary)
- aggregator (optional transitive)
- community (optional transitive)

For more information about path attributes in BGP updates, see Path Attributes on page 375.

BGP Route Selection

A BGP router determines the best path to a destination network. This path is then eligible for use in the IP forwarding table and the router also advertises the path to its eBGP peers. To choose the best of multiple BGP routes to a destination, the router executes a best path algorithm.

The algorithm chooses a route in the following order:

- highest weight

  Weight is a locally significant parameter associated with each BGP peer. You can use the weight to influence which peer paths the router uses.
- highest local preference

  The local preference has global significance within an AS. You can manipulate the preference using route policies to influence path selection.
- prefer locally originated paths

  The router prefers a path locally originated using the network, redistribution, or aggregate command over a path learned through a BGP update. The router prefers local paths sourced by network or redistribute commands over local aggregates sourced by the aggregate address command.
- shortest AS path

  The AS path parameter specifies the autonomous systems that the network prefix traversed. The AS path commonly determines the best path. For example, a router can choose a path based on whether the network passed through a specific AS. You can configure a route policy to match the AS, and then modify the local preference. Also, you can pad the AS path before the AS advertises it to a peer AS, so that downstream routers are less likely to prefer the advertised network path.

The AS_CONFED_SEQUENCE length will also be considered while picking the best path inside the confederation.

- lowest origin type

  The order of preference is IGP, EGP, INC (incomplete).

- lowest MED

  The MED parameter influences the preferred path from a remote AS to the advertising AS. This parameter applies when there are multiple exit points from the remote AS to the advertising AS. A lower MED value indicates a stronger path preference than a higher MED value. By default, the MED attribute is ignored as specified by the BGP global parameter Always Compare MED except when the routes come from the same AS. This parameter must be enabled for MEDs to be compared (and for this step of the best path algorithm to execute).

  The router compares MEDs regardless of what the first (neighboring) AS specified in the AS_PATH. Deterministic MED, when enabled, means that the first AS of the multiple paths must be the same. Paths received with no MED are assigned a MED of 0, unless the global BGP parameter Missing Is Worst is enabled. If so, received paths are assigned a MED of 4 294 967 294. Missing is Worst is enabled by default. The "no-med-path-is-worst" flag has an impact only when the “First AS” or the "Most Left AS" is the same for multiple routes received. The router changes paths received with a MED of 4 294 967 295 to 4 294 967 294 before insertion into the BGP table.

  Note

  You cannot enable or disable the MED selection process. BGP aggregation does not occur when routes have different MEDs or next hops.

  When MED value is set in route-map configuration, the configured MED value is not applicable if it is already set in the associated Path Attribute.

  1. When router A sets MED value of 100 by route-map, it will send Path Attribute with MED=100 to EBGP peer B.
  2. Router B sends Path Attribute with MED=100 to IBGP peer C.
  3. If the route-map is configured with "set MED 200", then router C does not apply MED=200 to the Path Attribute as it is already set to 100 when it is received from router B.
  4. Router D will get Path Attribute with MED=100 so that router C does not influence router D when it selects the best route.

```
Set:                                                Set:
MED100              MED100                MED:100   MED200                MED:100
A-----------------B-------------------------C-----------------------------D
         EBGP                        IBGP                                      EBGP
```

  Example: If Prefix: X is set as MED=100 from router A, it will be received at B with MED=100, and will carry same MED=100 value to router C, as it is an IBGP peer. Router C will not propagate MED=100 value to D as MED is a non-transitive attribute, so MED can travel maximum of 1 AS.

- lowest IGP metric to the BGP next-hop

  If multiple paths exist whose BGP next-hop is reachable through an IGP, the path with the lowest IGP metric to the BGP next-hop is chosen.

- prefer external paths (learned by eBGP) over internal paths (iBGP)

The system prefers external paths over internal paths.

- if Equal Cost Multipath (ECMP) is enabled, insert up to four paths in the routing table

  If you enable ECMP, multiple BGP learned routes that use the same metric to different IP next-hops are installed in the IP forwarding table for traffic load-balancing purposes.
- lowest router ID

  The lowest router ID, or Circuitless IP (CLIP) address, is preferred.

BGP and dampened routes

The switch supports route dampening (route suppression). When you use route dampening, a route accumulates penalties each time the route fails. After the accumulated penalties exceed a threshold, the router no longer advertises the route. The router enters the suppressed routes into the routing table only after the accumulated penalty falls below the reuse threshold.

Route flap dampening suppresses the advertisement of the unstable route until the route becomes stable. For information about how to enable flap-dampening, see Configure BGP on page 390. For information about viewing flap dampening configurations, see Viewing global flap-dampening configurations on page 421.

Dampening applies only to routes that are learned through an eBGP. Route flap dampening prevents routing loops and protects iBGP peers from having higher penalties for routes external to the AS.

The following paragraph describes the algorithm that controls route flaps.

After the route flaps the first time

- the router creates a route history entry
- a timer starts (180 seconds)

  If the route does not flap again, the router uses this timer to delete the history entry after the 180 seconds expires.

After the route flaps a second time

- The penalty is recalculated based on the decay function.

  If the penalty is greater than the cut-off value (1536), the route is suppressed and the reuse time is calculated based on the reuse time function.
- The reuse timer starts.

  After the reuse time expires, the suppressed route is announced again (the reuse time is recalculated if the route flaps again). The penalty decays slower for withdrawn routes than for update routes. The route history entry is kept longer if the route is withdrawn. For update history, the delete time is 90 seconds and the withdrawn history delete time is 180 seconds.

BGP Updates

BGP uses update messages to communicate information between two BGP speakers. The update message can advertise a single feasible route to a peer, or withdraw multiple unfeasible routes from service.

The following figure shows the format of an update message.

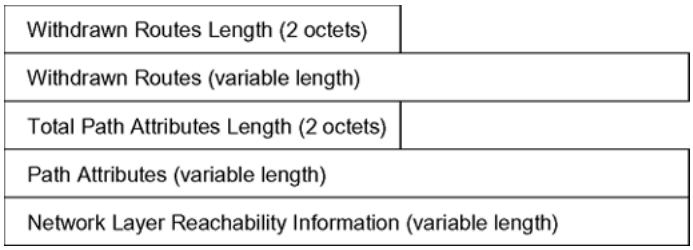

Figure 28: Update Message Format

This section describes how BGP uses the update message fields to communicate information between BGP speakers.

Withdrawn Routes Length

The withdrawn routes length parameter (referred to in RFC1771 as the Unfeasible Routes Length field) indicates the total length of the withdrawn routes field in octets. The withdrawn routes length field calculates the length of the NLRI field. For example, a value of 0 indicates that no routes are withdrawn from service, and that the withdrawn routes field is not present in this update message.

Withdrawn Routes

The withdrawn routes parameter is a variable-length parameter that contains a list of IP prefixes for routes that are withdrawn from service. The following figure shows the format of an IP prefix.

Figure 29: IP Prefix Format

The length indicates the number of bits in the prefix (also called the network mask).

For example, 192.0.2.0/24 is equivalent to 192.0.2.0 255.255.255.0 (the /24 indicates the number of bits in the length parameter to represent the network mask 255.255.255.0).

The prefix parameter contains the IP address prefix itself, followed by enough trailing bits to make the length of the whole field an integer multiple of 8 bits (1 octet).

Total Path Attributes Length

The total path attributes length parameter indicates the total length of the path attributes parameter in octets.

The total path attributes length calculates the length of the NLRI parameter. For example, a value of 0 indicates that no NLRI field is present in this update message.

Path Attributes

The path attributes parameter is a variable-length sequence of path attributes that exists in every BGP update. The path attributes contain BGP attributes associated with the prefixes in the NLRI parameter.

For example, the attribute values allow you to specify the prefixes that the BGP session can exchange, or which of the multiple paths of a specified prefix to use.

The attributes carry the following information about the associated prefixes:

- the path origin
- the AS paths through which the prefix is advertised
- the metrics that display degrees of preference for this prefix

The following figure shows the encoding used with the path attribute parameter.

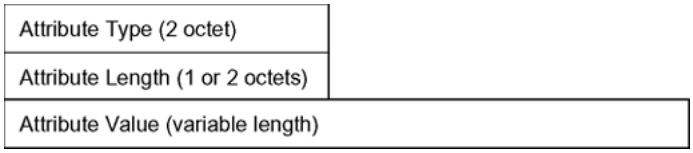

Figure 30: Path Attribute Encoding

Attribute Type

As shown in the following figure, the attribute type is a two-octet field that comprises two sub-fields: attribute flags and attribute type code.

Figure 31: Attribute Type Fields

The attribute flags parameter is a bit string that contains four binary values that describe the attribute, and four unused bits. The following list provides bit descriptions (from the high-order bit to the low-order bit):

- The high-order bit (bit 0) is the optional bit. When this bit is set (the value is 1), the attribute is optional. When this bit is clear (the value is 0), the attribute is well-known. Well-known attributes must be recognized by all BGP implementations and, when appropriate, passed on to BGP peers. Optional attributes are not required in all BGP implementations.
- The second high-order bit (bit 1) is the transitive bit. For well-known attributes, this bit must be set to 1. For optional attributes, it defines whether the attribute is transitive (when set to 1) or non-transitive (when set to 0).
- The third high-order bit (bit 2) is the partial bit. The partial bit defines whether the information in the optional transitive attribute is partial (when set to 1) or complete (when set to 0). For well-known attributes and for optional non-transitive attributes the partial bit must be set to 0.
- The fourth high-order bit (bit 3) is the extended length bit. The extended length bit defines whether the attribute length is one octet (when set to 0) or two octets (when set to 1). The attribute flag can use the extended length only if the length of the attribute value is greater than 255 octets.
  - If the extended length bit of the attribute flags octet is set to 0, the third octet of the path attribute contains the length of the attribute data in octets.
  - If the extended length bit of the attribute flags octet is set to 1, then the third and the fourth octets of the path attribute contain the length of the attribute data in octets.
- The lower-order four bits of the attribute flags octet are unused. The lower-order four bits must be zero (and must be ignored when received).

The attribute type code parameter contains the attribute type code, as defined by the Internet Assigned Numbers Authority (IANA). The attribute type code uniquely identifies the attribute from all others. The remaining octets of the path attribute represent the attribute value and are interpreted according to the attribute flags and the attribute type code parameters.

The following table shows the supported attribute type codes.

Table 42: BGP Mandatory Path Attributes

Attribute	Type code	Description
Origin	1	Defines the origin of the path information: • Value = 0 --- IGP (the path is valid all the way to the IGP of the originating AS) • Value = 1--- EGP (the last AS in the AS path uses an EGP to advertise the path) • Value = 2--- Incomplete (the path is valid only to the last AS in the AS path)
AS path	2	Contains a list of the autonomous systems that packets must traverse to reach the destinations. This code represents each AS path segment as follows: • path segment type • path segment length • path segment value
Next hop	3	Specifies the IP address of the border router to use as a next hop for the advertised destinations (destinations listed in the NLRI field of the update message).
Multiexit discriminator	4	Discriminates among multiple exit or entry points to the same neighboring AS on external (internal-AS) links.
Local preference	5	Indicates the preference that AS border routers assign to a chosen route when they advertise it to iBGP peers
Atomic aggregate	6	Ensures that certain NLRI is not deaggregated
Aggregator	7	Identifies which AS performed the most recent route aggregation. This attribute contains the last AS number that formed the aggregate route followed by the IP address of the BGP speaker that formed the aggregate route.

Attribute Length

The attribute length can be one or two octets in length, depending on the value of the extended length parameter in the attributes flag field.

This parameter indicates the length of the attribute value field.

Attribute Value

The attribute value contains the actual value of the specific attribute. The system implements the attribute value according to the values in the attribute flags and the attribute type code parameters.

NLRI

The NLRI parameter is a variable length field that contains a list of prefixes. The packet size that BGP speakers can exchange limits the number of prefixes in the list.

Equal Cost Multipath

Equal Cost Multipath (ECMP) support allows a BGP speaker to perform route or traffic balancing within an AS by using multiple equal-cost routes submitted to the routing table by OSPF, RIP, or static routes.

For more information about ECMP, see Equal Cost Multipath on page 1602.

MD5 message authentication

Authenticate BGP messages by using Message Digest 5 (MD5) signatures. After you enable BGP authentication, the BGP speaker verifies that the BGP messages it receives from its peers are actually from a peer and not from a third party masquerading as a peer.

BGPv4 TCP MD5 message authentication provides the following features:

- A TCP MD5 signature can exist for BGP peers. You can configure authentication and secret keys for each peer. Peers configured with common secret keys can authenticate each other and exchange routing information.
- The switch can concurrently have BGP peers with authentication enabled and other BGP peers with authentication disabled.
- The switch always encrypts the secret keys.

After you enable BGPv4 TCP MD5 authentication, the router computes an MD5 signature for each TCP packet based on the TCP packet and an individual peer secret key. The router adds this MD5 signature to the TCP packet that contains a BGP message and sends it with the packet, but it does not send the secret key.

The receiver of the TCP packet also knows the secret key and can verify the MD5 signature. A third party that tries to masquerade as the sender, however, cannot generate an authentic signature because it does not know the secret key.

In commands, the term password refers to the secret key. The secret keys provide security. If the keys are compromised, then the authentication itself is compromised. To prevent this, the switch stores the secret keys in encrypted form.

MD5 signature generation

BGP peers calculate MD5 signatures in BGP messages based on the following elements:

- TCP pseudo-header
- TCP header, excluding options
- TCP segment data
- TCP MD5 authentication key

If TCP receives an MD5 authentication key, it reduces its maximum segment size by 18 octets, which is the length of the TCP MD5 option. TCP adds an MD5 signature to each transmitted packet. The peer inserts the resulting 16-byte MD5 signature into the following TCP options: kind=19, length=18.

MD5 signature verification

After the switch receives a packet, it performs three tests. The following table lists the tests and the event message that TCP logs if a test fails.

Table 43: MD5 signature verification rules on BGP TCP packets

Condition tested	Action on success	Failure event message
Is the connection configured for MD5 authentication?	Verify that the packet contains a kind=19 option.	`TCP MD5 No Signature`
Is MD5 authentication enabled for this TCP connection?	TCP computes the expected MD5 signature.	`TCP MD5 Authentication Disabled`
Does the computed MD5 signature match the received MD5 signature?	TCP sends the packet to BGP.	`TCP MD5 Invalid Signature`

If a packet passes a test, it proceeds to the next test. After a packet passes all three tests, TCP accepts the packet and sends it to BGP.

If a packet fails a test, the switch logs an event, increments the count of TCP connection errors (wfTcpConnMd5Errors), and discards the packet. The TCP connection remains open.

BGP and route redistribution

Redistribution imports routes from one protocol to another. Redistribution sends route updates for a protocol-based route through another protocol. For example, if OSPF routes exist in a router and they must travel through a BGP network, then configure redistribution of OSPF routes through BGP. This sends OSPF routes to a router that uses BGP.

The switch can redistribute routes:

- on an interface basis.
- on a global basis between protocols on a single VRF instance (intraVRF).
- between the same or different protocols on different VRF instances (interVRF).

Configure interface-based redistribution by configuring a route policy and apply it to the interface. Configure the match parameter to the protocol from which to learn the routes.

You can redistribute routes on a global basis, rather than on an interface basis. Use the **`ip bgp redistribute`** command to accomplish the (intraVRF) redistribution of routes through BGP, so that BGP redistribution occurs globally on all BGP-enabled interfaces. This redistribution does not require a route policy, but you can use one for more control.

If you configure redistribution globally and on an interface, redistribution through the route policy takes precedence.

You can redistribute routes from a protocol in one VRF to BGP in another VRF. You can use a route policy for redistribution control. If you enable route redistribution between VRF instances, ensure that IP addresses do not overlap.

Use caution when you configure redistribution. An improperly configured parameter can cause the router to advertise learned eBGP routes out of your local AS. If this happens, the local AS can route other networks.

Do not use redistribution if you peer to an Internet Service Provider (ISP) and do not want traffic to transit your local AS.

When you redistribute OSPF routes into BGP, route priorities can create routing loops. Because BGP has a higher route preference than OSPF external type 1 and 2 routes, if you redistribute OSPF external type 1 and 2 routes into BGP, the router uses the BGP routes, which can cause a routing loop.

Route-maps and BGP neighbors

BGP Routing Information Base (BGP RIB) stores routing information received from different peers. BGP RIB has two types of BGP routes, External and Internal (Local). The routes learned from BGP neighbors are External routes and all imported routes are considered as Internal (Local) routes.

In BGP RIB, the OSPF routes redistributed into BGP are considered as Internal (Local) and are matched by route-type only when the keyword is set to **`local`**. When match route-type is set to **`external`**, the route-maps applied on BGP neighbors are ignored and the set operation is not performed.

Note

This is applied only on the route-maps applied to BGP neighbors in BGP RIB, and not considered when applying a route-map to the redistribute command.

BGP route redistribution and DvR

DvR Controllers redistribute routes (direct routes, static routes and the default route) into the DvR domain. You can configure redistribution of DvR host routes into BGP.

For information on DvR, see Distributed Virtual Routing on page 621.

BGP+

The switch extends the BGPv4 process to support the exchange of IPv6 routes using BGPv4 peering. BGP+ is an extension of BGPv4 for IPv6, which is indicated using the Address Family Identifier (AFI) in the BGP header.

The switch supports capabilities for AFI with the following values: 1 (IPv4) and 2 (IPv6). If the switch receives an OPEN message advertising an AFI with a different value, the connection is closed and a BGP notification message is sent to the peer mentioning unsupported capability.

BGP+ is only supported on the global VRF instance.

Note

Ensure you configure IPv6 forwarding for BGP+ to work.

Note that the BGP+ support on the switch is not an implementation of BGPv6. Native BGPv6 peering uses the IPv6 Transport layer (TCPv6) for establishing the BGPv6 peering, route exchanges, and data traffic.

The switch supports the exchange of IPv6 reachability information over IPv4 transport. To support BGP +, the switch supports two BGP protocol extensions, standards RFC 4760 (multi-protocol extensions to BGP) and RFC 2545 (MP-BGP for IPv6). These extensions allow BGPv4 peering to be enabled with IPv6 address family capabilities.

The implementation of BGP+ on the switch uses an existing TCPv4 stack to establish a BGPv4 connection. Optionally, nontransitive BGP properties are used to transfer IPv6 routes over the BGPv4 connection. Any BGP+ speaker has to maintain at least one IPv4 address to establish a BGPv4 connection.

Different from IPv4, IPv6 introduces scoped unicast addresses, identifying whether the address is global or link-local. When BGP+ is used to convey IPv6 reachability information for interdomain routing, it is sometimes necessary to announce a next hop attribute that consists of a global address and a link-local address. For BGP+, no distinction is made between global and site-local addresses.

The BGP+ implementation includes support for BGPv6 policies, including redistributing BGPv6 into OSPFv3, ISIS, RIPng, and advertising OSPFv3, ISIS, RIPng, IPv6 static and local routes into BGPv6 (through BGP+). It also supports the aggregation of global unicast IPv6 addresses.

When configuring BGP+ on the router that is enabled only for IPv6 (the router does not have an IPv4 address), then BGP router ID must be manually configured for the router.

BGP+ does not support confederations. You can configure confederations for IPv4 routes only.

The basic configuration of BGP+ is the same as BGPv4 with one additional parameter added and some existing commands altered to support IPv6 capabilities. You can enable and disable IPv6 route exchange by specifying the address family attribute as IPv6. Note that an IPv6 tunnel is required for the flow of IPv6 data traffic.

BGP+ tunnel

When you use BGP+ you must configure an IPv6 tunnel and static routes at BGP+ peers.

When BGP+ peers advertise route information, they use Update messages to advertise route information.

These RTM routes contain next-hop addresses from the BGP peer that the route was learned from.

The static routes correlate the next-hop addresses represented by the IPv4–mapped IPv6 address to a specific outgoing interface.

Following is one way to express a static route in an IPv6–configured tunnel for BGP+:

`ipv6 route 2001:DB8:0:0:0:ffff:192.0.2.0/24 cost 1 tunnel 10` where 2001:DB8:0:0:0:ffff:192.0.2.0 is the IPv4-mapped IPv6 address of the BGP peer at 192.0.2.0

ECMP with BGP+

The ECMP feature supports and complements BGP+ protocol.

The number of equal-cost-paths supported can differ by hardware platform. For more information, see *Fabric Engine Release Notes*.

You can use multiple paths for load sharing of traffic. These multiple paths allow faster convergence to other active paths in case of network failure. By maximizing load sharing among equal-cost paths, you can use your links between routers more efficiently when sending IP and IPv6 traffic. Equal Cost Multipath is formed using routes from the same protocol.

Note

To add BGP+ equal cost paths in the routing table, you must enable the following:

- IPv6 ECMP feature globally
- BGP multiple-paths attribute

BGPv6

BGP peering over IPv6 transport uses a BGPv6 peer to exchange IPv6 routes over an IPv6 transport layer. This is different than BGP+, which enables exchange of IPv6 routes over a BGPv4 peer. Also with BGP+, you must use an IPv6 tunnel to install and configure IPv6 routes in an IPv6 Routing Table Manager (RTM). BGP+ uses an IPv4 mapped IPv6 address for the next hop address and requires you to configure IPv6 static routes and install IPv6 routes in an IPv6 RTM where the next hop for the static route is an IPv6 tunnel interface.

BGPv6 supports the following:

- Input/Output policies.
- Redistribution of OSPFv3, IS-IS, IPv6 static route, and IPv6 direct routes into BGPv6.
- Aggregation of global unicast IPv6 addresses.

Note

BGP+ also supports the preceding features.

RFC

The switch supports the BGP mulitprotocol extension, as described in RFC 4760. Also supports RFC 2545 (MP-BGP for IPv6).

The BGP protocol extensions ensure peering can be enabled with IPv6 address family capabilities.

Route exchange

BGPv6 does not exchange any IPv4 routes. BGPv6 advertises or learns only IPv6 routes.

The following table shows the differences between BGPv4 and BGPv6 for route exchange.

	GRT/VRF	IPv4 Routes Exchange	IPv6 Routes Exchange
BGPv4	GRT	Supported	Supported (BGP+)
	VRF	Supported	Not supported **Note:** IPv6 over IPv4 tunnels is not yet virtualized.

	GRT/VRF	IPv4 Routes Exchange	IPv6 Routes Exchange
BGPv6	GRT	Not supported	Supported
	VRF	Not supported	Supported

Specify the address family attribute as IPv6 to enable IPv6 route exchange.

You can enable IPv6 route exchange by specifying the address family attribute as IPv6. Optionally, you can use non-transitive BGP properties to exchange IPv6 routes between the BGPv6 peering. Any BGPv6 speaker must maintain at least one IPv6 address to establish a BGPv6 connection. The IPv6 scoped unicast addresses can identify the address as global or link-local. If you use BGPv6 to convey IPv6 reachability information for interdomain routing, you can also announce a next hop attribute that consists of a global address and a link-local address.

Note

BGPv6 does not support adjacency on link-local.

Authentication

BGPv6 uses IPsec for security. MD-5 authentication is supported for BGPv4 and is not supported for BGPv6.

The following table shows the differences between BGPv4 and BGPv6 for authentication.

	MD5	IPsec	SHA1/SHA2
BGPv4	Supported	Not supported	Not supported
BGPv6	Not supported	Supported **Note:** IP Sec is not virtualized, hence BGPv6 is supported only in Global Router mode, and not supported in VRF mode.	Not supported

MD5 authentication

MD5 authentication is not supported in BGPv6 so it is not necessary to enable MD5 authentication.

IPsec

Only IPsec is supported. Therefore, MD5 authentication cannot be configured.

Consistency checking

Includes consistency checking for MD5 authentication. BGP peer and BGP peer group configuration for IPv6 addresses include a rule to block MD5 authentication. If you attempt to configure MD5 authentication, you will receive an error message.

IPv6 tunneling

With BGPv6, IPv6 tunneling is not required for IPv6 data traffic flow. An IPv6 tunnel is required for BGP +.

Circuitless IP

Circuitless IP (CLIP) is a virtual (or loopback) interface that you do not associate with a physical port. You can use a CLIP interface to provide uninterrupted connectivity to your switch as long as an actual path exists to reach the device. For example, as shown in the following figure, a physical point-to-point link exists between R1 and R2 along with the associated addresses (195.39.1.1/30 and 195.39.1.2/30). Note also that an iBGP session exists between two additional addresses 195.39.128.1/32 (CLIP 1) and 195.39.128.2/32 (CLIP 2).

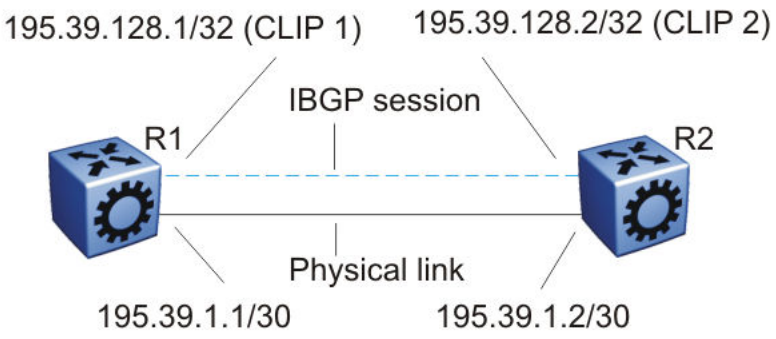

Figure 32: Routers with iBGP connections

The system treats the CLIP interface like an IP interface and treats the network associated with the CLIP as a local network attached to the device. This route always exists and the circuit is always up because no physical attachment exists.

The router advertises routes to other routers in the domain either as external routes using the route-redistribution process or after you enable OSPF in a passive mode to advertise an OSPF internal route. You can configure only the OSPF protocol on the CLIP interface. After you create a CLIP interface, the system software programs a local route with the CPU as the destination ID. The CPU processes all packets destined to the CLIP interface address. The system treats other packets with destination addresses associated with this network (but not to the interface address) as if they are from an unknown host.

A circuitless IP or CLIP address is a logical IP address for network management, as well as other purposes. The CLIP is typically a host address (with a 32 bit subnet mask). Configure the OSPF router ID to the configured CLIP address. By default, the BGP router ID is automatically equivalent to the OSPF router ID.

For information about how to configure CLIP interfaces, see Configure a CLIP Interface on page 1627 and Configure a Circuitless IPv4 Interface on page 1652.

BGP Configuration Considerations and Limitations

Use the information in this section to help you configure BGP on your switch, which supports BGPv4 as described in RFC 1771.

BGP Implementation Guidelines

The following list provides guidelines to successfully implement BGP:

- BGP does not operate with an IP router in nonforwarding (host-only) mode. Make sure that the routers you want BGP to operate with are in forwarding mode.
- If you use BGP for a multihomed AS (one that contains more than a single exit point), use OSPF for your IGP and BGP for your sole exterior gateway protocol, or use intra-AS iBGP routing.
- If OSPF is the IGP, use the default OSPF tag construction. Using EGP or modifying the OSPF tags makes network administration and proper configuration of BGP path attributes difficult.
- For routers that support both BGP and OSPF, the OSPF router ID and the BGP identifier must be the same IP address. The BGP router ID automatically uses the OSPF router ID.
- In configurations where BGP speakers reside on routers that have multiple network connections over multiple IP interfaces (the typical case for iBGP speakers), consider using the address of the circuitless (virtual) IP interface as the local peer address. In this configuration, you ensure that BGP is reachable as long as an active circuit exists on the router.
- By default, BGP speakers do not advertise or inject routes into the IGP. You must configure route policies to enable route advertisement.
- Coordinate routing policies among all BGP speakers within an AS so that every BGP border router within an AS constructs the same path attributes for an external path.
- Configure accept and announce policies on all iBGP connections to accept and propagate all routes. Make consistent routing policy decisions on external BGP connections.

Minimum Requirements

You must configure the following minimum parameters:

- router ID
- local AS number
- enable BGP globally
- BGP neighbor peer session: remote IP addresses
- enable BGP peers
- When you use both BGP and OSPF, the OSPF and BGP router ID must be the same.

The router ID must be a valid IP address of an IP interface on the router or a CLIP address. BGP update messages use this IP address. By default, the BGP router ID automatically uses the OSPF router ID.

You cannot configure the BGP router ID if you configure BGP before you configured the OSPF router ID. You must first disable BGP, configure the OSPF route ID, and then enable BGP globally.

You can add BGP policies to the BGP peer configuration to influence route decisions. BGP policies apply to the peer through the soft-reconfiguration commands.

After you configure the switch for BGP, some parameter changes can require you to enable or disable the BGP global state or the neighbor admin-state.

You can dynamically modify BGP policies. On the global level, the BGP redistribution command has an apply parameter that causes the policy to take effect after you issue the command.

BGP Neighbor Maximum Prefix Configuration

By default, the maximum prefix parameter limits 12 000 NLRI messages for each neighbor. The maximum prefix parameter limits the number of routes that the switch can accept.

The maximum prefix parameter prevents large numbers of BGP routes from flooding the network if you implement an incorrect configuration. You can assign a value to the maximum prefix limit, including 0 (0 means unlimited routes). When you configure the maximum prefix value, consider the maximum number of active routes that your equipment configuration can support.

BGP and OSPF Interaction

RFC1745 defines the interaction between BGP and OSPF when OSPF is the IGP within an autonomous system. For routers that use both protocols, the OSPF router ID and the BGP ID must be the same IP address. You must configure a BGP route policy to allow BGP advertisement of OSPF routes.

Interaction between BGPv4 and OSPF can advertise supernets to support CIDR. BGPv4 supports interdomain supernet advertisements; OSPF can carry supernet advertisements within a routing domain.

BGP and Internet Peering

By using BGP, you can perform Internet peering directly between the switch and another edge router. In such a scenario, you can use each switch for aggregation and link it with a Layer 3 edge router, as shown in the following figure.

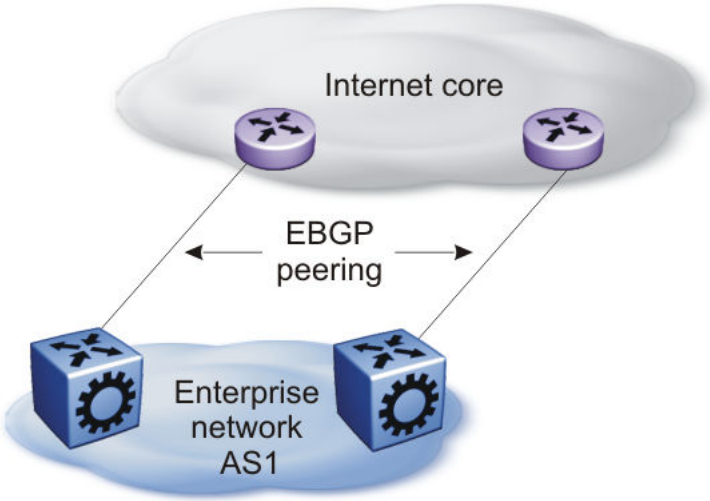

Figure 33: BGP and Internet peering

In cases where the Internet connection is single-homed, to reduce the size of the routing table, as a best practice, advertise Internet routes as the default route to the IGP.

For route scaling information, see *Fabric Engine Release Notes*.

Routing Domain Interconnection with BGP

You can implement BGP so that autonomous routing domains, such as OSPF routing domains, connect. This connection allows the two different networks to begin communicating quickly over a common

infrastructure, thus providing additional time to plan the IGP merger. Such a scenario is particularly effective when you need to merge two OSPF area 0.0.0.0s, as shown in the following figure.

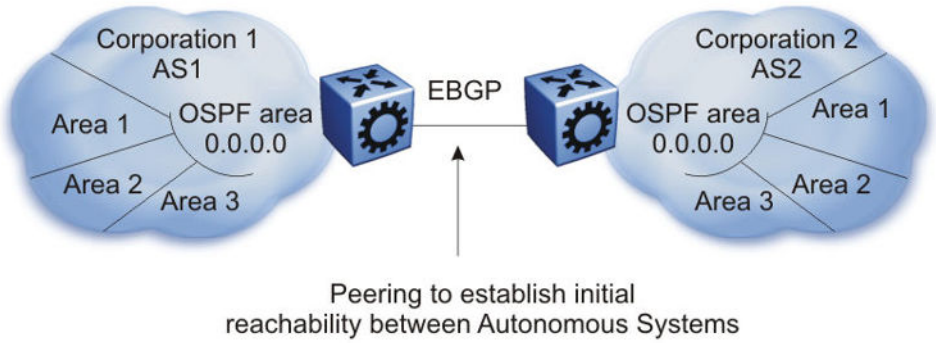

Figure 34: Routing Domain Interconnection with BGP

BGP and Edge Aggregation

You can perform edge aggregation with multiple point of presence or edge concentrations. The switch supports 12 pairs (peering services). You can use BGP to inject dynamic routes rather than using static routes or RIP (see the following figure).

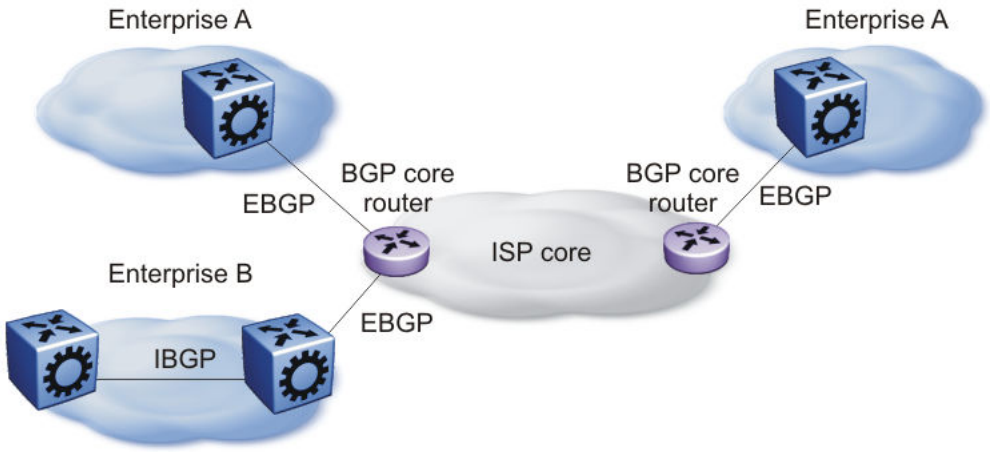

Figure 35: BGP and Edge Aggregation

BGP and ISP Segmentation

You can use the platform as a peering point between different regions or autonomous systems (AS) that belong to the same ISP. In such cases, you can define a region as an OSPF area, an AS, or a part of an AS.

You can divide the AS into multiple regions that each run different IGPs. Interconnect regions logically by using a full iBGP mesh. Each region then injects its IGP routes into iBGP and also injects a default route inside the region. For destinations that do not belong to the region, each region defaults to the BGP border router.

Use the community parameter to differentiate between regions. To provide Internet connectivity, this scenario requires you to make your Internet connections part of the central iBGP mesh (see the following figure).

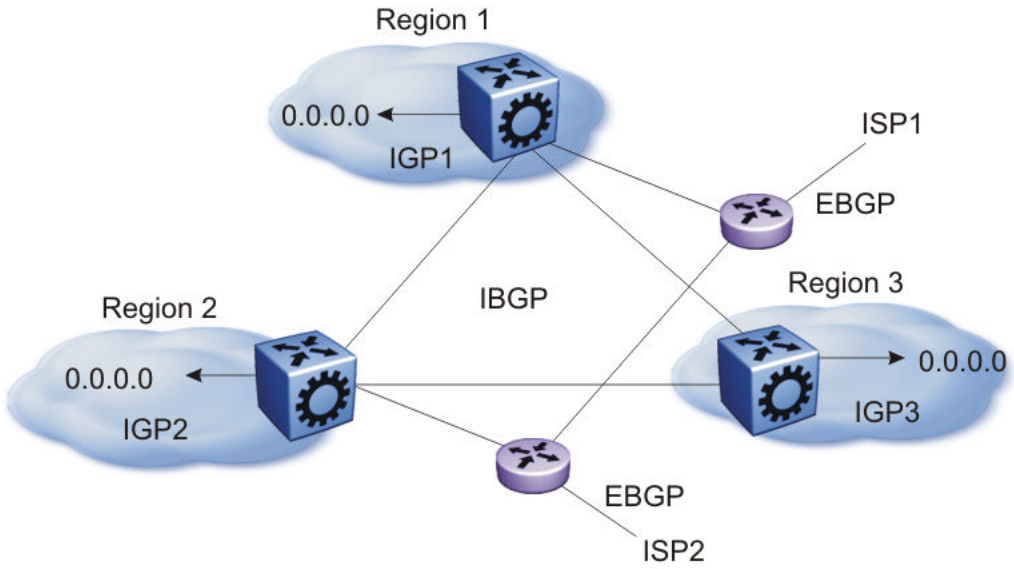

Figure 36: Multiple Regions Separated by iBGP

In the preceding figure, consider the following:

- The AS is divided into three regions that each run different and independent IGPs.
- Regions logically interconnect by using a full-mesh iBGP, which also provides Internet connectivity.
- Internal non-BGP routers in each region default to the BGP border router, which contains all routes.
- If the destination belongs to another region, the traffic is directed to that region; otherwise, the traffic is sent to the Internet connections according to BGP policies.

To configure multiple policies between regions, represent each region as a separate AS. Implement eBGP between autonomous systems, and implement iBGP within each AS. In such instances, each AS injects its IGP routes into BGP, where they are propagated to all other regions and the Internet.

The following figure shows the use of eBGP to join several autonomous systems.

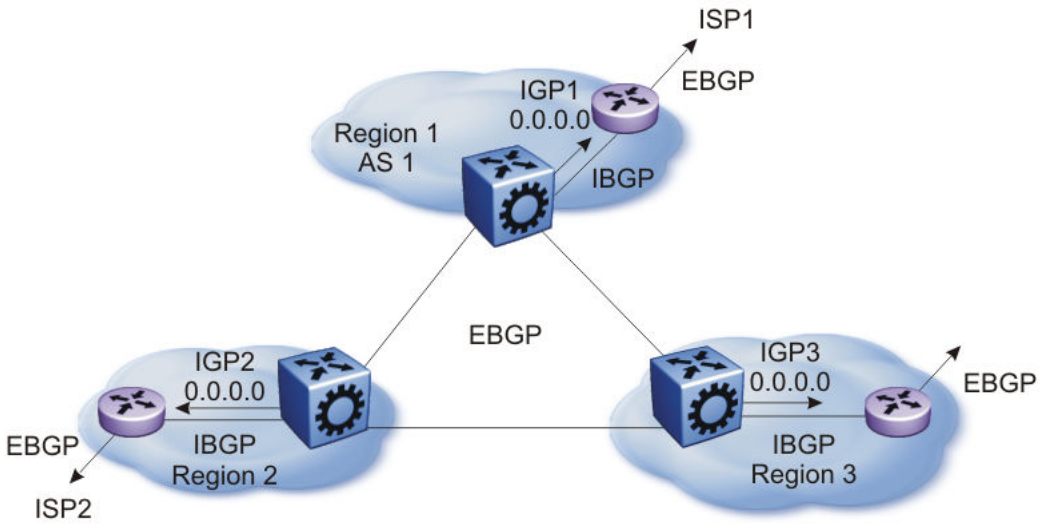

Figure 37: Multiple regions Separated by eBGP

You can obtain AS numbers from the Inter-Network Information Center (NIC) or use private AS numbers. If you use private AS numbers, be sure to design your Internet connectivity carefully. For example, you can introduce a central, well-known AS to provide interconnections between all private autonomous systems and the Internet. Before it propagates the BGP updates, this central AS strips the private AS numbers to prevent them from leaking to providers.

The following figure illustrates a design scenario in which you use multiple OSPF regions to enable peering with the Internet.

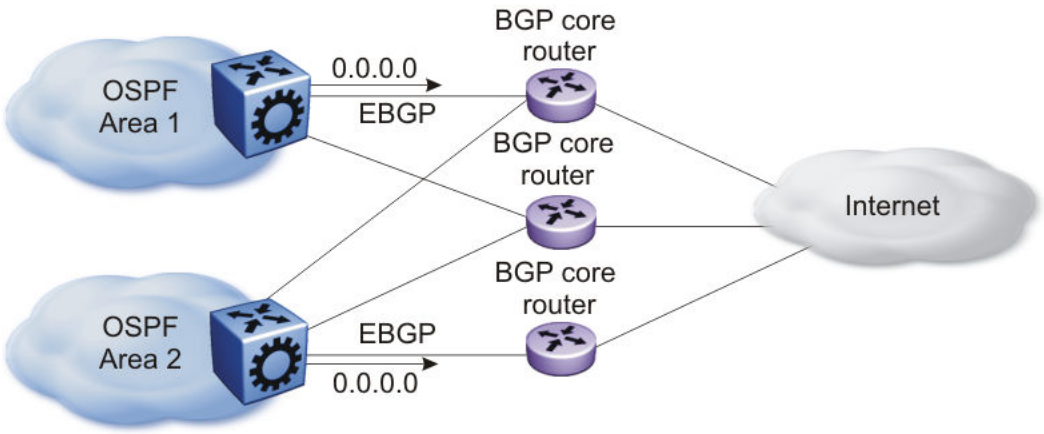

Figure 38: Multiple OSPF Regions Peering with the Internet

BGP Peers

The following list provides rules related to BGP peers:

- Only metric (=MED) attribute is applied to the output policy if its BGP peer is IBGP
- metric (=MED) and community attributes are applied to output policy if its BGP peer is EBGP

- To influence EBGP and IBGP peers with all applicable BGP attributes, configure **route-map** as an option to **neighbor** command, for example, `neighbor 192.0.2.2 out-route-map policy1`

BGP and Route Aggregation

When you configure the attribute-map with the aggregate command, community, metric, AS Path, and next-hop attributes are set, while the origin attribute is not set.

BGP Session Flapping when IPv6 Forwarding is Enabled or Disabled

In a BGP session that is established with IPv4 and IPv6 capability, disabling or enabling IPv6 forwarding results in BGP session flapping due to capability negotiation. The flapping session in turn affects the IPv4 routing through BGP and the BGP session gets terminated. Ultimately, a capability negotiation takes place to re-establish the IPv4 and IPv6 capable session.

BGP configuration using CLI

Configure the Border Gateway Protocol (BGP) to create and maintain an interdomain routing system that guarantees loop-free routing information between autonomous systems (AS).

For information about how to configure route policies for BGP, see Configure IP Route Policies on page 2610.

Configure BGP

Configure BGP globally to enable BGP on the switch and determine how BGP operates.

Before You Begin

- To configure the suppress-map, advertise-map, or attribute-map options, the route policy for those options must exist.
- For initial BGP configuration, you must know the AS number.
- You configure BGP on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. The VRF must have an RP Trigger of BGP.

Note

Route refresh is not currently supported on non-default VRFs.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Specify the AS number and enable BGP:

   ```
   router bgp [WORD <0-11>] [enable]
   ```

   Note

   - This command applies only on VRF 0. To enable BGP globally on other VRFs, use the **ip bgp enable** command. You must configure BGP locally before you configure it globally.
   - You can also confiure AS number on non-default VRFs. For more information, see Configure an AS Number for a Non-default VRF on page 416.

3. Access Router BGP Configuration mode:

   ```
   router bgp
   ```

4. Configure BGP variables or accept the default values.

Example

Specify the AS number and enable BGP:

```
Switch(config)#router bgp 3 enable
```

Access Router BGP Configuration mode:

```
Switch(config)#router bgp

Switch(router-bgp)#
```

Variable Definitions

The following table defines parameters for the **router bgp** command.

Variable	Value
WORD <0-11>	Specifies the AS number. You cannot enable BGP until you change the local AS to a value other than 0.
enable	Enables BGP on the router.

Use the data in the following table to use the BGP variables in BGP and VRF Router Configuration mode.

Variable	Value
aggregate-address WORD<1-256>	Specifies an IP address and its length in the form {a.b.c.d/len}, or an IPv6 address and its length in the form {ipv6addr/len}.
auto-peer-restart enable	Enables the process that automatically restarts a connection to a BGP neighbor. The default value is enable.
auto-summary	When enabled, BGP summarizes networks based on class limits, for example, Class A, B, and C networks. The default value is enable.

Variable	Value
bgp always-compare-med	Enables the comparison of the multi-exit discriminator (MED) parameter for paths from neighbors in different autonomous systems. The system prefers a path with a lower MED over a path with a higher MED. The default value is disable.
bgp aggregation	Enables the aggregation feature on the interface.
bgp client-to-client reflection	Enables or disables route reflection between two route reflector clients. This variable applies only if the route reflection value is enable. The default value is disable. You can enable route reflection even when clients are fully meshed. This variable only applies to VRF 0. Example: `Switch(router-bgp)# bgp client-to-client reflection System Response: Restart or soft-restart BGP for the change to take effect.`
bgp cluster-id {A.B.C.D}	Configures a cluster ID. This variable applies only if the route reflection value is enable, and if multiple route reflectors are in a cluster. *{A.B.C.D}* is the IP address of the reflector router. This variable only applies to VRF 0. Example: `Switch(router-bgp)# bgp cluster-id 0.0.0.0`
bgp confederation identifier <0-4294967295> [peers WORD<0-255>]	Configures a BGP confederation. *identifier<0-4294967295>* specifies the confederation identifier. Use 0–65535 for 2-byte AS and <0-4294967295> for 4-byte AS. *peers WORD<0-255>* lists adjoining autonomous systems that are part of the confederation in the format (5500,65535,0,10,...,...). Use quotation marks (") around the list of autonomous systems. **Note:** Use this command only on VRF 0. Example: `Switch(router-bgp)# bgp confederation identifier 1 peers "20 30 40"`
bgp default local-preference <0-2147483647>	Specifies the default value of the local preference attribute. The default value is 0. You must disable BGP before you can change the default value. Example: `Switch(router-bgp)# bgp default local-preference 2-12`
bgp deterministic-med enable	Enables deterministic MED. Example: `Switch(router-bgp)# bgp deterministic-med enable`

Variable	Value
bgp multiple-paths <1-8>	Configures the maximum number of equal-cost-paths that are available to a BGP router by limiting the number of equal-cost-paths the routing table can store. The default value is 1. Example: `Switch(router-bgp)# bgp multiple-paths 4` Note: Configuring the *bgp multiple-paths* variable does not affect existing routes. The routing table does not show ECMP routes; instead only one route is shown in the routing table. To view Equal-Cost Multipath (ECMP) routes, receive the routes after executing the *bgp multiple-paths* variable, or toggle the BGP state. The number of equal-cost-paths supported can differ by hardware platform. For more information, see *Fabric Engine Release Notes*.
comp-bestpath-med-confed enable	When enabled, compares MED attributes within a confederation. The default value is disable. This variable only applies to VRF 0. Example: `Switch(router-bgp)# comp-bestpaht-med-confed enable Restart or soft-restart BGP for the change to take effect`
debug-screen <off|on>	Displays debug messages on the console, or saves them in a log file. Disable BGP screen logging (off) or enable BGP screen logging (on). Example: `Switch(router-bgp)# debug-screen on System Response:BGP Screen Logging is On`
default-information originate	Enables the advertisement of a default route to peers, if the route exists in the routing table. The default value is disable.
default-information ipv6-originate	Enables the advertisement of an IPv6 default route to peers, if the route exists in the routing table. The default value is disable.
default-metric <-1-2147483647>	Configures a value to send to a BGP neighbor to determine the cost of a route a neighbor uses. A default metric value solves the problems associated with redistributing routes that use incompatible metrics. For example, whenever metrics do not convert, using a default metric provides a reasonable substitute and redistribution proceeds. Use this option in conjunction with the redistribute commands so the current routing protocol uses the same metric for all redistributed routes. The default value is 0.
flap-dampening enable	Enables route suppression for routes that flap on and off. The default value is disable.

Variable	Value
global-debug mask WORD<1-100>	Displays specified debug information for BGP global configurations. The default value is none. • *<WORD 1-100>* is a list of mask choices separated by commas with no space between choices. Mask choices are: • *none* disables all debug messages. • *all* enables all debug messages. • *error* enables display of debug error messages. • *packet* enables display of debug packet messages. • *event* enables display of debug event messages. • *trace* enables display of debug trace messages. • *warning* enables display of debug warning messages. • *state* enables display of debug state transition messages. • *init* enables display of debug initialization messages. • *filter* enables display of debug messages related to filtering. • *update* enables display of debug messages related to sending and receiving updates. Example: `Switch(router-bgp)# global-debug mask event, trace, warning, state`
ibgp-report-import-rt enable	Configures BGP to advertise imported routes to an interior BGP (iBGP) peer. This variable enables or disables advertisement of nonBGP imported routes to other iBGP neighbors. The default value is enable.
ignore-illegal-rtrid enable	When enabled, BGP overlooks an illegal router ID. For example, you can configure this variable to enable or disable the acceptance of a connection from a peer that sends an open message using a router ID of 0 (zero). The default value is enable.
neighbor-debug-all mask WORD<1-100>	Displays specified debug information for BGP neighbors. The default value is none. For mask options, see the *global-debug mask WORD<1-100>* variable. Example: `Switch(router-bgp)# neighbor-debug-all mask error, packet, event.trace, state, filter`
no-med-path-is-worst enable	Enables BGP to treat an update without a MED attribute as the worst path. The default value is disable.
quick-start enable	Enables the quick-start flag for exponential backoff.
route-reflector enable	Enables the reflection of routes from iBGP neighbors. The default value is disable. This variable only applies to VRF 0.
route-refresh	Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates it contains in its database that are eligible for the peer that issues the request. This variable only applies to VRF 0.

Variable	Value
router-id {A.B.C.D}	Specifies the BGP router ID in IP address format. This variable only applies to VRF 0.
synchronization	Enables the router to accept routes from BGP peers without waiting for an update from the IGP. The default value is enable.
traps enable	Enables BGP traps.
vrf-as WORD<0-11>	Configures an AS number on a specific VRF instance. Use 0–65535 for a 2-byte AS and <0-4294967295> for a 4-byte AS. The default value of 0, or configuring the local-as in the VRF to 0, is equivalent to deleting the local-as configured on user-defined VRFs, and in both cases the local-as on the VRF becomes the local-as on the GlobalRouter.

Job Aid

Use debug command values to control debug messages for global BGP message types, and for message types associated with a specified BGP peer or peer group.

Tip

The following tips can help you use the debug commands:

- Display debug commands for multiple mask choices by entering the mask choices separated by commas, with no space between choices.
- To end (disable) the display of debug messages, use the mask choice of none.
- You can save debug messages in a log file, or you can display the messages on your console using the debug-screen command.

For more information about the logged debug messages, see *Fabric Engine Alarms and Logs Reference*.

Configure 4-byte AS numbers

Configure Autonomous System (AS) numbers using the 4-byte format and represent the numbers in octets.

Before You Begin

- You cannot modify the global BGP configuration unless BGP is disabled.
- Configure the local AS number at Global Router (VRF0) only.
- Make sure that you define AS numbers in policies the same way that you configure them for the router. The AS list for the route policies accepts AS number only in the **asplain** format. If you create policies using **asplain** and configure the switch with **asdot**, the match will not occur.

About This Task

Use BGP 4-byte AS numbers to ensure the continuity of loop-free inter-domain routing information between autonomous systems and to control the flow of BGP updates as 2-byte AS numbers will deplete soon. AS Plain notation format is the default and the preferred form of representing 4-byte AS numbers over the AS dot notation format.

You have an option to configure AS dot notation format as well. With AS dot notation, analyzing and troubleshooting any issues encountered becomes difficult as it is incompatible with the regular expressions used by most of the network providers.

If you enable 4-byte AS numbers, or the dotted octet notation, for the Global Router (VRF0), the configuration is inherited by user-defined VRFs. You cannot enable 4-byte AS numbers on individual user-defined VRFs.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Disable BGP to change the AS number format.

   ```
   no router bgp enable
   ```

3. Enable the 4-byte AS numbering format.

   ```
   router bgp as-4-byte enable
   ```

4. To use the dotted octet notation, enable as-dot.

   ```
   router bgp as-dot enable
   ```

5. Configure the 4-byte AS number and enable BGP. If you have enabled as-dot, enter the AS number in octet.

   ```
   router bgp WORD<0-11> enable
   ```

6. Access Router BGP Configuration mode:

   ```
   router bgp
   ```

7. (Optional) Configure BGP confederation identifier.

   ```
   bgp confederation identifier <0-4294967295>
   ```

8. (Optional) Configure BGP confederation peers.

   ```
   bgp confederation peers WORD<0-255>
   ```

Example

Disable BGP to change the AS number format.

```
Switch(config)# no router bgp enable
```

Enable the 4-byte AS numbering format.

```
Switch(config)# router bgp as-4-byte enable
```

To use the dotted octet notation, enable as-dot.

```
Switch(config)# router bgp as-dot enable
```

Configure the 4-byte AS number and enable BGP.

```
Switch(config)# router bgp 65536 enable
```

Variable Definitions

The following table defines parameters for the **router bgp** command.

Variable	Value
as-4-byte <enable>	Enables the switch for using 4 byte numbers for an autonomous system (AS). The default value is disable.
as-dot <enable>	Enables or disables representing AS numbers in octets. The default is disable so the switch uses the plain notation format. If you enable the 4-byte-as and as-dot parameters, enter numbers in the range of 1.0 to 65535.65535. The default value is disable. Note: This parameter is not supported with BGP+.
WORD <0-11> enable	Sets the local autonomous system (AS) number. You cannot change local-as when BGP is set to enable. • To set a 2-byte local AS number, enter a local-as number in the range of 0 to 65535. • To set a 4-byte local-as number, enable the 4-byte as variable and enter a number in the range of 0 to 4294967295. Note: If as-4-byte is set to false, the range for AS number is 0–65535 and if as-4-byte is set to true, the range is 0–4294967295. If you enable as-dot, enter the AS number in octets in the range of 1.0 to 65535.65535. Note: This parameter is not supported with BGP+.

Configure Aggregate Routes

Configure aggregate routes so that the router advertises a single route (aggregate route) that represents all destinations. Aggregate routes also reduce the size of routing tables.

Before You Begin

- Disable BGP before you enable aggregation.
- You need the appropriate aggregate address and mask.
- If required, policies exist.
- You configure BGP on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. The VRF must have an RP Trigger of BGP.

Note

Route refresh is not currently supported on non-default VRFs.

Procedure

1. Enter BGP Router Configuration mode:

   ```
   enable

   configure terminal

   router bgp
   ```

2. Enable BGP aggregation:

   ```
   bgp aggregation enable
   ```

3. Add an aggregate route to the routing table:

   ```
   aggregate-address WORD<1-256> {advertise-map WORD<0-1536>] [as-set]
   [attribute-map WORD<0-1536>] [summary-only] [suppress-map WORD<0-
   1536>]
   ```

4. Exit to Global Configuration mode:

   ```
   exit
   ```

5. Enable BGP:

   ```
   router bgp [<0-65535>] [enable]
   ```

Example

Add an aggregate route to the routing table:

```
Switch(router-bgp)# aggregate-address 2001:DB8::/32 advertise-map map1
attribute-map map2
```

Enable BGP:

```
Switch(router-bgp)# router bgp 4 enable
```

Variable Definitions

The following table defines parameters for the **aggregate-address** command.

Variable	Value
advertise-map WORD<0-1536>	Specifies the route map name for route advertisements.
as-set	Enables autonomous system information. The default value is disable.
attribute-map WORD<0-1536>	Specifies the route map name.
WORD <1-256>	Specifies an IP address and its length in the appropriate form. The value must be entered in the format a.b.c.d/len or ipv6addr/len.

Variable	Value
summary-only	Enables the summarization of routes not included in routing updates. This variable creates the aggregate route and suppresses advertisements of more specific routes to all neighbors. The default value is disable.
suppress-map WORD<0-1536>	Specifies the route map name for the suppressed route list.

The following table defines parameters for the **router bgp** command.

Variable	Value
<0-65535>	Specifies the AS number. You cannot enable BGP until you change the local AS to a value other than 0.
enable	Enables BGP on the router.

Configure Allowed Networks

Configure network addresses to determine the network addresses that BGP advertises. The allowed addresses determine the BGP networks that originate from the switch.

Before You Begin

- You configure BGP on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. The VRF must have an RP Trigger of BGP.

Procedure

1. Enter BGP Router Configuration mode:

   ```
   enable

   configure terminal

   router bgp
   ```

2. Specify IGP network prefixes for BGP to advertise:

   ```
   network <WORD 1-256> [metric <0-65535>]
   ```

Example

Specify IGP network prefixes for BGP to advertise:

```
Switch(router-bgp)# network 2001:DB8::/32 metric 32
```

Variable Definitions

The following table defines parameters for the **network** command.

Variable	Value
WORD <1-256>	Specifies an IP address and its length in the appropriate form.
metric <0-65535>	Specifies the metric to use when the system sends an update for the routes in the network table. The metric configures the MED for the routes advertised to eBGP peers. The range is 0–65535.

Configure BGP Peers or Peer Groups

Configure peers and peer groups to simplify BGP configuration and make updates more efficient.

BGP speakers can have many neighbors configured with similar update policies. For example, many neighbors use the same distribute lists, filter lists, outbound route maps, and update source. Group the neighbors that use the same update policies into peer groups and peer associations.

Note

- If required, route policies exist.
- You configure BGPv4 on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. The VRF must have an RP Trigger of BGP.
- Route refresh is not currently supported on non-default VRFs.
- Not all parameters are supported on non-default VRFs.

About This Task

Many of the command variables in this procedure use default values. You can accept the default values or change them to customize the configuration.

Procedure

1. Enter BGP Router Configuration mode:

   ```
   enable

   configure terminal

   router bgp
   ```

2. Create a peer or peer group:

   ```
   neighbor WORD<0-1536>
   ```

3. Apply a route policy to all incoming routes:

   For BGPv4: `neighbor WORD<0-1536> in-route-map WORD<0-256>`

   For BGPv6: `neighbor WORD<0-1536> ipv6-in-route-map WORD<0-256>`

4. Apply a route policy to all outgoing routes:

   For BGPv4: `neighbor WORD<0-1536> out-route-map WORD<0-256>`

   For BGPv6: `neighbor WORD<0-1536> ipv6-out-route-map WORD<0-256>`
5. (Optional) Configure the source IP address:

   `neighbor WORD<0-1536> update-source WORD<1-256>`
6. Enable MD5 authentication (for BGPv4):

   `neighbor WORD<0-1536> MD5-authentication enable`
7. Specify an MD5 authentication password (for BGPv4):

   `neighbor password <nbr_ipaddr|peer-group-name> WORD<0-1536>`
8. Change the default values for other command variables as required.
9. Enable the configuration:

   `neighbor WORD<0-1536> enable`

Example

Create a peer or a peer group:

```
Switch(router-bgp)# neighbor peergroupa
```

Apply a route policy (in-route-map or out-route-map) to all incoming or outgoing routes:

```
Switch(router-bgp)# neighbor peergroupa in-route-map map1 out-route-map
map2
```

Configure the source IP address:

```
Switch(router-bgp)# neighbor peergroupa update-source 192.0.2.1
```

Enable MD5 authentication:

```
Switch(router-bgp)# neighbor peergroupa MD5-authentication enable
```

Specify an MD5 authentication password:

```
Switch(router-bgp)# neighbor password peergroupa password
```

Enable the configuration:

```
Switch(router-bgp)# neighbor peergroupa enable
```

Variable Definitions

The following table defines parameters for the **neighbor** command.

Variable	Value
address-family <ipv6>	Enables the IPv6 address family on BGP neighbor. `Switch(router-bgp)# neighbor peergroupa address-family ipv6`
advertisement-interval <5-120>	Specifies the time interval, in seconds, that transpires between each transmission of an advertisement from a BGP neighbor. The default value is 5 seconds. `Switch(router-bgp)# neighbor peergroupa advertisement-interval 26 enable` The route advertisement interval feature is implemented using the time stamp that indicates when each route is advertised. The time stamp is marked to each route so that the route advertisement interval is compared to the time stamp and BGP is then able to make a decision about whether the route advertisement can be sent or it should be delayed when a better route is received. This feature does not work for a withdraw route because the route entry is already removed when the processing route advertisement is sent and the time stamp marked in the route entry cannot be obtained.
allow-as-in	Allows BGP to inject updates.
default-ipv6-originate	Enables IPv6 BGP neighbor default originate. `Switch(router-bgp)# neighbor peergroupa default-ipv6-originate`
default-originate	Enables the switch to send a default route advertisement to the specified neighbor. A default route does not need to be in the routing table. The default value is disable. Do not use this command if **default-information originate** is globally enabled. `Switch(router-bgp)# neighbor peergroupa default-originate enable peer-group test`
ebgp-multihop	Enables a connection to a BGP peer that is more than one hop away from the local router. The default value is disable. `Switch(router-bgp)# neighbor peergroupa ebgp-multihop retry-interval 3 timers 4 5`
enable	Enables the BGP neighbor.
fall-over bfd	Enable fall-over Bidirectional Forwarding Detection (BFD).
in-route-map WORD<0-256>	Applies a route policy rule to all incoming routes that are learned from, or sent to, the peers or peer groups of the local router. The local BGP router is the BGP router that allows or disallows routes and configures attributes in incoming or outgoing updates. *WORD<0-256>* is an alphanumeric string length (0–256 characters) that indicates the name of the route map or policy. `Switch(router-bgp)# neighbor peergroupa in-route-map map1 address-family ipv6`

Variable	Value
ipv6-in-route-map WORD <0-256>	Creates IPv6 in route map. *WORD <0-256>* specifies the route map name in the range of 0 to 256 characters. `Switch(router-bgp)# neighbor peergroupa ipv6- in-route-map map1`
ipv6-max-prefix <0-2147483647>	Configures a limit on the number of routes that the router can accept from a neighbor. The default value is 12000 routes. A value of 0 (zero) indicates that no limit exists.
ipv6-out-route-map WORD <0-256>	Creates IPv6 out route map. *WORD <0-256>* specifies the route map name in the range of 0 to 256 characters. `Switch(router-bgp)# neighbor peergroupa ipv6-out-route-map map2`
max-prefix <0-2147483647>	Configures a limit on the number of routes that the router can accept from a neighbor. The default value is 12000 routes. A value of 0 (zero) indicates that no limit exists. `Switch(router-bgp)# neighbor peergroupa max-prefix 158 in-route-map map1 out-route-map map2`
MD5-authentication enable	Enables TCP MD5 authentication between two peers. The default value is disable.
neighbor-debug mask WORD<1-100>	Displays specified debug information for a BGP peer. The default value is none. *<WORD 1-100>* is a list of mask choices separated by commas with no space between choices. For example: *{<mask>,<mask>,<mask>...}*. Mask choices are: • *none* disables all debug messages. • *all* enables all debug messages. • *error* enables display of debug error messages. • *packet* enables display of debug packet messages. • *event* enables display of debug event messages. • *trace* enables display of debug trace messages. • *warning* enables display of debug warning messages. • *state* enables display of debug state transition messages. • *init* enables display of debug initialization messages. • *filter* enables display of debug messages related to filtering. • *update* enables display of debug messages related to sending and receiving updates. `Switch(router-bgp)# neighbor peergroupa neighbor-debug-mask event,trace,warning,state`
next-hop-self	When enabled, specifies that the next-hop attribute in an iBGP update is the address of the local router or the router that generates the iBGP update. The default value is disable. You can only configure this variable if the neighbor is disabled. `Switch(router-bgp)# neighbor peergroupa next-hop-self out-route-map map2 peer-group peergroupb`

Variable	Value
out-route-map WORD<0-256>	Applies a route policy rule to all outgoing routes that are learned from, or sent to, the peers or peer groups of the local router. The local BGP router is the BGP router that allows or disallows routes and configures attributes in incoming or outgoing updates. *WORD<0-256>* is an alphanumeric string length (0–256 characters) that indicates the name of the route map or policy.
peer-group <WORD 0-1536>	Adds a BGP peer to the specified subscriber group. You must create the specified subscriber group before you use this command.
remote-as <WORD 0-11>	Configures the remote AS number of a BGP peer or a peer-group. You must disable the admin-state before you can configure this variable. `Switch(router-bgp)# neighbor peergroupa remote-as As-number` *<WORD 0-11>* is an alphanumeric string length (0–11 characters) that indicates the AS number.
remove-private-as enable	Strips private AS numbers when an update is sent. The default value is enable.
retry-interval <1-65535>	Configures the time interval, in seconds, for the ConnectRetry timer. The default value is 120 seconds. `Switch(router-bgp)# neighbor 198.51.100.2 retry-interval 34` You can configure the retry interval for BGP neighbors only; you cannot configure the retry interval for BGP peer groups.
route-reflector-client	Configures the specified neighbor or group of neighbors as a route reflector client. The default value is disable. All configured neighbors become members of the client group and the remaining iBGP peers become members of the nonclient group for the local route reflector. **Note:** This variable only applies to VRF 0. `Switch(router-bgp)# neighbor`
route-refresh	Enables route refresh for the BGP peer. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates it contains in its database that are eligible for the peer that issues the request. **Note:** This variable only applies to VRF 0.
send-community	Enables the switch to send the update message community attribute to the specified peer. The default value is disable.
site-of-origin	Specifies a site of origin that is added to the extended communities list in each route from a specific peer.

Variable	Value
soft-reconfiguration-in enable	Enables the router to relearn routes from the specified neighbor or group of neighbors without restarting the connection after the policy changes in the inbound direction. The default value is disable.
timers <0-21845> <0-65535>	Configures timers, in seconds, for the BGP speaker for this peer. *<0-21845>* is the keepalive time. The default is 60. As a best practice, configure a value of 30 seconds. *<0-65535>* is the hold time. The default is 180. `Switch(router-bgp)# neighbor peergroupa timers 4 6`
update-source WORD<1-256>	Specifies the source IPv4 address {A.B.C.D.} or IPv6 address to use when the system sends BGP packets to this peer or peer group. You must disable the admin-state before you can configure this variable. `Switch(router-bgp)# neighbor peergroupa update-source 192.0.2.2 weight 560`
weight <0-65535>	Specifies the weight of a BGP peer or peer group, or the priority of updates the router can receive from that BGP peer. The default value is 0. If you have particular neighbors that you want to use for most of your traffic, you can assign a higher weight to all routes learned from that neighbor.
WORD<0-1536>	Specifies the peer IP address or the peer group name.

Configure a BGP Peer or Peer Group Password

Use this procedure to configure a BGP peer or peer group password for Transmission Control Protocol (TCP) MD5 authentication between two peers.

Note

You configure BGP peer on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix ip bgp. The VRF must have an RP Trigger of BGP. Route refresh is not currently supported on non-default VRFs.

Procedure

1. Enter BGP Router Configuration mode:

   ```
   enable

   configure terminal

   router bgp
   ```

2. Assign a BGP peer or peer group password:

   ```
   neighbor password <nbr_ipaddr|peer-group=name> WORD <0-1536>
   ```

Example

Assign a BGP peer or peer group password:

```
Switch(router-bgp)# neighbor password peergroupa password1
```

Variable Definitions

The following table defines parameters for the **neighbor password <nbr_ipaddr|peer-group-name>** command.

Variable	Value
password <nbr_ipaddr|peer-group-name> WORD <0-1536>	Specifies a password for TCP MD5 authentication between two peers. `WORD <0-1536>` is an alphanumeric string length from 0 to 1536 characters. To disable this option, use **no** operator with the command. To configure this option to the default value, use **default** operator with the command.

Configure Redistribution to BGP

Configure a redistribution entry to announce routes of a certain source protocol type into the BGP domain such as: DvR routes, static routes, Routing Information Protocol (RIP) routes, or direct routes. Use a route policy to control the redistribution of routes.

Note

When a route map with attributes set to `origin` and `local-pref` is applied to the BGP redistribute command, the attributes are not applied to the redistributed routes.

Before You Begin

- If required, a route policy exists.
- You can configure BGP on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. The VRF must have an RP Trigger of BGP.

  

  Note

  Route refresh is not currently supported on non-default VRFs.

- Before you redistribute DvR host routes to BGP, you must disable BGP aggregation and BGP auto-summarization of networks, using the commands **no ip bgp aggregation enable** and **no ip bgp auto-summary** respectively.

  Disabling these settings ensures that all the DvR host routes are correctly advertised into BGP and are not summarized.

Note

When applying a route map to an inter-vrf redistribution, the route map and any associated IP prefix lists must be configured first on the source VRF before configuring the redistribute policy on the destination VRF.

Inter-vrf redistribution is not supported on IPv6 routes.

Procedure

1. Enter BGP Router Configuration mode:

   ```
   enable

   configure terminal

   router bgp
   ```

2. Create a redistribution instance:

   ```
   redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|
   ospfv3|rip|ripng|static>
   ```

   Note

   Redistribution of ripng routes into BGP is supported only on VRF 0.

3. If required, specify a route policy to govern redistribution:

   ```
   redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|
   ospfv3|rip|ripng|static> route-map WORD<0-64> [vrf-src WORD<1-16>]
   ```

4. If required, configure the route metric:

   ```
   redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|
   ospfv3|rip|ripng|static> metric <0-65535> [vrf-src WORD<1-16>]
   ```

5. If required, configure the route metric-type:

   ```
   redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|
   ospfv3|rip|ripng|static> metric—type live-metric [vrf-src WORD<1-16>
   ```

6. Enable the instance:

   ```
   redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|
   ospfv3|rip|ripng|static> enable [vrf-src WORD<1-16>]
   ```

7. Exit BGP Router Configuration mode:

   ```
   exit
   ```

8. Apply the redistribution instance configuration:

   For IPv4: `ip bgp apply redistribute <direct|dvr|isis|ospf|rip|static> [vrf WORD<1-16>] [vrf-src <WORD 1-16>]`

   For IPv6: `ipv6 bgp apply redistribute <direct|dvr|isis|ospf|rip|static> [vrf <WORD 1-16>]`

9. Apply BGP redistribution to a specific VRF:

   ```
   ip bgp apply redistribute vrf WORD<1-16>
   ```

   Changes do not take effect until you apply them.

10. View all routes (including DvR host routes) that are redistributed into BGP:

    View routes redistributed from GRT to BGP:

    For IPv4: `show ip bgp imported-routes`

    For IPv6: `show bgp ipv6 imported-routes`

    View routes redistributed to BGP for a specific VRF instance:

    For IPv4: `show ip bgp imported-routes [vrf WORD<1-64>] [vrfids WORD<0-512>]`

    For IPv6: `show bgp ipv6 imported-routes [WORD<1-256>] [vrf WORD<1-16>] [vrfids WORD<0-255>]`

Examples

Redistribute direct routes from the VRF instance `source1` into BGP, in the GRT context.

Create a redistribution instance:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router bgp
Switch(router-bgp)#redistribute direct vrf-src source1
```

If required, specify a route policy to govern redistribution:

```
Switch(router-bgp)# redistribute direct route-map policy1 vrf-src source1
```

If required, configure the route metric:

```
Switch:1(router-bgp)# redistribute direct metric 4 vrf-src source1
```

Enable the instance:

```
Switch:1(router-bgp)# redistribute direct enable vrf-src source1
```

Exit BGP Router Configuration mode:

```
Switch:1(router-bgp)# exit
```

Apply the redistribution instance configuration:

```
Switch:1(config)# ip bgp apply redistribute direct vrf-src source1
```

Redistribute DvR routes from the GRT to BGP:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router bgpSwitch:1(router-bgp)#redistribute dvr
Switch:1(router-bgp)#redistribute dvr enable
Switch:1(router-bgp)#exit
Switch:1(config)#ip bgp apply redistribute dvr
```

View the host routes (including DvR host routes) that are redistributed from the GRT to BGP:

```
Switch:1(config)#show ip bgp imported-routes vrf vrf1

================================================================================
                        BGP Imported Routes - VRF vrf1
================================================================================
ROUTE                           METRIC COMMUNITY LOCALPREF NEXTHOP         ORIGIN

...
...
...
3 out of 763 Total Num of imported routes displayed
```

Redistribute DvR routes to BGP for the specific VRF instance `vrf1`:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router vrf vrf1
Switch:1(router-vrf)#ip bgp redistribute dvr
Switch:1(router-vrf)#ip bgp redistribute dvr enable
Switch:1(router-vrf)#exit
Switch:1(config)#ip bgp apply redistribute dvr vrf vrf1
```

View the DvR host routes that are redistributed to BGP for vrf `vrf1`:

```
Switch:1(config)#show ip bgp imported-routes vrf vrf1

================================================================================

This example demonstrates redistribution of inter-VRF routes (both direct and DvR routes) to BGP, with a route policy configured.

Redistribute inter-VRF DvR routes between VRFs (with VRF IDs `10` and `30`), to BGP.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf 10
Switch:1(router-vrf)#ip prefix-list "test10" 192.0.2.0/24  ge 25 le 32
Switch:1(router-vrf)#route-map "test10" 1
Switch:1(router-vrf)#permit
Switch:1(router-vrf)#enable
Switch:1(router-vrf)#match network "test10"
Switch:1(router-vrf)#set metric 99
Switch:1(router-vrf)#exit
```

```
Switch:1(config)#router vrf 30
Switch:1(router-vrf)#ip bgp redistribute direct vrf-src 10
Switch:1(router-vrf)#ip bgp redistribute direct enable vrf-src 10
Switch:1(router-vrf)#ip bgp redistribute dvr vrf-src 10
Switch:1(router-vrf)#ip bgp redistribute dvr route-map "test10" vrf-src 10
Switch:1(router-vrf)#ip bgp redistribute dvr enable vrf-src 10
Switch:1(router-vrf)#exit

Switch:1(config)#ip bgp apply redistribute direct vrf 30 vrf-src 10
Switch:1(config)#ip bgp apply redistribute dvr vrf 30 vrf-src 10
```

Variable Definitions

The following table defines parameters for the **redistribute** and **ip bgp apply redistribute** commands.

Variable	Value
<direct | dvr | ipv6-direct | ipv6-isis | ipv6-static | isis | ospf | ospfv3 | rip | ripng| static >	Specifies the type of routes to redistribute (the protocol source).
enable	Enables the BGP route redistribution instance.
metric <0-65535>	Configures the metric to apply to redistributed routes.
metric-type live-metric	Configures the metric type to apply to redistributed routes. When you enable the live-metric option, when BGP redistributes static, RIP, OSPF, IS-IS, or DvR routes, the metric value is taken from the routing table and is set to the Path attributes as a MED value. By default, this option is disabled, which means the BGP MED value is not derived from the metric in the routing table.
route-map WORD<0-64>	Configures the route policy to apply to redistributed routes.
vrf WORD<1-16>	Specifies the name of a VRF instance.
vrf-src WORD<1-16>	Specifies the source VRF instance by name for route redistribution.

Configure redistribution to BGP+ for VRF 0

Configure an IPv6 redistribute entry to announce IPv6 routes of a certain source protocol type into the BGP domain, for example, static, OSPF, IS-IS, RIPng, or direct routes. Use a route policy to control the redistribution of routes.

Note

When a route map with attributes set to `origin` and `local-pref` is applied to the BGP redistribute command, the attributes are not applied to the redistributed routes.

Before You Begin

- If required, a route policy exists.

Procedure

1. Enter BGP Router Configuration mode:

   ```
   enable

   configure terminal

   router bgp
   ```

2. Create a redistribution instance:

   ```
   redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|
   ospfv3|rip|ripng|static>
   ```

3. If required, specify a route policy to govern redistribution:

   ```
   redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|
   ospfv3|rip|ripng|static> route-map WORD <0-64>
   ```

4. If required, configure a route metric:

   ```
   redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|
   ospfv3|rip|ripng|static> metric <0-65535>
   ```

5. Enable the instance:

   ```
   redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|
   ospfv3|rip|ripng|static> enable
   ```

   Unlike IPv4 redistribution, you do not need to manually apply the IPv6 redistribution instance. Once you enable the IPv6 redistribution instance, it is automatically applied.

Example

Specify a route policy to govern redistribution by using the following command:

```
Switch:1(router-bgp)#redistribute ipv6-direct route-map policy2
```

Variable Definitions

The following table defines parameters for the **`redistribute <ipv6-direct|ipv6-static|ospfv3|ipv6-isis|ripng>`** command.

Variable	Value
`enable`	Enables the BGP route redistribution instance. The default value is none. To configure this option to the default value, use **`default`** operator with the command. To disable this option, use **`no`** operator with the command.
`metric<0-65535>`	Configures the metric to apply to redistributed routes. The default value is 0. To configure this option to the default value, use **`default`** operator with the command.
`route-map <Word 0-64>`	Configures the route policy to apply to redistributed routes. The default value is none. To configure this option to the default value, use **`default`** operator with the command.

Job Aid

Use the data in the following table to know how route policies are used for BGP from IPv6 perspective.

Table 44: BGP for IPv6 Route Policy Support

	REDISTRIBUTE					ACCEPT	ANNOUNCE
	IPv6 Direct	IPv6 Static	OSPFv3	IPv6 IS-IS	RIPng	BGP	BGP
MATCH							
as-path						Yes	Yes
community	Yes	Yes	Yes	Yes	Yes	Yes	Yes
community-exact						Yes	Yes
extcommunity						Yes	Yes
interface							
local-preference							
metric				Yes	Yes		
network				Yes	Yes		
next-hop				Yes	Yes		
protocol							
route-source						Yes	
route-type			Yes				Yes

metric	Yes	Yes	Yes	Yes	Yes	Yes	Yes
metric-type							
metric-type-internal							
next-hop						Yes	Yes

Table 44: BGP for IPv6 Route Policy Support (continued)

	REDISTRIBUTE					ACCEPT	ANNOUNCE
	IPv6 Direct	IPv6 Static	OSPFv3	IPv6 IS-IS	RIPng	BGP	BGP
nssa-pbit							
origin							Yes
origin-egp-as							
tag							
weight						Yes	

Configure AS Path Lists

Configure an AS path list to restrict the routing information a router learns or advertises to and from a neighbor. The AS path list acts as a filter that matches AS paths.

Before You Begin

- You configure BGP on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **`ip bgp`**. The VRF must have an RP Trigger of BGP.

  Note

  Route refresh is not currently supported on non-default VRFs.

Procedure

1. Enter BGP Router Configuration mode:

   ```
   enable

   configure terminal

   router bgp
   ```

2. Create the path list:

   ```
   ip as-list <1-1024> memberid <0-65535> <permit|deny> as-path WORD<0-1536>
   ```

   Use this command for each member by specifying different member IDs.

Example

Create the path list:

```
Switch(config)# ip as-list 234 memberid 3456 permit as-path "5"
```

Variable Definitions

The following table defines parameters for the **ip as-list** command.

Variable	Value
<0-65535>	Specifies an integer value between 0–65535 that represents the regular expression entry in the AS path list.
<1-1024>	Specifies an integer value from 1–1024 that represents the AS-path list ID you want to create or modify.
<permit|deny>	Permits or denies access for matching conditions.
WORD<0-1536>	Specifies the AS number as an integer value between 0–1536. Place multiple AS numbers within quotation marks ('').

Configure Community Lists

Configure community lists to specify permitted routes by using their BGP community. This list acts as a filter that matches communities or AS numbers.

Before You Begin

- You configure BGP on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. The VRF must have an RP Trigger of BGP.

Note

Route refresh is not currently supported on non-default VRFs.

Procedure

1. Enter BGP Router Configuration mode:

   ```
   enable

   configure terminal

   router bgp
   ```

2. Create a community list:

   ```
   ip community-list <1-1024> memberid <0-65535> <permit|deny> community-string WORD<0-256>
   ```

Example

Create a community list:

```
Switch(config)# ip community-list 1 memberid 4551 permit community-string internet
```

Variable Definitions

The following table defines parameters for the **ip community-list** command.

Variable	Value
<0-65535>	Specifies an integer value from 0–65535 that represents the member ID in the community list.
<1-1024>	Specifies an integer value from 1–1024 that represents the community list ID.
<permit|deny>	Configures the access mode, which permits or denies access for matching conditions.
WORD<0-256>	Specifies the community as an alphanumeric string value with a string length from 0–256 characters. Enter this value in one of the following formats: • (AS num:community-value) • (well-known community string) Well known communities include: internet, no-export, no-advertise, local-as (known as NO_EXPORT_SUBCONFED).

Configure Extended Community Lists

Configure community lists to specify permitted routes by BGP extended community attributes, including route targets and sites of origin (SOO). This list acts as a filter that matches route targets and SOO.

Before You Begin

- Configure BGP on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. The VRF must have an RP Trigger of BGP.

Note

Route refresh is not currently supported on non-default VRFs.

Procedure

1. Enter BGP Router Configuration mode:

   ```
   enable

   configure terminal

   router bgp
   ```

2. Create an extended community list based on the route target attribute:

   ```
   ip extcommunity-list <1-1024> memberId <0-65535> rt {<0-65535>
   <0-2147483647>|<A.B.C.D> <0-65535>} [soo {<0-65535> <0-2147483647>|
   <A.B.C.D> <0-65535>}]
   ```

   You can optionally configure the SOO attributes at the end of the same command or you can configure the SOO separately using the syntax in the following step.

3. Create an extended community list based on the SOO attribute:

   ```
   ip extcommunity-list <1-1024> memberId <0-65535> soo {<0-65535>
   <0-2147483647>|<A.B.C.D> <0-65535>}
   ```

Example

Create an extended community list based on the route target attribute:

```
Switch(config)# ip extcommunity-list 1 memberid 234 rt 192.0.2.1 5 soo
32 45
```

Variable Definitions

The following table defines parameters for the **`ip extcommunity-list`** command.

Variable	Value
<1-1024>	Specifies an integer value from 1–1024 that represents the community list ID you want to create or modify.
memberId <0-65535>	Specifies an integer value from 0–65535 that represents the member ID in the community list.
rt <0-65536> <0-2147483647> *rt <A.B.C.D> <0-65535>*	Specifies the route target in the format {AS number:assigned number} (that is, {0–65535}:{0–2147483647}) or {ipaddress:assigned number} (that is, {a.b.c.d}:{0–65535}).
soo <0-65535> <0-2147483647> *soo <A.B.C.D> <0-65535>*	Specifies the site of origin in the format {AS number:assigned number} (that is, {0–65535}:{0–2147483647}) or {ipaddress:assigned number} (that is, {a.b.c.d}:{0–65535}).

Configure an AS Number for a Non-default VRF

The Autonomous System (AS) number configured on the global Virtual Routing Forwarding (VRF) instance, called the GlobalRouter (GRT), is inherited by all user-created VRFs by default, however, you can override the AS number for the specific VRF instance using the following procedure.

Before You Begin

- Disable BGP synchronization.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

   ```
   enable

   configure terminal

   router vrf WORD<1-16>
   ```

2. Set the AS number:

   ```
   ip bgp vrf-as WORD<0-11>
   ```

Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
Switch:1(config)#router vrf vrfred
Switch:1(router-vrf)#ip bgp vrf-as 3
```

Variable Definitions

The following table defines parameters for the **ip bgp vrf-as** command.

Variable	Value
WORD<0-11>	Configures the local autonomous system (AS) number for the specific VRF instance. You cannot change local-as when BGP is set to enable. • To configure a 2-byte local AS number, enter a local-as number in the range of 0 to 65535. • To configure a 4-byte local-as number, enable the 4-byte as variable and enter a number in the range of 0 to 4294967295. Note: If as-4-byte is configured to false, the range for AS number is 0–65535 and if as-4-byte is configured to true, the range is 0–4294967295. If you enable as-dot, enter the AS number in octets in the range of 1.0 to 65535.65535. The AS number in a specific VRF instance inherits the AS number in the GlobalRouter in the following instances: • Configuring the AS number in a specific VRF instance to 0 (**ip bgp vrf-as 0**) . • Deleting the AS number in a specific VRF instance (**no ip bgp vrf-as** or **default ip bgp vrf-as**.

BGP Verification Using CLI

Use **show** commands to verify Border Gateway Protocol (BGP) configuration and to monitor or troubleshoot BGP operation.

Note

If the next hop of a BGP route is resolved using an IS-IS route, show commands can display the IS-IS internal next hop from the 127.1.x.y class rather than the IS-IS sys name.

Viewing BGP aggregate information

Display information about current aggregate addresses.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about current aggregates:

   ```
   show ip bgp aggregates [<prefix/len>] [vrf WORD <1-16>] [vrfids WORD<0-255>]
   ```

Variable Definitions

The following table defines parameters for the **show ip bgp aggregates** command.

Variable	Value
<prefix/len>	Specifies the IP address and the mask length.
vrf WORD<1-16>	Specifies a VRF instance by name.
vrfids WORD<0-255>	Specifies a range of VRFs by ID number.

Viewing IPv6 BGP+ aggregate information

Display information about current IPv6 aggregate addresses.

About This Task

Use BGP 4 byte AS numbers to ensure the continuity of loop-free inter-domain routing information between ASs and to control the flow of BGP updates as 2 byte AS numbers will deplete soon.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about current IPv6 aggregates:

   ```
   show bgp ipv6 aggregates [<WORD 1-256>] [vrf <WORD 1-16>] [vrfids
   <0-255>]
   ```

Variable Definitions

The following table defines parameters for the **show bgp ipv6 aggregates** command.

Variable	Value
WORD <1-256>	Specifies the IPv6 prefix and the prefix length (the length can be 0 to 128).
vrf WORD <1-16>	Specifies a VRF instance by name (the string length ranges from 1–16 characters).
vrfids <0-255>	Specifies a range of VRFs by ID number (the ID ranges from 0–255).

Viewing CIDR routes

Display information about classless interdomain routing (CIDR) routes.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about CIDR routes:

   ```
   show ip bgp cidr-only [<prefix/len>] [vrf WORD<1-16>] [vrfids WORD<0-
   512>]
   ```

Variable Definitions

The following table defines parameters for the **show ip bgp cidr-only** command.

Variable	Value
<prefix/len>	Specifies an exact match of the prefix. This variable is an IP address and an integer value from 0–32 in the format a.b.c.d/xx.
vrf WORD<1-16>	Specifies a VRF instance by name (the string length ranges from 1–16 characters).
vrfids WORD<0-512>	Specifies a range of VRFs by ID number (the ID ranges from 0–512).

View BGP Configuration

View information about the BGP configuration.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about the current BGP configuration:

   `show ip bgp conf [vrf WORD<1-16>] [vrfids WORD<0-512>]`

Example

```
================================================================================
                        BGP Configuration - VRF vrf1

================================================================================

                                    BGP version - 4

                                    global-debug - none
                           ibgp-report-import-rt - enable
                            ignore-illegal-rtrid - enable
                            max-equalcost-routes - 1
                            no-med-path-is-worst - enable
                                   route-refresh - disable
                                orig-def-route - disable
                             orig-v6-def-route - disable
                                   quick-start - disable
                                synchronization - enable

--More-- (q = quit)
```

Variable Definitions

The following table defines parameters for the **show ip bgp conf** command.

Variable	Value
vrf WORD<1–16>	Specifies a VRF instance by name (the string length ranges from 1–16 characters).
vrfids WORD<0–512>	Specifies a range of VRFs by ID number (the ID ranges from 0–512).

Viewing BGP confederation

Display information about BGP confederations.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about current BGP confederations:

   ```
   show ip bgp confederation
   ```

Example

```
Switch(config)#show ip bgp confederation
confederation identifier 0
confederation peer as
```

Viewing flap-dampened routes

Display information about flap-dampened routes to determine unreliable routes.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about flap-dampened routes:

   ```
   show ip bgp dampened-paths {A.B.C.D} [<prefix/len>] [longer-prefixes]
   [vrf WORD<1–16>] [vrfids WORD<0–512>]
   ```

Variable Definitions

The following table defines parameters for the **show ip bgp dampened-paths** command.

Variable	Value
{A.B.C.D}	Specifies the source IP address in the format a.b.c.d.
longer-prefixes	Shows long prefixes. The longer-prefixes indicate the mask length from a specified prefix to 32 (for example, show from prefix a.b.c.d/len to a.b.c./32).
<prefix/len>	Shows paths with this prefix. The prefix is the IP address and exact mask length (must be an integer value from 0–32).

Variable	Value
vrf WORD<1–16>	Specifies a VRF instance by name (the string length ranges from 1–16 characters).
vrfids WORD<0–512>	Specifies a range of VRFs by ID number (the ID ranges from 0–512).

Viewing global flap-dampening configurations

Display global information about flap-dampening.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display global information about flap-dampening:

   `show ip bgp flap-damp-config [prefix/len] [vrf WORD<1–16>] [vrfids WORD<0–512>]`

Example

```
Switch(config)# show ip bgp flap-damp-config vrf vrf1

================================================================
                      BGP Flap Dampening - VRF vrf1
================================================================
                                        Status - enable
                                    PolicyName - N/A
                                CutoffThreshold - 1536
                                 ReuseThreshold - 512
                                         Decay - 2
                                   MaxHoldDown - 180
```

Variable Definitions

The following table defines parameters for the **`show ip bgp flap-damp-config`** command.

Variable	Value
<prefix/len>	Shows paths with this prefix. The prefix is the IP address and exact mask length (must be an integer value from 0–32).
vrf WORD<1–16>	Specifies a VRF instance by name (the string length ranges from 1–16 characters).
vrfids WORD<0–512>	Specifies a range of VRFs by ID number (the ID ranges from 0–512).

Viewing imported routes

Display information about BGP imported routes.

Procedure

1. To enter User EXEC mode, log on to the switch.

2. Display information about BGP imported routes:

   ```
   show ip bgp imported-routes [<prefix/len>] [longer-prefixes] [vrf
   WORD<1-16>] [vrfids WORD<0-512>]
   ```

Variable Definitions

The following table defines parameters for the **show ip bgp imported-routes** command.

Variable	Value
longer-prefixes	Shows long prefixes. The longer-prefixes indicate the mask length from a specified prefix to 32 (for example, show from prefix a.b.c.d/len to a.b.c./32).
<prefix/len>	Shows paths with this prefix. The prefix is the IP address and exact mask length (must be an integer value from 0–32).
vrf WORD<1-16>	Specifies a VRF instance by name (the string length ranges from 1–16 characters).
vrfids WORD<0-512>	Specifies a range of VRFs by ID number (the ID ranges from 0–512).

Viewing BGPv6 imported routes

Display information about BGPv6 imported routes.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGPv6 imported routes:

   ```
   show bgp ipv6 imported-routes [<prefix/len>] [longer-prefixes] [vrf
   WORD<1-16>] [vrfids WORD<0-255>]
   ```

Variable Definitions

The following table defines parameters for the **show bgp ipv6 imported-routes** command.

Variable	Value
longer-prefixes	Shows long prefixes. The longer-prefixes indicate the mask length from a specified prefix to 32 (for example, show from prefix a.b.c.d/len to a.b.c./32).
<prefix/len>	Shows paths with this prefix. The prefix is the IP address and exact mask length (must be an integer value from 0–32).
vrf WORD<1-16>	Specifies a VRF instance by name (the string length ranges from 1–16 characters).
vrfids WORD<0-255>	Specifies a range of VRFs by ID number (the ID ranges from 0–255).

View BGP Neighbors Information

Display information about BGP neighbors.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGP neighbors:

   `show ip bgp neighbors [{A.B.C.D}] [vrf WORD<1-16>] [vrfids WORD<0-512>]`
3. Display information about BGP peer advertised routes:

   `show ip bgp neighbors {A.B.C.D} advertised-routes [<prefix/len>] [longer-prefixes] [vrf WORD<1-16>] [vrfids WORD<0-512>]`
4. Display information about BGP peer routes:

   `show ip bgp neighbors {A.B.C.D} routes [<prefix/len>] [community <enable|disable>] [longer-prefixes] [vrf WORD<1-16>] [vrfids WORD<0-512>]`
5. Display statistics for BGP peers:

   `show ip bgp neighbors {A.B.C.D} stats [vrf WORD<1-16>] [vrfids WORD<0-512>]`

Example

```
Switch:#show ip bgp neighbors vrf vrf1

================================================================================

BGP Neighbor Info - VRF vrf1
================================================================================

BGP neighbor is 200.200.200.63 remote AS 63, Internal Peer, MP-BGP-capable, BGP state

```

Variable Definitions

The following table defines parameters for the **show ip bgp neighbors** command.

Variable	Value
{A.B.C.D}	Specifies the IP address.
community <enable|disable>	Enables or disables the display of community attributes.
longer-prefixes	Shows long prefixes. The longer-prefixes indicate the mask length from a specified prefix to 32 (for example, show from prefix a.b.c.d/len to a.b.c./32).
prefix/len	Shows paths with this prefix. The prefix is the IP address and exact mask length (must be an integer value from 0–32).
vrf WORD<1-16>	Specifies a VRF instance by name.
vrfids WORD<0-512>	Specifies a range of VRFs by ID number.

Viewing BGPv6 neighbors information

View information about BGPv6 neighbors.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View information about BGPv6 neighbors:

   ```
   show bgp ipv6 neighbors [WORD<1-256>] [vrf <WORD 1-16>] [vrfids
   <0-255>]
   ```
3. View information about BGPv6 peer advertised routes:

   ```
   show bgp ipv6 neighbors WORD<1-256> advertised-routes [WORD<1-256>]
   [longer-prefixes] [vrf <WORD 1-16>] [vrfids <0-255>]
   ```
4. View information about BGPv6 peer routes:

   ```
   show bgp ipv6 neighbors WORD<1-256> routes [WORD<1-256>] [community
   <enable|disable>] [vrf <WORD 1-16>] [vrfids <0-255>]
   ```

Example

The following examples shows the summary output for **bgp ipv6 neighbors** command, and the *advertised-routes* and *routes* variable options.

```
Switch:1>show bgp ipv6 neighbors vrf vrf1

================================================================================
                       BGPv6 Neighbor Info - VRF vrf1

Variable Definitions

The following table defines parameters for the **show bgp ipv6 neighbors** command.

Variable	Value
WORD<1–256>	Specifies the IPv6 address.
advertised-routes	Specifies an IPv6 neighbors advertised routes.
routes	Specifies an IPv6 neighbors routes.
WORD<1–256>	Specifies an IPv6 address/length.
longer-prefixes	Shows long prefixes. The longer-prefixes indicate the mask length from any specified prefix to 128. For example, show from prefix :X::X:X/len to X:X::X:X/ 128.

Variable	Value
community <enable|disable>	Enables or disables the display of community attributes.
vrf	Specifies a VRF instance by name (the string length ranges from 1–16 characters).
vrfids	Specifies a range of VRFs by ID number (the ID ranges from 0–255).

Viewing BGP network configurations

Display information about BGP network configurations.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGP network configurations:

   ```
   show ip bgp networks [<prefix/len>] [vrf WORD<1-16>] [vrfids WORD<0-512>]
   ```

Variable Definitions

The following table defines parameters for the **show ip bgp networks** command.

Variable	Value
<prefix/len>	Shows paths with this prefix. The prefix is the IP address and exact mask length (must be an integer value from 0–32).
vrf WORD<1-16>	Specifies a VRF instance by name (the string length ranges from 1–16 characters).
vrfids WORD<0-512>	Specifies a range of VRFs by ID number (the ID ranges from 0–512).

Viewing IPv6 BGP+ network configurations

Display information about BGP+ network configurations.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGP+ network configurations:

   ```
   show bgp ipv6 networks <WORD 1-256> [vrf <WORD 1-16>] [vrfids <0-255>]
   ```

Variable Definitions

The following table defines parameters for the **show bgp ipv6 networks** command.

Variable	Value
<WORD 1–256>	Specifies the IPv6 prefix and the prefix length (must be an integer value between 0 and 128).
vrf	Specifies a VRF instance by name (the string length ranges from 1–16 characters).
vrfids	Specifies a range of VRFs by ID number (the ID ranges from 0–255).

Viewing BGP peer group information

Display information about BGP peer groups.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGP peer groups:

   ```
   show ip bgp peer-group [WORD<0–1536>] [vrf WORD<1–16>] [vrfids WORD<0–512>]
   ```

Variable Definitions

The following table defines parameters for the **show ip bgp peer-group** command.

Variable	Value
vrf WORD<1–16>	Specifies a VRF instance by name (the string length ranges from 1–16 characters).
vrfids WORD<0–512>	Specifies a range of VRFs by ID number (the ID ranges from 0–512).
WORD<0–1536>	Specifies the name of the peer group (the string length ranges from 0–1536 characters).

Viewing BGP redistributed routes

Display information about BGP redistributed routes.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGP redistributed routes:

   ```
   show ip bgp redistributed-routes [<prefix/len>] [vrf WORD<1–16>] [vrfids WORD<0–512>]
   ```

Variable Definitions

The following table defines parameters for the **show ip bgp redistributed-routes** command.

Variable	Value
<prefix/len>	Shows paths with this prefix. The prefix is the IP address and exact mask length (must be an integer value from 0–32).
vrf WORD<1-16>	Specifies a VRF instance by name (the string length ranges from 1–16 characters).
vrfids WORD<0-255>	Specifies a range of VRFs by ID number (the ID ranges from 0–255).

Viewing BGPv6 redistributed routes

Display information about BGPv6 redistributed routes.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGPv6 redistributed routes:

   ```
   show bgp ipv6 redistributed-routes [vrf <WORD 1-16] [vrfids <0-255>]
   ```

Variable Definitions

The following table defines parameters for the **show bgp ipv6 redistributed-routes** command.

Variable	Value
vrf	Specifies a VRF instance by name (the string length ranges from 1–16 characters).
vrfids	Specifies a range of VRFs by ID number (the ID ranges from 0–255).

View a Summary of BGP Configurations

Display summarized information about BGP.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display summarized information about BGP:

   ```
   show ip bgp summary [vrf WORD<1-16>] [vrfids WORD<0-512>]
   ```

Example

The following example shows partial output for the **show ip bgp summary** command.

```
Switch:1>show ip bgp summary vrf vrf1

================================================================================================
                            BGP Summary - VRF vrf1
```

```

==========================================================================
)
```

Variable Definitions

The following table defines parameters for the **show bgp ipv6 summary** command.

Variable	Value
vrf	Specifies a VRF instance by name (the string length ranges from 1–16 characters).
vrfids	Specifies a range of VRFs by ID number (the ID ranges from 0–255).

Viewing BGP routes

Display information about BGP routes.

Note

BGP stores route information on the AVL tree and this command retrieves that information. Information in the AVL tree is not sorted. The information returned by this command will not be displayed in any particular order.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGP routes:

   ```
   show ip bgp route [<prefix/len>] [community <enable|disable>] [ip
   {A.B.C.D}] [longer-prefixes] [vrf WORD<1-16>] [vrfids WORD<0-512>]
   ```

Variable Definitions

The following table defines parameters for the **show ip bgp route** command.

Variable	Value
community <enable|disable>	Enables or disables the display of community attributes.
ip {A.B.C.D}	Specifies an IP address.
longer-prefixes	Shows long prefixes. Longer-prefixes indicates the mask length from a specified prefix to 32 (for example, show from prefix a.b.c.d/len to a.b.c./32).
<prefix/len>	Shows paths with this prefix. The prefix is the IP address and exact mask length (must be an integer value from 0–32).
vrf WORD<1-16>	Specifies a VRF instance by name.
vrfids WORD<0-512>	Specifies a range of VRFs by ID number.

Viewing BGPv6 routes

Display information about BGPv6 routes.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Enter Privileged EXEC mode:

   ```
   enable
   ```
3. Display information about BGP routes:

   ```
   show bgp ipv6 route [<WORD 1-256> [longer-prefixes]] [community
   <enable|disable>] [ipv6 <WORD 1-256>] [vrf <WORD 1-16>] [vrfids
   <0-255>]
   ```

Variable Definitions

The following table defines parameters for the **show bgp ipv6 route** command.

Variable	Value
[<WORD 1-256>]	Specifies the IPv6 prefix and the prefix length (must be an integer value between 0 and 128).
community <enable|disable>	Enables or disables the display of community attributes.
ipv6 <WORD 1-256>]	Specifies an IPv6 address.
longer-prefixes	Shows long prefixes. The longer-prefixes indicate the mask length from any specified prefix to 128 (for example, show from prefix X:X::X:X/len to X:X::X:X/ 128).
vrf	Specifies a VRF instance by name (the string length ranges from 1–16 characters).
vrfids	Specifies a range of VRFs by ID number (the ID ranges from 0–255).

BGP configuration using EDM

Configure Border Gateway Protocol (BGP) to create an inter-domain routing system that guarantees loop-free routing information between autonomous systems.

For information about how to configure route policies, see Configure a Route Policy on page 2622.

Configure BGP

Enable BGP so that BGP runs on the router. Configure general BGP parameters to define how BGP operates on the system.

Before You Begin

- To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504. All parameters might not be available in non-default VRFs.
- The VRF must have an RP trigger of BGP.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Select **BGP**.
3. Select the **Generals** tab.
4. In AdminStatus, select **enable**.
5. Configure the local autonomous system (AS) ID.
6. In the **Aggregate** area, enable or disable route aggregation as required.
7. Configure the BGP options as required.
8. In the **DebugMask** area, select the type of information to show for BGP debugging purposes.
9. Configure BGP confederations as required.
10. Configure BGP route reflectors as required.
11. Select **Apply**.

Generals *Field Descriptions*

Use the data in the following table to use the **Generals** tab.

Name	Description
bgpVersion	Specifies the version of BGP that operates on the router. Note: This parameter only applies to VRF 0.
Identifier	Specifies the BGP router ID number.
AdminStatus	Enables or disables BGP on the router. The default is disable. You cannot enable AdminStatus until you change the LocalAS value to a nonzero value.

Name	Description
4ByteAs	Enables or disables 4–byte AS numbers. The default is disable. Note: This parameter only applies to VRF 0.
LocalAs	Configures the local AS number. You cannot change the LocalAs value if AdminStatus is enable. The switch does not support this parameter with BGP +. Note: If the inserted LocalAs is 0, then the LocalAs in that VRFcontext loses its significance and it becomes the LocalAs configured in GlobalRouter (the equivalence to CLI commands **`ip bgp vrf-as 0`** and **`no ip bgp vrf-as`** or **`default ip bgp vrf-as`**).
AsDot	Enables or disables representing AS numbers in octets. The default is disable so the switch uses the plain notation format The AS dot notation is easier to read and remember than the AS plain notation, but it can be difficult to convert from AS plain to AS dot. The IETF prefers the AS plain notation. The switch does not support this parameter with BGP +. Note: This parameter only applies to VRF 0.
Aggregate	Enables or disables aggregation. The default is enable.
DefaultMetric	Configures the metric sent to BGP neighbors. The default metric determines the cost of a route a neighbor uses. Use this parameter in conjunction with the redistribute parameters so that BGP uses the same metric for all redistributed routes. The default is -1. The range is -1–2147483647.
DefaultLocalPreference	Specifies the default local preference. The local preference indicates the preference that AS border routers assign to a chosen route when they advertise it to iBGP peers. The default is 100. The range is 0–2147483647.
AlwaysCompareMed	Enables or disables the comparison of the multi-exit discriminator (MED) parameter for paths from neighbors in different autonomous systems. The system prefers a path with a lower MED over a path with a higher MED. The default is disable.
DeterministicMed	Enables or disables deterministic MED. Deterministic MED compares the MEDs after routes advertised by different peers in the same AS are chosen. The default is disable.
AutoPeerRestart	Enables or disables the process that automatically restarts a connection to a BGP neighbor. The default is enable.

Name	Description
AutoSummary	Enables or disables automatic summarization. If you enable this varialble, BGP summarizes networks based on class limits (for example, Class A, B, or C networks). The default is enable.
NoMedPathIsWorst	Enables or disables NoMedPathIsWorst. If you enable this variable, BGP treats an update without a MED attribute as the worst path. The default is enabled.
BestPathMedConfed	Enables or disables the comparison of MED attributes within a confederation. The default is disable.
DebugMask	Displays the specified debug information for BGP global configurations. The default value is none. Other options are • none disables all debug messages. • event enables the display of debug event messages. • state enables display of debug state transition messages. • update enables display of debug messages related to updates transmission and reception. • error enables the display of debug error messages. • trace enables the display of debug trace messages. • init enables the display of debug initialization messages. • all enables all debug messages. • packet enables the display of debug packet messages. • warning enables the display of debug warning messages. • filter enables the display of debug messages related to filtering.
IgnoreIllegalRouterId	Enables BGP to overlook an illegal router ID. For example, this variable enables the acceptance of a connection from a peer that sends an open message using a router ID of 0. The default is enable.
Synchronization	Enables or disables the router to accept routes from BGP peers without waiting for an update from the IGP. The default is enable.
MaxEqualcostRoutes	Configures the maximum number of equal-cost-paths that are available to a BGP router by limiting the number of equal-cost-paths the routing table can store. The default value is 1; the range is 1–8.
IbgpReportImportRoute	Configures BGP to report imported routes to an interior BGP (iBGP) peer. This variable also enables or disables reporting of non-BGP imported routes to other iBGP neighbors. The default is enable.
FlapDampEnable	Enables or disables route suppression for routes that go up and down (flap). The default is disable.
QuickStart	Enables or disables the Quick Start feature, which forces the BGP speaker to begin establishing peers immediately, instead of waiting for the auto-restart timer to expire. The default is disable.
TrapEnable	Enables or disables the BGP traps. The default is disable.

Name	Description
ConfederationASIdentifier	Specifies a BGP confederation identifier in the range of 0–65535. Note: This parameter applies only to VRF 0.
ConfederationPeers	Lists adjoining autonomous systems that are part of the confederation in the format (5500,65535,0,10,...,...).. This value can use 0–255 characters. Note: This parameter applies only to VRF 0.
RouteReflectionEnable	Enables or disables the reflection of routes from iBGP neighbors. The default is enable. Note: This parameter applies only to VRF 0.
RouteReflectorClusterId	Configures a reflector cluster ID IP address. This variable applies only if you enable RouteReflectionEnable, and if multiple route reflectors are in a cluster. Note: This parameter applies only to VRF 0.
ReflectorClientToClientReflection	Enables or disables route reflection between two route reflector clients. This variable applies only if RouteReflectionEnable is enable. The default is enable. Note: This parameter applies only to VRF 0.
RouteRefresh	Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates it contains in its database that are eligible for the peer that issues the request. Note: This parameter only applies to VRF 0.

Configure 4-byte AS numbers

Configure AS numbers using the 4-byte format and represent the numbers in octets.

Before You Begin

- You cannot modify the global BGP configuration unless BGP is disabled.
- Make sure that you define AS numbers in policies the same way that you configure them for the router. The choices are asplain (regular expression) or asdot (dot notation). If you create policies using asplain and configure the switch with asdot, the match will not occur.

About This Task

Use BGP 4–byte AS numbers to ensure the continuity of loop-free inter-domain routing information between autonomous systems and to control the flow of BGP updates as 2 byte AS numbers will deplete soon. AS Plain notation format is the default and the preferred form of representing 4–byte AS numbers over the AS dot notation format.

You have an option to configure AS dot notation format as well. With AS dot notation, analyzing and troubleshooting any issues encountered becomes difficult as it is incompatible with the regular expressions used by most of the network providers.

If you enable 4-byte AS numbers, or the dotted octet notation, for the Global Router (VRF0), the configuration is inherited by user-defined VRFs. You cannot enable 4-byte AS numbers on individual user-defined VRFs.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Select **BGP**.
3. Select the **Generals** tab.
4. To change the AS number format, select **disable** for **AdminStatus**.
5. Select **Apply**.
6. In **4-byteAs** , select **enable**.
7. In **AsDot**, select **enable**.
8. In **LocalAs**, type the 4-byte AS number in octets.
9. In **AdminStatus**, select **enable**.
10. Select **Apply**.

Generals *Field Descriptions*

Use the data in the following table to use the **Generals** tab.

Name	Description
bgpVersion	Specifies the version of BGP that operates on the router. Note: This parameter only applies to VRF 0.
Identifier	Specifies the BGP router ID number.
AdminStatus	Enables or disables BGP on the router. The default is disable. You cannot enable AdminStatus until you change the LocalAS value to a nonzero value.
4ByteAs	Enables or disables 4–byte AS numbers. The default is disable. Note: This parameter only applies to VRF 0.

Name	Description
LocalAs	Configures the local AS number. You cannot change the LocalAs value if AdminStatus is enable. The switch does not support this parameter with BGP +. Note: If the inserted LocalAs is 0, then the LocalAs in that VRFcontext loses its significance and it becomes the LocalAs configured in GlobalRouter (the equivalence to CLI commands **ip bgp vrf-as 0** and **no ip bgp vrf-as** or **default ip bgp vrf-as**).
AsDot	Enables or disables representing AS numbers in octets. The default is disable so the switch uses the plain notation format The AS dot notation is easier to read and remember than the AS plain notation, but it can be difficult to convert from AS plain to AS dot. The IETF prefers the AS plain notation. The switch does not support this parameter with BGP +. Note: This parameter only applies to VRF 0.
Aggregate	Enables or disables aggregation. The default is enable.
DefaultMetric	Configures the metric sent to BGP neighbors. The default metric determines the cost of a route a neighbor uses. Use this parameter in conjunction with the redistribute parameters so that BGP uses the same metric for all redistributed routes. The default is -1. The range is -1–2147483647.
DefaultLocalPreference	Specifies the default local preference. The local preference indicates the preference that AS border routers assign to a chosen route when they advertise it to iBGP peers. The default is 100. The range is 0–2147483647.
AlwaysCompareMed	Enables or disables the comparison of the multi-exit discriminator (MED) parameter for paths from neighbors in different autonomous systems. The system prefers a path with a lower MED over a path with a higher MED. The default is disable.
DeterministicMed	Enables or disables deterministic MED. Deterministic MED compares the MEDs after routes advertised by different peers in the same AS are chosen. The default is disable.
AutoPeerRestart	Enables or disables the process that automatically restarts a connection to a BGP neighbor. The default is enable.
AutoSummary	Enables or disables automatic summarization. If you enable this varialble, BGP summarizes networks based on class limits (for example, Class A, B, or C networks). The default is enable.
NoMedPathIsWorst	Enables or disables NoMedPathIsWorst. If you enable this variable, BGP treats an update without a MED attribute as the worst path. The default is enabled.

Name	Description
BestPathMedConfed	Enables or disables the comparison of MED attributes within a confederation. The default is disable.
DebugMask	Displays the specified debug information for BGP global configurations. The default value is none. Other options are • none disables all debug messages. • event enables the display of debug event messages. • state enables display of debug state transition messages. • update enables display of debug messages related to updates transmission and reception. • error enables the display of debug error messages. • trace enables the display of debug trace messages. • init enables the display of debug initialization messages. • all enables all debug messages. • packet enables the display of debug packet messages. • warning enables the display of debug warning messages. • filter enables the display of debug messages related to filtering.
IgnoreIllegalRouterId	Enables BGP to overlook an illegal router ID. For example, this variable enables the acceptance of a connection from a peer that sends an open message using a router ID of 0. The default is enable.
Synchronization	Enables or disables the router to accept routes from BGP peers without waiting for an update from the IGP. The default is enable.
MaxEqualcostRoutes	Configures the maximum number of equal-cost-paths that are available to a BGP router by limiting the number of equal-cost-paths the routing table can store. The default value is 1; the range is 1–8.
IbgpReportImportRoute	Configures BGP to report imported routes to an interior BGP (iBGP) peer. This variable also enables or disables reporting of non-BGP imported routes to other iBGP neighbors. The default is enable.
FlapDampEnable	Enables or disables route suppression for routes that go up and down (flap). The default is disable.
QuickStart	Enables or disables the Quick Start feature, which forces the BGP speaker to begin establishing peers immediately, instead of waiting for the auto-restart timer to expire. The default is disable.
TrapEnable	Enables or disables the BGP traps. The default is disable.
ConfederationASIdentifier	Specifies a BGP confederation identifier in the range of 0–65535. Note: This parameter applies only to VRF 0.

Name	Description
ConfederationPeers	Lists adjoining autonomous systems that are part of the confederation in the format (5500,65535,0,10,...,...).. This value can use 0–255 characters. Note: This parameter applies only to VRF 0.
RouteReflectionEnable	Enables or disables the reflection of routes from iBGP neighbors. The default is enable. Note: This parameter applies only to VRF 0.
RouteReflectorClusterId	Configures a reflector cluster ID IP address. This variable applies only if you enable RouteReflectionEnable, and if multiple route reflectors are in a cluster. Note: This parameter applies only to VRF 0.
ReflectorClientToClientReflection	Enables or disables route reflection between two route reflector clients. This variable applies only if RouteReflectionEnable is enable. The default is enable. Note: This parameter applies only to VRF 0.
RouteRefresh	Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates it contains in its database that are eligible for the peer that issues the request. Note: This parameter only applies to VRF 0.

Viewing BGP Global Stats

View BGP global stats.

Procedure

1. In the navigation pane, expand the **Configuration** > **IP** folders.
2. Click **BGP**.
3. Click the **Global Stats** tab.

Global Stats Field Descriptions

Use the data in the following table to use the BGP Global Stats tab.

Name	Description
AbsoluteValue	Displays the counter value.
Cumulative	Displays the total value since you opened the Stats tab.
Average/sec	Displays the average value for each second.
Minimum/sec	Displays the minimum value for each second.
Maximum/sec	Displays the maximum value for each second.
LastVal/sec	Displays the last value for each second.
Starts	Displays the number of times the BGP connection started.
Stops	Displays the number of times the BGP connection stopped.
Opens	Displays the number of times BGP opens TCP.
Closes	Displays the number of times BGP closes TCP.
Fails	Displays the number of times TCP attempts failed.
Fatals	Displays the number of times TCP crashes due to fatal error.
ConnExps	Displays the number of times the TCP retry timer expired.
HoldExps	Displays the number of times the hold timer expired.
KeepExps	Displays the number of times the keepalive timer expired.
RxOpens	Displays the number of open instances BGP receives.
RxKeeps	Displays the number of keepalive instances BGP receives.
RxUpdates	Displays the number of update instances BGP receives.
RxNotifys	Displays the number of notification instances BGP receives.
TxOpens	Displays the number of open instances BGP transmitted.
TxKeeps	Displays the number of keepalive instances BGP transmitted.
TxUpdates	Displays the number of updates instances BGP transmits.
TxNotifys	Displays the number of notification instances BGP transmits.
BadEvents	Displays the number of invalid events FSM received.
SyncFails	Displays the number of times FDB sync failed.
TrEvent	Displays the trace event.
RxECodeHeader	Displays the total header errors received.
RxECodeOpen	Displays the total open errors received.
RxECodeUpdate	Displays the total update errors received.
RxECodeHoldtimer	Displays the total hold timer errors received.
RxECodeFSM	Displays the total FSM errors received.
RxECodeCease	Displays the total cease errors received.
RxHdrCodeNoSync	Displays the header not synchronized errors received.

Name	Description
RxHdrCodeInvalidMsgLen	Displays the header invalid message length errors received.
RxHdrCodeInvalidMsgType	Displays the header invalid message type errors received.
RxOpCodeBadVer	Displays the open errors received for Bad Version.
RxOpCodeBadAs	Displays the open errors received for le Bad AS Number.
RxOpCodeBadRtID	Displays the open errors received for Bad BGP Rtr ID.
RxOpCodeUnsuppOption	Displays the open errors received for Unsupported Option.
RxOpCodeAuthFail	Displays the open errors received for Auth Failures.
RxOpCodeBadHold	Displays the open errors received for Bad Hold Value.
RxUpdCodeMalformedAttrList	Displays the update errors received for Malformed Attr List.
RxUpdCodeWelKnownAttrUnrecog	Displays the update errors received for Welknown Attr Unrecog.
RxUpdCodeWelknownAttrMiss	Displays the update errors received for Welknown Attr Missing.
RxUpdCodeAttrFlagError	Displays the update errors received for Attr Flag Error.
RxUpdCodeAttrLenError	Displays the update errors received for Attr Len Error.
RxUpdCodeBadORIGINAttr	Displays the update errors received for Bad ORIGIN Attr.
RxUpdCodeASRoutingLoop	Displays the update errors received for AS Routing Loop.
RxUpdCodeBadNHAttr	Displays the update errors received for Bad NEXT-HOP Attr.
RxUpdCodeOptionalAttrError	Displays the update errors received for Optional Attr Error.
RxUpdCodeBadNetworkField	Displays the update errors received for Bad Network Field.
RxUpdCodeMalformedASPath	Displays the update errors received for Malformed AS Path.
TxECodeHeader	Displays the total Header errors transmitted.
TxECodeOpen	Displays the total Open errors transmitted.
TxECodeUpdate	Displays the total Update errors transmitted.
TxECodeHoldtimer	Displays the total Hold timer errors transmitted.
TxECodeFSM	Displays the total FSM errors transmitted.
TxECodeCease	Displays the total Cease errors transmitted.
TxHdrCodeNoSync	Displays the header Not Synchronized errors transmitted.
TxHdrCodeInvalidMsgLen	Displays the header Invalid msg len errors transmitted.
TxHdrCodeInvalidMsgType	Displays the header Invalid msg type errors transmitted.
TxOpCodeBadVer	Displays the open errors transmitted for Bad Version.
TxOpCodeBadAs	Displays the open errors transmitted for Bad AS Number.
TxOpCodeBadRtID	Displays the open errors transmitted for Bad BGP Rtr ID.
TxOpCodeUnsuppOption	Displays the open errors transmitted for Unsupported Option.
TxOpCodeAuthFail	Displays the open errors transmitted for Auth Failures.
TxOpCodeBadHold	Displays the open errors transmitted for Bad Hold Value.
TxUpdCodeMalformedAttrList	Displays the update errors transmitted for Malformed Attr List.

Name	Description
TxUpdCodeWelknownAttrUnrecog	Displays the update errors transmitted for Welknown Attr Unrecog.
TxUpdCodeWelknownAttrMiss	Displays the update errors transmitted for Welknown Attr Missing.
TxUpdCodeAttrFlagError	Displays the update errors transmitted for Attr Flag Error.
TxUpdCodeAttrLenError	Displays the update errors transmitted for Attr Len Error.
TxUpdCodeBadORIGINAttr	Displays the update errors transmitted for Bad ORIGIN Attr.
TxUpdCodeASRoutingLoop	Displays the update errors transmitted for AS Routing Loop
TxUpdCodeBadNHAttr	Displays the update errors transmitted for Bad NEXT-HOP Attr
TxUpdCodeOptionalAttrError	Displays the update errors transmitted for Optional Attr Error.
TxUpdCodeBadNetworkField	Displays the update errors transmitted for Bad Network Field.
TxUpdCodeMalformedASPath	Displays the update errors transmitted for Malformed AS Path.

Configure Aggregate Routes

Configure aggregate routes so that the router advertises a single route (aggregate route) that represents all destinations. Aggregate routes also reduce the size of routing tables.

Before You Begin

- Enable aggregate routes globally.
- You need the appropriate aggregate address and mask.
- If required, ensure the required policies exist.
- To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504. All parameters might not be available in non-default VRFs.
- The VRF must have an RP trigger of BGP.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Select **BGP**.
3. Select the **Aggregates** tab.
4. Click **Insert**.
5. Configure the aggregate **Address** and **PrefixLen**.
6. Select **AsSetGenerate** or **SummaryOnly** as required.
7. Configure policies for the aggregate route.
8. Select **Insert**.

***Aggregates** field descriptions*

Use the data in the following table to use the **Aggregates** tab.

Name	Description
Address	Specifies the aggregate IP address.
PrefixLen	Specifies the aggregate PrefixLen.
AsSetGenerate	Enables or disables AS-set path information generation. The default is disable.
SummaryOnly	Enables or disables the summarization of routes in routing updates. Enable this parameter to create the aggregate route and suppress advertisements of more-specific routes to all neighbors. The default is disable.
SuppressPolicy	Specifies the route policy (by name) used for the suppressed route list. Enable this parameter to create the aggregate route and suppress advertisements of the specified routes.
AdvertisePolicy	Specifies the route policy (by name) used for route advertisements. The route policy selects the routes that create AS-set origin communities.
AttributePolicy	Specifies the route policy (by name) used to determine aggregate route attributes.

Configure Aggregate IPv6 Routes

Configure IPv6 aggregate routes so that the router advertises a single route (aggregate route) that represents all destinations. Aggregate routes also reduce the size of routing tables.

To configure aggregate routes for IPv4, see Configure Aggregate Routes on page 442.

Before You Begin

- Aggregate routes are enabled.
- You have determined the appropriate aggregate prefix and length.
- If required, policies exist.
- To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504. All parameters might not be available in non-default VRFs.
- The VRF must have an RP trigger of BGP.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Select **BGP+**.
3. Select the **Aggregates** tab.
4. Select **Insert**.
5. Specify the aggregate **Address** and **PrefixLen**
6. (Optional) Configure **AsSetGenerate** and **SummaryOnly** as required.
7. (Optional) Configure policies for the aggregate route.

8. Select **Insert**.

***Aggregates** field descriptions*

Use the data in the following table to use the **Aggregates** tab.

Name	Description
Address	Specifies the aggregate address. The default is none.
PrefixLen	Specifies the length of the prefix (in bits).
AsSetGenerate	Enables or disables AS-set path information generation. The default is disable.
SummaryOnly	Enables or disables the summarization of routes in routing updates. Enable this parameter to create the aggregate route and suppress advertisements of more-specific routes to all neighbors. The default is disable.
SuppressPolicy	Specifies the route policy (by name) used for the suppressed route list. Enable this parameter to create the aggregate route and suppress advertisements of the specified routes.
AdvertisePolicy	Specifies the route policy (by name) used for route advertisements. The route policy selects the routes that create AS-set origin communities.
AttributePolicy	Specifies the route policy (by name) used to determine aggregate route attributes.

Configure Allowed Networks

Configure network addresses to determine the network addresses that BGP advertises. The allowed addresses determine the BGP networks that originate from the switch.

Before You Begin

- To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504. All parameters might not be available in non-default VRFs.
- The VRF must have an RP trigger of BGP.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Select **BGP**.
3. Select the **Network** tab.
4. Select **Insert**.
5. Configure the network address, mask, and metric.
6. Select **Insert**.

***Network** field descriptions*

Use the data in the following table to use the **Network** tab.

Name	Description
NetworkAfAddr	Specifies the network prefix that BGP advertises.
NetworkAfPrefixLen	Specifies the prefix length of the network address.
NetworkAfMetric	Specifies the metric to use when the system sends an update for the routes in the network table. The metric configures the MED for the routes advertised to eBGP peers. The range is 0–65535.

Configure Allowed IPv6 Networks

Configure IPv6 network addresses to determine the network addresses that BGP advertises. The allowed addresses determine the BGP networks that originate from the switch.

To configure allowed IPv4 networks, see Configure Allowed Networks on page 444.

Before You Begin

- To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504. All parameters might not be available in non-default VRFs.
- The VRF must have an RP trigger of BGP.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Select **BGP+**.
3. Select the **Network** tab.
4. Select **Insert**.
5. Configure the network address, prefix length, and metric.
6. Select **Insert**.

***Network** field descriptions*

Use the data in the following table to use the **Network** tab.

Name	Description
NetworkAfAddr	Specifies the network prefix that BGP advertises. The default is none.
NetworkAfPrefixLen	Specifies the network prefix length. The default is none.
NetworkAfMetric	Specifies the metric used when an update is sent for the routes in the network table. The metric configures the MED for the routes advertised to EBGP peers. The range is 0 to 65535. The default is 0.

Configure BGP Peers

Configure BGP peers to connect two routers to each other for the purpose of exchanging routing information. BGP peers exchange complete routing information only after they establish the peer connection.

Before You Begin

- To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504. All parameters might not be available in non-default VRFs.
- The VRF must have an RP trigger of BGP.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Select **BGP**.
3. Select the **Peers** tab.
4. Select **Insert**.
5. Configure the peer as required.
6. Select **Insert**.
7. In the **Enable** column, double-click the value, and then select **true**.

   By default, new peer configuration parameters are disabled.
8. Select **Apply**.
9. To modify a peer configuration, double-click the value, and then select a new value.
10. Select **Apply**.

Peers *Field Descriptions*

Use the data in the following table to use the **Peers** tab.

Name	Description
Instance	Specifies the BGP peer instance.
LocalAddrType	Specifies the local IP address type of the entered BGP peer.
LocalAddr	Specifies the local IP address of the entered BGP peer.
RemoteAddrType	Specifies the remote IP address type of the entered BGP peer.
RemoteAddr	Specifies the remote IP address of the entered BGP peer.
AdminStatus	Specifies the administrative status of the BGP peer.
GroupName	Specifies the peer group name to which the peer belongs (optional).
PeerState	Specifies the BGP peer connection state.
RemoteAs	Configures a remote AS number for the peer or peer-group in the range 0–65535.
Enable	Controls whether the peer connection is enabled or disabled. The default is disabled.
EbgpMultiHop	Enables or disables a connection to a BGP peer that is more than one hop away from the local router. The default value is disable.

Name	Description
RoutePolicyIn	Specifies the policy (by name) that applies to all network routes learned from this peer.
RoutePolicyOut	Specifies the policy (by name) that applies to all outgoing route updates.
RemovePrivateAs	Strips (when enabled) private AS numbers when the switch sends an update. The default is enable.
UpdateSourceInterface	Specifies the source IP address to use when the switch sends eBGP packets to this peer or peer group.
ConnectRetryInterval	Specifies the time interval, in seconds, for the connect retry timer. The suggested value for this timer is 120 seconds. The range is 1 to 65535.
HoldTimeConfigured	Specifies the time interval, in seconds, for the hold time for this BGP speaker with this peer. This value is in an open message sent to this peer by this BGP speaker. To determine the hold time with the peer, the switch compares this value with the HoldTime value in an open message received from the peer. The HoldTime must be at least three seconds. If the value is zero, the hold time does not establish with the peer. The suggested value for this timer is 180 seconds. The range is 0 to 65535.
KeepAliveConfigured	Specifies the time interval, in seconds, for the KeepAlive timer configured for this BGP speaker with this peer. KeepAliveConfigured determines the keep alive message frequency relative to HoldTimeConfigured; KeepAlive indicates the actual time interval for the keep alive messages. The maximum value for this timer is one-third of HoldTimeConfigured. If KeepAliveConfigured is zero, no periodic keep alive messages are sent to the peer after the peers establish a BGP connection. Configure a value of 60 seconds. The range is 0 to 21845.
MD5Authentication	Enables and disables MD5 authentication.
AdvertisementInterval	Specifies the time interval, in seconds, that elapses between each transmission of an advertisement from a BGP neighbor. The default value is 30 seconds and the range is 5–120 seconds. The route advertisement interval feature is implemented using the time stamp that indicates when each route is advertised. The time stamp is marked to each route so that the route advertisement interval is compared to the time stamp and BGP is then able to make a decision about whether the route advertisement can be sent or should be delayed when a better route is received. This feature does not work for a withdraw route because the route entry is already removed when the processing route advertisement is sent and the time stamp marked in the route entry cannot be obtained.
DefaultOriginate	When enabled, specifies that the current route originated from the BGP peer. This parameter enables or disables sending the default route information to the specified neighbor or peer. The default value is false.
DefaultOriginateIpv6	When enabled, specifies that the current IPv6 route originated from the BGP peer. This parameter enables or disables sending the default IPv6 route information to the specified neighbor or peer. The default value is false.

Name	Description
Weight	Specifies the peer or peer group weight, or the priority of updates the system can receive from this BGP peer. The default value is 100 and the range is 0–65535.
MaxPrefix	Configures a limit on the number of routes accepted from a neighbor. The default value is 12000 routes and the range is 0–2147483647. A value of 0 means no limit exists.
NextHopSelf	Specifies that the next-hop attribute in an iBGP update is the address of the local router or the router that generates the iBGP update. The default is disable.
RouteReflectorClient	Specifies that this peer is a route reflector client. Note: This parameter only applies to VRF 0.
SoftReconfigurationIn	When enabled, the router relearns routes from the specified neighbor or group of neighbors without restarting the connection after the policy changes in the inbound direction. The default value is disable. Enabling SoftReconfigurationIn stores all BGP routes in local memory (even non-best routes).
DebugMask	Displays the specified debug information for the BGP peer. The default value is none. • None disables all debug messages. • Event enables the display of debug event messages. • State enables display of debug state transition messages. • Update enables display of debug messages related to updates transmission and reception. • Error enables the display of debug error messages. • Trace enables the display of debug trace messages. • Init enables the display of debug initialization messages. • All enables all debug messages. • Packet enables the display of debug packet messages. • Warning enables the display of debug warning messages. • Filter enables the display of debug messages related to filtering.
SendCommunity	Enables or disables sending the community attribute of the update message to the specified peer. The default value is disable.
Vpnv4Address	Specifies the vpnv4 routes.
IpvpnLiteCap	Enable or disable IP VPN-lite capabilitiy on the BGP neighbor peer.
Ipv6Cap	Enable or disable the IPv6 capability on the BGP neighbor peer. The default value is disable.
SooAddress	Specifies the site-of-origin (SoO) address of the BGP peer.
SooAsNumber	Specifies the site-of-origin (SoO) Autonomous System (AS) number of the BGP peer.

Name	Description
SooAssignedNum	Specifies the site-of-origin (SoO) assigned number of the BGP peer.
SooType	Specifies the site-of-origin (SoO) type of the BGP peer.
RouteRefresh	Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates in the database that are eligible for the peer that issues the request. This parameter only applies to VRF 0.
AsOverride Note: This does not apply to 5320 Series switches.	Specifies that the AS Override parameter can be enabled or disabled for the BGP peer. The default is disable.
AllowAsIn Note: This does not apply to 5320 Series switches.	Specifies the number of AS-in allowed for the BGP peer. The range is 1–10.
Ipv6RoutePolicyIn	Specifies the policy (by name) that applies to all network IPv6 routes learned from this peer.
Ipv6RoutePolicyOut	Specifies the policy (by name) that applies to all outgoing IPv6 route updates.
Ipv6MaxPrefix	Configures a limit on the number of IPv6 routes accepted from a neighbor. A value of 0 means no limit exists.
BfdEnable	Enables Bidirectional Forwarding Detection (BFD) for this BGP peer.

Configure BGPv6 Peers

Configure BGPv6 peers to connect two routers to each other for the purpose of exchanging routing information. BGPv6 peers exchange complete routing information only after they establish the peer connection.

Before You Begin

- To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504. All parameters might not be available in non-default VRFs.
- The VRF must have an RP trigger of BGP.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Select **BGP+**.
3. Select the **Peers** tab.
4. Select **Insert**.

5. Configure the peer, as required.
6. Select **Insert**.
7. In the **Enable** column, double-click the value, and then select **enable**.

   By default, new peer configuration parameters are disabled.
8. Select **Apply**.
9. To modify a peer configuration, double-click the value, and then select a new value.
10. Select **Apply**.

Peers *Field Descriptions*

Use the data in the following table to use the **Peers** tab.

Name	Description
RemoteAddr	Specifies the remote IPv6 address of the entered BGP+ peer.
GroupName	Specifies the peer group name to which the peer belongs (optional).
PeerState	Specifies the BGPv6 peer connection state.
RemoteAs	Configures a remote AS number for the peer or peer-group in the range 0 to 65535.
Enable	Controls whether the peer connection is enabled or disabled. The default is disabled.
EbgpMultiHop	Enables or disables a connection to a BGPv6 peer that is more than one hop away from the local router. The default value is disable.
RoutePolicyIn	Specifies the policy (by name) that applies to all network routes learned from this peer.
RoutePolicyOut	Specifies the policy (by name) that applies to all outgoing route updates.
RemovePrivateAs	Strips (when enabled) private AS numbers when the switch sends an update. The default is enable.
UpdateSourceInterface	Specifies the source IP address to use when the switch sends eBGP packets to this peer or peer group.
ConnectRetryInterval	Specifies the time interval, in seconds, for the connect retry timer. The suggested value for this timer is 120 seconds. The range is 1 to 65535.
HoldTimeConfigured	Specifies the time interval, in seconds, for the hold time for this BGP speaker with this peer. This value is in an open message sent to this peer by this BGP speaker. To determine the hold time with the peer, the switch compares this value with the HoldTime value in an open message received from the peer. The HoldTime must be at least three seconds. If the value is zero, the hold time does not establish with the peer. The suggested value for this timer is 180 seconds. The range is 0 to 65535.

Name	Description
KeepAliveConfigured	Specifies the time interval, in seconds, for the KeepAlive timer configured for this BGP speaker with this peer. KeepAliveConfigured determines the keep alive message frequency relative to HoldTimeConfigured; KeepAlive indicates the actual time interval for the keep alive messages. The maximum value for this timer is one-third of HoldTimeConfigured. If KeepAliveConfigured is zero, no periodic keep alive messages are sent to the peer after the peers establish a BGP connection. Configure a value of 60 seconds. The range is 0 to 21845.
MD5Authentication	Enables and disables MD5 authentication.
AdvertisementInterval	Specifies the time interval, in seconds, that elapses between each transmission of an advertisement from a BGPv6 neighbor. The default value is 30 seconds and the range is 5 to 120 seconds. The route advertisement interval feature is implemented using the time stamp that indicates when each route is advertised. The time stamp is marked to each route so that the route advertisement interval is compared to the time stamp and BGP is then able to make a decision about whether the route advertisement can be sent or should be delayed when a better route is received. This feature does not work for a withdraw route because the route entry is already removed when the processing route advertisement is sent and the time stamp marked in the route entry cannot be obtained.
DefaultOriginateIpv6	When enabled, specifies that the current IPv6 route originated from the BGP peer. This parameter enables or disables sending the default IPv6 route information to the specified neighbor or peer. The default value is false.
Weight	Specifies the peer or peer group weight, or the priority of updates the system can receive from this BGP peer. The default value is 100 and the range is 0 to 65535.
MaxPrefix	Configures a limit on the number of routes accepted from a neighbor. The default value is 12000 routes and the range is 0 to 2147483647. A value of 0 means no limit exists.
NextHopSelf	Specifies that the next-hop attribute in an iBGP update is the address of the local router or the router that generates the iBGP update. The default is disable.
RouteReflectorClient	Specifies that this peer is a route reflector client. Note: This parameter only applies to VRF 0.
SoftReconfigurationIn	When enabled, the router relearns routes from the specified neighbor or group of neighbors without restarting the connection after the policy changes in the inbound direction. The default value is disable. Enabling SoftReconfigurationIn stores all BGP routes in local memory (even non-best routes).

Name	Description
DebugMask	Displays the specified debug information for the BGP peer. The default value is none. • None disables all debug messages. • Event enables the display of debug event messages. • State enables display of debug state transition messages. • Update enables display of debug messages related to updates transmission and reception. • Error enables the display of debug error messages. • Trace enables the display of debug trace messages. • Init enables the display of debug initialization messages. • All enables all debug messages. • Packet enables the display of debug packet messages. • Warning enables the display of debug warning messages. • Filter enables the display of debug messages related to filtering.
SendCommunity	Enables or disables sending the community attribute of the update message to the specified peer. The default value is disable.
IpvpnLiteCap	Enable or disable IP VPN-lite capabilitiy on the BGP neighbor peer.
Ipv6Cap	Enable or disable the IPv6 capability on the BGP neighbor peer. The default value is disable.
RouteRefresh	Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates in the database that are eligible for the peer that issues the request. This parameter only applies to VRF 0.
AsOverride Note: This field does not apply to 5320 Series switches.	Specifies that the AS Override parameter can be enabled or disabled for the BGP peer. The default is disable.
AllowAsIn Note: This field does not apply to 5320 Series switches.	Specifies the number of AS-in allowed for the BGP peer. The range is 1–10.
Ipv6RoutePolicyIn	Specifies the policy (by name) that applies to all network IPv6 routes learned from this peer.
Ipv6RoutePolicyOut	Specifies the policy (by name) that applies to all outgoing IPv6 route updates.
Ipv6MaxPrefix	Configures a limit on the number of IPv6 routes accepted from a neighbor. A value of 0 means no limit exists.
BfdEnable	Enables Bidirectional Forwarding Detection (BFD) for this peer.

Configure Peer Groups

Configure or edit peer groups to create update policies for neighbors in the same group.

Before You Begin

- To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504. All parameters might not be available in non-default VRFs.
- The VRF must have an RP trigger of BGP.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Select **BGP**.
3. Select the **Peer Groups** tab.

   You can modify an existing parameter by double-clicking the value.
4. Select **Insert**.
5. Configure the peer group as required.
6. Select **Apply**.

Peer Groups *field descriptions*

Use the data in the following table to use the **Peer Groups** tab.

Name	Description
Index	Specifies the index of this peer group.
GroupName	Specifies the peer group to which this neighbor belongs (optional).
Enable	Enables or disables the peer group.
RemoteAs	Configures a remote AS number for the peer-group in the range 0–65535.
DefaultOriginate	When enabled, the BGP speaker (the local router) sends the default route 0.0.0.0 to a group of neighbors for use as a default route. The default is disabled.
DefaultOriginateIpv6	When enabled, the BGP speaker (the local router) sends the default route to a group of neighbors for use as a default route. The default is disabled.
EbgpMultiHop	When enabled, the switch accepts and attempts BGP connections to external peers that reside on networks that do not directly connect. The default is disabled.
AdvertisementInterval	Specifies the time interval, in seconds, that elapses between BGP routing updates. The default value is 30 seconds.
KeepAlive	Specifies the time interval, in seconds, between sent BGP keep alive messages to remote peers. The default value is 60.
HoldTime	Configures the hold time for the group of peers in seconds. Use a value that is three times the value of the KeepAlive time. The default value is 180.

Name	Description
Weight	Assigns an absolute weight to a BGP network. The default value is 100.
MaxPrefix	Limits the number of routes accepted from this group of neighbors. A value of zero indicates no limit The default value is 12,000 routes.
NextHopSelf	Specifies that the switch must set the NextHop attribute to the local router address before sending updates to remote peers.
RoutePolicyIn	Specifies the route policy that applies to all networks learned from this group of peers.
RoutePolicyOut	Specifies the route policy that applies to all outgoing updates to this group of peers.
RouteReflectorClient	Specifies that this peer group is a route reflector client. Note: This parameter only applies to VRF 0.
SoftReconfigurationIn	When enabled, the router relearns routes from the specified neighbor or group of neighbors without restarting the connection after the policy changes in the inbound direction. The default value is enable. Enabling SoftReconfigurationIn stores all BGP routes in local memory (even non-best routes).
MD5Authentication	Enables and disables MD5 authentication. The default is disable.
RemovePrivateAs	Strips (when enabled) private AS numbers when the switch sends an update. The default is enable.
SendCommunity	Enables or disables sending the community attribute of the update message to the specified peer group. The default value is disable.
AfUpdateSourceInterfaceType	Specifies the interface type.
AfUpdateSourceInterface	Specifies the IP address used for circuitless IP (CLIP) for this peer group.
Vpnv4Address	Enables BGP address families for IPv4 (BGP) and Layer 3 VPN (MP-BGP) support. Enable this parameter for VPN/VRF Lite routes.
IpvpnLiteCap	Specifies (when enabled) that IP VPN Lite capability can be enabled or disabled on the BGP neighbor peer. The default is disable.
RouteRefresh	Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates in the database that are eligible for the peer that issues the request. This parameter only applies to VRF 0.
AsOverride	Specifies that the AS Override parameter can be enabled or disabled for the BGP peer group. The default is disable.
AllowedAsIn	Specifies the number of AS-in allowed for the BGP peer group. The range is 1–10.

Name	Description
IPv6Cap	Enable or disable the IPv6 capability on the BGP neighbor peer. The default value is disable.
Ipv6RoutePolicyIn	Specifies the policy (by name) that applies to all network IPv6 routes learned from this peer.
Ipv6RoutePolicyOut	Specifies the policy (by name) that applies to all outgoing IPv6 route updates.
Ipv6MaxPrefix	Configures a limit on the number of IPv6 routes accepted from a neighbor. A value of 0 means no limit exists.
BfdEnable	Enables Bidirectional Forwarding Detection (BFD) for the BGP peer group.

View IPv6 Community Attributes

View IPv6 community attributes for specific routes to utilize the update message fields to communicate information between BGP speakers. Use the Path Attribute values to specify the prefixes that the BGP session can exchanged, or which of the multiple paths of a specified prefix to use.

Before You Begin

- To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504. All parameters might not be available in non-default VRFs.
- The VRF must have an RP trigger of BGP.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Select **BGP+**.
3. Select the **Bgp Route Summary** tab.
4. Select a route for which you want to view the route summary information.
5. Select the **Route Comm Attr** option on the menu.

   The **BGP Path Attributes** tab opens with the BGP IPv6 community attribute information.

BGP Path Attributes *Field Descriptions*

Use the data in the following table to use the **BGP Path Attributes** tab.

Name	Description
Origin	Specifies the ultimate origin of the path information.
NextHopAddr	Specifies the address of the border router that is used to access the destination network. This address is the nexthop address received in the UPDATE packet associated with this prefix.

Name	Description
Med	This metric is used to discriminate between multiple exit points to an adjacent autonomous system. When the MED value is absent but has a calculated default value, this object will contain the calculated value.
LocalPref	Specifies the value used during route decision process in the BGP protocol. Applicable to BGP only.
AggregatorAS	Specifies the AS number of the last BGP4 speaker that performed route aggregation. If the AGGREGATOR path attribute is absent, this object will not be present in the conceptual row.
AggregatorAddr	Specifies the IP address of the last BGP4 speaker that performed route aggregation. If the AGGREGATOR path attribute is absent, this object will not be present in the conceptual row.
String	This is a string representing the autonomous system path to the network which was received from the peer which advertised it. The format of the string is implementation-dependent, and is designed for operator readability. Note: SnmpAdminString is only capable of representing a maximum of 255 characters. This may lead to the string being truncated in the presence of a large AS Path.

Display Dampened Routes Information

Display dampened path information to see which routes are suppressed.

Before You Begin

- To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504. All parameters might not be available in non-default VRFs.
- The VRF must have an RP trigger of BGP.
- Enable dampened routes.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Select **BGP**.
3. Select the **Dampened Routes** tab.

***Dampened Routes** field descriptions*

Use the data in the following table to use the **Dampened Routes** tab.

Name	Description
IpAddrPrefix	Specifies the IP address prefix in the NLRI field. This variable is an IP address that contains the prefix with a length specified by IpAddrPrefixLen. Bits beyond the length specified by IpAddrPrefixLen are set to zero.
IpAddrPrefixLen	Specifies the length, in bits, of the IP address prefix in the NLRI field.
Peer	Specifies the IP address of the peer from which the router learns the path information.
FlapPenalty	Specifies the penalty based on number of route flaps.
FlapCount	Specifies the number of times a route flapped (went down and up) since the last time the penalty was reset to zero.
RouteDampened	Indicates whether this route is suppressed or announced.
ReuseTime	Specifies the system-configured time for route reuse.

Configure Redistribution to BGP

Configure redistribute entries for BGP to announce routes of a certain source type to BGP, for example, DvR, direct, static, Routing Information Protocol (RIP), and Open Shortest Path First (OSPF). If you do not configure a route policy, then the switch uses the default action based on metric, metric type, and subnet. Use a route policy to perform detailed redistribution.

Before You Begin

- If required, configure a route policy.
- When you configure BGP on a specific VRF instance, the VRF must have an RP trigger of BGP.
- To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504. All parameters might not be available in non-default VRFs.
- Before you redistribute DvR host routes to BGP, ensure that you disable BGP aggregation and BGP auto-summarization of networks. Disabling these options ensures that all DvR host routes are advertised into BGP correctly, and are not summarized.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Select **BGP**.
3. Select the **Redistribute** tab.
4. Select **Insert**.
5. Configure the source protocol.
6. (Optional) If required, choose a route policy.
7. Configure the metric to apply to redistributed routes.
8. Enable the redistribution instance.
9. Select **Insert**.

***Redistribute** field descriptions*

Use the data in the following table to use the **Redistribute** tab.

Name	Description
DstVrfId	Specifies the destination VRF instance (read-only).
Protocol	Specifies the protocols that receive the redistributed routes.
SrcVrfId	Specifies the source VRF instance (read-only).
RouteSource	Specifies the source protocol for the route redistribution entry.
Enable	Enables (or disables) a BGP redistribute entry for a specified source type.
RoutePolicy	Configures the route policy to use for the detailed redistribution of external routes from a specified source into the BGP domain.
Metric	Configures the metric for the redistributed route. The value can be a range between 0–65535. The default value is 0. Use a value that is consistent with the destination protocol.

Configure Redistribution to BGPv6

Configure redistribute entries for BGPv6 to announce routes of a certain source type to BGPv6, for example, DvR, direct, static, Routing Information Protocol (RIP), and Open Shortest Path First (OSPF). If you do not configure a route policy, then the switch uses the default action based on metric, metric type, and subnet. Use a route policy to perform detailed redistribution.

Before You Begin

- If required, configure a route policy.
- When you configure BGPv6 on a specific VRF instance, the VRF must have an RP trigger of BGP.
- To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504. All parameters might not be available in non-default VRFs.
- Before you redistribute DvR host routes to BGPv6, ensure that you disable BGPv6 aggregation and BGPv6 autosummarization of networks. Disabling these settings ensures that all the DvR host routes are advertised into BGPv6 correctly, and are not summarized.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Select **BGP+**.
3. Select the **Redistribute** tab.
4. Select **Insert**.
5. Configure the source protocol.
6. (Optional) If required, choose a route policy.
7. Configure the metric to apply to redistributed routes.
8. Enable the redistribution instance.
9. Select **Insert**.

Redistribute *field descriptions*

Use the data in the following table to use the **Redistribute** tab.

Name	Description
DstVrfId	Specifies the destination VRF instance (read-only).
Protocol Note: This field does not apply to 5320 Series switches.	Specifies the protocols that receive the redistributed routes.
SrcVrfId	Specifies the source VRF instance (read-only).
RouteSource	Specifies the source protocol for the route redistribution entry.
Enable	Enables (or disables) a BGPv6 redistribute entry for a specified source type.
RoutePolicy	Configures the route policy to use for the detailed redistribution of external routes from a specified source into the BGPv6 domain.
Metric	Configures the metric for the redistributed route. The default value is 0. Use a value that is consistent with the destination protocol.
MetricType	Specifies the metric type. Specifies a type1 or a type2 metric. For metric type1, the cost of the external routes is equal to the sum of all internal costs and the external cost. For metric type2, the cost of the external routes is equal to the external cost alone. The default is type2.

View BGP+ or BGPv6 Route Summary Information

You can display current IPv6 BGP+ route information.

Before You Begin

- To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504. All parameters might not be available in non-default VRFs.
- The VRF must have an RP trigger of BGP.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Select **BGP+**.
3. Select the **Bgp Route Summary** tab to view the BGP route summary information

***Bgp Route Summary** field descriptions*

Use the data in the following table to use the **Bgp Route Summary** tab.

Name	Description
Prefix	Specifies the IP address prefix in the Network Layer Reachability Information (NLRI) field. This is an IP address that contains the prefix with a length specified by IpAddrPrefixLen. Any bits beyond the length specified by IpAddrPrefixLen are set to zero.
PrefixLen	Specifies the length, in bits, of the IP address prefix in the NLRI field.
LocalAddr	The local address of this entry's BGP connection.
RemoteAddr	Specifies the IP address of the peer from which path information was learned.

View BGP Route Summary

Display BGP route summary.

Before You Begin

- To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504. All parameters might not be available in non-default VRFs.
- The VRF must have an RP trigger of BGP.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Select **BGP**.
3. Select the **Bgp Route Summary** tab.

Bgp Route Summary field descriptions

Use the data in the following table to use the Bgp Route Summary tab.

Name	Description
Prefix	Configures the IP address of the route.
PrefixLen	Specifies the IP address and the mask length (the length can be 0–32).
LocalAddr	Specifies the local IP address of the entered BGP route.
RemoteAddr	Specifies the remote IP address of the entered BGP route.

Configure an AS Path List

Configure an AS path list to restrict the routing information a router learns or advertises to and from a neighbor. The AS path list acts as a filter that matches AS paths.

Before You Begin

- To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504. All parameters might not be available in non-default VRFs.
- The VRF must have an RP trigger of BGP.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Select **Policy**.
3. Select the **As Path List** tab.
4. Select **Insert**.
5. Enter the appropriate information for your configuration.
6. Select **Insert**.

As Path List *field descriptions*

Use the data in the following table to use the **As Path List** tab.

Name	Description
Id	Specifies the AS path list.
MemberId	Specifies the AS path access list member ID.
Mode	Specifies the action to take if the system selects a policy for a specific route. Select permit (allow the route) or deny (ignore the route).
AsRegularExpression	Specifies the expression to use for the AS path.

Configure a Community Access List

Configure community lists to specify permitted routes by using their BGP community. This list acts as a filter that matches communities or AS numbers.

Before You Begin

- To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504. All parameters might not be available in non-default VRFs.
- The VRF must have an RP trigger of BGP.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Select **Policy**.
3. Select the **Community List** tab.
4. Select **Insert**.
5. Configure the list as required.
6. Select **Insert**.

***Community List** field descriptions*

Use the data in the following table to use the **Community List** tab.

Name	Description
Id	Specifies the community list. The range is 0–1024.
MemberId	Specifies the community list member ID. The range is 0–65535.
Mode	Specifies the action to take if the system selects a policy for a specific route. Select permit (allow the route) or deny (ignore the route).
Community	Specifies the community access list community string.

BGP Configuration Examples

IPv6 Tunnel Configurations for BGP+

You must configure an IPv6 tunnel and static routes at BGP+ peers when you use BGP+.

When BGP+ peers advertise route information, they use Update messages to advertise route information. And, when route information is encapsulated in Update messages, BGP+ peers convert their own IPv4 peer addresses to IPv4-mapped IPv6 addresses and insert them into the next-hop field in the Update message.

When the BGP+ software module receives Update messages, it adds route information to the IPv6 Routing Manager (RTM). These RTM routes contain next-hop addresses from the BGP peer that the route was learned from. The next-hop addresses are represented as IPv4-mapped IPv6 addresses.

But, because the IPv6 RTM cannot correlate the IPv4-mapped IPv6 address to a specific outgoing interface, you must create a manually-configured static route to make the link between the BGP peer and the IPv6 tunnel interface so that traffic can reach networks advertised by the peer.

Following is one way to express a static route in an IPv6–configured tunnel for BGP+:

```
ipv6 route 0:0:0:0:0:ffff:192.0.2.0/24 cost 1 tunnel 10
```

Configure the IPv6 tunnel endpoint and the BGP peer to reside on the same switch.

If the IPv6 tunnel endpoint and the BGP peer must reside on different switches you can terminate the tunnel on a different switch, but you must consider the following:

- Because the IPv6 tunnel endpoint does not reside on the same switch as the BGP peer, the BGP device cannot use the tunnel as the outgoing interface. That is, to reach the IPv6-configured tunnel endpoint, if the BGP peer resides on a different switch from the IPv6 tunnel endpoint, the next-hop for the manually-configured IPv4-mapped IPv6 static route is the native IPv6 interface next-hop address.

- The node where the tunnel terminates must contain all of the information needed to route the packets between the remote IPv6 network clouds.

  Note

  In order for the tunnel endpoint switch to be aware of all of the necessary IPv6 routes, you may need to redistribute the BGP routes into OSPFv3.

IPv4–mapped IPv6 addresse

IPv4-mapped IPv6 addresses are IPv4 addresses that the system has mapped into the IPv6 address space.

The system uses these IPv4-mapped IPv6 addresses for devices that are only IPv4-capable.

These IPv4-mapped address have the first 80 bits set to zeros, followed by the next 16 bits set to ones, and the last 32 bits have IPv4 addresses.

When converted to an IPv4-mapped IPv6 address, an IPv4 device address of 192.0.2.1 would be represented as one of the following:

- 0:0:0:0:0:FFFF:192.0.2.1
- ::FFFF:192.0.2.1

The following figure illustrates the components in an IPv4-mapped IPv6 address.

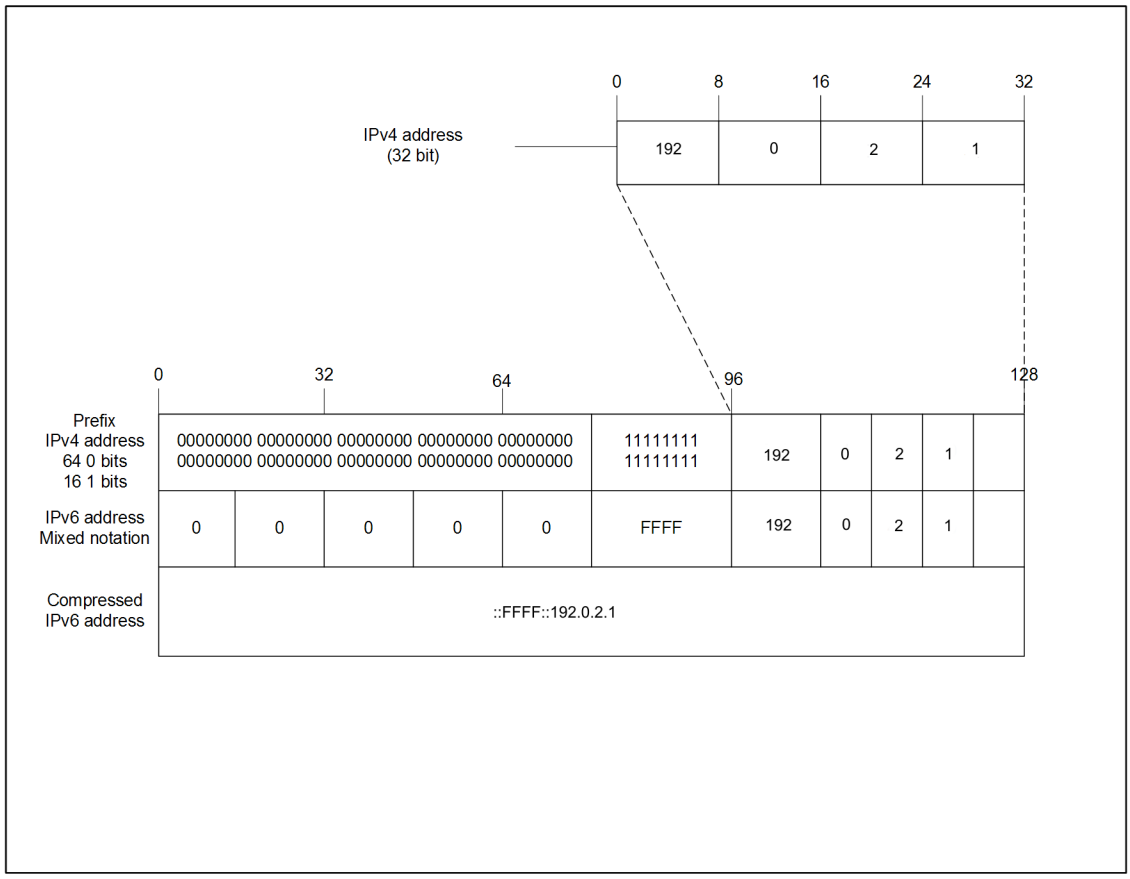

Figure 39: IPv4–mapped IPv6 address components

eBGP+ peership between two switches with IPv6 Tunneling

The following figure shows a sample network that contains eBGP+ peers using IPv6 tunneling.

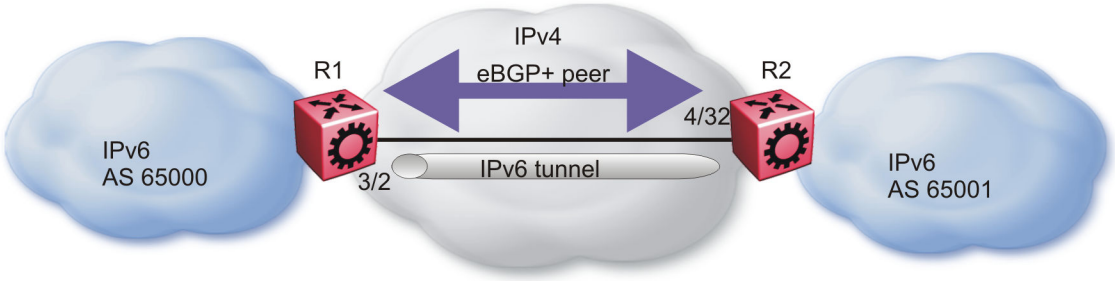

Figure 40: eBGP+ peers with IPv6 tunneling

The configuration in the figure, *eBGP+ peers with IPv6 tunneling* , assumes that the BGP peer IP address is the next hop.

When you configure the static route for the BGP+ tunnel, you must designate the BGP peer IP address as the next hop in most cases.

You can configure multiple static routes, using the same tunnel, but you must ensure reachability when you create the static routes.

R1 configuration

```
interface GigabitEthernet 3/2
brouter port 3/2 vlan 2090 subnet 192.0.2.1/255.255.255.0 mac-offset 2
exit

iBGP+ peership on CLIP between two switches with IPv6 Tunneling

The following figure shows a sample network that contains iBGP+ peers using IPv6 tunneling.

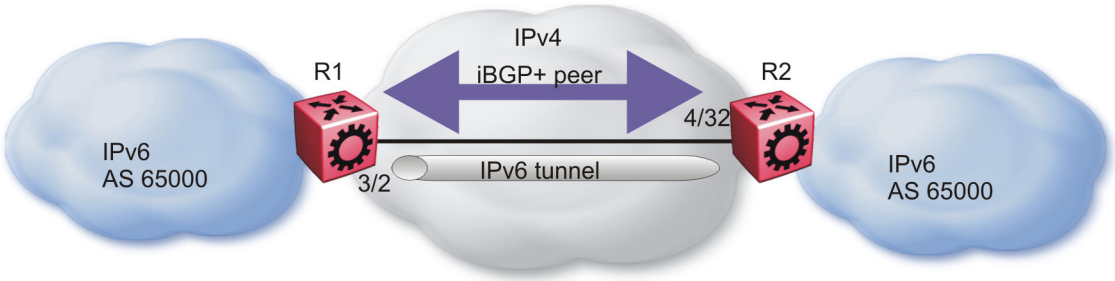

Figure 41: iBGP+ peers on CLIP interfaces with IPv6 tunneling

You must enable OSPF on the interface and globally as well.

If you cannot enable OSPF, you must configure static routes to provide reachability to the BGP+ peer.

The static route must point to the next hop for the routes to be installed in the IPv6 RTM.

The next hop must be the BGP peer IP address.

The IPv4 interfaces do not need to connect directly, but the routing table on each switch must include the IPv4 interface of the other switch.

iBGP between the CLIP interfaces needs to run OSPF as a routing protocol so that the BGP neighbor can remain reachable.

eBGP connections cannot use a CLIP interface as an end point.

R1 configuration

```

Native IPv6 eBGP peership between two switches on VRF

The following figure shows a sample network that contains native IPv6 eBGP peers on VRFs.

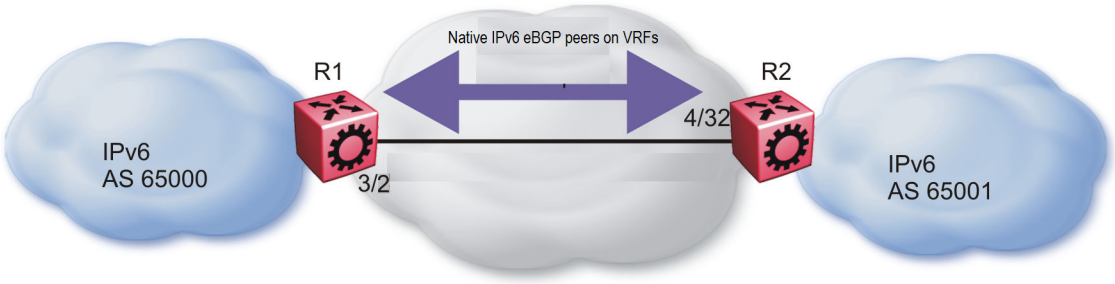

Figure 42: Native IPv6 eBGP peers on VRFs

Configure the local AS first on GRT (and it is inherited by all VRFs), and then enable BGP on GRT/VRF.

You must configure the **`address-family ipv6`** option for IPv6 peers, otherwise, peer-ship is formed, but no routing updates between them will take place.

You must configure the **ebgp-multihop** option for the given eBGP peer that is not on one of local subnets (remote peers), otherwise, peer-ship will not be formed.

Note

The switch does not accept any configuration command for BGP in router-vrf configuration mode unless a BGP instance associated to the VRF context is created. You can use `ip bgp` command in router-vrf configuration mode to create a BGP instance on VRF.

iBGP over User-created VRFs Configuration Example

This section shows examples of configured internal Border Gateway Protocol (iBGP) IPv4 and IPv6 peers over user-created Virtual Routing and Forwarding (VRF) instances.

Note

The Autonomous System (AS) number configured on the global VRF is inherited by all user-created VRFs, however, you can override the AS number for a specific user-created VRF. For more information, see Configure an AS Number for a Non-default VRF on page 416.

IPv4 iBGP Peers Configuration

Chassis Operations

The following sections provide information for chassis operations such as hardware and software compatibility.

Chassis operations fundamentals

This section provides conceptual information for chassis operations such as hardware and software compatibility and power management. Read this section before you configure the chassis operations.

Entity MIB – Physical Table

Table 45: Entity MIB product support

Feature	Product	Release introduced
Entity MIB - Physical Table	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
Entity MIB enhancements and integration for the following: • Physical Table • Alias Mapping Table • Physical Contains Table • Last Change Time object	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
Entity MIB - Logical Table includes the following logical interface entities: • VLANs • MLTs • Circuitless IP (CLIP) • Fabric Extend interfaces (logical layer 2 and layer 3 IS-IS interfaces)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.4
	5720 Series	Fabric Engine 8.7

The Entity MIB – Physical Table assists in the discovery of functional components on the switch. The Entity MIB – Physical Table supports a physical interface table that includes information about the chassis, power supply, fan, I/O cards, console, and management port.

Some hardware platforms support removable interface modules while others offer a fixed configuration. The names used for these modules can vary depending on the hardware platform.

The following table identifies the entity index range for the switch components.

Component	Entity index range
Chassis	1
Power supply slot	3 to 8
Fan tray and fan slot	9 to 16
I/O slot	17 to 30
SF Slot	31 to 36
I/O card or module	37 to 50
SF Card	51 to 56
Console port	57
Console port 2	58
Management port	64
Management port 2	65
Power supply	68 to 73
Fan tray	74 to 81
Fan module	82 to 105
Port	192 to 1023
Pluggable Module and Sensor	19201 to 102314

Power Manager

Table 46: Power Manager product support

Feature	Product	Release introduced
Power Management	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

Power Manager identifies the available power in the chassis (called the power budget), and determines if enough power is available to operate the installed components. Power Manager also gives you control

over which module slots to supply power to and enables you to prioritize the slots that should shut down first if there isn't enough power available.

If the power usage exceeds the power budget, the system powers off the module with the lowest priority. After a power over-usage occurs, the system uses a Simple Network Management Protocol (SNMP) trap to send a message to the network administrator configured to receive the trap.

The system compares the total chassis power consumed against the total chassis power available, and verifies that if one power supply fails, enough power still remains to operate the chassis and components. If enough power is available to keep all modules powered on in the case of a single failed power supply, then the system is considered to have redundant power.

Note

In a redundant power supply configuration, that is, a +1 configuration where the system has one or more power supplies above the actual requirement, the power management logic automatically employs load-sharing across all active power supplies. This load-sharing ensures that the switch draws power equally from all available power supplies to support the system requirements in a fully active model.

If the system does not have redundant power, then the system sends an SNMP trap to the receiver and a message to CLI to inform you that the device no longer operates in redundant power mode.

Software Lock-up Detection

The software lock-up detect feature monitors processes on the CPU to limit situations where the device stops functioning because of a software process issue. Monitored issues include

- software that enters a dead-lock state
- a software process that enters an infinite loop

The software lock-up detect feature monitors processes to ensure that the software functions within expected time limit.

The CPU logs detail about suspended tasks in the log file.

Jumbo frames

Jumbo packets and large packets are particularly useful in server and storage over Ethernet applications. If the payload to header relation increases in a packet, the bandwidth can be used more efficiently. For this reason, increasing Ethernet frame size is a logical option. The switch supports Ethernet frames as large as 9600 bytes, compared to the standard 1518 bytes, to transmit large amounts of data efficiently and minimize the task load on a server CPU.

Tagged VLAN support

A port with VLAN tagging activated can send tagged frames. If you plan to use Jumbo frames in a VLAN, ensure that you configure the ports in the VLAN to accept Jumbo frames and that the server or hosts in the VLAN do not send frames that exceed 9600 bytes. For more information about how to configure VLANs, see VLAN Configuration on page 3402.

Multi-speed Ports

If a port supports multiple speeds, the software configures the speed automatically based on the optic type it detects in the port; you do not need to configure the port speed. For multi-speed copper ports, Auto-Negotiation detects the speed.

Note

Some VIMs must operate with all ports at the same speed, or with a group of ports at the same speed, while others can operate with ports at different speeds. For more information, see *Fabric Engine Release Notes*. The **`sys vim-speed`** command is supported only on VIMs that must operate with all ports at the same speed. An error message displays if you run the command on an unsupported VIM.

In addition to the documented maximum port speed, and in cases where the hardware supports it:

- SFP ports are for 1 Gbps but can also support 100 Mbps.
- SFP+ ports are for 10 Gbps but can also support 1 Gbps or 100 Mbps.
- SFP28 ports are for 25 Gbps but can also support 10 Gbps or 1 Gbps.
- QSFP+ ports are for 40 Gbps but can also support 4x10 Gbps if channelization is supported and enabled.
- QSFP28 ports are for 100 Gbps but also can support 40 Gbps, or 4x25 Gbps or 4x10 Gbps if channelization is supported and enabled.

Note

A 100 Gbps DAC in a 100 Gbps port can negotiate down to 40 Gbps depending on the hardware and peer connection.

SFP28, SFP+ and SFP ports have the same physical size.

QSFP28 and QSFP+ ports have the same physical size.

To know if a port supports multiple speeds or channelization, see the applicable hardware documentation.

Auto-Negotiation

Table 47: Auto-Negotiation product support

Feature	Product	Release introduced
Auto-Negotiation	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4 Note: SFP-DD ports are only available if you disable Advanced Feature Bandwidth Reservation.
	5520 Series	VOSS 8.2.5 Only on the following switch models: 5520-24T 5520-24W 5520-48T 5520-48W 5520-12MW-36W 5520-48SE QSFP28/QSFP+ ports, and all fixed fiber ports, at 1 Gbps only Note: QSFP28 ports are only available if you disable Advanced Feature Bandwidth Reservation. 5520-VIM-4XE at 1 Gbps only and 5520-VIM-4YE at 25 Gbps only
	5720 Series	Fabric Engine 8.7

The Auto-Negotiation feature enables the device to switch between the various operational modes in an ordered fashion and lets you select a specific operational mode. The Auto-Negotiation feature also provides a parallel detection (called autosensing) function to recognize compatible devices, even if they do not support Auto-Negotiation and helps the device sense the link speed only; not the duplex mode.

You can use the **`show interfaces gigabitEthernet l1-config`** command to see the Auto-Negotiation operational state on a port. The operational state uses the configuration and transceiver type present in the port. If you enable Auto-Negotiation for the port but the transceiver type does not support Auto-Negotiation, the operational state is disabled (false).

Important

The software requires the same Auto-Negotiation configuration on link partners to avoid incorrect declaration of link status. Mismatched configuration can cause the links to stay down as well as unpredictable behavior. Ensure the Auto-Negotiation configuration between local ports and their remote link partners match before upgrading software releases.

Default Auto-Negotiation Behavior

The default Auto-Negotiation behavior depends on the switch model, port type, and transceiver type. The following table provides the default combinations.

Table 48: 5320 Series default behavior

Port type	Model	Transceiver type	Auto-Negotiation	FEC
10/100/1000Base-T	5320-24P-8XE 5320-24T-8XE 5320-48P-8XE 5320-48T-8XE 5320-16P-4XE 5320-16P-4XE-DC		Enabled	
First 4 XE SFP+ Note: By default, the first 3 XE ports on the 24- and 48-port models are not available for front panel use because they are reserved for Advanced Feature Bandwidth Reservation.	5320-24P-8XE 5320-24T-8XE 5320-48P-8XE 5320-48T-8XE 5320-16P-4XE 5320-16P-4XE-DC	100M	No 100M support	
		1GBASE-T	Enabled. The operational state is always enabled regardless of configuration.	
		1G SFP	Not Supported	
		10GBASE-T	Enabled. The operational state is always enabled regardless of configuration.	
		10G DAC	Not Supported	
		10G SFP+		

Table 48: 5320 Series default behavior (continued)

Port type	Model	Transceiver type	Auto-Negotiation	FEC
Last 4 XE SFP+	5320-24P-8XE 5320-24T-8XE 5320-48P-8XE 5320-48T-8XE	100M	100FX part number 10063 only	
		1GBASE-T	Enabled. The operational state is always enabled regardless of configuration.	
		1G SFP	Disabled	
		10GBASE-T	Enabled. The operational state is always enabled regardless of configuration.	
		10G DAC	Not Supported	
		10G SFP+

10/100/1000 Mbps Port Considerations

Auto-Negotiation lets devices share a link, and automatically configures both devices so that they take maximum advantage of their abilities. Auto-Negotiation uses a modified 10BASE-T link integrity test pulse sequence to determine device ability.

Configure Auto-Negotiation as shown in the following table, where A and B are two Ethernet devices.

Table 52: Auto-Negotiation configuration on 10/100/1000BASE-TX ports

Port on A	Port on B	Remarks	Best practice
Auto-Negotiation enabled	Auto-Negotiation enabled	Ports negotiate on highest supported mode on both sides.	Use this configuration if both ports support Auto-Negotiation mode.
Full-duplex	Full-duplex	Both sides require the same mode.	Use this configuration if you require full-duplex, but the configuration does not support Auto-Negotiation.

Auto-Negotiation cannot detect the identities of neighbors and cannot shut down misconnected ports. Upper-layer protocols perform these functions.

Note

10 GigabitEthernet (GbE) fiber-based I/O module ports can operate at either 1 Gigabit per second (Gbps) or 10 Gbps, depending upon the capabilities of the optical transceiver that you install.

This situation presents an ambiguity with respect to the Auto-Negotiation configuration of the port, while 1 GbE ports require Auto-Negotiation; Auto-Negotiation is not defined and is non-existent for 10 GbE ports.

For a 10-GbE fiber-based I/O module, you can swap between 1 GbE and 10 GbE operation by simply swapping transceivers. To help with the swap, you can configure Auto-Negotiation when you install a 10 GbE transceiver, even though Auto-Negotiation is not defined for 10 GbE.

You can do this in anticipation of a port changeover from 10 GbE to 1 GbE. In this manner, you can pre-configure a port in 1 GbE mode while the 10 GbE transceiver is still installed. The port is ready to go upon the changeover to the 1 GbE transceiver.

You can use a saved configuration file with Auto-Negotiation enabled, to boot a system with either 10 GbE or 1 GbE transceivers installed. If you install a 1 GbE transceiver, the system applies Auto-Negotiation. If you install a 10 GbE transceiver, the system does not remove the Auto-Negotiation settings from the configuration, but the system simply ignores the configuration because Auto-Negotiation settings are irrelevant to a 10 GbE transceiver. The system preserves the saved configuration for Auto-Negotiation when re-saved no matter which speed of transceiver you install.

25 GbE Port Considerations

25 GbE ports typically support 25 Gbps, 10 Gbps, and 1 Gbps operational speeds. Auto-Negotiation support varies depending on the pluggable type and speed.

For more information, see Default Auto-Negotiation Behavior on page 485.

Forward Error Correction (FEC) is a negotiated port attribute for 25 GbE connections that support Auto-Negotiation. For more information, see Forward Error Correction on page 497.

40 GbE Port Considerations

Auto-Negotiation must be enabled in 40 GbE ports when using 40GbCR4 (copper Direct Attached Cables - DACs) pluggable modules as Clause 73 of the 40 GbE standard lists it as mandatory. Though the links may come up in 40 GbE ports even without Auto-Negotiation, the best practice is to always enable Auto-Negotiation. Otherwise, there might be link instability or FCS errors.

Auto-Negotiation Advertisements

Auto-Negotiation advertisements use Custom Auto-Negotiation Advertisement (CANA) to control the speed and duplex settings that the interface modules advertise during Auto-Negotiation sessions between Ethernet devices. Modules can only establish links using these advertised settings, rather than at the highest common supported operating mode and data rate.

Use CANA to provide smooth migration from 10 Mbps to 10000 Mbps on host and server connections. Using Auto-Negotiation only, the switch always uses the fastest possible data rates. In limited-uplink-bandwidth scenarios, CANA provides control over negotiated access speeds, and improves control over traffic load patterns.

Use the **`auto-negotiation-advertisements`** command to configure CANA.

To use CANA, you must enable Auto-Negotiation.

Important

If a port belongs to a MultiLink Trunking (MLT) group and you configure CANA on the port (that is, you configure an advertisement other than the default), you must apply the same configuration to all other ports of the MLT group if they support CANA.

The following platforms support full duplex and half duplex modes for CANA:

Platform	Full duplex	Half duplex
5720 Series	Yes	Yes
5320 Series	Yes	Yes

Platform	Full duplex	Half duplex
5420 Series	Supported on • 5420F-24S-4XE • 5420F-24T-4XE • 5420F-24P-4XE • 5420M-24W-4YE • 5420M-24T-4YE • 5420M-24W-4YE • 5420M-24T-4YE • 5420F-8W-16P-4XE • 5420F-48P-4XE • 5420F-48T-4XE • 5420F-48P-4XL • 5420M-48W-4YE • 5420M-48T-4YE • only on ports 1/17-1/48 on 5420F-16W-32P-4XE, 5420F-16MW-32P-4XE, 5420M-16MW-32P-4YE	Supported on • 5420F-24T-4XE • 5420F-24P-4XE • 5420M-24W-4YE • 5420M-24T-4YE • 5420M-24W-4YE • 5420M-24T-4YE • 5420F-8W-16P-4XE • 5420F-48P-4XE • 5420F-48T-4XE • 5420F-48P-4XL • 5420M-48W-4YE • 5420M-48T-4YE • only on ports 1/17-1/48 on 5420F-16W-32P-4XE, 5420F-16MW-32P-4XE, 5420M-16MW-32P-4YE
5520 Series	Yes	Supported on 5520-24T, 5520-24W, 5520-48T, 5520-48W and ports 1/1/ - 1/36 on 5520-12MW-36W.
5720 Series	Yes	No

SynOptics Network Management Protocol

Table 53: SONMP product support

Feature	Product	Release introduced
SONMP	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

The switch supports an auto-discovery protocol known as the SynOptics Network Management Protocol (SONMP). SONMP allows a network management station (NMS) to formulate a map that shows the interconnections between Layer 2 devices in a network. SONMP is also called Topology Discovery Protocol (TDP).

All devices in a network that are SONMP-enabled send hello packets to their immediate neighbors, that is, to interconnecting Layer 2 devices. A hello packet advertises the existence of the sending device and provides basic information about the device, such as the IP address and MAC address. The hello packets allow each device to construct a topology table of its immediate neighbors. A network management station periodically polls devices in its network for these topology tables, and then uses the data to formulate a topology map.

If you disable SONMP, the system stops transmitting and acknowledging SONMP hello packets. In addition, the system removes all entries in the topology table except its own entry. If you enable SONMP, the system transmits a hello packet every 12 seconds. The default status is enabled.

SONMP for the Segmented Management Instance

SONMP and LLDP both advertise the same topology IP address for the Segmented Management Instance management interface. SONMP supports IPv4 advertisement only. If all three management interfaces are configured, the advertised default topology IP priority is management CLIP, then management VLAN, then management OOB. You can change the default topology IP using CLI or EDM. If multiple IPv4 addresses are configured on an OOB or VLAN management interface, the advertised IP priority is static IP address, then DHCP IP address, then link-local IP address.

Channelization

Table 54: Channelization product support

Feature	Product	Release introduced
Channelization of 40 Gbps ports	5320 Series	Not Applicable
	5420 Series	Not Applicable
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
Channelization of 100 Gbps ports	5320 Series	Not Applicable
	5420 Series	Not Applicable
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

Use the channelization feature to configure a single port to operate as four individual ports. Channelization can apply to the following port speeds:

- 40 Gbps (Quad Small Form-factor Pluggable) (QSFP+) — when channelized, operates as four 10 Gbps ports
- 100 Gbps (QSFP28) — when channelized, operates as four 25 Gbps ports

Note

In cases where the hardware supports it, you can insert a 40 Gbps QSFP+ transceiver in a 100 Gbps port, and use the 100 Gbps port as a 40 Gbps port. If you enable channelization on a 100 Gbps port and the switch detects a 40 Gbps QSFP+ transceiver in the port, the port operates as four individual 10 Gbps ports.

If the switch detects a 100 Gbps QSFP28 transceiver and you enable channelization, the port operates as four 25 Gbps ports.

To know if you can use a 100 Gbps port as a 40 Gbps port and support the channelization of that port, see the applicable hardware documentation.

You can use breakout direct attach cables (DAC) or transceivers with fiber breakout cables to connect the channelized ports to other servers, storage, and switches.

By default, the ports are not channelized, which means that the ports operate as one single port at the fully supported speed. You can enable or disable channelization on a port.

For the number of ports on the switch that support channelization, see the applicable hardware documentation.

If the product supports channelization and you enable or disable channelization on a port, the port QoS configuration resets to default values. For information about configuring QoS values, see Quality of Service on page 2371.

Note

When you use channelized ports in an Split Multi-Link Trunking (SMLT) configuration, the system does not display the channelized ports properly when you show MLT information for the remote port member if the remote switch runs a release that does not support channelization.

When a port is channelized, use only break out cables (copper or active optical DAC) in it. Using other cables in either a channelized port or a non-channelized port results in mismatched link status between link partners, which can lead to network issues.

SFP-DD Ports

Note

Product Notice: SFP-DD ports are specific to 5420 Series.

Advanced Feature Bandwidth is enabled by default on the SFP-DD ports. When Advanced Feature Bandwidth is disabled, SFP-DD ports can operate as 1 Gbps ports with an SFP and as 10 Gbps ports with an SFP+. When the SFP-DD split DAC is used, SFP-DD ports can accept two SFP+ with 10 Gbps port speed.

Note

SFP-DD split DAC applies to certain 5420 Series models.

For more information about SFP-DD ports, see 5420 Series on page 3568.

Feature Interaction with Channelization

Software features operate on channelized ports. When an interface is dechannelized, the interface cleans up all the channels.

If a feature operates on channel 1/1/1 and 1/1/2, and the circuit is dechannelized, the 1/1/1 configuration is saved and the commands are configured on 1/1. The configuration on 1/1/2 is deleted.

Forward Error Correction

Table 55: Forward Error Correction product support

Feature	Product	Release introduced
Forward Error Correction (FEC) (configurable)	5320 Series	Not applicable
	5420 Series	VOSS 8.4 5420M-24T-4YE, 5420M-24W-4YE, 5420M-16MW-32P-4YE, 5420M-48T-4YE, and 5420M-48W-4YE
	5520 Series	VOSS 8.2.5 5520-VIM-4YE only
	5720 Series	Fabric Engine 8.7

Forward Error Correction (FEC) is a method of obtaining error control in data transmission over an unreliable or noisy channel in which the source (transmitter) encodes the data in a redundant way by using an error correcting code (ECC). This redundancy enables a destination (receiver) to detect a limited number of errors and correct them without requiring a re-transmission.

FEC is useful where re-transmitting data is either expensive or impossible, for example, when transmitting to multiple receivers in multicast. However, although FEC provides more error control, it introduces a latency in data transmission.

FEC Configuration Options

You typically configure FEC on a port. The supported options are:

- cl91 (Clause 91 RS-FEC)
- cl108 (Clause 108 RS-FEC):
- cl74 (Clause 74 Firecode R-FEC):
- auto:

FEC is not supported on:

- Out-of-band (OOB) management ports.
- 100 GbE ports that are changed to 40 GbE ports by dynamically swapping 100 Gb modules with 40 Gb modules. FEC does not support the 40 Gbps speed.

Important

- On ports that support FEC configuration, ensure that you configure the same option at both end-points. Otherwise, the link does not come up.
- You must enable FEC to achieve proper functionality when using interconnects such as the 25Gb SR, 25 Gb SR-lite, 25 Gb ESR optics or the 25 Gb AOC and 25 Gb DAC.
- FEC is not required on 100 Gb or 25 Gb long-range optics because these optics do error checking internally.

Clause 91 RS-FEC

This option supports both the 25 Gbps and 100 Gbps speeds. You can configure this option on ports with either the 100GbSR4 or 100GbCR4 modules plugged in, or on 100 GbE channelized ports operating at 25Gbps speed.

Note

Ensure that you enable Auto-Negotiation for ports with the 100GbCR4 modules plugged in; it is mandatory.

Clause 108 RS-FEC

This option also supports both the 25 Gbps and 100 Gbps speeds. It is similar to Clause 91 but provides extra latency.

Clause 74 Firecode R-FEC

This option supports only the 25 Gbps speed and is used in applications that require reduced latency.

Auto

This option automatically configures FEC based on port speed and pluggable module type.

- For 25 Gbps speeds, FEC CL108 is enabled for all transceiver types.
- For 100Gbps speeds:
  - FEC is disabled for 100GbE LR4 and ER4 transceivers.
  - FEC CL91 is enabled for all other transceiver types (for example, 100GbE SR4, CR4, AOC, CWDM4, SWDM4).

FEC and Auto-Negotiation

FEC is a negotiated port attribute for 25 Gb and 100 Gb connections that support Auto-Negotiation. If you enable Auto-Negotiation on a port for a supported transceiver type, the switch uses the configured FEC value in the negotiation advertisement. Peers can advertise different values, which means the resulting FEC operational state can be different than the one advertised.

The following table lists the 25 Gb end-point advertisements and the resulting FEC operational state:

Table 56: 25 Gb end-point advertisements

Peer A	Peer B	Result
CL108	CL108	CL108
CL74	CL74	CL74
No FEC	No FEC	No FEC
No FEC	CL108	CL108
No FEC	CL74	CL74
CL74	CL108	CL108

The following table lists the 100 Gb end-point advertisements and the resulting FEC operational state:

Table 57: 100 Gb end-point advertisements

Peer A	Peer B	Result
CL91	CL91	CL91
No FEC	No FEC	CL91 Note: Even when both peers advertise no FEC, negotiation results in clause 91 FEC per IEEE standard mandatory setting.
No FEC	CL91	CL91

You can use the **`show interfaces gigabitEthernet config`** command to see the FEC operational state for a port.

For additional details about support, see Default Auto-Negotiation Behavior on page 485.

IEEE 802.3X Pause Frame Transmit

Table 58: IEEE 802.3X Pause Frame Transmit product support

Feature	Product	Release introduced
IEEE 802.3X Pause frame transmit	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

The switch uses MAC pause frames to provide congestion relief on full-duplex interfaces.

Overview

When congestion occurs on a port, the system can send or receive pause frames, also known as flow control, to temporarily pause the packet flow. The system uses flow control if the rate at which one or more ports receives or sends packets is greater than the rate the switch can process or accept the packets.

The switch can generate pause frames to tell the sending device to stop sending additional packets for a specified time period. After the time period expires, the sending device can resume sending packets. During the specified time period, if the switch determines the congestion is reduced, it can send pause frames to the sending device to instruct it to begin sending packets immediately.

Flow control mode and pause frames

If you enable flow control mode, the switch drops packets on ingress when congestion occurs. If the switch is not in flow control mode, it drops packets at egress when congestion occurs.

Configure an interface to send pause frames when congestion occurs to alleviate packet drops due to flow control mode.

Auto-Negotiation

Interfaces that support auto-negotiation advertise and exchange their flow control capability to agree on a pause frame configuration. IEEE 802.3 annex 28b defines the auto-negotiation ability fields and the pause resolution. The switch advertises only two capabilities. The following table shows the software bit settings based on the flow control configuration.

Note

Not all interfaces support Auto-Negotiation. For more information, see your hardware documentation.

Table 59: Advertised abilities

Interface configuration	Pause	ASM	Capability advertised
Flow control enabled	1	0	Symmetric pause
Flow control disabled	1	1	Both Symmetric pause and asymmetric pause

The following tables identifies the pause resolution.

Table 60: Pause resolution

Local device pause	Local device ASM	Peer device pause	Peer device ASM	Local device resolution	Peer device resolution
0	0	Do not care	Do not care	Disable pause transmit and receive.	Disable pause transmit and receive.
0	1	0	Do not care	Disable pause transmit and receive.	Disable pause transmit and receive.
0	1	1	0	Disable pause transmit and receive.	Disable pause transmit and receive.
0	1	1	1	Enable pause transmit. Disable pause receive.	Disable pause transmit. Enable pause receive.
1	0	0	Do not care	Disable pause transmit and receive.	Disable pause transmit and receive.
1	Do not care	1	Do not care	Enable pause transmit and receive.	Enable pause transmit and receive.
1	1	0	0	Disable pause transmit and receive.	Disable pause transmit and receive.
1	1	0	1	Disable pause transmit. Enable pause receive.	Enable pause transmit. Disable pause receive.

The following list identifies the type of interfaces that support auto-negotiated flow control:

- 10 Mbps/100 Mbps/1 Gbps copper
- 100 Mbps/1 Gbps/10 Gbps copper
- 1 Gbps fiber (in both SFP and SFP+ ports)

Auto MDIX

Automatic medium-dependent interface crossover (Auto-MDIX) automatically detects the need for a straight-through or crossover cable connection and configures the connection appropriately. This removes the need for crossover cables to interconnect switches and ensures either type of cable can be used. The speed and duplex setting of an interface must be set to Auto for Auto-MDIX to operate correctly.

Auto MDIX is supported on all platforms with fixed copper ports. All fixed copper ports are supported.

Chassis operations configuration using the CLI

This section provides the details to configure basic hardware and system settings.

Enabling jumbo frames

About This Task

Enable jumbo frames to increase the size of Ethernet frames the chassis supports.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable jumbo frames:

   ```
   sys mtu <1522-9600>
   ```

Example

```
Switch:1> enable

Switch:1# configure terminal
```

Enable jumbo frames to 9600 bytes:

```
Switch:1#(config)# sys mtu 9600
```

Variable Definitions

The following table defines parameters for the **sys mtu** command.

Variable	Value
<1522-9600>	Configures the frame size support for the data path. Possible sizes are 1522, 1950, or 9600 bytes. The default is 1950 bytes.

Configuring port lock

About This Task

Configure port lock to administratively lock a port or ports to prevent other users from changing port parameters or modifying port action. You cannot modify a locked port until you unlock the port.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable port lock globally:

   ```
   portlock enable
   ```

3. Log on to GigabitEthernet Interface Configuration mode:

   ```
   interface gigabitethernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

4. Lock a port:

   ```
   lock port {slot/port[/sub-port][-slot/port[/sub-port]][,...]} enable
   ```

Example

```
Switch:1> enable

Switch:1# configure terminal
```

Log on to GigabitEthernet Interface Configuration mode:

```
Switch:1(config)# interface GigabitEthernet 1/1
```

Unlock port 1/14:

```
Switch:1(config-if)# no lock port 1/14 enable
```

Variable Definitions

The following table defines parameters for the **`interface gigabitethernet`** and **`lock port`** commands.

Variable	Value
`{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}`	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. For the `lock port` command, use the no form of this command to unlock a port: `no lock port {slot/port[/sub-port][-slot/port[/sub-port]][,...]}`

Configuring SONMP

About This Task

Configure the SynOptics Network Management Protocol (SONMP) to allow a network management station (NMS) formulate a map that shows the interconnections between Layer 2 devices in a network. The default status is enabled.

Procedure

1. Enter Global Configuration mode:
   ```
   enable

   configure terminal
   ```
2. Disable SONMP:
   ```
   no autotopology
   ```
3. Enable SONMP:
   ```
   autotopology
   ```

Example

```
Switch:1> enable

Switch:1 configure terminal
```

Disable SONMP:

```
Switch:1(config)# no autotopology
```

View the Topology Message Status

About This Task

View topology message status to view the interconnections between Layer 2 devices in a network.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Show the contents of the topology table:

   ```
   show autotopology nmm-table
   ```

   Unless the witch is physically connected to other devices in the network, this topology will be blank.

Example

Note

In the following example, the column “ChassisType” uses a generic name. When you use the **`show autotopology nmm-table`**, your switch displays the actual chassis type.

```
Switch:1(config)#show autotopology nmm-table
================================================================================================
                                    Topology Table
================================================================================================
Local                                                                                    Rem
Port     IpAddress       SegmentId MacAddress   ChassisType             BT LS  CS     Port
------------------------------------------------------------------------------------------------
0/0      192.0.2.81     0x000000  0030ab707a00 ChassisType 1          12 Yes HtBt   0/0
1/1      192.0.2.81     0x000000  0050ea268800 ChassisType 2          12 Yes HtBt   1/50
1/42     192.0.2.81     0x000000  070ab307aa00 ChassisType 3          12 Yes HtBt   1/1
2/1      192.0.2.81     0x000000  0030ab57ab00 ChassisType 4          12 Yes HtBt   1/49
2/2      192.0.2.81     0x000000  0030ab307af0 ChassisType 5          12 Yes HtBt   1/50
2/41     192.0.2.81     0x000000  00e0ba327c00 ChassisType 6          12 Yes HtBt   2/1
2/42/1   192.0.2.81     0x000000  0050eb127400 ChassisType 7          12 Yes HtBt   1/2
```

Note

When a peer switch is running an older software version that does not include support for SONMP hello messages with channelization information, it can only show the slot/port. It cannot show the sub-port.

Associating a port to a VRF instance

Associate a port to a Virtual Router Forwarding (VRF) instance so that the port becomes a member of the VRF instance.

Before You Begin

- The VRF instance must exist. For more information about the creation of VRFs, see Create a VRF Instance on page 3487.

About This Task

You can assign a VRF instance to a port after you configure the VRF. The system assigns ports to the Global Router, VRF 0, by default.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]} or interface vlan <1-4059>
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Associate a VRF instance with a port:

   ```
   vrf <WORD 1-16>
   ```

Example

```
Switch:1> enable

Switch:1# configure terminal

Switch:1(config)# interface gigabitethernet 1/12

Switch:1(config-if)# vrf red
```

Configure Ethernet Ports with Auto-Negotiation

Configure Ethernet ports so they operate optimally for your network conditions.

About This Task

When you use 1 Gigabit Ethernet SFP transceivers, the software disables Auto-Negotiation on the port. If you use 1 Gbps SFP transceivers, the remote end must also have Auto-Negotiation disabled.

All ports that belong to the same MLT or Link Aggregation Control Protocol (LACP) group must use the same port speed. In the case of MLTs, the software does not enforce this.

The software requires the same Auto-Negotiation settings on link partners to avoid incorrect declaration of link status. Mismatched settings can cause the links to stay down. Ensure the Auto-Negotiation settings between local ports and their remote link partners match before you upgrade the software.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable Auto-Negotiation:

   ```
   auto-negotiate [port {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}] enable
   ```

3. Verify the configuration:

   ```
   show interfaces gigabitEthernet l1-config [{slot/port[/sub-port][-
   slot/port[/sub-port]][,...]}]
   ```

Example

```
Switch:>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitethernet 1/8
Switch:1(config-if)#auto-negotiate enable
Switch:1(config-if)#show interfaces gigabitEthernet l1-config 1/8
================================================================================================================
                                        Port Config L1
================================================================================================================
PORT     AUTO  OPERATE  CUSTOM AUTO NEGOTIATION CANA   ADMIN       OPERATE     ADMIN          OPERATE
NUM      NEG.  AUTO-NEG ADVERTISEMENTS          ORIGIN  DPLX SPD    DPLX SPD  TX-FLW-CTRL    TX-FLW-CTRL
----------------------------------------------------------------------------------------------------------------
1/8      true  true     Not Configured          RADIUS  full 10000    0           enable       enable
```

Variable Definitions

The following table defines parameters for the **auto-negotiate** command.

Variable	Value
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Specifies the port or ports that you want to configure.
enable	Enables auto-negotiation for the port or other ports of the module. The default Auto-Negotation behavior depends on the switch model and transceiver type.

Configure Auto-Negotiation Advertisements

Configure local port Auto-Negotiation advertisements to specify the speed and duplex mode for traffic between local ports and remote link partners. Supported speeds and duplex modes vary, depending on your hardware.

Before You Begin

You must enable Auto-Negotiation before you perform this procedure.

About This Task

Configure local port Auto-Negotiation advertisements.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure Auto-Negotiation advertisements on one or more ports:

   ```
   auto-negotiation-advertisements {25000-full|10000-full|2500-full|5000-
   full|1000-full|100-full|100-half|10-full|10-half}
   ```

   or

   ```
   auto-negotiation-advertisements port {slot/port[/sub-port][-slot/
   port[/sub-port]][,...]}] {25000-full|10000-full|2500-full|5000-full|
   1000-full|100-full|100-half|10-full|10-half}
   ```

3. Verify the configuration:

   ```
   show interfaces gigabitEthernet l1-config [{slot/port[/sub-port][-
   slot/port[/sub-port]][,...]}]
   ```

Variable Definitions

The following table defines parameters for the **auto-negotiation-advertisements** command.

Variable	Value
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Specifies the port or ports that you want to configure.
25000-full	Advertises 25 Gbps full-duplex.
10000-full	Advertises 10 Gbps full-duplex.

Variable	Value
5000-full	Advertises 5 Gbps full-duplex.
2500-full	Advertises 2.5 Gbps full-duplex.
1000-full	Advertises 1 Gbps full-duplex.
100-full	Advertises 100 Mbps full-duplex.
100-half	Advertises 100 Mbps half-duplex.
10-full	Advertises 10 Mbps full-duplex.
10-half	Advertises 10 Mbps half-duplex.
none	Configures the Auto-Negotiate value to none.

Configure IEEE 802.3X Pause Frame Transmit

Configure IEEE 802.3X Pause frame transmit to eliminate or minimize packet loss.

About This Task

By default, flow control mode is disabled. When disabled, the system does not generate nor configure the transmission of flow control messages. The system always honors received flow control messages regardless of the flow control mode status. You must enable this mode before you configure an interface to send pause frames.

By default, an interface does not send pause frames.

Note

If you enable MACsec on an interface and you send small packet size traffic near line rate, the **In FlowCtrl** frame might increment in the output of the **show interface gigabitEthernet statistics** command because of the processing overhead caused by adding the MACsec header of 32 bytes. This is part of the expected over-subscription footprint.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable flow control mode:

   ```
   boot config flags flow-control-mode
   ```

3. Save the configuration.
4. Exit Privileged EXEC mode:

   ```
   exit
   ```

5. Reboot the chassis.

   ```
   boot
   ```

6. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note
   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

7. Configure the interface to generate pause frames:

   ```
   tx-flow-control [enable]
   ```

8. (Optional) Configure other interfaces to generate pause frames:

   ```
   tx-flow-control port {slot/port[/sub-port] [-slot/port[/sub-port]]
   [,...]} enable
   ```

9. Verify the boot flag configuration:

   ```
   show boot config flags
   ```

10. Verify the interface configuration:

    ```
    show interfaces gigabitEthernet l1-config {slot/port[/sub-port] [-
    slot/port[/sub-port]] [,...]}
    ```

11. View the pause-frame packet count:

    ```
    show interfaces gigabitEthernet statistics {slot/port[/sub-port] [-
    slot/port[/sub-port]] [,...]}
    ```

Example

Enable flow control on the system and configure slot 1, port 10 to send pause frames. Verify the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#boot config flags flow-control-mode
Warning: Please save the configuration and reboot the switch
         for this configuration to take effect.
Switch:1<config>#save config
CP-1: Save config to file /intflash/config.cfg successful.
CP-1: Save license to file /intflash/license.xml successful.
Switch:1<config>#exit
Switch:1#boot
Are you sure you want to re-boot the switch (y/n) ?y
```

Note
Flag support can vary across hardware models.

```
Switch:1#show boot config flags
flags advanced-feature-bandwidth-reservation low
flags block-snmp false
flags debug-config false
flags debugmode false
```

```
flags dvr-leaf-mode false

```

Variable Definitions

The following table defines parameters for the **tx-flow-control** command.

Variable	Value
enable	Configures the interface to send pause frames. By default, flow control is disabled.
port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Use the data in the following table to use the **show interfaces gigabitEthernet l1-config** and **show interfaces gigabitEthernet statistics** commands.

Variable	Value
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Enable Channelization

Enable channelization on a port to configure it to operate as four channels, or ports.

Important

Enabling or disabling channelization resets the port QoS configuration to default values.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable channelization on a port:

   ```
   channelize [port {slot/port[-slot/port][,...]}] enable
   ```

3. Display the status of the ports:

   ```
   show interfaces gigabitEthernet channelize [{slot/port[-slot/port]
   [,...]}]
   ```

   To display the details of the sub-ports, use:

   ```
   show interfaces gigabitEthernet channelize detail [{slot/port/sub-
   port[-slot/port/sub-port][,...]}]
   ```

4. (Optional) To disable channelization on a port, enter:

   ```
   no channelize [port {slot/port[/sub-port] [-slot/port[/sub-port]]
   [,...]}] enable
   ```

Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface gigabitethernet 2/1
Switch:1(config-if)# channelize enable
Enabling channelization on port 2/1. Subport 2/1/1 will inherit port 2/1 configuration.
Subports 2,3,4 will use default config. QSFP will be reset as removal and re-insert.
    NOTE: Modify QOS configurations on all subports as required.
Do you wish to continue (y/n) ? y
```

Display the port status:

```
Switch:1(config)# show interfaces gigabitEthernet channelize 2/2-2/4

================================================================================
                              Port Channelization
================================================================================
--------------------------------------------------------------------------------
PORT         ADMIN MODE     CHANNEL TYPE
--------------------------------------------------------------------------------
2/2          true           40G
2/3          false          40G
2/4          false          40G
```

The following is an example of how to disable channelization on a port:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface gigabitethernet 2/2/1
Switch:1(config-if)# no channelize enable
```

Variable Definitions

The following table defines parameters for the **channelization** command.

Variable	Value
{slot/port[/sub-port][-slot/port[/sub-port]][,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Configure FEC on a Port

About This Task

Use this procedure to configure Forward Error Correction (FEC) on supported ports.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]} or interface vlan <1-4059>
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. (Optional) Specify the port or ports to configure for FEC:

   ```
   fec port {slot/port[/sub-port][-slot/port[/sub-port]][,...]}
   ```

3. Configure FEC on a port:

   ```
   fec {auto | cl108 | cl74 | cl91}
   ```

4. Verify the configuration:

   ```
   show interfaces gigabitEthernet config {slot/port[/sub-port][-slot/port[/sub-port]][,...]}
   ```

Examples

Configure Clause 108 FEC on a 25 Gbps port 1/1:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitethernet 1/1
Switch:1(config-if)#fec cl108
```

Verify the configuration when a 25 Gbps optic is present:

```
Switch:1(config-if)#show interfaces gigabitEthernet config 1/1
================================================================================================
                                  Port Config
================================================================================================
PORT                         DIFF-SERV    QOS   MLT   VENDOR
NUM      TYPE                EN    TYPE   LVL   ID    NAME
------------------------------------------------------------------------------------------------
1/1      25GbCX              true  core   1     0     Extreme
================================================================================================
                                  Port Config
================================================================================================

PORT   ADMIN   OPERATE AUTO     ACCESS-SERV  RMON     FLEX-UNI  ADMIN  APPLICABLE  OPERATE
NUM    ROUTING ROUTING RECOVER  EN                               FEC    FEC         FEC
------------------------------------------------------------------------------------------------
1/1   Enable   Disable Disable false         Disable  Disable   Auto  CL108      CL108
```

Verify the configuration when a 10 Gb optic is present in a 25 Gb port:

```
Switch:1(config-if)#show interfaces gigabitEthernet config 1/1
================================================================================================
                                  Port Config
================================================================================================
PORT                         DIFF-SERV    QOS   MLT   VENDOR

------------------------------------------------------------------------------------------------
1/1   Enable   Disable Disable  false        Disable  Disable   Auto  Not Applicable     Off
```

Variable Definitions

The following table defines parameters for the **fec** command.

Variable	Value
port *{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}*	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
{auto | cl108 | cl74 | cl91}	Configures one of the following options for FEC on the port: • auto • Clause 91 • Clause 108 • Clause 74 Note: On a 100 GbE port, only the Clause 91 and Clause 108 options are supported. On 100 GbE channelized ports (operating at 25 Gbps speed), you can configure Clause 108 for extra latency or Clause 74 for reduced latency. Configuration of FEC is not supported on a management port or on 100 GbE ports operating at 40 Gbps speed. Important: On ports that support FEC, always configure the same option on both end-points. Otherwise, the link does not come up.

Configuring Serial Management Port Dropping

Configure the serial management ports to drop a connection that is interrupted for any reason. If you enable serial port dropping, the serial management ports drop the connection for the following reasons:

- modem power failure
- link disconnection
- loss of the carrier

Serial ports interrupted due to link disconnection, power failure, or other reasons force out the user and end the user session. Ending the user session ensures a maintenance port is not available with an active session that can allow unauthorized use by someone other than the authenticated user, and prevents the physical hijacking of an active session by unplugging the connected cable and plugging in another.

By default, the feature is disabled with enhanced secure mode disabled. If enhanced secure mode is enabled, the default is enabled.

For more information on enhanced secure mode, see Enabling enhanced secure mode on page 3012.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the serial port to drop if a connection is interrupted:

   ```
   sys security-console
   ```

Example

Configure the serial port to drop if a connection is interrupted:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#sys security-console
```

Enable the Locator LED

About This Task

Perform this procedure to turn the system Locator LED on to provide a visual identification of a specific switch.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable the system Locator LED:

   ```
   sys locator-led
   ```

3. Display the system Locator LED status:

   ```
   show sys locator-led
   ```

Enable or Disable the USB Port

Perform this procedure to control USB access. For security reasons, you may want to disable this port to prevent individuals from using it. By default, the port is automatically mounted when a USB device is inserted.

Before You Begin

- The switch must be in Enhanced Secure mode.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Disable the USB port:

   ```
   sys usb disable
   ```

3. Enable a previously disabled USB port:

   ```
   no sys usb disable
   ```

View Fan Information

About This Task

View fan information to monitor the alarm status of the cooling ports in the chassis.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display fan information:

   ```
   show sys-info fan
   ```

Example

View fan information:

```
Switch:1>show sys-info fan
********************************************************************************
Tray      Unit      Oper Speed      Oper Speed (Rpm) Airflow Type      Status
1         1         LOW             5782             F2B               OK
1         2         LOW             3366             F2B               OK
```

Configure Port Speed

About This Task

Manually configure the port speed.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note
   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the speed for one or more ports:

   ```
   speed {10|100|1000|10000|2500|25000|5000}
   ```

   or

   ```
   speed port {slot/port[/sub-port][-slot/port[/sub-port]][,...]}] {10|
   100|1000|10000|2500|25000|5000}
   ```

Variable Definitions

The following table defines parameters for the **speed** command.

Variable	Value
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Specifies the port or ports that you want to configure.
10	Configures the port speed to 10 Mbps.
100	Configures the port speed to 100 Mbps.
1000	Configures the port speed to 1 Gbps.
10000	Configures the port speed to 10 Gbps.
2500	Configures the port speed to 2.5 Gbps.
25000	Configures the port speed to 25 Gbps.
5000	Configures the port speed to 5 Gbps.

Configure Ports Speeds for All VIM Ports

Note
This procedure only applies to 5520 Series and 5720 Series.

Configure all of the ports on an installed Versatile Interface Module (VIM) to operate at the same speed.

Note

Some VIMs must operate with all ports at the same speed, or with a group of ports at the same speed, while others can operate with ports at different speeds. For more information, see *Fabric Engine Release Notes*. The **sys vim-speed** command is supported only on VIMs that must operate with all ports at the same speed. An error message displays if you run the command on an unsupported VIM.

Before You Begin

Install the VIM before performing this procedure.

About This Task

Use this procedure to configure the speed of all ports in a multi-port VIM to operate at either 1 Gbps, 10 Gbps, or 25 Gbps.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the speed for all of the VIM ports:

   ```
   sys vim-speed {1000 | 10000 | 25000}
   ```

3. Configure all VIM ports into two speed setting groups:

   ```
   sys vim-speed group <1-2> {1000 | 10000 | 25000}
   ```

Variable Definitions

The following table defines parameters for the **sys vim-speed** command.

Variable	Value
1000 | 10000 | 25000 Note: Exception: 1 Gbps port speed applies to 5720-VIM-6YE only.	Configures all ports in a multi-port VIM to operate at either 1 Gbps, 10 Gbps, or 25 Gbps. The default is 25 Gbps.
group<1-2> Note: Exception: only applies to 5720-VIM-6YE.	Configures all ports into two speed setting groups. • group 1: ports 2/1, 2/2, 2/3 • group 2: ports 2/4, 2/5, 2/6 Ports in groups must be configured to operate at the same speed. For example, ports 2/1, 2/2, 2/3 can be configured for 10 Gbps, and ports 2/4, 2/5, 2/6 can be configured for 25 Gbps.

Display Ports Speeds for All VIM Ports

Note

This procedure only applies to 5520 Series and 5720 Series.

Display the configured speed on all VIM ports.

Note

Some VIMs must operate with all ports at the same speed, while others can operate with ports at different speeds. For more information, see *Fabric Engine Release Notes*. The **show sys vim-speed** command is supported only on VIMs that must operate with all ports at the same speed. An error message displays if you run the command with an unsupported VIM installed.

Before You Begin

Install the VIM before performing this procedure.

About This Task

Use this procedure to display the configured speed of all ports in a multi-port VIM.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the speed for all of the VIM ports:

```
show sys vim-speed
```

View the Management Port Statistics

Use this procedure to view the management port statistics.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```

2. View the management port statistics:

```
show interfaces mgmtethernet statistics
```

Example

View management port statistics:

```
Switch:1#show interfaces mgmtethernet statistics
================================================================================
                          Port Stats Interface
================================================================================
PORT  IN        OUT                IN                 OUT
NUM   OCTETS    OCTETS             PACKET             PACKET
--------------------------------------------------------------------------------
mgmt  7222116   44282              81789              586
```

```
PORT   IN         OUT                IN                 OUT     OUTLOSS
NUM    FLOWCTRL   FLOWCTRL           PFC                PFC     PACKETS
-------------------------------------------------------------------------------
mgmt    0          0                 0                  0       0
```

Displaying Detailed Statistics for Ports

Display detailed statistics for specific ports to manage network performance.

Note

Slot and port information can differ depending on hardware platform.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. View statistics for specific ports:

   ```
   show interfaces GigabitEthernet statistics verbose {slot/port[/sub-port][-slot/port[/sub-port]][,...]}
   ```

Example

View statistics for various ports:

```
Switch:1>enable
Switch:1#show interfaces gigabitethernet statistics verbose

Please widen the terminal for optimal viewing of data.

--More-- (q = quit)
```

Variable Definitions

Use the data in the following table to use the **show interfaces GigabitEthernet statistics verbose** command.

Variable	Value
{slot/port[/sub-port][-slot/port[/sub-port]][,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Chassis operations configuration using EDM

This section provides the details to configure basic hardware and system settings using Enterprise Device Manager (EDM).

Edit System Information

About This Task

Edit system identification information, configuration file information, and perform system actions.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Click **Chassis**.
3. Click the **System** tab.
4. Enter or edit the information as required.
5. Click **Apply**.

System *Field Descriptions*

Use the data in the following table to use the **System** tab.

Name	Description
sysDescr	Shows the system assigned name and the software version.
sysUpTime	Shows the elapsed time since the system last started.
sysContact	Configures the contact information.
sysName	Configures the name of this device.
sysLocation	Configures the physical location of this device.
VirtualIpAddr	Configures the virtual IP address that the primary CPU advertises and stores in the switch configuration file.

Name	Description
VirtualNetMask	Configures the net mask of the virtual management IP address.
VirtualIpv6Addr	Specifies the virtual IPv6 address.
VirtualIpv6PrefixLength	Specifies the length of the virtual IPv6 address prefix (in bits).
DnsDomainName	Configures the default domain for querying the DNS server.
LastChange	Displays the time since the last configuration change.
LastVlanChange	Displays the time since the last VLAN change.
LastStatisticsReset	Displays the time since the statistics counters were last reset.
LastRunTimeConfigSave	Displays the last run-time configuration saved.
DefaultRuntimeConfigFileName	Displays the default Run-time configuration file directory name.
ConfigFileName	Specifies the name of a new configuration file.
ActionGroup1	Performs one of the following actions: • **resetCounters**— Resets all statistic counters. • **saveRuntimeConfig**— Saves the current run-time configuration. • **loadLicense**— Loads a software license file to enable features. • **revokeLicensePremier**— Revokes the Premier license and generates a revocation certificate in XML format. • **revokeLicenseMacsec**—Revokes the MACsec license and generates a revocation certificate in XML format. • **revokeLicense10G4P**— Revokes the 4-port 10 Gbps Port License on 5320 Series and generates a revocation certificate in XML format. • **revokeLicense10G8P**— Revokes the 8-port 10 Gbps Port License on 5320 Series and generates a revocation certificate in XML format.
LicenseFileName	Specifies the name of the license file in the `/intflash` directory.
ActionGroup2	Specifies the following action: **resetIstStatCounters**—Resets the IST statistic counters
ActionGroup3	Can be the following action: • **flushIpRouteTbl**—flushes IP routes from the routing table

Name	Description
ActionGroup4	Can be the following action: • **softReset**—resets the device without running power-on tests • **cpuSwitchOver**—switches over to the other CPU • **softResetCoreDump** —reset with coredump
Result	Displays a message after you select **Apply**.
LocatorLED	Configures the system Locator LED on or off. The default is off.

Edit Chassis Information

About This Task

Edit the chassis information to make changes to chassis-wide settings.

Procedure

1. In the Device Physical View tab, select the device.
2. In the navigation pane, expand **Configuration** > **Edit**.
3. Select **Chassis**.
4. Select the **Chassis** tab.
5. Edit the necessary options.
6. Select **Apply**.

Chassis *Field Descriptions*

Use the data in the following table to use the **Chassis** tab.

Name	Description
Type	Specifies the chassis type.
ModelName	Specifies the chassis model name.
BrandName	Specifies the chassis brand name.
PartNumber	Specifies the device part number.
SerialNumber	Specifies a unique chassis serial number.
HardwareRevision	Specifies the current hardware revision of the device chassis.
NumSlots	Specifies the number of slots available in the chassis.
NumPorts	Specifies the number of ports currently installed in the chassis.
BaseMacAddr	Specifies the starting point of the block of MAC addresses used by the switch for logical and physical interfaces.
MacAddrCapacity	Specifies the number of routable MAC addresses based on the BaseMacAddr.

Name	Description
AutoRecoverDelay	Specifies the time interval, in seconds, after which auto-recovery runs on ports to clear actions taken by CP Limit or link flap. The default is 30.
MTUSize	Configures the maximum transmission unit size. The default is 1950 bytes.
MgidUsageVlanCurrent	Number of MGIDs for VLANs currently in use.
MgidUsageVlanRemaining	Number of remaining MGIDs for VLANs.
MgidUsageMulticastCurrent	Number of MGIDs for multicast currently in use.
MgidUsageMulticastRemaining	Number of remaining MGIDs for multicast.
DdmMonitor	Enables or disables the monitoring of the DDM. When enabled, the user gets the internal performance condition (temperature, voltage, bias, Tx power and Rx power) of the SFP/XFP. The default is disable.
DdmMonitorInterval	Configures the DDM monitor interval in the range of 5 to 60 in seconds. If any alarm occurs, the user gets the log message before the specific interval configured by the user. The default value is 5 seconds.
DdmTrapSend	Enables or disables the sending of trap messages. When enabled, the trap message is sent to the Device manager, any time the alarm occurs. The default is enable.
DdmAlarmPortdown	Sets the port down when an alarm occurs. When enabled, the port goes down when any alarm occurs. The default is disable.

View Physical Entities

Perform this procedure to view information about the functional components of the switch.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Click **Entity**.

Physical Entities Field Descriptions

The following table defines the use the Physical Entities tab.

Name	Description
Index	Indicates the index of the entry.
Descr	Indicates the name of the manufacturer for the physical entity.
VendorType	Indicates the vendor-specific hardware type for the physical entity. Because there is no vendor-specifier registration for this device, the value is 0.

Name	Description
ContainedIn	Indicates the index value for the physical entity which contains this physical entity. A value of zero indicates that this physical entity is not contained in any other physical entity.
Class	Indicates the general hardware type of the physical entity. The value is configured to the standard enumeration value that indicates the general class of the physical entity.
ParentRelPos	Indicates the relative position of the child component among the sibling components.
Name	Indicates the name of the component, as assigned by the local device, and that is suitable to use in commands you enter on the console of the device. Depending on the physical component naming syntax of the device, the name can be a text name such as console, or a component number such as port or module number. If there is no local name, there is no value.
HardwareRev	Indicates the vendor-specific hardware revision string for the physical entity. If no specific hardware revision string is associated with the physical component, or if this information is unknown, then this object contains a zero-length string, or there is no value. If there is no information available, there is no value.
FirmwareRev	Indicates the vendor-specific firmware revision string for the physical entity. If no specific firmware programs are associated with the physical component, or if this information is unknown, then this object contains a zero-length string, or there is no value. If there is no information available, there is no value.
SoftwareRev	Indicates the vendor-specific software revision string for the physical entity. If no specific software programs are associated with the physical component, or if this information is unknown, then this object contains a zero-length string, or there is no value. If there is no information available, there is no value.
SerialNum	Indicates the vendor-specific serial number string for the physical entity. The value is the serial number string printed on the component, if present. If there is no information available, there is no value.

Name	Description
MfgName	Indicates the name of the manufacturer of the physical component. The value is the manufacturer name string printed on the component, if present. If the manufacturer name string associated with the physical component is unknown, then this object contains a zero-length string. If there is no information available, there is no value.
ModelName	Indicates the vendor-specific model name identifier string associated with the physical component. The value is the part number which is printed on the component. If the model name string associated with the physical component is unknown, then this object contains a zero-length string.
Alias	Indicates an alias name for the physical entity that is specified by a network manager, and provides a nonvolatile handle for the physical entity. The software supports read-only and provides values for the port interface only.
AssetID	Indicates a user-assigned asset tracking identifier for the physical entity. This value is specified by a network manager, and provides nonvolatile storage of this information. Because this object is not supported, there is no value.
IsFRU	Indicates whether or not the physical entity is considered a field replaceable unit. • If the value is `true(1)`, then the component is a field replaceable unit. • If the value is `false(2)`, then the component is permanently contained within a field replaceable unit.
MfgDate	Indicates the manufacturing date of the managed entity. If the manufacturing date is unknown, then the value is `'0000000000000000'H`.
Uris	Indicates additional identification information about the physical entity. **Uris** is not supported, therefore there is no value.

View Entity Aliases

About This Task

Perform this procedure to view the entity aliases on the switch.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.

2. Click **Entity**.
3. Click the **Alias** tab.

Alias Field Descriptions

Use the data in the following table to use the **Alias** tab.

Name	Description
Index	The index of the entry
LogicalIndexOrZero	The index of the entry. The value of this object identifies the logical entity that defines the naming scope for the associated instance of the Mapping Identifier object. This is always 0.
MappingIdentifier	The value of this object identifies a particular conceptual row associated with the indicated Physical Index and Logical Index pair. Because only physical ports are modeled in this table, only entries that represent interfaces or ports are allowed. If an ifEntry exists on behalf of a particular physical port, then this object should identify the associated ifEntry. This is the OID of ifIndex.Port.

Viewing Entity Child Indexes

About This Task

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Click **Entity**.
3. Click the **Child Index** tab.

Child Index field descriptions

Use the data in the following table to use the **Child Index** tab.

Name	Description
Index	Indicates the index of the entry.
ChildIndex	The index of the entry. The value of Physical Index for the contained physical entity.

Configure System Flags

About This Task

Configure the system flags to enable or disable flags for specific configuration settings.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Chassis**.
3. Select the **System Flags** tab.
4. Select the system flags you want to activate.
5. Clear the system flags you want to deactivate.
6. Select **Apply**.

Important

After you change certain configuration parameters, you must save the changes to the configuration file.

System Flags *Field Descriptions*

Use the data in the following table to use the **System Flags** tab.

Name	Description
EnableAccessPolicy	Activates access policies. The default is disabled.
ForceTrapSender	Configures circuitless IP as a trap originator. The default is disabled.
ForceIpHdrSender	If you enable Force IP Header Sender, the system matches the IP header source address with SNMP header sender networks. The default is disabled.
AuthSuccessTrapEnable	Enables the system to send the authentication success trap, rcnAuthenticationSuccess. The default is disabled.
MrouteStrLimit	Enable or disable Mroute stream limit in system. The default is disabled.
DataPathFaultShutdownEnable	Enable or disable data path fault shutdown. The default is enabled.
PingTracerouteContextType	Configures the default context for executing ping commands and traceroute commands. The default is grt.
UdpSrcByVirtualIpEnable	Enables or disables virtual IP as the User Datagram Protocol (UDP) source. The default is disabled.
ForceTopologyIpFlagEnable	Activates or disables the flag that configures the CLIP ID as the topology IP. Values are true or false. The default is disabled.
CircuitlessIpId	Uses the CLIP ID as the topology IP. Enter a value from 1–256.

Configure Channelization

Use this procedure to enable or disable channelization on a port. Channelization configures the port to operate as four channels, or ports.

Important

Enabling or disabling channelization resets the port QoS configuration to default values.

Procedure

1. In the Device Physical View tab, select a port that supports channelization.
2. In the navigation pane, expand **Configuration** > **Edit** > **Port**.
3. Select **General**.
4. Select the **Channelization** tab.
5. To enable channelization on the port, select **enable** .
6. Select **Apply** . Alternatively, you can rignt-click the port on the Device Physical View tab, and then select **Channelization Enable**.
7. To disable channelization on a port, select the first sub-port for the corresponding port, slot/port/1.
8. In the navigation pane, expand **Configuration** > **Edit** > **Port**.
9. Select **General**.
10. Select the **Channelization** tab.
11. To disable channelization on the port, select **disable**. This action will disable the four sub-ports.
12. Select **Apply** . Alternatively, you can rignt-click the port on the Device Physical View tab, and then select **Channelization Disable**.

Channelization Field Descriptions

Use the data in the following table to use the **Channelization** tab.

Name	Description
Channelization	This field determines whether channelization is enabled or disabled on the selected port. The two options are **enable** and **disable**. The default is **disable**.

Configure Basic Port Parameters

Configure options for port operations.

About This Task

If you select more than one port, the format of the tab changes to a table-based tab.

When you use 1 Gigabit Ethernet SFP transceivers, the software disables Auto-Negotiation on the port. If you use 1 Gbps SFP transceivers, the remote end must also have Auto-Negotiation disabled.

Procedure

1. In the Device Physical View tab, select one or more ports.
2. In the navigation pane, expand **Configuration** > **Edit** > **Port**.
3. Select **General**.

4. Select the **Interface** tab.
5. Configure the fields as required.

   10/100BASE-TX ports do not consistently auto-negotiate with older 10/100BASE-TX equipment. You can sometimes upgrade the older devices with new firmware or driver revisions. If an upgrade does not enable auto-negotiation to correctly identify the link speed and duplex settings, you can manually configure the settings for the link in question.

   Check the Extreme Networks website for the latest compatibility information.
6. Select **Apply**.

Interface *Field Descriptions*

Use the data in the following table to use the **Interface** tab.

Name	Description
Index	Displays the index of the port, written in the slot/port[/sub-port] format.
Name	Configures the name of the port.
Descr	Displays the description of the port. A textual string containing information about the interface.
Type	Displays the type of connector plugged in the port.
Mtu	Displays the Maximum Transmission Unit (MTU) for the port. The size of the largest datagram which can be sent or received on the interface, specified in octets. For interfaces that are used for transmitting network datagrams, this is the size of the largest network datagram that can be sent on the interface.
PhysAddress	Displays the physical address of the port. The address of the interface at the protocol layer immediately `below' the network layer in the protocol stack. For interfaces which do not have such an address, for example, a serial line, this object should contain an octet string of zero length.
VendorDescr	Displays the vendor of the connector plugged in the port.
DisplayFormat	Identifies the slot and port numbers (slot/port). If the port is channelized, the format also includes the sub-port in the format slot/port/sub-port
AdminStatus	Configures the port as enabled (up) or disabled (down) or testing. The testing state indicates that no operational packets can be passed.
OperStatus	Displays the current status of the port. The status includes enabled (up) or disabled (down) or testing. The testing state indicates that no operational packets can be passed.

Name	Description
LicenseControlStatus Note: Exception: only supported on 5320 Series.	Shows the port license status.
ShutdownReason	Indicates the reason for a port state change.
LastChange	Displays the timestamp of the last change.
LinkTrap	Enable or disable link trapping.
AutoNegotiate	Enables or disables Auto-Negotiation for this port. The default Auto-Negotiation behavior depends on the switch model and transceiver type.
AutoNegAd	Specifies the port speed and duplex abilities to advertise during link negotiation. Supported speeds and duplex modes vary, depending on your hardware. The abilities specified in this object are only used when auto-negotiation is enabled on the port. If all bits in this object are disabled, and auto-negotiation is enabled on the port, then the physical link process on the port will be disabled (if hardware supports this ability). Any change to this configuration restarts the auto-negotiation process, which has the same effect as physically unplugging and reattaching the cable attached to the port. If you select **default**, all capabilities supported by the hardware are advertised.
AdminDuplex	Configures the administrative duplex setting for the port.
OperDuplex	Indicates the operational duplex setting for the port.
AdminSpeed	Configures the administrative speed for the port.
OperSpeed	Indicates the operational speed for the port.
QoSLevel	Selects the Quality of Service (QoS) level for this port. The default is level1.
DiffServ	Enables the Differentiated Service feature for this port. The default is disabled.
Layer3Trust	Configures if the system should trust Layer 3 packets coming from access links or core links only. The default is core.
Layer2Override8021p	Specifies whether Layer 2 802.1p override is enabled (selected) or disabled (cleared) on the port. The default is disabled (clear).
MltId	Shows the MLT ID associated with this port. The default is 0.
Locked	Shows if the port is locked. The default is unlocked.

Name	Description
UnknownMacDiscard	Discards packets that have an unknown source MAC address, and prevents other ports from sending packets with that same MAC address as the destination MAC address. The default is disabled.
DirectBroadcastEnable	Specifies if this interface forwards direct broadcast traffic.
OperRouting	Shows the routing status of the port.
HighSecureEnable	Enables or disables the high secure feature for this port.
RmonEnable	Enables or disables Remote Monitoring (RMON) on the interface. The default is disabled.
FlexUniEnable	Enables Flex UNI on the port. The default is disabled.
EgressRateLimitState	Enables or disables egress port-based shaping to bind the maximum rate at which traffic leaves the port. The default is disabled.
EgressRateLimit	Specifies the egress rate limit in Kbps. Different hardware platforms support different egress rate limits, depending on the port with the highest speed available on the platform. You cannot configure the egress shaper rate to exceed the port capability. If you configure this value to 0, shaping is disabled on the port.
TxFlowControl	Configures if the port sends pause frames. By default, an interface does not send pause frames. You must also enable the flow control feature globally before an interface can send pause frames.
TxFlowControlOperState	Shows the operational state of flow control.
BpduGuardTimerCount	Shows the time, starting at 0, since the port became disabled. When the BpduGuardTimerCount reaches the BpduGuardTimeout value, the port is enabled. Displays in 1/100 seconds.
BpduGuardTimeout	Specifies the value to use for port-state recovery. After a BPDU guard disables a port, the port remains in the disabled state until this timer expires. You can configure a value of 0 or to 65535. The default is 120 seconds. If you configure the value to 0, the expiry is infinity.
BpduGuardAdminEnabled	Enables BPDU Guard on the port. The default is disabled.

Name	Description
ForwardErrorCorrection	Configures one of the following options for Forward Error Correction (FEC) on the port: • CL 91 • CL 108 • CL 74 • disable • auto The disable option disables this configuration on the port.
ForwardErrorCorrectionApplicability	Displays whether FEC is applicable on the interface.
OperAutoNegotiate	Shows the operational state of Auto-Negotiation.
OperForwardErrorCorrection	Shows the negotiated operational FEC clause. If the value is off, the port supports FEC and is up but not configured for FEC. If the value is notApplicable, the port does not support FEC. If the value is unknown, the port supports FEC but is down.
Action	Performs one of the following actions on the port • none - none of the following actions • flushMacFdb - flush the MAC forwarding table • flushArp - flush the ARP table • flushIp - flush the IP route table • flushAll - flush all tables • triggerRipUpdate — manually triggers a RIP update The default is none.
Result	Displays the result of the selected action. The default is none.
AutoSense	Enables or disables Auto-sense on the specific port. The default value is disabled for existing configurations but enabled for new Zero Touch Fabric Configuration deployments.
AutoSenseKeepAutoConfig	Retains the Auto-sense configuration if you disable Auto-sense on the port. The dynamic configuration becomes a manual configuration and is visible in the **`show running-config`** output.
CustomAutoNegAdOrigin	Specifies the origin of Custom Auto Negotiation Advertisements (CANA) configuration on the port. The supported values are: • config - Set by the user. • radius - Set by the Remote Authentication Dial-In User Service (RADIUS) attribute.

Name	Description
BpduGuardOrigin	Specifies the origin of BPDU Guard configuration on the port. The supported values are: • config - Set by the user. • radius - Set by the Remote Authentication Dial-In User Service (RADIUS) attribute.
AutoSenseState	Displays the Auto-sense port state.
LinkDebounce	Specifies the extended debounce timer on the port. The range is 0 to 300000 milliseconds. The value 0 milliseconds disables debounce time. The default value is 1000.
AutoSenseDataIsid	Specifies the Auto-sense data I-SID per port. The range is 0 to 15999999.

Configure Basic Parameters on an Extreme Integrated Application Hosting Port

Note

This procedure only applies to 5720 Series.

About This Task

Perform this procedure to configure basic parameters on Extreme Integrated Application Hosting (IAH) ports, for example, auto negotiation, QoS level, and remote monitoring.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit** > **Insight Port**.
2. Select the IAH port you want to configure.
3. Select the **Interface** tab.
4. In the **Name** field, type a name for the IAH port.
5. Configure the fields as required.
6. Select **Apply**.

Interface *Field Descriptions*

Use data in the following table to use the **Interface** tab.

Name	Description
Index	Specifies the index of the Extreme Integrated Application Hosting (IAH) port, written in the slot/port[/sub-port] format.
Name	Specifies the name of the IAH port.
Descr	Specifies the information about the interface.
Type	Specifies the type of connector plugged in the IAH port.

Name	Description
Mtu	Specifies the Maximum Transmission Unit (MTU) for the port. The size of the largest datagram which can be sent or received on the interface, specified in octets. For interfaces that are used for transmitting network datagrams, this is the size of the largest network datagram that can be sent on the interface.
PhysAddress	Specifies the physical address of the IAH port. The address of the interface at the protocol layer immediately below the network layer in the protocol stack. For interfaces which do not have such an address (like a serial line), this object should contain an octet string of zero length.
VendorDescr	Specifies the vendor of the connector plugged in the IAH port.
DisplayFormat	Specifies the slot and port numbers (slot/port).
AdminStatus	Specifies the operational status of the IAH port. The testing state indicates that no operational packets can be passed.
OperStatus	Specifies the current status of the IAH port. The testing state indicates that no operational packets can be passed.
LicenseControlStatus	Specifies the IAH port license status.
ShutdownReason	Specifies the reason for the IAH port state change.
LastChange	Specifies the timestamp of the last change.
LinkTrap	Enables or disables link trapping. The default is enabled.
AutoNegotiate	Enables or disables auto-negotiation for the IAH port. The default is true (enabled).
AutoNegAd	Specifies the port speed and duplex abilities to be advertised during link negotiation. The abilities specified in this object are only used when auto-negotiation is enabled on the IAH port. If all bits in this object are disabled, and auto-negotiation is enabled on the IAH port, then the physical link process on the IAH port will be disabled (if hardware supports this ability). Any change in the value of this bit map will force the switch to restart the auto-negotiation process. The capabilities being advertised are either all the capabilities supported by the hardware or the user-configured capabilities, which is a subset of all the capability supported by hardware. By default, all capabilities supported by the hardware are enabled.
AdminDuplex	Specifies the administrative duplex setting for the IAH port.

Name	Description
OperDuplex	Specifies the operational duplex setting for the IAH port.
AdminSpeed	Specifies the administrative speed for the IAH port.
OperSpeed	Specifies the operational speed for the IAH port.
QoSLevel	Specifies the Quality of Service (QoS) level for the IAH port. The default is level1.
DiffServ	Enables the Differentiated Service feature for the IAH port. The default is enabled.
Layer3Trust	Specifies if the system should trust Layer 3 packets coming from access links or core links only. The default is core.
Layer2Override8021p	Specifies whether Layer 2 802.1p override is enabled or disabled. The default is disabled.
MltId	Specifies the MLT ID associated with the IAH port. The default is 0.
Locked	Specifies if the IAH port is locked. The default is false.
UnknownMacDiscard	Enables the functionality to discard packets with an unknown source MAC address, and prevents the other IAH port from sending packets with the same MAC address as the destination MAC address. The default is disabled.
DirectBroadcastEnable	Specifies if the IAH port forwards direct broadcast traffic.
OperRouting	Specifies the routing status of the IAH port. The default is disabled.
HighSecureEnable	Enables or disables the high secure feature for the IAH port. The default is disabled.
RmonEnable	Enables or disables Remote Monitoring (RMON) on the IAH port. The default is disabled.
FlexUniEnable	Enables or disables Flex UNI on the IAH port. The default is disabled.
EgressRateLimitState	Enables or disables egress port-based shaping to bind the maximum rate at which traffic leaves the IAH port. The default is disabled.
EgressRateLimit	Specifies the egress rate limit in Kbps. Different hardware platforms provide different port speeds. The default is 0.
TxFlowControl	Specifies if the IAH port is sending pause frames. The default is disabled. Note: You must enable the flow control feature globally.

Name	Description
TxFlowControlOperState	Specifies the operational state of flow control.
BpduGuardTimerCount	Specifies the duration since when the IAH port is disabled. When the BpduGuardTimerCount reaches the BpduGuardTimeout value, the IAH port is enabled.
BpduGuardTimeout	Specifies the time (in seconds) for the IAH port-state recovery. After the IAH port is disabled by the BPDU guard, the IAH port remains in the disabled state until this timer expires. The default is 120 seconds. If you configure the value to 0, the expiry is infinity.
BpduGuardAdminEnabled	Enables or disables BPDU Guard on the IAH port. The default is disabled.
ForwardErrorCorrection	Configures one of the following options for Forward Error Correction (FEC) on the IAH port: • CL 91 • CL 108 • CL 74 • disable • auto The disable option disables this configuration on the port.
ForwardErrorCorrectionApplicability	Displays whether FEC is applicable on the interface.
OperAutoNegotiate	Shows the operational state of Auto-Negotiation.
OperForwardErrorCorrection	Shows the negotiated operational FEC clause. If the value is off, the port supports FEC and is up but not configured for FEC. If the value is notApplicable, the port does not support FEC. If the value is unknown, the port supports FEC but is down.
Action	Specifies the following actions on the IAH port: • none - no action. • flushMacFdb - flush the MAC forwarding table. • flushArp - flush the ARP table. • flushIp - flush the IP route table. • flushAll - flush all tables. • triggerRipUpdate - manually triggers a RIP update. • clearLoopDetectAlarm - clears the loop detection alarm on the IAH port. The default is none.
Result	Specifies the result of the selected action. The default is none.

Name	Description
AutoSense	Enables or disables Auto-sense on the specific port. The default value is disabled for existing configurations but enabled for new Zero Touch Fabric Configuration deployments.
AutoSenseKeepAutoConfig	Retains the Auto-sense configuration if you disable Auto-sense on the port. The dynamic configuration becomes a manual configuration and is visible in the **`show running-config`** output.
AutoSenseState	Displays the Auto-sense port state.
CustomAutoNegAdOrigin	Specifies the origin of Custom Auto Negotiation Advertisements (CANA) configuration on the port. The supported values are: • config - Set by the user. • radius - Set by the Remote Authentication Dail-In User Service (RADIUS) attribute.
BpduGuardOrigin	Specifies the origin of BPDU Guard configuration on the port. The supported values are: • config - Set by the user. • radius - Set by the Remote Authentication Dail-In User Service (RADIUS) attribute.

Configure IEEE 802.3X Pause Frame Transmit

Configure IEEE 802.3X Pause frame transmit to eliminate or minimize packet loss.

About This Task

By default, flow control mode is disabled. When disabled, the system does not generate nor configure the transmission of flow control messages. The system always honors received flow control messages regardless of the flow control mode status. You must enable this mode before you configure an interface to send pause frames.

By default, an interface does not send pause frames.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Chassis**.
3. Select the **Boot Config** tab.
4. For EnableFlowControlMode, select **enable**.
5. Select **Apply**.
6. Save the switch configuration.
7. Reboot the chassis, and log in again.
8. In the Device Physical View, select a port or ports.
9. In the navigation pane, expand **Configuration** > **Edit** > **Port**.
10. Select **General**.

11. Select the **Interface** tab.
12. For TxFlowControl, select **enable** to enable the interface to generate pause frames.
13. Select **Apply**.

View the Boot Configuration

About This Task

View the boot configuration to determine the software version, as well as view the source from which the switch last started.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Chassis**.
3. Select the **Boot Config** tab.

Boot Config *Field Descriptions*

Use the data in the following table to use the **Boot Config** tab.

Name	Description
SwVersion	Specifies the software version that currently runs on the chassis.
LastRuntimeConfigSource	Specifies the last source for the run-time image.
PrimaryConfigSource	Specifies the primary configuration source.
PrimaryBackupConfigSource	Specifies the backup configuration source to use if the primary does not exist.
EnableFactoryDefaultsMode	Specifies whether the switch uses the factory default settings at startup. • **false**: The node does not use factory default settings at startup. • **fabric**: This mode is not supported. • **noFabric**: The node uses the factory default mode settings at startup. The default value is false. This flag is automatically reset to the default setting after the switch restarts. If you change this parameter, you must restart the switch for the change to take effect. Note: The factorydefaults flag deletes the runtime, primary and backup configuration files, local password files, authentication keys, and certificates. After a factory default, you must change the password on first login.

Name	Description
EnableDebugMode	Enabling the debugmode allows a user to enable TRACE on any port by prompting the selection on the console during boot up. This allows the user start trace for debugging earlier on specified port. It only works on console connection. The default value is disabled. Important: Do not change this parameter.
EnableRebootOnError	Activates or disables automatic reboot on a fatal error. The default value is activated. Important: Do not change this parameter.
EnableTelnetServer	Activates or disables the Telnet server service. The default value is disabled.
EnableFtpServer	Activates or disables the FTP server on the switch. The default value is disabled. To enable FTP, ensure that the TFTPD flag is disabled.
EnableTftpServer	Activates or disables Trivial File Transfer Protocol server service. The default value is disabled.
EnableSshServer	Activates or disables the SSH server service. The default value is disabled.
EnableSpbmConfigMode	Enables you to configure SPB and IS-IS, but you cannot configure PIM and IGMP either globally or on an interface. The boot flag is enabled by default.
EnableIpv6Mode	Enable this flag to support IPv6 routes with prefix-lengths greater than 64 bits. This flag is disabled by default.
EnableEnhancedsecureMode	Enables or disables the enhanced secure mode. Select either **jitc** or **non-jitc** to enable the enhanced secure mode in one of these sub-modes. The default is disabled. Note: As a best practice, enable the enhanced secure mode in the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.
EnableUrpfMode	Enables Unicast Reverse Path Forwarding (uRPF) globally. You must enable uRPF globally before you configure it on a port or VLAN. The default is disabled.

Name	Description
EnableFlowControlMode	Enables or disables flow control globally. When disabled, the system does not generate nor configure the transmission of flow control messages. The system always honors received flow control messages regardless of the flow control mode status. You must enable this mode before you configure an interface to send pause frames. The default is disabled.
AdvancedFeatureBwReservation Note: Exception: vim is only supported on 5520 Series and 5720 Series. Exception: high is only supported on 5720 Series. Exception: low is not supported on 5720 Series.	Enables the switch to support advanced features by reserving ports as loopback ports. When disabled, you can use all ports on the switch, but advanced features do not work. The default varies depending on the platform: • The default for 5320 Series and 5420 Series is enabled with low level. • The default for 5520 Series is enabled with vim level if Versatile Interface Module (VIM) is not installed, else low level is enabled. • The default for 5720 Series is enabled with vim level if Versatile Interface Module (VIM) is not installed, else high level is enabled. • The low level means that the switch reserves less bandwidth to support minimum functionality for advanced features. • The vim level means that the switch uses VIM ports as loopback ports and the Universal Ethernet ports for uplinks. • The high level parameter means that the switch reserves the maximum bandwidth for the advanced features. If you change this parameter, you must restart the switch.
EnableDvrLeafMode	Enables the switch to be configured as a DvR Leaf. When enabled, you cannot configure the switch to operate as a DvR Controller.
EnablevrfScaling	Changes the maximum number of VRFs and Layer 3 VSNs that the switch supports. If you select this check box, the maximum number increases. The default is disabled. Important: If you select both this check box and the **EnableSpbmConfigMode** check box, the switch reduces the number of configurable VLANs. For more information about maximum scaling numbers, see *Fabric Engine Release Notes*.

Name	Description
EnableSyslogRfc5424Format	Enables or disables the RFC 5424 syslog format. The default is enabled. If the pre-existing configuration file is for a release prior to this enhancement, then the flag is disabled automatically.
NniMstp	Enables MSTP, and allows non SPBM B-VLAN configuration on SPBM network-to-network interface (NNI) ports. The default is disabled. Note: Spanning Tree is disabled on all SPBM NNIs. You cannot add an SPBM NNI port or MLT port to any non SPBM B-VLAN.
EnableIpv6EgressFilterMode	Enables IPv6 egress filters. The default is disabled. If you change this parameter, you must restart the switch. For 5320 Series, 5420 Series, and 5720 Series platforms, **EnableIpv6EgressFilterMode** and **EnableMacsec** are mutually exclusive.
EnableMacsec Note: Exception: only required for 5320 Series and 5420 Series.	Enables Media Access Control Security (MACsec) mode globally. To enable MACsec mode, you must configure the boot flag. **EnableIpv6EgressFilterMode** and **EnableMacsec** are mutually exclusive.
EnableSpbmNodeScaling Note: Exception: only applies to 5320 Series and 5420 Series.	Enables the switch to increase the number of supported SPB nodes per area. By default, the switch supports up to 350 SPB nodes per area. The default is disabled. If you change this parameter, you must restart the switch.
Slot	Specifies the slot number.
TftpHash	Enables TFTP hashing.
TftpRetransmit	Set TFTP retransmit timeout counter.
TftpTimeout	Set TFTP timeout counter.
User	Configure host user.
Password	Configure host password.

Configure Boot Flags

About This Task

Change the boot configuration to determine the services available after the system starts.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit** > **Chassis**.

2. Select the **Boot Config** tab.
3. Select the services you want to enable.
4. Select **Apply**.

Boot Config *Field Descriptions*

Use the data in the following table to use the **Boot Config** tab.

Name	Description
SwVersion	Specifies the software version that currently runs on the chassis.
LastRuntimeConfigSource	Specifies the last source for the run-time image.
PrimaryConfigSource	Specifies the primary configuration source.
PrimaryBackupConfigSource	Specifies the backup configuration source to use if the primary does not exist.
EnableFactoryDefaultsMode	Specifies whether the switch uses the factory default settings at startup. • **false**: The node does not use factory default settings at startup. • **fabric**: This mode is not supported. • **noFabric**: The node uses the factory default mode settings at startup. The default value is false. This flag is automatically reset to the default setting after the switch restarts. If you change this parameter, you must restart the switch for the change to take effect. Note: The factorydefaults flag deletes the runtime, primary and backup configuration files, local password files, authentication keys, and certificates. After a factory default, you must change the password on first login.
EnableDebugMode	Enabling the debugmode allows a user to enable TRACE on any port by prompting the selection on the console during boot up. This allows the user start trace for debugging earlier on specified port. It only works on console connection. The default value is disabled. Important: Do not change this parameter.
EnableRebootOnError	Activates or disables automatic reboot on a fatal error. The default value is activated. Important: Do not change this parameter.

Name	Description
EnableTelnetServer	Activates or disables the Telnet server service. The default value is disabled.
EnableFtpServer	Activates or disables the FTP server on the switch. The default value is disabled. To enable FTP, ensure that the TFTPD flag is disabled.
EnableTftpServer	Activates or disables Trivial File Transfer Protocol server service. The default value is disabled.
EnableSshServer	Activates or disables the SSH server service. The default value is disabled.
EnableSpbmConfigMode	Enables you to configure SPB and IS-IS, but you cannot configure PIM and IGMP either globally or on an interface. The boot flag is enabled by default.
EnableIpv6Mode	Enable this flag to support IPv6 routes with prefix-lengths greater than 64 bits. This flag is disabled by default.
EnableEnhancedsecureMode	Enables or disables the enhanced secure mode. Select either **jitc** or **non-jitc** to enable the enhanced secure mode in one of these sub-modes. The default is disabled. Note: As a best practice, enable the enhanced secure mode in the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.
EnableUrpfMode	Enables Unicast Reverse Path Forwarding (uRPF) globally. You must enable uRPF globally before you configure it on a port or VLAN. The default is disabled.
EnableFlowControlMode	Enables or disables flow control globally. When disabled, the system does not generate nor configure the transmission of flow control messages. The system always honors received flow control messages regardless of the flow control mode status. You must enable this mode before you configure an interface to send pause frames. The default is disabled.

Name	Description
AdvancedFeatureBwReservation Note: Exception: vim is only supported on 5520 Series and 5720 Series. Exception: high is only supported on 5720 Series. Exception: low is not supported on 5720 Series.	Enables the switch to support advanced features by reserving ports as loopback ports. When disabled, you can use all ports on the switch, but advanced features do not work. The default varies depending on the platform: • The default for 5320 Series and 5420 Series is enabled with low level. • The default for 5520 Series is enabled with vim level if Versatile Interface Module (VIM) is not installed, else low level is enabled. • The default for 5720 Series is enabled with vim level if Versatile Interface Module (VIM) is not installed, else high level is enabled. • The low level means that the switch reserves less bandwidth to support minimum functionality for advanced features. • The vim level means that the switch uses VIM ports as loopback ports and the Universal Ethernet ports for uplinks. • The high level parameter means that the switch reserves the maximum bandwidth for the advanced features. If you change this parameter, you must restart the switch.
EnableDvrLeafMode	Enables the switch to be configured as a DvR Leaf. When enabled, you cannot configure the switch to operate as a DvR Controller.
EnablevrfScaling	Changes the maximum number of VRFs and Layer 3 VSNs that the switch supports. If you select this check box, the maximum number increases. The default is disabled. Important: If you select both this check box and the **EnableSpbmConfigMode** check box, the switch reduces the number of configurable VLANs. For more information about maximum scaling numbers, see *Fabric Engine Release Notes*.
EnableSyslogRfc5424Format	Enables or disables the RFC 5424 syslog format. The default is enabled. If the pre-existing configuration file is for a release prior to this enhancement, then the flag is disabled automatically.

Name	Description
NniMstp	Enables MSTP, and allows non SPBM B-VLAN configuration on SPBM network-to-network interface (NNI) ports. The default is disabled. Note: Spanning Tree is disabled on all SPBM NNIs. You cannot add an SPBM NNI port or MLT port to any non SPBM B-VLAN.
EnableIpv6EgressFilterMode	Enables IPv6 egress filters. The default is disabled. If you change this parameter, you must restart the switch. For 5320 Series, 5420 Series, and 5720 Series platforms, **EnableIpv6EgressFilterMode** and **EnableMacsec** are mutually exclusive.
EnableMacsec Note: Exception: only required for 5320 Series and 5420 Series.	Enables Media Access Control Security (MACsec) mode globally. To enable MACsec mode, you must configure the boot flag. **EnableIpv6EgressFilterMode** and **EnableMacsec** are mutually exclusive.
EnableSpbmNodeScaling Note: Exception: only applies to 5320 Series and 5420 Series.	Enables the switch to increase the number of supported SPB nodes per area. By default, the switch supports up to 350 SPB nodes per area. The default is disabled. If you change this parameter, you must restart the switch.
Slot	Specifies the slot number.
TftpHash	Enables TFTP hashing.
TftpRetransmit	Set TFTP retransmit timeout counter.
TftpTimeout	Set TFTP timeout counter.
User	Configure host user.
Password	Configure host password.

Reserve Bandwidth for Advanced Features

Use this procedure if you want the switch to support advanced features. When you enable the boot flag, you need to save and reboot with the new configuration.

Before You Begin

Procedure

1. In the navigation pane, expand **Configuration** > **Edit** > **Chassis**.
2. Select the **Boot Config** tab.

3. In the **AdvancedFeatureBWReservation** field, select **low**, **high**, or **vim** to enable the boot flag.

   Note
   high only applies to 5720 Series.
   low does not apply to 5720 Series.

4. Select **Apply**.

   A message displays to remind you that the configuration cannot include reserved ports, and that you must save the configuration and reboot the switch for changes to take effect.

5. Select **Yes** to continue or select **No** to cancel the change because the configuration includes reserved ports.

   If you selected No, you can modify your switch configuration to remove the reserved ports and then return to this tab to change the **AdvancedFeatureBWReservation** configuration.

6. Save the configuration, and then reboot the switch.

Enable Jumbo Frames

About This Task

Enable Jumbo frames to increase the size of Ethernet frames supported on the chassis.

Procedure

1. On the Device Physical View, select the Device.
2. In the navigation pane, expand **Configuration** > **Edit**.
3. Click **Chassis**.
4. Click the **Chassis** tab.
5. In **MTU size**, select either 1950, 9600 or 1522.
6. Click **Apply**.

Configure the Date and Time

Configure the date and time to correctly identify when events occur on the system.

About This Task

Note
According to a bill passed by the government of Russia, from October 2014 Moscow has moved from UTC+4 into UTC+3 time zone with no daylight savings. The software includes this change.

Procedure

1. On the Device Physical View, select the Device.
2. In the navigation pane, expand **Configuration** > **Edit**.
3. Click **Chassis**.
4. Click the **User Set Time** tab.
5. Type and select the correct details.

6. Click **Apply**.

User Set Time *field descriptions*

Use the data in the following table to use the **User Set Time** tab.

Name	Description
Year	Configures the year (integer 1998–2097). The default is 1998.
Month	Configures the month. The default is 1.
Date	Configures the day (integer 1–31). The default is 1.
Hour	Configures the hour (12am–11pm). The default is 0.
Minute	Configures the minute (integer 0–59). The default is 0.
Second	Configures the second (integer 0–59). The default is 0.
Time Zone	Configures the time zone.

Configure CP Limit

Configure CP Limit functionality to protect the switch from becoming congested by an excess of data flowing through one or more ports.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration** > **Edit** > **Port**.
3. Click **General**.
4. Click the **CP Limit** tab.
5. Select the **AutoRecoverPort** check box.
6. Click **Apply**.

CP Limit *field descriptions*

Use the data in the following table to use the **CP Limit** tab.

Name	Description
AutoRecoverPort	Activates or disables auto recovery of the port from action taken by CP Limit or link flap features. The default value is disabled.

Configure CP Limit on an Extreme Integrated Application Hosting Port

Note

This procedure only applies to 5720 Series.

About This Task

Perform this procedure to configure CP Limit functionality to protect the switch from becoming congested by excess data flow through Extreme Integrated Application Hosting (IAH) ports.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit** > **Insight Port**.
2. Select the IAH port you want to configure.
3. Select the **CP Limit** tab.
4. Select **AutoRecoverPort**.
5. Select **Apply**.

CP Limit *Field Descriptions*

Use data in the following table to use the **CP Limit** tab.

Name	Description
AutoRecoverPort	Enables or disables auto recovery of the Extreme Integrated Application Hosting port from action taken by CP Limit or the link flap features. The default is disabled.

Edit the Management Port Parameters

About This Task

Note

This procedure only applies to hardware with a dedicated physical management interface.

The management port on the switch is a 10/100/1000 Mb/s Ethernet port that you can use for an out-of-band management connection to the switch.

If you use EDM to configure the static routes of the management port, you do not receive a warning if you configure a non-natural mask. After you save the changes, the system deletes those static routes after the next restart, possibly causing the loss of IP connectivity to the management port.

If you are uncertain whether the mask you configure is non-natural, use the CLI to configure static routes.

Procedure

1. In the Device Physical View tab, select the management port.
2. In the navigation pane, expand **Configuration** > **Edit**.
3. Select **Mgmt Port**.
4. Select the **General tab**.
5. Modify the appropriate settings.
6. Select **Apply**.

***General** Field Descriptions*

Use the data in the following table to use the **General** tab.

Name	Description
Index	Specifies the slot and port number of the management port.
AdminStatus	Configures the administrative status of the device as up (ready to pass packets) or down. The testing state indicates that no operational packets can be passed.
OperStatus	Specifies the operational status of the device.
LicenseControlStatus	Shows the license status of the port: • Locked means the port requires a Port License but one is not present on the switch. • Unlocked means the port requires a Port License and one is present on the switch. • notApplicable means the port does not require a Port License.
Mtu	Shows the configuration for the maximum transmission unit. The size of the largest packet which can be sent/received on the interface, specified in octets. For interfaces that are used for transmitting network datagrams, this is the size of the largest network datagram that can be sent on the interface.
LinkTrap	Enables or disables traps for the link status.
PhysAddress	Shows the MAC address.
AutoNegotiate	Enables or disables Auto-Negotiation for the mangement port. The default is enabled.
AdminDuplex	Specifies the administrative duplex mode for the management port. The default is full.
OperDuplex	Specifies the operational duplex configuration for this port.
AdminSpeed	Specifies the administrative speed for this port. The default is 100 Mb/s.
OperSpeed	Shows the current operating data rate of the port.

Automatically Reactivating the Port of the SLPP Shutdown

About This Task

Use the following procedure to automatically reactivate the port that is shut down by the SLPP.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration** > **Edit** > **Port**.
3. Click **General**.
4. Click the **CP Limit** tab.
5. Select **AutoRecoverPort** to activate auto recovery of the port from the action taken by SLPP shutdown features. The default value is disabled.
6. Click **Apply**.

Edit Serial Port Parameters

About This Task

Perform this procedure to specify serial port communication settings. The serial port on the device is the console port. Depending on the hardware platform, the console port displays as console or 10101.

Procedure

1. In the Device Physical View tab, select the console port on the device.
2. In the navigation pane, expand **Configuration** > **Edit**.
3. Click **Serial Port**.
4. Edit the port parameters as required.
5. Click **Apply**.

Serial Port *Field Descriptions*

Use the data in the following table to use the **Serial Port** tab.

Name	Description
IfIndex	Identifies the port as a serial port.
BaudRate	Specifies the baud rate of this port.
DataBits	Specifies the number of data bits, for each byte of data, this port sends and receives. The default is eight.

Enable Port Lock

About This Task

Use the port lock feature to administratively lock a port or ports to prevent other users from changing port parameters or modifying port action. You cannot modify locked ports until you first unlock the port.

Procedure

1. In the navigation pane, expand **Configuration** > **Security** > **Control Path**.
2. Click **General**.
3. Click the **Port Lock** tab.
4. To enable port lock, select the **Enable** check box.
5. Click **Apply**.

Port Lock *field descriptions*

Use the data in the following table to use the **Port Lock** tab.

Name	Description
Enable	Activates the port lock feature. Clear this check box to unlock ports. The default is disabled.
LockedPorts	Lists the locked ports. Click the ellipsis (...) button to select the ports you want to lock or unlock.

Lock a Port

Before You Begin

- You must enable port lock before you lock or unlock a port.

About This Task

Use the port lock feature to administratively lock a port or ports to prevent other users from changing port parameters or modifying port action. You cannot modify locked ports until you first unlock the port.

Procedure

1. In the navigation pane, expand **Configuration** > **Security** > **Control Path**.
2. Click **General**.
3. Click the **Port Lock** tab.
4. In the **LockedPorts** box, click the ellipsis **(...)** button.
5. Click the desired port or ports.
6. Click **Ok**.
7. In the **Port Lock** tab, click **Apply**.

Port Lock *field descriptions*

Use the data in the following table to use the **Port Lock** tab.

Name	Description
Enable	Activates the port lock feature. Clear this check box to unlock ports. The default is disabled.
LockedPorts	Lists the locked ports. Click the ellipsis (...) button to select the ports you want to lock or unlock.

View Power Information

About This Task

View power information to see the amount of power available and used by the chassis and all components.

Procedure

1. On the Device Physical View, select the Device.
2. In the navigation pane, expand **Configuration** > **Edit**.
3. Select **Chassis**.
4. Select the **Power Info** tab.

***Power Info** field descriptions*

Use the data in the following table to use the **Power Info** tab.

Name	Description
TotalPower	Shows the total power for the chassis.
RedundantPower	Shows the redundant power for the chassis.
PowerUsage	Shows the power currently used by the complete chassis.
PowerAvailable	Shows the unused power.

View Power Status

About This Task

Perform the following procedure to view the power consumption of the modules in the chassis.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Click **Chassis**.
3. Click the **Power Consumption** tab.

Power consumption field descriptions

Use the data in the following table to use the **Power Consumption** tab.

Name	Description
Index	Displays an index value that identifies the component.
PowerStatus	Displays the power status: on or off.
BasePower	Displays the base power required for the slot.
ConsumedPower	Displays the actual consumed power for the slot. This value is 0 if the power status is off.
PowerPriority	Displays the priority of the slot for power management.
SlotDescription	Displays the slot number.
CardDescription	Identifies the type of module in the slot.

View Fan Tray Information

View fan tray information to see manufacturing information about the fans.

Procedure

1. On the Device Physical View, select the Device.
2. In the navigation pane, expand **Configuration** > **Edit**.
3. Select **Chassis**.
4. Select the **Fan Tray Info** tab.

***Fan Tray Info** field descriptions*

Use the data in the following table to use the **Fan Tray Info** tab.

Name	Description
Description	Shows a description of the fan tray.
FlowType	Specifies whether the air flow is front-to-back or back-to-front.

View USB Port Information

About This Task

Perform this procedure to view information about the USB port on the switch.

Procedure

1. In the Device Physical View, select the USB port.
2. In the navigation pane, expand **Configuration** > **Edit**.
3. Click **USB Port**.
4. Click the **General** tab.

General field descriptions

Use the data in the following table to use the **General** tab.

Name	Description
UsbStatus	Displays the current status of USB storage: either present or notPresent.
UsbDescription	Displays a description of the USB storage.

View Topology Status Information

About This Task

View topology status information (which includes MIB status information) to view the configuration status of the SynOptics Network Management Protocol (SONMP) on the system.

Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability** > **Diagnostics**.
2. Click **Topology**.
3. Click the **Topology** tab.

Topology *field descriptions*

Use the data in the following table to use the **Topology** tab.

Name	Description
IpAddr	Specifies the IP address of the device.
Status	Indicates whether topology (SONMP) is on or off for the device.
NmmLstChg	Specifies the value of sysUpTime, the last time an entry in the network management MIB (NMM) topology table was added, deleted, or modified, if the table did not change since the last cold or warm start of the agent.
NmmMaxNum	Specifies the maximum number of entries in the NMM topology table.
NmmCurNum	Specifies the current number of entries in the NMM topology table.

View the Topology Message Status

About This Task

View topology message status to view the interconnections between Layer 2 devices in a network.

Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability** > **Diagnostics**.
2. Click **Topology**.
3. Click the **Topology Table** tab.

Topology Table *Field Descriptions*

Use the data in the following table to use the **Topology Table** tab.

Name	Description
Slot	Specifies the slot number in the chassis that received the topology message.
Port	Specifies the port that received the topology message.
SubPort	Specifies the channel of a channelized 40 Gbps port that received the topology message.
IpAddr	Specifies the IP address of the sender of the topology message.
SegId (RemPort)	Specifies the segment identifier of the segment from which the remote agent sent the topology message. This value is extracted from the message.
MacAddr	Specifies the MAC address of the sender of the topology message.
ChassisType	Specifies the chassis type of the device that sent the topology message.
BkplType	Specifies the backplane type of the device that sent the topology message.

Name	Description
LocalSeg	Indicates if the sender of the topology message is on the same Ethernet segment as the reporting agent.
CurState	Specifies the current state of the sender of the topology message. The choices are • topChanged—Topology information recently changed. • heartbeat—Topology information is unchanged. • new—The sending agent is in a new state.

Configure a Forced Message Control Pattern

About This Task

Configure a forced message control pattern to enforce configured message control actions.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit** > **Chassis**.
2. Click the **Force Msg Patterns** tab.
3. Click **Insert**.
4. In the **PatternId** field, enter a pattern ID number.
5. In the **Pattern** field, enter a message control pattern.
6. Click **Insert**.

Force Msg Patterns Field Descriptions

Use the data in the following table to use the **Force Msg Patterns** tab.

Name	Description
PatternId	Specifies a pattern identification number in the range 1–32.
Pattern	Specifies a forced message control pattern of 4 characters. The software and the hardware log messages that use the first four bytes matching one of the patterns in the force-msg table undergo the configured message control action. You can specify up to 32 different patterns in the force-msg table, including a wildcard pattern (****). If you specify the wildcard pattern, all messages undergo message control.

View Fan Information

View fan information to monitor the alarm status of the cooling ports in the chassis.

About This Task

For platforms that support both back-to-front and front-to-back airflow, the airflow direction must be the same for both the power supply fans and the chassis fan.

Procedure

1. On the Device Physical View, select the Device.
2. In the navigation pane, expand **Configuration** > **Edit**.
3. Select **Chassis**.
4. Select the **Fan Info** tab.

Fan Info *field descriptions*

Use the data in the following tables to use the **Fan Info** tab.

Name	Description
Description	Specifies a description of the fan location.
OperStatus	Specifies the operation status of the fan.
OperSpeed	Specifies the actual fan speed.
OperSpeedRPM	Specifies the current operational speed of the fan in RPM.

Configure Ports Speeds for All VIM Ports

Note

This procedure only applies to 5520 Series and 5720 Series.

Configure all of the ports on an installed Versatile Interface Module (VIM) to operate at the same speed.

Note

Some VIMs must operate with all ports at the same speed, or a group of ports at the same speed, while others can operate with ports at different speeds. For more information, see *Fabric Engine Release Notes*. You can configure VIM ports speed only on VIMs that must operate with all ports at the same speed.

Before You Begin

Install the VIM before performing this procedure.

About This Task

Use this procedure to configure the speed of all ports in a multi-port VIM to operate at either 1 Gbps, 10 Gbps, or 25 Gbps.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Chassis**.
3. Select the **VIM** tab.
4. Select **mbps1000**, **mbps10000**, or **mbps25000**.
5. Select **Apply**.

VIM Field Descriptions

Use the data in the following table to use the VIM tab.

Name	Description
AdminSpeed Note: Exception: 1 Gbps port speed applies to 5720-VIM-6YE only.	• **mbps1000**: Configures all ports or a group of ports in a multi-port VIM to operate at 1 Gbps. • **mbps10000**: Configures all ports in a multi-port VIM to operate at 10 Gbps. • **mbps25000**: Configures all ports in a multi-port VIM to operate at 25 Gbps. The default is 25 Gbps.
GroupSpeed Exception: only applies to 5720-VIM-6YE.	Configures all ports into two speed setting groups. • **group1**: ports 2/1, 2/2, 2/3 • **group2**: ports 2/4, 2/5, 2/6 Ports in groups must be configured to operate at the same speed. For example, ports 2/1, 2/2, 2/3 can be configured for 10 Gbps, and ports 2/4, 2/5, 2/6 can be configured for 25 Gbps.

View Modular SSD Information

Note

This procedure only applies to 5720 Series.

About This Task

Perform this procedure to display information about an installed Solid State Drive (SSD) on a switch.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Chassis**.
3. Select the **SSD** tab.

SSD Field Descriptions

Use the data in the following table to use the SSD tab.

Name	Description
ProductName	Specifies Solid State Drive (SSD) product name.
VendorName	Specifies the SSD vendor.
ManufactureDate	Specifies the date on which the SSD was manufactured.
SerialNum	Specifies the SSD serial number.
PartNum	Specifies the SSD part number.
DeviceVersion	Specifies the version of the SSD.
TotalSize	Specifies the total memory size of the SSD.

Graphing Chassis Statistics

Create graphs of chassis statistics to generate a visual representation of your data.

Procedure

1. In the Device Physical View, select the chassis.
2. In the navigation pane, expand the **Configuration** > **Graph** folders.
3. Click **Chassis**.
4. On the Graph Chassis tab, select the tab with the data you want to graph:
   - System
   - SNMP
   - IP
   - ICMP In
   - ICMP Out
   - TCP
   - UDP
5. Select the statistic you want to graph.
6. Select the graph type:
   - line chart
   - area chart
   - bar chart
   - pie chart

Graphing Port Statistics

You can create a graph of the port statistics to generate a visual representation of your data.

Procedure

1. In the Device Physical View, select the port or ports for which you want to create a graph.
2. In the navigation pane, expand the **Configuration** > **Graph** folders, and then click **Port**.

   OR, use the following shortcut:

   Right-click the selected port or ports from Step 1, and choose **Graph**.
3. On the **Graph Port** tab for the selected port or ports, select the item you want to graph.
4. Click an icon to select the type of graph you require. The following list provides the graph types available:
   - Line Chart
   - Area Chart
   - Bar Chart
   - Pie Chart

Viewing Chassis System Statistics

Use the following procedure to create graphs for chassis statistics.

Procedure

1. In the Device Physical View, select the chassis.
2. In the navigation pane, expand the **Configuration** > **Graph** folders.
3. Click **Chassis**.
4. Click the **System** tab.

System *Field Descriptions*

The following table describes the fields on the **System** tab.

Name	Description
MemUsed	The percentage of memory space used. Only the AbsoluteValue column is valid in the System tab. All other columns display as N/A because they are percentages and not actual memory counters.
MemFree	The amount in kilobytes of free memory.
CpuUtil	Percentage of CPU utilization.

Viewing Chassis SNMP Statistics

View chassis SNMP statistics to monitor network performance.

Procedure

1. In the Device Physical View, select the chassis.
2. In the navigation pane, expand the **Configuration** > **Graph** folders.
3. Click **Chassis**.
4. Click the **SNMP** tab.

SNMP *Field Descriptions*

The following table describes parameters on the **SNMP** tab.

Name	Description
InPkts	The number of messages delivered to the SNMP entity from the transport service.
OutPkts	The number of SNMP messages passed from the SNMP protocol entity to the transport service.
InTotalReqVars	The number of MIB objects retrieved successfully by the SNMP protocol entity as the result of receiving valid SNMP Get-Request and Get-Next PDUs.
InTotalSetVars	The number of MIB objects altered successfully by the SNMP protocol entity as the result of receiving valid SNMP Set-Request PDUs.
InGetRequests	The number of SNMP Get-Request PDUs the SNMP protocol accepts and processes.
OutGetRequests	The number of SNMP Get-Request PDUs that are generated by the SNMP protocol entity.

Name	Description
InGetNexts	The number of SNMP Get-Next PDUs the SNMP protocol accepts and processes.
OutGetNexts	The number of SNMP Get-Next PDUs that are generated by the SNMP protocol entity.
InSetRequests	The number of SNMP Set-Request PDUs the SNMP protocol accepts and processes.
OutSetRequests	The number of SNMP Set-Request PDUs that are generated by the SNMP protocol entity.
InGetResponses	The number of SNMP Get-Response PDUs the SNMP protocol accepts and processes.
OutGetResponses	The number of SNMP Get-Response PDUs that are generated by the SNMP protocol entity.
InTraps	The number of SNMP Trap PDUs the SNMP protocol accepts.
OutTraps	The number of SNMP Trap PDUs the SNMP protocol generates.
OutTooBigs	The number of SNMP PDUs the SNMP protocol generates for which the value of the error-status field is tooBig.
OutNoSuchNames	The number of SNMP PDUs the SNMP protocol generates for which the value of the error-status field is noSuchName.
OutBadValues	The number of SNMP PDUs the SNMP protocol generates for which the value of the error-status field is badValue.
OutGenErrs	The number of SNMP PDUs the SNMP protocol generates for which the value of the error-status field is genErr.
InBadVersions	The number of SNMP messages delivered to the SNMP protocol entity for an unsupported SNMP version.
InBadCommunityNames	The number of SNMP messages delivered to the SNMP protocol entity that used an SNMP community name not known to said entity.
InBadCommunityUses	The number of SNMP messages delivered to the SNMP protocol entity that represented an SNMP operation not allowed by the SNMP community named in the message.
InASNParseErrs	The number of ASN.1 or BER errors the SNMP protocol encountered when decoding received SNMP messages.
InTooBigs	The number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is tooBig.
InNoSuchNames	The number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is noSuchName.
InBadValues	The number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is badValue.
InReadOnlys	The number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is readOnly. It is a protocol error to generate an SNMP PDU containing the value "readOnly" in the error-status field. This object is provided to detect incorrect implementations of the SNMP.
InGenErrs	The number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is genErr.

Viewing Chassis IP Statistics

View chassis IP statistics to monitor network performance.

Procedure

1. In the Device Physical View, select the chassis.
2. In the navigation pane, expand the **Configuration** > **Graph** folders.
3. Click **Chassis**.
4. Click the **IP** tab.

IP Field Descriptions

The following table describes parameters on the **IP** tab.

Name	Description
InReceives	The number of input datagrams received from interfaces, including those received in error.
InHdrErrors	The number of input datagrams discarded due to errors in the IP headers, including bad checksums, version number mismatch, other format errors, time-to-live exceeded, errors discovered in processing their IP options.
InAddrErrors	The number of input datagrams discarded because the IP address in the IP header destination field was not a valid address to be received at this entity. This count includes invalid addresses (for example, 0.0.0.0) and addresses of unsupported Classes (for example, Class E). For entities that are not IP Gateways and therefore do not forward datagrams, this counter includes datagrams discarded because the destination address was not a local address.
ForwDatagrams	The number of input datagrams for which this entity was not their final IP destination, as a result of which an attempt was made to find a route to forward them to that final destination. In entities that do not act as IP Gateways, this counter includes only those packets that were Source-Routed by way of this entity and had successful Source-Route option processing.
InUnknownProtos	The number of locally addressed datagrams received successfully but discarded because of an unknown or unsupported protocol.
InDiscards	The number of input IP datagrams for which no problems were encountered to prevent their continued processing but that were discarded (for example, for lack of buffer space). This counter does not include any datagrams discarded while awaiting reassembly.
InDelivers	The number of input datagrams successfully delivered to IP user-protocols (including ICMP).
OutRequests	The number of IP datagrams that local IP user-protocols (including ICMP) supplied to IP in requests for transmission. This counter does not include any datagrams counted in ipForwDatagrams.
OutDiscards	The number of output IP datagrams for which no problem was encountered to prevent their transmission to their destination, but that were discarded (for example, for lack of buffer space). This counter includes datagrams counted in ipForwDatagrams if any such packets met this (discretionary) discard criterion.

Name	Description
OutNoRoutes	The number of IP datagrams discarded because no route was found to transmit them to their destination. This counter includes any packets counted in ipForwDatagrams that meet this no-route criterion. This counter includes any datagrams a host cannot route because all default gateways are down.
FragOKs	The number of IP datagrams that were successfully fragmented at this entity.
FragFails	The number of IP datagrams that were discarded because they needed to be fragmented at this entity but can not be, for example, because the Don't Fragment flags were set.
FragCreates	The number of IP datagram fragments that were generated as a result of fragmentation at this entity.
ReasmReqds	The number of IP fragments received that needed to be reassembled at this entity.
ReasmOKs	The number of IP datagrams successfully reassembled.
ReasmFails	The number of failures detected by the IP reassembly algorithm (for whatever reason: timed out, errors, and so on). This number is not necessarily a count of discarded IP fragments because some algorithms (notably the algorithm in RFC 815) can lose track of the number of fragments by combining them as they are received.

Viewing Chassis ICMP In Statistics

View chassis ICMP In statistics to monitor network performance.

Procedure

1. In the Device Physical View, select the chassis.
2. In the navigation pane, expand the **Configuration** > **Graph** folders.
3. Click **Chassis**.
4. Click the **ICMP In** tab.

ICMP In *Field Descriptions*

The following table describes parameters on the **ICMP In** tab.

Name	Description
SrcQuenchs	The number of ICMP Source Quench messages received.
Redirects	The number of ICMP Redirect messages received.
Echos	The number of ICMP Echo (request) messages received.
EchoReps	The number of ICMP Echo Reply messages received.
Timestamps	The number of ICMP Timestamp (request) messages received.
TimestampReps	The number of ICMP Timestamp Reply messages received.
AddrMasks	The number of ICMP Address Mask Request messages received.
AddrMaskReps	The number of ICMP Address Mask Reply messages received.

Name	Description
ParmProbs	The number of ICMP Parameter Problem messages received.
DestUnreachs	The number of ICMP Destination Unreachable messages received.
TimeExcds	The number of ICMP Time Exceeded messages received.

Viewing Chassis ICMP Out Statistics

View chassis ICMP Out statistics to monitor network performance.

Procedure

1. In the Device Physical View, select the chassis.
2. In the navigation pane, expand the **Configuration** > **Graph** folders.
3. Click **Chassis**.
4. Click the **ICMP Out** tab.

ICMP Out *Field Descriptions*

The following table describes parameters on the **ICMP Out** tab.

Name	Description
SrcQuenchs	The number of ICMP Source Quench messages sent.
Redirects	The number of ICMP Redirect messages received. For a host, this object is always zero, because hosts do not send redirects.
Echos	The number of ICMP Echo (request) messages sent.
EchoReps	The number of ICMP Echo Reply messages sent.
Timestamps	The number of ICMP Timestamp (request) messages sent.
TimestampReps	The number of ICMP Timestamp Reply messages sent.
AddrMasks	The number of ICMP Address Mask Request messages sent.
AddrMaskReps	The number of ICMP Address Mask Reply messages sent.
ParmProbs	The number of ICMP Parameter Problem messages sent.
DestUnreachs	The number of ICMP Destination Unreachable messages sent.
TimeExcds	The number of ICMP Time Exceeded messages sent.

Viewing Chassis TCP Statistics

View TCP statistics to monitor network performance.

Procedure

1. In the Device Physical View, select the chassis.
2. In the navigation pane, expand the **Configuration** > **Graph** folders.
3. Click **Chassis**.
4. Click the **TCP** tab.

TCP Field Descriptions

The following table describes parameters on the **TCP** tab.

Name	Description
ActiveOpens	The number of times TCP connections made a direct transition to the SYN-SENT state from the CLOSED state.
PassiveOpens	The number of times TCP connections made a direct transition to the SYN-RCVD state from the LISTEN state.
AttemptFails	The number of times TCP connections made a direct transition to the CLOSED state from either the SYN-SENT state or the SYN-RCVD state, plus the number of times TCP connections made a direct transition to the LISTEN state from the SYN-RCVD state.
EstabResets	The number of times TCP connections made a direct transition to the CLOSED state from either the ESTABLISHED state or the CLOSE-WAIT state.
CurrEstab	The number of TCP connections for which the current state is either ESTABLISHED or CLOSE-WAIT.
InSegs	The number of segments received, including those received in error. This count includes segments received on currently established connections.
OutSegs	The number of segments sent, including those on current connections, but excluding those containing only retransmitted octets.
RetransSegs	The number of segments retransmitted that is, the number of TCP segments transmitted containing one or more previously transmitted octets.
InErrs	The number of segments received in error (for example, bad TCP checksums).
OutRsts	The number of TCP segments sent containing the RST flag.
HCInSegs	The number of segments received, including those received in error. This count includes segments received on currently established connections. This object is the 64-bit equivalent of InSegs.
HCOutSegs	The number of segments sent, including those on current connections, but excluding those containing only retransmitted octets. This object is the 64-bit equivalent of OutSegs.

Viewing Chassis UDP Statistics

Display User Datagram Protocol (UDP) statistics to see information about the UDP datagrams.

Procedure

1. In the Device Physical View, select the chassis.
2. In the navigation pane, expand the **Configuration** > **Graph** folders.
3. Click **Chassis**.
4. Click the **UDP** tab.
5. Select the information you want to graph.

6. Select the type of graph you want:
   - line
   - area
   - bar
   - pie
7. To clear counters, click **Clear Counters**. Discontinuities in the value of these counters can occur when the management system reinitializes, and at other times as indicated by discontinuities in the value of sysUpTime.

UDP *Field Descriptions*

Use the data in the following table to use the **UDP** tab.

Name	Description
NoPorts	The number of received UDP datagrams with no application at the destination port. Discontinuities in the value of this counter can occur at reinitialization of the management system, and at other times as indicated by discontinuities in the value of sysUpTime.
InErrors	The number of received UDP datagrams that were not delivered for reasons other than the lack of an application at the destination port. Discontinuities in the value of this counter can occur at reinitialization of the management system and at other times as indicated by discontinuities in the value of sysUpTime.
InDatagrams	The number of UDP datagrams delivered to UDP users, for devices that can receive more than 1 000 000 UDP datagrams for each second. Discontinuities in the value of this counter can occur at reinitialization of the management system, and at other times as indicated by discontinuities in the value of sysUpTime.
OutDatagrams	The number of UDP datagrams sent from this entity. Discontinuities in the value of this counter can occur at reinitialization of the management system, and at other times as indicated by discontinuities in the value of sysUpTime.
HCInDatagrams	The number of TCP connections for which the current state is either ESTABLISHED or CLOSE-WAIT.
HCOutDatagrams	The number of UDP datagrams sent from this entity, for devices that can transmit more than 1 million UDP datagrams for each second. Discontinuities in the value of this counter can occur at reinitialization of the management system, and at other times as indicated by discontinuities in the value of sysUpTime.

Viewing Port Interface Statistics

View port interface statistics to manage network performance.

Procedure

1. In the Device Physical View, select a port.
2. In the navigation pane, expand the **Configuration** > **Graph** folders.
3. Click **Port**.

4. Click the **Interface** tab.

Interface *Field Descriptions*

The following table describes parameters on the **Interface** tab.

Name	Description
InOctets	Specifies the number of octets received on the interface, including framing characters.
OutOctets	Specifies the number of octets transmitted from the interface, including framing characters.
InUcastPkts	Specifies the number of packets delivered by this sublayer to a higher sublayer that were not addressed to a multicast or broadcast address at this sublayer.
OutUcastPkts	Specifies the number of packets that higher-level protocols requested be transmitted that were not addressed to a multicast address at this sublayer. The total number includes those packets discarded or not sent.
InMulticastPkts	Specifies the number of packets delivered by this sublayer to a higher sublayer that were addressed to a multicast address at this sublayer. For a MAC layer protocol, this number includes both group and functional addresses.
OutMulticastPkts	Specifies the number of packets that higher-level protocols requested be transmitted, and that are addressed to a multicast address at this sublayer, including those that were discarded or not sent. For a MAC layer protocol, this number includes both group and functional addresses.
InBroadcastPkts	Specifies the number of packets delivered by this sublayer to a higher sublayer that are addressed to a broadcast address at this sublayer.
OutBroadcastPkts	Specifies the number of packets that higher-level protocols requested be transmitted, and that were addressed to a broadcast address at this sublayer, including those that were discarded or not sent.
InDiscards	Specifies the number of inbound packets that are discarded because of frames with errors or invalid frames or, in some cases, to fill up buffer space.
InErrors	For packet-oriented interfaces, specifies the number of inbound packets that contained errors preventing them from being deliverable to a higher-layer protocol. For character-oriented or fixed-length interfaces, the number of inbound transmission units that contained errors preventing them from being deliverable to a higher-layer protocol.
InUnknownProtos	For packet-oriented interfaces, specifies the number of packets received through the interface that are discarded because of an unknown or unsupported protocol. For character-oriented or fixed-length interfaces that support protocol multiplexing, the number of transmission units received through the interface that were discarded because of an unknown or unsupported protocol. For any interface that does not support protocol multiplexing, this counter is always 0.

Name	Description
HCInPfcPkts	Specifies the total number of Priority Flow Control (PFC) packets received by this interface. This number does not increment for port-level flow control.
HCOutPfcPkts	Specifies the total number of PFC packets transmitted by this interface. This number does not increment for port-level flow control.
InFlowCtrlPkts	Specifies the number of port-level flow control packets received by this interface.
OutFlowCtrlPkts	Specifies the number of port-level flow control packets transmitted by this interface.
InPfcPkts	Specifies the total number of port-level flow control packets received by this interface.
OutPfcPkts	Specifies the total number of port-level flow control packets transmitted by this interface.
NumStateTransition	Specifies the number of times the port went in and out of service; the number of state transitions from up to down.

Viewing Port Ethernet Errors Statistics

View port Ethernet errors statistics to manage network performance.

Procedure

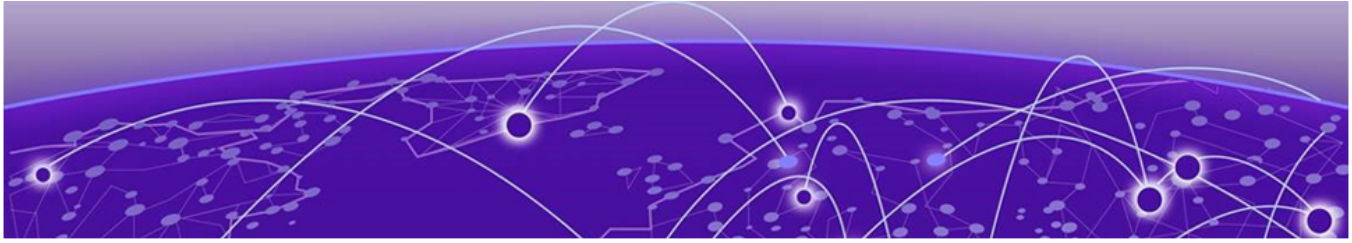
1. In the Device Physical View, select a port.
2. In the navigation pane, expand the **Configuration** > **Graph** folders.
3. Click **Port**.
4. Click the **Ethernet Errors** tab.

Ethernet Errors *Field Descriptions*

The following table describes parameters on the **Ethernet Errors** tab.

Name	Description
AlignmentErrors	Specifies acount of frames received on a particular interface that are not an integral number of octets in length and do not pass the FCS check. The count represented by an instance of this object increments when the alignmentError status is returned by the MAC service to the LLC (or other MAC user). Received frames for which multiple error conditions obtain are, according to the conventions of IEEE 802.3 Layer Management, counted exclusively according to the error status presented to the LLC.
FCSErrors	Specifies a count of frames received on a particular interface that are an integral number of octets in length but do not pass the FCS check. The count represented by an instance of this object increments when the frameCheckError status is returned by the MAC service to the LLC (or other MAC user). Received frames for which multiple error conditions obtained are, according to the conventions of IEEE 802.3 Layer Management, counted exclusively according to the error status presented to the LLC.
InternalMacTransmitErrors	Specifies a count of frames for which transmission on a particular interface fails due to an internal MAC sublayer transmit error. A frame is only counted by an instance of this object if it is not counted by the corresponding instance of either the LateCollisions object, the ExcessiveCollisions object, or the CarrierSenseErrors object. The precise meaning of the count represented by an instance of this object is implementation-specific. In particular, an instance of this object can represent a count of transmission errors on a particular interface that are not otherwise counted.
InternalMacReceiveErrors	Specifies a count of frames for which reception on a particular interface fails due to an internal MAC sublayer receive error. A frame is only counted by an instance of this object if it is not counted by the corresponding instance of either the FrameTooLongs object, the AlignmentErrors object, or the FCSErrors object. The precise meaning of the count represented by an instance of this object is implementation-specific. In particular, an instance of this object can represent a count of receive errors on a particular interface that are not otherwise counted.
CarrierSenseErrors	Specifies the number of times that the carrier sense condition is lost or not asserted when the switch attempts to transmit a frame on a particular interface. The count represented by an instance of this object increments at most once for each transmission attempt, even if the carrier sense condition fluctuates during a transmission attempt.

Name	Description
FrameTooLongs	Specifies a count of frames received on a particular interface that exceed the maximum permitted frame size. The count represented by an instance of this object increments when the frameTooLong status is returned by the MAC service to the LLC (or other MAC user). Received frames for which multiple error conditions obtained are, according to the conventions of IEEE 802.3 Layer Management, counted exclusively according to the error status presented to the LLC.
SQETestErrors	Specifies a count of times that the SQE TEST ERROR message is generated by the PLS sublayer for a particular interface. The SQE TEST ERROR message is defined in section 7.2.2.2.4 of ANSI/IEEE 802.3-1985 and its generation described in section 7.2.4.6 of the same document.
DeferredTransmissions	Specifies a count of frames for which the first transmission attempt on a particular interface is delayed because the medium is busy. The count represented by an instance of this object does not include frames involved in collisions.
SingleCollisionFrames	Specifies a count of successfully transmitted frames on a particular interface for which transmission is inhibited by exactly one collision. A frame that is counted by an instance of this object is also counted by the corresponding instance of either the UcastPkts, MulticastPkts, or BroadcastPkts objects and is not counted by the corresponding instance of the MultipleCollisionFrames object.
MultipleCollisionFrames	Specifies a count of successfully transmitted frames on a particular interface for which transmission is inhibited by more than one collision. A frame that is counted by an instance of this object is also counted by the corresponding instance of either the UcastPkts, MulticastPkts, or BroadcastPkts objects and is not counted by the corresponding instance of the SingleCollisionFrames object.
LateCollisions	Specifies the number of times that a collision is detected on a particular interface later than 512 bit-times into the transmission of a packet; 512 corresponds to 51.2 microseconds on a 10 Mb/s system. A (late) collision included in a count represented by an instance of this object is also considered as a (generic) collision for purposes of other collision-related statistics.
ExcessiveCollisions	Specifies a count of frames for which transmission on a particular interface fails due to excessive collisions.
FrameTooShorts	Specifies the number of frames, encountered on this interface, that are too short.
LinkFailures	Specifies the number of link failures encountered on this interface.
PacketErrors	Specifies the number of packet errors encountered on this interface.
CarrierErrors	Specifies the number of carrier errors encountered on this interface.
LinkInactiveErrors	Specifies the number of link inactive errors encountered on this interface.



Dynamic Host Configuration Protocol and User Datagram Protocol Configuration

Table 61: Dynamic Host Configuration Protocol product support

Feature	Product	Release introduced
Dynamic Host Configuration Protocol (DHCP) Relay	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
DHCP Option 82	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

Table 62: Dynamic Host Configuration Protocol Relay for IPv6 product support

Feature	Product	Release introduced
IPv6 DHCP Relay	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

DHCP option 82

The DHCP option 82 is the DHCP Relay Agent Information option. The DHCP relay agent inserts option 82 when it forwards the client-originated DHCP packets to a DHCP server. The Relay Agent Information option is organized as a single DHCP option that contains one or more sub-options that convey information known by the relay agent. The DHCP server echoes the option back to the relay agent in server-to-client replies, and the relay agent removes the option before forwarding the reply to the client.

The DHCP option 82 is added at the DHCP relay level as shown in the following image.

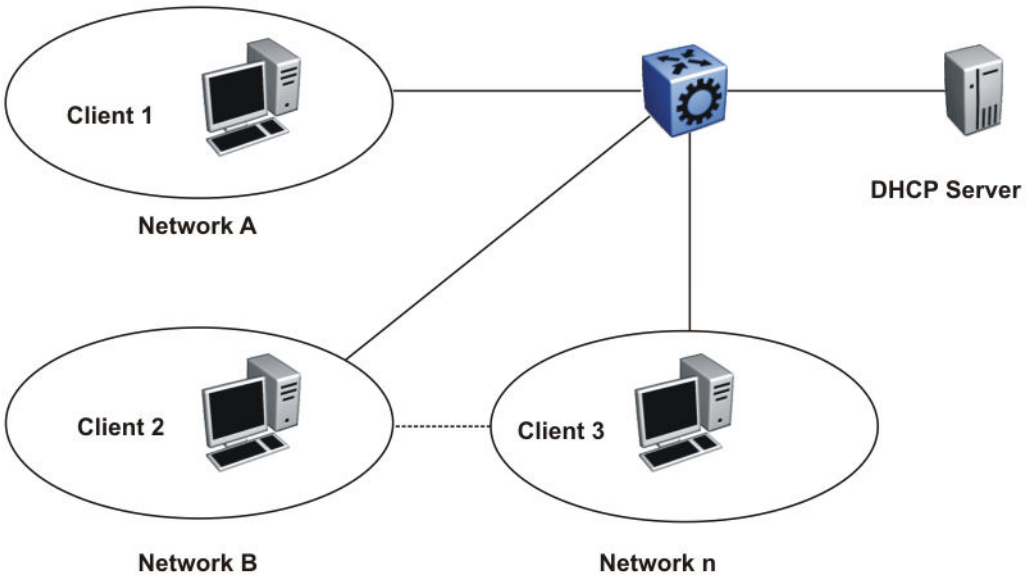


Figure 43: DHCP Client-Relay-Server Architecture

The Relay Agent Information option (code 82) is a container for specific agent-supplied suboptions; Agent Circuit ID (code 1) and Agent Remote ID (code 2). The suboptions can represent different information relevant for the relay. The fields are encoded in the following manner, where N or n is the total number of octets in the Agent Information Field (all bytes of the suboptions):

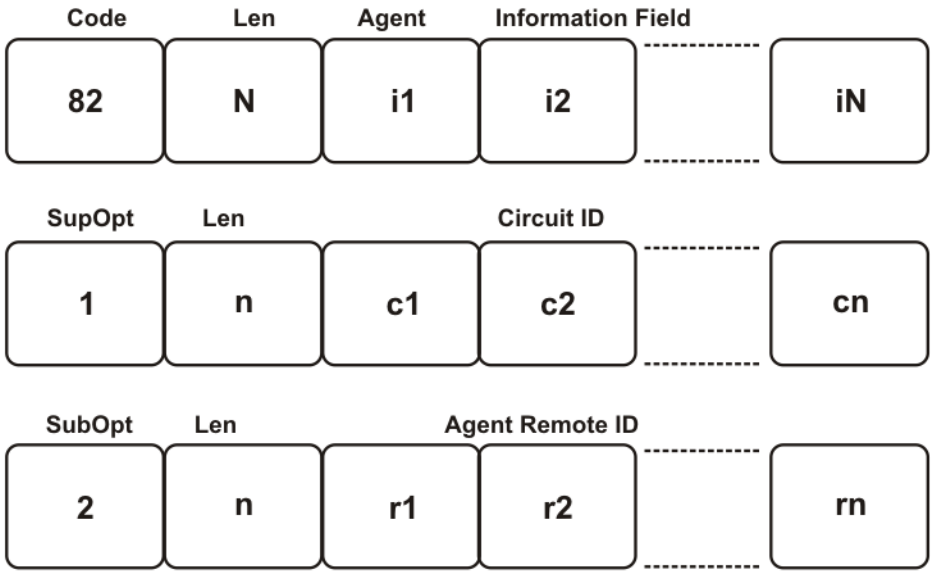

Figure 44: Format of the Relay Agent Information

Because at least one of the sub-options must be defined, the minimum Relay Agent Information length is two (2), and the length n of the suboption can be zero (0). The sub-options do not have to display in any particular order. No pad suboption is defined and the Information field is not terminated with 255 suboption.

DHCP Suboptions

The suboptions are Agent Circuit ID and Agent Remote ID.

The DHCP relay agents can add the Agent Circuit ID to terminate switched or permanent circuits. The Agent Circuit ID encodes an agent-local identifier of the circuit from which a DHCP client-to-server packet was received. Agents can use the Circuit ID to relay DHCP responses back to the proper circuit. In the switch, the Agent Circuit ID field contains the ifIndex of the interface on which the packet is received.

DHCP relay agents can add the Agent Remote ID to terminate switched or permanent circuits, and can identify the remote host end of the circuit. The switch uses the Agent Remote ID field to encode the MAC address of the interface on which the packet is received. The Agent Remote ID must be globally unique.

Agent Operations

A DHCP relay agent adds a Relay Agent Information field as the last option in the DHCP options field of any recognized BOOTP or DHCP packet forwarded from a client to a server. However, if the End Option

255 is present, then the DHCP relay agent adds a Relay Agent information field before the End Option 255 field.

Relay agents can receive a DHCP packet from an untrusted circuit with the gateway IP address (GIADDR) set to zero to indicate that the relay agent is the first-hop router from the gateway. If a Relay Agent Information option is present in the packet, the relay agent discards the packet and increments an error counter. A trusted circuit can contain a trusted downstream network element, for example, a bridge, between the relay agent and the client. The bridge can add a relay agent option but does not set the GIADDR field. In this case, the relay agent forwards the DHCP packet per normal DHCP relay agent operations, and sets the GIADDR field to the relay address. The relay agent does not add a second relay agent option.

You can distinguish between a trusted circuit and an untrusted circuit based on the type of circuit termination equipment you use. To make a circuit trusted, set the trusted flag under DHCP for each interface.

After packets append the Relay Agent Information option, the packets that exceed the MTU or the vendor size buffer of 64 bits, are forwarded without adding the Agent Information option, and an error counter is incremented.

The relay agent or the trusted downstream network element removes the Relay Agent Information option echoed by a server that is added when forwarding a server-to-client response back to the client.

The following list outlines the operations that the relay agent does not perform:

- The relay agent does not add an Option Overload option to the packet or use the file or sname fields to add the Relay Agent Information option. The agent does not parse or remove Relay Agent Information options , the system can display it in the sname or file fields of a server-to-client packet forwarded through the agent.
- The relay agent does not monitor or modify client-originated DHCP packets addressed to a server unicast address; this includes the DHCP-REQUEST sent when entering the RENEWING state.
- The relay agent does not modify DHCP packets that use the IPSEC Authentication Header or IPSEC Encapsulating Security Payload.

A DHCP relay agent can receive a client DHCP packet forwarded from a BOOTP/DHCP relay agent closer to the client. This packet has a GIADDR as non-zero, and may or may not already have a DHCP Relay Agent option in it.

Relay agents configured to add a Relay Agent option which receive a client DHCP packet with a nonzero GIADDR, discards the packet if the GIADDR spoofs a GIADDR address implemented by the local agent itself. Otherwise, the relay agent forwards any received DHCP packet with a valid non-zero GIADDR without adding any relay agent options. The GIADDR value does not change.

DHCP Relay for IPv6

The Dynamic Host Configuration Protocol (DHCP) for IPv6 (RFC 3315) enables DHCP servers to pass configuration parameters such as IPv6 network addresses to IPv6 nodes. DHCP supports automatic allocation of reusable network addresses and of additional configuration parameters. This protocol is a stateful counterpart to stateless address autoconfiguration, and you can use it separately or concurrently with the latter to obtain configuration parameters. For more information about stateless address autoconfiguration, see Host autoconfiguration on page 1747.

To request the assignment of one or more IPv6 addresses, a client first locates a DHCP server, and then requests the assignment of addresses and other configuration information from the server:

1. The client sends a solicit message to the All_DHCP_Relay_Agents_and_Servers (FF02::1:2) multicast address to find available DHCP servers.
2. Any server that can meet the requirements responds with an advertise message.
3. The client then chooses one of the servers and sends a request message to the server asking for confirmed assignment of addresses and other configuration information.
4. The server responds with a reply message that contains the confirmed addresses and configuration.

If a DHCP client does not need a DHCP server to assign it an IPv6 address, the client can obtain configuration information such as a list of available DNS servers or NTP servers through a single message and reply exchanged with a DHCP server.

IPv6 DHCP clients use link-local addresses to send and receive DHCP messages. To permit a DHCP client to send a message to a DHCP server that is not attached to the same link, you must configure a DHCP relay agent on the client link to relay messages between the client and server. The operation of the relay agent is transparent to the client.

A relay agent relays messages from clients and messages from other relay agents. The switch supports DHCP Relay for IPv6. Configure at least one relay agent when the client and server are in different networks.

You must configure the relay agent to use a list of destination addresses for available DHCP servers. The software does not support IPv6 multicast for site-local and global addresses.

The DHCP relay can be a Virtual Router Redundancy Protocol (VRRP) Address. The relay forwards the DHCP messages only if VRRP is in the Master state, otherwise the relay discards the messages.

Note

DHCP cannot work on the backup VRRP if the master fails. To achieve optimum results and to leverage redundancy, you must configure DHCP on the backup VRRP.

Clients listen for DHCP messages on UDP port 546. Servers and relay agents listen for DHCP messages on UDP port 547.

Remote ID

IPv6 DHCP Relay supports the remote ID parameter (RFC4649). After you enable remote ID on the switch, the relay agent adds information about the relay to DHCPv6 messages before relaying the messages to the DHCP server. The server can use the supplied information in the process of assigning the addresses, delegated prefixes, and configuration parameters that the client is to receive.

The remote ID option contains two fields:

- vendor ID
- MAC address of the client

The switch uses a vendor ID of 1584.

Limitations

The following list identifies configuration limitations:

- You can configure only one relay for a VLAN, regardless of how many addresses are configured on that VLAN. The default address is the smallest address configured. If the relay is a VRRP address, the default value is the first VRRP address configured.
- The maximum number of servers to which a relay can send a message from one client, is 10.
- You can configure the number of forwarding paths per system. For information on the maximum limit, see *Fabric Engine Release Notes*.

DHCP Relay Network Topology and Workflow

The following example depicts the interaction between a DHCP client and a server:

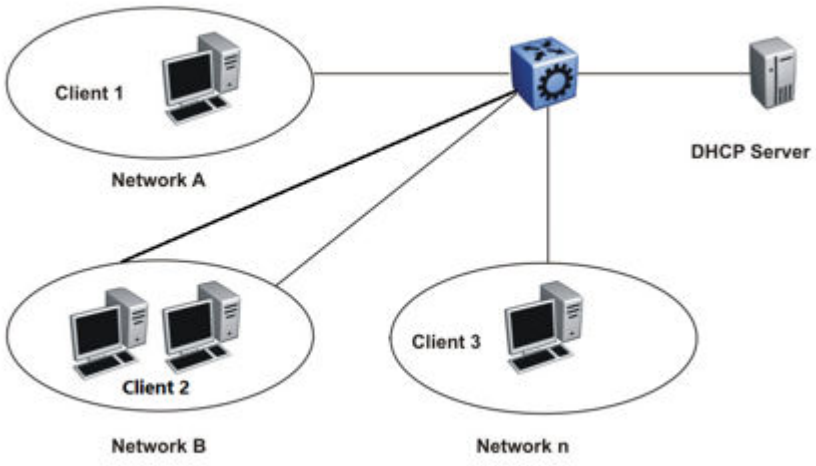

Figure 45: DHCP Client-Relay-Server Architecture

The following list outlines the operations that the DHCP relay agent performs to forward the message to the server :

- When a client sends a request for the IP address or configuration parameters, the server responds with the details as requested by the client.

  Note

  There should be at least one relay agent when client and server are located in different networks.

- A DHCP Relay IPv6 is established only between agents within the context of each VRF and when no cross VRF interaction is present.

  Note

  `All_DHCP_Servers` multicast address option is not implemented for IPv6, as there is no IPv6 MCAST support for site-local and global address.

UDP broadcast forwarding

Some network applications, such as the NetBIOS name service, rely on a User Datagram Protocol (UDP) broadcast to request a service or locate a server for an application. If a host is on a network, subnet segment, or VLAN that does not include a server for the service, UDP broadcasts are by default not forwarded to the server located on a different network segment or VLAN. You can resolve this problem by forwarding the broadcasts to the server through physical or virtual router interfaces.

UDP broadcast forwarding is a general mechanism for selectively forwarding limited UDP broadcasts received on an IP interface out to other router IP interfaces as a rebroadcast or to a configured IP address. If the address is that of a server, the packet is sent as a unicast packet to this address. If the address is that of an interface on the router, the frame is rebroadcast.

After a UDP broadcast is received on a router interface, it must meet the following criteria to be eligible for forwarding:

- It must be a MAC-level broadcast.
- It must be an IP limited broadcast.
- It must be for the specified UDP protocol.
- It must have a time-to-live (TTL) value of at least 2.

For each ingress interface and protocol, the policy specifies how the UDP broadcast is retransmitted: to a unicast host address or to a broadcast address.

DHCP and UDP configuration using the CLI

Use Dynamic Host Configuration Protocol (DHCP), an extension of the Bootstrap Protocol (BootP), to provide host configuration information to the workstations dynamically. Use the DHCP relay commands to configure DHCP relay behavior on a port or on a VLAN.

This section describes CLI commands for DHCP and User Datagram Protocol (UDP) configuration.

Configure DHCP Parameters Globally

Before You Begin

Configure an IP address on the interface to be used as the DHCP relay interface.

About This Task

Configure DHCP relay parameters for the port or the VLAN.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Create the forwarding path from the client to the server:

   ```
   ip dhcp-relay fwd-path <A.B.C.D> <A.B.C.D>
   ```

3. Enable the forwarding path from the client to the server:

   ```
   ip dhcp-relay fwd-path <A.B.C.D> <A.B.C.D> enable
   ```

   Note

   If the agent IP address (the first *<A.B.C.D>* variable) is a VLAN or port IP address, you must enable DHCP Relay on that VLAN or port by running **ip dhcp-relay** within the VLAN context. However, if the first *<A.B.C.D>* variable is a VRRP address, you do not need to enable DHCP Relay on the VLAN or port in which the VRRP address resides.

4. Modify DHCP mode to forward BOOTP messages only, DHCP messages only, or both:

   ```
   ip dhcp-relay fwd-path <A.B.C.D> <A.B.C.D> mode <bootp|bootp_dhcp|dhcp>
   ```

5. (Optional) Configure the forwarding path with source port 67 from client to the server.

   ```
   ip dhcp-relay fwd-path {A.B.C.D} {A.B.C.D} src-port-67
   ```

Example

Create the forwarding path from the client to the server. Enable the forwarding path from the client the server. Modify DHCP mode to forward both BOOTP and DHCP messages. Configure the forwarding path with source port 67 for BOOTP request.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip dhcp-relay fwd-path 192.0.2.120 192.0.2.50
Switch:1(config)#ip dhcp-relay fwd-path 192.0.2.128 192.0.2.50 enable
Switch:1(config)#ip dhcp-relay fwd-path 192.0.2.128 192.0.2.50 mode bootp_dhcp
Switch:1(config)#ip dhcp-relay fwd-path 192.0.2.128 192.0.2.50 src-port-67
```

Variable Definitions

The following table defines parameters for the **ip dhcp-relay fwd-path** command.

Variable	Value
{A.B.C.D}	The *{A.B.C.D}* variable is the agent IP address configured on an interface (a locally configured IP address).
{A.B.C.D}	The *{A.B.C.D}* variable is the IP address of the DHCP server in the network.
disable	Disables DHCP Relay globally.
enable	Enables DHCP Relay globally.
mode {bootp|bootp_dhcp|dhcp>	Modifies DHCP mode to forward BOOTP messages only, DHCP messages only, or both. The default is both.
src-port-67	Configures the UDP source port to 67 for BOOTP request. The default is 68.

Showing DHCP relay information

Display relay information to show relay information about DHCP routes and counters.

For scaling information on DHCP Relay forwarding (IPv4 or IPv6), see *Fabric Engine Release Notes*.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Display information about DHCP relay forward paths:

   ```
   show ip dhcp-relay fwd-path [vrf WORD<1-16>] [vrfids WORD<0-512>]
   ```

3. Display information about DHCP relay counters:

   ```
   show ip dhcp-relay counters [vrf WORD<1-16>] [vrfids WORD<0-512>]
   ```

4. Display the options for each listed interface:

   ```
   show ip dhcp-relay interface [gigabitethernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]}] [vlan <1-4059>] [vrf WORD <1-16>] [vrfids WORD <0-512>]
   ```

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1#show ip dhcp-relay interface

Variable definitions

Use the data in the following table to use the **show ip dhcp-relay** command.

Variable	Value
vrf WORD<1-16>	The name of the VRF.
vrfids WORD<0-512>	The ID of the VRF. The value is an integer in the range of 0–512.

Use the data in the following table to use the **show ip dhcp-relay interface** command.

Variable	Value
{slot/port[/sub-port][-slot/port[/sub-port]][,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
[vlan *<1-4059>*]	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
[vrf WORD<1-16>]	Specifies the name of the VRF.
[vrfids WORD<0-512>]	Specifies the ID of the VRF. The value is an integer from 0– 512.

Configuring DHCP option 82

Configure the DHCP option 82 to enable the circuit ID to encode an agent-local identifier of the circuit from which a DHCP client-to-server packet is received. Configure the DHCP option 82 to enable the remote ID to encode the MAC address of the interface on which the packet is received. By default, the DHCP option 82 is disabled.

Before You Begin

- You must enable ip and dhcp-relay on the VLAN.

About This Task

To configure the DHCP option 82 on a VLAN, you must enter the VLAN Interface Configuration mode.

To configure the DHCP option 82 on a brouter port, you must enter the GigabitEthernet Interface Configuration mode.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]}
   ```
   or `interface vlan <1-4059>`

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable the circuit ID:

   ```
   ip dhcp-relay circuitID
   ```

3. Enable the remote ID:

   ```
   ip dhcp-relay remoteID
   ```

4. Configure the circuit as trusted:

   ```
   ip dhcp-relay trusted
   ```

5. Show statistics for option 82, which is the relay agent information option:

   ```
   show ip dhcp-relay counters option82 [vrf WORD<1-16>] [vrfids WORD <0-512>]
   ```

Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface gigabitethernet 1/10
```

Enable the circuit ID:

```
Switch:1(config-if)# ip dhcp-relay circuitID
```

Enable the remote ID:

```
Switch:1(config-if)# ip dhcp-relay remoteID
```

Configure the circuit as trusted:

```
Switch:1(config-if)# ip dhcp-relay trusted
```

Show statistics for option 82, which is the relay agent information option:

```
Switch:1(config-if)# show ip dhcp-relay counters option82
```

Variable Definitions

Use the data in the following table to configure the DHCP option 82.

Variable	Value
circuitID	Enables the Circuit ID.
remoteID	Enables the Remote ID.
trusted	Sets the circuit as trusted.

Use the data in the following table to use the **show ip dhcp-relay counters option82 [vrf WORD<1-16>] [vrfids WORD <0-512>]** command.

Variable	Value
vrf WORD<1-16>	Displays DHCP counters for a particular VRF. WORD<1-16> specifies the VRF name.
vrfids WORD <0-512>	Displays a DHCP forward path for a particular VRF. WORD <0-512> specifies the VRF ID.

Configuring DHCP relay on a port or VLAN

You can view and configure the DHCP parameters on specific ports or on a VLAN.

Before You Begin

- You must configure IP on the interface.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]} or interface vlan <1-4059>
   ```

   Note
   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable DHCP parameters on a specified port or VLAN:

   ```
   ip dhcp-relay
   ```

Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface gigabitethernet 1/10
```

Enable DHCP parameters on a specified port or VLAN:

```
Switch:1(config-if)# ip dhcp-relay
```

Variable definitions

Use the data in the following table to use the **ip dhcp-relay** command.

Use the **no** operator to disable DHCP parameters on specified ports: **no ip dhcp-relay**.

Note
The **no ip dhcp-relay** command disables DHCP Relay, it does not delete the DHCP entry.

To configure this option to the default value, use the **default** operator with this command.

Variable	Value
broadcast	Enables the device to send the server reply as a broadcast to the end station. After you disable this variable, the device sends the server reply as a unicast to the end station. Use the **no** operator to disable broadcast: `no ip dhcp-relay broadcast`. To configure this option to the default value, use the **default** operator with this command.
circuitId	Enables Option 82 circuit ID on the interface.
clear-counters	Clears DHCP Relay counters for the interface.
fwd-path <A.B.C.D> [vrid <1-255>]	Creates a forward path server with a virtual router ID (or VRRP ID), a mode, and a state. *A.B.C.D* is the IP address. *vrid <1-255>* is the ID of the virtual router and is an integer from 1 to 255. Use the **no** operator to delete a forward path server with a specific value and virtual router ID: `no ip dhcp-relay fwd-path <A.B.C.D> [vrid <1-255>]` To configure this option to the default value, use the **default** operator with this command.
fwd-path <A.B.C.D> disable [vrid <1-255>]	Disables a forward path server with a specific value and virtual router ID. *A.B.C.D* is the IP address. *vrid <1-255>* is the ID of the virtual router (or VRRP ID) and is an integer from 1 to 255.
fwd-path <A.B.C.D> enable [vrid <1-255>]	Enables a forward path server with a specific value and virtual router ID (or VRRP ID). *A.B.C.D* is the IP address in the form a.b.c.d. *vrid <1-255>* is the ID of the virtual router and is an integer from 1 to 255.
fwd-path <A.B.C.D> mode <bootp|bootp_dhcp|dhcp> [vrid <1-255>]	Configures the forward path mode for a VLAN. This command string is available only in VLAN Interface Configuration mode. *A.B.C.D* is the IP address in the form a.b.c.d. *mode* is a choice of bootp, dhcp, or bootp_dhcp. *vrid <1-255>* is the ID of the virtual router (or VRRP ID) and is an integer from 1 to 255. To configure this option to the default value, use the **default** operator with this command.
max-hop <1-16>	Configures the maximum number of hops before a BootP/DHCP packet is discarded (1 to 16). The default is 4. To configure this option to the default value, use the **default** operator with this command.
min-sec <0-65535>	Configures the minimum seconds count for DHCP. If the secs field in the BootP/DHCP packet header is greater than this value, the device relays or forwards the packet; otherwise, the packet is dropped (0 to 65535). The default is 0 seconds. To configure this option to the default value, use the **default** operator with this command.

Variable	Value
mode <bootp|bootp_dhcp|dhcp>	Configures DHCP mode to forward BootP messages only, DHCP messages only, or both. The default is both. To configure this option to the default value, use the **default** operator with this command.
remoteId	Enables Option82 remote ID on the interface.
trusted	Configures the DHCP circuit as trusted.

Displaying DHCP-relay Statistics for Specific Ports

Display individual DHCP-relay statistics for specific ports to manage network performance.

Note

Slot and port information can differ depending on hardware platform.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. View DHCP-relay statistics for a specific port or VRF.

   ```
   show interfaces GigabitEthernet statistics dhcp-relay [vrf WORD<1-16>]
   [vrfids WORD<0-255>]|{slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}}
   ```

Example

View DHCP-relay statistics:

```
Switch:1>enable
Switch:1#show interfaces gigabitethernet statistics dhcp-relay

================================================================================
                              Port Stats Dhcp
================================================================================
PORT_NUM VRF NAME         NUMREQUEST NUMREPLY
--------------------------------------------------------------------------------
1/12     GlobalRouter     0          2
1/13     GlobalRouter     3          2
2/3      GlobalRouter     0          2
--------------------------------------------------------------------------------
```

Variable Definitions

Use the data in the following table to use the **show interfaces GigabitEthernet statistics dhcp-relay** command.

Variable	Value
vrf WORD<1-16>	Specifies a VRF instance by VRF name.
vrfids WORD<0-255>	Specifies the ID of the VRF.
{slot/port[/sub-port][-slot/port[/sub-port]][,...]}	Identifies the slot and port in one of the following formats: a single slot and port (1/1). Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Displaying DHCP-relay Statistics for all Interfaces

About This Task

Display DHCP-relay statistics for all interfaces to manage network performance.

Note
Slot and port information can differ depending on hardware platform.

Procedure

1. Show the number of requests and replies for each interface:

   `show ip dhcp-relay counters [vrf WORD<1-16>] [vrfids WORD<0-512>]`

2. Show counters for Option 82:

   `show ip dhcp-relay counters option82 [vrf WORD<1-16>] [vrfids WORD<0-512>]`

Example

```
Switch:1>show ip dhcp-relay counters option82
================================================================================================
=====
                    DHCP Counters Option82 - GlobalRouter
================================================================================================
=====
                IP              FOUND DROP CIRC ADD  DEL  REMOTE             ADD    DEL
INTERFACE       ADDR            OP82  PKT  ID   CIRC CIRC ID                 REMID  REMID
------------------------------------------------------------------------------------------------
-----
Port 1/12                       0     0    395   0     0  00:24:7f:9d:0a:00  0      0
Vlan40                          0     0    2088  0     0  00:24:7f:9d:0a:01  0      0
```

Variable Definitions

Use the data in the following table to use the **show ip dhcp-relay counters** command.

Variable	Value
vrf WORD<1-16>	Specifies a VRF instance by the VRF name.
vrfids WORD<0-512>	Specifies the ID of the VRF.

Configuring UDP broadcast forwarding

About This Task

By default, routers do not forward broadcasts. UDP broadcast forwarding is a generalized mechanism for the router to selectively forward UDP broadcasts. You must set up UDP broadcast forwarding on the system. Configure UDP broadcast forwarding to forward the UDP broadcasts of network applications to the required server through physical or virtual router interfaces.

Procedure

1. Enter protocols into a table.
2. Create policies (protocol/server pairs).
3. Assemble the policies into lists or profiles.
4. Apply the list to the appropriate interfaces.

Configuring UDP protocols

About This Task

Configure UDP protocols to determine which UDP broadcasts are forwarded.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

   ```
   enable

   configure terminal
   ```

   Optional: `router vrf WORD<1-16>`
2. Configure a UDP protocol:

   ```
   ip forward-protocol udp <1-65535> WORD<1-15>
   ```
3. Confirm your configuration:

   ```
   show ip forward-protocol udp interface [vrf WORD<1-16>]|[vrfids
   WORD<0-512>] portfwd [vrf WORD<1-16>]| [vrfids WORD<0-512>]
   portfwdlist <1-1000>[vrf WORD<1-16>]|[vrfids WORD<0-512>] vrf
   WORD<1-16> vrfids WORD<0-512>
   ```

Example

Configure a UDP protocol and confirm your configuration.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip forward-protocol udp 53 DNS
Switch:1(config)#show ip forward-protocol udp

================================================================================
                        Udp Protocol Tbl - GlobalRouter
================================================================================
UDP_PORT PROTOCOL_NAME
--------------------------------------------------------------------------------
37       Time Service
49       TACACS Service
53       DNS
69       TFTP
137      NetBIOS NameSrv
138      NetBIOS DataSrv
```

Variable definitions

Use the data in the following table to use the **ip forward-protocol udp** command.

Variable	Value
<1-65535> WORD<1-15>	Creates a new UDP protocol. *<1-65535> WORD<1-15>* is the UDP protocol name as a string. Use the **no** operator to delete a UDP protocol `no ip forward-protocol udp <1-65535>`.
portfwd	Displays portfwd information.
portfwdlist	Displays port forward list information.
vrf WORD<1-16>	Specifies the name of the VRF.
vrfids WORD<0-512>	Specifies the ID of the VRF.

Configuring a UDP port forward entry

Configure a UDP port forward entry to add or remove a port forward entry.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

   `enable`

   `configure terminal`

   Optional: `router vrf WORD<1-16>`
2. Configure a UDP port forward entry:

   `ip forward-protocol udp portfwd <1-65535> {A.B.C.D}`
3. Confirm your configuration:

   `show ip forward-protocol udp portfwd [vrf WORD<1-16>] [vrfids WORD<0-512>]`

Example

Configure a UDP port forward entry:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip forward-protocol udp portfwd 150 192.0.2.10
```

Variable definitions

Use the data in the following table to use the **ip forward-protocol udp portfwd** command.

Variable	Value
<1-65535> {A.B.C.D}	Adds a UDP protocol port to the specified port forwarding list. *1-65535* is a UDP protocol port in the range of 1–65535. *A.B.C.D* is an IP address in a.b.c.d format. Use the **no** operator to remove a protocol port forwarding entry and IP address from the list: `no ip forward-protocol udp portfwd <1-65535> <A.B.C.D>`. To configure this option to the default value, use the **default** operator with this command.
vrf WORD<1-16>	Specifies the name of the VRF.
vrfids WORD<0-512>	Specifies the ID of the VRF.

Configuring the UDP port forwarding list

Configure the UDP port forwarding list to assign protocols and servers to the port forward list.

About This Task

You can perform this procedure in Global Configuration mode, VLAN Interface Configuration mode, or VRF Router Configuration mode.

Procedure

1. Enter Global Configuration mode:
   ```
   enable
   ```
   ```
   configure terminal
   ```
2. Configure the UDP port forwarding list:
   ```
   ip forward-protocol udp portfwdlist <1-1000>
   ```

   Important
   The following two steps are not available in the Global Configuration or VRF Router Configuration mode. The following two commands are available in VLAN Interface Configuration mode only.

3. Enter VLAN Interface Configuration mode:
   interface vlan *<1-4059>*
4. Configure the broadcast mask:
   ```
   ip forward-protocol udp broadcastmask {A.B.C.D}
   ```

5. Configure the maximum time to live:

   ```
   ip forward-protocol udp maxttl <1-16>
   ```

6. Confirm your configuration:

   ```
   show ip forward-protocol udp portfwdlist <1-1000> [vrf WORD<1-16>]
   [vrfids WORD<0-512>]
   ```

Example

```
Switch:1> enable
Switch:1# configure terminal
```

Configure the UDP port forwarding list:

```
Switch:1(config)# ip forward-protocol udp portfwdlist 1
```

Log on to the VLAN interface configuration mode:

```
Switch:1(config)# interface vlan 3
```

Configure the broadcast mask:

```
Switch:1(config-if)# ip forward-protocol udp broadcastmask 192.0.2.255
```

Configure the maximum time to live:

```
Switch:1(config-if)# ip forward-protocol udp maxttl 10
```

Confirm the configuration:

```
Switch:1(config-if)# show ip forward-protocol udp portfwdlist
```

Variable definitions

Use the data in the following table to use the **ip forward-protocol udp portfwdlist** command.

Variable	Value
<1-1000>	Creates a UDP port forwarding list in the range of 1–1000.
<1-65535> {A.B.C.D}	Adds a UDP protocol port to the specified port forwarding list. *1-65535* is a UDP protocol port in the range of 1–65535. *A.B.C.D* is an IP address in a.b.c.d format. Use the **no** operator to remove or delete a port forwarding list ID, `no ip forward-protocol udp portfwdlist <1-1000> <1-65535> <A.B.C.D>`. To configure this option to use the default value, use the **default** operator with this command.
name WORD<0-15>	Changes the name of the port forwarding list.

Use the data in the following table to use the **ip forward-protocol udp** command.

Variable	Value
broadcastmask {A.B.C.D}	Configures the interface broadcast mask (the interface broadcast mask can be different from the interface mask). *A.B.C.D* is an IP address in a.b.c.d format. Use the **no** operator to delete the broadcast mask: `no ip forward-protocol udp broadcastmask {A.B.C.D}` To configure this option to the default value, use the **default** operator with this command.
maxttl <1-16>	Configures the maximum time-to-live value (TTL) for the UDP broadcast forwarded by the interface. The range is 1–16.
portfwdlist <1-1000>	Assigns the list to the VLAN.
vlan <1-4059> [portfwdlist <1-1000>]	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. If you use the portfwdlist variable with the VLAN variable, it assigns the list to the specified VLAN, regardless of which VLAN context you currently configure.

Showing UDP forward information

Show UDP forward information to view information about the UDP forwarding characteristics of the device. UDP forwarding only supports 128 entries.

About This Task

There are four show options:

- Show the interface information
- Show the port forward information
- Show the port forward list information
- Show the protocol information

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Display information about the UDP interface for all IP addresses or a specified IP address:

   ```
   show ip forward-protocol udp interface [<A.B.C.D>] [vrf WORD<1-16>] [vrfids WORD<0-512>]
   ```

3. Display the UDP port forwarding table:

   ```
   show ip forward-protocol udp portfwd [vrf WORD<1-16>] [vrfids WORD<0-512>]
   ```

4. Display the UDP port forwarding list table for the specified list or all lists on the device:

   ```
   show ip forward-protocol udp portfwdlist [vrf WORD<1-16>] [vrfids WORD<0-512>]
   ```

5. Display the UDP protocol table with the UDP port numbers for each supported or designated protocol:

   ```
   show ip forward-protocol udp [vrf WORD<1-16>] [vrfids WORD<0-512>]
   ```

Example

Display the UDP protocol table with the UDP port numbers for each supported or designated protocol:

```
Switch:1>enable
Switch:1#show ip forward-protocol udp

================================================================================
                        Udp Protocol Tbl - GlobalRouter
================================================================================
UDP_PORT PROTOCOL_NAME
--------------------------------------------------------------------------------
37       Time Service
49       TACACS Service
53       DNS
69       TFTP
137      NetBIOS NameSrv
138      NetBIOS DataSrv
```

Variable Definitions

Use the data in the following table to use the **show ip forward-protocol udp interface** command.

Variable	Value
<A.B.C.D>	Specifies the IP address for the interface in a.b.c.d format.
vrf WORD<1-16>	Specifies the name of the VRF.
vrfids WORD<0-512>	Specifies the ID of the VRF and is an integer in the range of 0 to 512.

IPv6 DHCP Relay Configuration using CLI

Configure a DHCP Relay Forwarding Path

Configure a forwarding path to specify the relay agent address and the DHCP server address to which to forward packets.

To use DHCP Relay for IPv6, you must configure at least one forwarding path and enable the relay on one interface.

Before You Begin

For a VRF other than GlobalRouter, the interface must be first associated to that VRF.

About This Task

The relay agent can use the IPv6 address of the interface or the VRRP global address linked to that interface. The relay forwards the DHCP messages only if VRRP is in the master state, otherwise the relay discards the messages.

You can configure only one relay agent on an interface. If you need to change the relay agent, you must delete all the forwarding paths with the old relay agent, and then configure the new relay agent.

For scaling information on DHCP Relay forwarding paths, see *Fabric Engine Release Notes*.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

   ```
   enable

   configure terminal
   ```

   Optional: `router vrf WORD<1-16>`
2. Configure a forwarding path:

   ```
   ipv6 dhcp-relay fwd-path WORD<0-255> WORD<0-255> [enable]
   ```

   If you configure the forwarding path globally, the relay agent address can be any configured IP address of the relay interface or the VRRP global address linked to the relay interface.
3. To configure a forwarding path on an interface, enter Interface Configuration mode:

   ```
   interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}

   OR

   interface vlan <1-4059>
   ```
4. Configure a forwarding path:

   ```
   ipv6 dhcp-relay fwd-path WORD<0-255> [enable] [vrid WORD<1-255>]
   ```

   If you configure the forwarding path on an interface, the relay agent address is either the smallest IP configured on the interface or the first VRRP global address configured, if the relay is the VRRP master. You do not specify the relay agent address as part of the command.

   Note

   IPv6 DHCP Relay is established only between agents within the context of each VRF.

Examples

Configure a forwarding path globally:

```
Switch:1(config)#ipv6 dhcp-relay fwd-path 1111::1111 1234::1234 enable
```

Configure a forwarding path on an interface:

```
Switch:1(config)#interface GigabitEthernet 1/1
Switch:1(config-if)#ipv6 dhcp-relay fwd-path 1234::1234 enable
```

Configure the VRRP master as the relay:

```
Switch:1(config-if)#ipv6 dhcp-relay fwd-path 1234::1234 vrid 12 enable
```

Variable Definitions

Use the data in the following table to use the **ipv6 dhcp-relay fwd-path** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
enable	Enables the forwarding path. The default is disabled.
{slot/port[/sub-port][-slot/port[/sub-port]][,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
vrid WORD<1-255>	Specifies the VRRP ID to use the VRRP master as the relay agent interface.
WORD<0-255>	Specifies the IPv6 address of the DHCP server for the interface configuration.
WORD<0-255> WORD<0-255>	Specifies the IPv6 address of the relay agent interface and the IPv6 address of the DHCP server for the global configuration.

Configuring DHCP Relay for an interface

Configure the DHCP relay behavior on the interface.

About This Task

You can configure only one relay for a VLAN, regardless of how many addresses are configured on that VLAN. The default address is the smallest address configured. If the relay is a VRRP address, the default value is the first VRRP address configured.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]}
   ```
   or
   ```
   interface vlan <1-4059>
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable DHCP on the interface:

   ```
   ipv6 dhcp-relay
   ```

3. Configure the maximum hop count:

   ```
   ipv6 dhcp-relay max-hop <1-32>
   ```

4. Enable the remote ID:

   ```
   ipv6 dhcp-relay remote-id
   ```

Example

Configure the maximum hop count:

```
Switch:1(config-if)#ipv6 dhcp-relay max-hop 30
```

Disable the remote ID:

```
Switch:1(config-if)#no ipv6 dhcp-relay remote-id
```

Variable Definitions

Use the data in the following table to use the **`ipv6 dhcp-relay`** command.

Variable	Value
`max-hop <1-32>`	Specifies the maximum number of hops a DHCP packet can take from the DHCP client to the DHCP server. The default is 32.
`remote-id`	Enables the relay agent to add information about the relay to DHCPv6 messages before relaying the messages to the DHCP server. The default is disabled

Use the data in the following table to use the **`interface`** command.

Variable	Value
`<1-4059>`	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *`vrf-scaling`* and *`spbm-config-mode`* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
`{slot/port[/sub-port][-slot/port[/sub-port]][,...]}`	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

View DHCP Relay Information

View DHCP Relay information to display the current configuration for the forwarding path and the interface configuration.

About This Task

Not all parameters are available in non-default VRFs.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. View DHCP Relay global information:

   ```
   show ipv6 dhcp-relay {counters [vrf WORD<1-16> | vrfids WORD<0-512>] |
   fwd-path [vrf WORD<1-16> | vrfids WORD<0-512>]
   ```

3. View IPv6 DHCP Relay interface configuration:

   ```
   show ipv6 dhcp-relay interface {gigabitEthernet {slot/port[/sub-port]
   [-slot/port[/sub-port]] [,...]} | vlan <1-4059>}
   ```

Note

The **no ipv6 dhcp-relay** command disables DHCP on the interface but does not delete the entry.

Example

```
Switch:1(config-if)#show ipv6 dhcp-relay fwd-path

================================================================================
                        DHCPv6 Fwd-path - GlobalRouter
================================================================================
INTERFACE                           SERVER                                ENABLE
--------------------------------------------------------------------------------
1111:0:0:0:0:0:0:1111               1234:0:0:0:0:0:0:1234                 enable
```

Variable Definitions

Use the information in the following table to help you use the **show ipv6 dhcp-relay** command.

Variable	Value
{slot/port[/sub-port][-slot/port[/sub-port]][,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
vlan<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
vrf WORD<1-16>	Specifies the VRF name.
vrfids WORD<0-512>	Specifies the VRF ID.

Viewing IPv6 DHCP Relay Statistics

Display individual IPv6 DHCP Relay statistics for specific interfaces to manage network performance.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View statistics:

   ```
   show ipv6 dhcp-relay counters
   ```

Note

Use the `sys action reset counters` command to clear DHCP Relay statistics.

Example

```
Switch:1#show ipv6 dhcp-relay counters

================================================================================
                                DHCPv6 Counters
================================================================================
INTERFACE                                REQUESTS   REPLIES
--------------------------------------------------------------------------------
1111:0:0:0:0:0:0:1111                    1          1
```

DHCP and UDP configuration using Enterprise Device Manager

Dynamic Host Configuration Protocol (DHCP), an extension of the Bootstrap Protocol (BootP), dynamically provides host configuration information to workstations. To lower administrative overhead, network managers prefer to configure a small number of DHCP servers in a central location. Using few DHCP servers requires the routers connecting to the subnets or bridge (or VLAN) domains to support the BootP/DHCP relay function so that hosts can retrieve the configuration information from servers several router hops away.

User datagram protocol (UDP) is a connectionless protocol that adds reliability and multiplexing to IP. It describes how messages reach application programs within a destination computer. Some network applications, such as the NetBIOS name service, rely on a UDP broadcast to request a service or to locate a service. By default, broadcasts are not forwarded by a router. UDP broadcast forwarding is a generalized mechanism for the router to selectively forward UDP broadcasts.

Important

BootP/DHCP relays are supported only on IP routed port-based VLANs and protocol-based VLANs.

Before You Begin

You must enable DHCP relay on the path for port or VLAN configuration to take effect.

Configuring DHCP on a brouter port or a VRF instance

Before You Begin

- You must first enable BootP/DHCP relay on a port (or VLAN).
- You must enable DHCP and forwarding path.
- You must enable IP Routing on the interface.

About This Task

Use the DHCP tab to configure the DHCP behavior on a brouter port or a VRF instance. The DHCP tab is available only if the port is routed (that is, assigned an IP address).

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation tree, expand the following folders: **Configuration** > **Edit** > **Port**.
3. Click **IP**.
4. Click the **DHCP Relay** tab.
5. Click **Enable** to select the DHCP option. The default is disable.
6. Configure the other parameters as needed.
7. Click **Apply**.

DHCP *field descriptions*

Use data from the following table in the DHCP Relay tab.

Name	Description
Enable	Lets you use BootP/DHCP on the port. The default is disable.
MaxHop	Sets the maximum number of hops before a BootP/DHCP packet is discarded (1 to 16). The default is 4.
MinSec	The secs field in the BootP/DHCP packet header represents the elapsed time since the client first sent the message. If the secs field in the packet header is greater than this value, the system relays or forwards the packet; otherwise, the packet is dropped. The default is 0 seconds.
Mode	Sets the interface to process only BootP, only DHCP, or both types of packets. The default is both.
AlwaysBroadcast	When enabled, the server reply is sent as a broadcast back to the end station. The default is disable.
CircuitId	Indicates whether DHCP Relay inserted the option 82 circuit ID information into the DHCP packets before sending the DHCP packets to the DHCP server. The default is disable.
RemoteId	Indicates whether DHCP Relay inserted the option 82 remote ID information into the DHCP packets before sending the DHCP packets to the DHCP server. The default is disable.
Trusted	Indicates if DHCP packets come through a trusted DHCP circuit. Only packets with GIADDR configured to 0 and containing option 82 are forwarded if the circuit is trusted. The default value is false.

Configuring BootP/DHCP on a VLAN or VRF instance

Before You Begin

- You must enable IP Routing on the interface.

About This Task

Use the DHCP Relay tab to configure the DHCP behavior on a VLAN. The DHCP Relay tab is available only if the VLAN is routed and is assigned an IP address.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **VLAN**.
2. Click **VLANs > Basic**.
3. Select a VLAN.
4. Click **IP**.
5. Click the **DHCP Relay** tab.
6. Select **Enable**.
7. Configure the parameters as required.
8. Click **Apply**.

DHCP Relay *field descriptions*

Use the data in the following table to use the **DHCP Relay** tab.

Variable	Value
Enable	Lets you use BootP/DHCP on the port. The default is disable.
MaxHop	Sets the maximum number of hops a BootP/DHCP packet can take from the DHCP client to the DHCP server. The maximum number of hops is 16. The default is 4.
MinSec	Represents the minimum number of seconds to wait between receiving a DHCP packet and forwarding the DHCP packet to the DHCP server. A value of 0 indicates that forwarding is done immediately. The default value is 0.
Mode	Indicates the type of DHCP packet required. The options are: • bootp • dhcp • both The default is both.
AlwaysBroadcast	When enabled, the DHCP Reply packets are sent as a broadcast to the DHCP client. The default is disable.
CircuitId	Indicates whether DHCP Relay inserted the option 82 circuit ID information into the DHCP packets before sending the DHCP packets to the DHCP server. The default is disable.

Variable	Value
RemoteId	Indicates whether DHCP Relay inserted the option 82 remote ID information into the DHCP packets before sending the DHCP packets to the DHCP server. The default is disable.
Trusted	Indicates if DHCP packets come through a trusted DHCP circuit. Only packets with GIADDR configured to 0 and containing option 82 are forwarded if the circuit is trusted. The default value is false.

Configure DHCP Relay

About This Task

After you configure the BOOTP/DHCP relay on an IP interface, you can configure forwarding paths to indicate where packets are forwarded. The forwarding paths are based on the type of packet and where the packet is received.

About This Task

Procedure

1. In the navigation tree, expand **Configuration** > **IP**.
2. Select **DHCP Relay**.
3. Select the **Globals** tab.
4. Select **Insert**.
5. In the **AgentAddr** box, type the agent address.
6. In the **ServerAddr** list, type the server address.
7. Select **Enable** to enable BOOTP/DHCP relay. You can enable or disable each agent server forwarding policy. The default is enabled.
8. In the **Mode** box, select the type of messages to relay.

   Both the mode setting for the DHCP interface and the mode setting for the agent interface determine which packets are forwarded.
9. Select **SrcPort67** to configure the source port for the BOOTP/DHCP relay request.
10. Select **Insert**.

***Globals** field descriptions*

Use the data in the following table to use the **Globals** tab.

Name	Description
AgentAddr	The IP address of the input interface (agent) on which the BOOTP/DHCP request packets are received for forwarding. This address is the IP address of either a brouter port or a VLAN for which forwarding is enabled.
ServerAddr	This parameter is either the IP address of the BOOTP/DHCP server or the address of another local interface. • If it is the address of the BOOTP/DHCP server, the request is unicast to the server address. • If the address is one of the IP addresses of an interface on the system, the BOOTP/DHCP requests are broadcast out of that local interface.
Enable	Enables BOOTP/DHCP relay.
Mode	Specifies the type of messages relayed: • Only BOOTP • Only DHCP • Both types of messages The default is to forward both BOOTP and DHCP messages.
SrcPort67	Assigns source port 67 to the UDP forwarding path. The default is source port 68.

Viewing DHCP relay configuration information

About This Task

Use the DHCP Relay Interfaces tab to view configuration information about the DHCP relay. To change the configuration information, double-click the value in the field under the required interface, and enter a new value.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IP**.
2. Click **DHCP Relay**.
3. Click the **Interfaces** tab.

***Interfaces** field descriptions*

Use the data in the following table to use the **Interfaces** tab.

Variable	Value
IfIndex	A read-only interface number that represents a physical interface, or the VLAN logical interface.
MaxHop	Sets the maximum number of hops a DHCP packet can take from the DHCP client to the DHCP server. The maximum number of hops is 16. The default is 4.
MinSec	Represents the minimum number of seconds to wait between receiving a DHCP packet and forwarding the DHCP packet to the DHCP server. A value of 0 indicates that forwarding is done immediately. The default value is 0.
Mode	Indicates the type of DHCP packet required. The options are: • bootp • dhcp • both The default is both.
AlwaysBroadcast	Indicates if DHCP Reply packets can be sent as a broadcast to the DHCP client. The default is false.
CircuitId	Indicates whether DHCP Relay inserted the option 82 circuit ID information into the DHCP packets before sending the DHCP packets to the DHCP server. The default is disable.
RemoteId	Indicates whether DHCP Relay inserted the option 82 remote ID information into the DHCP packets before sending the DHCP packets to the DHCP server. The default is disable.
Trusted	Indicates if DHCP packets come through a trusted DHCP circuit. Only packets with GIADDR configured to 0 and containing option 82 are forwarded if the circuit is trusted. The default value is false.

Viewing DHCP Statistics for an Interface

View DHCP statistics to manage network performance.

Procedure

1. In the navigation pane, expand the **Configuration** > **IP** folders.
2. Click **DHCP Relay**.
3. Click the **Interfaces Stats** tab.

Interfaces Stats *Field Descriptions*

Use the data in the following table to use the **Interfaces Stats** tab.

Name	Description
IfIndex	Identifies the physical interface.
AgentAddr	Shows the IP address configured as the relay on this interface. This address is either the IP of the physical interface or the IP of the VRRP address.
NumRequests	Shows the number of DHCP and BootP requests on this interface.
NumReplies	Shows the number of DHCP and BootP replies on this interface.

Graphing DHCP Statistics for a Port

View DHCP statistics to manage network performance.

Procedure

1. In the Device Physical View, select a port.
2. In the navigation pane, expand the **Configuration** > **Graph** folders.
3. Click **Port**.
4. Click the **DHCP** tab.
5. Select one or more values.
6. Click the type of graph to create.

DHCP *Field Descriptions*

The following table describes parameters on the **DHCP** tab.

Name	Description
NumRequests	The number of DHCP and/or BootP requests on this interface.
NumReplies	The number of DHCP and/or BootP replies on this interface.

Viewing DHCP Statistics for a Port

View DHCP statistics to manage network performance.

Procedure

1. In the Device Physical view, select a port.
2. In the navigation pane, expand the **Configuration** > **Edit** > **Port** folders.
3. Click **IP**.
4. Click the **DHCP Relay** tab.
5. Click **Graph**.
6. Select one or more values.
7. Click the type of graph.

DHCP Stats *Field Descriptions*

Use the data in the following table to use the **DHCP Stats** tab.

Name	Description
NumRequests	The number of DHCP and BootP requests on this interface.
NumReplies	The number of DHCP and BootP replies on this interface.

Displaying DHCP-relay Statistics for Option 82

Display DHCP-relay statistics for all interfaces to manage network performance.

Procedure

1. In the navigation pane, expand the **Configuration** > **IP** folders.
2. Click **DHCP-Relay**.
3. Click the **Option 82 Stats** tab.

Option 82 Stats *Field Descriptions*

Use the data in the following table to use the **Option 82 Stats** tab.

Name	Description
IfIndex	Shows the name of the interface on which you enabled option 82. Shows the port number if the interface is a brouter port or the VLAN number if the interface is a VLAN.
AgentAddr	Shows the IP address configured as the relay on this interface. This address is either the IP of the physical interface or the IP of the VRRP address.
FoundOp82	Shows the number of packets that the interface received that already had option82 in them.
Dropped	Shows the number of packets the interface dropped because of option 82–related issues. These reasons could be that the packet was received from an untrusted source or spoofing was detected. To determine the cause of the drop, you must enable trace on level 170.
CircuitId	Shows the value inserted in the packets as the circuit ID. The value is the index of the interface.
AddedCircuitId	Shows how many packets (requests from client to server) the circuit ID was inserted for that interface. If you expect this value to increase but it does not, and the interface does not drop a packet, it is possible the packet does not have enough space to insert the option. You must enable trace on level 170 to determine the cause.

Name	Description
RemovedCircuitId	Shows how many packets (replies from server to client) the circuit id was removed for that interface.
RemoteId	Shows the value inserted in the packets as the remote ID. The value is the MAC address of the interface.
AddedRemoteId	Shows how many packets (requests from client to server) the remote ID was inserted for that interface. If you expect this value to increase but it does not, and the interface does not drop a packet, it is possible the packet does not have enough space to insert the option. You must enable trace on level 170 to determine the cause.
RemovedRemoteId	Shows how many packets (replies from server to client) the remote ID was removed for that interface.

Graphing DHCP Statistics for a VLAN

View DHCP statistics to manage network performance.

Procedure

1. In the navigation pane, expand the **Configuration** > **VLAN** folders.
2. Click **VLANs**.
3. On the **Basic** tab, select a VLAN.
4. Click **IP**.
5. Click the **DHCP Relay** tab.
6. Click **Graph**.
7. Select one or more values.
8. Click the type of graph.

DHCP Stats *Field Descriptions*

Use the data in the following table to use the **DHCP Stats** tab.

Name	Description
NumRequests	The number of DHCP and BootP requests on this interface.
NumReplies	The number of DHCP and BootP replies on this interface.

Managing UDP forwarding protocols

About This Task

The switch configures the following protocols, by default:

- Time Service
- Terminal Access Controller Access Control System (TACACS) Service
- Domain Name System (DNS)
- Trivial file transfer protocol (TFTP)
- Network Basic Input/Output System (NetBIOS) NameSrv
- NetBIOS DataSrv

You can use these protocols to create forwarding entries and lists but you cannot delete them; you can add or remove other protocols to the list of protocols.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IP**.
2. Click **UDP Forwarding**.
3. Click **Insert**.
4. In the **PortNumber** field, type a UDP port number.

   This number defines the UDP port used by the server process as its contact port. The range is from 1 to 65535 and cannot be one of the UDP port numbers or a number previously assigned.
5. In the **Name** field, type a name for the protocol.
6. Click **Insert**.

   The protocol is added to the Protocol table. After you create a protocol, you cannot change its name or number.

Protocols *field descriptions*

Use the data in the following table to use the **Protocols** tab.

Name	Description
PortNumber	Defines the UDP port (1 to 65535).
Name	Specifies an administratively assigned name for this list (0 to 15 characters).

Managing UDP forwarding

About This Task

You manage UDP forwarding by defining the destination addresses for the UDP protocol.

Procedure

1. In the navigation tree, expand the following folders:**Configuration** > **IP**.
2. Click **UDP Forwarding**.
3. Click the **Forwardings** tab.

4. Click **Insert**.
5. In the Insert Forwardings dialog box, select a destination UDP port from the defined protocols in the **DestPort** box.
6. Enter a destination IP address in the **DestAddr** box.

   The destination address can be any IP server address for the protocol application or the IP address of an interface on the router.
7. Click **Insert**. The information is added to the Forwarding tab.

Forwardings *field descriptions*

Use the data in the following table to use the **Forwardings** tab.

Name	Description
DestPort	Specifies the port number defined for UDP, depending upon the protocol type.
DestAddr	Specifies the destination address can be any IP server address for the protocol application or the IP address of an interface on the router: • If the address is that of a server, the packet is sent as a unicast packet to this address. • If the address is that of an interface on the router, the frame is rebroadcast.
Id	Specifies an integer that identifies this entry internally.
NumFwdPackets	Specifies the total number of UDP broadcast packets forwarded using this policy.
NumDropPacketsTtlExpired	Specifies the total number of UDP broadcast packets dropped because the time-to-live value (TTL) expired.
NumDropPacketsDestUnreach	Specifies the total number of UDP broadcast packets dropped because the specified destination address was unreachable.

Creating the forwarding profile

About This Task

A forwarding profile is a collection of port and destination pairs. When you configure UDP forwarding list entries, be sure to first configure the UDP forwarding list. Then, configure your UDP forwarding list entries and assign them to a UDP forwarding list. If you do not assign a UDP forwarding list entry to at least one UDP forwarding list, the UDP forwarding list is lost after a restart.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IP**.
2. Click **UDP Forwarding**.
3. Click the **Forwarding Lists** tab.
4. Click **Insert**.
5. In the **Id** field, type the forwarding list ID.

6. In the **Name** field, type the name of the forwarding list if required.

   The system displays the forwarding list in the **FwdIdList** box.
7. Click **Insert**.

Forwarding Lists *field descriptions*

Use the data in the following table to use the **Forwarding Lists** tab and **Insert Forwarding Lists** dialog box.

Name	Description
Id	Specifies a value that uniquely identifies this list of entries (1 to 1000).
Name	Specifies an administratively assigned name for this list (0 to 15 characters).
FwdIdList	Specifies the zero or more port forwarding entries associated with this list. Each list identifier is stored as 2 bytes in this array, starting from 0 bytes (size=64). Clicking on the ellipsis (...) button in this field displays the ID list.

Managing the broadcast interface

About This Task

Manage the broadcast interface by specifying and displaying which router interfaces can receive UDP broadcasts to forward.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IP**.
2. Click **UDP Forwarding**.
3. Click the **Broadcast Interfaces** tab.
4. Click **Insert**.
5. In the **LocalIfAddr** field, click the ellipsis **(...)** to select a local interface IP address from the list, and then click **OK**.
6. In the **UdpPortFwdListId** field, click the ellipsis **(...)** to select a forwarding list ID from the list, and then click **OK**.
7. In the **MaxTtl** field, type the maximum number of hops an IP broadcast can take from the source device to the destination device (the default is 4; the range is 1 to 16).
8. In the **BroadCastMask** field, enter the subnet mask of the local interface that broadcasts the UDP broadcast packets.

   When you configure the UDP forwarding broadcast mask, the broadcast mask must be less specific (shorter in length) or equally specific (equal in length) to the subnet mask of the IP interface on which it is configured. If the UDP forwarding broadcast mask is more specific than the subnet mask of the corresponding IP interface, UDP forwarding does not function properly.
9. Click **Insert**.

Broadcast Interfaces *field descriptions*

Use the data in the following table to use the **Broadcast Interfaces** tab.

Name	Description
LocalIfAddr	Specifies the IP address of the local router interface that receives forwarded UDP broadcast packets.
UdpPortFwdListId	Specifies the number of the UDP lists or profiles that this interface is configured to forward (0 to100). A value of 0 indicates that the interface cannot forward any UDP broadcast packets.
MaxTtl	Specifies the maximum number of hops an IP broadcast packet can take from the source device to the destination device (the default is 4; the range is 1 to 16).
NumRxPkts	Specifies the total number of UDP broadcast packets received by this local interface.
NumFwdPkts	Specifies the total number of UDP broadcast packets forwarded by this local interface.
NumDropPktsMaxTtlExpired	Specifies the total number of UDP broadcast packets dropped because the time-to-live (TTL) value expired.
NumDropPktsDestUnreach	Specifies the total number of UDP broadcast packets dropped because the destination was unreachable.
NumDropPktsUnknownPort	Specifies the total number of UDP broadcast packets dropped because the destination port or protocol specified has no matching forwarding policy.
BroadCastMask	Specifies the subnet mask of the local interface that broadcasts the UDP broadcast packets.

Viewing UDP endpoint information

View UDP Endpoints to confirm correct configuration.

About This Task

You can use UDP endpoint information to display local and remote UDP activity.

Since UDP is a protocol used to establish connectionless network sessions, you need to monitor local and remote UDP activity and to know which applications are running over UDP.

You can determine which applications are active by checking the port number.

Processes are further identified with a UDP session to allow for the multiplexing of a port mapping for UDP.

Procedure

1. In the navigation pane, expand the **Configuration** > **IP** folders.
2. Click **TCP/UDP**.
3. Click the **UDP Endpoints** tab.

***UDP Endpoints** field descriptions*

Use the data in the following table to use the **UDP Endpoints** tab.

Name	Description
LocalAddressType	Displays the local address type (IPv6 or IPv4).
LocalAddress	Displays the local IPv6 address.
LocalPort	Displays the local port number.
RemoteAddressType	Displays the remote address type (IPv6 or IPv4).
RemoteAddress	Displays the remote IPv6 address.
RemotePort	Displays the remote port number.
Instance	Distinguishes between multiple processes connected to the UDP endpoint.
Process	Displays the ID for the UDP process.

IPv6 DHCP Relay Configuration using EDM

Configure a DHCP Relay Forwarding Path

Configure a forwarding path to specify the relay agent address and the DHCP server address to which to forward packets.

To use DHCP Relay for IPv6, you must configure at least one forwarding path and enable the relay on one interface.

Before You Begin

Change the VRF instance as required to configure a DHCP Relay forwarding path on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

About This Task

The relay agent can use the IPv6 address of the interface or the VRRP global address linked to that interface. The relay forwards the DHCP messages only if VRRP is in the Master state, otherwise the relay discards the messages.

You can configure only one relay agent on an interface. If you need to change the relay agent, you must delete all the forwarding paths with the old relay agent, and then configure the new relay agent.

For scaling information on DHCP Relay forwarding paths, see *Fabric Engine Release Notes*.

Procedure

1. In the navigation tree, expand **Configuration** > **IPv6**.
2. Select **DHCP Relay**.
3. Select the **Forward Path** tab.
4. Select **Insert**.

5. In the **AgentAddr** field, type the address of the input interface that forwards the packets.
6. In the **ServerAddr** field, type the address of the DHCP server.
7. Select **Enabled**.
8. Select **Insert**.

Forward Path *field descriptions*

Use the data in the following table to use the **Forward Path** tab.

Name	Description
AgentAddr	Specifies the IP address of the input interface (relay agent) on which the DHCP request packets are received for forwarding. This address is the IPv6 or VRRP global address of either a brouter port or a VLAN for which forwarding is enabled.
ServerAddr	Specifies the IP address of the DHCP server. The request is unicast to the server address.
Enabled	Enables DHCP Relay for the system. The default is disabled (clear).

Configuring DHCP Relay for an interface

Configure the DHCP relay behavior on the interface.

Before You Begin

Change the VRF instance as required to configure DHCP Relay for an interface on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

About This Task

You can configure only one relay for a VLAN, regardless of how many addresses are configured on that VLAN. The default address is the smallest address configured. If the relay is a VRRP address, the default value is the first VRRP address configured.

You can modify the DHCP Relay configuration for a brouter port through the **Edit** > **Port** > **IPv6** navigation path, and for a VLAN through the **VLAN** > **VLANs** > **Basic** > **IPv6** navigation path. This procedure uses the main IPv6 navigation path where you can configure both types of interfaces.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IPv6**.
2. Click **DHCP Relay**.
3. Click the **Interface** tab.
4. Click **Insert**.
5. Beside the **IfIndex** field, click **Port** or **Vlan**.
6. Select a port or VLAN, and then click **OK**.
7. Click **Insert**.

***Interface** field descriptions*

Use the data in the following table to use the **Interface** tab.

Name	Description
IfIndex	Shows the unique value to identify an IPv6 interface. For the brouter port, the value is the ifindex of the port and, in the case of the VLAN, the value is the ifindex of the VLAN.
MaxHop	Specifies the maximum number of hops a DHCP packet can take from the DHCP client to the DHCP server. The default is 32.
RemoteIdEnabled	Enables the relay agent to add information about the relay to DHCPv6 messages before relaying the messages to the DHCP server. The default is disabled (clear or false).

Modifying DHCP Relay for a VLAN

Modify the existing DHCP relay behavior on the VLAN interface.

About This Task

You can configure only one relay for a VLAN, regardless of how many addresses are configured on that VLAN. The default address is the smallest address configured. If the relay is a VRRP address, the default value is the first VRRP address configured.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **VLAN**.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select a VLAN.
5. Click **IPv6**.
6. Click the **DHCP Relay** tab.
7. Double-click a cell to change the value.
8. Click **Apply**.

***DHCP** field descriptions*

Use the data in the following table to use the **DHCP Relay** tab.

Name	Description
IfIndex	Shows the unique value to identify an IPv6 interface.
MaxHop	Specifies the maximum number of hops a DHCP packet can take from the DHCP client to the DHCP server. The default is 32.

Name	Description
RemoteIdEnabled	Enables the relay agent to add information about the relay to DHCPv6 messages before relaying the messages to the DHCP server. The default is disabled (clear or false).
DhcpEnabled	Enables (true) or disables (false) DHCP Relay for an interface with an existing DHCP Relay configuration.

Modifying DHCP Relay for a port

Modify the existing DHCP relay behavior on the brouter port interface.

About This Task

The default address is the smallest address configured. If the relay is a VRRP address, the default value is the first VRRP address configured.

Procedure

1. In the Device Physical View, select the port.
2. In the navigation pane, expand the following folders: **Configuration** > **Edit** > **Port**.
3. Click **IPv6**.
4. Click **DHCP Relay**.
5. Double-click a cell to change the value.
6. Click **Apply**.

DHCP Relay *field descriptions*

Use the data in the following table to use the **DHCP Relay** tab.

Name	Description
IfIndex	Shows the unique value to identify an IPv6 interface. For the brouter port, the value is the ifindex of the port and, in the case of the VLAN, the value is the ifindex of the VLAN.
MaxHop	Specifies the maximum number of hops a DHCP packet can take from the DHCP client to the DHCP server. The default is 32.

Name	Description
RemoteIdEnabled	Enables the relay agent to add information about the relay to DHCPv6 messages before relaying the messages to the DHCP server. The default is disabled (clear or false).
DhcpEnabled	Enables (true) or disables (false) DHCP Relay for an interface with an existing DHCP Relay configuration. The system displays this field on the **DHCP Relay** tab for a brouter port only if you modify an existing configuration. The system does not display this field if you create a new DHCP Relay port configuration.

Viewing DHCP Statistics for an IPv6 Interface

View IPv6 DHCP statistics to manage network performance.

Procedure

1. In the navigation pane, expand the **Configuration** > **IPv6** folders.
2. Select **DHCP Relay**.
3. Select the **Interfaces Stats** tab.

Interfaces Stats *Field Descriptions*

Use the data in the following table to use the **Interfaces Stats** tab.

Name	Description
IfIndex	Identifies the physical interface.
NumRequests	Shows the number of DHCP and BootP requests on this interface.
NumReplies	Shows the number of DHCP and BootP replies on this interface.

Viewing IPv6 DHCP Relay Statistics for a Port

Display individual IPv6 DHCP Relay statistics for specific ports to manage network performance. You can also create a graph of selected statistical values.

Procedure

1. On the Device Physical view, select a port.
2. In the navigation pane, expand the **Configuration** > **IPv6** folders.
3. Click the **DHCP Relay** tab.
4. Click the **Interface** tab.
5. Select the interface on which you want to view the IPv6 DHCP Relay statistics.
6. Click **Statistics**.
7. Select one or more values.
8. Click the type of graph.

Statistics *Field Descriptions*

Use the data in the following table to use the **Statistics** tab.

Name	Description
NumRequests	Shows the number of DHCP and BootP requests on this interface.
NumReplies	Shows the number of DHCP and BootP replies on this interface.

Domain Name Service

Table 63: Domain Name Service product support

Feature	Product	Release introduced
Domain Name Service (DNS) client (IPv4)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
DNS client (IPv6)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

The following sections provide information on the Domain Name Service (DNS) implementation for the switch.

DNS fundamentals

This section provides conceptual material on the Domain Name Service (DNS) implementation for the switch. Review this content before you make changes to the configurable DNS options.

DNS client

Every equipment interface connected to a Transmission Control Protocol over IP (TCP/IP) network is identified with a unique IPv4 or IPv6 address. You can assign a name to every machine that uses an IPv4 or IPv6 address. The TCP/IP does not require the usage of names, but these names make the task easier for network managers in the following ways:

- An IP client can contact a machine with its name, which is converted to an IP address, based on a mapping table. All applications that use this specific machine do not depend on the addressing scheme.
- It is easier to remember a name than a full IP address.

To establish the mapping between an IP name and an IPv4 or an IPv6 address you use the Domain Name Service (DNS). DNS is a hierarchical database that you can distribute on several servers for backup and load sharing. After you add a new hostname, update this database. The information is sent to all the different hosts. An IP client that resolves the mapping between the hostname and the IP address sends a request to one of the database servers to resolve the name.

After you establish the mapping of IP name and IP address, the application is modified to use a hostname instead of an IP address. The switch converts the hostname to an IP address.

If the entry to translate the hostname to IP address is not in the host file, the switch queries the configured DNS server for the mapping from hostname to IP address. You can configure connections for up to three different DNS servers—primary, secondary and tertiary. First the primary server is queried, and then the secondary, and finally the tertiary.

The DNS client tracks any server addresses or domain names provided from a DHCP server. If a DHCP server provides info to the DNS client, the DNS configuration is classified as dynamic. You can manually delete dynamic DNS entries, but cannot manually add dynamic DNS entries. You can view the Dynamic DNS entries with **`show ip dns`** or **`show sys dns`**. Dynamic DNS entries are not saved in the configuration file. The status monitoring of DNS occurs every 60 seconds.

DNS modifies Ping, Telnet, and copy applications. You can enter a hostname or an IP address to invoke Ping, Telnet, and copy applications.

A log/debug report is generated for all the DNS requests sent to DNS servers and all successful DNS responses received from the DNS servers.

IPv6 Support

The Domain Name Service (DNS) used by the switch supports both IPv4 and IPv6 addresses with no difference in functionality or configuration.

DNS configuration using CLI

This section describes how to configure the Domain Name Service (DNS) client using Command Line Interface (CLI).

DNS supports IPv4 and IPv6 addresses.

Configuring the DNS client

About This Task

Configure the Domain Name Service to establish the mapping between an IP name and an IPv4 or IPv6 address. DNS supports IPv4 and IPv6 addresses with no difference in

functionality or configuration using CLI.

You can configure connection for up to three different DNS servers—primary, secondary and tertiary. First the primary server is queried, and then the secondary, and finally the tertiary.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the DNS client:

   ```
   ip domain-name WORD<0-255>
   ```

3. (Optional) Add addresses for primary, secondary, or tertiary DNS servers:

   ```
   ip name-server <primary|secondary|tertiary> WORD<0-46>
   ```

4. (Optional) Delete addresses for primary, secondary, or tertiary DNS servers:

   ```
   no ip name-server <primary|primary-dynamic|secondary|secondary-
   dynamic|tertiary|tertiary-dynamic> WORD<0-46>
   ```

5. View the DNS client system status:

   ```
   show ip dns
   ```

Example

```
Switch:1> enable

Switch:1# configure terminal
```

Add addresses for a tertiary DNS server:

```
Switch:1(config)# ip name-server tertiary 254.104.201.141
```

Delete address for a secondary dynamic DNS server:

```
Switch:1(config)#no ip name-server secondary-dynamic 192.0.2.12
```

Variable Definitions

The following table defines parameters for the **`ip domain-name`** command.

Variable	Value
WORD<0-255>	Configures the default domain name. *WORD<0-255>* is a string 0–255 characters.

The following table defines parameters for the **`ip name-server`** command.

Variable	Value
primary|*secondary*|*tertiary* *WORD<0-46>*	Configures the primary, secondary, or tertiary DNS server address. Enter the IP address in a.b.c.d format for IPv4 or hexadecimal format (string length 0–46) for IPv6. You can specify the IP address for only one server at a time; you cannot specify all three servers in one command. Use the no operator before this parameter, `no ip name-server <primary|secondary|tertiatry>`

Querying the DNS host

About This Task

Query the DNS host for information about host addresses.

You can enter either a hostname, an IPv4 or IPv6 address. If you enter the hostname, this command shows the IP address that corresponds to the hostname and if you enter an IP address, this command shows the hostname for the IP address. DNS supports IPv4 and IPv6 addresses with no difference in functionality or configuration using CLI.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. View the host information:

   ```
   show hosts WORD<0-256>
   ```

Example

```
Switch:1> enable

Switch:1# configure terminal
```

View the host information:

```
Switch:1(config)# show hosts 192.0.2.1
```

Variable Definitions

The following table defines parameters for the **show hosts** command.

Variable	Value
WORD<0-256>	Specifies one of the following: • the name of the host DNS server as a string of 0–256 characters. • the IP address of the host DNS server in a.b.c.d format. • The IPv6 address of the host DNS server in hexadecimal format (string length 0–46).

DNS configuration using EDM

This section describes how to configure the Domain Name Service (DNS) using Enterprise Device Manager (EDM).

DNS supports IPv4 and IPv6 addresses with no difference in functionality or configuration except for the following. Under the **DNS Servers** tab, in the **DnsServerListAddressType** box, you must select **ipv4** or **ipv6**.

Configure the DNS Client

About This Task

You can configure connections for up to three different DNS servers—primary, secondary and tertiary. First the primary server is queried, and then the secondary, and finally the tertiary.

DNS supports IPv4 and IPv6 addresses. Under the **DNS Servers** tab, in the **DnsServerListAddressType** box, you must select **ipv4** or **ipv6**.

Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability** > **Diagnostics**.
2. Click **DNS**.
3. Click the **DNS Servers** tab.
4. Click **Insert**.
5. In the **DnsServerListType** box, select the DNS server type.
6. In the **DnsServerListAddressType** box, select the IP version.
7. In the **DnsServerListAddress** box, enter the DNS server IP address.
8. Click **Insert**.

DNS Servers *Field Descriptions*

Use the data in the following table to use the **DNS Servers** tab.

Name	Description
DnsServerListType	Configures the DNS server as primary, secondary, or tertiary. OR Removes a DNS server as primary, primaryDynamic, secondary, secondaryDynamic, tertiary, or tertiaryDynamic.
DnsServerListAddressType	Configures the DNS server address type as IPv4 or IPv6.
DnsServerListAddress	Specifies the DNS server address.
DnsServerListStatus	Specifies the status of the DNS server.
DnsServerListRequestCount	Specifies the number of requests sent to the DNS server.
DnsServerListSuccessCount	Specifies the number of successful requests sent to the DNS server.

Query the DNS Host

About This Task

Query the DNS host for information about host addresses.

You can enter either a hostname or an IPv4 or IPv6 address. If you enter the hostname, this command shows the IP address that corresponds to the hostname and if you enter an IP address, this command shows the hostname for the IP address. DNS supports IPv4 addresses with no difference in functionality or configuration in this procedure.

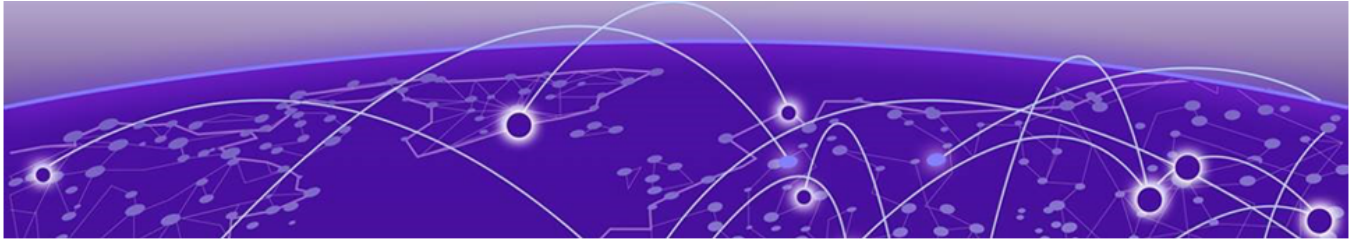
Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability** > **Diagnostics**.
2. Click **DNS**.
3. Click the **DNS Host** tab.
4. In the **HostData** text box, enter the DNS host name, IPv4 or the IPv6 address.
5. Click **Query**.

DNS Host *Field Descriptions*

Use the data in the following table to use the **DNS Host** tab.

Name	Description
HostData	Enter hostname or host IPv4 or IPv6 address to be identified.
HostName	Identifies the host name. This variable is a read-only field.
HostAddressType	Identifies the address type of the host.
HostAddress	Identifies the host IP address. This variable is a read-only field.
HostSource	Identifies the DNS server IP or host file. This variable is a read-only field.



Distributed Virtual Routing

Distributed Virtual Routing (DvR) is a technology for router redundancy in a Fabric deployment where IP subnets are stretched across multiple switches. DvR provides Default Gateway Redundancy and optimizes traffic flows to avoid traffic tromboning due to inefficient routing, thereby increasing the total routing throughput.

The topics in this section provide DvR concepts and configuration procedures.

Distributed Virtual Routing Fundamentals

You can deploy Distributed Virtual Routing (DvR) in Campus environments for stretching IP subnets between multiple aggregation layer switches and also simplifies data center deployments by introducing a Controller-Leaf architecture. In this architecture, Layer 3 configuration is required only on the Controller nodes, whereas the Leaf nodes require only Layer 2 configuration. All Layer 3 configuration is automatically distributed to the Leaf nodes by the Controller nodes.

For typical Campus DvR deployments, configure aggregation layer switches as DvR Controllers. Wiring closet access switches are then typically dual-homed to a pair of DvR Controllers.

IP subnets, which stretch between aggregation layer switches and multiple wiring closets, enable seamless IP roaming for wireless users while at the same time ensure optimal traffic forwarding. To optimize automation, Fabric Attach is typically deployed between wiring closet and aggregation switches. In this construct, there would likely be no DvR Leaf configured.

In Fabric deployments, DvR replaces VRRP (with VRRP-BackupMaster or RSMLT). The operator can chose for each I-SID/IP subnet what router redundancy method to use.

To migrate to a DvR-enabled I-SID/IP subnet, all member Fabric switches of this I-SID must be either DvR Controllers or DvR Leafs. You can connect non Fabric switches to DvR Leafs and DvR Controllers with manual configuration or Fabric Attach configuration. Until all Fabric switches that are members of the I-SID/IP subnet are DvR-enabled, use VRRP or RSMLT as the router redundancy protocol.

DvR Domain

To enable multi-site DvR deployments, a DvR domain concept has been introduced. Within a DvR domain, a set of up to eight DvR Controllers control the DvR domain Leaf switches. A domain can also include just DvR controllers without DvR Leafs. Typically, a DvR domain is restricted to one physical location. Traffic leaving this physical location always passes through DVR Controllers.

A DvR domain is a logical group of switches or nodes that are DvR enabled. These nodes are not physically connected but are connected over the SPB Fabric such that each node is aware of the BMAC addresses of all other nodes within the domain. A DvR domain does not contain nodes that are not DvR enabled. However, those nodes can coexist with other DvR enabled nodes within the same SPB Fabric network.

You configure a common DvR domain ID for all nodes belonging to a DvR domain. This domain ID translates internally to a Domain Data Distribution (DDD) I-SID. All switch nodes that share the same DvR domain ID or DDD I-SID receive the Layer 3 information that is distributed from all other nodes belonging to that DvR domain.

A DvR domain can contain multiple Layer 3 VSNs and Layer 2 VSNs. Layer 2 and Layer 3 VSNs can span multiple DvR domains.

A DvR domain typically has the following members:

1. DvR Controller(s)
2. DvR Leaf nodes

For scaling information on the number of Controllers and Leaf nodes to configure in a DvR domain, see *Fabric Engine Release Notes*.

DvR Controller

In a DvR domain, the Controller nodes are the central nodes on which Layer 3 is configured. They own all the Layer 3 configuration and push the configuration information to the Leaf nodes within the SPB network.

A DvR domain can have one or more controllers for redundancy and you must configure every Layer 2 VSN (VLAN) and Layer 3 VSN within the domain, on the Controller(s). A node that you configure as a DvR Controller is considered the controller for all the Layer 2 and Layer 3 VSNs configured on that node. A Controller is configured with its own subnet IP address for every DvR enabled Layer 2 VSN within the domain.

All Layer 2 VSNs on a DvR Controller need not be DvR enabled. A controller can be configured with individual Layer 2 VSNs that are DvR disabled.

The Layer 3 configuration data that is pushed to the Leaf nodes include the Layer 3 IP subnet information for all Layer 2 VSNs within the DvR domain. It also includes the IP routes learned or redistributed by the Controllers from networks outside the SPB network, into the DvR Domain. Controllers also send information on whether Multicast is enabled on a specific DvR enabled Layer 2 VSN, and the version of IGMP. DvR Controllers inject a default route into the DvR domain for external

route reachability. Use route policies to inject specific routes into a DvR domain or inject host routes into OSPF or BGP.

Note

When sFlow operates in a DvR domain and DvR Leaf nodes use the management CLIP address as the sFlow agent IP, DvR Leaf nodes always report the sFlow collector as reachable because DvR Controllers inject a default route into the DvR domain. You can use the **dvr controller inject-default-route-disable** command to withdraw the route and force DvR Leaf nodes to use either a DvR host route, a direct, or a static route that the DvR Controller can redistribute. The best practice is to perform appropriate analysis before you use this setting.

A Controller can only belong to one DvR domain, based on the domain ID that you configure on the node.

DvR Controllers include all DvR Leaf functions, thus a Leaf node free deployment is a valid network deployment. Especially if you use DvR in Campus deployments to replace VRRP or RSMLT, a Controller-only deployment, as Fabric Attach server nodes, is a valid deployment option.

DvR Leaf Node

DvR Leaf nodes are typically data center top of the rack (TOR) Fabric switches that aggregate physical and virtual servers or storage devices. DvR Leaf nodes operate in a reduced configuration mode, where Layer 3 is not configured locally, but pushed to them from the DvR Controller(s) within the domain. You need to configure only the IS-IS infrastructure and the Layer 2 VSNs on the Leaf nodes.

A DvR Leaf node also monitors local host attachments and communicates updates about the current state of those host attachments to the DvR domain. All DvR nodes exchange host attachment information using the DvR host distribution protocol, which leverages a DvR domain I-SID.

DvR leaf nodes are managed in-band through a local loopback address, which is exchanged using the IP Shortcut protocol.

Eligibility Criteria for a Leaf Node

A Leaf node must support the following criteria:

- configuration of basic parameters of IP Multicast over Fabric Connect, such as the system ID, nickname, B-VLANs, SPBM instance, area, peer system ID and virtual BMAC
- configuration of a physical port as either an SPB network-to-network interface (NNI), a FLEX-UNI interface or an FA interface
- configuration of an MLT as either an SPB NNI, a FLEX-UNI interface or an FA interface
- configuration of an SMLT as a Flex-UNI Interface or an FA Interface
- configuration of Layer 2 VSN I-SID instances of type ELAN
- configuration of FLEX-UNI end-points as part of a Layer 2 VSN
- FA Server functionality on FA enabled interfaces
- SMLT and vIST
- configuration of a in-band management interface for in-band management of the node

Summary of Controller and Leaf Node Functions

A DvR Controller performs the following functions:

- pushes Layer 3 configuration data (IPv4 Unicast and Multicast) to the Leaf nodes for all the Layer 2 VSNs or subnets within the DvR domain.
- pushes the Layer 3 learned host routes (host routes learned on its own UNI ports) and route data learned through route redistribution or route policies, to the Leaf nodes.
- configures learned remote host routes from other Controllers and Leaf nodes, on its own device.

A DvR enabled Leaf node performs the following functions:

- configures the gateway MAC when the gateway IPv4 address is learned.
- pushes the Layer 3 learned remote host routes to other Controllers and Leaf nodes in the domain.
- configures learned remote host routes from other Controllers and Leaf nodes on its own device.
- configures ECMP routes (in the datapath only) for the Layer 2 VSN subnets, with each next hop as the Controller in the DvR domain.
- configures learned routes from the Controllers that are redistributed using DvR.
- handles host route response packet interception based on the Controller VLAN MAC or the gateway MAC.

DvR backbone

The DvR backbone is automatically established among the DvR Controllers from all DvR domains. Every Controller node has an edge gateway to its DvR domain, to the DvR backbone and all other non-DvR domains within the network.

Controllers exchange host route information such that any host can be reached in a shortcut switched manner, irrespective of its location. For these host route information exchanges, controllers use an automatically assigned backbone I-SID. Local subnets to the Controllers are automatically injected into the DvR host route exchanges.

To redistribute DvR host routes into OSPF or BGP, you can configure route policies. These host routes are not injected into IS-IS.

DvR Backbone Members

You can configure a non-DvR backbone edge bridge (BEB) to join the DvR backbone. This enables the node to receive redistributed DvR host routes from all DvR Controllers in the SPB network, just like a DvR Controller. However, unlike the Controller, you can neither configure a DvR interface on this node nor can the node inject its host routes into the DvR domain.

DvR operation

In a DvR domain, DvR enabled Controller(s) handle the learning and distribution of Layer 3 configuration and route data to the DvR enabled Leaf nodes. The Leaf nodes in turn, use this data to automatically create distributed Layer 3 datapaths on themselves. In this way, Layer 3 configuration and learning remains only with the Controller(s) and there are distributed Layer 3 datapaths at the edges of the fabric network. This allows for destination lookups at the edge to happen quickly, and traffic is sent directly to their destinations without multiple lookups.

An important benefit of DvR is that only minimal configuration is required on the Leaf node. Based on the Layer 2 VSN that the Leaf node is a part of, all Layer 3 configuration information (IPv4 Unicast and Multicast configuration) is pushed from the Controllers in the domain. Thus the leaf nodes, although basically Layer 2 configured switches, become fully layer 3 capable devices.

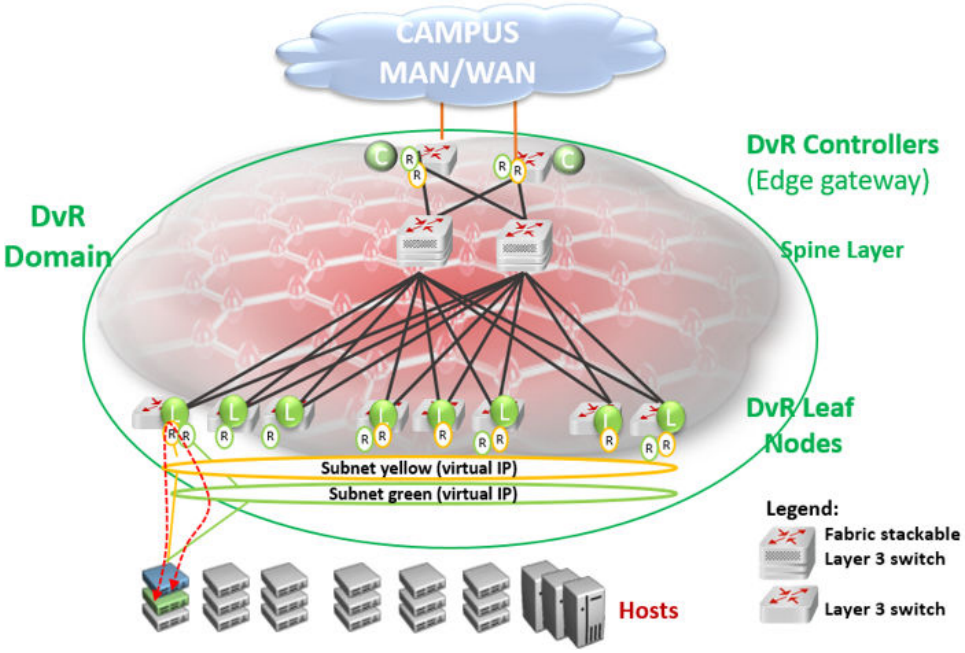

Figure 46: SPB Fabric network with central Layer 3 Controller and distributed Layer 3 datapath at the edges

ARP Learning

When DvR is enabled on a Controller, it initiates ARP requests for traffic to be routed to unknown destination hosts.

DvR enabled Controllers learn ARP requests from:

- DvR enabled Leaf nodes (here the Leaf node owns the ARPs)
- its own local UNI ports. Here, the controller owns the ARPs
- other DvR enabled Controllers

DvR enabled Leaf nodes learn ARP requests from:

- its own local UNI ports (here the Leaf node owns the ARPs)
- other DvR enabled Leaf nodes (that own the ARPs) and respond to ARP requests on their UNI ports
- DvR enabled Controllers (that own the local UNI ARPs)

Controllers only distribute ARP entries that are locally learned on its own UNI ports, to other DvR enabled nodes in the domain.

dvr-leaf-mode boot flag

To configure a node to operate as a DvR Leaf node, you must first enable the `dvr-leaf-mode` boot flag.

- The `dvr-leaf-mode` boot flag is disabled by default. You must explicitly enable this flag before you configure a switch node to operate as a Leaf node.

  When you enable the `dvr-leaf-mode` boot flag, you can configure the node as a DvR leaf node without rebooting, as long as there is no unsupported configuration discovered on the switch.
- After you enable or disable the boot flag, you must save the configuration.

Important

A node on which the `dvr-leaf-mode` boot flag is enabled cannot be configured as a DvR Controller.

In-band management

Use in-band management to manage a DvR enabled Leaf node that does not have an out-of-band management port or a console port.

For in-band management of the node within the management subnet (for example, from a Controller node), you must configure a unique IPv4 address to be used as the in-band management IP address, on that node. This IPv4 address functions like a CLIP address.

DvR deployment scenarios

The following sections describe typical deployments of the DvR infrastructure.

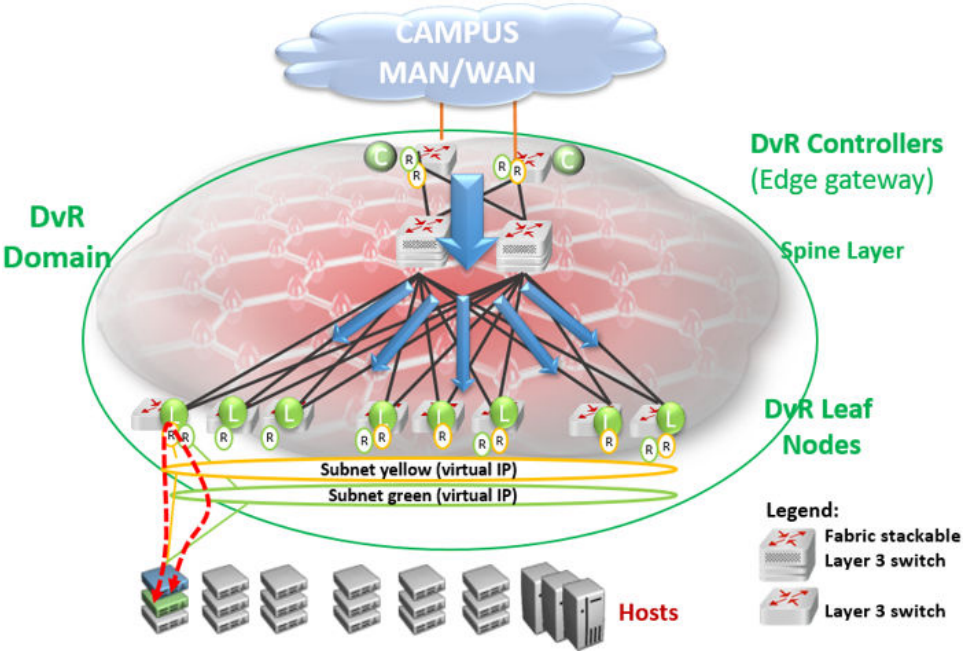
DvR deployment in a single data center

The following topology shows DvR deployment in a single data center. This deployment consists of a single DvR domain comprising a Controller layer and a Leaf node layer. The Controller layer has two controllers (for redundancy), which are deployed closer to the boundary of the DvR domain and the rest of the SPB Fabric network. The DvR Leaf nodes or Top of Rack (TOR) switches are typically access or edge switches.

All switches that belong to the DvR domain are configured with the same DvR domain ID and communicate with each other over a predefined I-SID.

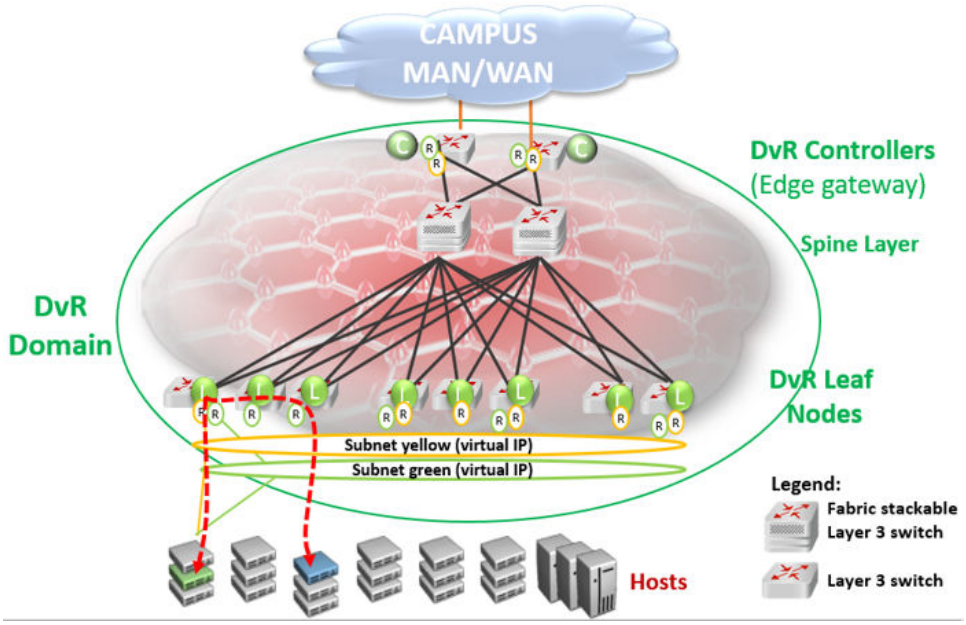
The Controller nodes control the Leaf nodes and also build the gateway between the DvR domain and the rest of the Fabric infrastructure. So traffic is either routed between the Leaf nodes, or through the Controllers, to the rest of the fabric infrastructure.

Two IP subnets (Layer 2 VSNs), yellow and green, span the Leaf nodes. Each subnet is configured with a virtual IP address that is a shared among all Controller and Leaf nodes that belong to the subnet. The Controller and Leaf nodes are configured with routing interfaces to the subnets, as shown in the figure.



DvR works by enabling each Leaf node or Top of Rack (TOR) switch to bi-directionally route traffic for each IP subnet of which it is a member. This is done by distributing the Layer 3 configuration information (IP Unicast, IP Multicast and virtual IP configuration) needed to handle Layer 3 routing, from the Controllers to the Leaf nodes. Configuration information is pushed over the DvR Domain I-SID, as indicated by the blue arrows in the above figure.

Routing between the two IP subnets is achieved directly at the Leaf nodes when the Layer 3 distributed datapath is programmed at the Leaf Nodes, based on the Layer 3 configuration data that is pushed. Thus traffic within and between IP subnets is shortcut switched without having to traverse the central routing nodes, as shown in the figure below, if there are direct physical connections between them.



Thus, in a DvR deployment, all virtual IP and Layer 3 configuration is performed on the Controller nodes and pushed to the Leaf nodes, so that the Leaf nodes though basically Layer 2 configured switches, become fully layer 3 capable devices.

DvR deployment in a dual data center

The following example deployment shows two data centers each having its own DvR domain, connected through a backbone.

All nodes in data center Campus 1 belong to DvR domain shown in green, and the nodes in the data center Campus 3 belong to the DvR domain shown in orange. The two DvR domains are individually managed, so in this scenario, the controllers colored orange manage the orange Leaf nodes and the controllers colored green manage the green Leaf nodes. However, subnets can still be stretched across the DvR domains (and possibly between buildings), as shown in the figure.

Each DvR domain learns its own Layer 3 data and distributes this information to its own Leaf nodes. Layer 3 host information that is redistributed from other DvR Domains is learned by the Controllers only (through inter-DvR domain redistribution) and is programmed on the Leaf nodes in the same domain, but not in the other Domain. For example, Layer 3 information redistributed from domain 2 is learned by all controllers including the domain 1 controllers, but this information is not distributed to the Leaf nodes in domain 1.Hosts in one DvR domain can reach the hosts in the other DvR domain only through the Controllers.

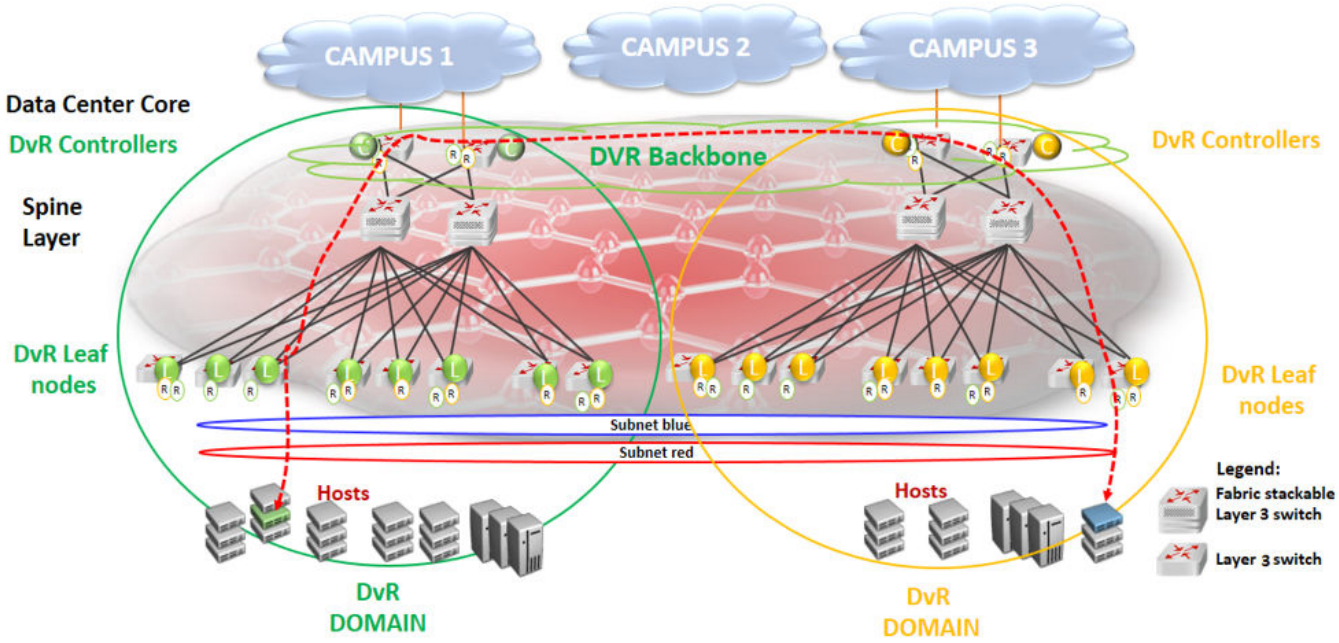


Figure 47: Shortest path routing between servers in different data centers

All controllers in all domains are always part of the DvR backbone by default, as they are connected by the SPB Fabric. The DvR backbone connects many DvR domains.

Thus DvR can scale to multiple campuses, allowing a simplified way to deploy a large scale fully-routed infrastructure.

DvR Route Redistribution

The following sections describe redistribution of IPv4 local and static routes from DvR Controllers into the DvR domain. It also describes redistribution of host routes that are learned on DvR enabled VLANs, to BGP and OSPF. You can configure route policies to control the selection of routes to be distributed. You can also configure IS-IS accept policies on DvR Controllers and non-DvR BEBs, to determine which DvR host routes to accept into the routing-table from the DvR backbone.

Redistribution of IPv4 Local and Static Routes

The DvR feature supports redistribution of IPv4 local and static routes into the DvR domain.

Note

For every VRF instance and the Global Router, the Controller automatically injects a default route to the Leaf node, with a next hop as the advertising Controller. However, if you require only local or static routes to be advertised to the Leaf nodes, you can manually disable the injection of default routes on the Controller.

On a DvR Controller, you can configure (enable or disable) the redistribution of direct or static routes. Direct routes are redistributed with the route type as internal. Static routes are redistributed with the route type as external. You can apply route policies on the Controller to selectively permit the redistribution of these routes and also configure a metric value for the route that is redistributed. The default metric for imported local routes is 1. For static routes, the configured route metric or cost is honored.

You can configure redistribution of static and direct routes from the Global Router, or within a VRF instance. For redistributed routes, the Controller configures the Layer 3 VSN as that of the VRF redistributing the route, and the next hop BEB as the system ID of the Controller injecting the route into the DvR domain.

The following example demonstrates how a DvR Leaf node benefits from the redistribution of local and static routes.

By default, if the injection of default routes is enabled on a DvR Controller, the DvR Leaf node can only route traffic to other nodes within the DvR enabled subnet. For the Leaf node to reach networks outside of the DvR enabled subnet, the Controllers must redistribute local and static routes from non-DvR subnets into the DvR domain. In the following figure, the DvR Leaf L1 can route traffic only to nodes in the DvR enabled subnet 10.10.10.0/24. To be able to reach hosts in VLAN 20 (20.20.20.0/24) or VLAN 30 (30.30.30.0/24), redistribution of local routes into DvR is required at each of the Controllers C1 and C2. For the Leaf node to reach hosts in remote networks 40.40.40.0/24 or 50.50.50.0/24, redistribution of static routes to the DvR domain is required.

You can apply route policies to control which local or static routes are to be redistributed into the DvR domain.

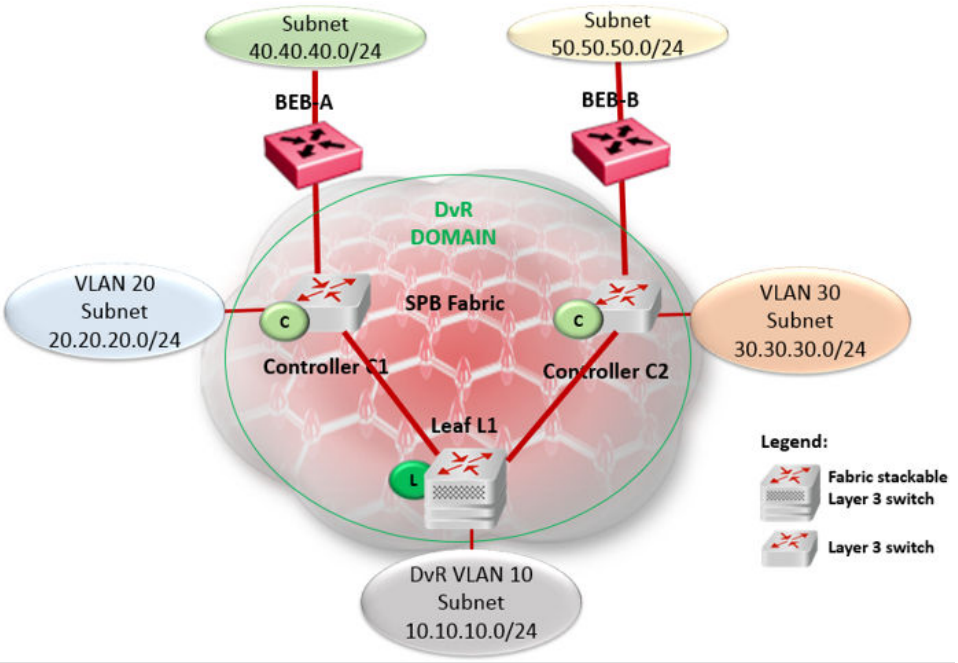

Figure 48: Redistribution of IPv4 local and static routes

Redistribution of Routes to OSPF or BGP

For non-SPB routers to benefit from the host accessibility information learned within a DvR domain, DvR supports the redistribution of host routes into OSPF or BGP. Redistribution of these host routes is only by the DvR Controllers and only for the intra-domain host routes within the DvR enabled subnets.

A DvR Controller can redistribute host routes for all hosts from a DvR domain into OSPF or BGP. You can also apply route policies on the Controller to select the routes to be redistributed. The Controller supports redistribution of routes from the Global Router or within a VRF instance. You can also configure the metric of the route before redistribution.

The following example demonstrates the benefit of redistribution of routes to BGP.

Consider a 10.1.0.0/16 network with a stretched Layer 2 VSN spanning two data centers. On the campus side of the network, BGP peering is configured between a non-Extreme router and one or more routers in the data center. BGP advertises the network route 10.1.0.0/16 to the campus BGP routers. Depending on which edge router the traffic is delivered to, it is possible that traffic from a host on the campus traverses the WAN a second time to reach the server that is physically connected to one segment of the data center, as shown in the following figure.

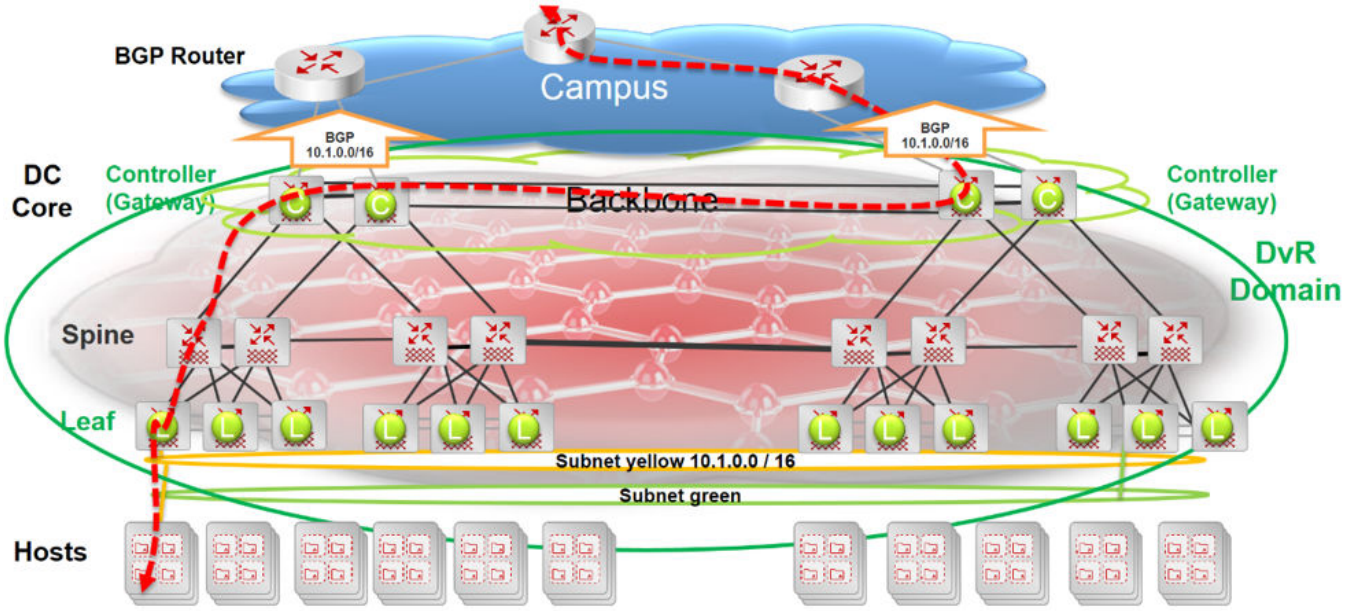

Figure 49: Inefficient traffic flow

Redistribution of the host routes from the DvR Controller to BGP solves this problem.

The following figure shows two DvR domains (show in green and orange) configured at each data center. Each campus edge router establishes a BGP peering session with one or more Controllers in each data center (DvR domain). This enables BGP to advertise more specific routes to the campus BGP router so that the optimal routing path is always taken. So, there is no need for traffic to traverse the WAN multiple times. Also, in the case of server movement within or between data centers, the updated DvR host routes are propagated to BGP, thus ensuring that traffic flowing into the data center continues along the most optimal path.

For example, in the following figure, only the Controller attached to the Leaf node where the 10.1.0.111 server exists, advertises its accessibility over the 10.1.0.111/32 route. Similarly, the DvR Controller associated with the Leaf node connected to the 10.1.0.222 server advertises the 10.1.0.222/32 host route.

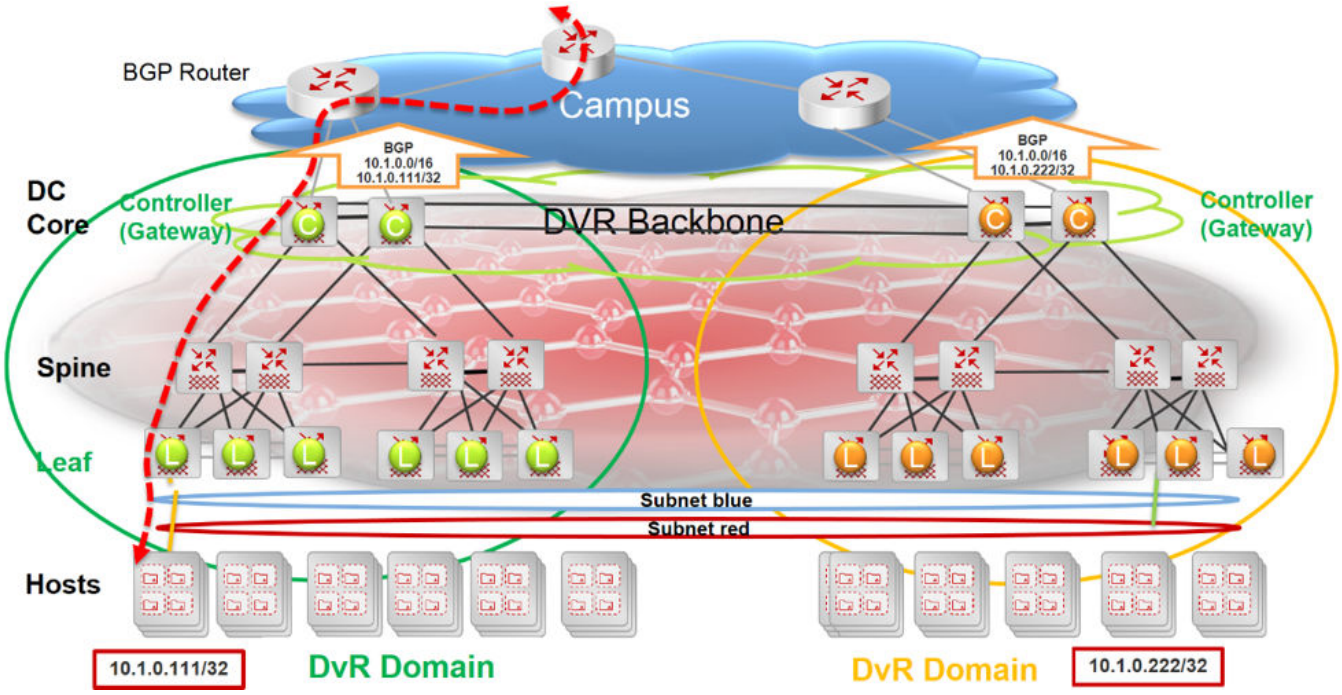

Figure 50: Traffic flow optimized with route redistribution

Controllers in each data center learn all host routes through the DvR backbone, but since those routes belong to different DvR domains, they are not all eligible for redistribution to OSPF or BGP.

Route Redistribution and IS-IS Accept Policies

DvR route redistribution leverages IS-IS accept policies to control (accept or reject) DvR routes learned from the DvR backbone. You can configure accept policies on both Controllers and non-DvR BEBs in the SPB network.

For more information about accept policies, see IS-IS Accept Policies on page 1137.

DvR Deployment for Wireless Roaming in Campus Deployments

In fabric deployments where IP subnets/I-SIDs stretch between multiple buildings, you can use DvR instead of VRRP or RSMLT to avoid traffic tromboning issues. This deployment is supported with non-fabric switches that have Fabric Attach enabled, or switches that do not support Fabric Attach. IP subnets can stretch across one or multiple DvR domains as shown in the following figure.

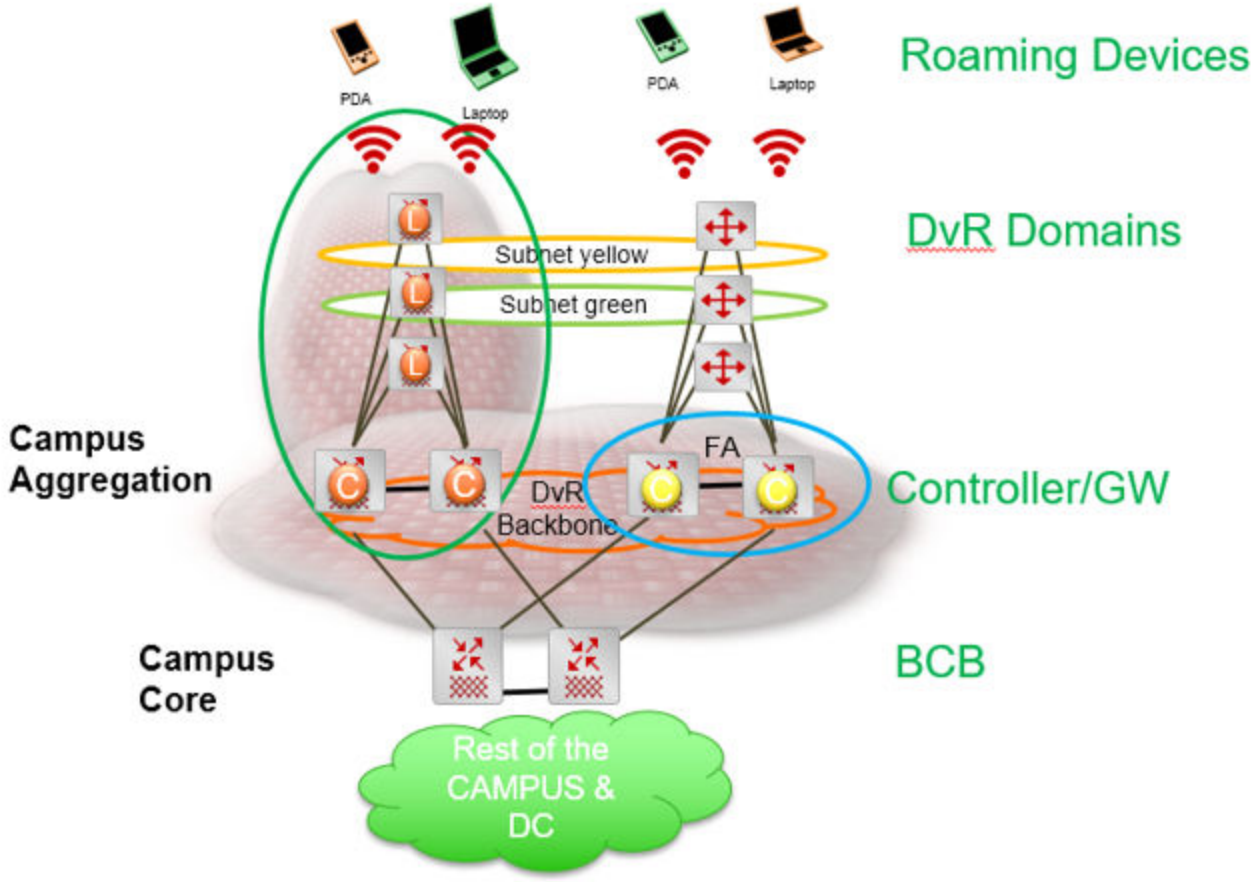

Figure 51: Wireless roaming in Campus

Management I-SID Assignment to DvR Leaf

The Management I-SID Assignment to DvR Leaf feature simplifies the process of creating a Management Instance VLAN interface on a DvR Leaf.

You can configure a Management Instance VLAN on a DvR Leaf node by specifying the I-SID. When you specify the I-SID, an internal VLAN is created and associated with the I-SID.

Operational Considerations

The following section describes operational considerations for assigning a Management I-SID to DvR Leaf node.

- If the specified I-SID is not associated with a VLAN, the Management Instance VLAN interface is created with the specified I-SID and an internal VLAN.

  Note
  The internal VLAN is not configurable.

- You cannot create a Management Instance VLAN interface if the I-SID is already associated with a VLAN. However, you can configure a Management Instance VLAN interface if the I-SID is associated with the onboarding VLAN.

- The I-SID cannot be learned dynamically. You cannot create a Management Instance VLAN interface if the I-SID sent from the DvR Controller is the same as the Management Instance VLAN I-SID.
- When you delete the Management Instance VLAN interface, the internal VLAN is deleted. You cannot delete the onboarding VLAN.
- You can migrate from a previous configuration or to a DvR Leaf only if an I-SID is associated with the Management Instance VLAN. If you disable DvR on a DvR Leaf by disabling the **dvr-leaf-mode** boot flag, the Management Instance VLAN is deleted. You can either restart the onboarding process or configure a Management Instance CLIP or Management Instance OOB interface.
- In DvR Leaf, you can create a Management Instance VLAN interface using the quick-config-mgmt utility script with the Management I-SID but not with port number or VLAN ID. This I-SID cannot be used if the Management Instance interface is already created. You can issue the **convert** command to use this I-SID.
- Migration from DvR leaf to non-DvR leaf deletes the Management Instance VLAN configuration.

Using Ping or IP Traceroute for Hosts in the DvR-One-IP Subnet

To use DvR-One-IP, a circuitless IP (CLIP) must exist in the VRF to which the DvR-One-IP interface belongs. If the DvR-One-IP interface is part of the global router (GRT), a CLIP must exist in the GRT and it must be configured as the IS-IS **ip-source-address**. If these CLIPs exist, pinging hosts in the DvR-One-IP subnet from the DvR Controller works as expected.

If the CLIPs do not exist, pinging hosts in the DvR-One-IP subnet is not possible from DvR Controllers. The ping attempt times out and the switch displays the following warning message: `Warning: For DVR one IP a loopback IP must be configured on the VRF`. If you provide a source IP address with the **ping** command, the switch does not display the warning message but the ping attempt fails.

This same restriction also applies to IP traceroute.

DvR Restrictions

Review the following limitations and behavioral characteristics associated with DvR.

- The DvR feature does not affect out-of-band management on a switch chassis, if the chassis supports it.
- The DvR feature does not support a non-DvR BEB in a DvR enabled Layer 2 VSN.
- The number of host route records that can be stored in the datapath of a Leaf node is limited to the scaling capacity of the switch node. Different switch platforms have different scaling capacities.

  For information on the scaling capacities of different platforms, see *Fabric Engine Release Notes*.
- You must first disable DvR on a Controller or Leaf node, before you attempt to change the domain ID of the node.
- You cannot configure IGMP snooping on DvR enabled nodes.

Configuration Restrictions on a DvR Controller

- If you are using two different IP addresses for the DvR VLAN and the DvR GW IP, you must first configure a gateway IPv4 address and then configure an IP interface for the VLAN before you enable

DvR on a Layer 2 VSN (VLAN). Both the VLAN IP address and the gateway IPv4 address must be in the same subnet.

If you use same IP address for VLAN interface and DvR GW IP, you can use the command **ip address {A.B.C.D/X} dvr-one-ip**.

For more information, see Enable DvR on a Layer 2 VSN (VLAN) on page 3451 and Configure a Single IP Address for All DvR Controllers on a VLAN Subnet on page 3453.

- You cannot configure IPv4 VRRP on a DvR-enabled VLAN.
- You cannot configure RSMLT on a DvR-enabled VLAN.
- You cannot configure SPB-PIM Gateway (SPB-PIM GW) on a DvR VLAN.
- You cannot configure dynamic routing protocols, such as OSPF, RIP, BGP, IPv6 OSPFv3, IPv6 RIPng, IPv6 MLD, and IPv6 PIM-GW on a DvR-enabled VLAN.
- You can configure DvR on a VLAN that has configured IPv6 interface. You must first delete the IPv6 interface, configure DvR, and then reconfigure IPv6 interface.

  A DvR VLAN is a VLAN configured on a DvR Controller with a VLAN IP address, a VLAN/I-SID, the DvR gateway IP address, and DvR enabled. This Layer 3 configuration for the DvR VLAN (the DvR gateway IP address and this DvR subnet) is pushed to the DvR Leaf nodes. The DvR gateway IP address must be the same address across all DvR Controllers for that DvR VLAN.
- You cannot configure an IPv6 interface on a DvR-enabled VLAN from a subnet that is used as next-hop in a IPv6 static route.
- You cannot configure an IPv6 address on a DvR-enabled VLAN from a subnet used as an IPv6 BGP Peer.
- DvR-enabled VLAN/I-SIDs are for host connectivity only; you cannot connect a router to a DvR-enabled VLAN/I-SID and use dynamic or static routing. Use a non-DvR VLAN/I-SID instead to connect an external router.

Configuration Limitations on a DvR Leaf

- Enabling the **DvR-leaf-mode** boot flag before you configure a node as a DvR Leaf, automatically removes all existing non-DvR configuration on the node such as platform VLANs and their IP address configuration, CLIP configuration, routing protocol configuration and VRF configuration. The gateway IPv4 address, if configured, is also removed.
- You cannot configure SPB-PIM GW on a Leaf node. The configuration is supported only on a DvR Controller.
- You cannot perform Layer 3 configuration (for example, IP interfaces, IP routing, and VRFs). You can only perform Layer 2 configuration.

  You cannot configure Microsoft NLB on a Leaf node.
- You cannot configure Fabric Extend on a Leaf node.
- You cannot configure the VXLAN Gateway on a Leaf node.
- You cannot configure a T-UNI on a Leaf node.
- You cannot configure IPv4 multicast on a Leaf node. The configuration is supported only on a DvR Controller.
- You can configure only one instance of vIST on a Leaf node pair. Also, you cannot configure vIST on Leaf nodes from different domains.

- Platform VLANs are not supported. You cannot configure a platform VLAN directly on a DvR leaf node. However, you can configure a VLAN Management Instance on a DvR leaf node. After you configure the management VLAN, you can configure a platform VLAN.
- You cannot configure IP Shortcuts and IP Multicast over Fabric Connect on Leaf nodes. This configuration is pushed from the DvR Controllers in the domain.
- You must manually configure an I-SID on a Layer 2 VSN Leaf node. This configuration is not pushed from a DvR Controller.
- DvR-enabled VLAN/I-SIDs are for host connectivity only; you cannot connect a router to a DvR-enabled VLAN/I-SID and use dynamic or static routing. Use a non-DvR VLAN/I-SID instead to connect an external router.

Migrate from VRRP to DvR

About This Task

If you have a VRRP network with a mix of existing routers that do not support DvR and devices that do support DvR, you can migrate your VRRP network to DvR using this high-level process. This migration process assumes the following design:

- Existing routers are the VRRP masters.
- Existing routers are the default gateways for all subnets.
- Fabric Connect network with DvR-capable nodes where DvR is configured globally, but not on I-SIDs, on the VOSS devices; and VOSS devices operate in Layer 2 mode for the VRRP VLANs that need to be migrated.

Important

When you configure DvR on Controllers with existing VRRP VLANs, ensure there is no VRRP VLAN with VRID 37 or VRID 38. VRID 37 conflicts with the DvR gateway MAC used by all DvR nodes. The DvR gateway MAC is a constant value 00:00:5e:00:01:25; VRRP VRID 37 translates to the same MAC. Similarly, VRRP VRID 38 translates to 00:00:5e:00:01:26, and is used within DvR. If you have a VRRP VLAN with either of these VRIDs, change the VRID to a different value.

Procedure

1. Enable VRRP interfaces on the DvR Controllers but keep VRRP mastership on the existing routers.
2. Change VRRP mastership on the VLAN or IP Subnet in question on the DvR Controller by applying a higher priority than the current master.

   

   Note

   You can easily fall back to the original VRRP master to change VRRP priorities back.

3. Disable VRRP on the existing routers.

4. Subnet by subnet (VLAN/I-SID), delete VRRP interfaces on all DvR Controllers first (this includes removing VRRP and removing the VLAN IP address), and then configure DvR interfaces (this includes adding the DVR-GW-IP, enabling DvR, and then adding the VLAN IP address) on the VLAN/I-SID instead. This might lead to a short traffic interruption.

   Note

   For each VLAN/I-SID, ensure that VRRP is disabled on all nodes before you configure DvR interfaces on the Controllers for the VLAN/I-SID.

   Keep in mind that you can only enable DvR on VLAN or I-SIDs where all participating BEBs are DvR-capable.

   Anytime when falling back, you can delete the DvR interface on the I-SID (this includes disabling DvR, removing the DVR-GW-IP and removing the VLAN IP address) and configure the VRRP interface again (this includes adding the VLAN IP address and adding VRRP again), however, ensure you delete the DvR interfaces on all Controllers first before you enable VRRP again.

Example

Start with VRRP VLAN:

```
vlan create 250 name vlan_test250 type port-mstprstp 0
vlan i-sid 250 111250
interface vlan 250
ip address 192.0.2.3 255.255.255.0
interface vlan 250
ip vrrp version 2
ip vrrp address 10 192.0.2.1
ip vrrp 10 priority 180
ip vrrp 10 backup-master enable
ip vrrp 10 enable
exit
```

Change to DvR VLAN:

```
interface vlan 250
no ip vrrp address 10 192.0.2.1
no ip address 192.0.2.3
exit
interface vlan 250
dvr gw-ipv4 192.0.2.1
dvr enable
ip address 192.0.2.3 255.255.255.0
exit
```

Change back to VRRP VLAN:

```
interface vlan 250
no dvr enable
no dvr gw-ipv4
no ip address 192.0.2.3
exit
interface vlan 250
ip address 192.0.2.3 255.255.255.0
ip vrrp version 2
ip vrrp address 10 192.0.2.1
ip vrrp 10 priority 180
ip vrrp 10 backup-master enable
```

```
ip vrrp 10 enable
exit
```

DvR and IPv6 VRRP Coexistence on the Same I-SID

You can configure IPv6 VRRP and IPv6 DHCP relay on a DvR-enabled VLAN or I-SID.

You must perform the following steps in order:

1. Enable DvR on a VLAN interface.
2. Configure an IPv6 interface.
3. Configure IPv6 VRRP.

Configuration Examples

The following example shows how you can configure an IPv6 interface and IPv6 VRRP on a DvR-enabled VLAN:

```
vlan create 10 name vlan_test10 type port-mstprstp 0
vlan i-sid 10 111010
interface vlan 10
dvr gw-ipv4 192.0.2.1
dvr enable
ip address 192.0.2.2 255.255.255.0
ipv6 interface enable
ipv6 interface address 2001:DB8:0::1/64
ipv6 vrrp address 1 link-local fe80::1234
ipv6 vrrp address 1 global 2001:DB8:0::1234/64
ipv6 vrrp 1 enable
exit
```

You cannot enable DvR on a VLAN interface that has IPv6 VRRP configuration. You must first delete IPv6 interface from the VLAN, configure DvR and then reconfigure IPv6 interface.

```
interface vlan 10
no ipv6 vrrp 1
no ipv6 interface
dvr gw-ipv4 192.0.2.1
dvr enable
ip address 192.0.2.2 255.255.255.0
ipv6 interface enable
ipv6 interface address 2001:DB8:0::1/64
ipv6 vrrp address 12 link-local fe80::1234
ipv6 vrrp address 1 global 2001:DB8:0::1234/64
ipv6 vrrp 1 enable
exit
```

DvR configuration using the CLI

The following sections describe configuration of Distributed Virtual Routing (DvR) using the Command Line Interface (CLI).

Configuring a DvR Controller

About This Task

Configuring a node as a DvR Controller enables DvR globally on that node.

Perform this procedure to create a DvR domain with the domain ID that you specify, and configure the role of the node as the Controller of that domain. A Controller can belong to only one DvR domain.

Note

For a node to perform the role of both a Controller and a Leaf within a DvR domain, you must configure it as a Controller.

Before You Begin

- Ensure that you configure IP Shortcuts on the node. This is necessary for proper functioning of the node as a DvR Controller.
- Ensure that the `dvr-leaf-mode` boot flag is disabled on the node.

  To verify the setting, enter **`show boot config flags`** in Privileged EXEC mode.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure a DvR Controller.

   ```
   dvr controller <1-255>
   ```

3. (Optional) Disable DvR on a DvR Controller.

   ```
   no dvr controller
   ```

   

   Caution

   Disabling DvR on a DvR Controller destroys the domain ID and all dynamic content learned within the DvR domain.

   However the switch retains the VLAN specific configuration and you can view the information using the command **`show running-config`**.

4. View a summary of the Controller configuration. Enter:

   ```
   show dvr
   ```

Example

Configure a node as a DvR Controller:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#dvr controller 5
Switch:1(config)#show dvr

================================================================
                    DVR Summary Info
================================================================
Domain ID                       : 5
Domain ISID                     : 16678219
Backbone ISID                   : 16678216
Role                            : Controller
My SYS ID                       : 00:bb:00:00:81:21
Operational State               : Up
```

```
GW MAC                          : 00:00:5e:00:01:25
InjectDefaultRouteDisable(GRT)  : Disabled
```

Variable definitions

Use the data in the following table to use the **dvr controller** command.

Variable	Value
<1-255>	Specifies the domain ID of the DvR domain that the controller belongs.

Disabling injection of default routes on a Controller

About This Task

By default, a DvR Controller injects default routes into the DvR domain and all the Leaf nodes in that domain learn these routes with the next hop as the Controller that advertised them.

You can however disable default route injection for the GRT or a specific VRF on a Controller, to override this behavior.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

   ```
   enable

   configure terminal
   ```

   Optional: `router vrf WORD<1-16>`
2. Disable default route injection for the GRT or a specific VRF, on the Controller.

   On the GRT:

   ```
   dvr controller inject-default-route-disable
   ```

   The `default` or the `no` operator enables injection of default routes for the GRT into the domain.

   On a VRF instance:

   ```
   dvr inject-default-route-disable
   ```

   The `default` or the `no` operator enables injection of default routes for a specific VRF into the domain.
3. Verify the configuration.

   On the GRT:

   ```
   show dvr
   ```

   On a VRF instance:

   ```
   show dvr l3vsn
   ```

Example

Disable injection of default routes for the GRT on a Controller.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#dvr controller inject-default-route-disable
Switch:1(config)#show dvr

==========================================================================

Configuring DvR route redistribution

About This Task

Configure redistribution of direct or static routes into the DvR domain, on the Global Router or for a specific VRF instance.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

   ```
   enable

   configure terminal
   ```

   Optional: `router vrf WORD<1-16>`

2. Configure route redistribution of direct routes:
   a. Configure route redistribution of direct routes on a VRF. The route type is internal.
      `dvr redistribute direct [metric <0-65535>]|[route-map WORD<1-64>]`
   b. Enable route redistribution.
      `dvr redistribute direct enable`
   c. Apply the configuration:
      `dvr apply redistribute direct`
   d. (Optional) Disable route redistribution of direct routes.
      `no dvr redistribute direct`
3. Configure route redistribution of static routes:
   a. Configure route redistribution of static routes on a VRF. The route type is external.
      `dvr redistribute static [metric <0-65535>]|[route-map WORD<1-64>]`
   b. Enable route redistribution.
      `dvr redistribute static enable`
   c. Apply the configuration.
      `dvr apply redistribute static`
   d. (Optional) Disable route redistribution of static routes.
      `no dvr redistribute static`
4. Verify the route redistribution configuration. You can also verify it on a specific VRF instance.
   `show dvr redistribute [vrf WORD<1-16>]`

Example

Configure route redistribution of direct and static routes on the Global Router. Ensure that you apply the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

Switch:1(config)#dvr redistribute static
Switch:1(config)#dvr redistribute static metric 200
Switch:1(config)#dvr redistribute static enable
Switch:1(config)#dvr apply redistribute static

Switch:1(config)#dvr redistribute direct
Switch:1(config)#dvr redistribute direct metric 100
Switch:1(config)#dvr redistribute direct enable
Switch:1(config)#dvr apply redistribute direct
```

Verify configuration on the Global Router:

```
Switch:1(config)#show dvr redistribute
================================================================================
                    DVR Redistribute List - GlobalRouter
================================================================================

SOURCE MET MTYPE      ENABLE RPOLICY
--------------------------------------------------------------------------------
STAT   200 External   TRUE  -
LOC    100 Internal   TRUE  -
```

Configure redistribution of direct and static routes on the specific VRF instance `vrf1`. Ensure that you apply the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

Switch:1(config)#router vrf vrf1
Switch:1(router-vrf)#dvr redistribute static
Switch:1(router-vrf)#dvr redistribute static metric 20000
Switch:1(router-vrf)#dvr redistribute static enable
Switch:1(router-vrf)#exit
Switch:1(config)#dvr apply redistribute static

Switch:1(router-vrf)#dvr redistribute direct
Switch:1(router-vrf)#dvr redistribute direct metric 10000
Switch:1(router-vrf)#dvr redistribute direct enable
Switch:1(router-vrf)#exit
Switch:1(config)#dvr apply redistribute static
```

Verify configuration on `vrf1`:

```
Switch:1(router-vrf)#show dvr redistribute vrf vrf1
================================================================================
                  DVR Redistribute List - VRF vrf1
================================================================================

SOURCE MET MTYPE      ENABLE RPOLICY
--------------------------------------------------------------------------------
STAT   20000 External   TRUE  -
LOC    10000 Internal   TRUE  -
```

Variable definitions

Use the data in the following table to use the **dvr redistribute direct** or the **dvr redistribute static** commands.

Variable	Value
enable	Enables DvR route redistribution on the VRF instance. Route redistribution is enabled by default.
metric <0-65535>	Specifies the DvR route redistribution metric.
route-map WORD<1-64>	Specifies the route policy for DvR route redistribution.

Use the data in the following table to use the **show dvr redistribute** command.

Variable	Value
vrf WORD<1-16>	Specifies the VRF name.

Clearing DvR host entries

About This Task

Clear DvR host entries (IPv4 remote host routes) on a Controller. The host entries are learned on the switch, either locally on its UNI port or dynamically from other nodes in the DvR domain.

Note

You can clear DvR host entries only on a DvR Controller.

An error message displays if you attempt clearing of host entries on a DvR Leaf node.

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Clear the DvR host entries.

   ```
   clear dvr host-entries [ipv4 {A.B.C.D}] | [l2isid <0-16777215>] |
   [l3isid <0-16777215>]
   ```

Example

In this example, you clear host entries for IP address `50.0.1.0` to clear host entries for IP addresses `50.0.1.2` and `50.0.1.3`.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#clear dvr host-entries 50.0.1.0
```

Variable definitions

Use the data in the following table to use the **`clear dvr host-entries`** command.

Variable	Value
ipv4	Specifies the IP address (IPv4) of the DvR host entries to clear.
l2isid	Specifies the Layer 2 VSN I-SID of the DvR host entries to clear The range is 1 to 16777215.
l3isid	Specifies the Layer 3 VSN I-SID of the DvR host entries to clear. The range is 0 to 16777215.

Configuring a DvR Leaf

About This Task

Perform this procedure to create a DvR domain with the domain ID that you specify, and configure the role of the node as a Leaf node. Configuring a node as a DvR Leaf automatically enables DvR globally on the node.

A Leaf node can belong to only one DvR domain.

Note

For a node to perform the role of both a Controller and a Leaf within the domain, you must configure it as a Controller.

Note

You must enable the VRF-scaling boot configuration flag on a DvR Leaf node, if more than 24 VRFs are required in the DvR domain.

For additional scaling information, see *Fabric Engine Release Notes*.

Before You Begin

- You must enable the `dvr-leaf-mode` boot flag before you configure a node as a DvR Leaf node.

  Note

  When you enable the `dvr-leaf-mode` boot flag, you can configure the node as a DvR leaf node without rebooting, as long as there is no unsupported configuration discovered on the switch.

  To verify the setting, enter **`show boot config flags`** in Privileged EXEC mode.

  Caution

  Ensure that you save the current configuration on the switch, before you enable the flag.

  Enabling the flag removes all existing non-DvR configuration on the switch, such as platform VLANs and their IP address configuration, circuitless IP (CLIP) configuration, routing protocol configuration and VRF configuration. The gateway IPv4 address, if configured, is also removed.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure a node as a DvR Leaf.

   ```
   dvr leaf <1-255>
   ```

3. (Optional) Disable DvR on a DvR Leaf.

   ```
   no dvr Leaf
   ```

   Caution
   Disabling DvR on a Leaf node removes its membership with the DvR domain and all the dynamic content learned from the Controllers of that domain.

4. View a summary of the Leaf configuration.

   ```
   show dvr
   ```

5. Restart the switch for your change to take effect.

Example

Configure a node as a DvR Leaf:

```
Switch2:1>enable
Switch2:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

Switch2:1(config)#boot config flags dvr-leaf-mode
Switch2:1(config)#save config
Switch2:1(config)#dvr Leaf 5

Switch2:1(config)#show dvr

================================================================================

Virtual Ist ISID              :
```

Variable definitions

Use the data in the following table to use the **dvr leaf** command.

Variable	Value
<1–255>	Specifies the domain ID of the DvR domain to which the Leaf node belongs.

Configuring vIST on a DvR Leaf node pair

Before You Begin

Ensure that the nodes are configured as DvR Leaf nodes, before you configure vIST.

About This Task

When you configure vIST on a DvR Leaf node pair, the switch generates an I-SID from the configured cluster ID. This I-SID is unique across the SPB network as long as the cluster ID is unique across the SPB network, for the vIST pair. You can configure only one instance of vIST on the Leaf node pair.

To configure vIST, both nodes must be Leaf nodes. You cannot configure vIST, for example, on a Controller-Leaf node pair.

Also both the nodes must belong to the same DvR domain. vIST configuration over Leaf nodes in different domains is not supported.

Procedure

1. Enter Global Configuration mode:
   ```
   enable

   configure terminal
   ```
2. Configure vIST on the Leaf nodes:
   ```
   dvr leaf virtual-ist {<A.B.C.D/X|<A.B.C.D> <A.B.C.D>} peer-ip
   {A.B.C.D} cluster-id <1-1000>
   ```
3. (Optional) Disable vIST on the DvR Leaf node pair.
   ```
   no dvr leaf virtual-ist
   ```

   Caution

   Disabling DvR on a Leaf node in a vIST pair removes all vIST configuration on that node, but not on the pair. The node on which DvR is disabled also loses its membership with the DvR domain and all the dynamic content learned from the Controllers in that domain.

   If DvR is re-enabled on the node, you must manually configure vIST on that node again.

4. View a summary of vIST configuration on the Leaf nodes.
   ```
   show dvr
   ```

Example

Configure vIST on DvR Leaf nodes, with IP addresses `51.51.51.1` and `51.51.51.2` respectively:

```
Switch2:1>enable
Switch2:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch2:1(config)#dvr leaf virtual-ist 51.51.51.1 peer-ip 51.51.51.2 cluster-id 255
Switch2:1#show dvr

================================================================================
                          DVR Summary Info
================================================================================
Domain ID                     : 5
Domain ISID                   : 16678219
Role                          : Leaf
My SYS ID                     : 00:bb:00:00:71:23
Operational State             : Up
GW MAC                        : 00:00:5e:00:01:25
Inband Mgmt Clip IP           :
Virtual Ist local address     : 51.51.51.1
Virtual Ist local subnet mask : 255.255.255.0
```

```
Virtual Ist peer address       : 51.51.51.2
Virtual Ist cluster-id         : 255
Virtual Ist ISID               : 16677226
```

Variable definitions

Use the data in the following table to use the **dvr leaf virtual-ist** command.

Variable	Value
{<A.B.C.D/X|<A.B.C.D> <A.B.C.D>}	Specifies the local IP (IPv4) address and subnet mask of the node.
{<A.B.C.D>}	Specifies the IP address (IPv4) of the vIST peer.
<1–1000>	Specifies the cluster ID of vIST. It is set to 0 if vIST is not configured.

Configure a Management VLAN on a DvR Leaf Node

About This Task

On a DvR leaf node, you can configure a Management Instance VLAN by specifying the I-SID. Use the following procedure to configure a Management Instance VLAN on a DvR leaf node.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure a Management Instance VLAN I-SID:

   ```
   mgmt vlan i-sid <1-16777215>
   ```

Variable Definitions

The following table defines parameters for the **mgmt vlan i-sid** command.

Variable	Value
1-16777215	Specifies the VLAN I-SID to associate with the management VLAN.

Delete a Management VLAN on a DvR Leaf Node

About This Task

Perform this procedure to delete a Management Instance VLAN on a DvR leaf node.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Delete the management VLAN:
   ```
   no mgmt vlan
   ```

Moving a vIST Leaf node pair from one domain to another

About This Task

Use this procedure to move a vIST Leaf node pair from one DvR domain to another.

For vIST to work properly, both Leaf nodes must be in the same domain.

Procedure

1. Disable IS-IS on each vIST peer Leaf node, to remove the node from the SPB network.
   ```
   no router isis enable
   ```
2. Disable DvR on each Leaf node.
   ```
   no dvr leaf
   ```

   Caution
   Disabling DvR on a Leaf node in a vIST pair automatically removes all vIST configuration on that node, but not on the pair. The node on which DvR is disabled also loses its membership with the DvR domain and all the dynamic content learned from the Controllers in that domain.
   When you re-enable DvR on the node, you must manually configure vIST on that node again.

3. Configure each node as a DvR Leaf node, with the new domain ID.
   Ensure that you configure both nodes as Leaf nodes and with the same domain ID.
   ```
   dvr leaf <1-255>
   ```
4. Configure vIST on the DvR Leaf nodes.
   ```
   dvr leaf virtual-ist {<A.B.C.D/X|<A.B.C.D> <A.B.C.D>} peer-ip
   {A.B.C.D} cluster-id <1-1000>
   ```
5. Enable IS-IS on each vIST peer Leaf node, to add back the node to the SPB network.
   ```
   router isis enable
   ```

Example

Consider two vIST peer Leaf nodes `Switch1 (IP address 51.51.51.1)` and `Switch2 (51.51.51.2)` that belong to a DvR domain (with domain ID 4), that you need to move to another domain (with domain ID 5).

View a summary of existing Leaf configuration on each node.

```
Switch1:1(config)#show dvr

```

Disable IS-IS globally on each Leaf node.

```
Switch1:1>en
Switch1:1>conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch1:1(config)#router isis
Switch1:1(config-isis)#no router isis enable
Switch1:1(config-isis)#exit
Switch1:1(config)#
Switch2:1>en
Switch2:1>conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch2:1(config)#router isis
Switch2:1(config-isis)#no router isis enable
Switch1:1(config-isis)#exit
Switch1:1(config)#
```

Disable DvR on each node. This automatically removes all vIST configuration on the node, but not on the vIST pair. The node also loses its membership with the DvR domain and all the dynamic content learned from the Controllers in that domain.

```
Switch1:1(config)#no dvr leaf
Switch2:1(config)#no dvr leaf
```

Configure each node as a DvR Leaf, with domain ID 5.

```
Switch1:1(config)#dvr leaf 5
Switch2:1(config)#dvr leaf 5
```

Configure vIST on each of the DvR Leaf nodes.

```
Switch1:1(config)#dvr leaf virtual-ist 51.51.51.1 peer-ip 51.51.51.2 cluster-id 255
Switch2:1(config)#dvr leaf virtual-ist 51.51.51.2 peer-ip 51.51.51.1 cluster-id 255
```

Enable IS-IS globally on each Leaf node.

```
Switch1:1(config)#router isis
Switch1:1(config-isis)#router isis enable
Switch1:1(config-isis)#exit
Switch1:1(config)#

Switch2:1(config)#router isis
Switch2:1(config-isis)#router isis enable
Switch2:1(config-isis)#exit
Switch2:1(config)#
```

View a summary of Leaf configuration on each node.

```
Switch1:1(config)#show dvr

Moving a vIST Controller pair from one domain to another

About This Task

Use this procedure to move a vIST Controller node pair from one DvR domain to another.

For vIST to work properly, both Controller nodes must be in the same domain.

Procedure

1. Disable IS-IS on each vIST peer Controller node, to remove the node from the SPB network.

   ```
   no router isis enable
   ```

2. Disable DvR on each Controller node:

   ```
   no dvr controller
   ```

   

   Caution

   Disabling DvR on a DvR Controller destroys the domain ID and all dynamic content learned within the DvR domain. However, the switch retains the VLAN specific configuration which you can view using the command **`show running-config`**.

3. Configure each node as a DvR Controller node, with the new domain ID. Ensure that you configure both nodes as Controller nodes and with the same domain ID.

   ```
   dvr controller <1-255>
   ```

4. Enable IS-IS on each vIST peer Controller node, to add back the node to the SPB network.

   ```
   router isis enable
   ```

Example

Consider two vIST peer Controller nodes `Switch1 (IP address 51.51.51.3)` and `Switch2 (51.51.51.4)` that belong to a DvR domain (with domain ID 4), that you need to move to another domain (with domain ID 5).

View a summary of Controller configuration on each node:

```
Switch1:1(config)#show dvr

Configure a non-DvR BEB to Join the DvR Backbone

About This Task

Configure a non-DvR backbone edge bridge (BEB) to join the DvR backbone so that it can receive redistributed DvR host routes from all DvR Controllers in the SPB network.

Note

On a non-DvR BEB, the redistributed host routes from the DvR backbone are not automatically installed in the IP routing table. To utilize the backbone host routes to optimize traffic forwarding (forwarding in the data plane), you must explicitly configure an IS-IS accept policy with a backbone route policy using the command **accept backbone-route-map <route-map-name>**, and specifying a suitable route-map to select the list or range of DvR backbone host routes to be installed in the routing table.

For more information on configuring an IS-IS accept policy with a backbone route policy, see Configuring IS-IS Accept Policies on page 1154.

Procedure

1. Enter IS-IS Router Configuration mode:

   ```
   enable

   configure terminal

   router isis
   ```

2. Configure a non-DvR BEB to join the DvR backbone.

   ```
   backbone enable
   ```

3. Verify the configuration using the following commands.
   - `show dvr backbone-members`
   - `show dvr backbone-members non-dvr-beb`
   - `show dvr backbone-entries`
   - `show isis`

Examples

```
Switch3:1>enable
Switch3:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch3:1(config)#router isis
Switch3:1(config-isis)#show dvr

================================================================================

DvR show commands

The following section explains the show commands for DvR.

Viewing DvR summary

Use this procedure to view a summary of the DvR configuration on a DvR Controller or a DvR Leaf.

Procedure

1. Enter Privileged EXEC mode:
   `enable`
2. View a summary of DvR configuration:
   `show dvr`

Example

View the information on a DvR Controller:

```
Switch:1#show dvr

=========================================================================
                    DVR Summary Info
=========================================================================
Domain ID                      : 5
Domain ISID                    : 16678219
Backbone ISID                  : 16678216
Role                           : Controller
My SYS ID                      : 00:bb:00:00:81:21
Operational State              : Up
GW MAC                         : 00:00:5e:00:01:25
InjectDefaultRouteDisable(GRT) : Enabled
```

View the information on a DvR Leaf:

```
Switch2:1#show dvr

=========================================================================
                         DVR Summary Info
=========================================================================
Domain ID                      : 5
Domain ISID                    : 16678219
Role                           : Leaf
My SYS ID                      : 00:bb:00:00:71:23

Virtual Ist local subnet mask  : 255.255.255.0
Virtual Ist peer address       : 51.51.51.2
Virtual Ist cluster-id         : 255
Virtual Ist ISID               : 16677226
```

Viewing members of a DvR domain

About This Task

View the members of all DvR domains, namely the Controllers and Leaf nodes.

You can view this information on either a Controller or a Leaf node. Both the Controller and the Leaf node displays those members of the DvR domain to which it belongs.

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```
2. `show dvr members [controller|leaf]`

Example

View all members of a DvR domain:

```
Switch:1#show dvr members

================================================================================================
                                        DVR Members (Domain ID: 255)

Leaf-2:K:124                            0.71.24          00:bb:00:00:71:24         Leaf
Leaf-3:K:125                            0.71.25          00:bb:00:00:71:25         Leaf

4 out of 6 Total Num of DVR Members displayed
------------------------------------------------------------------------------------------------
```

Viewing DvR interfaces

View the DvR interfaces on either a Controller or a Leaf node.

On Controllers, DvR interfaces are created when you configure IP on a DvR enabled Layer 2 VSN (VLAN, I-SID). Only Controllers display the administrative state of the interfaces because this is where you enable or disable the interfaces. The Leaf nodes display DvR interface information that is pushed from the Controllers, for example, subnet routes or gateway IP addresses for the Layer 2 VSNs.

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```
2. View the DvR interface information.
   On a Controller:

   ```
   show dvr interfaces [l3isid <0-16777215>] [vrf WORD<1-16>] [vrfids WORD<0-512>]
   ```

   On a Leaf node:

   ```
   show dvr interfaces [l3isid <0-16777215>]
   ```

   Viewing the DvR interface information for a specific VRF or VRF ID is not supported on a DvR Leaf node.

Example

View DvR interfaces on a Controller node:

You can view DvR interface information on all interfaces or for a specific Layer 3 I-SID, VRF, or VRF ID.

```
Switch:1#show dvr interfaces

================================================================================================================
                                                DVR Interfaces
================================================================================================================
                                                                                    Admin    SPBMC  IGMP
Interface       Mask           L3ISID  VRFID    L2ISID     VLAN     GW IPv4     State    State  Version
----------------------------------------------------------------------------------------------------------------
50.0.1.2        255.255.0.0    55500   1        50500      500      50.0.1.1    enable   disable 2

1 out of 1 Total Num of DVR Interfaces displayed
----------------------------------------------------------------------------------------------------------------
```

View DvR interfaces on a Leaf node:

You can view DvR interface information on all interfaces or for a specific Layer 3 I-SID. Viewing the interface information for a specific VRF or VRF ID is not supported on a DvR Leaf node.

```
Switch:1#show dvr interfaces l3isid 401

================================================================================
                              DVR Interfaces
```

```
================================================================================

```

Variable definitions

Use the data in the following table to use the **show dvr interfaces** command.

Variable	Value
l3isid	Specifies the Layer 3 I-SID of the DvR interface. The range is 0 to 16777215.
vrf	Specifies the VRF name.
vrfids	Specifies the VRF ID. The range is 0 to 512.

Viewing DvR host entries

About This Task

View DvR host entries (IPv4 remote host routes) on either a Controller or a Leaf node. The node displays the host entries learned either locally on its Switched UNI port or dynamically from other nodes within the DvR domain.

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. View the DvR host entries.

   On a Controller:

   ```
   show dvr host-entries [domain-id <1-255>]|[ipv4 {A.B.C.D}]|[l2isid
   <1-16777215>]|[l3isid <0-16777215>]|[nh-as-mac]|[type <1-2>]|[vrf
   WORD<1-16>] [vrfids WORD<0-512>]
   ```

   On a Leaf node:

   ```
   show dvr host-entries [domain-id <1-255>]|[ipv4 {A.B.C.D}]|[l2isid
   <1-16777215>]|[l3isid <0-16777215>]|[nh-as-mac]|[type <1-2>]
   ```

   Viewing the DvR host entries for a specific VRF or VRF ID is not supported on a DvR Leaf node.

Example

View DvR host entries on either a Controller or a Leaf node.

Viewing the DvR host entries for a specific VRF or VRF ID is not supported on a DvR Leaf node.

```
Switch:1#show dvr host-entries domain-id 255 l3isid 55500

Variable definitions

Use the data in the following table to use the **show dvr host-entries** command.

Variable	Value
domain-id	Specifies the domain ID of the DvR host entry. The range is 1 to 255.
ipv4	Specifies the IP address (IPv4) of the DvR host entry.
l2isid	Specifies the Layer 2 VSN I-SID of the DvR host entry. The range is 1 to 16777215.
l3isid	Specifies the Layer 3 VSN I-SID of the DvR host entry. The range is 0 to 16777215.
nh-as-mac	Specifies the MAC address of the next hop node instead of the system name.
type	Specifies the host type of the DvR host entry. A value of 1 indicates local hosts and a value of 2 indicates dynamic hosts.
vrf	Specifies the VRF name of the DvR host entry.
vrfids	Specifies the VRF ID of the DvR host entry. The range is 0 to 512.

Viewing DvR routes

About This Task

View the DvR routes (IPv4 network routes) on a DvR Controller or a Leaf node.

Controllers display all the IP subnet routes configured for that DvR domain. The Leaf nodes display the IP subnet routes that are learned from the Controller(s) for the Layer 2 VSNs in the DvR Domain. Leaf nodes also display routes that are redistributed by Controllers (direct routes, static routes and the default route), into the DvR domain.

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. View the DvR routes.

   On a Controller:

   ```
   show dvr routes [ipv4 {A.B.C.D}]|[l3isid <0-16777215>]|[nh-as-mac]|
   [vrf WORD<1-16>]|[vrfids WORD<0-512>]
   ```

   On a Leaf node:

   ```
   show dvr routes [ipv4 {A.B.C.D}]|[l3isid <0-16777215>]|[nh-as-mac]
   ```

   Viewing the DvR routes for a specific VRF or VRF ID is not supported on a DvR Leaf node.

Example

View DvR routes on either a Controller or a Leaf node.

Viewing the DvR routes for a specific VRF or VRF ID is not supported on a DvR Leaf node.

```
Switch:1#show dvr routes

================================================================================================================================
                                                    DVR Routes
================================================================================================================================
                                  NEXT                                    L3VSN         L2VSN
DEST            MASK              HOP                           VRFID     ISID          ISID        TYPE      COST

```

Variable definitions

Use the data in the following table to use the **show dvr routes** command.

Variable	Value
ipv4 {A.B.C.D}	Specifies the IP address (IPv4) of the DvR route.
l3isid <0-16777215>	Specifies the Layer 3 I-SID of the DvR route. The range is 0 to 16777215.

Variable	Value
nh-as-mac	Specifies the MAC address of the next hop node instead of the system name.
vrf	Specifies the VRF name of the DvR route.
vrfids	Specifies the VRF ID of the DvR route. The range is 0 to 512.

Viewing DvR database information

About This Task

View all DvR routes on a Controller or a Leaf node.

The Controller node displays all the IP subnet routes configured for that DvR domain. A Leaf node displays all IP subnet routes learned from the Controller(s) for the Layer 2 VSNs in the DvR Domain. It also displays the Host Routes (ARPs) learned from other DvR enabled nodes.

Before You Begin

Ensure that DvR is enabled globally on the node.

Procedure

1. Enter Privileged EXEC mode:
   `enable`
2. View the DvR database.
   On a Controller:

   `show dvr database [home]|[ipv4 {A.B.C.D}]|[l3isid<0-16777215>]|[nh-as-mac]|[remote]|[vrf WORD<1-16>]|[vrfids WORD<0-512>]`

   On a Leaf node:

   `show dvr database [home]|[ipv4 {A.B.C.D}]|[l3isid<0-16777215>]|[nh-as-mac]|[remote]`

   Viewing the DvR database for a specific VRF or VRF ID is not supported on a DvR Leaf node.

Example

View the DvR database on either a Controller or a Leaf node.

Viewing the DvR database for a specific VRF or VRF ID is not supported on a DvR Leaf node.

```
Switch:1#show dvr database

Variable definitions

Use the data in the following table to use the **show dvr database** command.

Variable	Value
home	Specifies the DvR database information for home instance.
ipv4 {A.B.C.D}	Specifies the IP address (IPv4) of the DvR database entry.
l3isid <0-16777215>	Specifies the Layer 3 I-SID of the DvR database entry. The range is 0 to 16777215.
nh-as-mac	Specifies the MAC address of the next hop node instead of the system name.
remote	Specifies the DvR database information for remote instance.
vrf	Specifies the VRF name of the DvR database entry.
vrfids	Specifies the VRF ID of the DvR database entry. The range is 0 to 512.

Viewing DvR Backbone Entries

About This Task

View the DvR backbone entries (redistributed host routes) learned from all Controllers in all DvR domains.

Note

DvR backbone entries can be viewed only on a Controller. Viewing backbone entries is not applicable on a Leaf node.

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. View DvR backbone entries:

   ```
   show dvr backbone-entries [adv-controller WORD<1-255>]|[domain-id
   <1-255>]|[home]|[host-mac-address 0x00:0x00:0x00:0x00:0x00:0x00]|[ipv4
   {A.B.C.D}]|[l2isid <1-16777215>]|[l3isid <0-16777215>]|[next-hop
   WORD<1-255>]|[nh-as-mac]|[remote]
   ```

Example

View all DvR backbone entries:

```
Switch:1#show dvr backbone-entries
================================================================================================================================
                                          DVR Backbone-Entries
================================================================================================================================

Variable definitions

Use the data in the following table to use the **`show dvr backbone entries`** command.

Variable	Value
adv-controller WORD<1-255>	Specifies the system name of the advertising Controller.
domain-id <1-255>	Specifies the domain ID of the DvR backbone entry. The range is 1 to 255.
home	Display the DvR backbone entries for the home instance.
host-mac-address 0x00:0x00:0x00:0x00:0x00:0x00	Specifies the host MAC address of the DvR backbone entry.
ipv4 {A.B.C.D}	Specifies the IP address (IPv4) of the DvR backbone entry.
l2isid <1-16777215>	Specifies the Layer 2 I-SID of the DvR backbone entry. The range is 1 to 16777215.
l3isid <0-16777215>	Specifies the Layer 3 I-SID of the DvR backbone entry. The range is 0 to 16777215.
next-hop WORD<1-255>	Specifies the system name of the next hop node.
nh-as-mac	Specifies the MAC address of the next hop node instead of the system name.
remote	Display the DvR backbone entries for the remote instance.

Viewing DvR backbone members

About This Task

DvR backbone members are either DvR Controllers or non-DvR BEBs that receive redistributed host routes from all other DvR Controllers in the SPB network.

Before You Begin

Ensure that DvR is enabled globally on the node.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```
2. View DvR backbone member information:
   ```
   show dvr backbone-members [controller | home | non-dvr-beb | remote]
   ```

Example

View all DvR backbone members:

```
Switch:1#show dvr backbone-members

================================================================================================================
                                          DVR BB Members
================================================================================================================
System Name       Nick-Name    Nodal MAC             Role          Domain Id  Area      Area-Name
----------------------------------------------------------------------------------------------------------------
DVR-D2-C1-40      0.82.40      00:00:82:84:40:00     NON-DVR-BEB   2          HOME      area-0.00.20
Ctrl-2:8200:122   0.81.22      00:bb:00:00:81:22     Controller    2          HOME      area-0.00.20

Home: 2 out of 2 Total Num of DVR Backbone Members displayed
----------------------------------------------------------------------------------------------------------------
```

View backbone members that are DvR controllers:

```
Switch:1#show dvr backbone-members controller

================================================================================================================
                                    DVR BB Members (Domain ID: 255)
================================================================================================================
System Name         Nick-Name    Nodal MAC             Role        Domain Id   Area      Area-Name
----------------------------------------------------------------------------------------------------------------
Ctrl-2:8200:122     0.81.22      00:bb:00:00:81:22     Controller  2           HOME      area-0.00.20

Home: 1 out of 2 Total Num of DVR Backbone Members displayed
----------------------------------------------------------------------------------------------------------------
```

View backbone members that are non-DvR BEBs:

```
Switch:1#show dvr backbone-members non-dvr-beb

================================================================================================================
                                          DVR BB Members
================================================================================================================
System Name     Nick-Name    Nodal MAC           Role         Domain Id   Area      Area-Name
----------------------------------------------------------------------------------------------------------------
DVR-D2-C1-40    0.82.40      00:00:82:84:40:00   NON-DVR-BEB  2           HOME      area-0.00.20
```

```
Home: 1 out of 2 Total Num of DVR Backbone Members displayed
-------------------------------------------------------------------------------------------------------------
```

Variable definitions

Use the data in the following table to use the **show dvr backbone-members** command.

Variable	Value
controller	Specifies backbone members that are DvR Controllers.
home	Specifies DvR backbone members information for the home instance.
non-dvr-beb	Specifies backbone members that are non-DvR BEBs.
remote	Specifies DvR backbone members information for the remote instance.

Viewing Layer 3 VSN information

About This Task

View VRFs corresponding to Layer 3 (routed) VSN I-SIDs on either a Controller or a Leaf node.

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. View the Layer 3 VSN information:

   ```
   show dvr l3vsn [l3isid <0-16777215>] | [vrf WORD<1-16>] | [vrfids WORD<0-512>]
   ```

Example

View Layer 3 VSN information on a DvR Controller:

```
Switch:1#show dvr l3vsn

=================================================================
                        DVR L3VSN
=================================================================
VRF ID            L3VSN ISID    VRF NAME   INJECT-DEFAULT-ROUTE-DISABLE
-----------------------------------------------------------------
1                 55500         vrf600     Disabled
2                 55501         vrf601     Disabled
3                 55502         vrf602     Disabled
4                 55503         vrf603     Disabled

4 out of 4 Total Num of DVR L3VSN displayed
-----------------------------------------------------------------
```

View Layer 3 VSN information on a DvR Leaf node:

```
Switch2:1#show dvr l3vsn
```

```
==========================================================================
                          DVR L3VSN
==========================================================================
VRF ID            L3VSN ISID    VRF NAME
--------------------------------------------------------------------------
1                 55500         vrf600
2                 55501         vrf601
3                 55502         vrf602

3 out of 3 Total Num of DVR L3VSN displayed
--------------------------------------------------------------------------
```

Variable definitions

Use the data in the following table to use the **show dvr l3vsn** command.

Variable	Value
l3isid <0-16777215>	Specifies the Layer 3 VSN I-SID. The range is 0 to 16777215.
vrf WORD<1-16>	Specifies the VRF name of the VRF corresponding to the Layer 3 VSN I-SID.
vrfids WORD<0-512>	Specifies the VRF ID of the VRF.

Viewing DvR domain redistribution information

About This Task

View DvR domain redistribution information on a Controller or a Leaf node.

Note

You can view DvR domain redistribution information only on a DvR Controller.

An error message displays if you attempt to view this information on a DvR Leaf node.

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. View DvR domain redistribution information:

   ```
   show dvr redistribute [vrf WORD<1-16>] | [vrfids WORD<0-512>]
   ```

Example

View DvR domain redistribution information on a Controller:

```
Switch:1#show dvr redistribute
==========================================================================================================
                          DVR Redistribute List - GlobalRouter
==========================================================================================================

SOURCE MET MTYPE      ENABLE RPOLICY
----------------------------------------------------------------------------------------------------------
```

```
STAT   1   External   TRUE  -
```

View DvR domain redistribution information for a particular VRF.

```
Switch:1#show dvr redistribute vrf vrf1
================================================================================================
                              DVR Redistribute List - VRF vrf1
================================================================================================

SOURCE MET MTYPE      ENABLE RPOLICY
------------------------------------------------------------------------------------------------
STAT   20000 External   TRUE  -
LOC    10000 Internal   TRUE  -
```

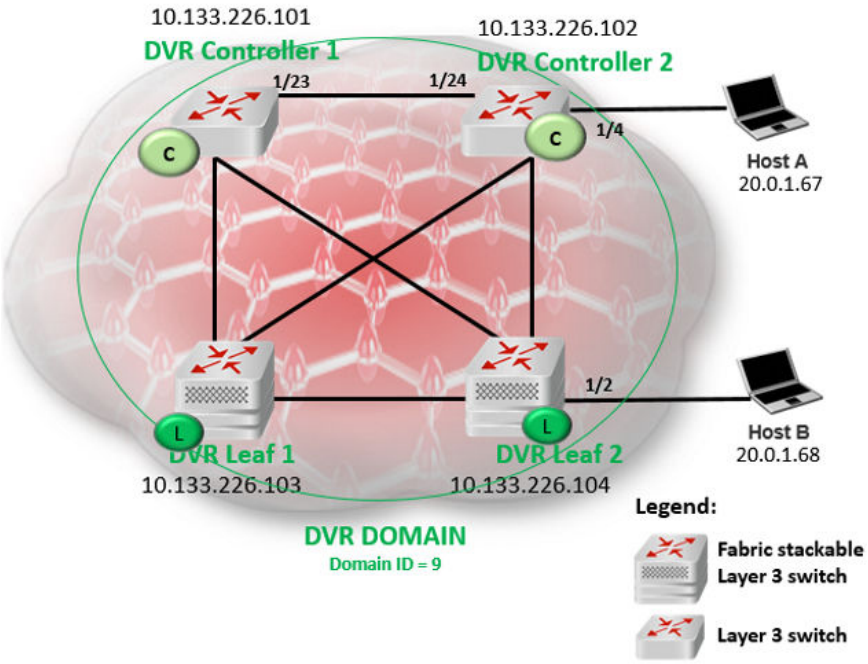
Variable definitions

Use the data in the following table to use the **show dvr redistribute** command.

Variable	Definitions
vrf WORD<1-16>	Specifies the VRF name.
vrfids WORD<0-512>	Specifies the VRF ID of the VRF.

Configure a DvR Solution

The following section describes a simple configuration example to configure Distributed Virtual Routing (DvR) over a Fabric Connect (SPB) network.



About This Task

In this example, you configure two DvR Controllers (with IP addresses `10.133.226.101` and `10.133.226.102`) and two DvR Leaf nodes (with IP addresses `10.133.226.103` and

10.133.226.104), in a single DvR domain with domain ID 9. Hosts connect to the DvR nodes as shown in the figure.

Before You Begin

On the switches to be configured as DvR Controllers:

- Ensure that you configure Fabric Connect.
- Ensure that you configure IP Shortcuts on the node. This is necessary for proper functioning of the node as a DvR Controller.
- Verify that the dvr-leaf-mode boot flag is disabled on the node. To verify the setting, enter **show boot config flags** in Privileged EXEC mode.

On the switches to be configured as DvR Leaf nodes:

- Ensure that you configure Fabric Connect.

Procedure

DvR Controller configuration — Controller 1 and Controller 2:

1. Verify configuration of Fabric Connect on each of the switches to be configured as the DvR Controllers.

   The following examples show verification on one of the switches. Perform this verification on both switches.

   a. Verify the SPB configuration:

```
Switch1:1>en
Switch1:1#show spbm
                                      spbm : enable
                                 ethertype : 0x8100
                           nick-name server : enable
                        nick-name allocation : static
                      nick-name server range : B.00.00-B.FF.FF
```

```
Switch1:1#show isis spbm

================================================================================================================
                               ISIS SPBM Info
================================================================================================================
SPBM       B-VID      PRIMARY    NICK     LSDB     IP       IPV6     MULTICAST  SPB-PIM-GW  STP-MULTI  ORIGIN
INSTANCE              VLAN       NAME     TRAP                                               HOMING
----------------------------------------------------------------------------------------------------------------
1          4051-4052  4051       0.10.01  disable  enable   disable  enable     disable     disable   dynamic

================================================================================================================
                             ISIS SPBM SMLT Info
================================================================================================================

```

2. Configure the DvR Controllers.

a. Configure Controller 1 (IP address `10.133.226.101`) with DvR domain ID `9`.

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#dvr controller 9
Switch:1(config)#show dvr

Layer 2 VSN (VLAN) configuration on the DvR Controllers:

3. Configure Layer 2 VSN on the DvR Controllers, Controller 1 and Controller 2.

   a. Configure platform VLANs on Controller 1 (VLAN ID=200 and VLAN ID=202). Associate the VLANs with the I-SIDs 20200 and 20202 respectively. Configure gateway IPv4 addresses 20.0.1.1 and 20.2.1.1 respectively, and enable DvR on those interfaces.

```
Switch1:1(config)#vlan create 200 type port-mstprstp 0
Switch1:1(config)#vlan i-sid 200 20200
Switch1:1(config)#interface vlan 200
Switch1:1(config)#dvr gw-ipv4 20.0.1.1
Switch1:1(config)#dvr enable
Switch1:1(config)#ip address 20.0.1.2 255.255.0.0

Switch1:1(config)#vlan create 202 type port-mstprstp 0
Switch1:1(config)#vlan i-sid 202 20202
Switch1:1(config)#interface vlan 202
Switch1:1(config)#dvr gw-ipv4 20.2.1.1
Switch1:1(config)#dvr enable
Switch1:1(config)#ip address 20.2.1.2 255.255.0.0
Switch1:1(config)#exit
Switch1:1#
```

   b. Configure the platform VLANs on Controller 2. Ensure that you configure the same gateway IPv4 addresses on the corresponding VLANs, as on Controller 1.

```
Switch2:1(config)#vlan create 200 type port-mstprstp 0
Switch2:1(config)#vlan i-sid 200 20200
Switch2:1(config)#interface vlan 200
Switch2:1(config)#dvr gw-ipv4 20.0.1.1
Switch2:1(config)#dvr enable
Switch2:1(config)#ip address 20.0.1.3 255.255.0.0

Switch2:1(config)#vlan create 202 type port-mstprstp 0
Switch2:1(config)#vlan i-sid 202 20202
Switch2:1(config)#interface vlan 202
Switch2:1(config)#dvr gw-ipv4 20.2.1.1
Switch2:1(config)#dvr enable
Switch2:1(config)#ip address 20.2.1.3 255.255.0.0
Switch2:1(config)#exit
Switch2:1#
```

c. Verify Layer 2 VSN (VLAN) configuration on the Controllers. The following example shows the verification on Controller 1. Perform this verification on both Controllers.
View the DvR interfaces.

On Controllers, DvR interfaces are created when you configure IP on a DvR enabled Layer 2 VSN (VLAN, I-SID). You can also view the administrative state of these interfaces on the Controller.

```
Switch1:1#show dvr interfaces

Layer 3 configuration on the DvR Controllers

4. Configure Layer 3 (VRF) on the DvR Controllers, Controller 1 and Controller 2.
   a. Configure Layer 3 on Controller 1. As part of this configuration, you configure a VRF `vrf501` and associate it with a DvR VLAN.

```
Switch1:1(config)#ip vrf vrf501 vrfid 501
Switch1:1(config)#vlan create 501 type port-mstprstp 0
Switch1:1(config)#vlan i-sid 501 50501
Switch1:1(config)#interface Vlan 501
Switch1:1(config)#vrf vrf501
Switch1:1(config)#dvr gw-ipv4 50.1.1.1
Switch1:1(config)#dvr enable
Switch1:1(config)#ip address 50.1.1.2 255.255.0.0

Switch1:1(config)#router vrf vrf501
Switch1:1(router-vrf)#i-sid 55501
Switch1:1(router-vrf)#ipvpn enable
Switch1:1(router-vrf)#exit
Switch1:1(config)#
```

   b. Configure Layer 3 on Controller 2.

```
Switch2:1(config)#ip vrf vrf501 vrfid 501
Switch2:1(config)#vlan create 501 type port-mstprstp 0
Switch2:1(config)#vlan i-sid 501 50501
Switch2:1(config)#interface Vlan 501
Switch2:1(config)#vrf vrf501
Switch2:1(config)#dvr gw-ipv4 50.1.1.1
Switch2:1(config)#dvr enable
Switch2:1(config)#ip address 50.1.1.3 255.255.0.0

Switch2:1(config)#router vrf vrf501
Switch2:1(router-vrf)#i-sid 55501
Switch2:1(router-vrf)#ipvpn enable
Switch2:1(router-vrf)#exit
Switch2:1(config)#
```

   c. Verify Layer 3 configuration. The following example shows verification on Controller 1. Perform this verification on both Controllers.

      View the DvR host entries.

```
Switch2:1(config)#show dvr host-entries l3isid 55501

DvR Leaf configuration — Leaf 1 and Leaf 2

5. Configure the boot flag `dvr-leaf-mode` on the switches to be configured as DvR Leaf nodes.

Caution

Ensure that you save the current configuration on the switch, before you enable the flag.

Enabling the flag removes all existing non-DvR configuration on the switch, such as platform VLANs and their IP address configuration, CLIP configuration, routing protocol configuration and VRF configuration. The gateway IPv4 address, if configured, is also removed.

On switch with IP address `10.133.226.104`, configure the boot flag and reboot the switch.

```
Switch3:1>en
Switch3:1#conf t
Enter configuration commands, one per line.  End with CNTL/Z.
Switch3:1(config)#boot config flags dvr-leaf-mode
Switch3:1(config)#save config
Switch3:1(config)#reset
```

On switch with IP address `10.133.226.105`, configure the boot flag and reboot the switch.

```
Switch4:1>en
Switch4:1#conf t
Enter configuration commands, one per line.  End with CNTL/Z.
Switch4:1(config)#boot config flags dvr-leaf-mode
Switch4:1(config)#save config
Switch4:1(config)#reset
```

6. After the switches come back up, configure the nodes as DvR Leaf nodes.

   Configure switch with IP address `10.133.226.104` as DvR Leaf 1; verify the configuration.

```
Switch3:1(config)#dvr Leaf 9
Switch3:1(config)#show dvr

DvR Configuration Using the EDM

The following sections describe configuration of Distributed Virtual Routing (DvR) using the Enterprise Device Manager (EDM).

Configure a DvR Controller or a DvR Leaf Globally

About This Task

Configure a node to perform the role of either a Controller or a Leaf, within the DvR domain.

Before You Begin

Important

For DvR Leaf Configuration only:

You must enable the `dvr-leaf-mode` boot flag before you configure a node as a DvR Leaf node. Navigate to **Configuration** > **Edit** > **Chassis**. On the **Boot Config** tab, select **EnableDvrLeafMode**.

Ensure that you save the current configuration on the switch, before you enable the flag. Enabling the flag removes all non-DvR configuration on the switch.

Procedure

1. In the navigation pane, expand the **Configuration** > **Fabric** folders.

2. Click **DVR**.
3. Click the **Globals** tab.
4. Enter the domain ID in the **DomainId** field.

   Note

   A Controller or a Leaf node can belong to only one DvR domain.

5. Select the role of the node in the **Role** field.
6. (Optional) On a Controller node, disable injection of default routes into the DvR domain. Select **InjectDefaultRouteDisable**.

   Note

   This field applies only to Controllers. Attempting to select this field on a Leaf node displays an error message.

7. Update the fields as necessary, and then click **Apply** to save your configuration.

Globals *Field Descriptions*

Use the data in the following table to use the **Globals** tab.

Field	Descriptions
DomainId	Uniquely identifies the domain that the node belongs to. The range for a Controller or a Leaf is 1 to 255. Set to 0 if is not configured.
Role	Specifies the role of the node in the domain, that is, either a Controller or a Leaf.
Enable	Specifies whether DvR is enabled on the node. Configuring a Controller or Leaf sets this parameter to true.
DomainIsid	Uniquely identifies the domain I-SID that the node belongs to. 0 indicates that is not configured.
BackboneIsid	Uniquely identifies the backbone I-SID that the node belongs to. The valid backbone I-SID is 16678216. It is set to 0 if is not configured.
GatewayMac	Specifies the Gateway MAC address used by all Domains.
InbandMgmtIp	Specifies the In-band Management IP address configured under IS-IS. You can use this IP address to manage the node, irrespective of whether DvR is enabled on it.

Field	Descriptions
InjectDefaultRouteDisable	Specifies whether injection of default routes is disabled on the Controller in the domain. By default, Controllers inject default routes into the domain so that all Leaf nodes in the domain learn these routes with the next hop as the Controller that advertised it. Selecting this field disables this behavior.
VirtualIstLocalAddr	Specifies the local IP address of vIST, if vIST is configured on a Leaf. vIST cannot be configured on a Controller.
VirtualIstLocalMask	Specifies the local subnet mask of vIST, if vIST is configured on a Leaf. vIST cannot be configured on a Controller.
VirtualIstPeerAddr	Specifies the peer IP address of vIST, if vIST is configured on a Leaf. vIST cannot be configured on a Controller.
VirtualIstClusterId	Specifies the cluster ID of vIST, if vIST is configured on a Leaf. vIST cannot be configured on a Controller. Set to 0 if vIST is not configured.
VirtualIstIsid	Specifies the I-SID if vIST is configured.
OperState	Specifies the operational state of the node.

View DvR Routes

About This Task

View the DvR routes (host routes and the IPv4 network routes) that are learned on a DvR Controller or a Leaf node.

Controllers display all the IP subnet routes configured for that DvR domain. Leaf nodes display the IP subnet routes learned from the Controller(s) for the Layer 2 VSNs in the DvR Domain. Leaf nodes also display any redistributed routes into the DvR Domain that are learned from the Controllers (direct routes, static routes and the default route).

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. In the navigation pane, expand the **Configuration** > **Fabric** folders.
2. Click **DVR**.
3. Click the **Routes** tab.
4. To filter the rows based on the specific criteria, click **Filter**.

Routes *field descriptions*

Use the data in the following table to use the **Routes** tab.

Name	Description
DestIpAddrType	Specifies the IPv4 destination address type of the DvR route.
DestIpAddr	Specifies the IPv4 destination address of the DvR route.
DestMask	Specifies the destination mask of the DvR route.
L3Isid	Specifies the Layer 3 I-SID of the DvR route.
EcmpIndex	Specifies the ECMP index for the ECMP routes of the DvR route.
NextHopMac	Specifies the MAC address of the next hop BEB in the DvR route.
L2Isid	Specifies the Layer 2 I-SID of the DvR route.
VrfId	Specifies the VRF ID.
Cost	Specifies the SPB cost of the DvR route.
NextHopName	Specifies the host name of the next hop BEB, in the DvR route.
Type	Specifies the route type of the DvR route.

View Members of a DvR Domain

About This Task

View the members of all DvR domains namely the Controllers and Leaf nodes.

You can view this information on either a Controller or a Leaf node. Both the Controller and the Leaf node displays the members of the DvR domain to which it belongs.

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **DVR**.
3. Select the **Members** tab.
4. (Optional) To filter the rows based on specific criteria, click **Filter**.

Members *field descriptions*

Use the data in the following table to use the **Members** tab.

Name	Description
MacAddress	Specifies the system ID or the nodal MAC address of this DvR member.
SysName	Specifies the system name of this DvR member.

Name	Description
NickName	Specifies the nick name of this DvR member.
Role	Specifies the DvR role (Controller or Leaf) of this DvR member.
DomainId	Specifies the domain ID of the DvR domain that this member belongs to.

View DvR Backbone Members

About This Task

DvR backbone members are either DvR Controllers or non-DvR BEBs that receive redistributed host routes from all other DvR Controllers in the SPB network.

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. In the navigation pane, expand the **Configuration** > **Fabric** folders.
2. Click **DVR**.
3. Click the **Backbone Members** tab.
4. (Optional) To filter the rows based on specific criteria, click **Filter**.

Backbone Members *field descriptions*

Use the data in the following table to use the **Backbone Members** tab.

Name	Description
MacAddress	Specifies the system ID or the nodal MAC address of this DvR backbone member.
SysName	Specifies the system name of this DvR backbone member.
NickName	Specifies the nick name of this DvR backbone member.
Role	Specifies the role of this DvR backbone member. It is either a DvR Controller or a non-DvR BEB.
DomainId	Specifies the domain ID of the DvR domain that this backbone member belongs to. The domain ID is 0 for a non-DvR BEB.

View DvR Interfaces

About This Task

View the DvR interfaces on either a Controller or a Leaf node.

On Controllers, DvR interfaces are created when you configure IP on a DvR enabled Layer 2 VSN (VLAN, I-SID). Only Controllers display the administrative state of the interfaces because this is where you enable or disable the interfaces. On a Leaf node, the DvR interface information that the Controllers push, for example, subnet routes and the gateway IP addresses for the Layer 2 VSNs, are displayed.

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. In the navigation pane, expand the **Configuration** > **Fabric** folders.
2. Click **DVR**.
3. Click the **Interfaces** tab.

   Click **Filter** to filter rows based on specific filter criteria.

Interfaces *field descriptions*

Use the data in the following table to use the **Interfaces** tab.

Name	Description
VlanIpAddrType	Specifies the VLAN IP address type of the DvR interface.
VlanIpAddr	Specifies the VLAN IP address (IPv4) of the DvR interface.
L3Isid	Specifies the Layer 3 I-SID of the DvR interface. The range is 1 to 16777215.
L2Isid	Specifies the Layer 2 I-SID of the DvR interface. The range is 1 to 16777215.
VlanIpMask	Specifies the VLAN IP address mask of the DvR interface.
VrfId	Specifies the VRF ID of the DvR interface. The VRF ID is 0 for the GRT.
VlanId	Specifies the VLAN ID of the DvR interface.
GwIpAddrType	Specifies the address type of the DvR gateway IP address (IPv4).
GwIpAddr	Specifies the DvR gateway IP address (IPv4).
AdminState	Specifies the administrative state of the DvR interface.
SpbmcState	Specifies the state of IP Multicast over Fabric Connect, on the DvR interface.
IgmpVersion	Specifies the version of IGMP that runs on the DvR interface.

View DvR Host Entries

About This Task

View DvR host entries (IPv4 remote ARPs) on either a Controller or a Leaf node. The node displays the host entries learned either locally on its UNI port or dynamically from other nodes in the DvR domain.

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. In the navigation pane, expand the **Configuration** > **Fabric** folders.
2. Click **DVR**.
3. Click the **Host Entries** tab.
4. (Optional) To filter the rows based on the specific criteria, click **Filter**.

Host Entries *field descriptions*

Use the data in the following table to use the **Host Entries** tab.

Name	Description
IpAddrType	Specifies the address type of the DvR host entry (IPv4 remote ARP).
IpAddr	Specifies the IPv4 address of the DvR host entry.
Mask	Specifies the subnet mask of the DvR host entry.
L3Isid	Specifies the Layer 3 I-SID of the DvR host entry.
MacAddr	Specifies the MAC address of the DvR host entry.
L2Isid	Specifies the Layer 2 I-SID of the DvR host entry.
VrfId	Specifies the VRF ID associated with the DvR host entry.
Port	Specifies the port of the DvR host entry.
DomainId	Specifies the DvR domain ID of the DvR host entry.
Type	Specifies the host type of the DvR host entry.
NextHopName	Specifies the next hop system name of the DvR host entry.
NextHopMac	Specifies the next hop system MAC address of the DvR host entry.
ClearEntry	Clears the entry if the configured value is true.

Clear DvR Host Entries

About This Task

Clear DvR host entries (IPv4 remote host routes) on a Controller. The host entries are learned on the switch either locally on its UNI port or dynamically from other nodes in the DvR domain.

Note

You can clear DvR host entries only on a DvR Controller.

An error message displays if you attempt clearing of host entries on a DvR Leaf node.

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. In the navigation pane, expand the **Configuration** > **Fabric** folders.
2. Click **DVR**.
3. Click the **Clear Host Entries** tab.
4. Update the fields as necessary, and then click **Apply** to save your configuration.

Clear Host Entries *field descriptions*

Use the data in the following table to use the **Clear Host Entries** tab.

Name	Description
ClearAll	Select to clear all DvR host entries.
ClearIpv4	Specifies the IPv4 address of the DvR host entries to clear. The IPv4 address must not be the VLAN IP address on any Controller within the DvR domain.
ClearL2Isid	Specifies the Layer 2 VSN I-SID of the DvR host entries to clear. The range is 0 to 16777215.
ClearL3Isid	Specifies the Layer 3 VSN I-SID of the DvR host entries to clear. The range is 0 to 16777215.

View Layer 3 VSN Information

About This Task

View VRFs corresponding to Layer 3 (routed) VSN I-SIDs on either a Controller or a Leaf node.

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. In the navigation pane, expand the **Configuration** > **Fabric** folders.
2. Click **DVR**.
3. Click the **L3–VSN** tab.

   Click **Filter** to filter rows based on specific filter criteria.

***L3–VSN** field descriptions*

Use the data in the following table to use the **L3–VSN** tab.

Name	Description
VrfId	Specifies the VRF ID of the VRF corresponding to the Layer 3 VSN I-SID.
Isid	Specifies the Layer 3 VSN I-SID.
VrfName	Specifies the VRF name of the VRF corresponding to the Layer 3 VSN I-SID.
InjectDefaultRouteDisable	Specifies whether injection of default routes is disabled.

View the DvR Database

About This Task

View all DvR routes on a Controller or a Leaf node.

The Controller node displays all the IP subnet routes configured for that DvR domain. A Leaf node displays all IP subnet routes learned from the Controller(s) for the Layer 2 VSNs in the DvR Domain. It also displays the Host Routes (ARPs) learned from other DvR enabled nodes.

Before You Begin

Ensure that you enable DvR on the node.

Procedure

1. In the navigation pane, expand the **Configuration** > **Fabric** folders.
2. Click **DVR**.
3. Click the **Database** tab.
4. (Optional) To filter the rows based on the specific criteria, click **Filter**.

***Database** field descriptions*

Use the data in the following table to use the **Database** tab.

Name	Description
DestIpAddrType	Specifies the address type of the IPv4 destination address of the DvR database entry.
DestIpAddr	Specifies the IPv4 destination address of the DvR database entry.
DestMask	Specifies the destination mask of the DvR database entry.
L3Isid	Specifies the Layer 3 I-SID of the DvR database entry.
EcmpIndex	Specifies the ECMP index for the DvR database entry.
NextHop	Specifies the MAC address of the next hop BEB, in the DvR database entry.
L2Isid	Specifies the Layer 2 I-SID of the DvR database entry.
VrfId	Specifies the VRF ID for the DvR database entry.
OutgoingInterface	Specifies the outgoing interface (port or MLT) of the DvR database entry.
SpbCost	Specifies the SPB cost of the DvR database entry.
PrefixCost	Specifies the prefix cost of the DvR database entry.
NextHopName	Specifies the host name of the next hop BEB, in the DvR database table entry.
Age	Specifies the uptime since creation of the DvR database table entry.

View DvR Backbone Entries on a Controller

About This Task

View the DvR backbone entries (redistributed host routes) learned from all Controllers in all DvR domains.

Note

You can view DvR backbone entries only on a Controller. Viewing backbone entries does not apply to a Leaf node.

Before You Begin

Ensure that you enable DvR globally on the node.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric** folders.
2. Select **DVR**.
3. Select the **Backbone Entries** tab.

4. (Optional) To filter the rows based on the specific criteria, click **Filter**.

Backbone Entries *field descriptions*

Use the data in the following table to use the **Backbone Entries** tab.

Name	Description
IpAddrType	Specifies the address type of the DvR backbone host (IPv4 remote ARP).
IpAddr	Specifies the IPv4 address of the DvR backbone host.
L3Isid	Specifies the Layer 3 I-SID of the DvR backbone host.
DomainId	Specifies the domain ID of the DvR backbone host.
EcmpIndex	Specifies the ECMP index of the DvR backbone host.
HostMacAddr	Specifies the MAC address of DvR backbone host.
L2Isid	Specifies the Layer 2 I-SID of the DvR backbone host.
AdvControllerName	Specifies the host name of the advertising Controller.
AdvController	Specifies the host MAC address of the advertising Controller.
NextHopName	Specifies the host name of the next hop Backbone host in the DvR route.
NextHopMac	Specifies the MAC address of the next hop Backbone host in the DvR route.

EAPoL

Extensible Authentication Protocol over LAN (EAPoL or EAP) is a port-based network access control protocol. EAP provides security by preventing users from accessing network resources before they are authenticated. The EAP authentication feature prevents users from accessing a network to assume a valid identity and access confidential material or launch denial-of-service attacks.

You can use EAP to set up network access control on internal LANs and to exchange authentication information between an end station or server that connects to a switch and an authentication server (such as a RADIUS server). This security feature extends the benefits of remote authentication to internal LAN clients. For example, if a new client PC fails the authentication process, EAP prevents the new client PC from accessing the network.

EAP terminology

This section lists some components and terms used with EAP-based security.

- Supplicant—a device, such as a PC, that applies for access to the network.
- Authenticator—software on a switch that authorizes or rejects a Supplicant attached to the other end of a LAN segment.
  - Port Access Entity (PAE)—software that controls each port on the device. The PAE, which resides on the switch, supports the Authenticator functionality.
  - Controlled Port—any port on the device with EAP enabled.

- Authentication Server—a RADIUS server that provides AAA services to the authenticator.

EAP Configuration Considerations

This section lists EAP configuration considerations.

- You must configure at least one EAP RADIUS server and shared secret fields.
- You cannot configure EAP on ports that are currently configured for the following:
  - Shared segments
  - MultiLink Trunking
- Change the authentication status to auto for each port that you want to control. The *auto* setting automatically authenticates the port according to the results of the RADIUS server. The default authentication setting for each port is *authorized*.
- When multiple clients are authenticated on the same port, the priority of the latest incoming client is applied on the port, and this priority is retained until all the clients log out on that port.

Configuration Process

The Authenticator facilitates the authentication exchanges that occur between the Supplicant and the Authentication Server. The Authenticator PORT ACCESS ENTITY (PAE) encapsulates the EAP message into a RADIUS packet, and then sends the packet to the Authentication Server.

The Authenticator manages the access to controlled port. At system initialization, or when a Supplicant initially connects to one of the controlled ports on the device, the system blocks data traffic of the Supplicant until gets authenticated. After the Authentication Server notifies the Authenticator PAE about the success or failure of the authentication, the Authenticator decides whether to permit/deny the traffic of client on controlled port.

non-EAPoL (NEAP) frames transmit according to the following rules:

- If authentication succeeds, the client blocked from accessing is allowed to the controlled port, which means the system allows all the incoming and outgoing traffic from that client through the port.
- If authentication fails, client is blocked from accessing, which means both incoming and outgoing traffic is not allowed to client.

The following figure illustrates how the switch, configured with EAP, reacts to a new network connection.

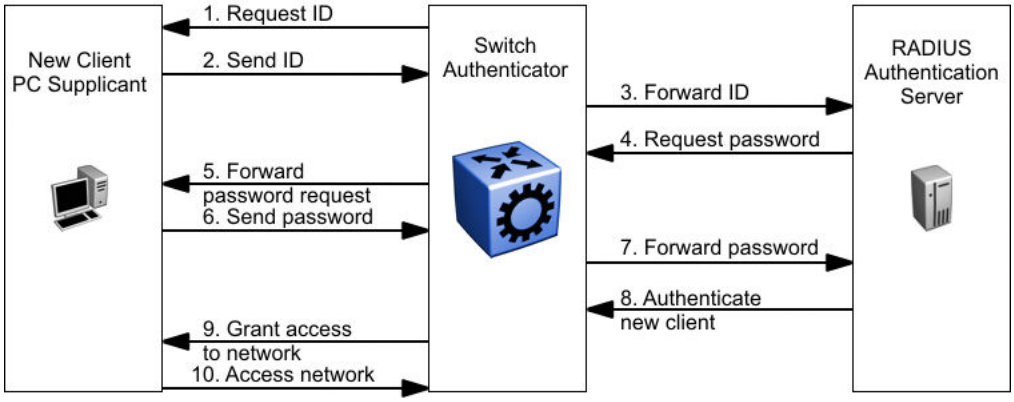

Figure 52: EAP configuration example

In the preceding figure, the switch uses the following steps to authenticate a new client:

1. The switch detects a new connection on one of its EAP-enabled ports and requests a user ID from the new client PC.
2. The new client sends its user ID to the switch.
3. The switch uses RADIUS to forward the user ID to the RADIUS server.
4. The RADIUS server responds with a request for the password of the user.
5. The switch forwards the request from the RADIUS server to the new client.
6. The new client sends an encrypted password to the switch, within the EAP packet.
7. The switch forwards the EAP packet to the RADIUS server.
8. The RADIUS server authenticates the password.
9. The switch grants the new client access to the network.
10. The new client accesses the network.

If the RADIUS server cannot authenticate the new client, it denies the new client access to the network.

The following figure shows the Ethernet frames and the corresponding codes for EAP as specified by 802.1x.

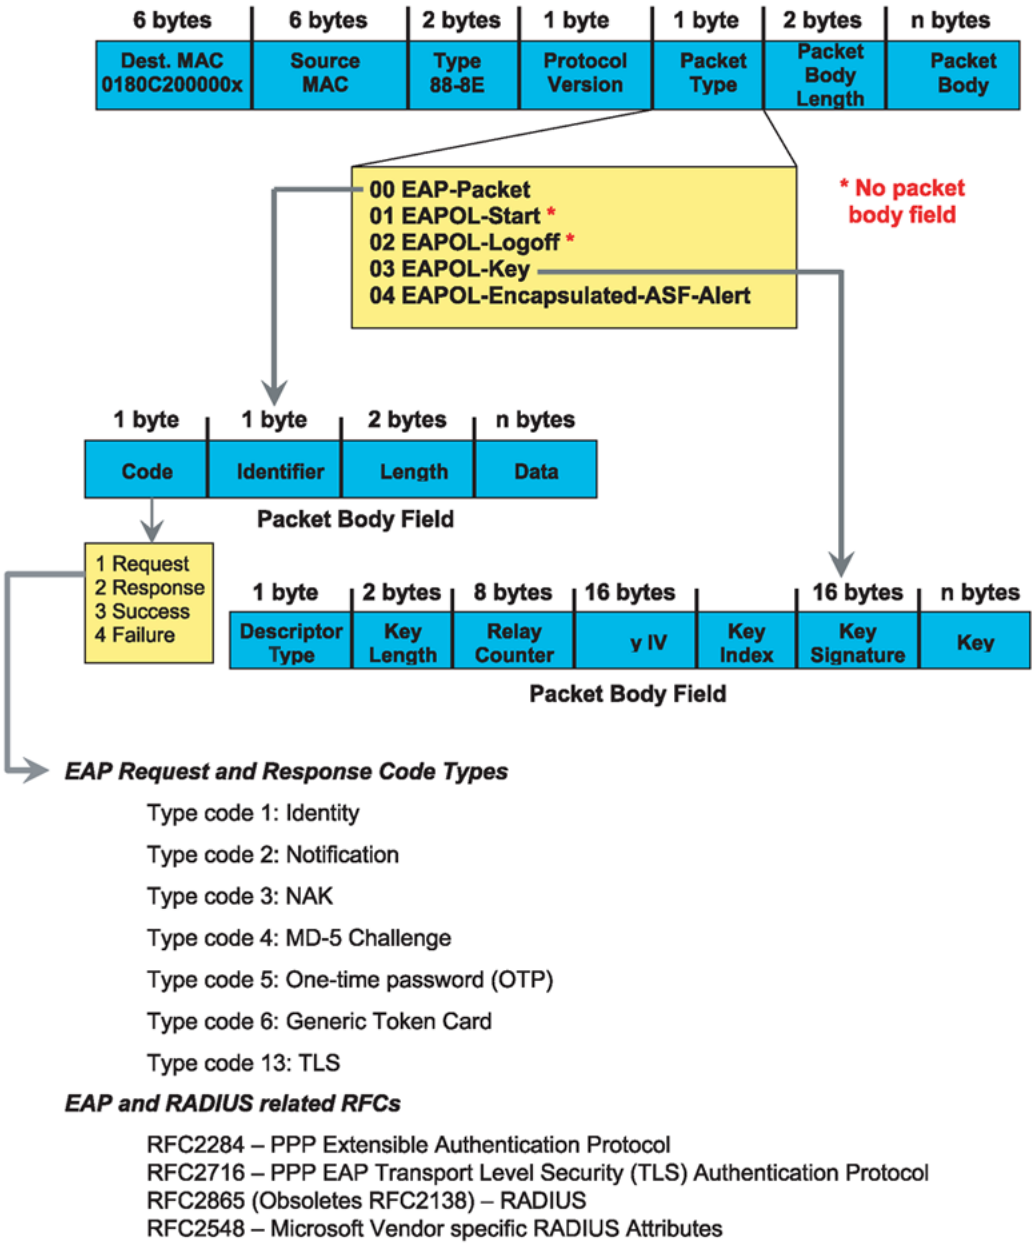

Figure 53: 802.1x Ethernet frame

The following figure shows the flow diagram for EAP on a switch.

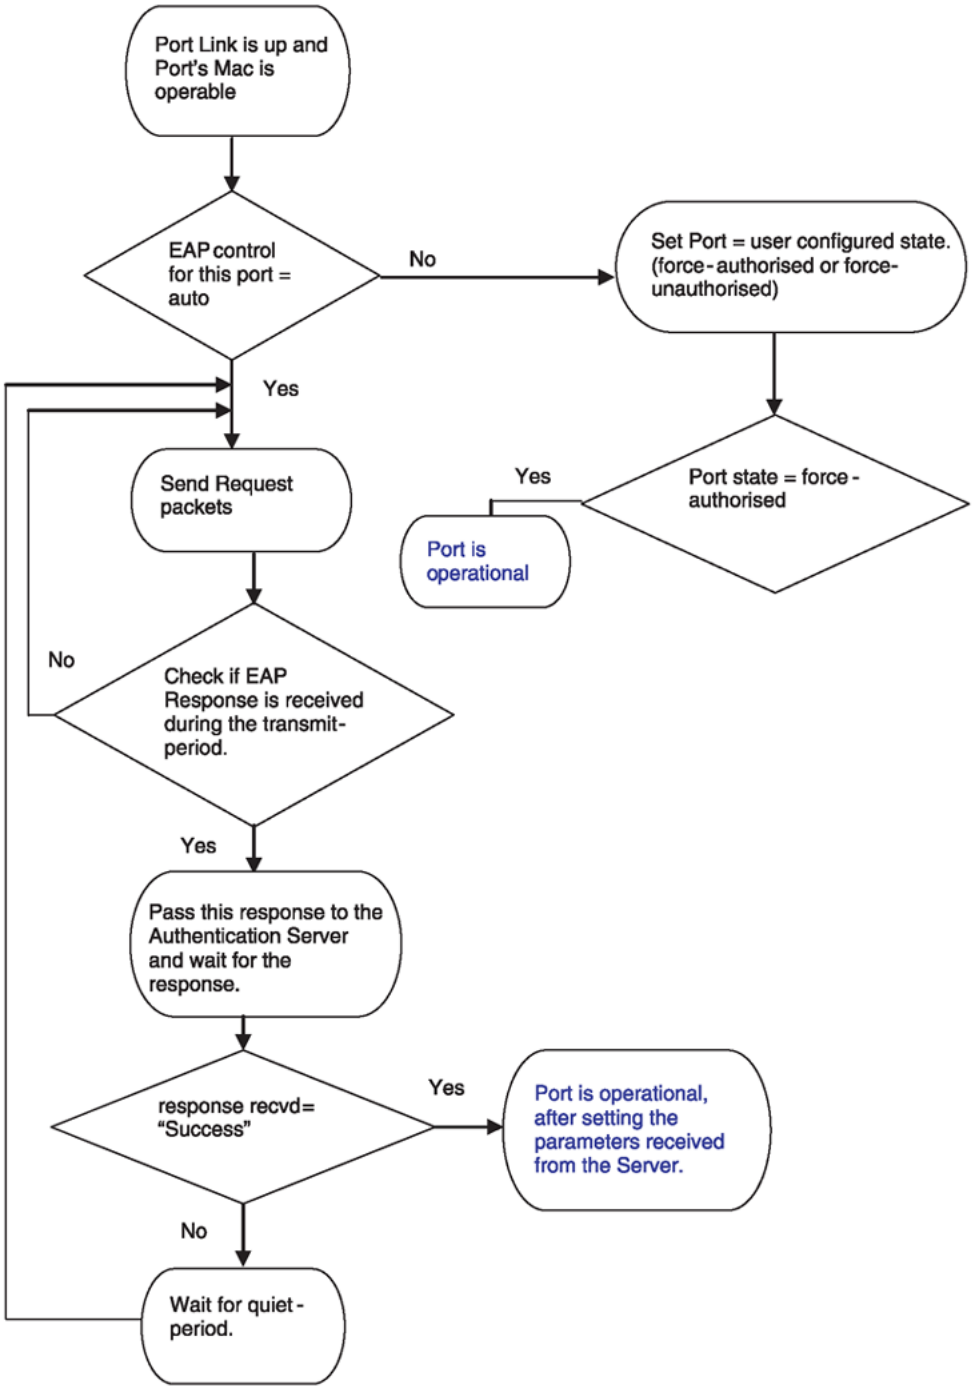

Figure 54: EAP flow diagram

EAP System Requirements

The following are the minimum system requirements for EAP:

- RADIUS server

- Client software that supports EAP

You must specify the RADIUS server that supports EAP as the primary RADIUS server for the switch. You must configure your switch for VLANs and EAP security.

If you configure EAP on a port, the following limitations apply:

- You cannot enable EAP on ports that belong to an MLT group.
- You cannot add EAP-enabled ports to an MLT group.
- You can configure a total of 32 MAC clients, EAP and NEAP hosts, on an EAP-enabled port. Two MAC clients per port is a typical configuration.
- You cannot configure EAP on MLT/LACP interfaces.
- You cannot add EAP-enabled ports to an MLT/LACP group.
- You cannot enable VLACP on EAP enabled ports.
- Manual VLAN changes on a EAP enabled port is restricted.
- You cannot change the VLAN port tagging on EAP enabled ports.
- You cannot configure the default VLAN ID. Use the Guest VLAN configuration to access unauthenticated devices.
- You cannot enable MACsec on EAP enabled ports.
- You cannot enable EAP on network-to-network interface (NNI).
- You cannot egress mirror an EAP PDU.
- Do not use EAP with a brouter port.
- Ping to and from services between nodes over the NNI will work even when it contains only EAP enabled ports with no authenticated clients on it.
- MHSA and Fail Open VLAN are mutually exclusive.
- Fail-Open I-SID is not supported in MHSA mode.
- You cannot change the EAP operation mode on EAP enabled ports.
- You cannot configure private VLANs as Fail Open VLAN or Guest VLAN.
- You cannot configure SPBM B-VLAN as Fail Open VLAN or Guest VLAN.
- You cannot delete a VLAN if the VLAN is configured as Fail Open VLAN or Guest VLAN.

EAP Dynamic VLAN Assignment

If you configure a RADIUS server to send a VLAN ID in the Access-Accept response, the EAP feature dynamically changes the VLAN configuration of the port by adding the port to the specified VLAN.

EAP dynamic VLAN assignment affects the following VLAN configuration values:

- Port membership
- Port priority
- Default VLAN ID

When you disable EAP on a port that was previously authorized, VLAN configuration values for that port are restored directly from the nonvolatile random access memory (NVRAM) of the device.

You can set up your Authentication Server (RADIUS server) for EAP dynamic VLAN assignments. You can use the Authentication Server to configure user-specific settings for VLAN memberships and port priority.

When you log on to a system that is configured for EAP authentication, the Authentication Server recognizes your user ID and notifies the device to assign preconfigured (user-specific) VLAN membership and port priorities to the device. The configuration settings are based on configuration parameters that were customized for your user ID and previously stored on the Authentication Server.

Note

Static entries like IGMP, ARP, FDB configured on a port of an VLAN interface, will not be retained if the port is assigned a same VLAN by the RADIUS server and the client authenticated on the port gets disconnected or unauthenticated.

Multiple Host Multiple VLAN

With the MHMV feature, you can assign multiple authenticated devices to different VLANs on the same EAP-enabled port using device MAC addresses. Using RADIUS VLAN attributes, different clients can access different VLANS. This separates traffic for different MAC clients.

In MHMV mode, the port-priority assigned by the RADIUS server is configured by MAC address for each authenticated client. After configuration, the QoS level on the port does not change.

Use MHMV to assign multiple authenticated devices to different VLANs on the same port. Clients can access different VLANs access using the MAC address of the devices. Different clients with different level of access (unauthorized to authorized) in different VLANs and with different QoS priorities, can exist on the same port.

With MHMV, EAP Multihost VLAN supports tagged and untagged ports. A port can be a member of multiple tagged and untagged VLANs.

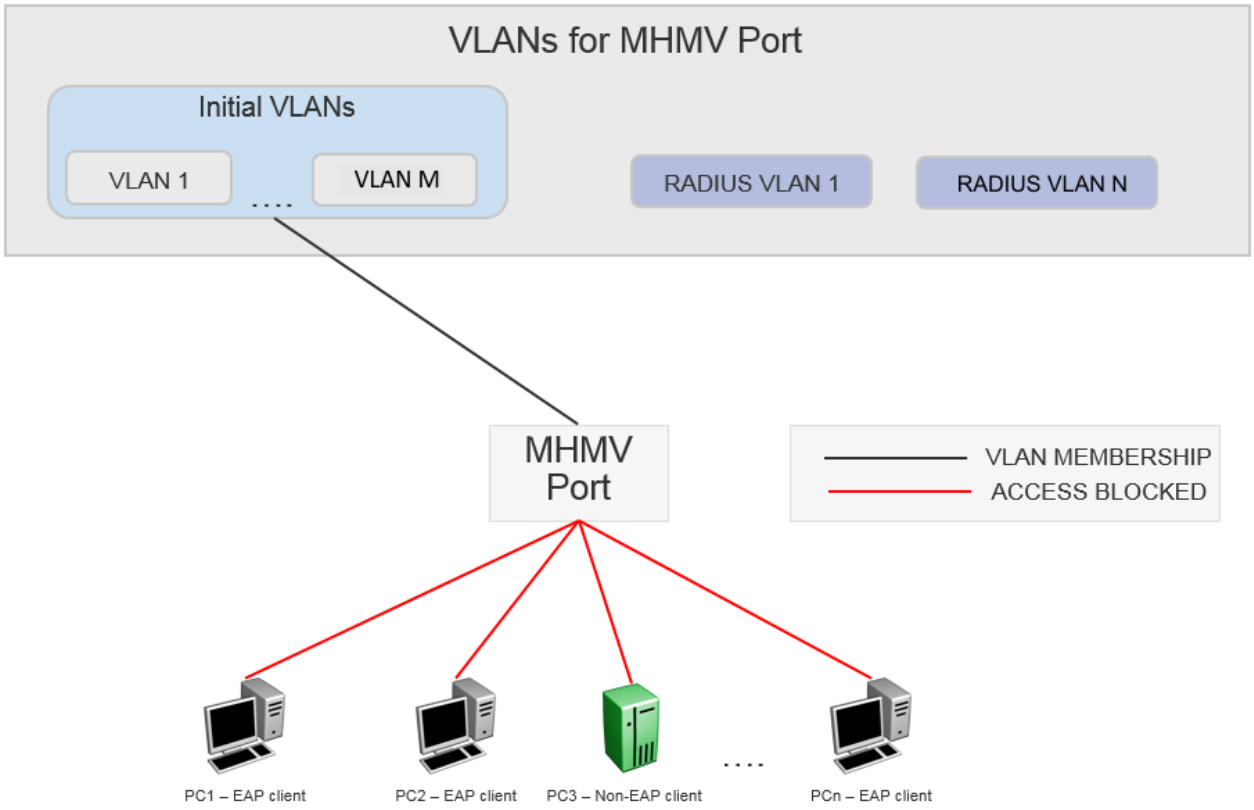
In MHMV mode, MAC based VLANs support traffic separation between different authenticated MAC clients. MAC based VLAN traffic separation applies only to untagged VLAN traffic. If the data traffic is tagged and if VLAN is configured on the port, then the traffic is forwarded to the VLAN associated with the tag.

Multiple Host Multiple VLAN Usage

The following example illustrates the usage scenario for a MHMV port with n unauthenticated clients:

- Clients (n) connect to a switch port. The maximum number of clients (EAP + NEAP) allowed on a port is 8192.
- EAP is enabled and the default operation mode is MHMV.
- Modify client counters to authenticate n clients.
- Initial VLANs are the VLANS which are manually set up before EAP is enabled.
- Port default VLAN ID is equal to one of the initial VLAN ID.
- All clients are unauthenticated, hence the clients cannot access the network.

The following figure represents the functionality when clients are not authenticated.



Note

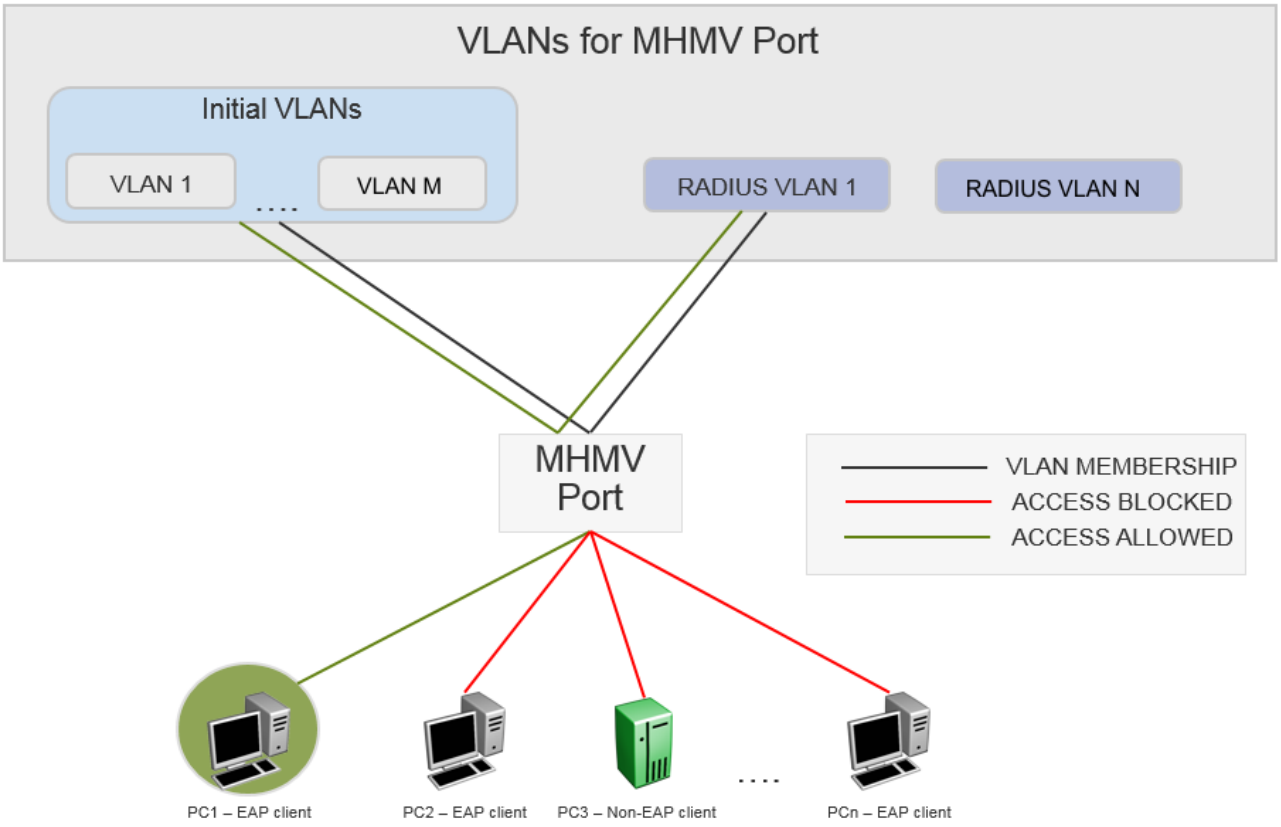
The clients cannot access the network as they are not authenticated.

When client PC1 authenticates, there are two scenarios:

1. Client PC1 does not receive RADIUS VLAN attribute:
   - There are no changes to the port membership and port default VLAN ID.
   - PC1 is the only client that is allowed access to the initial VLANs.
   - A VLAN MAC rule is added that associates the MAC with the default VLAN ID.
   - If the VLAN is configured on the port, then the tagged traffic from PC1 is forwarded to the VLAN associated with the tag.
   - Untagged traffic from PC1 is forwarded to the port default VLAN.
2. Client PC1 receives RADIUS VLAN attribute:
   - The port is left in all initial VLANs and added to the VLAN corresponding to the RADIUS VLAN attribute.
   - Port default VLAN remains unchanged.
   - A VLAN MAC based rule is configured for client PC1.
   - Using the VLAN MAC based capabilities, the untagged traffic from PC1 goes to the RADIUS assigned VLAN 1 as shown in the figure below.

- Client PC1 can access all initial VLANs using tagged frames.
- The remaining clients stay unauthenticated and cannot access any VLANs.

The following figure represents the functionality when client PC1 authenticates.



Note

PC1 is authenticated with RADIUS VLAN 1. The other clients cannot access the network as they are unauthenticated.

When a client disconnects the following happens:

- The MAC VLAN rule is removed from the switch.
- If the RADIUS VLAN attribute was used with the client was authenticated and no other clients are authenticated on that RADIUS VLAN, then the port is removed from the VLAN.
- The RADIUS accounting attribute Acct-Terminate-Cause indicates how a session was terminated.
- The RADIUS accounting attribute Event-Timestamp indicates the time that an event occurred on the Network Access Server (NAS).

EAP Functionality on Flex UNI Ports

After you enable EAP on a port, all client MACs (MHMV mode) must be authenticated by the RADIUS server in order to have network access. In Multiple Host Multiple VLAN (MHMV) mode, the RADIUS server allocates a MAC to I-SID binding to each client that connects to the switch and uses it to transmit

traffic. The binding is not between the MAC and the VLAN. Untagged S-UNIs generated from the RADIUS server for a MAC or MACs are considered as MAC-based S-UNIs.

The RADIUS server also provides the VLAN:ISID binding for the MAC, which results in the addition of an untagged Switched UNI (S-UNI) for that particular I-SID. Only the MAC or MACs that receive the I-SID from the RADIUS server can transmit traffic to Extensible Authentication Protocol (EAP)-enabled Flex UNI ports.

The switch uses MAC-based S-UNIs with EAP-enabled Flex UNI ports in MHMV mode only.

The MAC-based S-UNI model does not apply to MHSA mode. In Multiple Host Single Authentication (MHSA) mode used in the untagged S-UNI model that exists on VOSS switches. S-UNIs generated from the information obtained from the RADIUS server are considered as classic or default untagged S-UNIs.

Note

EAP is not supported on MLT/SMLTs. Only the EAP I-SIDs are synchronized between one vIST peer and another vIST peer. S-UNIs are not synchronzied with the vIST peer.

EAP with Flex UNI is supported on Distributed Virtual Routing (DvR) Leafs. An untagged S-UNI (where the system learns MACs based on the I-SID to MAC binding) must have a platform VLAN associated with it. If a default untagged S-UNI is used, the corresponding S-UNI must be received from the DvR Controllers.

EAP and Fabric Attach

With Extensible Authentication Protocol (EAP) and Fabric Attach (FA), FA-capable switches can forward traffic from EAP/NEAP clients over the SPB cloud. The traffic for authenticated clients is mapped to I-SIDs received from RADIUS server.

You must configure the desired bindings for EAP/NEAP clients on the RADIUS server. When confirming the authentication request, the RADIUS server also sends the corresponding binding for the EAP/NEAP client.

The FA Proxy sends to the FA Server the binding received from the RADIUS server. If the FA Server rejects all the bindings, the client is disconnected. EAP clients are moved from AUTHENTICATED state to HELD state.

On an FA Server, when an EAP/NEAP device is authenticated and an FA binding is received from the RADIUS server, a Switched UNI (S-UNI) is created.

After an EAP/NEAP client is disconnected, the switch cleans-up the binding associated with the client, if no other EAP/NEAP client on that port uses it.

EAP and FA can be enabled in any order; however, EAP must have Flex UNI enabled in order to function on an FA-enabled port.

FA clients that generate S-UNI bindings must be used with EAP MHSA mode, while FA clients that do not generate S-UNI bindings should be used with EAP MHMV mode.

MAC Move Detection on EAP Ports

The MAC moves mechanism detects when a MAC address migrates from one port to another port, such as:

- EAPoL-enabled port to EAPoL-enabled port
- EAPoL-enabled port to non-EAPoL (NEAP)-enabled port
- non EAPoL-enabled port to EAPoL-enable port

When a MAC address migrates from one port to another port, the new EAPoL-enabled port triggers a new RADIUS authentication. New bindings are applied on the new EAPoL-enabled port. The old port detects the MAC is moved and automatically deletes the old binding or bindings.

The Mac moves mechanism works between vIST peers when a MAC address on one peer migrates to the other peer but only if the I-SID in which the MAC address is learned exists on the new and the old peer.

Auto-sense Ports

EAP and NEAP is integrated with Auto-sense infrastructure. If a RADIUS server is configured on the switch, Auto-sense-enabled ports activate EAP and NEAP authentication automatically.

For more information about Auto-sense functionality, see Auto-sense on page 12.

RADIUS-Assigned VLAN or VLAN:ISID Bindings

RADIUS-assigned VLAN and VLAN:ISID bindings provide greater flexibility and a more centralized assignment. The RADIUS server can dynamically assign VLANs or VLAN:ISID bindings to a port.

Use VLAN attributes for RADIUS assignments in VLAN mode. This mode applies when the EAP-enabled port does not have Flex-UNI enabled.

Use VLAN:ISID attributes for RADIUS assignments in I-SID mode. This mode applies when the EAP-enabled port does have Flex-UNI enabled.

For more information, see RADIUS Attributes on page 2480.

RADIUS Configuration Prerequisites for EAP

Connect the RADIUS server to a force-authorized port. This ensures that the port is always available and not tied to whether or not the device is EAP-enabled.

RADIUS Accounting for EAP

The switch provides the ability to account EAP and NEAP sessions using the RADIUS accounting protocol. A user session is defined as the time frame between when a user is authenticated until the user is unauthenticated.

The following table summarizes the accounting events and information logged.

Table 67: Summary of accounting events and information logged

Event	RADIUS attributes	Description
User is authenticated by EAP	Acct-Status-Type	Start
	Nas-IP-Address	IP address to represent the switch
	Nas-Port	Port number on which the user is EAP or NEAP authorized
	Acct-Session-ID	Unique string representing the session
	User-Name	EAP user name or NEAP MAC
User logs off	Acct-Status-Type	Stop
	Nas-IP-Address	IP address to represent the switch
	Nas-Port	Port number on which the user is EAP or NEAP unauthorized
	Acct-Session-ID	Unique string representing the session
	User-Name	EAP user name
	Acct-Input-Octets	Number of octets input to the port during the session
	Acct-Output-Octets	Number of octets output to the port during the session
	Acct-Terminate-Cause	Reason for terminating user session. For more information about the mapping of 802.1x session termination cause to RADIUS accounting attribute, see the following table.
	Acct-Session-Time	Session interval

The following table describes the mapping of the causes of 802.1x session terminations to the corresponding RADIUS accounting attributes.

Table 68: 802.1x session termination mapping

IEEE 802.1Xdot1xAuthSessionTerminateCause Value	RADIUSAcct-Terminate-Cause Value
supplicantLogoff(1)	User Request (1)
portFailure(2)	Lost Carrier (2)
supplicantRestart(3)	Supplicant Restart (19)
reauthFailed(4)	Reauthentication Failure (20)
authControlForceUnauth(5)	Admin Reset (6)
portReInit(6)	Port Reinitialized (21)

Table 68: 802.1x session termination mapping (continued)

IEEE 802.1Xdot1xAuthSessionTerminateCause Value	RADIUSAcct-Terminate-Cause Value
portAdminDisabled(7)	Port Administratively Disabled (22)
notTerminatedYet(999)	

RADIUS Dynamic User-Based Policies

RADIUS Dynamic User-Based Policies is a security feature to control access services on user devices that connect to the network. Before enabling any services on the user device, the RADIUS server authenticates each device that connects to the switch port and assigns that port to a VLAN or a VLAN to I-SID binding. RADIUS Dynamic User-Based Policies implement a dynamic method to apply filter Access Control List (ACL) rules to Extensible Authentication Protocol (EAP) and Non-EAP (NEAP) authenticated user traffic. The RADIUS server authenticates the user device for switch access and sends rules for that user device to the switch.

The system clears the rules when the following events occur:

- You disable EAPoL globally on the switch.
- EAP and NEAP sessions are cleared.
- You shutdown the port.

Note

- You must enable RADIUS and EAP over LAN (EAPoL) on the switch. For more information, see Enabling RADIUS authentication on page 2439 and Globally enabling EAP on the device on page 718.
- You must configure an EAP-enabled RADIUS server. For more information, see Configure an EAP-enabled RADIUS Server on page 721.

RADIUS Dynamic User-Based Policies support one time configuration of policy attributes on the RADIUS server and dynamically creates the policies on multiple switches within the network. This process of automatically creating policies enhances the speed of network access for authenticated users and also facilitates faster network synchronization in the event of network-wide policy changes.

Extreme Vendor ID 1916 supports the following RADIUS Vendor Specific Attribute (VSA) for RADIUS Dynamic User-Based Policies:

- Extreme-Dynamic-ACL (ID 251)

For more information, see RADIUS Attributes on page 2480.

The RADIUS server contains the RADIUS VSAs in a configuration file for each EAP or NEAP client that the switch authenticates. Following is an example of a RADIUS VSA configured on the RADIUS server:

```
00000000000a Cleartext-Password :="00000000000a"
Service-Type = Framed-User,
Framed-Protocol = PPP,
Auth-Type := Accept,
Fabric-Attach-ISID = 10:100,
Extreme-Dynamic-ACL = CLIENT RadiusGuest
Extreme-Dynamic-ACL = acl inPort
```

```
Extreme-Dynamic-ACL = ace 1 sec name ACE-A1 ethernet ether-type eq 0x800 & action deny count & ip
ipprotocol-type eq 17 & protocol dst-port eq 4000
Extreme-Dynamic-ACL = ace 2 sec name ACE-A2 ethernet ether-type eq ip & ip dst-ip eq 10.10.10.1 &
action deny
Extreme-Dynamic-ACL = acl set default-action deny
```

When the switch receives a new VSA with ACL and Access Control Entries (ACE) rules from the RADIUS server, the switch dynamically creates the ACL infrastructure based on the following:

- Dynamic ACLs - the switch allocates one dynamic ACL for each EAP enabled port. You cannot manually configure the dynamic ACL. The dynamic behavior of the ACL depends on the EAP port state (MHMV or MHSA). RADIUS Dynamic User-Based Policies support the inPort and outPort ACL types. You can display the filter ACL configuration on the switch using the **`show filter acl`** command, to identify the source of ACL configuration (static or dynamic).
- Dynamic ACEs - after the switch configures an ACL as dynamic, the system automatically considers the ACEs in that ACL as dynamic. You cannot manually configure the ACEs in a dynamic ACL. When the switch receives an ACE rule from the RADIUS server, the system allocates an ACE ID to it. Each ACE rule carries a relative order that helps the switch to set priority for the ACE rules that the switch receives. For handling of Radius ACL rules, the switch parses the rules first. Based on the actions, the system classifies the rules as security ACEs or QoS ACEs. If the switch is unable to recognize the qualifiers or actions in a rule, then the switch ignores that rule.
- Multiple Host Multiple VLAN (MHMV) operating mode - the system authenticates each MAC that the switch receives on the EAP-enabled port and assigns the MAC to a specific VLAN or VLAN to I-SID binding. The system uses the VLAN to I-SID binding when Flex UNI is enabled on a port. The system processes the ACE rules that the switch receives from the RADIUS server on a per MAC basis, the system translates the default-action into an ACE rule with actions, deny or permit. When the switch processes the RADIUS VSAs, the system adds the MAC as a qualifier for each ACE rule.
- Multiple Host Single Authentication (MHSA) operating mode - the system processes the ACE rules that it receives from the RADIUS server on a per port basis.

NEAP host

The following section provides information about NEAP hosts on EAP-enabled ports and RADIUS authentication.

NEAP Hosts on EAP Enabled Ports

For an EAP-enabled port configured for NEAP host support, devices with MAC addresses getting authenticated are allowed access to the port.

The switch allows the following types of NEAP users:

- NEAP hosts whose MAC addresses are authenticated by RADIUS.

Support for NEAP hosts on EAP-enabled ports is primarily intended to accommodate printers and other passive devices sharing a hub with EAP clients.

Support for NEAP hosts on EAP-enabled ports includes the following features:

- Authenticated NEAP clients are hosts that satisfy one of the following criteria:
  - Host MAC address is authenticated by RADIUS.
- NEAP hosts are allowed even if no authenticated EAP hosts exist on the port.

- When a new host is seen on the port, NEAP authentication is performed as follows:
  - The switch generates a <username, password> pair, which it forwards to the network RADIUS server for authentication.

NEAP MAC RADIUS Authentication

For RADIUS authentication of a NEAP host MAC address, the switch generates a <username, password> pair as follows:

- The username is the NEAP MAC address in string format.
- The password is a string that combines the switch IP address, MAC address, port number and user-configurable key string. If padding option is enabled, the system will specify a dot(.) for every missing parameter. IP address is represented by three decimal characters per octet.

Important

Follow these Global Configuration examples to select a password format that combines one or more of these three elements:

- Padding enabled , password = 010010011253..05. (when the switch IP address and port are used).
- Padding enabled, password = 010010011253... (when only the switch IP address is used).
- No padding (default option). Password = 000011220001 (when only the user's MAC address is used).

The following example illustrates the <username, password> pair format with no padding enabled and using the IP address, MAC address, and key-string as the password.

```
switch IP address = 192.0.2.5
non-EAP host MAC address = 00 C0 C1 C2 C3 C4
port = 25
Key-String = abcdef
```

- username = 00C0C1C2C3C4
- password = 010010011253.00C0C1C2C3C4.25.abcdef

Use the command **show eapol system** to verify the formatting.

```
Switch:1>show eapol system

================================================================================================
                                    Eapol System
================================================================================================
                       eap : enabled
             Eapol Version : 3
          non-eap-pwd-fmt : mac-addr
      non-eap-pwd-fmt key : ******
  non-eap-pwd-fmt padding : disabled
  auto-isid-offset status : disabled
   auto-isid-offset value : 15980000
```

NEAP client

The following section provides information for NEAP client.

NEAP Client Re-Authentication

The NEAP client re-authentication feature supports the re-authentication of NEAP clients at defined intervals.

When you enable NEAP client re-authentication, an authenticated NEAP client is only removed from the authenticated client list if you remove the client account from the RADIUS server, or if you clear the NEAP authenticated client from the switch.

If an authenticated NEAP client does not generate traffic on the network, the system removes the MAC address for that client from the MAC address table when MAC ages out. Although the system does not display the client MAC address in the MAC Address table and it can display the client as an authenticated client.

If you enable NEAP client re-authentication and the RADIUS server that the switch connects to becomes unavailable, the system clears all authenticated NEAP and removes those clients from the switch NEAP client list.

You cannot authenticate one NEAP client on more than one switch port simultaneously. If you connect NEAP clients to a switch port through a hub, those clients are authenticated on that switch port. If you disconnect a NEAP client from the hub and connect it directly to another switch port, the client is authenticated on the new port and its authentication is removed from the port to which the hub is connected.

MAC Move for Authenticated Non-EAP Clients

When you move a Non-EAP client that is authenticated on a specific port, to another port on which EAPoL or Non-EAP is enabled, MAC move of the client to the new port does not automatically happen. This is as designed.

As a workaround, do one of the following:

- Clear the non-EAP session on the port that the client is first authenticated on, before you move the client to another port.
- Create a VLAN on the switch with the same VLAN ID as that dynamically assigned by the RADIUS server during client authentication. Use the command **`vlan create <2-4059> type port-mstprstp <0-63>`**. Ensure that the new port is a member of this VLAN.

NEAP MAC Learning and Authentication

The system learns the MACs based on the I-SID to MAC binding. When a packet ingresses on a port, which is associated with Switched UNI (S-UNI) I-SID, the system performs MAC look up based on the I-SID. The RADIUS server provides the VLAN:I-SID assignment.

Important
If the default untagged S-UNI is used, you must have a platform VLAN associated with it. This is required to properly transmit traffic and to generate MAC learning events for traffic sent to MAC-based S-UNIs.

When an untagged S-UNI is present on the port, the untagged MAC is initially learned on that S-UNI. When an untagged S-UNI does not exist on the port, the untagged MAC is learned on a special (internal) VLAN. The RADIUS server provides the VLAN:I-SID assignment.

MAC learning for tagged traffic occurs only if there is a tagged S-UNI with the corresponding C-VID on that port. The RADIUS server reconfirms the S-UNI that performed MAC learning.

EAP and NEAP Limitations

The EAP and NEAP MAC clients on port limits the maximum number of all EAP and NEAP clients per port. EAP and NEAP MAC clients on port enhancements independently limits the EAP and NEAP clients per port.

The following enhancements are added:

- EAP-MAC-MAX : Limits the total number of EAP clients
- NON-EAP-MAC-MAX: Limits the total number of NEAP clients

Note

Do not connect more than 100 EAP and 100 NEAP devices on the switch.

EAP and NEAP mac-max Settings

The total number of EAP clients can be set between 0 and 32, while the total number of NEAP clients can be set between 0 and 8192.

Note

EAP-MAC-MAX is overwritten by MAC-MAX. Even if EAP-MAC-MAX is set to a higher limit, then MAC-MAX must not exceed and you must not authenticate more than MAC-MAX clients.

Note

NON-EAP-MAC-MAX is overwritten by MAC-MAX. Even if NON-EAP-MAC-MAX is set to a higher limit, then MAC-MAX must not exceed and you must not authenticate more than MAC-MAX clients.

Example Scenarios

1. Scenario 1:
   - EAP-MAC-MAX 32
   - NON-EAP-MAC-MAX 32
   - MAC-MAX 10

   In this scenario, there are ten EAP and NEAP authenticated clients, in the order of authentication.
2. Scenario 2:
   - EAP-MAC-MAX 1
   - NON-EAP-MAC-MAX 1
   - MAC-MAX 1

   In this scenario, only one EAP or one NEAP client is authenticated, in the order of authentication.
3. Scenario 3:
   - EAP-MAC-MAX 5
   - NON-EAP-MAC-MAX 10
   - MAC-MAX 32

In this scenario, up to five EAP clients and ten NEAP clients are allowed.

4. Scenario 4:
   - EAP-MAC-MAX 5
   - NON-EAP-MAC-MAX 8
   - MAC-MAX 7

   In this scenario, up to five EAP clients and seven NEAP clients are allowed. The total number of EAP or NEAP clients is limited to seven.

Multiple Host Single Authentication

Multiple Host Single Authentication (MHSA) allows MACs to access the network without EAP and NEAP authentication. Unauthenticated devices can access the network only after an EAP or NEAP client is successfully authenticated on a port. The VLAN to which the devices are allowed is the client authenticated VLAN. Unless Guest VLAN is configured, there is no authenticated client on the port, and no MAC is allowed to access the network.

MHSA is primarily intended to accommodate printers and other passive devices sharing a hub with EAP and NEAP clients.

MHSA support is on a port-by-port basis for EAP enabled ports.

MHSA supports the following functionality:

- The port remains unauthorized when no authenticated hosts exist on the port. Before the first successful authentication occurs, both EAP and NEAP clients are allowed to negotiate access on that port but only one host is allowed to perform authentication.
- In MHSA mode, QoS level is configured when processing the Port-Priority attribute, because there can only be one authenticated client. The devices behind the authenticated client use the port priority established by the main client.
- In MHSA mode, the Guest VLAN applies only when no authenticated client is present on the port.
- After the first EAP or NEAP client successfully authenticates on a port, other clients cannot negotiate authentication on that port.
- After the first successful authentication, MACs that are already learned on that port is flushed.
- NEAP clients are not removed at age event in MHSA mode.
- There is no limit to the number of MACs that are allowed after first successful authentication.

EAP and NEAP MAC Clients on a Port with MHSA

EAP and NEAP client counters, such as MAC-MAX, EAP-MAC-MAX, and NON-EAP-MAC-MAX do not apply when the port operates in MHSA mode. In MHSA mode, there can be only one authenticated client (EAP or NEAP). Subsequent MACs seen on the port are allowed automatically without authentication.

Guest VLAN

Guest VLAN support provides limited network access until the client is authenticated. Guest VLAN is configured irrespective of the number of authenticated clients present on the port. Guest VLAN is

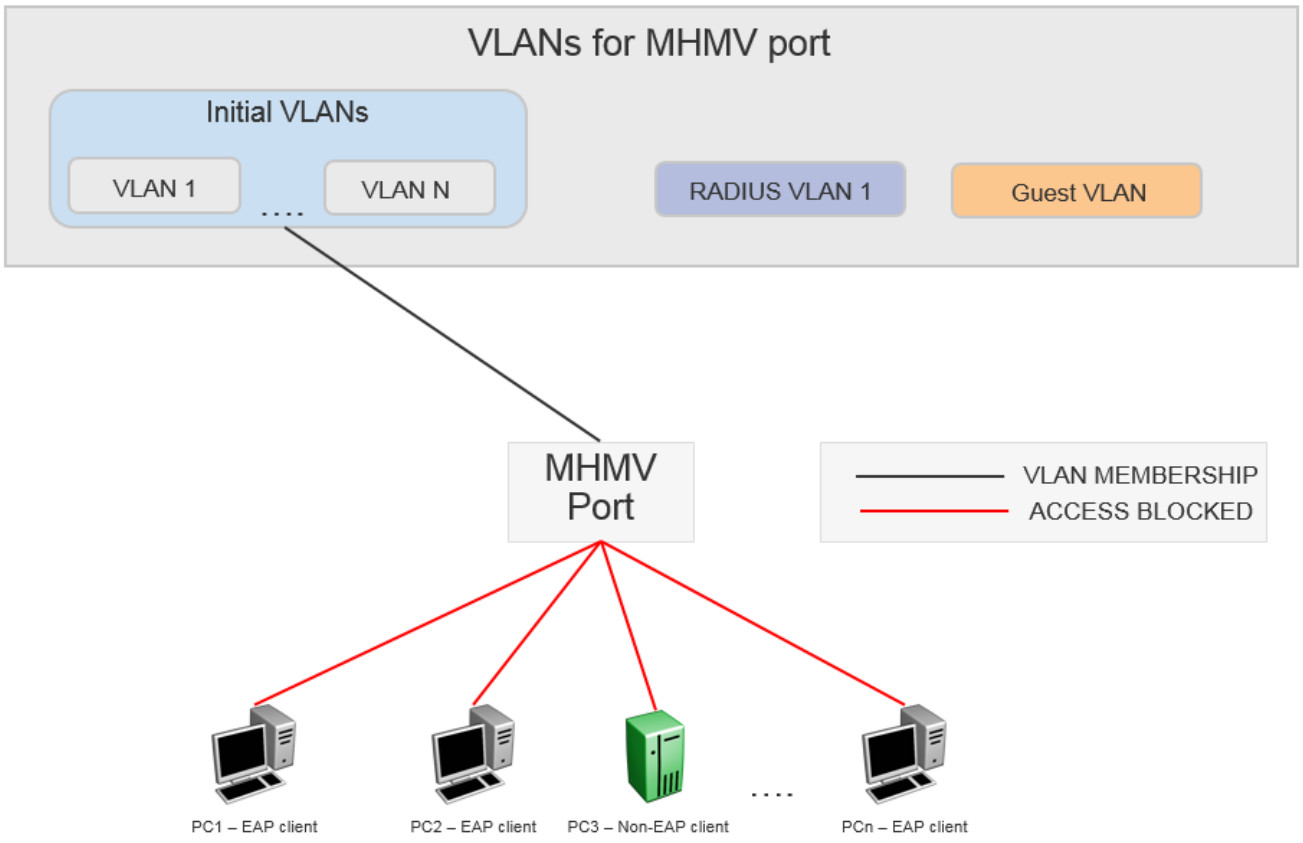
available for each port. Only port based VLANs are used as Guest VLANs. When the Guest VLAN is active, port is added to the VLAN ID, and port default VLAN ID changes to Guest VLAN ID.

Guest VLAN on a MHMV Port Usage Scenario

The following example illustrates the configuration of Guest VLAN support with an EAP MHMV port:

- Clients connect to a switch port through a hub.
- The initial VLANs are the VLANs on which the ports resides after a switch reboot.
- EAP is enabled.
- The port is a member of initial VLANs. The clients cannot access the VLANs since the VLANs are not authenticated. The port default VLAN ID corresponds to one of the initial VLAN IDs.
- Guest VLAN support is not activated.

The following figure represents the functionality when clients are not authenticated.



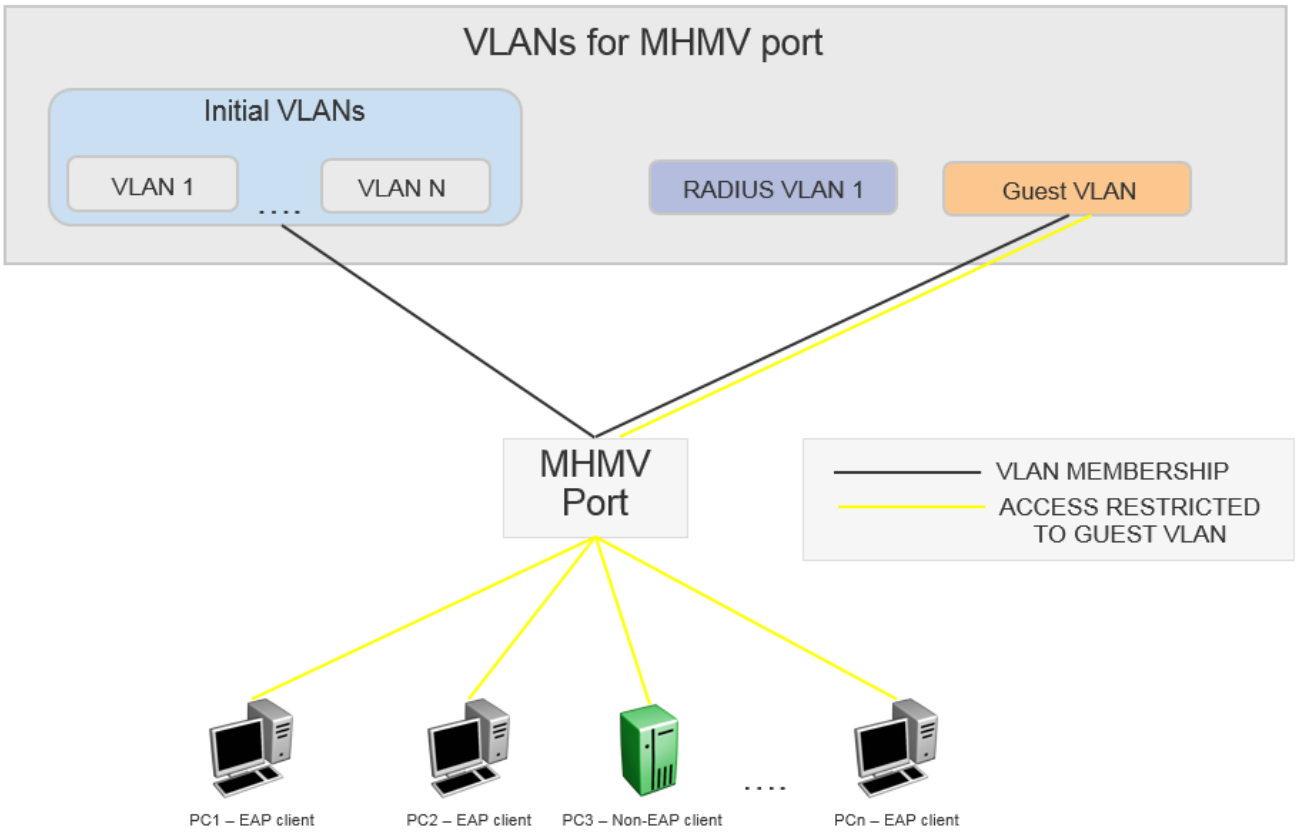
Note

The clients cannot access the network as they are not authenticated and Guest VLAN is not configured.

- Guest VLAN support is activated.
- The MHMV port is in the initial VLAN stage but gets added to the Guest VLAN ID. The default VLAN ID is updates to correspond to the Guest VLAN ID.

- All Clients behind the port can access the Guest VLAN.

The following figure represents the functionality when Guest VLAN is activated.

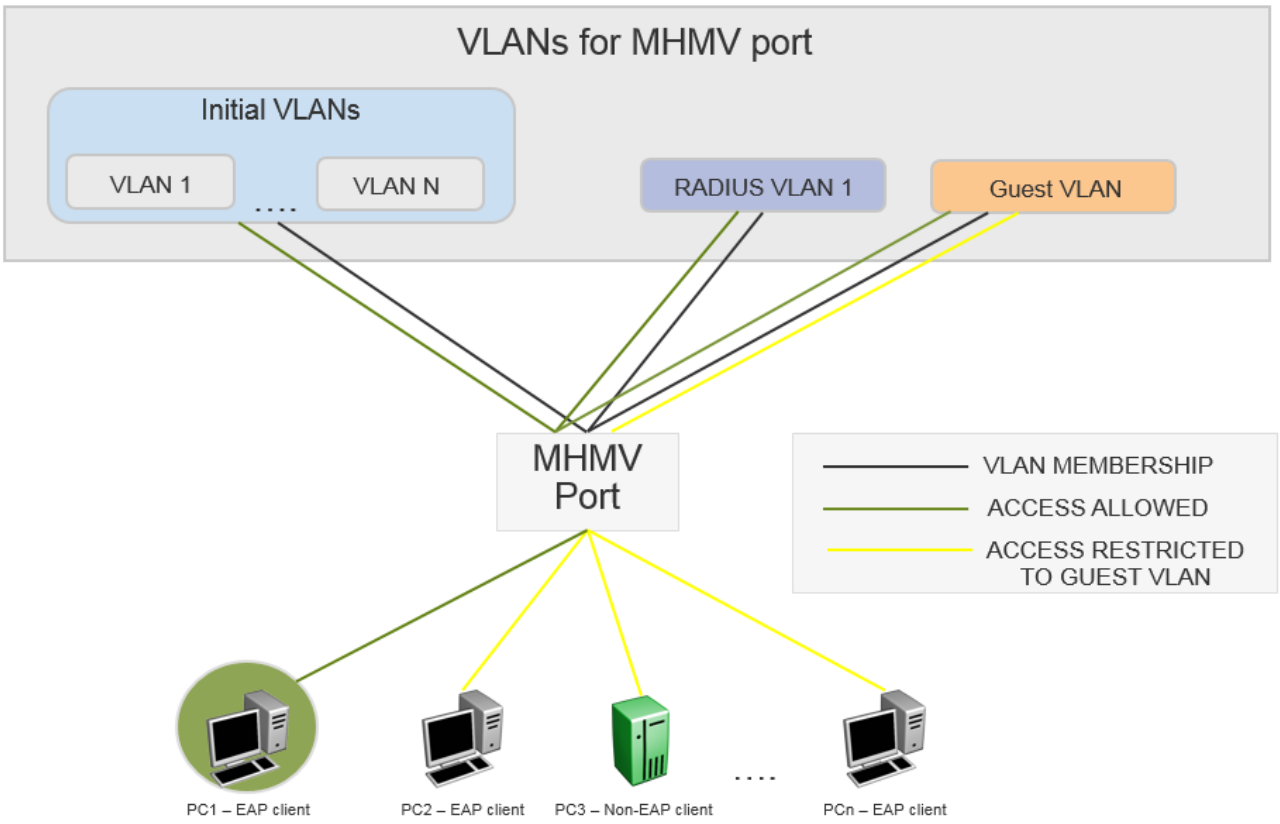


Note

All clients have Guest VLAN access.

- A client behind the MHMV port gets authenticated. For this usage scenario let us consider PC1 as the authenticated client.
- The port default VLAN ID is equal to the Guest VLAN ID and remains unchanged.
- The port is copied into the RADIUS assigned VLAN (if any).
- The untagged traffic that originates from PC1 (identified by MAC address) can access only the RADIUS assigned VLAN or the initial port default VLAN ID, if the RADIUS VLAN attribute is missing.
- The remaining clients that send untagged traffic are unauthenticated devices. The unauthenticated devices can access only the Guest VLAN because the port VLAN ID is equal to the Guest VLAN ID.
- The initial VLANs are accessed by the following devices:
  - Authenticated devices that are missing RADIUS VLAN attributes.
  - Authenticated devices that send corresponding tagged packets.
- When another client gets authenticated, the authenticated client undergoes the same process as PC1.

The following figure represents the functionality when a client gets authenticated:



Note

PC1 is authenticated with RADIUS VLAN 1. The remain clients have guest VLAN access.

When a client disconnects the following happens:

- The MAC VLAN rule is removed from the switch.
- If the RADIUS VLAN attribute was used with the client was authenticated and no other clients are authenticated on that RADIUS VLAN, then the port is removed from the VLAN. If other clients are authenticated on that RADIUS VLAN, then the VLAN MAC rule is deleted.
- If RADIUS VLAN attribute is not used when the client is authenticated, then only the VLAN MAC rule is deleted.

Guest VLAN on a MHSA Port Usage Scenario

The following is a usage example when Guest VLAN is configured with an EAP MHSA port:

- There are no authenticated EAP or NEAP clients on a port.
- The port is removed from the initial VLANs and moved to Guest VLAN ID.
- The default port VLAN ID changes to Guest VLAN ID.
- All MACs seen on the port have Guest VLAN access.
- Port is removed from the Guest VLAN ID.
- If no RADIUS assigned VLAN is present, then the VLAN membership and the default port VLAN ID is restored to default settings.

- If the RADIUS assigned VLAN is present, then the VLAN membership and the default port VLAN ID is changed according to its value.
- Guest VLAN loses its purpose because all MACs are allowed automatically without authentication

In MHSA mode, the Guest VLAN applies only when no authenticated client is present on the port.

Guest I-SID

Guest I-SID support provides limited network access until the client is authenticated. The switches uses the Guest I-SID to forward traffic until the client authenticates and receives other VLAN:ISID bindings from the RADIUS server.

Guest I-SID is a per-port option. You must configure an I-SID either as a C-VLAN or as an ELAN with an associated platform VLAN before you can configure it as the Guest I-SID. After you configure the Guest I-SID and you enable EAP, an untagged S-UNI is created based on the supplied I-SID. When you change the Guest I-SID while EAP is enabled, the untagged S-UNI is replaced on the port.

In MHSA mode, only one untagged S-UNI can exist on a port at one time. Consider the following:

- If there is a manually configured untagged S-UNI on the port, the untagged S-UNI, which uses the Guest I-SID replaces it.
- If the RADIUS server provides an untagged S-UNI after the client is authenticated, it replaces the untagged S-UNI, which was created based on the Guest I-SID.
- If the Guest I-SID is removed, the previous manually configured untagged S-UNI is automatically restored.
- If the RADIUS-assigned untagged S-UNI is no longer present, EAP recreates the untagged S-UNI created base on the Guest I-SID.

In MHMV mode, the untagged S-UNIs provided by the RADIUS server are treated as MAC-based untagged S-UNIs, which are different from the untagged S-UNI on the port. Consider the following factors:

- If there is a manually configured untagged S-UNI on the port, the untagged S-UNI, which uses the Guest I-SID, replaces it.
- If the Fail-Open I-SID and the Guest I-SID are both configured, the Guest I-SID is applied, as long as a RADIUS server is reachable.
- If the RADIUS server becomes unreachable, the untagged S-UNI based on the Fail-Open I-SID is removed and the untagged S-UNI is created based on the Guest I-SID.

EAP and NEAP separation

EAP and NEAP separation provide the ability to have only NEAP clients allowed on one port. This is done by allowing eap-mac-max to be set to 0. This enhancement gives you the ability to disable EAP clients authentication without disabling NEAP clients. There are no additional configuration commands. For more information, see Configuring maximum EAP clients on page 733 and Configuring maximum NEAP clients on page 734.

EAP and NEAP VLAN names

VLAN names configures VLAN membership of EAP and NEAP clients. You do not have to configure this feature as this mode is always enabled by default.

Fail Open VLAN with Continuity Mode

Fail Open VLAN provides network connectivity when the switch cannot connect to a RADIUS server. If an authentication failure occurs that is based on a RADIUS timeout, the port immediately transitions to the Fail Open VLAN.

Note

Prior to releases that support Continuity Mode, transition to the Fail Open VLAN is based on interval-based RADIUS server reachability checks. If the RADIUS server is reachable, the switch continues to check the reachability at a default interval of three minutes. This interval-based check can lead to a transition delay of up to three minutes, from the moment when the RADIUS Server becomes unreachable until the port moves to the Fail Open VLAN.

If the switch cannot connect to the primary and secondary RADIUS servers, then after a specified number of attempts to restore connectivity, the switch declares the RADIUS servers unreachable.

Fail Open VLAN provides the below functionality:

- When the EAP RADIUS servers are not reachable, Fail Open VLAN provides restricted access to devices, which is separate from the Guest VLAN.
- The EAP and NEAP clients are not affected when the RADIUS servers are not reachable.

To use Fail Open VLAN:

- Fail Open VLAN is a per-port configuration.
- Enable Fail Open VLAN by configuring a valid Fail Open VLAN ID and configure the selected VLAN ID on the switch.
- Use only port-based VLANs as Fail Open VLANs.

When you configure Fail Open VLAN on a port and the RADIUS servers are not reachable, then the Fail Open VLAN provides the following functionality:

- The port is removed from Guest VLAN, if configured, but all other VLAN membership is kept and the port is added to the Fail Open VLAN.
- The default VLAN ID is changed to the Fail Open VLAN ID.
- Traffic from the authenticated EAP and NEAP clients are forwarded as before.
- If re-authentication is enabled in Fail Open VLAN mode, then EAP and NEAP clients stop performing re-authentication.
- All new MACs seen on the port are considered as potential EAP and NEAP clients and are granted Fail Open VLAN access.

When at least one RADIUS server recovers, all EAP-enabled ports are removed from the Fail Open VLAN. All unauthenticated MACs are flushed to give the MACs an opportunity to authenticate.

Fail Open VLAN with Guest VLAN scenarios

When an EAP port is configured with both Fail Open VLAN and Guest VLAN, consider the following scenarios:

1. EAP port operating in MHMV mode:
   - If the EAP RADIUS servers are reachable, then all the authenticated clients have Guest VLAN ID access.
   - If the EAP RADIUS servers are not reachable, then Guest VLAN must be removed from the port completely. The Fail Open VLAN is the new default VLAN. All unauthenticated MACs have Fail Open VLAN access.
2. EAP port operating in MHSA mode:
   - Fail Open VLAN has no impact on the Guest VLAN functionality in MHSA mode.

Fail Open I-SID with Continuity Mode

Fail Open I-SID provides network connectivity with restricted access to devices when the switch cannot connect to a RADIUS server. If a failure occurs that is based on a RADIUS timeout, the port immediately transitions to the Fail Open I-SID.

Note

Prior to releases that support Continuity Mode, transition to the Fail Open I-SID is based on interval-based RADIUS server reachability checks. If the RADIUS server is reachable, the switch continues to check the reachability at a default interval of three minutes. This interval-based check can lead to a transition delay of up to three minutes, from the moment when the RADIUS Server becomes unreachable until the port moves to the Fail Open I-SID.

Note

EAP and NEAP clients are not affected when the RADIUS servers are unreachable.

To use Fail Open I-SID:

- Fail Open I-SID is a per-port configuration.
- You must configure an I-SID either as a C-VLAN or as an ELAN with an associated platform VLAN before you can configure it as the Fail-Open I-SID.
- After you configure the Fail Open I-SID and you enable EAP, an untagged S-UNI is created based on the supplied I-SID. When you change the Fail Open I-SID while EAP is enabled, the untagged S-UNI is replaced on the port.

Note

Fail Open I-SID is not supported in MHSA mode.

In MHMV mode, the untagged S-UNIs provided by the RADIUS server are treated as MAC-based untagged S-UNIs, which are different from the untagged S-UNIs on the port. Consider the following factors:

- If there is a manually configured untagged S-UNI on the port, the untagged S-UNI, which uses the Fail Open I-SID, replaces it.

- Caution is advised when both Fail-Open I-SID and Guest I-SID are configured. In this scenario, if a RADIUS server becomes reachable, the untagged S-UNI created based on the Fail-Open I-SID is removed and another untagged S-UNI based on the Guest I-SID is created.

EAP Auto-ISID-Offset

EAP auto-isid-offset functionality is used for MACs that do not receive an I-SID attribute from the RADIUS server. The configured I-SID offset value is used to calculate an I-SID value for a Switched UNI (S-UNI) when the switch receives only the VLAN attribute from the RADIUS server (not the FA VLAN:I-SID binding). In that case, the I-SID value is calculated as follows: I-SID = VLAN ID + configured I-SID offset value.

Wake On LAN

Wake On LAN (WoL) networking standard enables remotely powering-up a shutdown computer from a sleeping state. In this process, the computer is shutdown with power reserved for the network card. A packet known as Magic Packet is broadcast on the local LAN or subnet. The network card on, receiving the Magic Packet, verifies the information. If the information is valid, the network card powers-up the shutdown computer.

The WoL Magic Packet is a broadcast frame sent over a variety of connectionless protocols, such as UDP. The most commonly used connectionless protocol is UDP. The Magic Packet contains data that is a defined constant represented in hexadecimal as FF:FF:FF:FF:FF:FF, followed by 16 repetitions of the target computer MAC address and possibly by a four or six byte password.

If you implement enhanced network security using 802.1X, the transmission of Magic Packets to sleeping or unauthorized network devices is blocked. You can use an interface specific 802.1X feature known as traffic-control to address this requirement of supporting both WoL and 802.1X Authentication simultaneously. The default mode is *in-out*. This mode blocks both ingress and egress unauthenticated traffic on an 802.1X port. Configuring the traffic control mode to *in* enables the transmission of Magic Packets to sleeping or unauthenticated devices. This mode allows any network control traffic, such as a WoL Magic Packet, to be sent to a workstation irrespective of the authentication or sleep status.

Important

If a PC client is assigned to a VLAN based on a previous RADIUS Assigned VLAN, when the client goes into sleep or hibernation mode it reverts to either the default port-based VLAN or Guest VLAN configured for that port. Therefore, the WoL Magic Packet must be sent to the default VLAN or Guest VLAN.

EAPoL Configuration Using CLI

EAPoL (EAP) uses RADIUS protocol for EAP-authorized logons. RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration.

Before configuring your device, you must configure at least one EAP RADIUS server and shared secret fields.

You cannot configure EAP on ports that are currently configured for:

- Shared segments
- MultiLink Trunking (MLT)

Change the status of each port that you want to be controlled to auto. The auto setting automatically authenticates the port according to the results of the RADIUS server. The default authentication setting for each port is authorized.

Globally enabling EAP on the device

Enable EAP globally on the switch before you enable it on a port or interface.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Globally configure EAP:

   ```
   eapol enable
   ```

Example

Enable EAP globally:

```
Switch:1> enable
Switch:1#config t
Switch:1(config)#eapol enable
```

Configure EAP on an Interface

Configure EAP on an interface.

Before You Begin

- EAP must be globally enabled.

About This Task

When you configure a port with the EAP status of auto (Authorization depends on result of EAP authentication), only one supplicant is allowed on this port. Multiple EAP supplicants are not allowed on the same physical switch port.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable EAP on an interface:

   ```
   eapol status {authorized|auto}
   ```

3. Disable EAP on on interface:

   ```
   no eapol status
   ```

Examples

Enable EAP on an interface:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface GigabitEthernet 1/2
Switch:1(config-if)# eapol status auto
```

Disable EAP on an interface:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface GigabitEthernet 1/2
Switch:1(config-if)# no eapol status
```

Variable Definitions

The following table defines parameters for the **`eapol status`** command.

Variable	Value
`authorized`	Specifies that the port is always authorized. The default value is authorized.
`auto`	Specifies that port authorization depends on the results of the EAP authentication by the RADIUS server. The default value is authorized.

Configuring EAP on a port

Configure EAP on a specific port when you do not want to apply EAP to all of the switch ports.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the maximum EAP requests sent to the supplicant before timing out the session:

   ```
   eapol port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} max-
   request <1-10>
   ```

3. Configure the time interval between authentication failure and the start of a new authentication:

   ```
   eapol port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
   quiet-interval <1-65535>
   ```

4. Enable reauthentication:

   ```
   eapol port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} re-
   authentication enable
   ```

5. Configure the time interval between successive authentications:

   ```
   eapol port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} re-
   authentication-period <1-65535>
   ```

6. Configure the EAP authentication status:

   ```
   eapol port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
   status {authorized|auto}
   ```

Example

Configure the maximum EAP requests sent to the supplicant before timing out the session:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface GigabitEthernet 1/2
Switch:1(config-if)#eapol max-request 10
Switch:1(config-if)#eapol port 1/2 quiet-interval 500
```

Variable Definitions

The following table defines parameters for the **eapol port** command.

Variable	Value
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Specifies the port or list of ports used by EAP. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
max-request <1-10>	Specifies the maximum EAP requests sent to the supplicant before timing out the session. The default is 2.
quiet-interval <1-65535>	Specifies the time interval in seconds between the authentication failure and start of a new authentication. The default is 60.
re-authentication enable	Enables reauthentication of an existing supplicant at a specified time interval.
re-authentication-period <60-65535>	Specifies the time interval in seconds between successive reauthentications. The default is 3600 (1 hour).
status {authorized|auto}	Specifies the desired EAP authentication status for this port.

Configure an EAP-enabled RADIUS Server

The switch uses RADIUS servers for authentication and accounting services. Use the no form to delete a RADIUS server.

Before You Begin

- You must enable EAP globally.

About This Task

The RADIUS server uses the secret key to validate users.

RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Add an EAP-enabled RADIUS server:

   ```
   radius server host WORD <0-46> used-by eapol acct-enable

   radius server host WORD <0-46> used-by eapol acct-port <1-65536>

   radius server host WORD <0-46> used-by eapol enable

   radius server host WORD <0-46> used-by eapol key WORD<0-20>

   radius server host WORD <0-46> used-by eapol port <1-65536>

   radius server host WORD <0-46> used-by eapol priority <1-10>

   radius server host WORD <0-46> used-by eapol retry <0-6>

   radius server host WORD <0-46> used-by eapol secure-enable

   radius server host WORD <0-46> used-by eapol secure-log-level

   radius server host WORD <0-46> used-by eapol secure-mode

   radius server host WORD <0-46> used-by eapol secure-profile

   radius server host WORD <0-46> used-by eapol timeout <1-180>
   ```

   By default, the switch uses RADIUS UDP port 1812 for authentication, and port 1813 for accounting. You can change the port numbers or other RADIUS server options.

Example

Add an EAP RADIUS server:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#radius server host fe80:0:0:0:21b:4fff:fe5e:73fd key radiustest used-
by eapol
```

Variable Definitions

The following table defines parameters to configure an EAP-enabled RADIUS server with the **`radius server host`** command.

Variable	Value
host WORD<0-46>	Specifies the IP address of the selected server. RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration.
WORD<0-20>	Specifies the secret key, which is a string of up to 20 characters.

The following table defines parameters to use optional arguments of the **radius server host** command.

Variable	Value
port <1-65535>	Specifies the port ID number.
priority <1-10>	Specifies the priority number. The lowest number is the highest priority.
retry <0-6>	Specifies the retry count of the account.
timeout <1-180>	Specifies the timeout of the server. The default is 30.
enable	Enables the functions used by the RADIUS server host.
acct-port <1-65536>	Specifies the port account.
acct-enable	Enables the account.
secure-enable	Enable secure mode on the server.
secure-log-level	Specifies the RADIUS secure server log severity level. Possible values are: • critical • debug • error • info • warning
secure-mode	Specifies the protocol for establishing the secure connection with the server.
secure-profile	Specifies the secure profile name.

Configure the Switch for EAP and RADIUS

Perform the following procedure to configure the switch for EAP and RADIUS.

About This Task

You must configure the switch, through which user-based-policy (UBP) users connect to communicate with the RADIUS server to exchange EAP authentication information, as well as user role information. You must specify the IP address of the RADIUS server, as well as the shared secret (a password that authenticates the device with the RADIUS server as an EAP access point). You must enable EAP globally on each device, and you must configure EAP authentication on each device port, through which EAP/UBP users connect.

RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration.

For more information about EPM and UBP, see the user documentation for your Enterprise Policy Manager (EPM) application.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Create a RADIUS server that is used by EAP:

   ```
   radius server host WORD <0-46> key WORD<0-20> used-by eapol
   ```

3. Log on to the Interface Configuration mode:

   ```
   interface vlan <1-4059>
   ```

4. Enable the device to communicate through EAP:

   ```
   eapol enable
   ```

5. Exit from VLAN interface mode:

   ```
   exit
   ```

6. Enter Interface Configuration mode:

   ```
   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

7. Enable device ports for EAP authentication:

   ```
   eapol port {slot/port[/sub-port][-slot/port[/sub-port]][,...]} status
   auto
   ```

8. Enable periodic supplicant re-authenticating:

   ```
   eapol port {slot/port[/sub-port][-slot/port[/sub-port]][,...]} re-
   authentication enable
   ```

9. Save your changes:

   ```
   save config
   ```

Example

```
Switch:1> enable

Switch:1# configure terminal
```

Create a RADIUS server that is used by EAP:

```
Switch:1(config)# radius server host fe90:0:0:0:21b:4eee:fe5e:75fd key
radiustest used-by eapol

Switch:1(config)# interface vlan 2
```

Enable the device to communicate through EAP:

```
Switch:1(config-if)# eapol enable
```

Save your changes:

```
Switch:1(config-if)# save config
```

Variable Definitions

The following table defines parameters for the **radius server host WORD<0-46> usedby eapol** command.

Variable	Value
host WORD<0-46>	Specifies the IP address of the selected server. This address tells the device where to find the RADIUS server, from which it obtains EAP authentication and user role information. RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration.
key WORD<0-20>	Specifies the shared secret key that you use for RADIUS authentication. The shared secret is held in common by the RADIUS server and all EAP-enabled devices in your network. It authenticates each device with the RADIUS server as an EAP access point. When you configure your RADIUS server, you must configure the same shared secret value as you specify here.

Change the Authentication Status of a Port

The switch authorizes ports by default, which means that the ports are always authorized and are not authenticated by the RADIUS server.

You can also make the ports controlled so that they are dependent on being authorized by the Radius Server when you globally enable EAP (auto).

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the authorization status of a port:

   ```
   eapol status {authorized|auto}
   ```

Example

Configure the authorization status of a port:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface GigabitEthernet 3/1
Switch:1(config-if)#eapol status auto
```

Variable Definitions

The following table defines parameters for the **`eapol status`** command.

Variable	Value
`authorized`	Specifies that the port is always authorized. The default value is authorized.
`auto`	Specifies that port authorization depends on the results of the EAP authentication by the RADIUS server. The default value is authorized.

Deleting an EAP-enabled RADIUS server

Delete an EAP-enabled RADIUS server if you want to remove the server.

About This Task

RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Delete an EAP-enabled RADIUS server:

   ```
   no radius server host WORD<0-46> used-by eapol
   ```

Example

```
Switch:1> enable

Switch:1# configure terminal

Switch:1(config)# no radius server host fe79:0:0:0:21d:4fdf:fe5e:73fd
used-by eapol
```

Variable Definitions

The following table defines parameters for the **radius server host WORD<0-46> usedby eapol** command.

Variable	Value
host WORD<0-46>	Specifies the IP address of the selected server. This address tells the device where to find the RADIUS server, from which it obtains EAP authentication and user role information. RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration.
key WORD<0-20>	Specifies the shared secret key that you use for RADIUS authentication. The shared secret is held in common by the RADIUS server and all EAP-enabled devices in your network. It authenticates each device with the RADIUS server as an EAP access point. When you configure your RADIUS server, you must configure the same shared secret value as you specify here.

Configuring Fail Open VLAN

About This Task

Use this procedure to configure Fail Open VLAN.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure Fail Open VLAN:

   ```
   eapol fail-open-vlan <1-4059>
   ```

Example

Configure the Fail Open VLAN.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config)#eapol fail-open-vlan 10
```

Variable Definitions

The following table defines parameters for the **eapol fail-open-vlan** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.

Display the Current EAP-Based Security Status

Use the following procedure to display the status of the EAP-based security.

Procedure

1. Enter Privileged EXEC mode:
   `enable`
2. Display the current EAP-based security status:
   - `show eapol auth-stats interface [gigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]`
   - `show eapol port {interface [gigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}] | {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}}`
   - `show eapol session-stats interface [gigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]`
   - `show eapol sessions {eap | neap} [vlan <1-4059>] [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} [verbose]`
   - `show eapol summary port [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]`
   - `show eapol system`

Examples

```
Switch:>enable
Switch:1#config terminal
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#show eapol port 1/2

Variable Definitions

The following table defines parameters for the **show eapol** command.

Variable	Value
auth-stats [gigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]	Displays the authentication statistics interface. Note: *auth-stats [gigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]* is useful only for EAP supplicants. The command output changes only when the EAP supplicant tries to access the network.
port {interface [gigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]|{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}}	Specifies the ports to display. If no port is entered, all ports are displayed.

Variable	Value
session-stats interface [gigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]	Displays the authentication session statistics interface.
sessions {eap | neap} [vlan<1-4059>][{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}] [verbose]	Displays EAP and non-EAP authentication sessions on the port.
summary port[*{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}*]	Displays EAP and NEAP clients.
system	Displays EAP settings.

Displaying the port VLAN information

Use the following procedure to display the port VLAN information.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Display the port VLAN information:

   ```
   show interfaces [gigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}] [vlan <1-4059>]
   ```

Example

```
Switch:#enable
Switch:1#show interfaces gigabitethernet vlan
================================================================================
                                  Port Vlans

1/2   enable  false   false     1       1,3,10       normal   disable  P        1,10
1/3   enable  false   false     1       1,10,20      normal   disable  P
```

Variable Definitions

The following table defines parameters for the **show interfaces** command.

Variable	Value
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.

Configuring the format of the RADIUS password attribute when authenticating NEAP MAC addresses using RADIUS

Use the following procedure to configure the format of the RADIUS password when authenticating NEAP MAC addresses using RADIUS.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the RADUIS password format:

   ```
   eapol multihost non-eap-pwd-fmt {[ip-addr] [key WORD<1-32>] [mac-addr] [padding] [port-number]}
   ```

Variable Definitions

The following table defines parameters for the **eapol multihost non-eap-pwd-fmt** command.

Variable	Value
ip-addr	Management ip-address of the switch.
key WORD<1-32>	Key value used for non-eap password format.
mac-addr	Mac-Address of the client.

Variable	Value
padding	Includes a dot in the RADIUS password for every missing parameter.
port-number	Index of the port on which MAC is received.

Note

To derive the port number for an interface, use the command **show interfaces gigabit [{slot/port[/sub-port][-slot/port[/sub-port]][,...]}]** .

If you configure interface 1/6 on the product, to derive the port-number for this interface, use the command **show interfaces gigabitEthernet 1/6**. From this command, you can ascertain that port number used in the NEAP password is 197.

```
Switch:1(config)# show interfaces gigabitEthernet 1/6

================================================================================================
                                     Port Interface
================================================================================================
PORT                              LINK  PORT           PHYSICAL          STATUS
NUM      INDEX DESCRIPTION        TRAP  LOCK     MTU   ADDRESS           ADMIN  OPERATE
------------------------------------------------------------------------------------------------
1/6      197   1000BaseTX         true  false    1950  f8:15:47:e1:dd:05 up     up
```

Enabling RADIUS authentication of NEAP hosts on EAP enabled ports

For RADIUS authentication of NEAP hosts on EAP-enabled ports, you must enable EAP globally on the switch and then enable NEAP hosts on the local interface.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable RADIUS authentication of NEAP hosts on the local interface:

   ```
   eapol multihost radius-non-eap-enable
   ```

Configuring the maximum MAC clients

Use this procedure to configure the maximum EAP and NEAP MAC clients supported on a port.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]}
   ```
   or `interface vlan <1-4059>`

   Note
   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Set the maximum limit of allowed EAP and NEAP MAC clients supported on the port:

   ```
   eapol multihost mac-max <1-8192>
   ```

Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface GigabitEthernet 1/16
Switch:1(config-if)# eapol multihost mac-max <1-8192>
```

Variable Definitions

The following table defines parameters for the **`eapol multihost mac-max`** command.

Variable	Value
mac-max <1-8192>	Specifies the maximum number of EAP and NEAP MAC addresses allowed on the port. The maximum limit is 8192 MAC addresses.

Configuring maximum EAP clients

About This Task

Use this procedure to configure the maximum EAP clients allowed on the port at one time.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]}
   ```

   Note
   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the maximum EAP clients:

   ```
   eapol multihost eap-mac-max <0-32>
   ```

   Note

   eap-mac-max is also used to provide EAP and NEAP separation functionality. By default the EAP clients are enabled per port and *eap-mac-max* limit is 2. If *eap-mac-max* is set to 0 then EAP client authentication is disabled.

Example

Configure the maximum EAP clients allowed on the port at one time.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config)#eapol multihost eap-mac-max 10
```

Variable Definitions

The following table defines parameters for the **eapol multihost eap-mac-max** command.

Variable	Value
<0-32>	Specifies the maximum EAP clients allowed on the port at one time. The default is 2.

Configuring maximum NEAP clients

About This Task

Use this procedure to configure the maximum NEAP clients allowed on the port at one time.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the maximum NEAP clients:

   ```
   eapol multihost non-eap-mac-max <0-8192>
   ```

   Note

   non-eap-mac-max is also used to provide EAP and NEAP separation functionality. By default the NEAP clients are enabled per port and *non-eap-mac-max* limit is 2. If *non-eap-mac-max* is set to 0 then NEAP client authentication is disabled.

Example

Configure the maximum NEAP clients allowed on the port at one time.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config)#eapol multihost non-eap-mac-max 10
```

Variable Definitions

The following table defines parameters for the **eapol multihost non-eap-mac-max** command.

Variable	Value
<0-8192>	Specifies the maximum NEAP clients allowed on the port at one time. The default is 2.

Configuring the Guest VLAN ID

About This Task

Use this procedure to configure the Guest VLAN ID.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the Guest VLAN ID:

   ```
   eapol guest-vlan <1-4059>
   ```

Example

Configure the Guest VLAN ID.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config)#eapol guest-vlan 10
```

Variable Definitions

The following table defines parameters for the **eapol guest-vlan** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.

Clearing NEAP session

Use this procedure to clear the NEAP session that is learnt on the switch.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Clear the NEAP session:

   ```
   clear eapol non-eap [<0x00:0x00:0x00:0x00:0x00:0x00>] [{slot/port[/
   sub-port][-slot/port[/sub-port]][,...]}
   <0x00:0x00:0x00:0x00:0x00:0x00>]
   ```

Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# clear 1/16 00:1b:63:84:45:e6
```

Variable Definitions

The following table defines parameters for the **clear eapol non-eap** command.

Variable	Value
{slot/port[/sub-port][-slot/port[/sub-port]][,...]}	Specifies the port list on which the NEAP MAC is learnt.
0x00:0x00:0x00:0x00:0x00:0x00	Specifies the MAC-Address on the NEAP session.

Configuring EAP operational mode

About This Task

Use this procedure to configure the EAP operational mode.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]}
   ```

   Note
   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. configure the EAP operational mode:

   ```
   eapol multihost eap-oper-mode {mhmv | mhsa}
   ```

   Note
   The default EAP operational mode is MHMV.

Example

Configure the EAP operational mode:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config)#eapol eap-oper-mode mhsa
```

Variable Definitions

The following table defines parameters for the **`eapol multihost eap-oper-mode`** command.

Variable	Value
mhmv	Specifies the EAP operational mode as Mutiple Host Multiple VLAN.
mhsa	Specifies the EAP operational mode as Mutiple Host Single Authentication.

Enabling dynamic changes to EAP sessions on a port

About This Task

Configure a port to allow dynamic changes to EAP sessions. The default is enable.

Before You Begin

You must enable EAP globally and at the port level.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]} or interface vlan <1-4059>
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable RADIUS dynamic authorization server processing requests.

   ```
   eapol radius-dynamic-server enable
   ```

Example

```
Switch:1>enable
Switch:1#config terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 1/4
Switch:1(config-if)#eapol radius-dynamic-server enable
```

Configure EAP auto-isid-offset

Before You Begin

- Enable EAP globally or on the port.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure an I-SID offset value:

   ```
   eapol auto-isid-offset <0-15995903>
   ```

3. Enable EAP globally:

   ```
   eapol enable
   ```

4. Confirm that your configuration is correct:

   ```
   show eapol system
   ```

Examples

Configure an I-SID offset value and enable I-SID offset globally on the switch:

```
Switch:1> enable
Switch:1#config terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#eapol auto-isid-offset 1000
Switch:1(config)#eapol enable
```

View the current device configuration:

```
Switch:1>show eapol system
================================================================================
                                 Eapol System
================================================================================
                     eap : disabled
           Eapol Version : 3
         non-eap-pwd-fmt : mac-addr
     non-eap-pwd-fmt key : ******
 non-eap-pwd-fmt padding : disabled
 auto-isid-offset status : disabled
 auto-isid-offset value  : 1000
```

Variable Definitions

The following table defines parameters for the **eapol auto-isid-offset** command.

Variable	Value
<0-15995903>	Specifies the auto I-SID offset value. The default is 15995903.
enable	Enables auto I-SID offset. The default is disabled.

Configure the Guest I-SID

Before You Begin

Configure a platform VLAN and associate the Guest I-SID. 0 indicates that Guest I-SID is not enabled for this port.

About This Task

Use this procedure to configure the Guest I-SID.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the Guest I-SID:

   ```
   eapol guest-isid <1-16000000>
   ```

Example

Configure the Guest I-SID.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 1/10
Switch:1(config-if)#eapol guest-isid 1000
```

Variable Definitions

The following table defines parameters for the **eapol guest-isid** command.

Variable	Value
<0–16000000>	Specifies the Guest I-SID value. 0 indicates that Guest I-SID is not enabled for this port.

Configure Fail Open I-SID

Before You Begin

Configure a platform VLAN and associate the Fail Open I-SID.

About This Task

Use this procedure to configure Fail Open I-SID. If the switch declares the RADIUS servers unreachable, then all new devices gain access into the configured Fail Open I-SID. 0 indicates that Fail Open I-SID is not enabled for this port.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure Fail Open I-SID:

   ```
   eapol fail-open-isid <0-16000000>
   ```

Example

Configure the Fail Open I-SID.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config-if)#interface gigabitEthernet 1/10
Switch:1(config-if)#eapol fail-open-isid 1000
```

Variable Definitions

The following table defines parameters for the **`eapol fail-open-isid`** command.

Variable	Value
<0-16000000>	Specifies the Fail Open I-SID value. 0 indicates that Fail Open I-SID is not enabled for this port.

Configure Wake-On-LAN

Use the following procedure to configure Wake-On-LAN functionality.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure Wake-On-LAN:

   ```
   eapol traffic-control <in | in-out>
   ```

Variable Definitions

The following table defines parameters for the **eapol traffic-control** command.

Variable	Value
in	Specifies incoming traffic is blocked when there is no authenticated device.
in-out	Specifies incoming and outgoing traffic is blocked when there is no authenticated device. The default value is in-out.

Show the EAPoL Status of the Device

Display the current device configuration.

Note

Use the **clear-stats** command to clear EAP or NEAP statistics.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the current device configuration by using the following command:

   ```
   show eapol system
   ```

Example

```
Switch:1>show eapol system
================================================================================
                                Eapol System
================================================================================
                     eap : disabled
           Eapol Version : 3
         non-eap-pwd-fmt : mac-addr
     non-eap-pwd-fmt key : ******
 non-eap-pwd-fmt padding : disabled
 auto-isid-offset status : disabled
 auto-isid-offset value  : 1000
```

Show EAPoL Authenticator Statistics

Display the authenticator statistics to manage network performance.

Note

Use the **clear-stats** command to clear EAP or NEAP statistics.

Procedure

1. To enter User EXEC mode, log on to the switch.

2. Display the authenticator statistics:

```
show eapol auth-stats interface [gigabitEthernet [{slot/port[/sub-port][-slot/port[/sub-port]][,...]}]]
```

Example

```
Switch:1#show eapol auth-stats interface
================================================================================
                          Eap Authenticator Statistics
================================================================================
PORT   EAP    AUTH-EAP    START LOGOFF INVALID LENGTH LAST-RX    LAST-RX
       RCVD   TX          RCVD  RCVD   FRAMES  ERROR  VER        SRC
--------------------------------------------------------------------------------
1/1    716    1074        0     0      0       0      1          18:a9:05:b1:04:ce
1/2    0      0           0     0      0       0      0          00:00:00:00:00:00
1/3    0      0           0     0      0       0      0          00:00:00:00:00:00
1/4    0      5           0     0      0       0      0          00:00:00:00:00:00
1/5    0      0           0     0      0       0      0          00:00:00:00:00:00
1/6    0      0           0     0      0       0      0          00:00:00:00:00:00
1/7    0      0           0     0      0       0      0          00:00:00:00:00:00
1/8    0      0           0     0      0       0      0          00:00:00:00:00:00
1/9    0      0           0     0      0       0      0          00:00:00:00:00:00
1/10   0      0           0     0      0       0      0          00:00:00:00:00:00
--More-- (q = quit)
```

Variable Definitions

Use the data in the following table to use the **show eapol auth-stats interface** command.

Variable	Value
{slot/port[/sub-port][-slot/port[/sub-port]][,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

View EAPoL Session Statistics

View EAPoL session statistics to manage network performance.

Note

Use the **clear-stats** command to clear EAP/NEAP statistics.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the session statistics:

```
show eapol session—stats interface [gigabitEthernet [{slot/port[/sub-port][-slot/port[/sub-port]][,...]}]
```

Example

```
Switch:1#show eapol session-stats interface
================================================================================================================
                     Eap Authenticator Session Statistics
```

```
================================================================================================================
PORT  MAC                 SESSION   AUTHENTIC       SESSION              TERMINATE       USER
NUM                       ID        METHOD          TIME                 CAUSE           NAME
----------------------------------------------------------------------------------------------------------------
1/1   18:a9:05:b1:04:ce   cb000000  remote-server   0 day(s), 05:58:16   not-terminated  sachin
1/4   00:00:00:00:00:01   cb000002  remote-server   0 day(s), 05:48:01   not-terminated  000000000001
----------------------------------------------------------------------------------------------------------------
```

Variable Definitions

Use the data in the following table to use the **show eapol session-stats interface** command.

Variable	Value
{slot/port[/sub-port][-slot/port[/sub-port]][,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

EAP Configuration Using Enterprise Device Manager

EAPoL (EAP) uses RADIUS protocol for EAP-authorized logons. RADIUS supports IPv4 and IPv6 addresses with no difference in functionality or configuration in all but the following case. When adding a RADIUS server in Enterprise Device Manager (EDM) or modifying a RADIUS configuration in EDM, you must specify if the address type is an IPv4 or an IPv6 address.

Before You Begin

- Before configuring your device, you must configure at least one EAP RADIUS server and shared secret fields.
- You cannot configure EAP on ports that are currently configured for:
  - Shared segments
  - MultiLink Trunking (MLT)
- Change the status of each port that you want to be controlled to auto. For more information on changing the status, see Configure EAP on a Port on page 745. The auto setting automatically authenticates the port according to the results of the RADIUS server. The default authentication setting for each port is force-authorized.

Globally Configure EAP on the Server

About This Task

Globally enable or disable EAP on the switch. By default, EAP is disabled.

Procedure

1. In the navigation pane, expand **Configuration** > **Security** > **Data Path**.
2. Select **802.1X - EAPOL**.
3. Select the **Global** tab.
4. From the AccessControl options, select **enable**.

5. (Optional) Select the appropriate **NonEapRadiusPwdAttrFmt** check boxes to configure the format of the RADIUS password when authenticating non-EAP MAC addresses using RADIUS.
6. (Optional) Enter the key string in the **NonNonEapRadiusPwdAttkeystring** field.
7. (Optional) Check the **ClearNonEap** check box to clear the NEAP session that is learned on the switch.
8. (Optional) Type an I-SID offset number in the **AutoIsidOffset** field.
9. (Optional) Select the **AutoIsidOffsetEnable** check box to enable Auto I-SID offset on the switch.
10. Select **Apply**.

Global *field descriptions*

Use the data in the following table to use the **Global** tab.

Name	Description
EapolVersion	Displays the EAP version on the switch.
AccessControl	Enables system authentication control. EAP is disabled by default.
NonEapRadiusPwdAttrFmt	Specifies the password attribute format for non EAP RADIUS authentication. • ipAdd: Specifies IP address. • macAddr: Specifies MAC address. • portNumber: Specifies port number • padding: Specifies padding.
NonEapRadiusPwdAttrKeyString	Specifies the attribute key string for non EAP RADIUS password.
ClearNonEap	Clears the NEAP session that is learned on the switch.
AutoIsidOffset	Specifies the Auto I-SID Offset value.
AutoIsidOffsetEnable	Enables or disables the Auto I-SID Offset feature.

Configure EAP on a Port

About This Task

Configure EAP or change the authentication status on one or more ports.

Ports are force-authorized by default. Force-authorized ports are always authorized and are not authenticated by the RADIUS server. You can change this setting so that the ports are always unauthorized.

Procedure

1. In the Device Physical View tab, select the port you need to configure.
2. In the navigation pane, expand **Configuration** > **Edit** > **Port**.
3. Select **General**.
4. Select the **EAPOL** tab.

5. (Optional) Select the **AllowNonEapHost** check box to enable hosts that do not participate in 802.1X authentication to get network access.
6. Select the **Status** option as **auto** or **forceAuthorized**.
7. In the **MultiHostMaxClients** field, type the maximum limit of allowed EAP and NEAP clients supported on this port.
8. In the **GuestVlanId** field, type the VLAN ID to be used as a Guest VLAN ID.
9. In the **FailOpenVlanId** field, type the Fail Open VLAN ID.
10. In the **NonEapMaxClients** field, type the maximum number NEAP authentication MAC addresses allowed on this port.
11. In the **EapMaxClients** field, type the maximum number of EAP authentication MAC addresses allowed on this port.
12. Select the **MultiHostSingleAuthEnabled** check box to automatically authenticate NEAP MAC addresses on this port.
13. In the **PortGuestIsid** field, type the I-SID to be used as a Guest I-SID.
14. In the **FailOpenIsid** field, type the Fail Open I-SID.
15. Select the **AdminTrafficControl** option as **inOut** or **in**.
16. (Optional) Select the **LldpAuthEnabled** check box to enable LLDP authentication for network access.
17. Select the **ReAuthEnabled** field.
18. In the **QuietPeriod** field, type the time interval.
19. In the **ReauthPeriod** field, type the time between reauthentication.
20. In the **RetryMax** field, type the number of times.
21. Select **Apply**.

EAPoL *Field Descriptions*

Use the data in the following table to use the **EAPoL** tab.

Name	Description
PortCapabilities	Displays the capabilities of the Port Access Entity (PAE) associated with the port. This parameter indicates whether Authenticator functionality, supplicant functionality, both, or neither, is supported by the PAE of the port. The following capabilities are supported by the PAE of the port: • authImplemented: A Port Access Controller Protocol (PACP) Extensible Authentication Protocol (EAP) authenticator functions are implemented. • virtualPortsImplemented: Virtual Port functions are implemented.
PortVirtualPortsEnable	Displays the status of the Virtual Ports function for the real port as True or False.
PortCurrentVirtualPorts	Displays the current number of virtual ports running in the port
PortAuthenticatorEnable	Displays the status of the Authenticator function in the Port Access Entity (PAE) as True or False.

Name	Description
PortSupplicantEnable	Displays the Supplicant function in the Port Access Entity (PAE) as True or False.
AllowNonEapHost	Enables network access to hosts that do not participate in 802.1X authentication. The default is disabled.
Status	Configures the authentication status for this port. The default is forceAuthorized. • auto: enables the EAP authentication process by sending the EAP request messages to the RADIUS server. • forceAuthorized: disables the EAP authentication and puts the port into force-full authorized mode.
MultiHostMaxClients	Specifies the value representing the maximum number of supplicants allowed to get authenticated on the port.
GuestVlanId	Specifies the VLAN to be used as a Guest VLAN. Access to unauthenticated hosts connected to this port is provided through this VLAN. 0 indicates that Guest VLAN is not enabled for this port.
FailOpenVlanId	Specifies the Fail Open VLAN ID for this port. If the switch declares the RADIUS servers unreachable, then all new devices are allowed access into the configured Fail Open VLAN. 0 indicates that Fail Open VLAN is not enabled for this port.
NonEapMaxClients	Specifies the maximum number of NEAP authentication MAC addresses allowed on this port. Zero indicates that NEAP authentication is disabled for this port.
EAPMaxClients	Specifies the maximum number of EAP authentication MAC addresses allowed on this port. Zero indicates that EAP authentication is disabled for this port
MultiHostSingleAuthEnabled	Indicates that the unauthenticated devices can access the network only after an EAP or NEAP client is successfully authenticated on the port. The VLAN to which the devices are allowed access is the authenticated client's VLAN. The default is false.
PortGuestIsid	Specifies the I-SID to be used as a Guest I-SID. Access to unauthenticated hosts connected to this port is provided through this I-SID. 0 indicates that Guest I-SID is not enabled for this port.
FailOpenIsid	Specifies the Fail Open I-SID for this port. If the switch declares the RADIUS servers unreachable, then all new devices are allowed access into the configured Fail Open I-SID. 0 indicates that Fail Open I-SID is not enabled for this port.
FlexUniStatus	Displays the current Flex-UNI status for this port.
AdminTrafficControl	Configures the Administrative Traffic Control. The default is inOut. • inOut: enables the Admin Traffic Control for input and output traffic. • in: enables the Admin Traffic Control for input traffic only.

Name	Description
OperTrafficControl	Displays the current Operational Traffic Control status.
LldpAuthEnabled	Enables LLDP authentication for this port. The default is disabled.
PortOrigin	Specifies the source of EAP configuration on the port: • config - through CLI or EDM • autoSense - through Zero Touch Fabric Configuration
DynamicMHSAEnabled	Displays the Dynamic MHSA configuration status.
ReauthOrigin	Specifies the origin of EAPOL reauthentication configuration on the port, either manually configured through CLI or dynamically configured through RADIUS.
ReauthPeriodOrigin	Specifies the origin of EAPOL reauthentication period configuration on the port, either manually configured through CLI or dynamically configured through RADIUS.
TrafficControlOrigin	Specifies the origin of Traffic Control configuration on the port. The supported values are: • config - Traffic Control is enabled by the user. • radius - Traffic Control is enabled by Extensible Authentication Protocol (EAP) through Remote Authentication Dial-In User Service (RADIUS) response.
Authenticator configuration	Displays the current Authenticator Port Access Entity (PAE) state. The states are: • authenticate • authenticated • Failed
ReAuthEnabled	Reauthenticates an existing supplicant at the time interval specified in ReAuthPeriod. The default is disabled.
QuietPeriod	Configures the time interval (in seconds) between authentication failure and the start of a new authentication.
ReAuthPeriod	Reauthenticates an existing supplicant at the time interval specified in ReAuthPeriod. Configures the time interval (in seconds) between successive reauthentications. The default is 3600 (1 hour).
RetryMax	Specifies the maximum Extensible Authentication Protocol (EAP) requests sent to the supplicant before timing out the session. The default is 2.
RetryCount	Specifies the maximum number of retries attempted.

Configure EAP on an Extreme Integrated Application Hosting Port

Note

This procedure only applies to 5720 Series.

About This Task

Perform this procedure to configure EAP or change the authentication status on Extreme Integrated Application Hosting (IAH) ports. IAH ports are force-authorized by default and are not authenticated by the RADIUS server. You can change this setting so that the IAH ports stay unauthorized.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit** > **Insight Port**.
2. Select the IAH port you want to configure.
3. Select the **EAPOL** tab.
4. (Optional) Select **AllowNonEapHost**.
5. In the **Status** field, select the required option.
6. In the **MultiHostMaxClients** field, enter a value.
7. In the **GuestVlanId** field, enter a VLAN ID.
8. In the **FailOpenVlanId** field, enter a VLAN ID.
9. In the **NonEapMaxClients** field, enter a value.
10. In the **EapMaxClients** field, enter a value.
11. Select **MultiHostSingleAuthEnabled**.
12. In the **PortGuestIsid** field, type the I-SID to be used as a Guest I-SID.
13. In the **FailOpenIsid** field, type the Fail Open I-SID.
14. Select the **AdminTrafficControl** option as **inOut** or **in**.
15. Select the **LldpAuthEnabled** check box to enable LLDP authentication for network access.
16. Select **ReAuthEnabled**.
17. In the **QuietPeriod** field, enter a time interval.
18. In the **ReAuthPeriod** field, enter a time interval.
19. In the **RetryMax** field, type a value.
20. Select **Apply**.

EAPOL *Field Descriptions*

Use data in the following table to use the **EAPOL** tab.

Name	Description
PortCapabilities	Shows the capabilities of the Port Access Entity (PAE) associated with the Extreme Integrated Application Hosting (IAH) port. This parameter indicates whether Authenticator functionality, supplicant functionality, both, or neither, is supported by the PAE of the IAH port. The following capabilities are supported by the PAE of the IAH port: • **authImplemented**: A Port Access Controller Protocol (PACP) Extensible Authentication Protocol (EAP) authenticator functions are implemented. • **virtualPortsImplemented**: Virtual Port functions are implemented.
PortVirtualPortsEnable	Shows the status of the Virtual Ports function for the IAH port.
PortCurrentVirtualPorts	Shows the current number of virtual ports running on the IAH port.
PortAuthenticatorEnable	Shows the status of the Authenticator function in the PAE.
PortSupplicantEnable	Shows the Supplicant function in the PAE.
AllowNonEapHost	Enables network access to hosts that do not participate in 802.1X authentication. The default is disabled.
Status	Specifies the authentication status for the IAH port. • **auto** - enables EAP authentication process by sending the EAP request messages to the RADIUS server. • **forceAuthorized** - disables EAP authentication and puts the IAH port into force-full authorized mode. The default is forceAuthorized.
MultiHostMaxClients	Specifies the maximum number of supplicants authenticated on the IAH port.
GuestVlanId	Specifies the VLAN ID to be used as a Guest. Access to unauthenticated hosts connected to the IAH port is provided through this VLAN. 0 indicates that Guest VLAN is not enabled.
FailOpenVlanId	Specifies the Fail Open VLAN ID for the specific IAH port. If RADIUS server is not reachable on the switch, then all new devices are allowed access to the configured Fail Open VLAN ID. 0 indicates that Fail Open VLAN ID is not enabled.

Name	Description
NonEapMaxClients	Specifies the maximum number of NEAP authentication MAC addresses allowed on the specific IAH port. 0 indicates that NEAP authentication is disabled.
EAPMaxClients	Specifies the maximum number of EAP authentication MAC addresses allowed on the specific IAH port. 0 indicates that EAP authentication is disabled.
MultiHostSingleAuthEnabled	Enables the functionality for network access to the unauthenticated devices only after an EAP or NEAP client is successfully authenticated on the IAH port. The VLAN ID to which the devices are allowed access is the authenticated client's VLAN. The default is disabled.
PortGuestIsid	Specifies the I-SID to be used as a Guest I-SID. Access to unauthenticated hosts connected to the IAH port is provided through this I-SID. 0 indicates that Guest I-SID is not enabled for this port.
FailOpenIsid	Specifies the Fail Open I-SID for the IAH port. If the switch declares the RADIUS servers unreachable, then all new devices are allowed access into the configured Fail Open I-SID. 0 indicates that Fail Open I-SID is not enabled for this port.
FlexUniStatus	Displays the current Flex-UNI status for this IAH port.
AdminTrafficControl	Configures the Administrative Traffic Control. The default is inOut. • inOut: enables the Admin Traffic Control for input and output traffic. • in: enables the Admin Traffic Control for input traffic only.
OperTrafficControl	Displays the current Operational Traffic Control status.
LldpAuthEnabled	Enables LLDP authentication for this IAH port. The default is disabled.
PortOrigin	Specifies the source of EAP configuration on the IAH port: • config - through CLI or EDM • autoSense - through Zero Touch Fabric Configuration
DynamicMHSAEnabled	Displays the Dynamic MHSA configuration status.

Name	Description
TrafficControlOrigin	Indicates the origin of Traffic Control configuration on the port. The supported values are: • config - Traffic Control is enabled by the user. • radius - Traffic Control is enabled by Extensible Authentication Protocol (EAP) through Remote Authentication Dail-In User Service (RADIUS) response.
Authenticate	Shows the current Authenticator Port Access Entity (PAE) authenticate status.
Authenticated	Shows the current Authenticator Port Access Entity (PAE) authenticated status.
Failed	Shows the current Authenticator Port Access Entity (PAE) failure status.
ReAuthEnabled	Enables reauthentication of an existing supplicant based on the specified reauthentication time interval. The default is disabled.
QuietPeriod	Specifies the time interval (in seconds) between authentication failure and start of authentication.
ReauthPeriod	Specifies the time interval (in seconds) between successive reauthentications. The default is 3600 (1 hour).
RetryMax	Specifies the maximum Extensible Authentication Protocol (EAP) requests sent to the supplicant before timing out the session. The default is 2.
RetryCount	Specifies the maximum number of retries attempted.

Show the Port Access Entity Port Table

About This Task

Use the Port Access Entity (PAE) Port Table to display system-level information for each port the PAE supports. An entry display in this table for each port of this system.

Procedure

1. In the navigation pane, expand **Configuration** > **Security** > **Data Path**.
2. Select **802.1X - EAPOL**.
3. Select the **EAP Security** tab.

EAP Security *Field Descriptions*

Use the data in the following table to use the **EAP Security** tab.

Name	Description
PortNumber	Indicates the port number associated with this port.
PortCapabilties	Indicates the capabilities of this PAE port. • authImplemented—PACP EAP authenticator functions are implemented in this PAE. • virtualPortsImplemented—Virtual Port functions are implemented in this PAE.
PortVirtualPortsEnable	Displays the status of the Virtual Ports function for the real port as True or False.
PortCurrentVirtualPorts	Displays the current number of virtual ports running in the port
PortAuthenticatorEnable	Displays the status of the Authenticator function in the Port Access Entity (PAE) as True or False.
PortSupplicantEnable	Displays the Supplicant function in the Port Access Entity (PAE) as True or False.
AllowNonEapHost	Displays the status if the system is enabled to allow hosts that do not participate in 802.1X authentication to get network access.
Status	Displays the authentication status for this port. The default is forceAuthorized.
MultiHostMaxClients	Indicates the value representing the maximum number of supplicants allowed to get authenticated on the port.
GuestVlanId	Specifies the VLAN to be used as a Guest VLAN. Access to unauthenticated hosts connected to this port is provided through this VLAN. 0 indicates that Guest VLAN is not enabled for this port.
FailOpenVlanId	Specifies the Fail Open VLAN ID for the port. If the switch declares the RADIUS servers unreachable, then all new devices are allowed access into the configured Fail Open VLAN. 0 indicates that Fail Open VLAN is not enabled for this port.
NonEapMaxClients	Indicates the maximum number of non-EAPoL authentication MAC addresses allowed on this port. Zero indicates that non-EAPol authentication is disabled for this port.
EapMaxClients	Indicates the maximum number of EAPoL authentication MAC addresses allowed on this port. Zero indicates that EAPol authentication is disabled for this port.
MultiHostSingleAuthEnabled	Indicates that the unauthenticated devices can access the network only after an EAP or NEAP client is successfully authenticated on the port. The VLAN to which the devices are allowed access is the authenticated client's VLAN. The default is false.
ProcessRadiusCOAPackets	Specifies whether to process any RADIUS requests-server packets that are received on this port.

Name	Description
PortGuestIsid	Specifies the I-SID to be used as a Guest I-SID. Access to unauthenticated hosts connected to this port is provided through this I-SID. 0 indicates that Guest I-SID is not enabled for this port.
FailOpenIsid	Specifies the Fail Open I-SID for the port. If the switch declares the RADIUS servers unreachable, then all new devices are allowed access into the configured Fail Open I-SID. 0 indicates that Fail Open I-SID is not enabled for this port.
FlexUniStatus	Displays the Flex-UNI status for the port.
AdminTrafficControl	Specifies the Administrative Traffic Control for the port. The default is inOut.
OperTrafficControl	Displays the Operating Traffic Control for the port.
LldpAuthEnabled	Specifies if LLDP Authentication is enabled. The default is 0 (disabled).
PortOrigin	Displays the Port Origin configuration status for the port.
DynamicMHSAEnabled	Displays the Dynamic MHSA status for the port.
TrafficControlOrigin	Specifies the origin of Traffic Control configuration on the port. The supported values are: • config - Traffic Control is enabled by the user. • radius - Traffic Control is enabled by Extensible Authentication Protocol (EAP) through Remote Authentication Dial-In User Service (RADIUS) response.
ReauthOrigin	Specifies the origin of EAPOL reauthentication configuration on the port, either manually configured through CLI or dynamically configured through RADIUS.
ReauthPeriodOrigin	Specifies the origin of EAPOL reauthentication period configuration on the port, either manually configured through CLI or dynamically configured through RADIUS.

Show EAP Authentication

About This Task

Use the Authenticator Configuration table to display configuration objects for the Authenticator PAE associated with each port.

Procedure

1. In the navigation pane, expand **Configuration** > **Security** > **Data Path**.
2. Click **802.1X - EAPOL**.
3. Click the **Authentication** tab.

Authentication *Field Descriptions*

Use the data in the following table to use the **Authentication** tab.

Name	Description
PortNumber	Indicates the number associated with this port.
Authenticate	Indicates the status of the Port Access Entity (PAE) authenticator requesting authentication.
Authenticated	Indicates the current authentication status of the Port Access Entity (PAE) authenticator.
Failed	Indicates the authentication status for failed or terminated state .
ReAuthEnabled	Indicates the re-authentication status of an existing supplicant at the time interval specified in ReAuthPeriod. The default is false.
QuietPeriod	Indicates the time interval (in seconds) between authentication failure and the start of a new authentication. The default is 60.
ReAuthPeriod	Indicates the time interval in seconds between successive re-authentications. The default is 3600 (1 hour).
RetryMax	Indicates the maximum Extensible Authentication Protocol (EAP) requests sent to the supplicant before timing out the session. The default is 2.
RetryCount	Indicates the count of the number of authentication attempts.

View Multihost Status Information

Use the following procedure to display multiple host status for a port.

Procedure

1. In the navigation pane, expand **Configuration** > **Security** > **Data Path**.
2. Select **802.1X – EAPOL**.
3. Select the **MultiHost Status** tab.

MultiHost Status *Field Descriptions*

The following table describes values on the **MultiHost Status** tab.

Name	Description
PortNumber	Indicates the port number associated with this port.
ClientMACAddr	Indicates the MAC address of the client.
PaeState	Indicates the current state of the authenticator PAE state machine.

Name	Description
VlanId	Indicates the VLAN assigned to the client.
Priority	Specifies the priority associated with this client MAC. This priority could be the Radius assigned priority or the port QOS level.
SwUniBindings	Indicates the Extensible Authentication Protocol (EAP) VLAN:ISID bindings that the switch represents as an hexadecimal value.
IsidSource	Indicates the origin of I-SID value: • radius - received from the RADIUS server. • autoconfig - calculated using the **auto-isid-offset** command, that the user configures on the switch. • config - configured statically. • notAvaliable - does not use EAP with FlexUNI, hence there is no I-SID to use.
AclId	Indicates the dynamic Access Control List (ACL) on the specific port.
AceIdList	Indicates the list of dynamic Access Control Entries (ACE) on the specific port.
DynamicSettings	Displays the Dynamic settings received from the Remote Authentication Dial-In User Service (RADIUS) server.

View EAP Session Statistics

Use the following procedure to display multiple host session information for a port.

Procedure

1. In the navigation pane, expand **Configuration** --> **Security** --> **Data Path**.
2. Click **802.1X – EAPOL**.
3. Click the **MultiHost Session** tab.

MultiHost Session Field Descriptions

The following table describes values on the **MultiHost Session** tab.

Name	Description
StatsPortNumber	Indicates the port number associated with this port.
StatsClientMACAddr	Indicates the MAC address of the client.
Id	Indicates the unique identifier for the session.
AuthenticMethod	Indicates the authentication method used to establish the session.
Time	Indicates the elapsed time of the session.

Name	Description
TerminateCause	Indicates the cause of the session termination.
UserName	Indicates the user name that represents the identity of the supplicant PAE.

Viewing EAPoL Authenticator Statistics

Use EAPoL Authenticator statistics to display the Authenticator Port Access Entity (PAE) statistics for each selected port.

Procedure

1. On the Device Physical View, select the port you want to graph.

   The system displays a yellow outline around the selected ports

   If you want to select multiple ports, press Ctrl and hold down the key while you click the ports you want to configure. The system displays a yellow outline around the selected ports.
2. In the navigation pane, expand the **Configuration** > **Graph** folders.
3. Click **Port**.
4. Click **EAPOL Stats**.
5. If you selected multiple ports, from the Graph port EAPoL Stats tab Show list, select: Absolute Value, Cumulative, Average/sec, Minimum/sec, Maximum/sec, or LastVal/sec.

EAPOL Stats *Field Descriptions*

The following table describes values on the **EAPOL Stats** tab.

Name	Description
InvalidFramesRx	Displays the number of EAPoL frames received by this Authenticator in which the frame type is not recognized.
EapLengthErrorFramesRx	Displays the number of EAPoL frames received by this Authenticator in which the Packet Body Length field is invalid.
StartFramesRx	Displays the number of EAPoL start frames received by this Authenticator.
EapFramesRx	Displays the number of EAPoL-EAP frames received by this Authenticator.
LogoffFramesRx	Displays the number of EAPoL Logoff frames received by this Authenticator.
LastRxFrameVersion	Displays the last received version of the EAPoL frame by this Authenticator.
LastRxFrameSource	Displays the source MAC address of the last received EAPoL frame by this Authenticator.
AuthEapFramesTx	Displays the number of EAPoL-EAP frames transmitted by the Authenticator.

View NEAP MAC Information

Use this procedure to view NEAP client MAC information on a port.

Procedure

1. In the navigation pane, expand **Configuration** --> **Security** --> **Data Path**.
2. Select **802.1X – EAPOL**.
3. Select **NEAP Radius** tab.

NEAP Radius *Field Descriptions*

The following table describes values on the **NEAP Radius** tab.

Name	Description
MacPort	Indicates the port number associated with this port.
MacAddr	Indicates the MAC address of the client.
MacStatus	Indicates the authentication status of the NEAP host that is authenticated using the RADIUS server.
VlanId	Indicates the VLAN assigned to the client.
MacClear	Clears the non EAP MAC entry associated with a specific index.
MacPriority	Indicates the priority associated with this Non-EAP client MAC. This priority could be the Radius assigned priority or the port QOS level.
SwUniBindings	Indicates the VLAN and I-SID bindings. VLAN is represented with 2 bytes and I-SID is represented with 4 bytes. The output is a continuous hexadecimal representation of the VLAN that is followed by the corresponding I-SID.
IsidSource	Indicates the source of the I-SID value. An I-SID value is generated in one of the following ways: • radius—Indicates that that I-SID value is learned from the RADIUS server. • autoconfig—Indicates that I-SID value is calculated by using the auto-isid-offset that you configured. • config—Indicates that the I-SID value is statically configured. • notAvailable—Indicates that no I-SID value is available because EAP with FlexUNI is not used.
NonEapAuthType	Indicates the authentication type of the Non-EAP client: • radius - received from RADIUS server. • lldp - received from Link Layer Discovery Protocol (LLDP).

Name	Description
AclId	Indicates the dynamic Access Control List (ACL) on the specific port.
AceIdList	Indicates the list of dynamic Access Control Entries (ACE) on the specific port.
DynamicSettings	Displays the Dynamic settings received from the Remote Authentication Dial-In User Service (RADIUS) server.

ExtremeCloud IQ Agent

Table 69: IQ Agent product support

Feature	Product	Release introduced
ExtremeCloud IQ Agent	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

For the most current information on switches supported by ExtremeCloud™ IQ, see ExtremeCloud™ IQ Learning What's New.

ExtremeCloud IQ provides cloud-managed networking, and delivers unified, full-stack management of wireless access points, switches, and routers. It enables onboarding, configuration, monitoring, troubleshooting, reporting, and more. Using innovative machine learning and artificial intelligence technologies, ExtremeCloud IQ analyzes and interprets millions of network and user data points, from the network edge to the data center, to power actionable business and IT insights, and to deliver new levels of network automation and intelligence.

The switch supports a zero touch connection to ExtremeCloud IQ. Zero touch deployment is used to deploy and configure a switch using ExtremeCloud IQ.

The switch integrates with ExtremeCloud IQ using ExtremeCloud IQ Agent. When you enable IQAgent, you can configure and monitor VOSS devices using ExtremeCloud IQ.

ExtremeCloud IQ supports the following features for the switch:

- Firmware upgrade
- IQAgent upgrade
- Supplemental CLI

You can configure the following features using the ExtremeCloud IQ interface:

- Hostname configuration
- SNMP location

- Device-level MTU
- Flow control
- Port state, usage type, and settings
- VLAN configuration
- DNS, NTP, SNMP, and Syslog servers

For more information about ExtremeCloud IQ, see https://www.extremenetworks.com/support/documentation/extremecloud-iq/.

ExtremeCloud IQ Agent Configuration Considerations

The following configuration considerations apply to ExtremeCloud IQ Agent:

- SSH and SSH password authenticaton is required.

  boot config flag ssh is enabled when ExtremeCloud IQ Agent is enabled. **boot config flag ssh** cannot be disabled while ExtremeCloud IQ Agent is enabled.

- SNMP is required.

  boot config flag block-snmp is disabled when ExtremeCloud IQ Agent is enabled. **boot config flag block-snmp** cannot be enabled while ExtremeCloud IQ Agent is enabled.

- High Secure mode disables ExtremeCloud IQ Agent automatically. ExtremeCloud IQ Agent must be enabled manually when this mode is enabled.
- ExtremeCloud IQ Agent is not supported in Enhanced Secure mode.
- An IP address that corresponds to the ExtremeCloud IQ pool and can display it in the NTP list. The IP does not try to synchronize if NTP is globally disabled on the switch. If NTP is enabled, you can see synchronization failure messages if the IP for the pool is blocked or is unreachable. As a best practice, if you have issues connecting to the cloud, check the clock on the switch and if it is incorrect, resolve this by either configuring an NTP server or manually configuring the correct time.

Note

You must configure a Segmented Management Instance to use ExtremeCloud IQ Agent. For more information, see Segmented Management on page 63.

For information about onboarding switches, see https://www.extremenetworks.com/support/documentation/extremecloud-iq/.

Zero Touch Deployment

Zero Touch Deployment enables a VOSS switch to be deployed automatically with ExtremeCloud IQ but you still must onboard the switch on the ExtremeCloud IQ side. When the switch powers on, the DHCP Client obtains the IP address and gateway from the DHCP Server, and discovers the Domain Name Server, connecting the switch automatically to Extreme Management Center or ExtremeCloud IQ - Site Engine or to ExtremeCloud IQ cloud management applications.

With Zero Touch Deployment, ExtremeCloud IQ Agent is enabled by default.

To use zero touch functionality, your switch must be in a Zero Touch Deployment-ready configuration mode, which means the switch cannot have existing primary or secondary configuration files loaded.

Factory shipped switches are Zero Touch Deployment ready because they deploy without configuration files. However, existing switches require manual preparation before Zero Touch Deployment can function.

For more information about preparing your switch for Zero Touch Deployment, see Zero Touch Deployment on page 52.

DHCP Option 43 Support

With the support of DHCP option 43, DHCP can dynamically configure the IP address of a private/non-public ExtremeCloud IQ server for zero touch deployments when the default ExtremeCloud IQ server (hac.extremecloudiq.com) is not desired.

To use this functionality, DHCP Client must be enabled. For information about DHCP Client for a Segmented Management Instance, see DHCP Client for Segmented Management Instance on page 72.

Considerations

The following considerations apply with DHCP option 43:

- A dynamic IP address overwrites the default value (hac.extremecloudiq.com) or 0.0.0.0.
- A static server IP address overwrites a dynamic server IP address.
- A dynamic server IP address does not overwrite an existing static server IP address.

  If a static server IP address is already configured and a new value is received from the DHCP server, the following warning displays on the console: `WARNING Dynamic Cloud IQ Server Address x.x.x.x provided by DHCP option 43 could not be set. Static configured server address y.y.y.y cannot be overwritten by a dynamic address`.
- The default value (hac.extremecloudiq.com) replaces the dynamic server IP address if the DHCP Client is disabled on the switch.
- The dynamic server IP address is not saved in the running configuration.

ExtremeCloud IQ Agent Configuration using CLI

After your device is onboarded (that is, the serial number for the device is associated with your ExtremeCloud IQ account), you are only required to enable ExtremeCloud IQ Agent. Other feature configuration, such as configuring proxy parameters and configuring access to ExtremeCloud IQ is optional.

Note

You must configure a Segmented Management Instance to use ExtremeCloud IQ Agent. For more information, see Segmented Management Instance Configuration using the CLI on page 75.

For information about onboarding switches, see https://www.extremenetworks.com/support/documentation/extremecloud-iq/.

Configure ExtremeCloud IQ Agent

You must first onboard the device. When zero touch connection establishes, IQ Agent is enabled, by default. Before IQ Agent is operational, you must first disable IQ Agent, configure the ExtremeCloud IQ IPv4 address or DNS name, and then reneable IQ Agent.

Before You Begin

You must first onboard the device.

Procedure

1. Enter Application Configuration mode:

   ```
   enable

   configure terminal

   application
   ```

2. Disable IQ Agent:

   ```
   no iqagent enable
   ```

3. Configure the ExtremeCloud IQ IPv4 address or DNS name:

   ```
   iqagent server address WORD<1-255>
   ```

4. Enable IQ Agent:

   ```
   iqagent enable
   ```

Example

Configure IQ Agent:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#application
Switch:1(config-app)#no iqagent enable
Switch:1(config-app)#iqagent server address hac.extremecloudiq.com
Switch:1(config-app)#iqagent enable
```

Display default IQ Agent configuration:

```
Switch:1>show application iqagent

================================================================================
                                IQAgent Info
================================================================================
Agent Admin State       : true
Agent Version           : 0.4.3
Agent Oper State        : disconnected
Server Address          : hac.extremecloudiq.com
Server Address Origin   : None
Proxy Address           : 0.0.0.0
Proxy TCP Port          : 0
Proxy Username          :
```

Configure Access to ExtremeCloud IQ

Use this task to configure IQ Agent parameters to access ExtremeCloud IQ.

Before You Begin

You must onboard the device and configure any optional IQ Agent parameters on the supported device before you enable IQ Agent.

You can configure the IQ Agent parameters on the supported devices first, and then onboard the devices (that is, add the serial numbers for the devices in the ExtremeCloud IQ GUI) or vice versa.

For information about onboarding switches, see https://www.extremenetworks.com/support.

Procedure

1. Enter Application Configuration mode:

   ```
   enable

   configure terminal

   application
   ```

2. Configure the ExtremeCloud IQ IPv4 address or DNS name:

   ```
   iqagent server address WORD<1-255>
   ```

Examples

Configure access to ExtremeCloud IQ using an IPv4 address:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#application
Switch:1(config-app)#iqagent server address 192.0.2.1
```

Configure access to ExtremeCloud IQ using a DNS name:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#application
Switch:1(config-app)#iqagent server address extremecloudiq.com
```

Variable Definitions

The following table defines parameters for the **`iqagent server`** command.

Variable	Value
`address <WORD 1-255>`	Specifies the ExtremeCloud IQ IPv4 address or DNS name.

Configure Proxy Parameters

If you use a proxy https server in your network, you must configure proxy parameters so that the IQ Agent on the device can communicate with ExtremeCloud IQ through the proxy.

Use this task to configure the proxy parameters for ExtremeCloud IQ on the IQ Agent.

Note

You must onboard the device and configure any optional IQ Agent parameters on the supported device before you enable IQAgent.

You can configure the IQ Agent parameters on the supported devices first, and then onboard the devices (that is, add the serial numbers for the devices in the ExtremeCloud IQ GUI) or vice versa.

For information about onboarding switches, see https://www.extremenetworks.com/support.

Procedure

1. Enter Application Configuration mode:

   ```
   enable

   configure terminal

   application
   ```

2. Configure the proxy IPv4 address or DNS name:

   ```
   iqagent proxy address <WORD 1-255> tcp-port <1-49151>
   ```

3. Configure the proxy username and password for the ExtremeCloud IQ account:

   ```
   iqagent proxy username <WORD 1-64> password <WORD 1-128>
   ```

Examples

Configure proxy parameters using an IPv4 address:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#application
Switch:1(config-app)#iqagent proxy address 192.0.2.254 tcp-port 21
Switch:1(config-app)#iqagent proxy username admin password ****
```

Configure proxy parameters using a DNS name:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#application
Switch:1(config-app)#iqagent proxy address hac.extremecouldiq.com tcp-port 21
Switch:1(config-app)#iqagent proxy username admin password ****
```

Variable Definitions

The following table defines parameters for the **iqagent proxy** command.

Variable	Value
address <WORD 1-255>	Specifies the proxy IPv4 address or DNS name.
tcp-port <1-49151>	Specifies the TCP port.
username <WORD 1-64>	Specifies the proxy server username.
password <WORD 1-128>	Specifies the proxy server password.

Display ExtremeCloud IQ Agent Information

About This Task

Use this task to display ExtremeCloud IQ Agent configuration information and status.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display IQ Agent configuration information and status:

   ```
   show application iqagent
   ```

Example

Display IQ Agent configuration information and status when IQ Agent is enabled using the default ExtremeCloud IQ server:

```
Switch:1>show application iqagent

================================================================================
                                IQAgent Info
================================================================================
Agent Admin State       : true
Agent Version           : 0.2.7
Agent Oper State        : connected
Server Address          : hac.extremecloudiq.com
Server Address Origin   : None
Proxy Address           : extremeiq.com
Proxy TCP Port          : 21
Proxy Username          : admin
```

Display IQ Agent disabled state:

```
Switch:1>show application iqagent

================================================================================
                                IQAgent Info
================================================================================
Agent Admin State       : false
Agent Version           : 0.2.7
Agent Oper State        : disconnected
Server Address          : 0.0.0.0
Server Address Origin   : None
Proxy Address           : 0.0.0.0
Proxy TCP Port          : 0
Proxy Username          :
```

Display IQ Agent configuration information and status when DHCP provides a dynamic server IP address:

```
Switch:1>show application iqagent

================================================================================
                                IQAgent Info
================================================================================
Agent Admin State       : true
Agent Version           : 0.2.7
Agent Oper State        : disconnected
Server Address          : 192.0.2.1
Server Address Origin   : DHCP
Proxy Address           : 0.0.0.0
Proxy TCP Port          : 0
Proxy Username          :
```

Display IQ Agent configuration information and status when DHCP Client is disabled on the switch:

```
Switch:1>show application iqagent

================================================================================
                                IQAgent Info
================================================================================
Agent Admin State       : false
Agent Version           : 0.2.7
Agent Oper State        : disconnected
Server Address          : hac.extremecloudiq.com
Server Address Origin   : None
Proxy Address           : 0.0.0.0
Proxy TCP Port          : 0
Proxy Username          :
```

Display ExtremeCloud IQ Agent Status

About This Task

Use this task to display IQ Agent status information.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display IQ Agent status information:
   `show application iqagent status`

Example

```
Switch:1>show application iqagent status
================================================================================
                               IQAgent Status
================================================================================
Connection Status               : Connected
Last Onboard Time               : 18:54:23 11 27 2019 UTC
Agent Version                   : 0.2.7
Association URL                 : https://10.16.231.98/hac-webapp/rest/v1/association
Poll URL                        : https://10.16.231.98/hac-webapp/rest/v1/poll/1904Q-20028
Monitor Frequency               : 600
Poll Frequency                  : 30
Last Poll Status                : SUCCESS
Last Poll Success Time          : 14:39:16 11 28 2019 UTC
Last Health Status              : SUCCESS
```

```
Last Health Success Time        : 14:38:35 11 28 2019 UTC
Last Monitor Status             : SUCCESS
Last Monitor Success Time       : 14:38:35 11 28 2019 UTC
```

Reinstall ExtremeCloud IQ Agent Firmware

Perform this procedure to return the ExtremeCloud IQ Agent firmware version on the switch to the version bundled with the OS image currently installed on the switch, for example, if you downgrade the OS image version and do not reconnect to ExtremeCloud IQ automatically.

Procedure

1. Enter Application Configuration mode:

   ```
   enable

   configure terminal

   application
   ```

2. Disable ExtremeCloud IQ Agent:

   ```
   no iqagent enable
   ```

3. Reinstall the ExtremeCloud IQ Agent firmware:

   ```
   software iqagent reinstall
   ```

4. Enable ExtremeCloud IQ Agent:

   ```
   iqagent enable
   ```

ExtremeCloud IQ Agent Configuration using EDM

Perform the procedures in this section to configure ExtremeCloud IQ Agent on the switch using the Enterprise Device Manager (EDM).

Configure ExtremeCloud IQ Agent

Before You Begin

You must first onboard the device and configure any optional IQ Agent parameters before you enable IQ Agent.

Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability.**
2. Select **IQAgent**.
3. Select the **Globals** tab.
4. Configure optional parameters as required.
5. Select **Apply**.
6. Select **Enable**.
7. Select **Apply**.

Globals *Field Descriptions*

Use the data in the following table to use the **Global** tab to configure the ExtremeCloud IQ Agent.

Name	Description
Enable	Specifies whether IQ Agent is enabled. The default is enabled.
Version	Displays the ExtremeCloud IQ Agent firmware version running on the switch.
OperStatus	Displays the operational status of ExtremeCloud IQ Agent on the switch.
ServerAddressType	Specifies the address type of the ExtremeCloud IQ server address.
Server/Address	Specifies the ExtremeCloud IQ IPv4 address or DNS name. The default is hac.extremcloudiq.com.
ServerAddressOrigin	Specifies the origin for the ExtremeCloud IQ server address: • none–not configured • configured–manual configuration • dhcp–obtained through DHCP
Address	Specifies the proxy IPv4 address or DNS name.
TcpPort	Specifies the TCP connection port.
UserName	Specifies the proxy server password.
Password	Specifies the proxy server username.
AssociationUrl	Displays the association URL of ExtremeCloud IQ.
PollUrl	Displays the poll URL of ExtremeCloud IQ.
MonitorFreq	Displays the monitoring frequency, in seconds, of ExtremeCloud IQ.
PollFreq	Displays the polling frequency, in seconds, of ExtremeCloud IQ.
LastOnboardTime	Displays the last onboard time of ExtremeCloud IQ.
LastPollStatus	Displays the last poll status of ExtremeCloud IQ.
LastPollTime	Displays the last poll time for a successful attempt.
LastMonitorStatus	Displays the last monitoring status of ExtremeCloud IQ.
LastMonitorTime	Displays the last monitor time for a successful attempt.
LastHealthStatus	Displays the last health status of ExtremeCloud IQ.
LastHealthTime	Displays the last health time for a successful attempt.

Extreme Integrated Application Hosting

Table 70: Extreme Integrated Application Hosting product support

Feature	Product	Release introduced
Extreme Integrated Application Hosting	5320 Series	Not Supported
	5420 Series	Not Supported
	5520 Series	Not Supported
	5720 Series	Fabric Engine 8.7 5720-24MXW and 5720-48MXW
Fabric IPsec Gateway virtual machine	5320 Series	Not Supported
	5420 Series	Not Supported
	5520 Series	Not Supported
	5720 Series	Fabric Engine 8.7 5720-24MXW and 5720-48MXW
Egress Shaper for Fabric Extend tunnels on Fabric IPsec Gateway virtual machine	5320 Series	Not Supported
	5420 Series	Not Supported
	5520 Series	Not Supported
	5720 Series	Fabric Engine 8.7 5720-24MXW and 5720-48MXW

Extreme Integrated Application Hosting

Extreme Integrated Application Hosting (IAH) architecture provides a flexible and open solution that enables organizations to deploy high-performance and flexible visibility applications pervasively throughout their network for improved monitoring and troubleshooting. Enabled by the Network Operating System (NOS), this preconfigured Quick Emulator (QEMU) Kernel-based Virtual Machine (KVM) environment leverages high performance x86 CPUs to host these applications, extending visibility customized to the business and operational needs of the organization across the entire network.

The QEMU KVM environment supports several pretested and well-known packet capture applications in a Linux virtual machine, including Wireshark and tcpdump. There are a wide variety of additional applications, tools, and utilities that organizations are able to run in this environment, such as data analytics applications, packet generators, monitoring tools, troubleshooting utilities, and many others. While the QEMU KVM environment is open and can host any application, it is designed and ideally suited for networking applications, tools, and utilities.

IAH architecture supports the creation and use of virtualization domains, such as virtual machines, and Docker containers. This design creates a common-use host, which coordinates and automates multiple guest-networking functions into chains. The hardware boots into the virtual Linux OS, providing the ability to run additional applications or services within a specific virtual machine or a Docker container, and simultaneously supporting the regular functionality of the switch.

Yet Another Next Generation (YANG) model is used to manage configuration and retrieve operational data. You access the YANG model through Representational State Transfer Configuration Protocol (RESTCONF) using a northbound interface, namely ExtremeCloud IQ - Site Engine, that provides an additional way to configure and monitor the switch. For more information on RESTCONF, see Representational State Transfer Configuration Protocol (RESTCONF) Fundamentals on page 2491.

Virtual Services Resources

The virtual services resources are isolated from each other, as well as from the Network Operating System (NOS) running the switch.

The resources available for all virtual services on 5720-24MXW and 5720-48MXW switches are as follows:

Note

You must install a modular SSD unit to use virtual services on 5720-24MXW and 5720-48MXW switches.

- ◦ Two CPU cores
  - ◦ 4 GB RAM
  - ◦ 120 GB SSD flash memory (separately available modular SSD unit), with 104 GB dedicated for IAH storage.

The switch OS uses the following resources on 5720-24MXW and 5720-48MXW:

- Two CPU cores
- 4 GB RAM
- 8 GB internal flash memory storage

Extreme Integrated Application Hosting Ports

Extreme Integrated Application Hosting (IAH) ports are labeled as Insight ports, which are internal ports used to support Ethernet connectivity by the virtual services configured on the switch. IAH ports operate at 10 Gigabits per second (Gbps). The following features support IAH ports on the switch:

- VLANs
- Filters

- Port Statistics
- Basic Interface Configuration
- Mirroring
- Switched UNI
- Transparent Port UNI

Note

Network-to-network interface (NNI) support is not available for IAH ports. IS-IS adjacencies cannot be established on IAH ports.

For information about how to configure IAH ports, see the following tasks:

- Configure a Virtual Service on page 779
- Configure Virtual Ports on page 795

Connection Types

The VM and Docker virtual ports map to a physical Extreme Integrated Application Hosting port using the following connection types:

- Open vSwitch (OVS)
- Single Root I/O Virtualization (SR-IOV).
- Virtualization Technology for Directed I/O (VT-d)

Note

You must enable trunking on the Extreme Integrated Application Hosting port when you use SR-IOV and OVS connection types. For more information about enabling trunking, see MultiLink Trunking and Split MultiLink Trunking on page 2090.

You can configure Extreme Integrated Application Hosting ports 1/s1 and 1/s2 to accommodate different connect types. Extreme Integrated Application Hosting ports 1/s1 and 1/s2 can accommodate virtual ports of SR-IOV, OVS, or VT-d connect types as shown in the table below. Using the **`virtual-service`** command, you can specify which Extreme Integrated Application Hosting port is associated with the configured connect type. You can also configure the Network Interface Card (NIC) type of the virtual port using the **`virtual-service`** command.

The following table lists the compatible Extreme Integrated Application Hosting port connect type configurations.

Extreme Integrated Application Hosting port 1/s1	Extreme Integrated Application Hosting port 1/s2
SR-IOV	OVS
SR-IOV	SR-IOV
SR-IOV	VT-d
OVS	SR-IOV
OVS	OVS
OVS	VT-d

Extreme Integrated Application Hosting port 1/s1	Extreme Integrated Application Hosting port 1/s2
VT-d	VT-d
VT-d	SR-IOV
VT-d	OVS

Link Flapping

When the switch initializes, the Extreme Integrated Application Hosting ports connect to the underlying Linux hypervisor. When a virtual port of connection type OVS or SR-IOV is configured on the switch, the Linux hypervisor saves this connection, and the link state of the Extreme Integrated Application Hosting port does not change. However, when a virtual port of connection type VT-d is configured on the switch, control of the Extreme Integrated Application Hosting port is passed from the Linux hypervisor to the configured Virtual Machine (VM). The Extreme Integrated Application Hosting port flaps due to this transition, and the switch reports it in the system log. The Extreme Integrated Application Hosting port flaps twice during the transition:

1. when the Extreme Integrated Application Hosting port is removed from the Linux hypervisor.
2. when the Extreme Integrated Application Hosting port is added to the VM.

A similar link flap sequence takes place on the Extreme Integrated Application Hosting port when the associated VM is disabled on the switch, and the control of the Extreme Integrated Application Hosting port is passed from the VM back to the Linux hypervisor.

Configuration Requirements

- To use an Extreme Integrated Application Hosting port as an analyzer port on a monitoring BEB for Fabric RSPAN (Mirror to I-SID), you must associate outer-tag 4091 to egress port 1/s1 or 1/s2 if the connect type is OVS or SR-IOV. Use the **monitor-by-isid <1–1000> map-to-vid <1–4093>** command to configure VLAN 4091for Fabric RSPAN.
- To use an Extreme Integrated Application Hosting port with a connect type as OVS or SR-IOV for Port Mirroring, associate VLAN 4091 to the virtual machine (VM) vport to send the mirrored packets to the VM.
- To enable Flex UNI on an Extreme Integrated Application Hosting port with a connect type of VT-d, enable dot1q encapsulation on the VM interfaces. Flex UNI enables tagging on these ports by default; you must tag the VM ports with the VLANs that these ports use.

Third Party Virtual Machine

The Extreme Integrated Application Hosting (IAH) feature supports the pre-installed Third Party Virtual Machine (TPVM). For switches that use a modular Solid State Drive (SSD) for IAH , the virtual machine is pre-installed on the modular SSD. For switches that do not use a modular Solid State Drive (SSD) for IAH , the virtual machine is pre-installed on the switch.

Note

The Third Party Virtual Machine (TPVM) version is based on Ubuntu 20.04.04 LTS.

You can use the **show virtual-service config** command to view the information about the pre-installed virtual machine on the switch. For more information, see Display Virtual Service Configuration on page 785.

Important

You must upgrade virtual services independently of switch software upgrade; separate images for virtual services are available. For more information, see Upgrade a Virtual Service on page 790.

For more information about how to configure virtual services, see Virtual Services Configuration using CLI on page 778 and Virtual Services Configuration using EDM on page 791.

Third Party Virtual Machine (TPVM) provides a set of troubleshooting tools on the switch. The following installed packages are available on TPVM:

- build-essential
- checkinstall
- iperf
- mtools
- netperf
- qemu-guest-agent
- tshark
- valgrind
- vim-gnome
- wireshark
- xterm
- isc-dhcp-client
- isc-dhcp-server
- iperf3
- libpcap
- rpcapd
- resolvconf

Important

TPVM includes an administrator account with a default username and password. To ensure security, you must change the default password when you access TPVM for the first time, before enabling the IAH ports using the **no shutdown** command. The software automatically prompts you to change this password at first boot; no action can be taken with the VM until you change the password.

The following user applications are available on TPVM:

- Dynamic Host Configuration Protocol (DHCP) server
- Domain Name Server (DNS)
- Authentication, authorization, and accounting (AAA) server for Remote Access Dial-In User Service (RADIUS) and Terminal Access Controller Access Control Service Plus (TACACS+).

- Syslog server
- Simple Network Management Protocol (SNMP) trap receiver
- Surricata - a free and open-source robust network threat detection engine that provides real time intrusion detection (IDS), inline intrusion prevention (IPS), network security monitoring (NSM), and offline packet capture (pcap) processing.
- Wireshark – a protocol analyzer that provides packet capturing and analysis.
- Ostinato - provides packet crafting, network traffic generation, and analysis with a user-friendly Graphical User Interface (GUI).

Note

If you start the console for TPVM without network connectivity to a DHCP server, the VM remains in a retry loop for approximately 5 minutes while it tries to obtain a DHCP address. The system displays the following message: `[FAILED] Failed to start Raise network interfaces`, and then the VM continues to boot. The VM does start but with the virtual port, eth0, in the administratively down state.

The following are the virtual services resources for TPVM:

- Two CPU cores
- 4 GB RAM
- One virtual port of VT-d connection type
- 1.8 GB up to 32 GB SSD

Note

To use this feature on the applicable models of 5720 Series, you must install an SSD module in the switch.

Important

Fabric IPsec Gateway Fundamentals

The Fabric IPsec Gateway feature introduces a Virtual Machine (VM) that supports aggregation of Fabric Extend Tunnels with fragmentation, reassembly, and Internet Protocol Security (IPsec) encryption functions.

The minimum configuration requirements for the Fabric IPsec Gateway VM are as follows:

- Two Central Processing Unit (CPU) cores
- 4 GB Random Access Memory (RAM)
- One Virtualization Technology for Directed I/O (VT-d) vport (eth0)
- Minimum 10 GB SSD

Note

To use this feature on the applicable models of 5720 Series, you must install an SSD module in the switch

To configure IPsec on a switch through the Fabric IPsec Gateway VM, see Fabric IPsec Gateway Configuration using CLI on page 799.

Fabric IPsec Gateway supports the following services through the VM:

- IPsec with fragmentation and reassembly - The system supports fragmentation and reassembly for IPsec tunnels that you configure on the VM, and a minimum of 1300 bytes of Maximum Transmission Unit (MTU) value. You can configure fragmentation to occur before the packets are encrypted.
- Fragmentation and reassembly - the Fabric IPsec Gateway VM performs fragmentation and reassembly for IPsec tunnels, for which the network routes the packets through the VM. The system supports a minimum of 750 bytes of Maximum Transmission Unit (MTU) value.

IPsec Decoupled Mode

A device is in IPsec decoupled mode when IPsec and Fabric Extend (FE) termination takes place on two different IP addresses. A device is in IPsec coupled mode when IPsec and Fabric Extend (FE) termination takes place on the same IP address.

The 5720 Series devices, which use Fabric IPsec Gateway for Fabric Extend over IPsec, support IPsec in decoupled mode only. You must configure the IPsec tunnel in decoupled mode to enable IPsec termination in the Fabric IPsec Gateway VM. For more information about how to configure IPsec tunnels on the VM, see Configure IPsec Tunnels on Fabric IPsec Gateway VM on page 808.

Digital Certificates for Fabric IPsec Gateway

Fabric IPsec Gateway supports digital certificates for IPsec authentication of Fabric Extend tunnels. To support different certificates for different IPsec tunnels, you can configure multiple certificate authority (CA) trustpoints and identity subject certificates.

If you are not familiar with digital certificates, see Digital Certificate/PKI on page 2697 for additional background information like digital certificate terminology.

Online Certificate Provisioning

The switch uses IPsec Simple Certificate Enrollment Protocol (SCEP) to obtain the CA certificate, and then validates the CA certificate against the certificate chain.

Note

Extreme validated the Fabric IPsec Gateway SCEP implementation with EJBCA CA Server only. Fabric IPsec Gateway SCEP cannot currently use Win CA like digital certificate support in VOSS.

Use trustpoints to manage and track CAs and certificates. The switch can enroll with a trustpoint to obtain an identity certificate. You must configure the CA URL, the CA common name, and select the HTTP request type to configure the CA server trustpoint.

Configure the certificate subject parameters to provide the device distinguished name (DN) and key name for the generated key pair (the private key). If you do not configure a private key, the switch generates one. The switch validates the returned certificate against the trustpoint's CA certificate.

You can remove subject certificates from the CA trustpoint or clean the CA trustpoint only if the subject-label is not configured on an IPsec tunnel.

Offline Certificate Provisioning

Offline certificate management supports switches that cannot communicate with the CA to obtain the identity certificate online by certificate enrollment operation.

The switch generates the certificate signing request (CSR) using the subject DN and the private key that you configure in the CLI. If you do not configure a private key, the switch generates one.

Transfer the CSR to the offline CA to be signed. Retrieve the signed certificate to validate against the original CSR. You must manually transfer all certificates in the certificate chain to the switch. The signed certificate must include the subject-label to map it to a locally-generated CSR for validation.

You must manually download Certificate Revocation List (CRL) files. You can remove offline subject certificates only if the subject-label is not configured on an IPsec tunnel.

Egress Shaping for Fabric Extend Tunnels on Fabric IPsec Gateway

You can configure the egress shaping rate to limit egress bandwidth for tunnels on the Fabric IPsec Gateway Virtual Machine (VM).

Considerations

Consider the following when you configure the egress shaper rate:

- If the ingress data traffic receives excessive packets with the following DSCP or 802.1p values (high priority control packets) and egress shaping is configured, a IS-IS flap can be seen.

DHCP value	802.1p value
0x28	6
0x2E	6
0x2F	6
0x30	7
0x38	7

- The egress tunnel shaping rate is impacted if the incoming packet size is greater than the Fabric Extend tunnel MTU. This is due to the additional packet header required for fragmentation.

Operational Considerations and Restrictions

Consider the following when deploying Extreme Integrated Application Hosting (IAH) on various switches:

Table 71: Operational Considerations

Number of IAH ports	5720-24MXW: 2 5720-48MXW: 2
Multiple simultaneous VMs	Supported

Table 71: Operational Considerations (continued)

Pre-installed VM	Third Party Virtual Machine Fabric IPsec Gateway
Additional components required	None

Virtual Services Configuration using CLI

Perform the procedures in this section to configure Extreme Integrated Application Hosting (IAH) virtual services on the switch using the command line interface (CLI).

Access a Virtual Service Console

The virtual services running on a Virtual Machine (VM) require a console for configuration and monitoring purposes.

About This Task

Perform this procedure to access the virtual service console port for the specific VM.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```
2. Enter the following command to access the virtual service console:
   ```
   virtual-service WORD<1-128> console
   ```

Note

Type `CTRL+Y` to exit the console.

Example

```
Switch:1>enable
Switch:1#virtual-service tpvm console
```

Variable Definitions

The following table defines parameters for the **`virtual-service`** command.

Variable	Value
`WORD<1-128>`	Specifies the virtual service name.
`console`	Accesses the console for the specific virtual service.

Install a Virtual Service

A virtual service provides the ability to support additional applications or services and simultaneously support the regular switching functionality. Each virtual service provides an Open Virtual Appliance (OVA) image, which is installed on Extreme Integrated Application Hosting (IAH) through ExtremeCloud IQ - Site Engine.

Before You Begin

Use FTP, SFTP, or SCP to transfer the OVA image to the `/var/lib/insight/packages/` directory on the switch.

Note

The Fabric IPsec Gateway image includes no integrity check. Use SCP to copy the file to the switch and confirm the file size before installation.

About This Task

Perform this procedure to install a package file to a specific location indicated by a virtual service name. This procedure also verifies if the package is in OVA format, and if a certificate is provided in the package.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Install the virtual service package:

   ```
   virtual-service WORD<1-128> install package WORD<1-512>
   ```

Variable Definitions

The following table defines parameters for the **`virtual-service`** command.

Variable	Value
`WORD<1-128>`	Specifies the virtual service name.
`install`	Installs the virtual service package.
`package WORD<1-512>`	Specifies the package name and path.

Configure a Virtual Service

About This Task

Perform this procedure to configure a virtual service on the switch.

Note

- Following procedure lists the general sequence to configure a virtual service.
- The names of Ethernet ports appearing in a specific Virtual Machine (VM) are not correlated to the configured virtual port names. Each VM renames the Ethernet ports as per its requirements, after they are discovered during the VM initialization.
- By default, the system displays all virtual ports of OVS connection type first in the alphabetical order of their configured names, followed by the virtual ports of SR-IOV and VT-d connection types.

Before You Begin

- You must enable trunking on the Extreme Integrated Application Hosting (IAH) port when you use SR-IOV and OVS connection types. For more information about enabling trunking, see MultiLink Trunking and Split MultiLink Trunking on page 2090.
- Ensure the switch has the Ethernet drivers installed as per the SR-IOV standard, to support the VT-d and the SR-IOV connection type for the configured virtual ports.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Create a VLAN:

   Note
   Virtual service configuration supports port-based VLANs only.

   ```
   vlan create <2-4059> name WORD<0-64> type {port-mstprstp <0-63>}
   [color <0-32>]
   ```

3. Add the IAH and faceplate port to the VLAN:

   ```
   vlan members add <1-4059> {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

4. Enter GigabitEthernet Interface Configuration mode:

   ```
   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note
   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

5. Enable the IAH and faceplate ports:

   ```
   no shutdown
   ```

6. Exit to Global Configuration mode:

   ```
   exit
   ```

7. (Optional) Create a virtual service:

   ```
   virtual-service WORD<1-128>
   ```

8. (Optional) Configure the number of CPU cores to be assigned to the virtual service created:

   ```
   virtual-service WORD<1-128> num-cores <num_cores>
   ```

9. (Optional) Configure the memory size to be assigned to the virtual service created:

   ```
   virtual-service WORD<1-128> mem-size <mem-size>
   ```

10. (Optional) Configure the disk to be assigned to the virtual service created:

    ```
    virtual-service WORD<1-128> disk WORD<1-32> size <1-30>
    ```

11. Configure the virtual port connection type:

    

    Note

    Ensure the connection type you configure for the virtual port matches the connection type supported by the IAH port.

    ```
    virtual-service WORD<1-128> vport WORD<1-32> connect-type {ovs | sriov
    | vtd}
    ```

12. Configure the IAH port to associate with the connection type:

    ```
    virtual-service WORD<1-128> vport WORD<1-32> port WORD<1-32>
    ```

    

    Important

    You cannot configure two virtual services with conflicting connect types on the same IAH port. You cannot configure two virtual services with VT-d connect type on the same IAH port.

13. Configure the NIC type of the IAH port:

    ```
    virtual-service WORD<1-128> vport WORD<1-32> port WORD<1-32> nic-type
    {virtio | e1000}
    ```

14. Add the virtual port to the VLAN created:

    ```
    virtual-service WORD<1-128> vport WORD<1-32> vlan <1-4096>
    ```

15. Enable the virtual service:

    ```
    virtual-service WORD<1-128> enable
    ```

Example

Configuring the TPVM virtual service using IAH port 1/s1 with an SR-IOV connection type:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface GigabitEthernet 1/s1
Switch:1(config-if)#encapsulation dot1q
Switch:1(config-if)#exit
Switch:1(config)#vlan create 10 name tpvm-lan-vlan type port-mstprstp 0
Switch:1(config)#vlan members add 10 1/s1,1/6/2
Switch:1(config)#interface GigabitEthernet 1/s1,1/6/2
Switch:1(config-if)#no shutdown
Switch:1(config-if)#exit
Switch:1(config)#virtual-service tpvm vport eth0 connect-type sriov
Switch:1(config)#virtual-service tpvm vport eth0 vlan 10
Switch:1(config)#virtual-service tpvm enable
```

Configuring the TPVM virtual service on IAH port 1/s2 with a VT-d connection type:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#vlan create 10 type port-mstprstp 0
Switch:1(config)#vlan member add 10 1/1,1/s2
Switch:1(config)#interface GigabitEthernet 1/s2,1/1
Switch:1(config-if)#no shutdown
Switch:1(config-if)#exit
Switch:1(config-if)virtual-service tpvm vport eth0 port 1/s2
Switch:1(config)#virtual-service tpvm enable
```

Variable Definitions

The following table defines parameters for the **vlan create** command.

Variable	Value
<2-4059>	Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.
color<0-32>	Specifies the color of the VLAN.
nameWORD<0-64>	Specifies a name for the VLAN to be created.
type {port-mstprstp<0-63>}	Creates a VLAN by port, with the STP instance ID ranging from 0 to 63. Note: MSTI instance 62 is reserved for SPBM if SPBM is enabled on the switch.

The following table defines parameters for the **vlan members** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
{slot/port[/sub-port][-slot/port[/sub-port]][,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
add	Adds ports to a specified VLAN ID.

The following table defines parameters for the **virtual-service** command.

Variable	Value
WORD<1-128>	Specifies a name for virtual service.
connect-type {ovs | sriov | vtd}	Specifies the connection type for the virtual port created. The default is VT-d. The switch supports the following maximums for virtual ports: • OVS - 16 • SR-IOV - 16 • VT-d - 2
disk WORD<1-32>	Specifies the disk assigned to the virtual service.
mem-size <1-5120>	Specifies the memory size in Megabytes assigned to the virtual service. The default value is 1024 Megabytes.
nic-type [virtio | e1000]	Specifies the Virtual Port NIC type. The default is e1000. Note: Configure this value only when the **connect-type** parameter is ovs.
num-cores <num_cores>	*<num_cores>* specifies the number of cores assigned to the virtual service. Different platforms support different ranges. Note: 5720-24MXW and 5720-48MXW support *<1-2>* cores. The default value is 1.
port WORD<1-32>	Specifies the name of the Extreme Integrated Application Hosting (IAH) port associated with the virtual port. Depending on the hardware, the switch can support the following IAH ports: • 1/s1 • 1/s2
size <1-30>	Specifies the size of the disk in Gigabytes.
vlan <1-4096>	Specifies the VLAN ID used by the virtual port.
vport WORD<1-32>	Specifies the name of the virtual port.

Shut Down a Virtual Service

About This Task

Perform this procedure to disable the virtual service.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Disable the virtual service:

   ```
   no virtual-service WORD<1-128> enable
   ```

Example

Disable the virtual service.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#no virtual-service tpvm enable
```

Delete Virtual Service Resources

About This Task

Perform this procedure to delete the virtual service resource allocation.

Note

If a corresponding virtual machine is running, it is stopped, and then the virtual service configuration is deleted.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Delete the virtual service resource allocation:

   ```
   no virtual-service WORD<1-128> [disk WORD<1-32>] [vport WORD<1-32>]
   ```

Example

Delete all virtual service resource allocation.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#no virtual-service tpvm
```

Uninstall a Virtual Service

About This Task

Perform this procedure to uninstall a configured virtual service.

Note
If a virtual machine is running, it is stopped, and then the service directory is uninstalled.

Before You Begin

You must disable the virtual service before you uninstall it.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```
2. Uninstall a specific virtual service:
   ```
   virtual-service WORD<1-128> uninstall
   ```

Example

```
Switch:1>enable
Switch:1#virtual-service tpvm uninstall
```

Variable Definitions

Use data in the following table to use the **`virtual-service`** command.

Variable	Value
`WORD<1-128>`	Specifies the virtual service name.
`uninstall`	Uninstalls the specified virtual service name.

Display Virtual Service Configuration

About This Task

Perform this procedure to display the virtual service configuration on the switch.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the virtual-service configuration:
   ```
   show virtual-service config [WORD<1-128>]
   ```

Example

Display the configuration of all virtual services:

```
Switch:1>show virtual-service config
================================================================================================
==========
                                Installed Packages
================================================================================================
```

```
==========
    Package:             FIGW-SHAPE
    Package App Name:    FabricIPSecGW_VM_5.0.0.0_20.04
    Package Version:     5.0.0.0
    Package Name:        FabricIPSecGW_VM_5.0.0.0_20.04.ova

```

Display Virtual Service Installation Status

About This Task

Perform this procedure to display the installation status for the specific virtual service. This procedure indicates if the installation finished successfully or failed to complete.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display installation status for a specific virtual service:

   ```
   show virtual-service install WORD<1-128>
   ```

Example

Display installation status for a specific virtual service:

```
Switch:1>show virtual-service install tpvm
        Stage:   Convert
        Status:  In Progress
```

Display Virtual Services Resources

About This Task

Perform the following procedure to display the number of remaining virtual services resources on the switch.

Procedure

1. To enter User EXEC mode, log on to the switch.

2. Display statistics for all virtual services configured on the switch or a specific virtual service:

   ```
   show virtual-service statistics [WORD<1-128>]
   ```

Example

```
Switch:1>show virtual-service statistics

Run a VM command from Network Operating System (NOS) CLI

About This Task

Perform this task to run a virtual machine (VM) command from the NOS CLI.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Run the **ls** command for the VM configs directory from the CLI:

   ```
   virtual-service WORD<1-128> exec-command WORD<1-256>
   ```

3. Run a Fabric IPsec Gateway command from the CLI:

   `virtual-service` *WORD<1-128>* `figw-cli` *WORD<1-256>*

Examples

From NOS, list the contents of the `home/rwa/configs` directory in the Fabric IPsec Gateway VM:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#virtual-service figw exec-command "ls /home/rwa/configs"
config.cfg
figw_cli.log
shadov.txt
```

From NOS, configure the source VLAN ID for the IPsec tunnel in the Fabric IPsec Gateway VM:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#virtual-service figw figw-cli "set global ipsec-tunnel-src-vlan 71"
```

Variable Definitions

The following table defines parameters for the **`virtual-service`** command.

Variable	Value
WORD<1-128>	Specifies the virtual service name.
WORD<1-256>	Specifies the VM command to run. To include spaces in the syntax, include the text string in quotation marks ('').

Copy VM Files

About This Task

Perform this task to copy files between the Network Operating System (NOS) and a VM, or between VMs.

Procedure

1. Enter Privileged EXEC mode:

   `enable`

2. Copy a file:

   `virtual-service copy-file` *WORD<1-256>* *WORD<1-256>*

Examples

Copy a file from the NOS to a VM:

```
Switch:1>enable
Switch:1#virtual-service copy-file /intflash/config_figw.cfg figw:/home/rwa/configs/
config.cfg
```

Copy a file from a VM to the NOS:

```
Switch:1>enable
Switch:1#virtual-service copy-file figw:/home/rwa/configs/config.cfg /intflash/
config_figw.cfg
```

Copy a file between VMs:

```
Switch:1>enable
Switch:1#virtual-service copy-file figw:/home/rwa/configs/config.cfg figw2:/home/rwa/
configs/config.cfg
```

Variable Definitions

The following table defines parameters for the **`virtual-service copy-file`** command.

Variable	Value
WORD<1-256>	Specifies the source and destination file to copy. To specify a VM location, use the format <VM_name>:<VM_file_path/filename>. To specify a NOS location, use the format </file_path/filename> where the valid path can be one of the following: • /intflash • /extflash • /usb • /var/lib/insight/packages

Change a VM User Password from Network Operating System (NOS) CLI

About This Task

Perform this task to change the password for a VM user. The password must be greater than, or equal to, 8 characters.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Change the password:

   ```
   virtual-service WORD<1-128> change-user-pass WORD<1-20>
   ```

3. Enter the new password.
4. Enter the new password a second time.

Example

Change the password for the rwa user account in the Fabric IPsec Gateway VM:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
```

```
Switch:1(config)#virtual-service figw change-user-pass rwa
Enter password : ********
Re-enter password : ********
```

Variable Definitions

The following table defines parameters for the **virtual-service WORD<1-128> change-user-pass** command.

Variable	Value
WORD<1-20>	Specifies the username.
WORD<1-128>	Specifies the virtual service name.

Upgrade a Virtual Service

If Extreme Networks makes a new version of the virtual service available, uninstall the original virtual service and install the newer virtual service. The following generic procedure can apply to all virtual services. For a Fabric IPsec Gateway-specific procedure, see Upgrade a Fabric IPsec Gateway VM on page 799.

Important

You can perform an upgrade of Linux inside the virtual service by standard Linux upgrade procedures. For example, TPVM is Ubuntu based, so you can use **sudo apt-get update** and **sudo apt-get upgrade**. If you complete such an upgrade, Extreme Networks is not responsible for the behavior of the VM; it has not been tested with every version of the network operating system (NOS).

Before You Begin

- Ensure the new virtual service image version is compatible with the NOS release that runs on the switch. For compatibility statements, see *Fabric Engine Release Notes*. If necessary, upgrade the NOS image before you upgrade the virtual service image.
- If you installed applications in the Third Party Virtual Machine (TPVM), you must migrate important data for those applications before you perform this procedure.
- If you created new users in the TPVM, follow standard Linux procedures to back up user names and passwords.
- For Fabric IPsec Gateway, back up the configuration files (*.cfg) and the `shadov.txt` file, which is an encrypted file that contains the authentication keys for the IPsec tunnels. You can use the **ls** command within the VM to see the file list. Use FTP within the VM to transfer the files for backup or see Copy VM Files on page 788.
- Use FTP or SFTP to transfer the new OVA image to the `/var/lib/insight/packages/` directory on the switch.

Note

The Fabric IPsec Gateway image includes no integrity check. Use SCP to copy the file to the switch and confirm the file size before installation.

About This Task

When you uninstall the original virtual service, the system removes the complete virtual service configuration from the configuration file.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Disable the virtual service:

   ```
   no virtual-service WORD<1-128> enable
   ```

3. Return to Privileged EXEC mode:

   ```
   end
   ```

4. Uninstall the virtual service:

   ```
   virtual-service WORD<1-128> uninstall
   ```

5. Install the virtual service package using the new OVA image:

   ```
   virtual-service WORD<1-128> install package WORD<1-512>
   ```

6. Reconfigure the virtual service; for more information, see Configure a Virtual Service on page 779.
7. Remove the original OVA image from the `/var/lib/insight/packages/` directory on the switch:

   ```
   remove WORD<1-255>
   ```

Virtual Services Configuration using EDM

Perform the procedures in this section to configure Extreme Integrated Application Hosting (IAH) virtual services on the switch using the Enterprise Device Manager (EDM).

Viewing Virtual Services Resources

About This Task

Perform the following procedure to view the number of remaining virtual services resources on the switch.

Procedure

1. In the navigation pane, expand the **Configuration** > **Serviceability** folders.
2. Click **Virtual Service**.
3. Click the **Globals** tab.

Globals *Field Descriptions*

Use data in the following table to use the **Globals** tab.

Name	Description
DiskRemain	Shows the remaining disk space available, in Gigabytes (GB).
NumCoresRemain	Shows the remaining number of CPU cores available.
MemSizeRemain	Shows the remaining amount of memory size available, in Megabytes (MB).
CopySourceFile	Specifies the source file to copy. To specify a location, use the format: {VM_NAME_SRC}:{VM_FILE_PATH} or {NOS_FILE_PATH}. For example, `figw:/home/rwa/configs/ipsec1.cfg` identifies a file located in the VM. `/intflash/ipsec1.cfg` identifies a file located in the NOS. The valid path for a NOS location can be one of the following: • `/intflash` • `/extflash` • `/usb` • `/var/lib/insight/packages`
CopyDestinationFile	Specifies the destination file to copy. To specify a location, use the format: {VM_NAME_DST}:{VM_FILE_PATH} or {NOS_FILE_PATH}. For example, `figw:/home/rwa/configs/ipsec1.cfg` identifies a file located in the VM. `/intflash/ipsec1.cfg` identifies a file located in the NOS. The valid path for a NOS location can be one of the following: • `/intflash` • `/extflash` • `/usb` • `/var/lib/insight/packages`
CopyAction	Specifies an action to copy a file from source to destination. The switch supports the following action: • **Copy** • **None**
ScalarsName	Specifies the virtual service name. You must specify the virtual service name if you use this tab to change the password or run a command.
ExecuteCommand	Specifies the Virtual Machine (VM) command to run. To include spaces in the syntax, include the text string in quotation marks (").
User	Specifies the virtual service user name. The range is 0-20 characters.

Name	Description
Password	Specifies the virtual service password.
FigwCli	Specifies the command to send to the Fabric IPsec Gateway VM. For more information about Fabric IPsec Gateway commands, see *Fabric Engine CLI Commands Reference*.

Configure a Virtual Service

About This Task

Perform this procedure to configure a virtual service on the switch.

Before You Begin

You must configure at least one virtual port to enable the virtual service. For more information, see Configure Virtual Ports on page 795.

Procedure

1. In the navigation pane, expand the **Configuration** > **Serviceability** folders.
2. Select **Virtual Service**.
3. Select the **Virtual Service** tab.
4. Select **Insert**.
5. In the **Name** field, enter a unique name.
6. (Optional) In the **NumCores** field, enter a value.
7. (Optional) In the **MemSize** field, enter a value.
8. Select **Insert**.
9. In the **Enable** field for the newly inserted row, change the value to true.
10. Select **Apply**.

Virtual Service *Field Descriptions*

Use data in the following table to use the **Virtual Service** tab.

Name	Description
Name	Specifies the name of the virtual service. Every virtual service must have a unique name.
NumCores	Specifies the number of CPU cores assigned to the virtual service. The default is 1.
MemSize	Specifies the memory size (in Megabytes) assigned to the virtual service. The default value is 1024 Megabytes.

Name	Description
Enable	Enables the virtual service. Note: You must configure at least one virtual port to enable the virtual service.
PackageInfoName	Shows the package name used by the virtual service.
PackageAppName	Shows the application name used by the virtual service.
PackageAppVersion	Shows the application version used by the virtual service.
UtilCpuAllot	Specifies the number of CPUs allocated to the virtual service.
UtilCpuUtil	Specifies the average percentage of CPU utilization over the past 30 seconds.
UtilMemAllot	Specifies the memory (in Megabytes) allocated to the virtual service.
UtilMemUsed	Specifies the memory used (in Megabytes) by the virtual service.
UtilMemAvailable	Specifies the memory available (in Megabytes) for the virtual service.
State	Specifies the operational state of the virtual service.
UpTime	Specifies the operational time of the virtual service.

Configuring Disks to be used by the Virtual Service

About This Task

Perform the following procedure to configure the number of disks to be used by the virtual service configured on the switch.

Procedure

1. In the navigation pane, expand the **Configuration** > **Serviceability** folders.
2. Click **Virtual Service**.
3. Click the **Disks** tab.
4. Click **Insert**.
5. In the **ServName** field, enter the virtual service name.
6. In the **Name** field, enter the disk name.
7. (Optional) In the **Size** field, enter a value.
8. Click **Insert**.

Disks *Field Descriptions*

Use data in the following table to use the **Disks** tab.

Name	Description
ServName	Specifies the virtual service name. Note: The specified name must match the virtual service name configured on the switch.
Name	Specifies the name of the disk used by the virtual service.
Size	Specifies the disk size (in Gigabytes). The default is 10 Gigabytes.
SizeAllot	Shows the disk size (in Megabytes) allocated to the virtual service.
SizeAvailable	Shows the available disk storage space (in Megabytes).
SizeUsed	Shows the amount of disk storage space (in Megabytes) used by the virtual service.

Configure Virtual Ports

About This Task

Perform the following procedure to configure virtual ports to be used by the virtual service configured on the switch.

Note

The names of Ethernet ports appearing in a specific Virtual Machine (VM) are not correlated to the configured virtual port names. Each VM renames the Ethernet ports as per its requirements, after they are discovered during the VM initialization.

By default, the system displays all virtual ports of OVS connection type first in the alphabetical order of their configured names, followed by the virtual ports of SR-IOV and VT-d connection types.

Before You Begin

- You must enable trunking on the Extreme Integrated Application Hosting (IAH) port when you use SR-IOV and OVS connection types.
- Ensure the switch has the Ethernet drivers installed as per the SR-IOV standard, to support the VT-d and the SR-IOV connection type for the configured virtual ports.

Procedure

1. In the navigation pane, expand the **Configuration** > **Serviceability** folders.
2. Select **Virtual Service**.
3. Select the **VPorts** tab.
4. Select **Insert**.

5. In the **Virtual Service Name** field, enter the virtual service name.
6. In the **Interface Name** field, enter a name for the virtual port.
7. (Optional) In the **VlanIdList** field, enter a VLAN ID.
8. (Optional) In the **ConnectType** field, select a connection type.

   Note

   Ensure the connection type you configure for the virtual port matches the connection type supported by the IAH port.

9. Select **Insert**.

VPorts *Field Descriptions*

Use data in the following table to use the **VPorts** tab.

Name	Description
Virtual Service Name	Specifies the virtual service name. Note: The specified name must match the virtual service name configured on the switch.
Interface Name	Specifies the virtual port.
VlanIdList	Specifies the VLAN ID to which the virtual port is assigned.
ConnectType	Specifies the virtual port connect type. The default is VT-d. The switch supports the following maximums for virtual ports: • OVS - 16 • SR-IOV - 16 • VT-d - 2
Port	Specifies the name of the Extreme Integrated Application Hosting port associated with the virtual port. Depending on hardware, the switch can support the following Extreme Integrated Application Hosting ports: • 1/s1 • 1/s2
NicType	Specifies the Virtual Port NIC type. The default is e1000. • virtio • e1000 Note: Configure this value only when the **ConnectType** field is OVS.

Install a Virtual Service

Before You Begin

- Use FTP or SFTP to transfer the OVA image to the `/var/lib/insight/packages/` directory on the switch.

About This Task

Perform the following procedure to configure the package information to be used by the virtual service.

Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability**.
2. Select **Virtual Service**.
3. Select the **Application** tab.
4. Select **Insert**.
5. In the **Name** field, enter the virtual service name.
6. Next to the **PackageName** field, select the ellipsis, select the package to install, and then select **Ok**.
7. Select **Insert**.

Application *Field Descriptions*

Use data in the following table to use the **Application** tab.

Name	Description
Name	Specifies the name of the virtual service.
PackageName	Specifies the name and location of the package.
InstallResult	Shows the status of the virtual service installation.
InstallStage	Shows the stages of a package installation.
PackageAppName	Shows the application name used by the virtual service.
PackageAppVersion	Shows the application version used by the virtual service.

Run a VM command from EDM

About This Task

Perform this task to run a VM command from EDM. To include spaces in the syntax, include the text string in quotation marks (").

Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability**.
2. Select the **Virtual Service**.
3. Select the **Globals** tab.
4. In the **ScalarsName** field, type a virtual service name.

5. In the **ExecuteCommand** field, type the **`ls`** command for the VM `configs` directory. For example, `"ls /home/rwa/configs"`.
6. In the **FigwCli** field, type a command to send it to the Fabric IPsec Gateway. For more information about Fabric IPsec Gateway commands, see *Fabric Engine CLI Commands Reference*.
7. Select **Apply**.

Copy VM Files

About This Task

Perform this task to copy files between the Network Operating System (NOS) and a VM or between VMs. The valid path for a NOS location can be one of the following:

- `/intflash`
- `/extflash`
- `/usb`
- `/var/lib/insight/packages`

Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability**.
2. Select **Virtual Service**.
3. Select the **Globals** tab.
4. In the **CopySourceFile** field, type a location of the source file using the following format: `{VM_NAME_SRC}:{VM_FILE_PATH} or {NOS_FILE_PATH}`. For example, `figw:/home/rwa/configs/ipsec1.cfg` identifies a file located in the VM. `/intflash/ipsec1.cfg` identifies a file located in the NOS.
5. In the **CopyDestinationFile** field, type a location of the destination file using the following format: `{VM_NAME_DST}:{VM_FILE_PATH} or {NOS_FILE_PATH}`. For example, `figw:/home/rwa/configs/ipsec1.cfg` identifies a file located in the VM. `/intflash/ipsec1.cfg` identifies a file located in the NOS.
6. In the **CopyAction** field, select **Copy**.
7. Select **Apply**.

Change a VM User Password from EDM

About This Task

Perform this task to change the password for a VM user.

Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability**.
2. Select **Vitual Sevice**.
3. Select the **Globals** tab.
4. In the **ScalarsName** field, type a virtual service name.
5. In the **User** field, type the user name.
6. In the **Password** field, type a password.

7. Select **Apply**.

Viewing Virtual Services Package File Information

About This Task

Perform the following procedure to view information about the package files available in the `/var/lib/insight/packages` directory, which you can use to install a new virtual service.

Procedure

1. In the navigation pane, expand the **Configuration** > **Serviceability** folders.
2. Click **Virtual Service**.
3. Click the **PackageFile** tab.

PackageFile *Field Descriptions*

Use data in the following table to use the **PackageFile** tab.

Name	Description
Name	Shows the name and absolute path information for package files available in the `/var/lib/insight/packages` directory.
Date	Shows the date and time when the package file was added to the directory.
Size	Shows the size (in bytes) of the package file.

Fabric IPsec Gateway Configuration using CLI

Perform the procedures in this section to configure services like IPsec, fragmentation and reassembly, and to manage the Fabric IPsec Gateway Virtual Machine using the command line interface (CLI).

Upgrade a Fabric IPsec Gateway VM

If Extreme Networks makes a new version of the Fabric IPsec Gateway available, disable or uninstall the original virtual service, and then install the newer virtual service.

Before You Begin

- Ensure the image version is compatible with the NOS release that runs on the switch. For compatibility statements, see *Fabric Engine Release Notes*. If necessary, upgrade the NOS image before you upgrade the virtual service image.
- 

  Note

  The Fabric IPsec Gateway image includes no integrity check. Use SCP to copy the file to the switch and confirm the file size before installation.

About This Task

Steps in this procedure include examples or links to background procedures if you are unfamiliar with how to complete a particular step.

Procedure

1. Within the VM, save the configuration. For more information, see Save Running Configuration to a File on page 821.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#virtual-service figwOld console
Connected to domain figw5.2 Escape character is ^Y
FIGW> save config
File already exists, do you want to overwrite [y/n]: y
FIGW>
```

2. Copy the configuration files (*.cfg), the `shadov.txt` file, which is an encrypted file that contains the authentication keys for the IPsec tunnels, and the `default-config-file.txt` file from the VM to intflash within the NOS. For more information, see Run a VM command from Network Operating System (NOS) CLI on page 787 and Copy VM Files on page 788.

```
Switch:1(config)#mkdir figw
Switch:1(config)#virtual-service figwOld exec-command "ls /home/rwa/configs/"
    config.cfg
    figw.cfg
    figw_cli.log
    new.cfg
    shadov.txt
Switch:1(config)#exit
Switch:1#virtual-service copy-file figwOld:/home/rwa/configs/config.cfg /intflash/figw/
config.cfg
Switch:1#virtual-service copy-file figwOld:/home/rwa/configs/new.cfg /intflash/figw/
new.cfg
Switch:1#virtual-service copy-file figwOld:/home/rwa/configs/figw.cfg /intflash/figw/
figw.cfg
Switch:1#virtual-service copy-file figwOld:/home/rwa/default-config-file.txt /intflash/
figw/default-config-file.txt
Switch:1#virtual-service copy-file figwOld:/home/rwa/configs/shadov.txt /intflash/figw/
shadov.txt
```

3. Verify the file copy:

```
Switch:1#ls figw/
Listing Directory /intflash/figw/:
drwxr-xr-x 2 0 0 4096 Jun 17 13:46 ./
drwxr-xr-x 31 0 0 4096 Jun 17 13:43 ../
-rw-r--r-- 1 0 0 851 Jun 17 13:44 config.cfg
-rw-r--r-- 1 0 0 8 Jun 17 13:46 default-config-file.txt
-rw-r--r-- 1 0 0 0 Jun 17 13:45 figw.cfg
-rw-r--r-- 1 0 0 851 Jun 17 13:45 new.cfg
-rw-r--r-- 1 0 0 32 Jun 17 13:45 shadov.txt
```

4. Enter Global Configuration mode:

```
enable

configure terminal
```

5. Disable the virtual service:

   ```
   no virtual-service WORD<1-128> enable
   ```

   Note

   If you instead uninstall the original virtual service, the system removes the complete virtual service configuration from the configuration file.

6. Return to Privileged EXEC mode:

   ```
   end
   ```

7. Install the virtual service package using the new image:

   ```
   virtual-service WORD<1-128> install package WORD<1-512>
   ```

8. Reconfigure the virtual service. For more information, see Configure a Virtual Service on page 779.
9. Copy the files you saved from the old VM to the same folder path in the new VM:

   ```
   Switch:1(config)#exit
   Switch:1#virtual-service copy-file /intflash/figw/config.cfg figwNew:/home/rwa/configs/
   config.cfg
   Switch:1#virtual-service copy-file /intflash/figw/figw.cfg figwNew:/home/rwa/configs/
   figw.cfg
   Switch:1#virtual-service copy-file /intflash/figw/new.cfg figwNew:/home/rwa/configs/
   new.cfg
   Switch:1#virtual-service copy-file /intflash/figw/shadov.txt figwNew:/home/rwa/configs/
   shadov.txt
   Switch:1#virtual-service copy-file /intflash/figw/default-config-file.txt figwNew:/
   home/rwa/default-config-file.txt
   ```

10. Verify the file copy:

    ```
    configure terminal
    Enter configuration commands, one per line.  End with CNTL/Z.
    Switch:1(config)#virtual-service figwNew exec-command "ls /home/rwa/configs"
    config.cfg
    figw.cfg
    figw_cli.log
    new.cfg
    shadov.txt
    ```

11. Reboot the Fabric IPsec Gateway VM. For more information, see Reboot Fabric IPsec Gateway VM on page 827.

    Tip

    As an alternative, you can disable and reenable the Fabric IPsec Gateway virtual service.

12. Verify the running configuration of the new VM matches the configuration of the old VM:

    ```
    Switch:1(config)#virtual-service figwNew figw-cli "show running-config"
    set global ipsec-tunnel-src-vlan 30
    set global ipsec-tunnel-src-ip 30.30.30.2/24
    set global lan-intf-vlan 100
    set global lan-intf-ip 100.100.100.2/24
    set global lan-intf-gw-ip 100.100.100.102
    set global fe-tunnel-src-ip 102.102.102.102
    set global wan-intf-gw-ip 30.30.30.102
    set global mtu 1950
    set global services sshd enable
    set ipsec 104 auth-key ******
    set ipsec 104 responder-only true
    set ipsec 104 fe-tunnel-dest-ip 104.104.104.104
    set ipsec 104 fragment-before-encrypt enable
    ```

```
set ipsec 104 admin-state enable
set ipsec 105 auth-key ******
set ipsec 105 responder-only true
set ipsec 105 fe-tunnel-dest-ip 105.105.105.105
set ipsec 105 fragment-before-encrypt enable
set ipsec 105 admin-state enable
set ipsec 107 auth-key ******
set ipsec 107 responder-only true
set ipsec 107 fe-tunnel-dest-ip 192.168.22.107
set ipsec 107 admin-state enable
```

13. Remove the original image from the `/var/lib/insight/packages/` directory on the switch:

    ```
    remove WORD<1-255>
    ```

Configure FTP Connection to an IP Address

Fabric IPsec Gateway Virtual Machine (VM) provides a File Transfer Protocol (FTP) CLI to copy the configuration files to the VM.

About This Task

Perform this procedure to configure an FTP connection to a specific IP Address.

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable
   ```

   ```
   virtual-service WORD<1-128> console
   ```

   Note

   Type **CTRL+Y** to exit the console.

2. Configure FTP connection:

   ```
   ftp {A.B.C.D}
   ```

Example

Configuring FTP connection to 192.0.2.50:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

  <cr>
FIGW> ftp 192.0.2.50
```

Variable Definitions

The following table defines the variable for **`ftp`** command.

Variable	Value
`{A.B.C.D}`	Specifies the IP Address to establish the FTP connection with.

Display the Default Directory on Fabric IPsec Gateway VM

About This Task

Perform this procedure to display content in the default directory on the Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable

   virtual-service WORD<1-128> console
   ```

   Note
   Type **CTRL+Y** to exit the console.

2. Display the configured directory:

   ```
   ls
   ```

Example

Displaying the configured directory on the VM.

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

  <cr>
FIGW> ls
coupled.cfg
```

Load Configuration File to Fabric IPsec Gateway VM

About This Task

Perform this procedure to load a configuration file to the Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable

   virtual-service WORD<1-128> console
   ```

   Note
   Type **CTRL+Y** to exit the console.

2. Load a specific configuration file to the VM :

   ```
   load WORD <1-255>
   ```

Example

Loading a configuration file to the VM.

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

  <cr>
FIGW> load coupled.cfg
```

Variable Definitions

The following table defines the variable for **load** command.

Variable	Value
WORD <1-255>	Specifies the configuration file name.

Ping an IP Address on Fabric IPsec Gateway VM

About This Task

Perform this procedure to ping an IP Address on the Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable

   virtual-service WORD<1-128> console
   ```

   Note

   Type **CTRL+Y** to exit the console.

2. Ping an IP Address:

   ```
   ping {A.B.C.D}
   ```

Example

Pinging an IP Address on the VM.

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

  <cr>
FIGW> ping 192.0.2.35
```

Variable Definitions

The following table defines parameters for the **ping** command.

Variable	Value
{A.B.C.D}	Specifies the IP address.

Configure Global Parameters on Fabric IPsec Gateway VM

About This Task

Perform this procedure to configure IPsec source IP address, Local Area Network (LAN) interface IP and gateway IP address, maximum transmission unit (MTU) value, and so on globally, on the Fabric IPsec Gateway Virtual Machine (VM).

Note

You must perform this procedure only after the VM boots up.

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable

   virtual-service WORD<1-128> console
   ```

   Note

   Type **CTRL+Y** to exit the console.

2. Configure IPsec source IP address for a Fabric Extend (FE) tunnel for IPsec in decoupled mode:

   ```
   set global ipsec-tunnel-src-ip {A.B.C.D/X}
   ```

3. Assign VLAN ID to the configured IPsec source IP address:

   ```
   set global ipsec-tunnel-src-vlan <2-4059>
   ```

4. Configure the LAN interface IP address on the first Ethernet interface (eth0) of Fabric IPsec Gateway VM:

   ```
   set global lan-intf-ip {A.B.C.D/X}
   ```

5. Assign VLAN ID to the configured LAN interface IP address:

   ```
   set global lan-intf-vlan <2-4059>
   ```

6. Configure the LAN interface gateway IP address on the VOSS switch:

   ```
   set global lan-intf-gw-ip {A.B.C.D}
   ```

7. Configure the logical interface gateway IP address, to add routes for FE tunnels that need Fragmentation:

   ```
   set global fe-tunnel-gw-ip {A.B.C.D}
   ```

8. Configure the logical interface source IP address for the FE tunnel:

   ```
   set global fe-tunnel-src-ip {A.B.C.D}
   ```

   Note

   The logical interface source IP address must be same as the source IP address configured on the VOSS switch.

9. Configure the global MTU value:

   ```
   set global mtu <mtu-value>
   ```

   Note

   - The switch applies the global MTU value, if you do not configure MTU during the IPsec tunnel configuration.
   - If an IPsec tunnel is not using the fragmentation and reassembly capabilities, the default MTU value is 1950.

10. Configure the Wide Area Network (WAN) interface gateway IP address, which is the next hop for IPsec tunnels.

    ```
    set global wan-intf-gw-ip {A.B.C.D}
    ```

11. Configure the virtual reassembly interface IP address:

    ```
    set global virtual-reassembly-intf-ip {A.B.C.D/X}
    ```

    Note

    You must configure the virtual reassembly interface IP address to use the fragmentation and reassembly service.

12. Assign VLAN ID to the configured virtual reassembly interface IP address:

    ```
    set global virtual-reassembly-intf-vlan <2-4059>
    ```

13. Disable IPsec on all configured tunnels:

    ```
    set global ipsec-disable
    ```

14. Set IPsec log level:

    ```
    set global ipsec-log-level <-1-5>
    ```

Example

Configuring global parameters on Fabric IPsec Gateway VM to configure an IPsec tunnel between two switches:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

  <cr>
FIGW> set global ipsec-tunnel-src-ip 192.0.2.10/24
FIGW> set global ipsec-tunnel-src-vlan 101
FIGW> set global lan-intf-ip 192.0.2.20/24
FIGW> set global lan-intf-vlan 30
FIGW> set global lan-intf-gw-ip 192.0.2.30
FIGW> set global fe-tunnel-src-ip 192.0.2.40
```

```
FIGW> set global wan-intf-gw-ip 192.0.2.50
FIGW> set global mtu 1950
```

Variable Definitions

The following table defines parameters for the **set global** command.

Variable	Value
ipsec-tunnel-src-ip {A.B.C.D/X}	Specifies the source IP address and subnet mask for IPsec tunnel.
ipsec-tunnel-src-vlan <2-4059>	Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.
lan-intf-ip {A.B.C.D/X}	Specifies the IP address and subnet mask for Local Area Network (LAN) interface.
lan-intf-vlan <2-4059>	Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.
lan-intf-gw-ip {A.B.C.D}	Specifies the gateway IP address for LAN interface.
fe-tunnel-gw-ip {A.B.C.D}	Specifies the gateway IP address for Fabric Extend (FE) tunnel.
fe-tunnel-src-ip {A.B.C.D}	Specifies the source IP address for FE tunnel.
mtu <750-9000>	Specifies the Maximum Transmission Unit (MTU) value. Note: If an IPsec tunnel is not using the fragmentation and reassembly capabilities, the default MTU value is 1950.
wan-intf-gw-ip {A.B.C.D}	Specifies the Wide Area Network (WAN) interface gateway IP address.
virtual-reassembly-intf-ip {A.B.C.D/X}	Specifies the virtual-reassembly interface IP address and subnet mask on the Fabric IPsec Gateway (VM). Note: You must configure the virtual reassembly interface IP address to use the fragmentation and reassembly service.
virtual-reassembly-intf-vlan <2-4059>	Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.

Variable	Value
ipsec-disable	Disables IPsec operationally on all tunnels in the Fabric IPsec Gateway VM.
ipsec-log-level <-1-5>	Specifies the IPsec log levels on Fabric IPsec Gateway VM. Following are the three levels: • -1: Absolutely Silent • 0-4: Log levels • 5: Clear Logs

Configure IPsec Tunnels on Fabric IPsec Gateway VM

About This Task

Perform this procedure to configure IPsec tunnels on Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable

   virtual-service WORD<1-128> console
   ```

   Note

   Type **CTRL+Y** to exit the console.

2. Configure the Maximum Transmission Unit (MTU) value for the specific IPsec tunnel:

   ```
   set ipsec <1-255> mtu <1300 - 9000>
   ```

   Note

   The MTU range <1300-9000> is applicable for FE tunnels with IPsec and fragmentation and reassembly capabilities.

3. Configure the ESP cipher suite for the IPsec tunnel:

   ```
   set ipsec <1-255> esp <aes128gcm16-sha256 | aes256-sha256 |
   aes256gcm16-sha256>
   ```

4. Configure the authentication key for specific IPsec tunnel:

   ```
   set ipsec <1-255> auth-key WORD <1-32>
   ```

   Note

   Do not use special characters ?, \, &, <, >, #.

5. Configure VXLAN destination IP address for IPsec tunnel:

   ```
   set ipsec <1-255> fe-tunnel-dest-ip {A.B.C.D}
   ```

   Note

   The VXLAN destination IP address for IPsec tunnel must be the same as the VXLAN destination IP address for FE tunnel.

6. Configure the IPsec destination IP address for the specific tunnel deployed in decoupled mode:
   `set ipsec <1-255> ipsec-dest-ip {A.B.C.D}`
7. Configure a name for the IPsec tunnel:
   `set ipsec <1-255> tunnel-name WORD <1-64>`
8. Identify if the specific tunnel is a responder or initiator in Network Address Translation (NAT) cases:
   `set ipsec <1-255> responder-only <true | False>`
9. Enable the IPsec on a specific tunnel:
   `set ipsec <1-255> admin-state enable`

Example

Configure parameters for IPsec tunnel on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

  <cr>
FIGW> set ipsec 1 ipsec-dest-ip 192.0.2.5
FIGW> set ipsec 1 mtu 1950
FIGW> set ipsec 1 auth-key abcd
FIGW> set ipsec 1 tunnel-name Tunnel-to-BEB2
FIGW> set ipsec 1 fe-tunnel-dest-ip 192.0.2.15
FIGW> set ipsec 1 esp aes256gcm16-sha256
FIGW> set ipsec 1 admin-state enable
```

Variable Definitions

The following table defines parameters for the **`set ipsec`** command.

Variable	Value
<1-255>	Specifies the unique ID for the IPsec tunnel.
admin-state <enable | disable>	Enables or disables IPsec on the specific IPsec tunnel.
auth-key WORD <1-32>	Specifies the pre-shared authentication key. Note: Do not use special characters ?, \, &, <, >, #.
encryption-key-length <128 | 256>	Specifies the encryption key length for the IPsec tunnel. The default encryption key length is 128. As a best practice, use the newer *esp* parameter instead; the *encryption-key-length* parameter remains for backward compatibility.
esp <aes128gcm16-sha256 | aes256-sha256 | aes256gcm16-sha256>	Specifies the ESP cipher suites for the IPsec tunnel. The default is aes128gcm16-sha256. aes256-sha256 is not supported in the current release.
fe-tunnel-dest-ip {A.B.C.D}	Specifies the destination IP address for Fabric Extend (FE) tunnel.

Variable	Value
ipsec-dest-ip {A.B.C.D}	Specifies the destination IP address for IPsec tunnel.
mtu <1300-9000	Specifies the Maximum Transmission Unit (MTU) value for the FE tunnel with both IPsec and fragmentation and assembly capabilities.
responder-only <true | false>	Specifies if the IPsec session in the FE tunnel will be in responder only mode or initiator mode. When in responder mode the FE tunnel will only respond to the incoming request and not initiate the IPsec connection. By default both sides of IPSec connection will be initiators in the FE tunnel. Configure the IPsec tunnel to be in responder only mode when there is Network Address Translation (NAT) between the IPsec connection. Note: IPsec Network Address Translation (NAT) is not supported on 5720 Series.
tunnel-name WORD <1-64>	Specifies a name for the IPsec tunnel.
egress-shaping-rate <1-1000>	Specifies the egress shaper rate for the IPsec tunnel.

Configure IPsec Compression

Before You Begin

Ensure IPsec fragmentation before encryption is disabled.

About This Task

Perform this procedure to enable IPsec compression on Fabric IPsec Gateway Virtual Machine (VM).

Note

By default, IPsec compression is disabled. You must enable IPsec compression on both ends of the adjacency.

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable

   virtual-service WORD<1-128> console
   ```

   Note

   Type **CTRL+Y** to exit the console.

2. Enable IPsec compression:

   ```
   set ipsec compression
   ```

Enable Fragmentation Before Encryption on Fabric IPsec Gateway VM

Perform this procedure to fragment packets larger than the IPsec tunnel maximum transmission unit (MTU) before the packets are sent for encryption.

Before You Begin

- Ensure IPsec is disabled on the tunnel. The administrative state must be disabled before you can enable or disable fragmentation before encryption.
- Configure the IPsec destination IP address or enable responder mode.

About This Task

By default, fragmentation before encryption is disabled.

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:
   ```
   enable

   virtual-service WORD<1-128> console
   ```
   Note
   Type **CTRL+Y** to exit the console.
2. Enable fragmentation before IPsec encryption:
   ```
   set ipsec <1-255> fragment-before-encrypt enable
   ```

Configure the Subject Identity on Fabric IPsec Gateway VM

About This Task

Use this procedure to configure the subject parameters to identify the device.

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:
   ```
   enable

   virtual-service WORD<1-128> console
   ```
   Note
   Type **CTRL+Y** to exit the console.
2. Configure the distinguished name of the device:
   ```
   set certificate subject <subject-label> DN <name>
   ```
3. (Optional) Configure the name of the generated key-pair:
   ```
   set certificate subject <subject-label> key-label <key-label>
   ```

Example

```
Switch:1>enable
Switch:1#virtual-service FIGW console
FIGW>set certificate subject ExtremeLab DN "CN=subca5, OU=Test, O=Extreme, L=Town,
```

```
ST=State, E=email@extremenetworks.com"
FIGW>set certificate subject ExtremeLab key-label key1
```

Variable Definitions

The following table defines parameters for the **set certificate subject** command.

Variable	Value
DN <name>	Specifies the distinguished name. You can create a comma-separated list.
key-label <key-label>	Specifies the key name of the generated key pair. This parameter is optional. If you do not configure one, the switch generates one the same as the subject-label.
<subject-label>	Specifies the subject identity. You cannot use the following special characters: • question mark (?) • backslash (\) • ampersand (&) • less than (<) • greater than (>) • pound (#)

Generate the Key Pair on Fabric IPsec Gateway VM

About This Task

Use the following procedure to generate the private and public key pair. By default, VOSS generates a 2,048 RSA key when the system starts. You can use this procedure to generate a new key.

Before You Begin

- Configure an EJBCA CA server.
- Configure a route from Fabric IPsec Gateway to the EJBCA CA server.

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable

   virtual-service WORD<1-128> console
   ```

   

   Note

   Type **CTRL+Y** to exit the console.

2. Generate the key:

   ```
   certificate generate key <type> <size> <key-label>
   ```

Example

```
Switch:1>enable
Switch:1#virtual-service FIGW console
FIGW>certificate generate key rsa 2048 key_rsa
  fingerprint:    09ac0c64b9bf3ad04dc67f20942c674e
```

Variable Definitions

The following table defines parameters for the **`certificate generate key`** command.

Variable	Value
`key-label`	Specifies the key name of the generated key pair.
`size`	Specifies the size of key-pair to be generated. The switch supports 2048.
`type`	Specifies the type of cryptography algorithm used to generate the key-pair. The switch uses only rsa as the cryptography algorithm type.

Configure a Trustpoint CA on Fabric IPsec Gateway VM

About This Task

Use this procedure to configure the certificate authority (CA) to use Simple Certificate Enrollment Protocol (SCEP) with a CA server for online certificate provisioning.

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable

   virtual-service WORD<1-128> console
   ```

   Note

   Type **CTRL+Y** to exit the console.

2. Configure the trusted CA URL:

   ```
   set certificate ca-trustpoint <ca-label> ca-url <ca-url>
   ```

3. Configure the common name of the CA:

   ```
   set certificate ca-trustpoint <ca-label> caname <caname>
   ```

4. Configure the HTTP request type to support the type of CA:

   ```
   set certificate ca-trustpoint <ca-label> get-method <post | get>
   ```

5. Configure the appropriate action:

   - Configure the trustpoint, authenticate the trustpoint CA by getting the certificate of the CA, and store the CA certificate locally:

     ```
     certificate ca <ca-trustpoint> caAuth
     ```

   - Generate the certificate enrollment request, get the digital certificate, and store it locally, associating with the trustpoint CA:

     ```
     certificate ca <ca-trustpoint> enroll <subject-label>
     ```

   - Get the Certificate Revocation List (CRL) from the CDP and store into a file:

     ```
     certificate get crl-from <A.B.C.D> <user> <file-path> <cacert-
     filename>
     ```

- Get the CA certificate obtained from the trustpoint CA:

  ```
  certificate get cacert-from <A.B.C.D> <user> <file-path>
  ```

- Get the subject certificate obtained from the trustpoint CA:

  ```
  certificate get signedcert-from <A.B.C.D> <user> <file-path>
  <subject-label>
  ```

- Release the locally stored certificate associated with the trustpoint CA after revocation:

  ```
  certificate ca <ca-trustpoint> remove <subject-label>
  ```

- Remove all certificates from the CA trustpoint:

  Note

  You can clean the CA trustpoint only if the subject-label is not configured on an IPsec tunnel.

  ```
  certificate ca <ca-trustpoint> clean
  ```

Example

```
Switch:1>enable
Switch:1#virtual-service FIGW console
FIGW>set certificate ca-trustpoint caExtremeEJBCA ca-url http://192.0.2.9:8080/ejbca/
publicweb/apply/scep/test/pkiclient.exe
FIGW>set certificate ca-trustpoint caExtremeEJBCA caname subca5
FIGW>set certificate ca-trustpoint caExtremeEJBCA get-method post
```

Variable Definitions

The following table defines parameters for the **`set certificate ca-trustpoint`** command.

Variable	Value
<ca-label>	Specifies the name of the certificate authority (CA). The name can use alphanumeric characters and is case-sensitive. The maximum length is 45 characters.
ca-url <ca-url>	Specifies the trusted CA URL.
caname <caname>	Specifies the name of the owner of the device or user.
get-method <post | get>	Specifies the HTTP request style. You can use post for EJBCA or get for Win2012 CA. The default value is post.

The following table defines parameters for the **`certificate ca`** command.

Variable	Value
<ca-trustpoint>	Specifies the name of the certificate authority. The name can be alphanumeric and is case-sensitive. The maximum length is 45 characters.
<subject-label>	Specifies the subject identity.

The following table defines parameters for the **certificate get** command.

Variable	Value
cacert-from <A.B.C.D> <user> <file-path>	Specifies where to obtain the CA certificate. Specify the IP address, username, and remote file path.
crl-from <A.B.C.D> <user> <file-path> <cacert-filename>	Specifies where to obtain the Certificate Revocation List. Specify the IP address, username, remote file path, and the CA certificate file to verify the CRL.
signedcert-from <A.B.C.D> <user> <file-path> <subject-label>	Specifies where to obtain the subject certificate. Specify the IP address, username, remote file path, and subject label.

Generate the Certificate Signing Request on Fabric IPsec Gateway VM

About This Task

Use this procedure to generate a certificate signing request (CSR) and store it into a file. This CSR is required to obtain the offline subject certificate.

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable

   virtual-service WORD<1-128> console
   ```

   Note

   Type **CTRL+Y** to exit the console.

2. Generate the CSR:

   ```
   certificate generate csr <subject-label>
   ```

3. Configure where to send the CSR for signing:

   ```
   certificate send-csr-to <A.B.C.D> <user> <remote-path> <subject-label>
   ```

Variable Definitions

The following table defines parameters for the **certificate generate csr** command.

Variable	Value
<subject-label>	Specifies the subject identity.

The following table defines parameters for the **certificate send-csr-to** command.

Variable	Value
<A.B.C.D>	Specifies the IP address for the certificate authority.
<remote-path>	Specifies the file path on the certificate authority.
<subject-label>	Specifies the subject identity.
<user>	Specifies the username for the certificate authority.

Remove Keys and Certificates on Fabric IPsec Gateway VM

Before You Begin

You can remove subject certificates from the certificate authority (CA) trustpoint only if the subject-label is not configured on an IPsec tunnel.

About This Task

Use this procedure to remove keys or certificates from the certificate store.

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable

   virtual-service WORD<1-128> console
   ```

   Note
   Type **CTRL+Y** to exit the console.

2. Remove a key:

   ```
   certificate remove key <key-label>
   ```

3. Remove a specific certificate from the store:

   ```
   certificate remove offline-cacert <filename>
   ```

4. Remove a Certificate Revocation List (CRL) certificate from the store:

   ```
   certificate remove offline-crl <filename>
   ```

5. Remove signed certificates for a specific subject label:

   ```
   certificate remove offline-subject-certs <subject-label>
   ```

6. Remove a specific identity certificate from the CA trustpoint:

   ```
   certificate ca <ca-trustpoint> remove <subject-label>
   ```

7. Remove all certificates from the CA trustPoint:

   ```
   certificate ca <ca-trustpoint> clean
   ```

Variable Definitions

The following table defines parameters for the **certificate remove** command.

Variable	Value
key <key-label>	Specifies the key name to remove.
offline-cacert <filename>	Specifies the certificate filename to remove.
offline-crl <filename>	Specifies the Certificate Revocation List (CRL) certificate filename to remove.
offline-subject-certs <subject-label>	Specifies the subject label for which to remove signed certificates.

The following table defines parameters for the **certificate ca** command.

Variable	Value
<ca-trustpoint>	Specifies the name of the certificate authority. The name can be alphanumeric and is case-sensitive. The maximum length is 45 characters.
<subject-label>	Specifies the subject identity.

View the Certificate Details on Fabric IPsec Gateway VM

About This Task

Use this procedure for the following tasks:

- Display the digital certificate for a certificate type or list all the certificate details from the local store.
- Display the certificate authority (CA) details for a trustpoint CA name or list all the CA details from the local store if the CA name is not specified.
- Display the configured key details for a key name.
- Display the configured subject details.

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable

   virtual-service WORD<1-128> console
   ```

   Note

   Type **CTRL+Y** to exit the console.

2. Display all digital certificates:

   ```
   show certificates all
   ```

3. Display the CA details:

   ```
   show certificates cacert [<ca-label>]
   ```

4. Display Certificate Revocation List (CRL) certificate details:

   ```
   show certificates crl [<ca-label>]
   ```

5. Display the certificate signing request (CSR) details:

   ```
   show certificates csr [<ca-label>]
   ```

6. Display the name and public key of all the key-pairs:

   ```
   show certificate keys
   ```

7. Display the details of signed certificates:

   ```
   show certificate signed [<ca-label>]
   ```

Example

```
Switch:1>enable
Switch:1#virtual-service FIGW console
FIGW>show certificates keys key_rsa
Key Label:     key_rsa
private key with:
pubkey:    RSA 2048 bits
keyid:     ef:4c:1d:a7:cc:84:6f:87:da:e4:de:99:07:3d:96:fc:9a:d1:c9:f4
subjkey:   cb:d1:67:a0:da:9c:05:ce:c0:0d:a3:5c:1b:ba:ce:3f:ff:af:8f:77
```

Variable Definitions

The following table defines parameters for the **`show certificates`** command.

Variable	Value
ca <ca-label>	Specifies the name of the certificate authority (CA). If you do not specify the name, the command displays the details of all configured CAs.

View the Certificate Configuration on Fabric IPsec Gateway VM

About This Task

Use this procedure to view the certificate configuration for the VM.

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable
   ```

   ```
   virtual-service WORD<1-128> console
   ```

   Note

   Type **CTRL+Y** to exit the console.

2. Display all configured entries:

   ```
   show running-config
   ```

3. Display the CA trustpoint configuration:

   ```
   show certificate-config ca-trustpoint [<ca-label>]
   ```

4. Display the subject-related configuration:

   ```
   show certificate-config subject [<subject-label>]
   ```

Examples

```
Switch:1>enable
Switch:1#virtual-service FIGW console
FIGW>show certificate-config ca-trustpoint
certificate {
    ca-trustpoint {
        ca-label a;
        caname subCaVpn;
        ca-url http://10.2.38.35:8080/ejbca/publicweb/apply/scep/test/pkiclient.exe;
        get-method post;
    }
```

```
Switch:1>enable
Switch:1#virtual-service FIGW console
FIGW>show certificate-config subject
certificate {
    subject {
        subject-label fig;
        DN CN=FIGW;
        key-label gigi;
    }
    subject {
        subject-label figv;
        DN CN=figvpn;
    }
```

Configure Egress Shaping Rate for IPsec Tunnels on Fabric IPsec Gateway VM

Before You Begin

Before you can configure the egress shaping rate for the IPsec tunnel on the VM, you must first disable the IPsec tunnel.

About This Task

Perform this procedure to configure the egress shaping rate for IPsec tunnels on Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable

   virtual-service WORD<1-128> console
   ```

   

   Note

   Type **CTRL+Y** to exit the console.

2. Disable the IPsec tunnel:

   ```
   delete ipsec <1-255> admin-state enable
   ```

3. Configure the egress shaping rate for the IPsec tunnel:

   ```
   set ipsec <1-255> egress-shaping-rate <1-1000>
   ```

4. Enable the IPsec tunnel:

   ```
   set ipsec <1-255> admin-state-enable
   ```

Example

Configuring egress-shaping-rate for the IPsec tunnel on the Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

  <cr>
FIGW> delete ipsec 1 admin-state enable
FIGW> set ipsec 1 egress-shaping-rate 200
FIGW> set ipsec 1 admin-state enable
```

Variable Definitions

The following table defines parameters for the **`set ipsec`** command.

Variable	Value
<1-255>	Specifies the unique ID for the IPsec tunnel.
admin-state <enable | disable>	Enables or disables IPsec on the specific IPsec tunnel.
egress-shaping-rate <1-1000>	Specifies the egress shaping rate for the IPsec tunnel.

Configure Logical Interface Tunnel on Fabric IPsec Gateway VM

About This Task

Perform this procedure to configure a Fabric Extend (FE) tunnel with only fragmentation and reassembly capabilities, on the Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable

   virtual-service WORD<1-128> console
   ```

   Note

   Type **CTRL+Y** to exit the console.

2. Configure the logical interface destination IP address for the specific tunnel:

   ```
   set logical-intf-tunnel <1-255> fe-tunnel-dest-ip {A.B.C.D}
   ```

3. Configure the Maximum Transmission Unit (MTU) value for the specific tunnel:

   ```
   set logical-intf-tunnel <1-255> mtu <750-9000>
   ```

   Note

   The MTU range <750-9000> is applicable for FE tunnels with only fragmentation and reassembly capabilities.

4. Configure tunnel name:

   ```
   set logical-intf-tunnel <1-255> tunnel-name WORD <1-64>
   ```

5. Configure the egress shaping rate for a specific tunnel:

   ```
   set logical-intf-tunnel <1-255> egress-shaping-rate <1-1000>
   ```

Example

Configuring logical interface tunnel on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

  <cr>
FIGW> set logical-intf-tunnel 2 fe-tunnel-dest-ip 192.0.2.50
FIGW> set logical-intf-tunnel 2 mtu 1300
FIGW> set logical-intf-tunnel 2 egress-shaping-rate 5
FIGW> set logical-intf-tunnel 2 tunnel-name Tunnel-to-BEB2
```

Variable Definitions

The following table defines parameters for the **`set logical-intf-tunnel`** command.

Variable	Value
<1-255>	Specifies the unique ID for the logical interface tunnel.
fe-tunnel-dest-ip {A.B.C.D}	Specifies the FE tunnel destination IP address for the logical interface.
mtu <750-9000>	Specifies the Maximum Transmission Unit (MTU) value for the FE tunnel with only fragmentation and assembly capabilities.
tunnel-name WORD <1-64>	Specifies a name for the the logical interface tunnel.
egress-shaping-rate<1-1000>	Specifies the egress shaping rate for the logical interface tunnel.

Save Running Configuration to a File

About This Task

Perform this procedure to save the current configuration on Fabric IPsec Gateway Virtual Machine (VM) to a specific file.

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable

   virtual-service WORD<1-128> console
   ```

   Note

   Type **CTRL+Y** to exit the console.

2. Save configuration to the default configuration file:

   ```
   save config [-y]
   ```

3. Save configuration to a specific file in the Fabric IPsec Gateway VM.
   `save config file WORD <1-255> [-y]`

Example

Save the Fabric IPsec Gateway configuration to file "test":

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

  <cr>
FIGW>save config file test.txt
File already exists, do you want to overwrite [y/n]: y
```

Save the Fabric IPsec Gateway configuration to file "test", forcing the switch to overwrite the file without confirmation:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

  <cr>
FIGW> save config file test.txt -y
```

Variable Definitions

The following table defines parameters for the **`save config`** command.

Variable	Value
`file WORD <1-255>`	Specifies the name of file to save the configuration of the Fabric IPsec Gateway VM.
`-y`	Forces the switch to overwrite the configuration file without confirmation.

Remove Configuration File from Fabric IPsec Gateway VM

About This Task

Perform this procedure to remove a specific configuration file from Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:
   `enable`

   `virtual-service WORD<1-128> console`

   Note
   Type **CTRL+Y** to exit the console.

2. Remove the configuration file:
   `remove WORD <1-255>`

Example

Remove configuration file "test" from Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

  <cr>
FIGW> remove test
```

Variable Definitions

The following table defines parameters for the **remove** command.

Variable	Value
WORD <1-255>	Specifies the configuration file name that the system removes from Fabric IPsec Gateway VM.

Delete Global Configuration on Fabric IPsec Gateway VM

About This Task

Perform this procedure to delete the global parameters that you configure on Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable

   virtual-service WORD<1-128> console
   ```

   Note

   Type **CTRL+Y** to exit the console.

2. Delete configuration of specific global parameters:

   ```
   delete global <fe-tunnel-gw-ip | fe-tunnel-src-ip | ipsec-disable |
   ipsec-tunnel-src-ip | ipsec-tunnel-src-vlan | lan-intf-gw-ip | lan-
   intf-ip | lan-intf-vlan | mtu | virtual-reassembly-intf-ip | virtual-
   reassembly-intf-vlan | wan-intf-gw-ip>
   ```

Example

Deleting the global Maximum Transmission Unit (MTU) configuration on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

  <cr>
FIGW> delete global mtu
```

Variable Definitions

The following table defines parameters for the **delete global** command.

Variable	Value
fe-tunnel-gw-ip	Deletes the global gateway IP address for Fabric Extend (FE) tunnel.
fe-tunnel-src-ip	Deletes the global source IP address for FE tunnel.
ipsec-disable	Deletes the global IPsec configuration.
ipsec-tunnel-src-ip	Deletes the global source IP address and subnet mask for IPsec tunnel.
ipsec-tunnel-src-vlan	Deletes the global source VLAN configuration for IPsec tunnel.
lan-intf-gw-ip	Deletes the global gateway IP address on the Local Area Network (LAN) interface.
lan-intf-ip	Deletes the global IP address and subnet mask on LAN interface.
lan-intf-vlan	Deletes the global VLAN configuration on LAN interface.
mtu	Resets the Maximum Transmission Unit (MTU) value to its default, that is 1950 bytes.
virtual-reassembly-intf-ip	Deletes the global virtual-reassembly interface IP address and subnet mask.
virtual-reassembly-intf-vlan	Deletes the global virtual-reassembly interface VLAN configuration.
wan-intf-gw-ip	Deletes the global gateway IP address on the Wide Area Network (WAN) interface.

Delete IPsec Tunnel Configuration on Fabric IPsec Gateway VM

Before You Begin

You must disable the IPsec administrative state on the tunnel before you can remove IPsec configuration.

About This Task

Perform this procedure to delete the configuration of a specific IPsec tunnel on Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable

   virtual-service WORD<1-128> console
   ```

   Note

   Type **CTRL+Y** to exit the console.

2. Delete the configuration of a specific tunnel:

```
delete ipsec <1-255> <admin-state enable | auth-key | encryption-key-length | fe-tunnel-dest-ip | fragment-before-encrypt enable | ipsec-dest-ip | mtu | responder-only | tunnel-name | egress-shaping-rate>
```

Example

Delete configuration on IPsec tunnel ID 2:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

  <cr>
FIGW>delete ipsec 2 admin-state enable
FIGW>delete ipsec 2 auth-key
FIGW>delete ipsec 2 tunnel-name
FIGW>delete ipsec 2 fragment-before-encrypt enable
```

Variable Definitions

The following table defines parameters for the **`delete ipsec`** command.

Variable	Value
<1-255>	Specifies the unique ID of the configured IPsec tunnel.
admin-state enable	Disables the IPsec status on the specific IPsec tunnel.
auth-key	Deletes the authentication key that you configure on the specific IPsec tunnel.
encryption-key-length	Resets the encryption key length for the specific IPsec tunnel to its default value, that is 128 bit.
fe-tunnel-dest-ip	Deletes the destination IP address that you configure on the Fabric Extend (FE) tunnel.
fragment-before-encrypt enable	Disables the fragmentation of packets before IPsec encryption on the tunnel. By default, fragmentation before encryption is disabled.
ipsec-dest-ip	Deletes the destination IP address that you configure on the IPsec tunnel.
mtu	Resets the Maximum Transmission Unit (MTU) value for the specific IPsec tunnel to the MTU value configured globally.
responder-only	Deletes the mode that you configure for the IPsec session in FE tunnel.
tunnel-name	Deletes the name that you configure for the IPsec tunnel.
egress-shaping-rate	Deletes the egress shaping rate for the IPsec tunnel.

Delete Logical Interface Tunnel Configuration on Fabric IPsec Gateway VM

About This Task

Perform this procedure to delete configuration of a specific logical interface tunnel on Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable

   virtual-service WORD<1-128> console
   ```

   Note

   Type **CTRL+Y** to exit the console.

2. Delete configuration of specific logical interface tunnel:

   ```
   delete logical-intf-tunnel <1-255> < fe-tunnel-dest-ip | mtu | egress-shaping-rate>
   ```

Example

Deleting the destination IP address for Fabric Extend (FE) tunnel configured on the logical interface tunnel with ID 3.

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

  <cr>
FIGW> delete logical-intf-tunnel 3 fe-tunnel-dest-ip
```

Variable Definitions

The following table defines parameters for the **`delete logical-intf-tunnel`** command.

Variable	Value
<1-255>	Specifies the unique ID of the logical interface tunnel.
fe-tunnel-dest-ip	Deletes the destination IP address that you configure on the logical interface tunnel.
mtu	Resets the Maximum Transmission Unit (MTU) value for the specific logical interface tunnel to the MTU value configured globally.
egress-shaping-rate	Deletes the egress shaping rate on the logical interface tunnel.

Display Data in a File on Fabric IPsec Gateway VM

About This Task

Perform this procedure to display the data in a specific file on Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable

   virtual-service WORD<1-128> console
   ```

   Note
   Type **CTRL+Y** to exit the console.

2. Display data in a file:

   ```
   more WORD <1-255>
   ```

Example

Display the data from coupled.cfg file:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

  <cr>
FIGW> more coupled.cfg
set global ipsec-tunnel-src-vlan 125
set global ipsec-tunnel-src-ip 192.0.2.10/24
set global lan-intf-vlan 30
set global lan-intf-ip 192.0.2.20/24
set global lan-intf-gw-ip 192.0.2.25
set global fe-tunnel-src-ip 192.0.2.45
set global wan-intf-gw-ip 192.0.2.11
set global mtu 1950
set ipsec 1 auth-key ******
set ipsec 1 fe-tunnel-dest-ip 192.0.2.50
set ipsec 1 encryption-key-length 128
set ipsec 1 admin-state enable
```

Reboot Fabric IPsec Gateway VM

About This Task

Perform this procedure to reboot the Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable

   virtual-service WORD<1-128> console
   ```

   Note
   Type **CTRL+Y** to exit the console.

2. Reboot the VM:

   ```
   reboot
   ```

Example

Rebooting Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

  <cr>
FIGW> reboot
```

Reset Current Configuration on Fabric IPsec Gateway VM

About This Task

Perform this procedure to reset the current configuration on Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable

   virtual-service WORD<1-128> console
   ```

   Note

   Type **CTRL+Y** to exit the console.

2. Reset current configuration:

   ```
   reset-config
   ```

   Note

   Reboot the Fabric IPsec Gateway VM after you reset the configuration.

Example

Resetting current configuration on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

  <cr>
FIGW> reset-config
```

Traceroute to an IP address on Fabric IPsec Gateway VM

About This Task

Perform this procedure to traceroute to an IP address on Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable

   virtual-service WORD<1-128> console
   ```

   Note
   Type **CTRL+Y** to exit the console.

2. Traceroute to an IP address:

   ```
   traceroute {A.B.C.D}
   ```

Example

Traceroute to IP address.

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

  <cr>
FIGW> traceroute 192.0.2.100
```

Variable Definitions

The following table defines parameters for the **traceroute** command.

Variable	Value
{A.B.C.D}	Specifies the IP address to initiate traceroute to.

Display the Default Configuration File on Fabric IPsec Gateway VM

About This Task

Perform this procedure to display the default configuration file on the Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable

   virtual-service WORD<1-128> console
   ```

   Note
   Type **CTRL+Y** to exit the console.

2. Display default configuration file:

   ```
   show default-config-file
   ```

Example

Displaying default configuration file on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

  <cr>
FIGW> show default-config-file
coupled.cfg
```

Display IPsec Logs on Fabric IPsec Gateway

About This Task

Perform this procedure to display IPsec session logs on the Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable

   virtual-service WORD<1-128> console
   ```

   

   Note

   Type **CTRL+Y** to exit the console.

2. Display IPsec session logs:

   ```
   show ipsec-logs
   ```

Example

Displaying IPsec session logs on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

  <cr>
FIGW> show ipsec-logs
<<Month dd>> <<hh:mm:ss>> 15[IKE] <ipsec0-192.0.2.10|29> sending DPD request

```

Display IPsec Routes on Fabric IPsec Gateway VM

About This Task

Perform this procedure to display the IPsec routes configured on the Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable

   virtual-service WORD<1-128> console
   ```

   Note

   Type **CTRL+Y** to exit the console.

2. Display IPsec routes installed:

   ```
   show ipsec-routes
   ```

Example

Displaying the IPsec routes configured on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

  <cr>
FIGW> show ipsec-routes
192.0.2.30 via 192.0.2.20 dev eth0.125  mtu lock 1950

192.0.2.10 via 192.0.2.45 dev eth0.30
192.0.2.100/24 dev eth0.125  proto kernel  scope link  src 192.0.2.60
192.0.2.11/16 dev docker0  proto kernel  scope link  src 192.0.2.12 linkdown
```

Display IPsec Encryption Statistics on Fabric IPsec Gateway VM

About This Task

Perform this procedure to display the IPsec encryption statistics on the Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable

   virtual-service WORD<1-128> console
   ```

   

   Note

   Type **CTRL+Y** to exit the console.

2. Display IPsec encryption statistics:

   ```
   show ipsec-stats
   ```

Example

Displaying IPsec encryption statistics on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

  <cr>
FIGW> show ipsec-stats

Display the Status of IPsec Tunnels on Fabric IPsec Gateway VM

About This Task

Perform this procedure to display the status of configured IPsec tunnel on the Fabric IPsec Gateway Virtual Machine (VM):

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable

   virtual-service WORD<1-128> console
   ```

   Note
   Type **CTRL+Y** to exit the console.

2. Display the status of IPsec tunnels configured on the VM:

   ```
   show ipsec-status
   ```

Example

Displaying the status of configured IPsec tunnel on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

  <cr>

Displays the IPsec Configuration on the Fabric IPsec Gateway VM

About This Task

Perform this procedure to display the IPsec configuration on the Fabric IPsec Gateway Virtual Machine (VM):

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable

   virtual-service WORD<1-128> console
   ```

   Note

   Type **CTRL+Y** to exit the console.

2. Display the IPsec configuration on the configured on the VM:

   ```
   show ipsec-config <1-255>
   ```

Example

Displaying the IPsec configuration on the configured on the VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

FIGW> show ipsec-config 2
ipsec {
    tunnel_id 2;
    encryption-key-length 128;
    fe-tunnel-dest-ip 10.10.10.10;
    ipsec-dest-ip 70.70.70.73;
    mtu 1950;
    responder-only false;
    tunnel-name ----;
    auth-method psk;
    cert-subject;
    auth-key *****;
    egress-shaping-rate 110;
    fragment-before-encrypt enable;
    admin-state enable
```

Display the Logical Interface IPsec Configurations on the Fabric IPsec Gateway VM

About This Task

Perform this procedure to display the logical interface IPsec configurations on the Fabric IPsec Gateway Virtual Machine (VM):

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable

   virtual-service WORD<1-128> console
   ```

   Note
   Type **CTRL+Y** to exit the console.

2. Display the logical interface IPsec configurations on the VM:

   ```
   show logical-intf-config <1-255>
   ```

Example

Displaying the logical interface IPsec configurations on the on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

  <cr>
FIGW>
FIGW> show logical-intf-config 1
logical-intf-tunnel {
    tunnel_id 1;
    tunnel-name ----;
    fe-tunnel-dest-ip 20.20.20.20;
    mtu 1950;
    egress-shaping-rate 110;
```

Display Current Configuration on Fabric IPsec Gateway VM

About This Task

Perform this procedure to display the parameters configured currently on the Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable

   virtual-service WORD<1-128> console
   ```

   Note
   Type **CTRL+Y** to exit the console.

2. Display the parameters currently configured on the VM:

   ```
   show running-config
   ```

Example

Displaying the parameters configured on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

  <cr>
FIGW> show running-config
set global ipsec-tunnel-src-vlan 125
set global ipsec-tunnel-src-ip 192.0.2.1/24
set global lan-intf-vlan 30
set global lan-intf-ip 192.0.2.10/24
set global lan-intf-gw-ip 192.0.2.25
set global fe-tunnel-src-ip 192.0.2.55
set global wan-intf-gw-ip 192.0.2.11
set global mtu 1950
set ipsec 1 auth-key ******
set ipsec 1 fe-tunnel-dest-ip 192.0.2.70
set ipsec 1 encryption-key-length 128
set ipsec 1 admin-state enable
```

Display Current Version of Fabric IPsec Gateway VM

About This Task

Display current version of the Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable

   virtual-service WORD<1-128> console
   ```

   Note

   Type **CTRL+Y** to exit the console.

2. Display current version of the VM:

   ```
   show version
   ```

Example

Displaying current version of the Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

  <cr>
FIGW>show version
FabricIPSecGW_VM_4.0.0.0
```

Log Out of Fabric IPsec Gateway VM

About This Task

Perform this procedure to log out of the Fabric IPsec Gateway Virtual Machine (VM).

Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

   ```
   enable

   virtual-service WORD<1-128> console
   ```

   Note

   Type **CTRL+Y** to exit the console.

2. Log out of VM:

   ```
   exit
   ```

Example

Logging out of the Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

  <cr>
FIGW> exit
```

Fabric Configuration Work Flow

This section describes the generic work flow to configure SPBM and IS-IS infrastructure and services on your network.

Note

This section is an overview. For further details on the SPBM and IS-IS infrastructure and configuration, see the sections described in the Documentation Sources section that follows.

1. Infrastructure configuration

   As a first step, you must configure your basic infrastructure for Shortest Path Bridging MAC (SPBM).
2. Services configuration

   After you complete the infrastructure configuration, you configure the appropriate services for your network to run on top of your base architecture. This includes:

   - Layer 2 and Layer 3 VSNs
   - IP Shortcuts
   - Inter-VSN routing
3. Fabric interoperations

   You can also configure Fabric gateway functionality like SPB-PIM Gateway.
4. Operations and Management

   To debug connectivity issues and isolate network faults in the SPBM network, you can use Connectivity Fault Management (CFM).

Documentation Sources

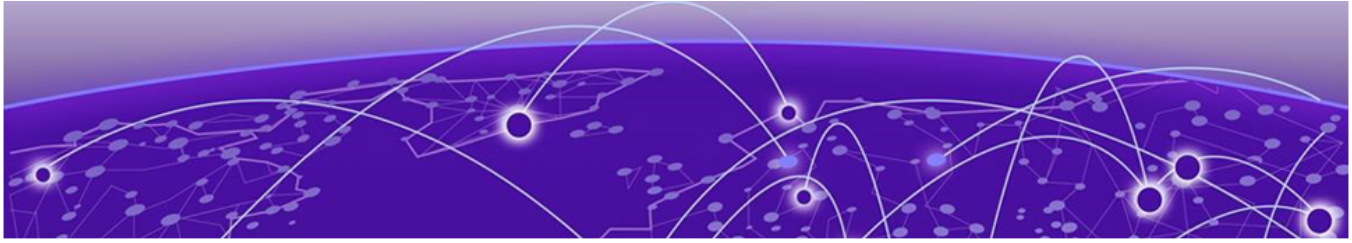
See the following documentation sources:

- For information on basic SPBM infrastructure and IS-IS configuration and Layer 2 services, see Fabric Basics and Layer 2 Services on page 840.

  This section also contains information on configuring Fabric Extend, which enables your enterprise to extend Fabric Connect technology over Layer 2 or Layer 3 core networks.
- For information on Fabric Layer 3 services configuration, see Fabric Layer 3 Services on page 1121.
- For information on IP Multicast over Fabric Connect configuration and services, see IP Multicast over Fabric Connect on page 1454. SPB-PIM Gateway configuration on page 2862 also contains information about configuring the SPB-PIM Gateway (SPB-PIM GW), which provides multicast inter-

domain communication between an SPB network and a PIM network. The SPB-PIM GW can also connect two independent SPB domains.

- For information on CFM, see Connectivity Fault Management on page 3169.



Fabric Basics and Layer 2 Services

SPBM and IS-IS Infrastructure Configuration

SPBM and IS-IS Infrastructure Fundamentals

Shortest Path Bridging MAC (SPBM) is a next generation virtualization technology that revolutionizes the design, deployment, and operations of carriers and service providers, along with enterprise campus core networks and the enterprise data center. SPBM provides massive scalability while at the same time reducing the complexity of the network.

SPBM eliminates the need for multiple overlay protocols in the core of the network by reducing the core to a single Ethernet based link-state protocol that provides all virtualization services in an integrated model. In addition, by relying on endpoint service provisioning only, the idea of building your network once and not touching it again becomes a true reality. This technology provides all the features and benefits required by carrier-grade, enterprise and service provider deployments without the complexity of alternative technologies, for example, Multiprotocol Label Switching (MPLS).

SPBM simplifies deployments by eliminating the need to configure multiple points throughout the network. When you add new connectivity services to an SPBM network you do not need intrusive core provisioning. The simple endpoint provisioning is done where the application meets the network, with all points in between automatically provisioned through the robust link-state protocol, Intermediate-System-to-Intermediate-System (IS-IS).

Most Ethernet based networks use 802.1Q tagged interfaces between the routing switches. SPBM uses two Backbone VLANs (B-VLANs) that are used as the transport instance. A B-VLAN is not a traditional VLAN in the sense that it does not flood unknown, broadcast or multicast traffic, but only forwards based on IS-IS provisioned backbone MAC (B-MAC) tables. After you configure the B-VLANs and the IS-IS protocol is operational, you can map the services to service instances.

SPBM uses IS-IS to discover and advertise the network topology, which enables it to compute the shortest path to all nodes in the SPBM network. SPBM uses IS-IS shortest path trees to populate forwarding tables for the individual B-MAC addresses of each participating node.

To forward customer traffic across the core network backbone, SPBM uses IEEE 802.1ah Provider Backbone Bridging (PBB) MAC-in-MAC encapsulation, which hides the customer MAC (C-MAC) addresses in a backbone MAC (B-MAC) address pair. MAC-in-MAC encapsulation defines a B-MAC destination address (BMAC-DA) and a B-MAC source address (BMAC-SA). Encapsulating customer MAC addresses in B-MAC addresses improves network scalability (no end-user C-MAC learning is required in the core) and also significantly improves network robustness (loops have no effect on the backbone infrastructure.)

The SPBM B-MAC header includes a Service Instance Identifier (I-SID) with a length of 32 bits with a 24-bit ID. I-SIDs identify and transmit virtualized traffic in an encapsulated SPBM frame. You can use I-SIDs in a Virtual Services Network (VSN) for VLANs or VRFs across the MAC-in-MAC backbone:

- Unicast
  - For a Layer 2 VSN, the device associates the I-SID with a customer VLAN, which the device then virtualizes across the backbone. Layer 2 VSNs associate one VLAN per I-SID.
  - With Layer 3 VSN, the device associates the I-SID with a customer VRF, which the device virtualizes across the backbone. Layer 3 VSNs associate one VRF per I-SID.
  - With Inter-VSN routing, Layer 3 devices, routers, or hosts connect to the SPBM cloud using the SPBM Layer 2 VSN service. The Backbone Core Bridge can transmit traffic between different VLANs with different I-SIDs.
  - With IP shortcuts, no I-SID is required, forwarding for the Global Routing Table (GRT) is done using IS-IS based shortest path BMAC reachability.

  For more information on Fabric Layer 3 services, see Fabric Layer 3 Services on page 1121.

- Multicast
  - With Layer 2 VSN with IP multicast over Fabric Connect, the BEB associates a data I-SID with the multicast stream and the scope I-SID is based on the Layer 2 VSN I-SID.
  - With Layer 3 VSN with IP multicast over Fabric Connect, the BEB associates a data I-SID with the multicast stream and the scope I-SID is based on the Layer 3 VSN I-SID.
  - With IP Shortcuts with IP multicast over Fabric Connect, the BEB associates a data I-SID with the multicast stream, but there is no I-SID for the scope, which is the Global Routing Table (GRT).

  For more information on IP multicast over Fabric Connect, see IP Multicast over Fabric Connect on page 1454.

  Note
  Inter-VSN routing for IP multicast over Fabric Connect is not supported.

The switch supports the IEEE 802.1aq standard of SPBM, which allows for larger Layer 2 topologies and permits faster convergence.

Multiple tenants using different SPBM services

The following figure shows multiple tenants using different services within an SPBM metro network. In this network, you can use some or all of the SPBM implementation options to meet the needs of the community while maintaining the security of information within VLAN members.

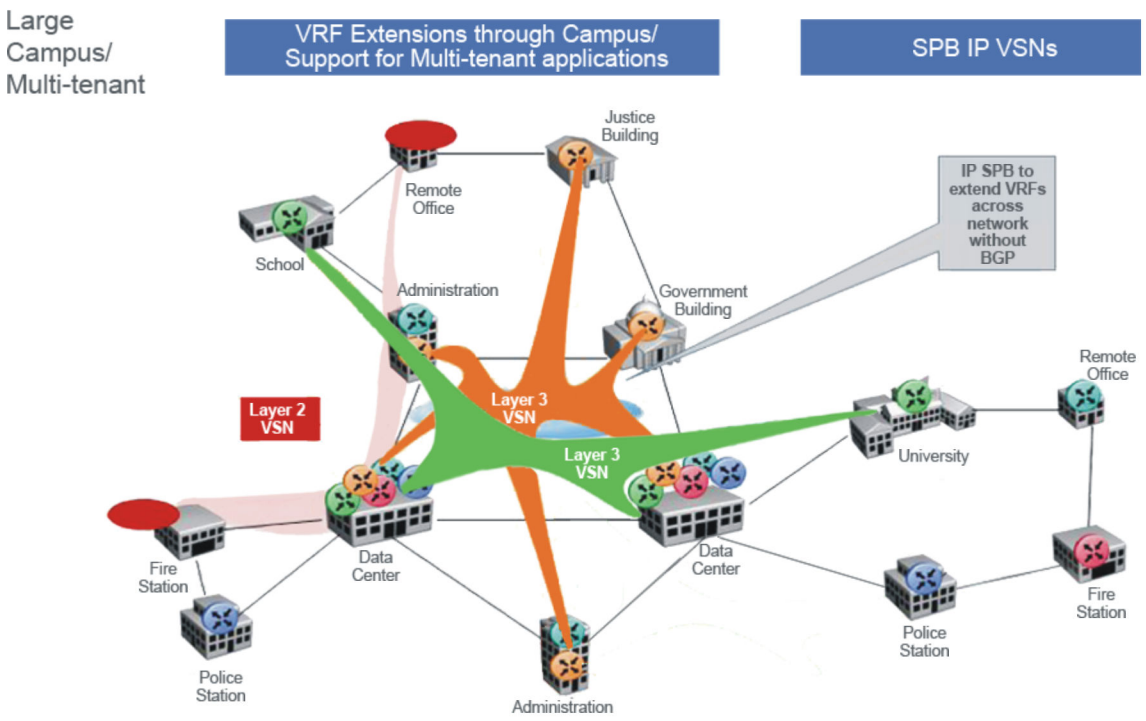


Figure 55: Multi-tenant SPBM metro network

To illustrate the versatility and robustness of SPBM even further, the following figure shows a logical view of multiple tenants in a ring topology. In this architecture, each tenant has its own domain where some users have VLAN requirements and are using Layer 2 VSNs and others have VRF requirements and are using Layer 3 VSNs. In all three domains, they can share data center resources across the SPBM network.

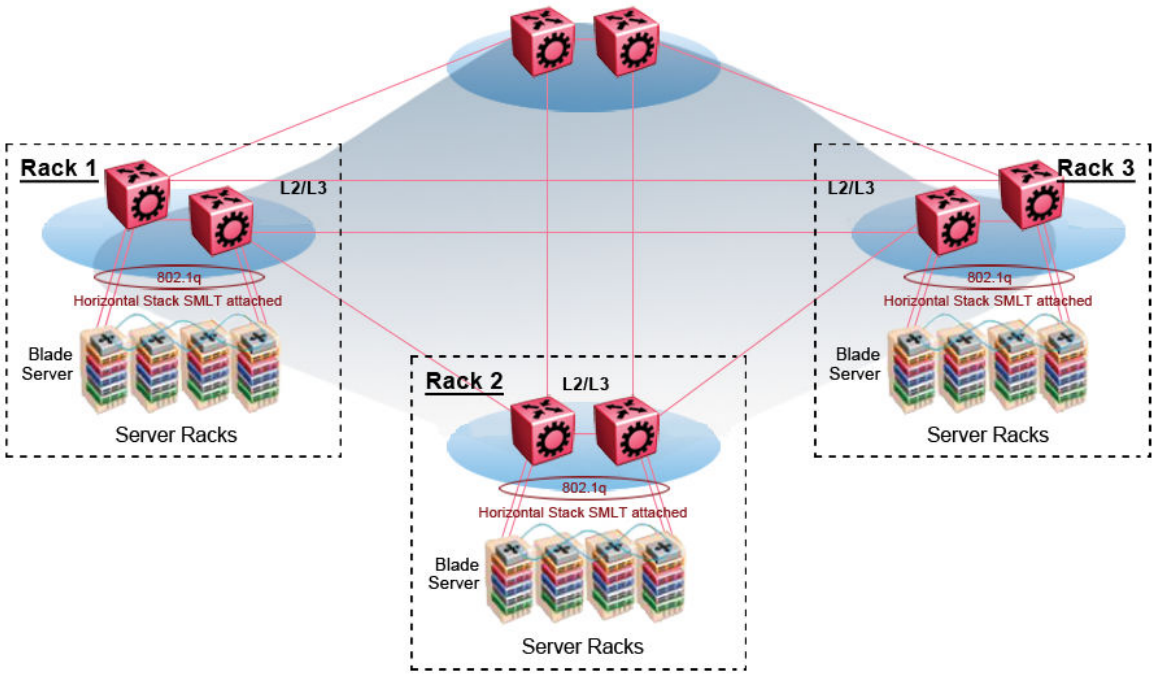

Figure 56: SPBM ring topology with shared data centers

spbm-config-mode boot flag

Shortest Path Bridging (SPB) and Protocol Independent Multicast (PIM) cannot interoperate with each other on the switch at the same time. The boot flag called **spbm-config-mode** ensures that SPB and PIM stay mutually exclusive.

- The **spbm-config-mode** boot flag is enabled by default. This enables you to configure SPB and IS-IS, but you cannot configure PIM either globally or on an interface.
- If you disable the boot flag, save the configuration and reboot with the saved configuration. After you enable the flag, you can configure PIM and IGMP Snooping, but you cannot configure SPB or IS-IS.

Important

- Any change to the **spbm-config-mode** boot flag requires a reboot for the change to take effect.
- If you disable the boot flag, save the configuration and reboot with the saved configuration. After you disable the flag, you can configure PIM and IGMP Snooping, but you cannot configure SPB or IS-IS.

For more information, see IP Multicast on page 1230.

vxlan-gw-full-interworking-mode Boot Configuration Flag

The VXLAN Gateway implementation is available in the following modes:

- Base Interworking Mode – This is the default mode. In this mode, VXLAN Gateway supports Layer 2 gateway communication between VXLAN and traditional VLAN environments.
- Full Interworking Mode – This mode supports the Base mode communication between VXLAN and traditional VLAN environments as well as VXLAN-to-VXLAN communication and all SPB functionality including vIST and SMLT. To enter this mode, you must enable the **vxlan-gw-full-interworking-mode** boot configuration flag.

Note

Changing the mode requires a reboot for the change to take effect.

MAC-in-MAC encapsulation

To forward customer traffic across the core network backbone, SPBM uses IEEE 802.1ah Provider Backbone Bridging (PBB) MAC-in-MAC encapsulation, which hides the customer MAC (C-MAC) addresses in a backbone MAC (B-MAC) address pair. MAC-in-MAC encapsulation defines a B-MAC source address (BMAC-SA) and a B-MAC destination address (BMAC-DA) to identify the backbone source and destination addresses.

The originating node creates a MAC header that is used for delivery from end to end. As the MAC header stays the same across the network, there is no need to swap a label or do a route lookup at each node, allowing the frame to follow the most efficient forwarding path end to end.

Encapsulating customer MAC addresses in B-MAC addresses improves network scalability (no end-user C-MAC learning is required in the core) and also significantly improves network robustness (loops in access networks do not impact forwarding results in the backbone infrastructure.)

I-SID

SPBM introduces a service instance identifier called I-SID. SPBM uses I-SIDs to separate services from the infrastructure. After you create an SPBM infrastructure, you can add additional services (such as VLAN extensions or VRF extensions) by provisioning the endpoints only. The SPBM endpoints are Backbone Edge Bridges (BEBs), which mark the boundary between the core MAC-in-MAC SPBM domain and the edge customer 802.1Q domain. I-SIDs are provisioned on the BEBs to be associated with a particular service instance. In the SPBM core, the bridges are Backbone Core Bridges (BCBs). BCBs forward encapsulated traffic based on the BMAC-DA.

The SPBM B-MAC header includes a Service Instance Identifier (I-SID) with a length of 32 bits with a 24-bit ID. I-SIDs identify a service instance for virtualized traffic in an encapsulated SPBM frame. You can use I-SIDs in a Virtual Services Network (VSN) for VLANs or VRFs across the MAC-in-MAC backbone:

- For a Layer 2 VSN, the I-SID is associated with a customer VLAN, which is then virtualized across the backbone. Layer 2 VSNs offer an any-any LAN service type. Layer 2 VSNs associate one VLAN per I-SID.
- For a Layer 2 VSN with IP multicast over Fabric Connect, the BEB associates a data I-SID with the multicast stream and a scope I-SID that defines the scope as Layer 2 VSN. A multicast stream with a scope of Layer 2 VSN can only transmit a multicast stream for the same Layer 2 VSN.
- For a *Transparent Port UNI*, the I-SID is associated with a port or MLT, which is then virtualized across the backbone. *Transparent Port UNI* associates multiple ports or MLT to an I-SID.
- For a Layer 3 VSN, the I-SID is associated with a customer VRF, which is also virtualized across the backbone. Layer 3 VSNs are always full-mesh topologies. Layer 3 VSNs associate one VRF per I-SID.
- For a Layer 3 VSN with IP multicast over Fabric Connect, the BEB associates a data I-SID with the multicast stream and a scope I-SID that defines the scope as Layer 3 VSN. A multicast stream with a scope of Layer 3 VSN can only transmit a multicast stream for the same Layer 3 VSN.
- For IP Shortcuts with IP multicast over Fabric Connect, the BEB associates a data I-SID with the multicast stream and defines the scope as Layer 3 GRT. A multicast stream with a scope of Layer 3 GRT can only transmit a multicast stream for a Layer 3 GRT.

Note

I-SID configuration is required only for virtual services such as Layer 2 VSN and Layer 3 VSN. With IP Shortcuts with unicast, no I-SID is required, forwarding for the Global Routing table is done using IS-IS based shortest path B-MAC reachability.

Note

I-SID to VLAN binding is used to automatically determine the path between client and server in order to attach network devices to FA Zero touch services.

BCBs and BEBs

Table 72: Fabric Mode product support

Feature	Product	Release introduced
Fabric BCB mode	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
Fabric BEB mode	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

The boundary between the core MAC-in-MAC SPBM domain and the edge customer 802.1Q domain is handled by Backbone Edge Bridges (BEBs). I-SIDs are provisioned on the BEBs to be associated with a particular service instance.

In the SPBM core, the bridges are referred to as Backbone Core Bridges (BCBs). BCBs forward encapsulated traffic based on the BMAC-DA.

Important

SPBM separates the payload from the transport over the SPBM infrastructure. Configure all virtualization services on the BEBs at the edge of the network. There is no provisioning required on the core SPBM switches. This provides a robust carrier grade architecture where configuration on the core switches never needs to be touched when adding new services.

A BEB performs the same functionality as a BCB, but it also terminates one or more Virtual Service Networks (VSN). A BCB does not terminate any VSNs and is unaware of the VSN traffic it transports. A BCB simply knows how to reach any other BEB in the SPBM backbone.

VLANs without member ports

If a VLAN is attached to an I-SID there must be another instance of that same I-SID in the SPBM network.

- If another instance of that I-SID exists, the device designates that VLAN as operationally up regardless of whether it has a member port or not.

  When the VLAN is operationally up, the IP address of the VLAN will be in the routing table.
- If no matching instance of the I-SID exists in the SPBM network, then that VLAN has no reachable members and does not act as a network-to-network interface (NNI).

  The VLAN does not act as a UNI interface because it does not have a member port.

  Therefore, the device does not designate the VLAN as operationally up because the VLAN does not act as a UNI or an NNI.

If the device acts as a BCB with two VLANs configured and two I-SIDs, there must be a UNI side with the corresponding I-SID existing in the network.

If the device acts as both BEB and BCB, then there must be a member port in that VLAN to push out the UNI traffic.

Basic SPBM network topology

The following figure shows a basic SPBM network topology, specifically a Layer 2 VSN. Switches A and D are the Backbone Edge Bridges (BEB) that provide the boundary between the customer VLANs (C-VLAN) and the Backbone. Switches B and C are the Backbone Core Bridges (BCB) that form the core of the SPBM network.

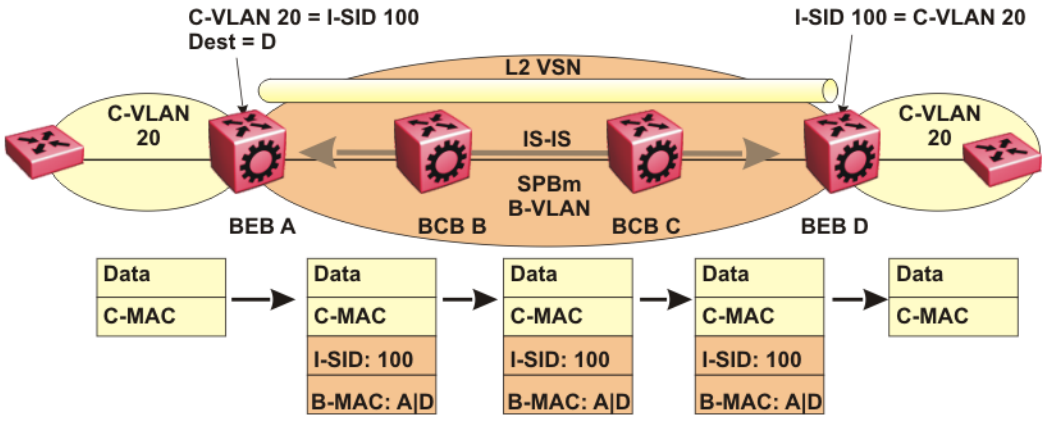

Figure 57: SPBM L2 VSN

SPBM uses IS-IS in the core so that all BEBs and BCBs learn the IS-IS System-ID (B-MAC) of every other switch in the network. For example, BEB-A uses IS-IS to build an SPBM unicast forwarding table containing the B-MAC of switches BCB-B, BCB-C, and BEB-D.

The BEBs provide the boundary between the SPBM domain and the virtualized services domain. For a Layer 2 VSN service, the BEBs map a C-VLAN to an I-SID based on local service provisioning. Any BEB in the network that has the same I-SID configured can participate in the same Layer 2 VSN.

In this example, BEB A and BEB D are provisioned to associate C-VLAN 20 with I-SID 100. When BEB A receives traffic from C-VLAN 20 that must be forwarded to the far-end location, it performs a lookup and determines that C-VLAN 20 is associated with I-SID 100 and that BEB D is the destination for I-SID 100. BEB A then encapsulates the data and C-MAC header into a new B-MAC header, using its own nodal B-MAC: A as the source address and B-MAC: D as the destination address. BEB A then forwards the encapsulated traffic to BCB B.

To forward traffic in the core toward the destination node D, BCB B and BCB C perform Ethernet switching using the B-MAC information only.

At BEB D, the node strips off the B-MAC encapsulation, and performs a lookup to determine the destination for traffic with I-SID 100. BEB D identifies the destination on the C-VLAN header as C-VLAN 20 and forwards the packet to the appropriate destination VLAN and port.

E-Tree and Private VLAN topology

Table 73: E-Tree and Private VLANs product support

Feature	Product	Release introduced
E-Tree and Private VLANs	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
Routing on Private VLANs	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.5
	5520 Series	VOSS 8.5
	5720 Series	Fabric Engine 8.7

Ethernet Private Tree (E-Tree) extends Shortest Path Bridging MAC (SPBM) to Private VLANs (PVLAN).

Transport within the SPBM network is achieved by associating the private VLAN with an I-SID. Flooded traffic from both promiscuous and isolated devices is transported over the same I-SID multicast tree and suppression for spoke-to-spoke traffic is done on the egress SPB Backbone Edge Bridge (BEB). This means the Private VLAN IDs are globally significant and must be the same on all BEBs

The following list provides details for E-Tree and Private VLAN topology:

- E-Tree associates a Private VLAN with an I-SID.

  Note
  The same I-SID could be attached to a regular VLAN. In that case, all ports on the regular VLAN behave like Promiscuous ports on the PVLAN.

- Other SPB BEBs can associate a regular CVLAN to the same I-SID that E-Tree uses.

  Note
  The CVLAN ID must match the primary PVLAN ID.

- CVLAN devices assigned to the same I-SID that E-Tree uses have Promiscuous connectivity within the segment.

The following figure shows a basic E-Tree network topology consisting of groups of private VLANs connected by the SPBM core network.

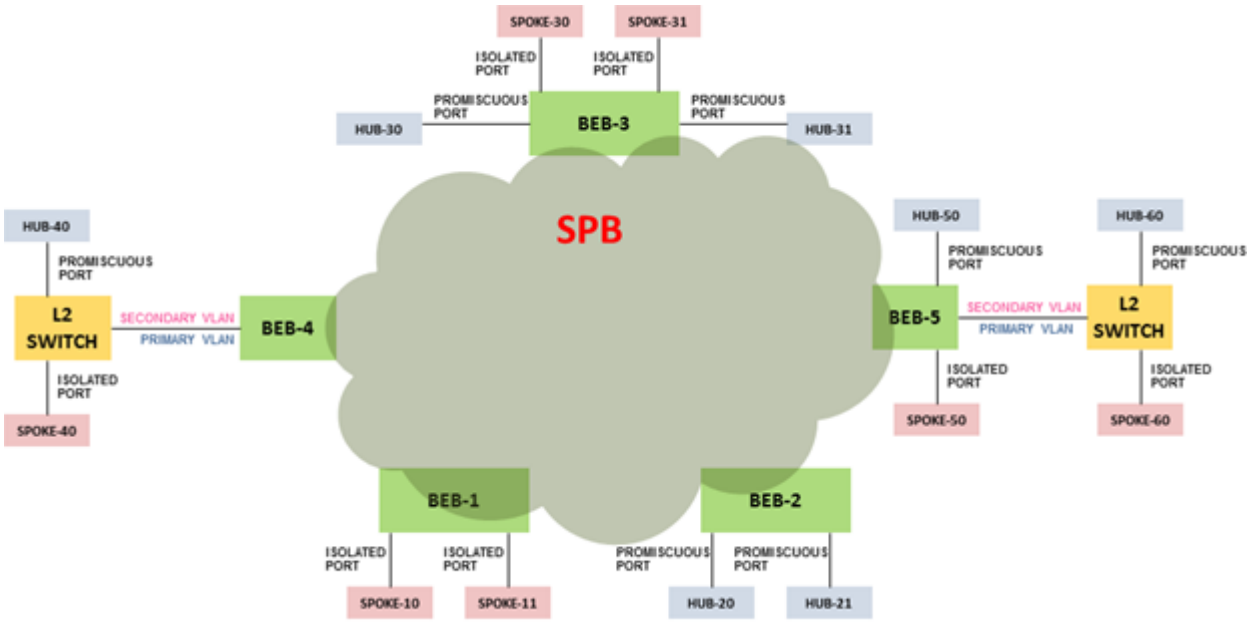

Figure 58: Sample E-Tree configuration

Private VLAN port types

The private VLAN port type is isolated, promiscuous, or trunk. If the port is a member of an MLT, then the port inherits the private VLAN type of the MLT.

In terms of network topology, the isolated port is considered a spoke. The isolated port, or spoke, does not communicate with any other isolated port in the network. The isolated port only communicates with the promiscuous ports, or hubs.

E-Tree and Private VLAN limitations

The following limitations apply to E-Tree and Private VLAN topology:

- A port that is of Private VLAN type trunk must be tagged. Isolated and Promiscuous Private VLAN ports can be either tagged or untagged.
- When a port or MLT that has a Private VLAN type set to Isolated or Promiscuous is added to a private VLAN, if that port is used by other non private VLANs, then those non private VLANs are removed.
- A port which is Private VLAN type Isolated and is tagged can belong to only one Private VLAN.

IS-IS

	5720 Series	Fabric Engine 8.7

SPBM eliminates the need for multiple overlay protocols in the core of the network by reducing the core to a single Ethernet-based, link-state protocol (IS-IS). IS-IS provides virtualization services using a pure Ethernet technology base. SPBM also uses IS-IS to discover and advertise the network topology, which enables it to compute the shortest path to all nodes in the SPBM network.

IS-IS is a link-state, interior gateway protocol that was developed for the International Organization for Standardization (ISO). ISO terminology refers to routers as Intermediate Systems (IS), hence the name Intermediate System-to-Intermediate System (IS-IS).

To provide a loop-free network and to learn and distribute network information, SPBM uses the Intermediate-System-to-Intermediate-System (IS-IS) link state routing protocol. IS-IS is designed to find the shortest path from any one destination to any other in a dynamic fashion. IS-IS creates any-to-any connectivity in a network in an optimized, loop-free manner, without the long convergence delay experienced with the Spanning Tree Protocol. IS-IS does not block ports from use, but rather employs a specific path. As such, all links are available for use.

IS-IS dynamically learns the topology of a network and constructs unicast and multicast mesh connectivity. IS-IS parallel adjacency support allows you to configure multiple IS-IS links between the two nodes. Each node in the network calculates a shortest-path tree to every other network node based on System-IDs (B-MAC addresses). Only one adjacency with the shortest path is selected as an active adjacency.

Note

Only an active interface with an active adjacency is added into local SPF calculations. This mechanism ensures the local node selects the shortest path and has the same view as the rest of the SPB network.

In the SPBM environment for Layer 2 VSNs, IS-IS carries only pure Layer 2 information with no requirement for an underlying IP control plane or forwarding path. IS-IS runs directly over Layer 2.

Note

SPBM carries Layer 3 information for Layer 3 VSNs.

In SPBM networks, IS-IS performs the following functions:

- Discovers the network topology
- Builds shortest path trees between the network nodes:
  - Forwards unicast traffic
  - Determines the forwarding table for multicast traffic
- Communicates network information in the control plane:
  - Service Instance Identifier (I-SID) information

SPBM can distribute I-SID service information to all SPBM nodes, as the I-SIDs are created. SPBM includes I-SID information in the IS-IS Link State protocol data units (PDUs). When a new service instance is provisioned on a node, its membership is flooded throughout the topology using an IS-IS advertisement.

Standard TLVs

IS-IS uses Type-Length-Value (TLV) encoding. SPBM employs IS-IS as the interior gateway protocol and implements additional TLVs to support additional functionality. The switch also supports Sub-TLVs. TLVs exist inside IS-IS packets and Sub-TLVs exist as additional information in TLVs.

The switch supports and is in full compliance with standard 802.1 aq TLVs. The IEEE ratified the 802.1aq standard that defines SPBM and the Type-Length-Value (TLV) encoding that IS-IS uses to support SPBM services. The following table lists all the TLVs that the switch supports.

Table 75: Standard TLVs

TLV	Description	Usage
1	Area addresses — The Area Addresses TLV contains the area addresses to which the IS-IS is connected.	IS-IS area
22	Extended IS reachability — The Extended IS Reachability TLV contains information about adjacent neighbors.	IS-IS adjacencies Sub-TLV 29: SPBM link metric is carried within this TLV.
129	Protocols supported — The Protocol supported TLV carries the Network Layer Protocol Identifiers (NLPID) for the Network Layer protocols where the IS-IS can be used.	SPBM in addition to existing NLPID (IPV4 0xCC, IPV6 0x*E..), IEEE 802.1aq defined SPBM NLPID as 0xC1.
135	Extended IP reachability — The Extended IP Reachability TLV 135 is used to distribution IP reachability between IS-IS peers.	SPBM uses this existing IS-IS TLV to carry IP Shortcut routes in the Global Routing Table (GRT).

Table 75: Standard TLVs (continued)

TLV	Description	Usage
143	Multi-topology port aware capability (MT-Port-Capability) TLV This TLV carries the SPB instance ID in a multiple SPB instances environment. This TLV is carried within IS-IS Hello Packets (IIH), only when parallel links exist.	This TLV carries the following SPBM Sub TLV: • Sub-TLV 6: SPB B-VID Sub TLV indicates the mapping between a VLAN and its equal cost tree (ECT) algorithm. To form an adjacency, both nodes must have a matching primary (B-VLAN, ECT) pair, and secondary (B-VLAN, ECT) pair, the number of B-VLANs must be equal, B-VLAN values must match, ECT values for the B-VLANs must match. Used in IS-IS Hellos only. • MCID Sub TLV: The MCID is a digest of the VLANs and MSTI. Neighboring SPBM nodes must agree on the MCID to form an adjacency. The MCID is set to all zeros (0). After the switch receives a non-zero MCID Sub TLV, it reflects content back to the neighbor. • Link L1 Metric Sub-TLV 7: Contains L1 metric of the link
144	Multi-topology Capability (MT-Capability) TLV. This TLV carries the SPB instance ID in a multiple SPB instance environment. This TLV is carried within LSPs. In multicast over Fabric Connect, TLV 144 on the BEB bridge, where the sender is located, has the transmit (Tx) bit set. On the BEB bridge, where the receiver is located the receive (Rx) bit is set.	TLV 144 is the service identifier TLV. TLV 144 advertizes B-MAC and I-SID information. This TLV carries the following Sub TLVs: Sub-TLV 1: SPB instance Sub TLV contains a unique SPSourceID (nickname) to identify the SPBM node within this SPB topology. Sub-TLV 3: SPB Service ID (I-SID) is stored in TLV 144 sub-TLV 3. Sub-TLV 3 carries service group membership (I-SIDs) for a particular SPBM B-VLAN.
184	SPBM IP VPN reachability — IS-IS TLV 184 is used to advertise SPBM L3 VSN route information across the SPBM cloud.	IP reachability for Layer 3 VSNs

Table 75: Standard TLVs (continued)

TLV	Description	Usage
185	IPVPN multicast TLV with IPMC sub TLV — The IPVPN multicast TLV contains information about the scope I-SID.	TLV 185 on the BEB bridge, where the source is located, displays the multicast source and group addresses and has the transmit (Tx) bit set. Each multicast group has its own data I-SID that maps to the source and group addresses. As part of the IPVPN TLV, sub-TLVs define IPv4 unicast, IPv6 unicast and IPv4 multicast information. Layer 2 VSN IP multicast over Fabric Connect and Layer 3 VSN IP multicast over Fabric Connect (using VRF) use TLV 185.
186	IP multicast TLV (GRT) — TLV 186 on the BEB bridge, where the source is located, displays the multicast source and group addresses and has the transmit (Tx) bit set. Each multicast group has its own data I-SID that maps to the source and group addresses.	IP Shortcuts with IP multicast over Fabric Connect use TLV 186. All multicast streams are constrained within the level in which they originate, which is called the scope level.
236	IPv6 Reachability — The IPv6 reachability TLV 236 is used to distribute IPv6 network reachability between IS-IS peers.	SPBM uses the existing IS-IS TLV to carry IPv6 shortcut routes through the SPBM core.

For more information on IP multicast over Fabric Connect, see IP Multicast over Fabric Connect on page 1454.

IS-IS hierarchies

IS-IS is a dynamic routing protocol that operates within an autonomous system (or domain). IS-IS provides support for hierarchical routing, which enables you to partition large routing domains into smaller areas. When used separately from SPBM, IS-IS uses a two-level hierarchy, dividing the domain into multiple Level 1 areas and one Level 2 area. When used separately from SPBM, the Level 2 area serves as backbone of the domain, connecting to all the Level 1 areas. SPBM currently uses only Level 1 areas.

Important

The IEEE 802.1aq standard currently only defines the use of one hierarchy, Level 1. Level 2 function is disabled.

IS-IS PDUs

Intermediate System to Intermediate System Hello (IIH) packets discover IS-IS neighbors and establish and maintain IS-IS adjacencies. An IIH is sent in every Hello-interval to maintain the established

adjacency. If a node has not heard IIHs from its neighbor for (hello-interval x hello-multiple) seconds, the node tears down the adjacency. IIH carries TLV 143 and SPB B-VLAN Sub-TLV (among other sub-TLVs). For two nodes to form an adjacency the B-VLAN pairs for primary B-VLAN and secondary B-VLAN must match.

Link State Packets (LSP) advertise link state information. The system uses the link state information to compute the shortest path. LSP also advertises MT-capability TLV 144 and SPB instance Sub-TLV, and SPB I-SIDs Sub-TLV.

Complete Sequence Number Packets (CSNP) contain the most recent sequence numbers of all LSPs in the database. CSNP notifies neighbors about the local LSDB. After a neighbor receives a CSNP, it compares the LSPs in the CSNP with the LSP in the local LSDB. If the neighbor is missing LSPs, it sends a Partial Sequence Number Packets (PSNP) to request the missing LSPs. This process synchronizes the LSDBs among neighbors. A synchronized LSDB among all nodes in the network is crucial to producing a loop-free shortest path.

IS-IS configuration parameters

IS-IS system identifiers

The IS-IS system identifiers consist of three parts:

- System ID — The system ID is any 6 bytes that are unique in a given area or level. The system ID defaults to the baseMacAddress of the chassis but you can configure a non-default value. The system ID must use a unicast MAC address; do not use a multicast MAC address. A MAC address that has the low order bit 1 set in the highest byte is a multicast MAC address. For example, the following are multicast MAC addresses: x1xx.xxxx.xxxx, x3xx.xxxx.xxxx, x5xx.xxxx.xxxx, x7xx.xxxx.xxxx, x9xx.xxxx.xxxx, xBxx.xxxx.xxxx, xDxx.xxxx.xxxx, and xFxx.xxxx.xxxx.
- Manual area — The manual area or area ID is up to 13 bytes long. The first byte of the area number (for example, 49) is the Authority and Format Indicator (AFI). The next bytes are the assigned domain (area) identifier, which is up to 12 bytes (for example, 49.0102.0304.0506.0708.0910.1112). IS-IS supports a maximum of three manual areas, but the switch software only supports one manual area.
- NSEL — The last byte (00) is the n-selector. In this implementation, this part is automatically attached. There is no user input accepted.

The Network Entity Title (NET) is the combination of all three global parameters.

All routers have at least one manual area. Typically, a Level 1 router does not participate in more than one area.

The following are the requirements for system IDs:

- All IS-IS enabled routers must have one manual area and a unique system ID.
- All routers in the same area must have the same area ID.
- All routers must have system IDs of the same length (6 bytes).
- All IS-IS enabled routers must have a unique nickname.

PSNP interval

You can change the PSNP interval rate. A longer interval reduces overhead, while a shorter interval speeds up convergence.

CSNP periodic and interval rate

You can configure the CSNP periodic and interval rate. A longer interval reduces overhead, while a shorter interval speeds up convergence.

Parameters for the link state packet

Link state packets (LSPs) contain vital information about the state of adjacencies, which must be exchanged with neighboring IS-IS systems. Routers periodically flood LSPs throughout an area to maintain synchronization. You can configure the LSP to reduce overhead or speed up convergence.

The following list describes IS-IS parameters related to LSPs:

- The **`max-lsp-gen-interval`** is the time interval at which the generated LSP is refreshed. The default is 900 seconds with a range of 30 to 900.
- The **`retransmit-lsp-interval`** is the minimum amount of time between retransmission of an LSP. When transmitting or flooding an LSP an acknowledgement (ACK) is expected. If the ack is not received within **`retransmit-lsp-interval`**, the LSP is re-transmitted. The default is 5 seconds with a range of 1 to 300.

Point-to-point mode

All SPBM links are point-to-point links. The switch does not support broadcast links.

IS-IS interface authentication

Configure IS-IS interface authentication to improve security and to guarantee that only trusted routers are included in the IS-IS network. Interface level authentication only checks the IIH PDUs. If the authentication type or key in a received IIH does not match the locally-configured type and key, the IIH is rejected. By default, authentication is disabled.

You can use either one of the following authentication methods:

- Simple password authentication — Uses a text password in the transmitted packet. The receiving router uses an authentication key (password) to verify the packet.
- MD5 authentication — Creates a Message Digest (MD5) key.
- SHA-256 — Adds a Hash-based Message Authentication Code (HMAC) digest to each IS-IS Hello packet.

Important

If the .isis_md5key.txt and .isis_simplekey.txt are missing, IS-IS adjacencies cannot be established.

Password considerations

To reset the authentication password type, you must set the type to none.

The switch software supports only interface level authentication. The switch software does not support area level or domain level authentication.

SHA-256 considerations

IS-IS Hello packets are sent periodically to discover IS-IS neighbors, and to establish and maintain IS-IS adjacencies. If you enable SHA-256 authentication, the switch adds an HMAC-SHA256 digest to each Hello packet.

Note

The interfaces used to make the adjacencies must have SPBM configured.

The switch that receives the Hello packet computes the digest of the packet and compares it with the received digest. If the digests match, the packet is accepted. If the digests do not match, the receiving switch discards the packet.

Directly connected switches must share the same key (secret), which can have a maximum length of 16 characters.

Hellos

To update the identities of neighboring routers, you can configure the:

- IS-IS Interface Level 1 Hello interval
- IS-IS Interface Level 1 Hello multiplier

IS-IS Interface Level 1 Hello interval

IS-IS uses level 1 Hello packets to initialize and maintain adjacencies between neighboring routers.

You can configure the IS-IS interface level 1 Hello interval to change how often Hello packets are sent out from an interface level.

IS-IS Interface Level 1 Hello multiplier

You can configure the IS-IS interface level 1 Hello multiplier to specify how many Hellos the switch must miss before it considers the adjacency with a neighboring switch down. By default, the hold (wait) time is the Hello interval multiplied by the Hello multiplier. By default, if the Hello interval is 9 and the Hello multiplier is 3, the hold time is 27. If the Hello multiplier is increased to 10, the hold time is increased to 90.

IS-IS Interface Level 1 Link metric

You can configure the IS-IS interface level 1 link metric to overwrite the default metric value. By configuring the metric, you can specify a preferred path. Low cost reflects high-speed media, and high cost reflects slower media. For the wide metric, the value ranges from 1 to 16,777,215.

- The switch only supports the wide metric.
- The total cost of a path equals the sum of the cost of each link.

- The default value for wide metrics is 10.

Note

When multiple paths exist to reach a node, the path with the lowest sum of metrics of the individual links is chosen. If the sum of the paths are the same, the one with the lowest number of hops is chosen. If the number of hops is the same as well, then the tie-breaking is done by the system ID.

For the primary B-VLAN, the path that has a node with the lowest system ID is chosen. Whereas, for the secondary B-VLAN, the path that has a node with the highest system ID is chosen.

Disabling IS-IS

You can disable IS-IS globally or at the interface level. If IS-IS is globally disabled, then all IS-IS functions stop. If IS-IS is enabled at the global level and disabled at one of the interface levels, then IS-IS continues on all other interfaces.

Overload Bit

A node sends the overload bit in LSP updates to inform other devices whether to use that node to pass transit traffic. For example, when a device receives an LSP with an overload bit, the device ignores that LSP in its Shortest Path First (SPF) calculation to avoid sending transit traffic through the overloaded node; however, the overloaded node can still receive traffic destined to itself.

The system activates the overload bit on bootup and clears it after 20 seconds. You can use the **`overload-on-startup`** parameter to control the time before the overload bit is cleared after bootup.

You can permanently configure the overload bit using the **`overload`** parameter. If you use this parameter, the system does not clear the overload bit after bootup and sends it in all LSP updates. If the overload bit is configured, other devices do not include this node for use as a transit node in IS-IS computations. By default, the **`overload`** parameter is set to false.

The **`overload`** and **`overload-on-startup`** parameters are configured under the `router isis` configuration mode in the CLI.

When IS-IS is enabled on a switch, the switch delays a reset by two seconds so that LSPs with the overload bit can be sent to all Backbone Edge Bridges (BEB) and Backbone Core Bridges (BCB) in the SPB domain.

SPBM B-VLAN

Each SPBM network instance is associated with at least one backbone VLAN (B-VLAN) in the core SPBM network.

Note

SPB internally uses spanning tree group (STG) 63 or Multiple Spanning Tree Instance (MSTI) 62. STG 63 or MSTI 62 cannot be used by another VLAN or MSTI. For non-SPB customer networks, if you use STG 63 or MSTI 62 in the configuration, you must delete STG 63 or MSTI 62 before you can configure SPBM.

This VLAN is used for both control plane traffic and dataplane traffic.

Note

Always configure two B-VLANs in the core to allow load distribution over both B-VLANs.

SPBM alters the behavior of the VLAN. When a B-VLAN is associated with an SPBM network the following VLAN attributes and behaviors are modified for the B-VLAN:

- Flooding is disabled
- Broadcasting is disabled
- Source address learning is disabled
- Unknown MAC discard is disabled

You cannot add ports to a B-VLAN manually, IS-IS enabled ports are automatically added to the B-VLAN.

Essentially the B-MAC addresses are programmed into the B-VLAN Forwarding Information Bases (FIBs) by IS-IS instead of the traditional VLANs flooding and learning approach.

Modification of the VLAN behavior is necessary to ensure proper control over the SPBM traffic.

Pre-populated FIB

An Ethernet network usually learns MAC addresses as frames are sent through the switch. This process is called reverse learning and is accomplished through broadcast.

SPBM does not allow any broadcast flooding of traffic on the B-VLAN in order to prevent looping accomplished through flooding packets with unknown destinations (although multicast traffic is supported). As such, MAC addresses must be distributed within SPBM. This is accomplished by carrying the necessary B-MAC addresses inside the IS-IS link state database. To that end, SPBM supports an IS-IS TLV that advertises the I-SID and B-MAC information across the network. This functionality enables the powerful end-point-provisioning of SPBM.

These Backbone MAC addresses are populated into the SPBM VLAN Forwarding Information Base (FIB) to maximize efficiency and to allow Reverse Path Forwarding Check (RPFC) to operate properly.

RPFC

A loop prevention mechanism is required at Layer 2 to stop wayward traffic from crippling the network. Reverse Path Forwarding Check (RPFC) is the chosen method of suppressing loop traffic with SPBM. RPFC was originally designed for IP traffic at Layer 3 where it checks the source address of the packet against the routing entry in the routing table. The source address must match the route for the port it came in on otherwise the packet is illegitimate and therefore dropped.

With SPBM, the node matches the source B-MAC address against the ingress port to establish validity. If the frame is not supposed to come in that port, it is immediately suppressed imposing a guaranteed loop control. If there is no VLAN FDB entry to the source MAC address with the outgoing port as the ingress port, the frame will be dropped.

SPBM Unicast FIB

Unicast FIB

The unicast computation runs a single Dijkstra (unlike all pair Dijkstras for multicast). SPBM produces only one Shortest Path First (SPF) tree and the tree is rooted on the computing node.

The unicast computation generates an entry for each node in the network. The Destination Address (DA) for that entry is the system-id of the node. In addition, if a node advertises MAC addresses other than the system-id, each MAC address has an entry in the unicast FIB table, and the shortest path to that MAC should be exactly the same as the path to the node.

Unicast FIB entries are installed to the vlan-fdb table.

The following text shows an example of the unicast FIB.

```
Switch:1# show isis spbm unicast-fib
================================================================================================
                          SPBM UNICAST FIB ENTRY INFO

SPBM Restrictions

RSTP and MSTP

The following list identifies restrictions and limitations associated with RSTP and MSTP:

- RSTP mode does not support SPBM.
- A C-VLAN-level loop across SPBM network-to-network interface (NNI) ports cannot be detected and needs to be resolved at the provisional level.
- SPBM NNI ports are not part of the Layer 2 VSN C-VLAN, and BPDUs are not transmitted over the SPBM tunnel. SPBM can only guarantee loop-free topologies consisting of the NNI ports. You should always use Simple Loop Prevention Protocol (SLPP) in an SMLT environment.

  Note

  Deploy SLPP on C-VLANs to detect loops created by customers in their access networks. However, SLPP is not required on B-VLANs, and it is not supported. The B-VLAN active topology is controlled by IS-IS that has loop mitigation and prevention capabilities built into the protocol.

- SPB internally uses spanning tree group (STG) 63 or Multiple Spanning Tree Instance (MSTI) 62. STG 63 or MSTI 62 cannot be used by another VLAN or MSTI. For non-SPB customer networks, if you use

STG 63 or MSTI 62 in the configuration, you must delete STG 63 or MSTI 62 before you can configure SPBM.

- You must configure SPBM B-VLANs on all devices in the same MSTP region. MSTP requires this configuration to generate the correct digest.
- Configure the SPBM B-VLANs to use matching VLAN IDs.

Best Practices for SPB Regarding MSTP

Use NNI ports exclusively to transport traffic for SPB-based services and not be configured as members of any VLANs other than SPB B-VLANs. In releases that do not support nni-mstp, when an SPBM IS-IS interface is created on an NNI port or an MLT, MSTP is automatically disabled for MSTI-62 on the port/MLT. However, MSTP is not automatically disabled on NNI ports for the CIST (default MSTI). In releases that support the **boot config flags nni-mstp** command, the default behavior of the MSTP NNI ports is that CIST is disabled automatically on the NNI and the NNI ports cannot be members of any VLANs other than B-VLANs. The default boot config flags nni-mstp must be set to false (which is the default). The following example shows the command to disable the MSTP on the NNI ports.

```
Switch:1(config)#interface gigabitEthernet 1/8
Switch:1(config-if)#no spanning-tree mstp
```

Coexistence of MSTP and SPB-Based Services on NNI Ports

In releases that do not support nni-mstp boot configuration, you can support the coexistence of non-SPB based services on the NNI ports, by adding NNI ports as members of VLANs, except for B-VLANs. These other VLANs rely on the use of MSTP for Loop prevention. The network operator must carefully consider the implications of keeping MSTP enabled on the NNI ports because any MSTP topology changes detected on the NNI ports impacts all services and causes most dynamically learned information on the UNI side to be flushed and relearned. This includes, but is not limited to, all customer MAC and ARP records. This can also cause all the UNI ports on a BEB to be temporarily put into a spanning-tree blocking state before transitioning to a forwarding state again. The net result is that MSTP topology changes on the NNI ports adversely impact traffic for SPB-based services. Therefore, the NNI ports be used exclusively for SPB traffic.

SPBM IS-IS

The following list identifies restrictions and limitations associated with SPBM IS-IS:

- The switch does not support IP over IS-IS as defined by RFC 1195. IS-IS protocol is only to facilitate SPBM.
- The switch uses level 1 IS-IS. The switch does not support level 2 IS-IS. The CLI command **show isis int-l2-contl-pkts** is not supported because the IEEE 802.1aq standard currently only defines the use of one hierarchy, Level 1.
- The IS-IS standard defines wide (32bit) metrics and narrow (8 bits) metrics. The switch supports the wide metric.
- To run IS-IS on an MLT, add the ports to the MLT, and then enable IS-IS on the MLT.

SPBM NNI SMLT

The switch does not support NNI on SMLT links.

VLACP

VLACP is generally used when a repeater or switch exists between connected switches to detect when a connection is down even when the link LED is lit. You can enable VLACP on Ethernet ports that are NNI, as well as Ethernet ports that are part of a NNI MLT.

SNMP Traps

On each SPBM peer, if you configure the SPBM B-VLANs to use different VLAN IDs, for example, VLAN 10 and 20 on one switch, and VLAN 30 and 40 on the second, the system does not generate a trap message to alert of the mismatch because the two switches cannot receive control packets from one another. Configure the SPBM B-VLANs to use matching VLAN IDs.

System MTU

Do not change the system MTU to less than the default value of 1950 bytes. The system MTU must be 1950 or jumbo because of the header size increase when transmitting packets over the SPBM cloud.

IP Multicast over Fabric Connect

IP multicast over Fabric Connect cannot connect to existing Protocol Independent Multicast (PIM) networks that connect to SPB originated streams or that add PIM network streams into the SPB network. SPB-PIM Gateway (SPB-PIM GW), however, provides multicast interdomain communication between an SPB network and a PIM network. SPB-PIM GW accomplishes this interdomain communication across a special Gateway VLAN. The Gateway VLAN communicates with the PIM network through the PIM protocol messaging and translates the PIM network requirements into SPB language, and vice versa. For more information about SPB-PIM GW, see SPB-PIM Gateway configuration on page 2862.

Other

The following list identifies other restrictions or considerations:

- You cannot use 3.33.33 as the SPB nickname because of a conflict with reserved IPv6 Ethernet multicast address 33:33:xx:xx:xx:xx.
- The software does not support I-SID filters.
- You cannot enable C-VLAN and B-VLAN on the same port.
- To ensure proper cleanup of MAC tables after you run the **no spbm** command, save the configuration, and then reboot the switch.

Network Load Balancing (NLB)

Table 76: Network Load Balancing product support

Feature	Product	Release introduced
Network Load Balancing (NLB) - multicast operation	5320 Series	Not Supported
	5420 Series	Not Supported
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

Table 76: Network Load Balancing product support (continued)

Feature	Product	Release introduced
Network Load Balancing (NLB) - unicast operation	5320 Series	Not Supported
	5420 Series	Not Supported
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

SPBM supports Network Load Balancing (NLB) Unicast and Multicast modes.

NLB is a clustering technology available with Microsoft Windows 2000, Microsoft Windows 2003, Microsoft Windows 2008, and Microsoft Windows 2012 server family of operating systems. You can use NLB to share the workload among multiple clustering servers. NLB uses a distributed algorithm to load balance TCP/IP network traffic across a number of hosts, enhancing the scalability and availability of mission critical, IP based services, such as web, VPN, streaming media, and firewalls. NLB also provides high availability by detecting host failures and automatically redistributing traffic to remaining operational hosts.

SPBM Script

Table 77: run spbm installation script product support

Feature	Product	Release introduced
run spbm installation script	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

You can use a CLI script to quickly configure the SPB and IS-IS infrastructure to enable Fabric Connect on a switch. You can use the SPB script, rather than manually configure the minimum SPBM and IS-IS parameters.

You can use the command **`run spbm`** to quickly configure the following:

- Configure the SPB Ethertype.
- Create an SPB instance.
- Create an SPBM backbone VLAN and associate it to the SPB instance.
- Create an SPBM secondary backbone VLAN and associate it to the SPB instance.
- Add an SPB nickname.
- Create a manual area.
- Enable IS-IS on one of the switch interfaces.
- Enable IS-IS globally.
- Configure the IS-IS system name.
- Configure the IS-IS system ID.

- Configure SPBM port and MLT interfaces.
- Clean up any SPBM configuration.

The following table displays the default values applied if you use the **run spbm** command. The SPB script creates some of the default values based on the MAC address of the switch, including the nickname and System ID value.

Parameter	Default values
Ethertype	0x8100
Primary B-VLAN	4051
Secondary B-VLAN	4052
Manual area	49.0000
Nickname	Derived from the chassis MAC
System name	Derived from the command line prompt
System ID value	Derived from the chassis MAC, using a different algorithm from that for the Nickname

Note

The SPB script only creates the SPBM instance, VLAN, or other parameters if they do not already exist. For example, if the SPBM instance and VLAN already exist, the SPB script does not create them. If the SPB script cannot create one of the parameters because the parameter is already configured, the script stops and an error message displays.

IS-IS external metric

The software supports the IS-IS external metric to differentiate between internal and external routes with Accept Policies.

With this feature you can use IS-IS to:

- change the external metric-type of a route when redistributing it from another protocol to IS-IS through route redistribution using a route-map.
- change the external metric-type of a route when accepting a remote IS-IS route with the help of IS-IS accept policies using a route-map.
- match the external metric-type when redistributing IS-IS routes into other protocols using the match option in the route-map.
- match the external metric-type when accepting a remote IS-IS route with the help of IS-IS accept policies by using a route-map
- process the external metric-type in the route selection process.

The IS-IS metric type can also be set using the base redistribute command without using the route-map.

SPB Ethertype

The switch aligns the SPB ethertype to BCB's locally configured SPB ethertype. The BCBs mark the BTAG Ethertype of a transit MAC-in-MAC packet to match its locally configured value when it exits on a

different network-to-network interface (NNI) port, even if the BTAG Ethertype on the incoming packet (CFM or SPB) does not match its configured value.

Note

ISIS Hello packets are always marked with 0x8100 ethertype, and do not change according to the BCB's locally configured values.

Equal Cost Multipath Pathlist with Fabric Connect

Table 78: ECMP Pathlist with Fabric Connect product support

Feature	Product	Release introduced
ECMP Pathlist with Fabric Connect (IS-IS routes)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

If you use Equal Cost Multipath (ECMP) in a Shortest Path Bridging (SPB) scenario, the Intermediate System-to-Intermediate System (IS-IS) protocol sends multiple routes with the same destination to the routing manager. IS-IS can add up to eight equal cost routes with the same destination to the routing table and the router uses one route for traffic forwarding based on load management. Use the ECMP Pathlist feature to control how many equal-cost paths to add to the routing manager for the same destination.

Note

Different hardware platforms can support a different number of ECMP paths. For more information about the maximum number of ECMP paths supported on the switch, see the scaling information in *Fabric Engine Release Notes*.

For information about how to configure ECMP Pathlist, see Configure ECMP on page 1615 and Configure ECMP on page 1641.

FAN Transit

Fabric Area Network (FAN) transit refers to the ability of a switch to forward traffic between SPB nodes participating in a FAN. The switch is neither a part of the FAN nor does it originate or sink FAN traffic. It only forwards the traffic between the FAN end-points.

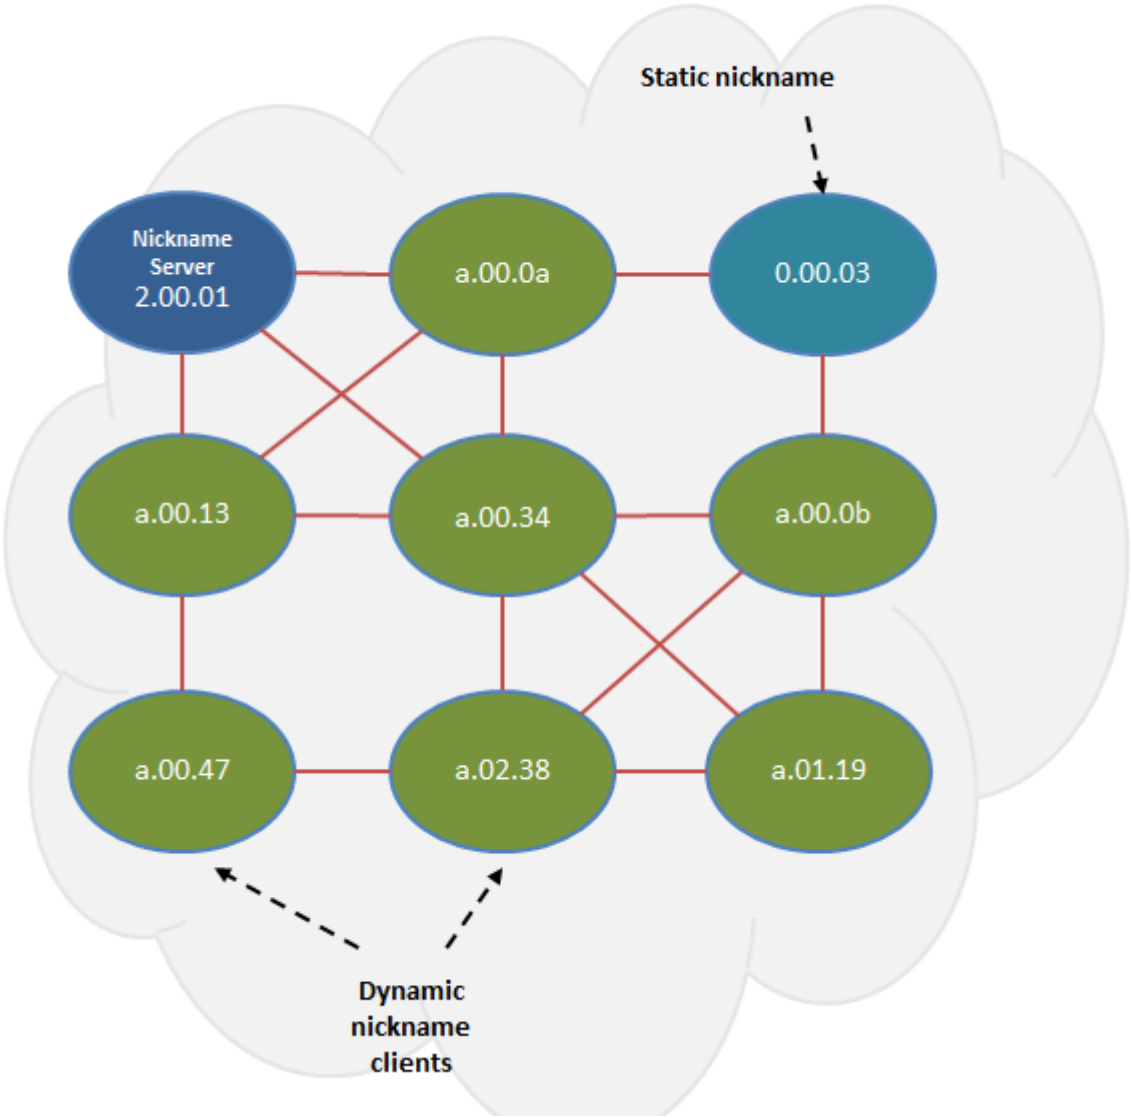
For information on how to verify the functioning of a transit switch within a FAN, see Troubleshooting FAN Transit on page 3345.

Dynamic Nickname Assignment

Table 79: Dynamic Nickname Assignment product support

Feature	Product	Release introduced
Dynamic Nickname Assignment	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
Extends the assignment behavior with a *prefix* parameter	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.3
	5720 Series	Fabric Engine 8.7

Dynamic Nickname Assignment is a service that provides unique nicknames to compatible switches across a Fabric Area Network (FAN).



You can configure a node in a FAN as a nickname server. The nickname server cannot be started until you configure it with a static nickname. As a best practice, configure at least two nickname servers in a FAN to provide redundancy.

Note

Configure the nickname server with a static nickname that is outside any configured dynamic nickname server range in the network, or you can configure the nickname server with a static nickname from the first 10 values of the configured dynamic nickname server range in the network.

The nickname server interrogates FAN nodes that have been assigned a dynamic nickname to avoid nickname duplication.

A client joining the dynamic FAN in factory default mode initially does not have a nickname, and issues a broadcast soliciting a valid nickname assignment. The nickname server receives the request and

responds with a nickname assignment offer. The client then explicitly requests the particular nickname offered and the nickname server sends an acknowledgment.

The client maintains the nickname in persistent memory regardless of whether the active nickname server is the same server that originally provided the nickname. The client generates a trap and notifies the user if it is unable to receive a nickname from the server. When IS-IS starts, it issues a trap if a client does not have a nickname and clears the trap when the client receives a nickname from the nickname server.

A client rebooting or reconnecting to the FAN requests the same nickname assignment it had before reboot. If the requested nickname is within the nickname server's configured range of nicknames and is still available, the server acknowledges the nickname. If the requested nickname is outside of the nickname server's configured range or if the nickname has been assigned to another client, the request is denied by the nickname server and the client must request a new nickname.

Static and Dynamic Nickname Servers

You can use static nickname assignment and Dynamic Nickname Assignment in the same FAN.

You can configure Dynamic Nickname Assignment using a range prefix that can use a range from 0.00.00 to F.FF.FF. This method provides 256 groups that cover the range of 0.00.00 to F.FF.FF.

Note

You can configure the nickname server with a static nickname from the first 10 values of the configured dynamic nickname server range in the network.

Do not use nicknames from the dynamic nickname range when you assign nicknames statically to non-server nodes. However, if there are existing nodes in the network with static nicknames in the dynamic nickname range, it is not a requirement to change their nickname assignment. If a node is assigned a dynamic nickname that is being used in the network, duplicate nickname protection is initiated. If the node that has the dynamic nickname loses the nickname election, it requests a different nickname from the nickname server. If a node with a static nickname loses the nickname election, IS-IS is disabled on that node and you must manually re-assign the nickname and re-enable IS-IS.

You can configure nicknames from a dynamic range if the nickname server is not started.

Note

You must disable Dynamic Nickname Assignment before you can change the nickname prefix.

Debugging

A node must be a member of a FAN to host Dynamic Nickname Assignment applications. FAN connectivity enables the exchange of information between nickname clients and servers, such as nickname requests or nickname assignments. You can use Connectivity Fault Management (CFM) to debug connectivity issues or isolate faults. For more information about CFM, see Connectivity Fault Management on page 3169.

Dynamic Nickname Assignment Considerations

Consider the following information when implementing this feature:

- You must configure a nickname server to assign unique nicknames to clients based on established policies.

- You can configure multiple nickname servers in a FAN to provide resiliency. If you configure multiple nickname servers, you must ensure that the ranges for nickname allocation do not overlap.
- Dynamic Nickname Assignment is not supported in a FAN that contains ERS 4900 or ERS 5900 products, or on products running VOSS releases prior to 7.0.

MSTP-Fabric Connect Multi Homing

Table 80: MSTP-Fabric Connect Multi Homing product support

Feature	Product	Release introduced
MSTP-Fabric Connect Multi Homing	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

The MSTP-Fabric Connect Multi Homing feature allows MSTP or RSTP network to be multi-homed into a Fabric Connect network, providing a loop-free topology. MSTP-Fabric Connect Multi Homing enables an MSTP network to be multihomed into the SPB Fabric network through single node-to-multiple nodes or multiple nodes-to-multiple nodes.

Important

You must enable MSTP-Fabric Connect Multi Homing before you establish multihoming with an MSTP network.

MSTP-Fabric Connect Multi Homing uses I-SID 16777003. The switch creates this I-SID automatically and it cannot be modified.

MSTP-Fabric Connect Multi Homing is supported on SPBM mode only.

Fabric Extend

Table 81: Fabric Extend product support

Ability to configure a specific IPsec source IP per tunnel	5320 Series	Not Supported
	5420 Series	Not Supported
	5520 Series	Not Supported
	5720 Series	Not Supported

Some hardware platforms support Fabric Extend natively. You can use these switches in a main office of a hub and spoke deployment or to connect one Data Center to another Data Center.

Fabric Extend enables Enterprises to extend the Fabric Connect technology over Layer 2 or Layer 3 core networks. The *logical IS-IS interface* is the mechanism that enables Fabric Extend to connect SPB fabric nodes. Logical IS-IS interfaces create virtual tunnels and encapsulate SPB traffic by adding a VXLAN header to SPB packets.

The following figure illustrates two Fabric Connect "islands" separated by a third-party core IP network. The IP network could be third-party equipment in an enterprise or a service provider's infrastructure such as an MPLS VPN service.

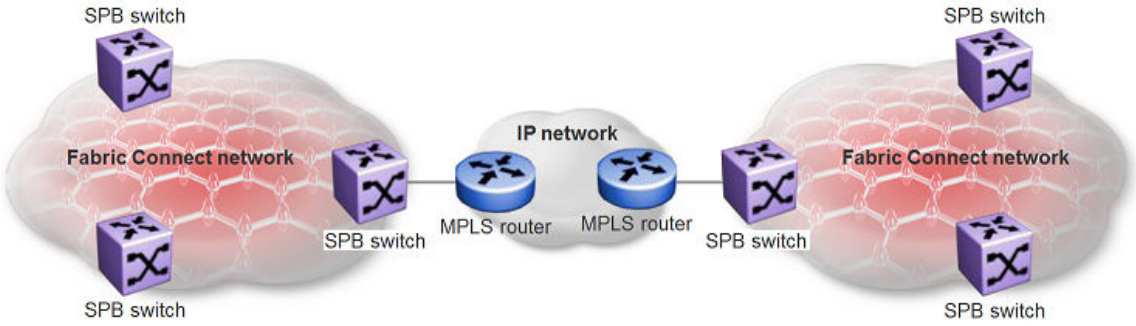

Figure 59: Fabric Connect networks connected by an IP network

The following figure illustrates how Fabric Extend enables you to connect the fabric islands to create ONE Fabric Connect network. This figure shows a Layer 3 core network where Fabric Extend uses IP tunneling by adding a VXLAN header to the SPBM packets. This can be over a third party IPv4 transport network such as MPLS IP-VPN or in a Campus IP backbones.

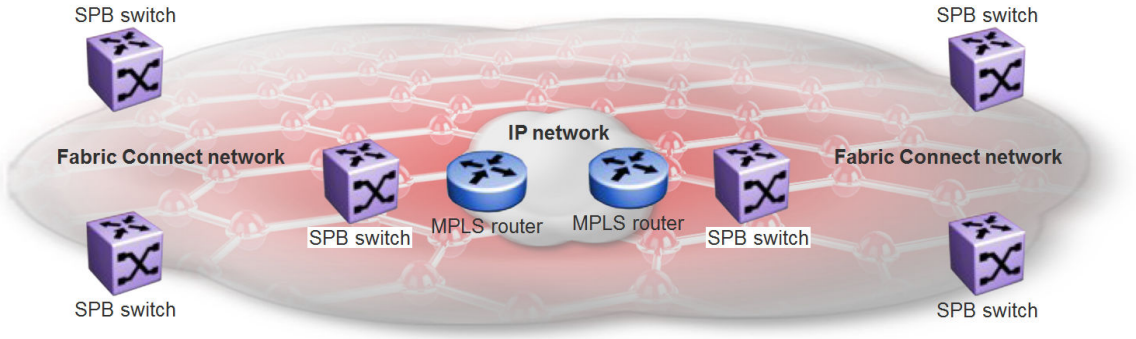

Figure 60: Single Fabric Connect Domain realized using Fabric Extend

The following figure shows a Layer 2 core network where Fabric Extend can transport SPBM packets over a Layer 2 MPLS VPLS or PBB E-LINE service by creating layer 3 tunnels over a Layer 2 third party network.

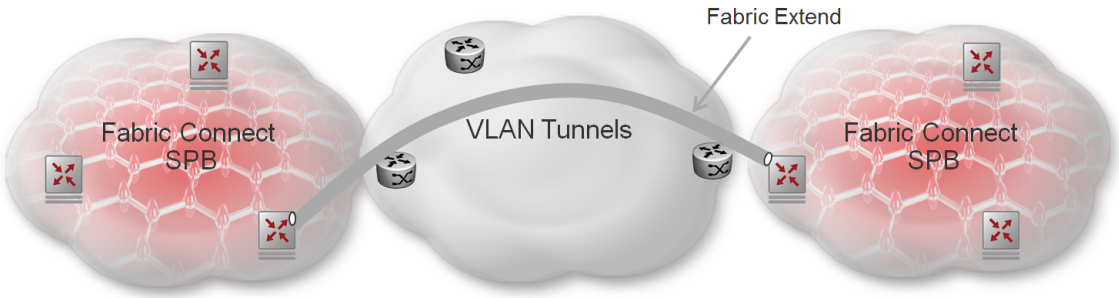

Figure 61: Fabric Extend over VLAN tunnels

Advantages of Fabric Extend

Fabric Connect is an Ethernet-based, industry-standard (IEEE 802.1aq) networking virtualization solution. With Fabric Connect, you can have thousands of virtualized service instances at any point in the network. Other Fabric Connect advantages include rapid time to service, Layer 2 and Layer 3 Unicast and IP Multicast virtualization, and scalable IP multicast. But the most significant advantage of Fabric Connect is that you provision services at the network edge only, not the core.

The Fabric Extend feature enables you to extend the Fabric Connect model over Layer 2 and Layer 3 core networks. The interconnection of Fabric Connect deployments can be over any IP-based network whether it's a campus backbone, Data Center, or a MAN/WAN IP MPLS network.

Logical IS-IS interface

The logical IS-IS interface is the mechanism that enables Fabric Extend to connect SPB fabric nodes.

Logical IS-IS interfaces perform the following functions depending on the type of core network:

- In a Layer 3 core network, logical IS-IS interfaces create virtual IP tunnels and encapsulate SPB traffic by adding a Virtual Extensible LAN (VXLAN) header to SPB packets.
- In a Layer 2 core network, logical IS-IS interfaces do not use VXLAN. The tunnels are point-to-point VLAN connections so there is no need to encapsulate a VXLAN header to SPB packets. The logical IS-IS interfaces translate the Backbone VLAN IDs (B-VIDs) and maps them to each of the branch provider VIDs.

Fabric Extend uses virtual tunnels in Layer 3 core solutions to connect SPB fabric nodes. These nodes can stretch over IP routed campus networks, service provider Layer 2 core networks, or service provider Layer 3 core networks such as IP MPLS VPNs.

Note

VLACP cannot be used on logical IS-IS interface connections.

Layer 2 core network

If the service provider has a Layer 2 core network, note the following points:

- The syntax for configuring a logical interface is:

```
logical-intf isis <id> vid <list of vlans> primary-vid <vlanId> port
<slot/port> Mlt <mltId> [name <name>]
```

- `vid <list of vlans>` should have two VLANs, not more than two or less than two. The VID range is <2-4059>. You do not have to configure the VIDs as platforms VLANs.
- `primary-vid` should be included in `vid <list of vlans>`.
- Each logical interface must have a unique set of VIDs for each port or MLT. The same VIDs however, can be reused across a different set of ports or MLTs.
- Logical interface VIDs and B-VLANs cannot be the same.
- Configuring the same VIDs as primary and secondary is not allowed.
- The `port/MLT` on which the Layer 2 core IS-IS logical interface is configured cannot be part of any other user configured VLANs.
- Cannot delete an MLT that is configured as a logical interface tunnel MLT.

- A logical interface consists of a port/MLT and a list of VLANs, where port/MLT is the physical connectivity to the Layer 2 core network and VLANs are the list of VLANs used to transport/bridge IS-IS control packets and Mac-in-Mac data traffic.
- VXLAN headers are not used in Layer 2 core Fabric Extend solutions.
- IS-IS control packets are not encapsulated before they are sent over a logical interface. Instead, the VLAN in the outer Ethernet header (SPB primary bvid) is replaced by the user configured logical interface VLAN.
- Spanning tree is disabled by default on **`port/MLT`** on which a Layer 2 core logical IS-IS interface is configured.

Layer 3 core network

If the service provider has a Layer 3 core network, note the following points:

- The syntax for configuring a logical interface is:

  ```
  logical-intf isis <id> dest-ip <destIpAddr> [name <name>]
  ```

- A logical IS-IS interface points to a remote BEB destination IP address.
- Port and VlanId are not needed to create a logical IS-IS interface, instead they can be retrieved from the next hop of destination IP address.
- IS-IS control packets (IS-IS hello, LSDB, CSNP, PSNP) are encapsulated with a VXLAN header and sent over a logical IS-IS interface.

IPsec Compression

IPsec compression reduces the size of the IP datagram to improve the communication performance between hosts connected behind Backbone Edge Bridges (BEB).

Note

This feature is supported on 5720-24MXW and 5720-48MXW using Fabric IPsec Gateway.

Tip

As a best practice, use IPsec compression only for Fabric Extend tunnels where latency is greater than 70ms.

The following list identifies how you can implement IPsec compression:

- You can configure multiple IPsec Fabric Extend (FE) adjacencies with or without compression simultaneously.
- You must enable IPsec compression on both BEBs to use IPsec compression for an FE adjacency.
- You cannot configure IPsec compression if fragmentation before encryption is already enabled.
- You can change the IPsec compression configuration only if IPsec is disabled.

To configure IPsec compression, see Configure IPsec Compression on page 810.

IS-IS Hello Padding

To detect maximum transmission unit (MTU) mismatches, Intermediate System-to-Intermediate System (IS-IS) pads hello packets to the full interface MTU. All hello packets on Fabric Extend network-to-network interface (NNI) links are padded . On non-Fabric Extend point-to-point NNI links, hello packets are padded until a hello packet is received from the other side.

Note

If you downgrade to a release that does not support this feature, you must disable the feature and save the configuration before you downgrade. You must have a compatible configuration file if you downgrade to an earlier release.

IPsec Fragmentation Before Encryption

5720-24MXW and 5720-48MXW switches support IPsec fragmentation before encryption of Fabric Extend tunnels using Fabric IPsec Gateway.

The best practice is to enable fragmentation before encryption only for an IPsec adjacency over a WAN.

Configure IPsec fragmentation of the packets to occur before encryption and IPsec encapsulation. Packets are fragmented based on the tunnel maximum transmission unit (MTU) without the IPsec header so that the final packet does not exceed the tunnel MTU. The MTU value is a per tunnel configuration, which means packet fragmentation occurs per tunnel. For a tunnel with this functionality enabled, packets that egress the specific NNI port are encapsulating security payload (ESP) packets only.

The following list identifies how you can implement IPsec fragmentation before encryption:

- You must configure IPsec over Fabric Extend in IPsec decoupled mode, which means the IPsec source and destination IP addresses are different than the Fabric Extend addresses.
- You cannot configure IPsec compression if fragmentation before encryption is already enabled.

IPsec Decoupled Mode

A device is in IPsec decoupled mode when IPsec and Fabric Extend (FE) termination takes place on two different IP addresses. A device is in IPsec coupled mode when IPsec and Fabric Extend (FE) termination takes place on the same IP address.

The 5720 Series devices, which use Fabric IPsec Gateway for Fabric Extend over IPsec, support IPsec in decoupled mode only. You must configure the IPsec tunnel in decoupled mode to enable IPsec termination in the Fabric IPsec Gateway VM. For more information about how to configure IPsec tunnels on the VM, see Configure IPsec Tunnels on Fabric IPsec Gateway VM on page 808.

For more information, see Enable Fragmentation Before Encryption on Fabric IPsec Gateway VM on page 811.

Adjusting the TCP Maximum Segment Size

You can adjust the TCP maximum segment size (MSS) to improve the throughput for the TCP session over a Fabric Extend (FE) adjacency.

TCP MSS Overview

When a client initiates a connection with a server, it uses TCP SYN packets to negotiate the MSS to avoid fragmentation. The client and server use the outgoing maximum transmission unit (MTU) to advertise the MSS.

If a tunnel exists between the client and server, the encapsulation consumes more room in the outer IP header. As a result, the router that performs the tunnel encapsulation fragments the packet to fit over the tunnel. Adjust the MSS to modify the value in the TCP SYN packet so the client and server negotiate a lower number and leave headroom for tunnel encapsulation.

This adjustment functionality applies to IPv4 only.

Important

If you enable this functionality and port mirroring simultaneously, the switch does not mirror CP-generated packets.

Support

TCP MSS adjustment applies unidirectionally when a packet is forwarded from a UNI interface to any other interface. To use this functionality, you must enable TCP MSS adjustment on both sides of the FE tunnel.

Types of Fabric Extend Deployments

As the number of Fabric Connect networks increased, the need to connect those networks became more and more desirable. Fabric Extend solves the problem of going beyond the Ethernet Fabric Connect connections to include the following IP routed wide area network (WAN) and campus solutions:

1. Fabric Extend over an MPLS IP-VPN provider WAN
2. Fabric Extend over an MPLS Virtual Private LAN Service (VPLS) or Provider Backbone Bridging (PBB) Ethernet LAN (ELAN) provider network
3. Fabric Extend over an IP campus network
4. Fabric Extend over an MPLS Pseudo-Wire or Ethernet Virtual Private Line (E-Line) provider network

Fabric Extend over an MPLS IP-VPN Provider WAN

The most common Fabric Extend deployment is a hub and spoke topology that connects the Main office over a service provider's MPLS IP VPN to multiple Branch offices. The following figure illustrates how the hub device on the main site establishes virtual tunnels with all of the spoke devices in the same domain. In this scenario, the traffic flows are bidirectional: from hub-to-spoke and spoke-to-hub.

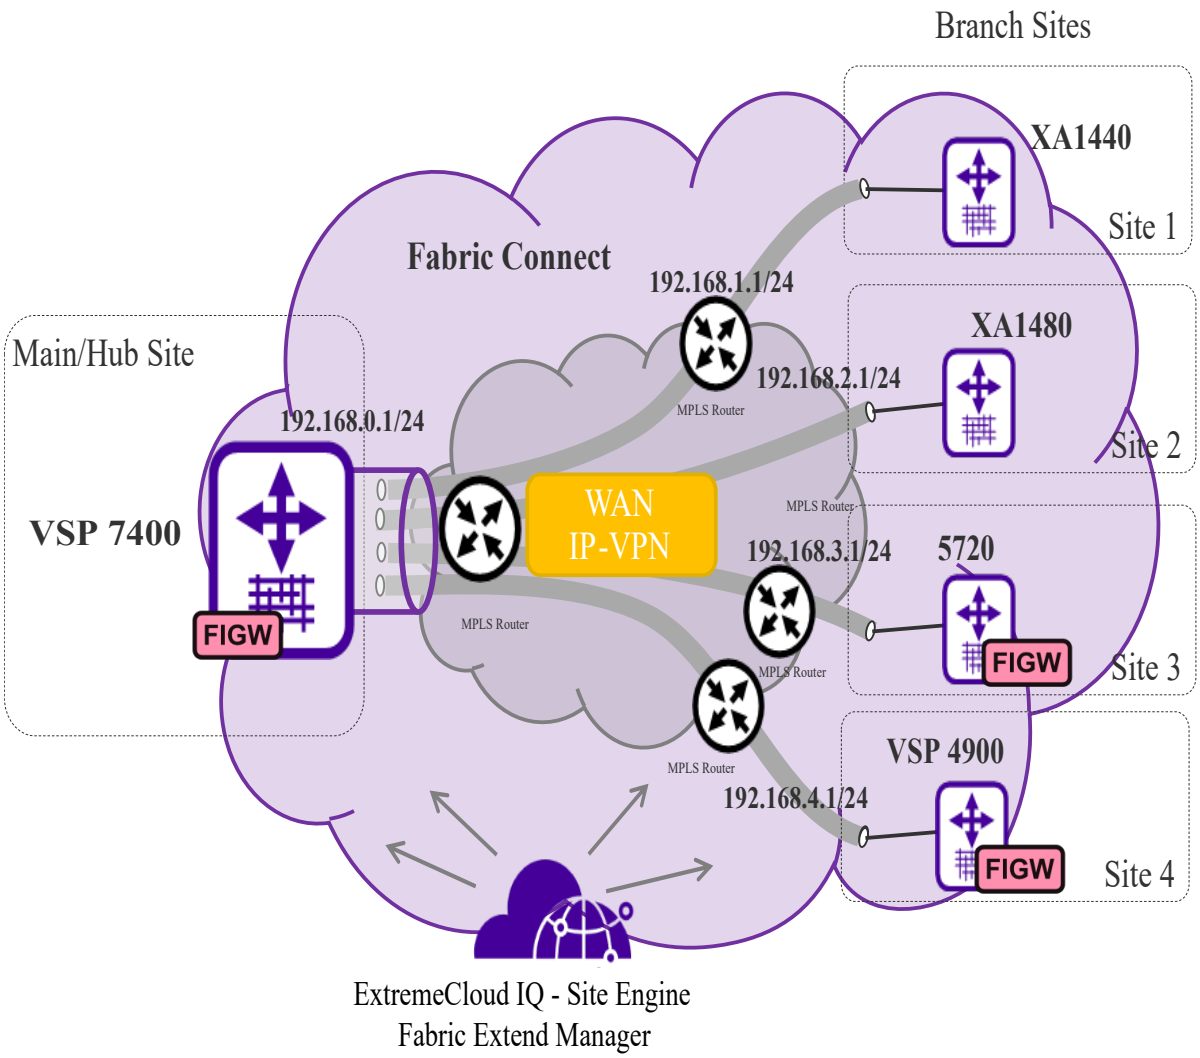

Figure 62: Fabric Extend IP VPN Deployment Option

Note

If Fabric Extend with IPsec or fragmentation and reassembly is a requirement, depending on your requirements, you can use a mix of VSP 7400 Series, VSP 4900 Series, or 5720 Series with Fabric IPsec Gateway and XA1400 Series at the main and branch sites.

Fabric Extend over an MPLS VPLS/P2P-VPLS/E-LINE/P2P-VLAN Provider Network

Where the preceding hub and spoke deployment is over a Layer 3 MPLS IP-VPN, the following VPLS deployment is over a Layer 2 segment. This type of hub and spoke deployment extends the fabric over an MPLS Virtual Private LAN Service (VPLS) or Provider Backbone Bridging (PBB) Ethernet LAN (E-LINE) network. In this scenario, the SPB nodes are connected with a point-to-point Ethernet link.

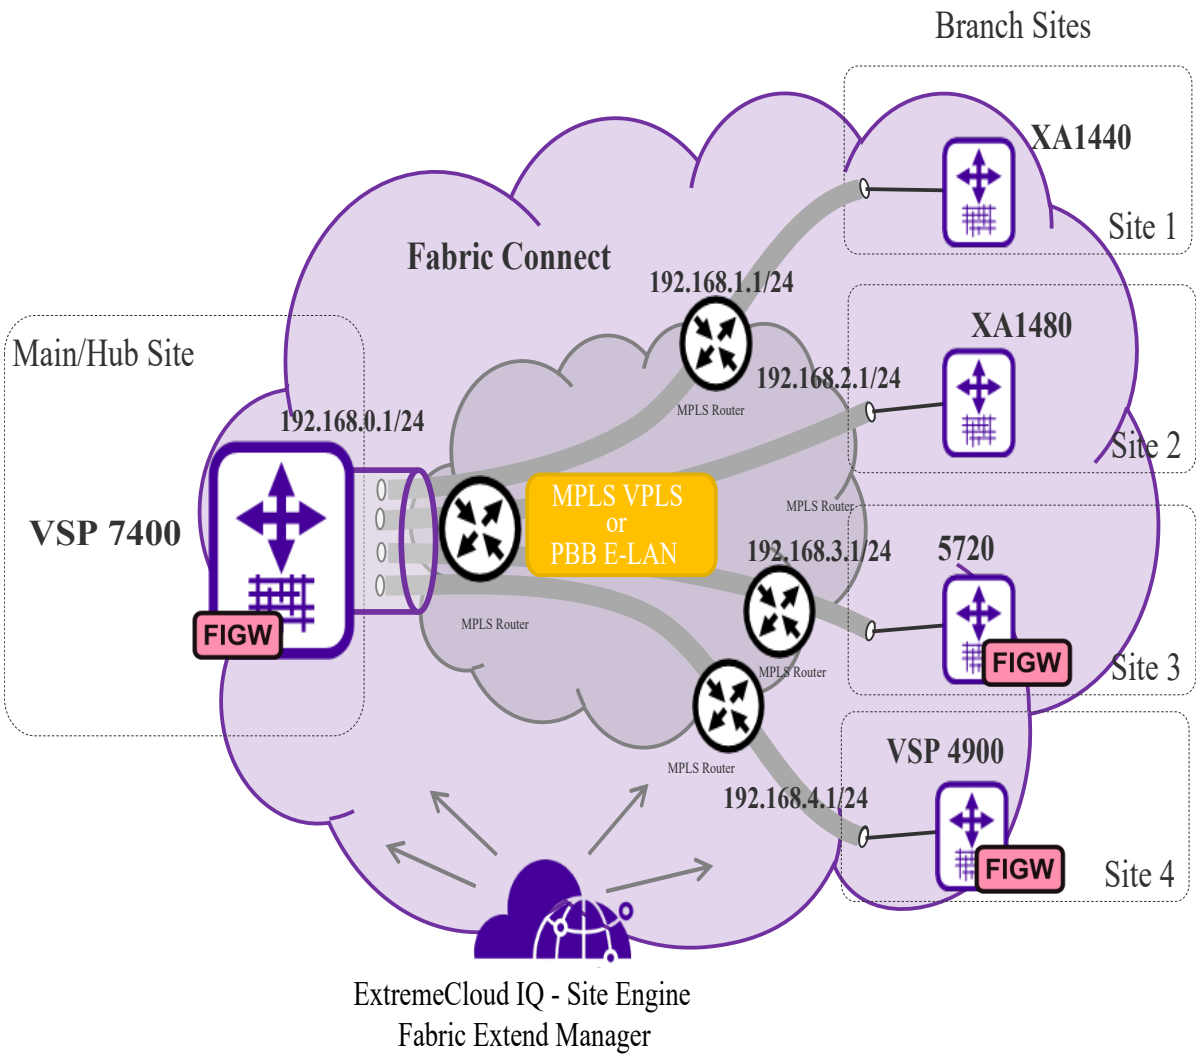

Figure 63: Fabric Extend VPLS Deployment Option

Fabric Extend over an IP Campus Network

Some customers do not want to migrate their infrastructures to SPB immediately. They want to keep their existing IP core network and deploy SPB on the edge. In this scenario, Fabric Extend supports a fabric overlay on top of the existing campus infrastructure.

The following figure illustrates how this deployment supports any-to-any traffic with full-mesh tunnels between fabric nodes. The fabric nodes serve as campus switches, support routing into the IP infrastructure, and provide an overlay fabric that enables all fabric benefits.

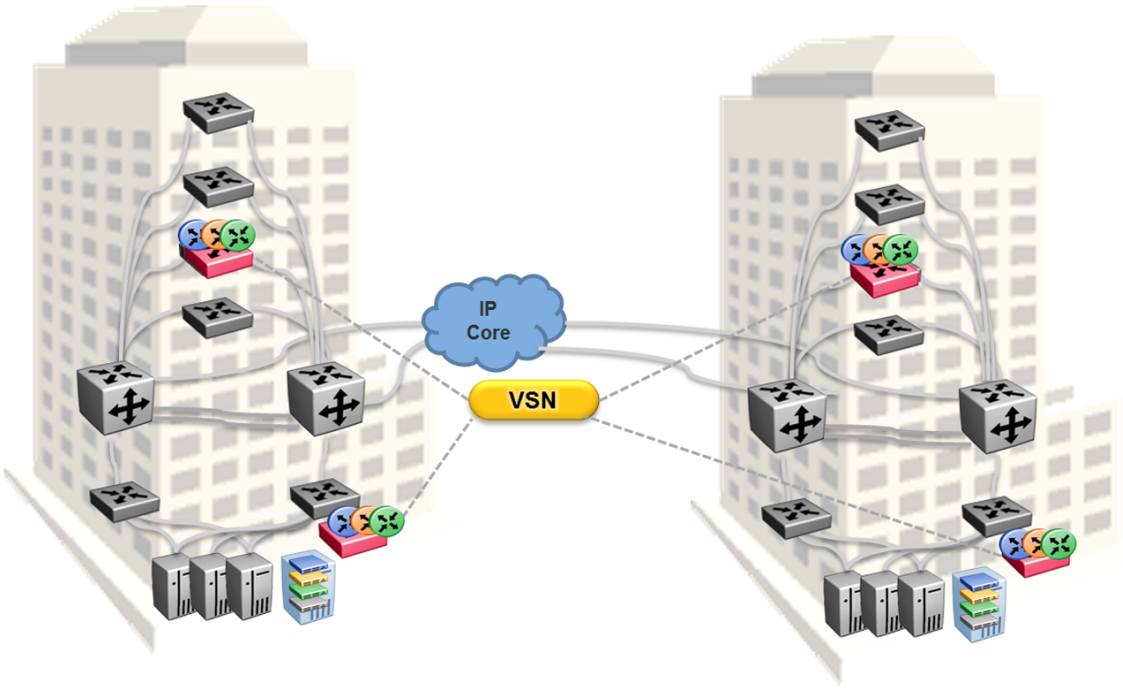

Figure 64: Fabric Extend Full Mesh Campus Deployment Option

Fabric Extend over an MPLS PWE3/E-Line Provider Network

The following hub and spoke deployment over an MPLS Pseudowire or Ethernet Virtual Private Line (E-Line) uses service provider VLAN tunnels. Because you can map many (VID, port/mlt list) sets to an I-SID, this gives Service Providers the flexibility to let more than one customer use the same VLAN with different I-SIDs.

The following figure illustrates how two dedicated Backbone VLAN IDs (B-VIDs) are mapped from the hub to spoke sites. Logical IS-IS interfaces translate the B-VIDs and maps them to each of the branch provider VIDs.

For a detailed configuration example showing logical interfaces using B-VID translation to two different logical VLAN IDs, see *Shortest Path Bridging (802.1aq) Technical Configuration Guide*.

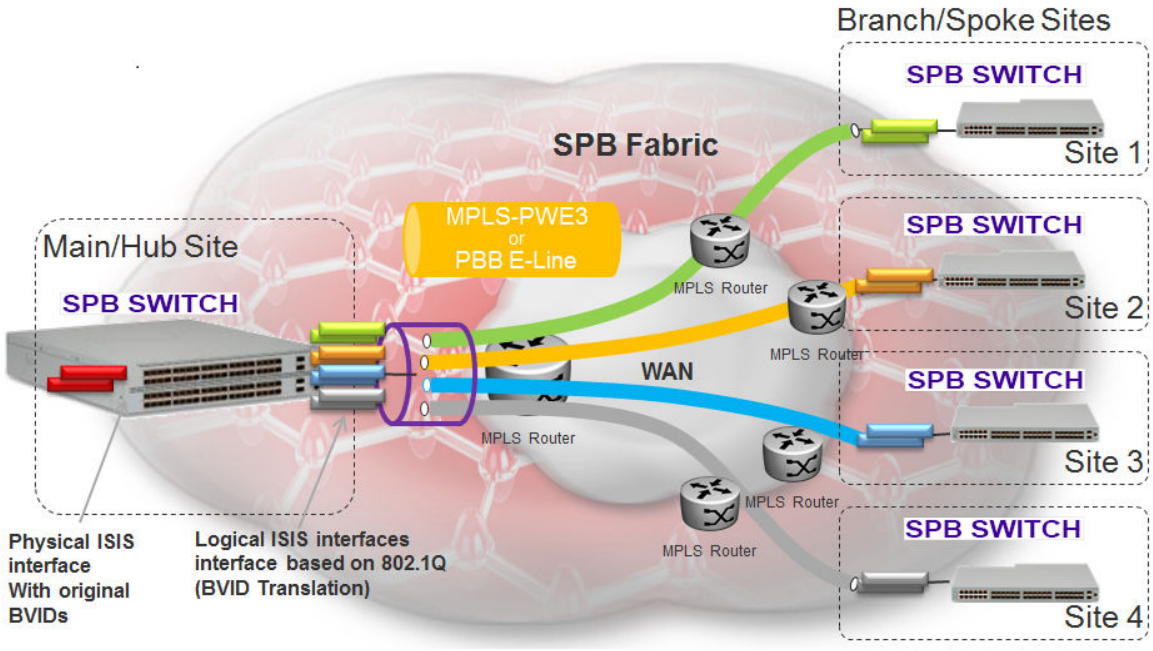

Figure 65: Fabric Extend Pseudowire Deployment Option

Fabric Extend Considerations

Review the following restrictions, limitations, and behavioral characteristics that are associated with Fabric Extend.

Tunnel Source IP

Fabric Extend supports the tunnel source IP address using a brouter port interface, a CLIP IP, or a VLAN IP.

For the 16-port and 24-port 5320 Series switches, you must configure a route-map policy to suppress IS-IS redistribution of the FE tunnel subnet:

- Configure route-maps to not permit redistribution of the local route used as the tunnel source address (**`ip-tunnel-source-address`** command).
- Configure an accept policy to deny IS-IS routes that overlap with the destination tunnel IP address.

Tunnel Failover Time

With IS-IS interface default values, tunnel failure detection can take up to 27 seconds. You can reduce the IS-IS interface hello timers to speed up logical link failure detection, but be careful to avoid link flapping due to values that are too low.

Note

If the number of IS-IS interfaces on a node is greater than 100, it is a good practice to set the hello timer not lower than 5 seconds.

ACL Filters over VXLAN

IP filters configured to match IP header fields in the headers of VXLAN encapsulated packets, work only when the switch acts as a transit router and does not participate in the initiation or termination of VXLAN traffic.

VLACP

VLACP is not supported over logical IS-IS interfaces.

CFM CCM

CFM Continuity Check Messages are not supported over logical IS-IS interfaces.

CFM traceroute and tracemroute

If CFM packets transit over a layer 3 tunnel (that is the CFM packets ingress a Fabric Extend layer 3 core tunnel and egress through another layer 3 core tunnel), the transit SPBM nodes do not display as intermediate hops in the output for CFM **`l2 traceroute`** and **`l2 tracemroute`**.

This is because the CFM packets are encapsulated in the outer layer 3 header as part of VXLAN encapsulation, and the transit SPBM nodes cannot look into the payload of the VXLAN packet and send a copy of the CFM packet to local CPU for processing.

CFM L2 Ping

CFM Layer 2 ping to MCoSPB source mac is not supported and can fail if they are reachable via Fabric Extend tunnel.

MACsec

Switch-based MAC Security (MACsec) encryption is Layer 2 so it cannot be used with Fabric Extend IP, which is Layer 3.

MTU Minimum in Layer 2 Pseudowire Core Networks

Service provider Layer 2 connections must be at least 1544 bytes. In this type of deployment the tunnels are point-to-point VLAN connections that do not require VXLAN encapsulation. The default MTU value is 1950.

Logical IS-IS Interfaces

Layer 2 core and Layer 3 core logical IS-IS interfaces are not supported on the same switch at the same time.

Fragmentation and Reassembly

There is no fragmentation and reassembly support in Layer 2 core solutions.

Layer 2 Logical IS-IS Interfaces

Layer 2 logical IS-IS interfaces are created using VLANs. Different Layer 2 network Service Providers can share the same VLAN as long as they use different ports or MLT IDs.

MTU Minimum in Layer 3 Core Networks

Service provider IP connections must be at least 1594 bytes to establish IS-IS adjacency over FE tunnels. The 1594 bytes includes the actual maximum frame size with MAC-in-MAC and VXLAN headers. If this

required MTU size is not available, a log message reports that the IS-IS adjacency was not established. MTU cannot be auto-discovered over an IP tunnel so the tunnel MTU will not be automatically set. The default MTU value is 1950.

IP Shortcuts

The tunnel destination IP cannot be reachable through an IP Shortcuts route.

Important

If you enable IP Shortcuts and you are using the GRT as the tunnel source VRF, you must configure an IS-IS accept policy or exclude route-map to ensure that tunnel destination IP addresses are not learned through IS-IS.

If you enable IP Shortcuts and you are using a VRF as the tunnel source VRF, this is not an issue.

Layer 3 over Layer 2 Limitation

- The switch requires a single next hop (default gateway) for all tunnels.
  - Over a Layer 3 core network, on a given outgoing port or MLT, there is no issue as the one router next hop can support multiple VXLAN tunnels to one or more remote sites.
  - For Layer 3 tunneling over a Layer 2 core, the switch without any specific configuration supports only one Fabric Extend tunnel to one remote site. The workaround for this single next hop issue is to create an additional VRF, VLAN, and loopback interface.
- You cannot establish a Virtual IST (vIST) session over a logical IS-IS interface. IST hellos cannot be processed or sent over a logical IS-IS interface if that is the only interface to reach BEBs in vIST pairs.

  Assume that vIST is established over a regular network-to-network interface (NNI) and the NNI goes down. If the vIST pairs are reachable through a logical IS-IS interface, then the vIST session goes down in up to 240 seconds (based on the IST hold down timer). During this time, the error message `IST packets cannot be sent over Fabric Extend tunnels, vist session may go down` is logged.

  

  Caution

  Expect traffic loss when the vIST session is down or when the error message is being logged.

Port Mirroring Resources

Port mirroring resources are limited to four ports simultaneously (where each mirroring direction counts as one). For example, if two mirroring ports are designated to mirror both ingress and egress traffic then all four mirroring ports are consumed.

Port mirroring shares these four resources with other applications such as port mirroring RSPAN, Fabric Extend, Application Telemetry, IPFIX, and ACL with mirror action. Each one of these applications

consumes at least one port mirroring resource. (port mirroring RSPAN consumes two if you configure both Ingress and Egress modes.)

Important

To enable any one of the preceding applications, you must have at least one free mirroring resource. If all four port mirroring resources are already in use, the switch displays a `Resource not available` error message when you try to enable the application.

Fabric Extend over IPsec Limitations

- Fabric Extend over IPsec is only supported on 5720 Series using Fabric IPsec Gateway.
- Only pre-shared authentication key IPsec parameters are user configurable. Other, third-party solutions are not configurable.
- IKEv2 protocol key exchange only.
- IPsec support is only added for Fabric Extend tunnels.
- IPsec is not supported for regular Layer 3 routed packets.

Fabric Attach

Table 82: Fabric Attach product support

Feature	Product	Release introduced
Fabric Attach Server	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

With Fabric Attach, network edge devices that do not support Shortest Path Bridging (SPB), MAC-in-MAC encapsulation (802.1ah) or service identifiers (I-SIDs) can take advantage of SPB infrastructure. To attach to an SPB network, edge devices signal an SPB-aware FA Server to automatically configure the I-SIDs. The edge devices can then utilize existing SPB features across the fabric and leverage SPB infrastructure capabilities without manual configuration. Fabric Attach uses the IEEE 802.1AB Logical Link Discovery Protocol (LLDP) to signal a desire to join the SPB network.

FA uses the client-server model. An initial handshake occurs between the FA Server and the FA Client. After the discovery phase is complete, the FA Server accepts requests (from FA Clients) to add the C-VID (VLAN ID) and I-SID elements in the SPB network, and also automatically configures the necessary C-VID and I-SID. The FA Server then responds with an acknowledgement of whether the request succeeded. FA Clients can also be aggregated into a proxy device that handles the handshakes and requests on behalf of many clients, to the server. All of the discovery handshakes and I-SID mapping requests are then transferred using LLDP Type, Length, Value (TLV) fields.

FA leverages LLDP to discover directly connected FA peers and to exchange information associated with FA between those peers. Based on the LLDP standard, FA information is transmitted using organizational TLVs within LLDP Protocol Data Units (PDU).

FA Zero Touch Client Attachment

Table 83: Fabric Attach Zero Touch Client Attachment product support

Feature	Product	Release introduced
Fabric Attach Zero Touch Client Attachment	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

FA Zero Touch Client Attachment eases the configuration process on FA-capable devices by automating specific configuration tasks required for FA functionality.

Note

Only the base functionality of Zero Touch Client Attachment is supported.

After you initially configure Zero Touch Client Attachment on the FA Server, the settings are exported to receiving FA devices, where the required configuration tasks are automatically performed.

Base Zero Touch Client Attachment operation is tightly coupled with FA operation. Although you can enable or disable Zero Touch Client Attachment separately from FA, the feature is dependant on data that is only available during exchanges between the FA Server and FA Proxies, after a primary FA Server has been selected. By default, base Zero Touch Client Attachment support is enabled.

Base Zero Touch Client Attachment operation, when enabled, extracts management VLAN data from the primary FA Server advertisements and uses this data to update the in-use management VLAN if applicable. An FA Client can also utilize FA-provided management VLAN data after the FA Proxy or Server is discovered.

Zero Touch is active when the following criteria are met:

- On an FA Proxy:
  - Zero Touch Client Attachment is enabled
  - Fabric Attach is enabled
  - A primary FA Server is discovered and selected
- On an FA Server:
  - Zero Touch Client Attachment is enabled
  - FA is enabled
  - FA Proxies or FA Clients are discovered

The switch supports configurable VLANs in the range of 1 to 4059. VLAN 0 is invalid. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. VLAN IDs on the switch range from 2 to 4094 but, by default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support

the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.

Note

You must enable Base Zero Touch **auto-client attach** and define the target Fabric Attach client in order to initiate Zero Touch Client Attachment processing.

FA Signaling generated by an FA Proxy or Server contains management VLAN data. If the management VLAN advertised by the primary FA Server differs from the management VLAN currently configured on the FA Proxy, Zero Touch Client Attachment initiates the following:

- VLAN creation — If the FA Server-specified management VLAN does not exist on the FA Proxy, Zero Touch Client Attachment creates a port-based VLAN.
- Management VLAN update — The created port-based VLAN becomes the designated management VLAN for the FA Proxy. No operations related to the previous management VLAN, such as port membership updates or VLAN deletion, are performed.
- Port VLAN membership update (FA Proxy/Server) — If required, Zero Touch Client Attachment updates the port VLAN membership to ensure that the uplink port through which the primary FA Server is accessed is a member of the management VLAN, for network accessibility.
- Port Default VLAN (PVID) update — The port-based PVID is automatically updated based on the VLAN ID value.
- Port Default Priority update — The default 802.1p user priority for the port is updated based on the specified port priority value of the Zero Touch client (range is 0–7).
- Zero Touch Client Specification removal — All Zero Touch client-related settings are updated based on the FA client discovery. Deleting a Zero Touch client specification or disabling any related Zero Touch option does not result in the immediate removal of any previously applied settings.

Note

The FA Proxy does not update the acquired management VLAN if the primary FA Server is lost. This data is updated if the management VLAN advertised by the current primary FA Server changes or if another primary FA Server is selected and new management VLAN data is advertised by the server.

Management VLAN and port membership updates performed by Zero Touch are maintained in non-volatile storage and are restored following a system reset. You must remove or update these configuration settings if they are deemed unnecessary at a later time.

- IP Address Source Mode Update — Updates the IP address source mode of the receiving device to DHCP-When-Needed, to initiate DHCP-based IP address acquisition if necessary.
- Automation of the FA Client Port Mode — Automates the configuration of EAP port modes based on the type of discovered FA Clients. Applies to FA Proxy and FA Server devices. Automated configuration is applied only to FA-enabled ports.
- ZTC Installation — Initiates ZTC installation on applicable ports on the receiving device. Applies to FA Proxy and, in a limited manner, to FA Server devices. Automated configuration is applied only to FA-enabled ports.
- Auto PVID FA Client Port Mode — Initiates automatic port PVID, port management VLAN membership and post tagging mode based on the type of discovered FA device. Applies to FA Proxy and FA Server devices. Automated configuration is applied only to FA-enabled ports. This

configuration is incompatible with the automatic FA Client Port Mode and ZTC Automatic attach options.

Fabric Attach Components

FA components dynamically communicate with each other using FA signaling.

FA Signaling

FA has defined organizational specific TLVs within the standard LLDP protocol, to exchange messages and data amongst components of an FA solution. The FA TLVs facilitate handshaking and authentication, processing of requests for the creation of services, and providing responses on whether the requests succeeded. In addition, these services are deleted when the service requests are terminated, or when the authentication criteria are no longer valid. All components that participate in FA must be able to send, receive, and interpret the FA TLVs.

FA Components

FA includes the following network elements as components:

- FA Server:

  An SPB-capable switch at the edge of a Fabric Connect cloud.

  An FA Server receives requests from FA Clients or FA Proxies to create services with specific I-SID-to-VLAN bindings. The FA Server completes the association between conventional networks and fabric-based virtual service networks. For more details on the operation of an FA Server, see Fabric Attach Server on page 883.
- FA Proxy:

  A network switch that supports the definition of I-SID-to-VLAN assignments and has the ability to advertise these assignments for possible use by an FA Server. FA Proxy switches also support the client mode for directly attached users or end devices. Typically, FA Proxies support downstream FA Client devices, while being directly connected to an upstream FA Server device.
- FA Client:

  A network attached end-point device that advertises I-SID-to-VLAN binding requests for service creation, to an FA Proxy or an FA Server. FA Clients use FA signaling to automatically attach to fabric services.

Fabric Attach Server

FA Server operation

In an FA solution, the FA Server performs the role of connecting FA Clients and FA Proxies to the SPB fabric, with minimal configuration. As part of the discovery handshake between the FA Server and client or proxy devices, LLDP PDUs are exchanged. Using standard LLDP, the FA Server learns neighbors, that include the proxy and client devices. In addition, the FA Server transmits organizational-specific element-discovery TLVs that are used by the client or proxy device to recognize its attachment to the FA Server.

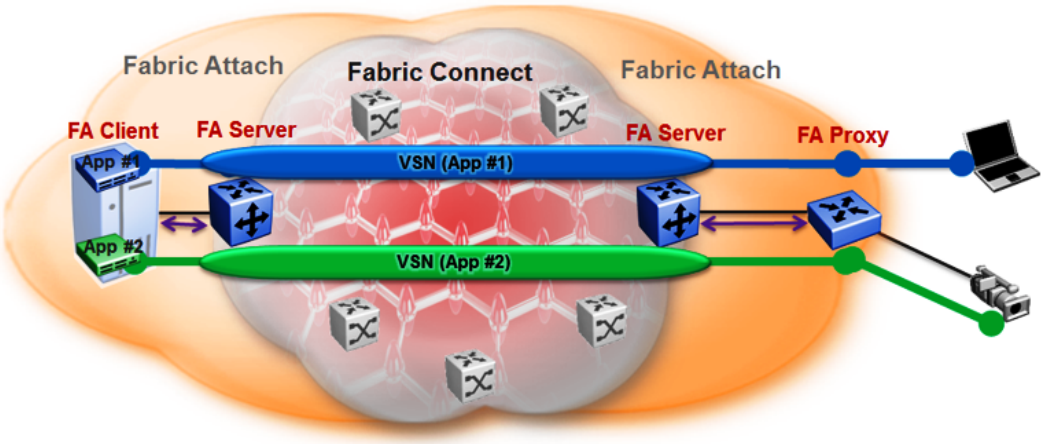

Figure 66: Fabric Attach Server connecting client or proxy devices to the Fabric network

After the initial discovery handshake is complete, the client or proxy device transmits I-SID-to-VLAN assignment mapping requests to the FA Server to join the SPB fabric. These requests include the C-VID (VLAN ID) and the I-SID that the client or proxy device needs to join. The FA Server then creates the requested C-VID and I-SID on its device. It then responds with a PDU (containing the FA-specific TLV) to indicate whether the request succeeded. The I-SID thus created is a ELAN I-SID with endpoints of type Switched UNI. After I-SID creation, the I-SID is also advertised to the SPB network by IS-IS.

The traffic that is sent to or received from the SPB cloud is MAC-in-MAC (MiM) encapsulated. The FA Server, being SPB-capable, decapsulates the MiM traffic. If the I-SID matches the I-SID created on behalf of the client or proxy, the FA Server sends the traffic to that client or proxy and passes it on the C-VID that it expects.

FA Server configuration

An FA Server can be configured at two levels—global and interface.

Configuration at the global level enables or disables FA on the entire switch. However, for attachment of clients or proxy devices, you must also configure FA at the interface level. Interfaces can be ports (including channelized ports), MLTs, SMLT or LACP MLTs. Enabling FA on an interface also enables transmission of LLDP packets that contain the FA-specific TLVs.

When you disable FA on an interface, LLDP transmission automatically stops on that interface.

Caution

Disabling FA or IS-IS triggers a flush of FA information on the switch. Disabling FA at the global level flushes all FA element-discovery information and mappings. Disabling at the interface level flushes element-discovery information and mappings associated with that interface.

Important

The only provisioning mode supported on the FA Server is SPB.

FA Proxies and FA Clients

The configuration mode of FA Proxies and FA Clients is not supported. However, in an FA solution, the FA Server interacts with FA Proxies and FA Clients by accepting LLDP PDUs (containing FA TLVs) and

using them to automatically create Switched UNI I-SIDs and endpoints, based on the mapping requests contained in those TLVs. For more information, see FA TLVs on page 885.

Fabric Attach operation

The following sections detail FA operation.

FA TLVs

FA leverages LLDP to discover directly connected FA peers and to exchange information associated with FA amongst those peers. FA information is transmitted using company-specific proprietary organizational Type, Length, Value (TLV) fields within LLDP Protocol Data Units (PDU). The following section describes the TLVs for FA.

FA uses two TLVs:

- FA Element TLV
- FA Assignment TLV

FA Element TLV

The FA Element TLV is used by FA elements to advertise Fabric Attach capabilities. This data forms the basis for FA element discovery and is used in the initial handshake between the FA Server and a client or proxy device.

TLV Type [127]	TLV Length [50 octets]	OUI [00-04-0D]	Subtype [11]	HMAC-SHA Digest	Element Type	State	Mgmt VLAN	Rsvd	System ID
7 bits	9 bits	3 octets	1 octet	32 octets	6 bits	6 bits	12 bits	1 octet	10 octets

Figure 67: FA Element TLV format

Table 84: FA Element TLV field descriptions

Field	Description
TLV Type	Indicates whether the discovered element is a client or a proxy device.
OUI and Subtype	The information in these fields is used in LLDP packet handling.
HMAC-SHA Digest	Data integrity and source validation is supported through the use of the HMAC-SHA256 message authentication. This field supports a digest exchange between the source and destination devices. Symmetric private keys are used for digest generation. The HMAC-SHA256 generated digest size is 32 octets. The HMAC-SHA256 digest is computed starting with the Element Type data, that is, it starts at zero-based byte 38 of the TLV. The digest is then placed in the HMAC-SHA256 Digest field in the TLV prior to transmission. Upon receipt, the digest is again computed and the resulting digest is compared against the received digest. If the received digest is the same as the newly computed digest, the TLV is considered valid and processing commences. If the comparison fails, the TLV is discarded and processing is terminated. Caution: If FA communication occurs between non-secure systems, the HMAC-SHA256 Digest data must always be zero. If one system operates in secure mode and the other operates in non-secure mode, the FA Element TLV is discarded before it is processed by the system operating in secure mode.

Table 84: FA Element TLV field descriptions (continued)

Field	Description
Element Type	Indicates the supported element type. The primary element types are the FA Server, FA Proxy and FA Client. An FA Server is an SPB capable device that accepts externally generated I-SID-to-VLAN assignments. An FA Proxy is a non-SPBM device that supports I-SID-to-VLAN assignment definitions and advertises these assignments for possible use by an FA Server. An FA Client, also a non-SPBM device, advertises I-SID-to-VLAN assignments to a directly connected FA Proxy or an FA Server. Both tagged and untagged FA Client connections are supported. The list of supported element types and their values are: • FA Element Type - Other (1) • FA Server (2) • FA Proxy (3) • FA Server No Authentication (4) • FA Proxy No Authentication (5) • FA Client - Wireless Access Point Type 1, which directly attaches to the SPBM network. • FA Client - Wireless Access Point Type 2, which is tunneled to a controller. • FA Client - Switch (8) • FA Client - Router (9) • FA Client - IP Phone (10) • FA Client - IP Camera (11) • FA Client - IP Video (12) • FA Client - Security Device (13) • FA Client – Virtual Switch (14) • FA Client – Server/Endpoint (15)
State	Indicates the link tagging requirements in FA Client-sourced frames. This field also indicates the current provisioning mode. The Link VLAN Tagging bit (bit 1) has one of the following values: • 0 — indicates that all traffic on the link is tagged. In this case, all discovered FA Clients are treated as tagged. • 1 — indicates that traffic on the link is either tagged or untagged. Here, all discovered FA Clients are treated as untagged. The automatic provisioning mode bits (bits 2 and 3) always have the value 1 for SPB provisioning. The switch only supports the SPB provisioning mode.
Mgmt VLAN	When you configure a management VLAN on the FA Server, it is included in this field in FA Server or FA Proxy sourced frames, and is used to support management VLAN auto-configuration on the downstream proxy and client devices.
System ID	This field contains connection information that a TLV recipient can use to enforce connectivity restrictions. It contains the system MAC address (6 octets) for MLT configurations and the virtual BMAC address for vIST and SMLT configurations. It also contains information on the connection type such as MLT or SMLT.

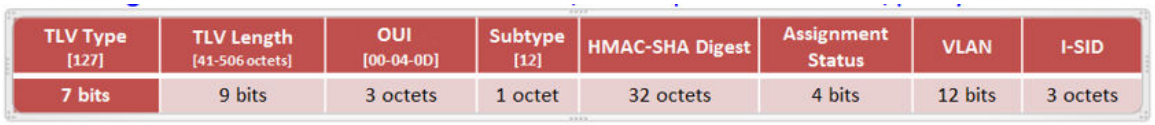
Limitations

- The FA Element TLV exists only once in an LLDP PDU and is included in all PDUs when the FA service is enabled.

- The maximum length of the FA Element TLV is 56 bytes.

FA I-SID-to-VLAN Assignment TLV

The FA I-SID-to-VLAN Assignment TLV is used by FA Clients to distribute I-SID-to-VLAN assignments that need to be supported by an FA Proxy or an FA Server.



TLV Type [127]	TLV Length [41-506 octets]	OUI [00-04-0D]	Subtype [12]	HMAC-SHA Digest	Assignment Status	VLAN	I-SID
7 bits	9 bits	3 octets	1 octet	32 octets	4 bits	12 bits	3 octets

Figure 68: FA Assignment TLV format

FA I-SID-to-VLAN Assignment TLV fields

Some fields are common to both the FA Element and FA Assignment TLVs. The following fields are specific only to the FA Assignment TLV.

TLV Field	Description
HMAC-SHA Digest	The HMAC-SHA256 digest is computed for the series 1 to 94 of I-SID-to-VLAN assignments, that is, the data for the digest computation starts at zero-based byte 38 of the TLV. The digest is then placed in the HMAC-SHA256 Digest field in the TLV prior to transmission. Upon receipt, the digest is again computed for the series 1 to 94 of I-SID-to-VLAN assignments in the received TLV and the resulting digest is compared against the received digest. If the received digest is the same as the newly computed digest, the TLV is considered valid and processing can commence. If the comparison fails, the TLV is discarded and processing is terminated. Caution: If FA communication occurs between non-secure systems, the HMAC-SHA256 Digest data must always be zero. If one system operates in secure mode and the other operates in non-secure mode, the FA I-SID-toVLAN Assignment TLV is discarded before it is processed by the system operating in secure mode.
Assignment status	Indicates whether the FA Server accepted or rejected the I-SID-to-VLAN mapping request from a client or proxy device.
VLAN	Indicates the C-VID value advertised by the client or proxy device in the FA I-SID-to-VLAN mapping request.
I-SID	Indicates the I-SID that is advertised by a client or proxy device in the FA I-SID-to-VLAN mapping request. This I-SID is used to create a Switched UNI (ELAN) I-SID. Note: This I-SID cannot be used by IPVPN, MVPN, SPBM dynamic multicast range, or Transparent Port UNI.

Limitations

- The FA I-SID-to-VLAN Assignment TLV is included in an LLDP PDU only if the FA Server and proxy or client devices are directly connected to each other.
- This TLV can exist only once in an LLDP PDU.

- The size limit of this TLV is 511 bytes. This limits the maximum number of I-SID-to-VLAN assignments supported in an LLDP PDU to 94.
- For an FA I-SID-to-VLAN Assignment TLV to be processed, the FA Element TLV must also be present in the LLDP PDU.

FA Element Discovery

The first stage of establishing FA connectivity is element discovery.

On an FA Server, FA is enabled globally by default. However, you must explicitly enable FA on a desired port or MLT interface. After FA is enabled, the FA Server begins transmitting LLDP PDUs that contain the element discovery TLVs. This information is received by FA Client and FA Proxy devices which in turn also transmit their FA capabilities and settings. After the element handshake completes, the FA Server receives I-SID-to-VLAN assignment mappings from the connected client or proxy devices.

An FA Server can communicate with multiple different FA Client and FA Proxy devices.

FA data processing

In the following FA deployment, a client device (Client 1) attaches to the FA Server (FA Server 1) using a proxy device. Another client device (Client 2) attaches to the FA Server (FA Server 2) at the other edge of the network. The following section describes how data is processed when data traffic is transmitted from Client 1 to Client 2.

When Client 1 successfully attaches to FA Server 1, FA Server 1 creates a unique I-SID-to-VLAN mapping for Client 1 on its device. This mapping contains the I-SID and C-VID advertised by Client 1, using the FA Assignment TLV. For example, assume that Client 1 advertises I-SID 200 and C-VID 250.

Similarly, when Client 2 attaches to FA Server 2, FA Server 2 creates an I-SID-to-VLAN mapping for Client 2 on its device with, for example, I-SID 200 and C-VID 100. This is depicted in the following figure.

Figure 69: Learning of I-SID-to-VLAN mappings

When data traffic ingresses FA Server 1 at the FA-enabled port 1/1, it contains the C-VID of Client 1, which is, 250. The data is VLAN-encapsulated at this stage. As traffic egresses FA Server 1 into the SPB cloud, it is encapsulated with the ELAN I-SID created on FA Server 1 on behalf of Client 1, that is I-SID 200. The traffic is now MiM encapsulated with I-SID 200.

The following figure depicts VLAN encapsulation of data traffic from the FA Client to the FA Server (at either end of the SPB cloud) and its MiM encapsulation as it traverses the SPB cloud.

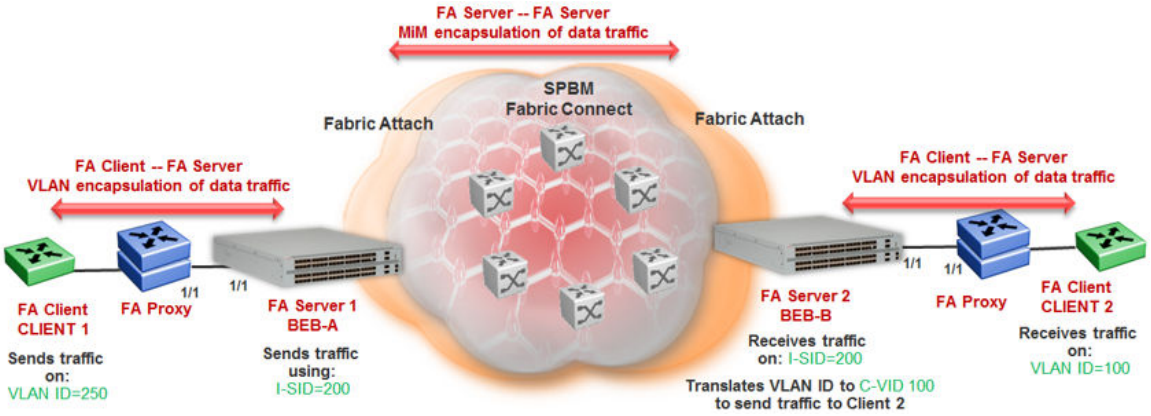


Figure 70: Data encapsulation — VLAN encapsulation and MiM encapsulation

As traffic exits the SPB cloud and ingresses the remote FA Server 2, it continues to be MiM encapsulated with I-SID 200.

At FA Server 2, the MiM traffic is decapsulated. Since the I-SID in the data packet matches the I-SID created on its device on behalf of Client 2, FA Server 2 prepares to send traffic to Client 2. At this stage, to successfully transmit the data traffic to Client 2, FA Server 2 must additionally know the C-VID that Client 2 expects traffic on. This information is obtained from the I-SID-to-VLAN mapping on FA Server 2 created on behalf of Client 2, which is C–VID 100. Thus FA Server 2 translates the C-VID in its data packets to this VLAN ID, and then passes it on to Client 2.

The following figure depicts the typical MiM encapsulation of a data packet. The B-DA and B-SA components indicated the system ID of the FA Server running SPB.

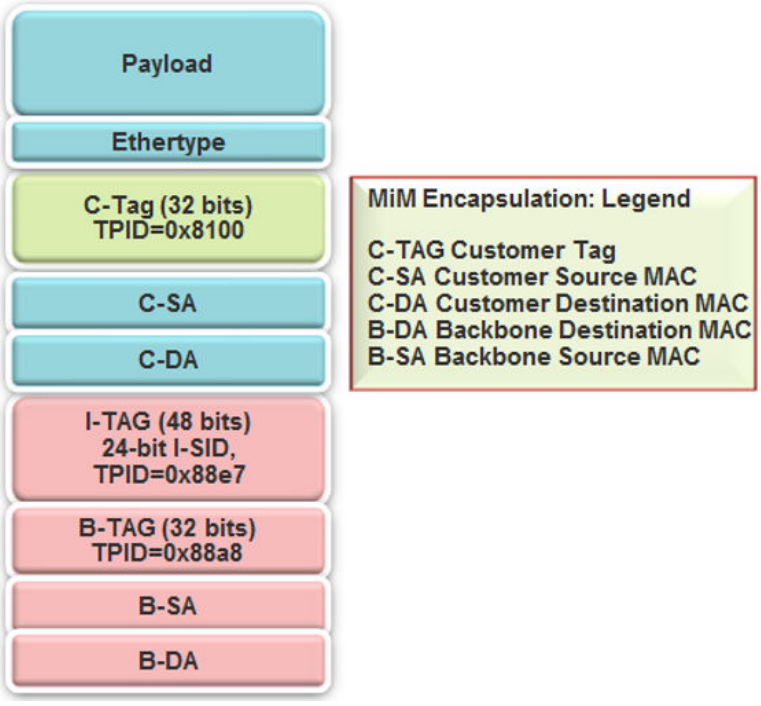

Figure 71: MiM encapsulation

FA Server and I-SID-to-VLAN Assignments

FA Client or FA Proxy devices advertise I-SID-to-VLAN assignments to be supported on the FA Server. These assignments can be accepted or rejected by the FA Server. All communication between FA Proxies or Clients and the FA Server is using LLDP. Successful assignments result in the creation of a Switched UNI I-SIDs and endpoints based on the mapping requests.

The FA Server rejects I-SID-to-VLAN assignment requests if:

- FA is not configured properly on the port or MLT.
- Router IS-IS is disabled.

  Note

  For Fabric Attach to operate properly and for the FA Server to accept I-SID-to-VLAN assignment requests, IS-IS must be enabled.

  The following error message is logged immediately after IS-IS is disabled, and displays the error message only once in the log file. The system does not display it again when an assignment request is made from the FA Proxy.

  ```
  CP1 [12/04/15 00:33:49.733:UTC] 0x00374589 00000000
  GlobalRouter FA INFO Fabric Attach Assignments will be rejected
  since ISIS is disabled.
  ```

- The C-VID and I-SID are not within the supported range.

  Different hardware platforms support different customer C-VID ranges. The value 4095 is not supported. The value 4096 indicates that the port is untagged. An I-SID value of 0 is not supported on the FA Server.
- The I-SID is already assigned to an IP VPN.

  The system displays the error message `I-SID is already assigned to an IPVPN`.
- The I-SID is already in use for SPB multicast.

  The system displays the error message `SPB Multicast is enabled, ISID 16000000 and greater reserved for dynamic data-isid's used to carry Multicast traffic over SPB`.
- The I-SID has a value that is reserved for internal use.
- The I-SID cannot be used in an IS-IS accept policy.
- The I-SID is associated with a platform VLAN and that VLAN is used as a private VLAN (that is, has a secondary VLAN specified).
- The I-SID is already in use for Transparent Port UNI.
- The port that receives the I-SID-to-VLAN assignment is a member of an MLT, but FA is not successfully enabled on that MLT interface.
- There is a resource error on the FA Server system, such as lack of memory.
- The number of I-SID-to-VLAN assignments on a port exceeds the maximum limit which is 94.
- The number of I-SIDs on the switch exceeds the maximum limit.
- The same endpoint is configured on more than one I-SID.
- The port or MLT is associated with more than one C-VID in the same I-SID.

When the FA Server rejects I-SID-to-VLAN assignments, aside from viewing the log file, you can use trace to troubleshoot the cause of rejection.

For an example on troubleshooting rejection of I-SID-to-VLAN assignments on the FA Server and for more information on using trace, see Troubleshooting Fabric Attach on page 3335.

FA management

You can configure a management I-SID on an FA-enabled port or MLT. This I-SID includes an optional C-VID parameter, which is a VLAN ID that is locally significant to the port or MLT and does **not** represent a platform VLAN.

Depending on whether the C-VID value is specified, the behavior is as follows:

- If the C-VID value is specified, the FA Server transmits this VLAN ID as the management VLAN in the FA Element TLV. A client or proxy receiving this TLV uses this VLAN ID for management traffic on the FA Server uplink.

  Different hardware platforms support different customer C-VID ranges.
- If the C-VID value is not specified, the FA Server transmits a management VLAN with a VLAN ID value of 4095 in the FA Element TLV. A client or proxy receiving this TLV uses **untagged** traffic for network management on the FA Server uplink.

If you do not configure a management I-SID, the FA Server transmits a management VLAN ID value of 0 in the FA Element TLV. A client/proxy that receives the FA Element TLV retains the initial management configuration (if any) on its device.

Limitations of FA management I-SIDs

- A management I-SID value of 0 is not supported on the FA Server.
- You cannot enable BPDU on a management I-SID.

FA management configuration considerations

A Switched UNI I-SID that is created when an FA assignment is learned on a port or MLT, is uniquely identified by a tuple comprising of one of the combinations of (port, I-SID and C-VID) or (MLT ID, I-SID and C-VID). When you configure FA management, similar tuples are used. You can configure FA management on an FA-enabled port or MLT on which FA assignment mappings are learned, as long as the FA management tuple exactly matches the tuple created by the learned FA mapping.

The following scenarios describe the behavior when you configure FA management on a port or MLT that also receives learned FA mappings, but the tuples do not match.

- **Scenario 1**: You attempt to configure FA management on a port or MLT where an FA assignment mapping is already learned.

  For example, consider an FA-enabled port 1/1 on which an assignment mapping is learned, with I-SID 100 and C-VID 20. You can configure FA management on port 1/1 as long as the I-SID and C-VID values exactly match that of the learned FA mapping. However, if you attempt to configure FA management on the port with a different I-SID and C-VID value, the configuration is not successful and an error message displays.
- **Scenario 2**: An FA assignment mapping is learned on a port or MLT that already has FA management configured.

For example, consider that FA management is configured on port 1/1. If an FA assignment mapping is learned on the port with the same I-SID and C-VID values as that of the FA management configuration, then the mapping is accepted. Otherwise the mapping is rejected.

FA message authentication and integrity protection

For the security of FA communication in terms of data integrity and authenticity, a keyed-hash message authentication code can be transmitted within every FA TLV.

It protects the I-SID-to-VLAN assignment exchanges between the FA Server and FA Proxy. The standard HMAC-SHA256 algorithm calculates the message authentication code (digest) involving a cryptographic hash function (SHA-256) in combination with a shared secret key. The key is symmetric, that is, it is known by both the source and destination parties.

By default, on the FA Server, message authentication is enabled at the interface level and a default key is defined to provide secure communication.

You can configure a different authentication key on an interface (port or MLT) on the FA Server, to authenticate a client on that interface. The authentication key is stored in encrypted form when you save configuration on the FA Server. For an FA Client to authenticate and attach to the FA Server, the authentication key must match on both the client and the server. In general, the FA authentication key must match between two FA components exchanging FA TLVs through LLDP.

When you enable FA message authentication, the message authentication key (default or configured) generates a Hash-based Message Authentication Code (HMAC) digest that is included in FA I-SID-to-VLAN Assignment TLV. Upon receipt, the HMAC digest is recomputed for the TLV data and compared against the digest included in the TLV. If the digests are the same, the data is valid. If the digests are not the same, the data is considered invalid and is ignored.

The FA secure communication setting (enabled/disabled) and the symmetric key data are maintained across resets and restored during FA initialization.

Fabric Attach and Switched UNI

With the C-VLAN UNI feature, I-SID-to-VLAN mappings must be unique across the network. With the Transparent Port UNI (ELAN Transparent) feature, you can map an entire port or MLT to an I-SID.

With the Switched UNI feature, you can associate many different C-VID/port or C-VID/MLT list combinations to a single I-SID.

Switched UNI and FA

FA brings the capability of automatically creating Switched UNI I-SIDs on a switch, without manual intervention. The I-SIDs thus created are ELAN I-SIDs with endpoints of type Switched UNI, and are by default for Layer 2. MAC learning takes place and there is an any-to-any relationship. For Layer 3 participation, you must configure a platform VLAN with the same I-SID value as that of the I-SID in a learned FA mapping.

Note

The number of Switched UNI I-SIDs created are different for different product families. For more information, see *Fabric Engine Release Notes*.

Limitations of FA-created Switched UNI I-SIDs

- An FA-created Switched UNI I-SID is always ELAN.
- You cannot enable BPDU on an FA-created Switched UNI I-SID.
- The ELAN I-SIDs created are by default for Layer 2. For Layer 3 participation, you must manually configure a platform VLAN with the same I-SID value as that of the I-SID in a learned FA mapping. You can configure the platform VLAN with the same VLAN ID as that of the C-VID, or use a different value.
- The Switched UNI (ELAN) I-SID cannot be used by IPVPN, MVPN, SPBM dynamic multicast range, or a T-UNI.
- You cannot change from one UNI type to another dynamically. The I-SID must be deleted and created with the new UNI type (Customer VLAN (C-VLAN), Transparent Port user-network-interface (T-UNI), ELAN).
- If the port is a member of an MLT, you must add the entire MLT to the C-VID.
- The port is always in the forwarding state.
- You cannot associate a port or MLT with more than one C-VID in the same I-SID.
- The same C-VID, port or MLT cannot be a member of more than one I-SID. Different hardware platforms support different customer C-VID ranges. The value 4095 is not supported and cannot be configured. The value 4096 indicates that the port is untagged.
- An I-SID value of 0 is not supported on the FA Server.

Fabric Attach Deployment Scenarios

Fabric Attach is typically deployed in the access layer(s) of a Fabric Connect network.

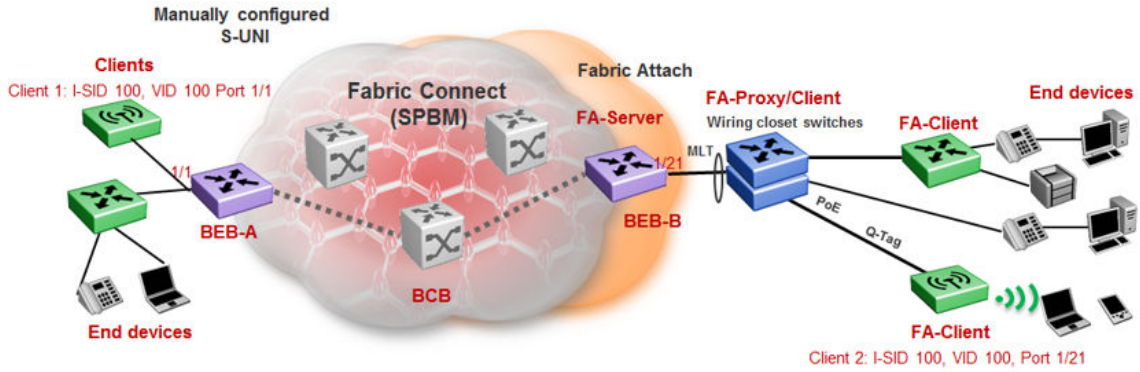
Fabric Attach, when used with a Fabric Connect solution, provides the same capabilities at the access layer, but those services and policies are now mapped across the entire network end-to-end. FA makes user and end device attachment simple and creates network configuration and sets up resources only when needed.

An FA Server can be connected to FA Client or FA Proxy devices on three types of interfaces, namely, a port, MLT or an SMLT. The following sections discuss FA in SMLT and non-SMLT deployments.

FA and Switched UNI in non-SMLT deployments

The following deployment shows an SPBM network in which one edge has manually configured Switched UNI I-SIDs and the other edge has Fabric Attach (FA). At the FA edge, the I-SIDs are learned using FA TLVs and are automatically created on the FA Server as ELAN I-SIDs with Switched UNI endpoints.

This deployment demonstrates that the FA-created I-SIDs can communicate with any other I-SID (manually created Switched UNI or a C-VLAN with an I-SID), on the local switch or across the SPBM fabric, as long as the I-SID values are the same.



BEB-B is a switch acting as the FA Server with a network-to-network interface (NNI) to the SPBM cloud. FA Client and FA Proxy devices send I-SID-to-VLAN mapping requests to the FA Server on the respective FA-enabled ports, using LLDP TLVs. This enables the I-SID endpoints to communicate with the SPB cloud.

If several clients are aggregated in an MLT, at least one of the ports must send the mapping requests for the FA Server to create the I-SID endpoints for that MLT. For example, let Client 2 be a wireless FA Client (such as an WLAN 9100 AP device) on port 1/21, that sends an FA mapping request for I-SID 100 and C-VID (VLAN ID) 100. The FA Server (BEB-B) creates the requested I-SID 100 on its device, and advertises it to the SPB cloud.

BEB-A has manually configured Switched UNI endpoints, one of which is Client 1 (connected at port 1/1) using the same I-SID value 100.

With this setup, data traffic can freely flow between Client 1 and Client 2 through the two BEBs and the BCB.

Thus the Switched UNI I-SIDs learned using FA TLVs on one edge of the Fabric Connect (SPBM) network can communicate with the manually created I-SIDs on the other edge, as long as they both have the same value.

FA and Switched UNI in SMLT deployments

The following examples discuss FA in dual-homed and single-homed SMLT deployments.

Fabric Attach in a dual-homed SMLT deployment

The following section describes FA in a dual-homed SMLT deployment. A pair of switches that operate as IST peers act as the FA Server. An FA Proxy (typically a wiring closet switch or an access switch) is connected to FA Clients and in turn to end devices. The FA Clients or FA Proxies advertise I-SID-to-VLAN mappings namely the interface C-VID and the I-SID to the FA Server switches. Both switches receive the mapping information using LLDP TLVs. The switch that learns the mapping first from the LLDP TLV considers the I-SID endpoint to be discovered locally, and creates the I-SID on its device. It then sends the mapping information to its peer switch. When the peer switch receives the mapping

across IST in a new SMLT message, it too creates the I-SID and endpoint on its device. This I-SID however, is considered to be discovered remotely, because the data was synchronized from its peer.

Note

- For the peer switches acting as the FA Server to transmit the same FA System ID (based on the virtual MAC), SMLT configuration must be the same on both peers.
- For successful FA operation, configuration of FA message authentication and the authentication key must be the same on both peers.
- For successful operation in Layer 3, a platform VLAN must be configured on both peers. This is necessary for proper MAC learning.

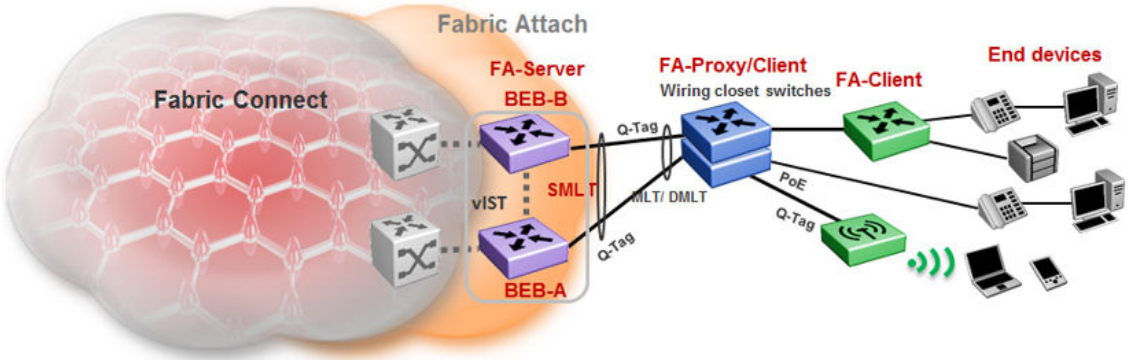


Figure 72: FA in a dual-homed SMLT deployment

In the above example deployment, BEB-A and BEB-B are IST peers collectively acting as the FA Server. FA TLVs sent from the clients (through the proxy) are learned on FA-enabled ports on BEB-A and BEB-B. When BEB-A learns the mapping for the first time on its port, it creates an I-SID on its device. This is considered locally discovered. In addition, it sends an SMLT message to its peer BEB-B, which also creates the I-SID on its device. This time, the I-SID is considered remotely discovered. Similarly, if BEB-B receives a mapping from a client for the first time, it creates an I-SID (locally discovered) and also sends an IST message to its peer to create an I-SID (remotely discovered).

Irrespective of whether the I-SID creation on the FA peers is triggered by a local TLV event or by messaging from the IST peer, they can both receive data traffic. Thus in a dual-homed SMLT deployment, any I-SID can be learned irrespective of whether it is discovered locally, discovered remotely or both.

Note

On the IST peers, if an FA TLV is learned on a port or normal MLT (instead of the admin SMLT), only the I-SID is sent to the peer switch.

Fabric Attach in a single-homed SMLT deployment

In the single-homed SMLT, as shown in the following deployment, the FA Server creates either a locally discovered I-SID (if received from a client using FA TLVs) or a remotely discovered I-SID (if synchronized from its IST peer), but not both.

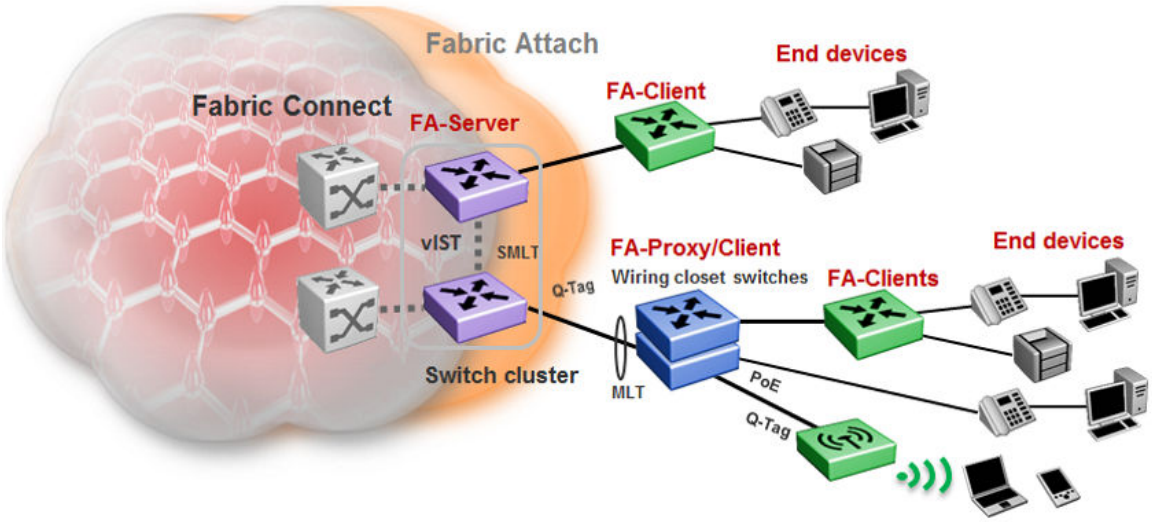

Figure 73: Fabric Attach in a single-homed SMLT deployment

Fabric Attach Considerations

Review the following restrictions, limitations, and behavioral characteristics for Fabric Attach.

- IS-IS and FA must be globally enabled on the FA Server, for FA to operate successfully.
- Static MAC, Static ARP and configuration of a static IGMP group are not supported on FA-enabled ports.
- An FA port cannot be a BROUTER port.
- You cannot enable FA on an existing Transparent Port UNI or a C-VLAN UNI port.
- FA I-SID-to-VLAN assignment mapping requests from a client or proxy device can be accepted or rejected by the FA Server.
- On an FA-enabled port or MLT, you must first disable LACP before you change the LACP key.
- You can only enable VLACP on an FA enabled MLT; VLACP is not supported on FA enabled non-MLT ports.
- On VLACP enabled ports, FA and LLDP signaling run independent of the VLACP state. Therefore, requests and responses are exchanged between the FA Server and client or proxy devices even if VLACP is operationally down. However, forwarding of data traffic is dependent on VLACP being operationally up on the port.

  For example, if VLACP is enabled on the FA Server side of the link but not on the proxy or the client side, the FA Server learns the I-SID-to-VLAN assignment mappings and creates the required I-SIDs on its device. However, data traffic is not forwarded on the port until VLACP is operationally up.
- FA uses the virtual MAC to create the FA system ID when the FA is on an SMLT. If you delete the SPBM instance, then this information is no longer available. Therefore, you must delete the FA on SMLT before deleting the SPBM instance.
- You cannot enable FA and Endpoint Tracking simultaneously on the same interface.

Endpoint Tracking

Table 85: Endpoint Tracking product support

Feature	Product	Release introduced
Endpoint Tracking	5320 Series	Not Supported
	5420 Series	Not Supported
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

Endpoint Tracking Overview

Endpoint Tracking provides dynamic assignment of virtual machines (VMs) to IP subnets as they attach to a Shortest Path Bridging (SPB) cloud. Deployment scenarios include VMs connecting to DvR Leaf nodes, or regular SPBM deployments.

Extreme Management Center or ExtremeCloud IQ - Site Engine is integral to the Endpoint Tracking solution. Extreme Management Center or ExtremeCloud IQ - Site Engine delivers automation; there is no need to manually configure server VLANs on data center access switches. Additionally, Extreme Management Center or ExtremeCloud IQ - Site Engine) provides the ability to see what VM MACs exist, and where they are located.

Extreme Management Center or ExtremeCloud IQ - Site Engine's ExtremeConnect module integrates with third-party virtualization software (such as VMware or Microsoft HyperV) and communicates with the ExtremeControl module to automatically extract all of the VM MACs (including VLAN assignment for each MAC) and then automatically create all of the necessary authentication profiles, rules and mappings.

When the switch detects a new VM on a port, it sends a RADIUS request to Extreme Management Center or ExtremeCloud IQ - Site Engine. ExtremeConnect checks with VCenter for the Port Group, VLAN ID, and I-SID information that corresponds with the VM, communicates with the ExtremeControl module for the RADIUS authentication, and sends the RADIUS response back to the switch with the VLAN:ISID binding information. Based on the binding, the switch then automatically creates a dynamic Switched UNI (S-UNI). Dynamic S-UNIs are not saved into the configuration file.

Typical Endpoint Tracking Implementation Example

The following example shows a typical implementation of Endpoint Tracking and the dynamic I-SID assignment process, as provisioned in Extreme Management Center or ExtremeCloud IQ - Site Engine.

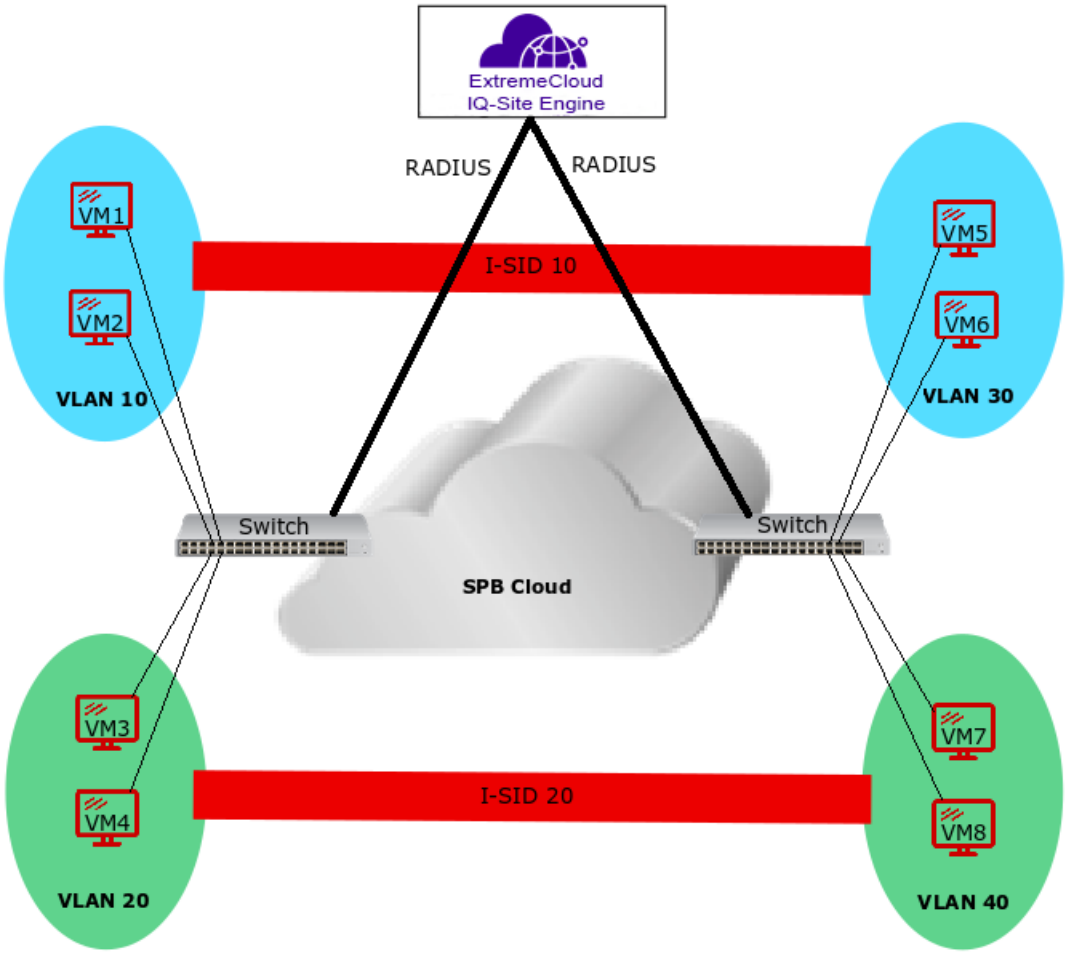

Figure 74: Endpoint Tracking Example

The sequence within and among the four example VLANs in this configuration is as follows:

1. The RADIUS server authenticates VM1, and the switch automatically creates a Switched UNI with VLAN 10 and I-SID 10 binding, (using the outbound attributes received from the RADIUS server). Subsequently, the server authenticates VM2, which uses the same Switched UNI.
2. Similarly, on the other side of the SPB cloud, the RADIUS server authenticates VM5 and the switch automatically creates a Switched UNI with VLAN 30 and I-SID 10 binding, (using the outbound attributes received from the RADIUS server). Subsequently, the server authenticates VM6, which uses the same Switched UNI.
3. The same sequence occurs for VMs 3 and 4, and PCs 7 and 8, with the first authentication in each VLAN providing the outbound RADIUS attributes needed for the creation of a Switched UNI for that VLAN.
4. The final result is that VMs 1, 2, 5, and 6 can access each other on I-SID 10, and VMs 3, 4, 7, and 8 can access each other on I-SID 20.

Static S-UNIs and Visibility Mode

Endpoint Tracking can also be used in cases where static S-UNIs are configured on Endpoint Tracking-enabled ports. In this case, the MACs are allowed by default on the static S-UNI. However, by default, the

MACs learned on a static S-UNI are not learned at the Endpoint Tracking level. Endpoint Tracking Visibility Mode allows tracking of MACs that are learned on static S-UNIs. This implies that a binding is created for these MACs, but these bindings do not create dynamic S-UNIs, they are used for tracking purposes only.

Interface Support

Endpoint Tracking is supported on Ethernet ports, MLTs, and SMLTs.

If the switch is a Virtual IST (vIST) peer, the dynamic Switched UNI is synchronized to its vIST peer as follows:

- If the MAC is learned on an SMLT UNI interface, all Switched UNI information is synchronized to the vIST peer.
- If the MAC is learned on a non-SMLT UNI interface, only the I-SID is synchronized to the vIST peer.

VM Moves and VLAN:ISID Bindings

When a VM moves to a new switch within a network (with no change to the VLAN segment), the new switch triggers a new RADIUS authentication, which points that VM MAC to the new switch, and new bindings are applied on the new switch. The old switch detects that the VM MAC is moved and automatically deletes the old binding, if the old binding has not already aged out.

However, if a VM remains attached to the same (previously authenticated) switch, but the VLAN segment is changed, you must push a reauthentication request from Extreme Management Center or ExtremeCloud IQ - Site Engine to force the required binding updates. For more information about managing binding updates using RADIUS Change-of-Authorization (CoA) functionality, see Extreme Management Center or ExtremeCloud IQ - Site Engine Integration on page 899.

Operational Considerations

Consider the following when implementing Endpoint Tracking:

- A RADIUS server used for Endpoint Tracking provides authorization only; no accounting processes are supported. Although accounting is enabled by default for all RADIUS servers, it is not currently supported for use with Endpoint Tracking, even if left enabled.
- Fabric Attach is not supported on ports or MLT/SMLTs that have Endpoint Tracking enabled.

Extreme Management Center or ExtremeCloud IQ - Site Engine Integration

Endpoint Tracking integrates with Extreme Management Center or ExtremeCloud IQ - Site Engine ExtremeConnect and ExtremeControl modules. The ExtremeConnect module offers API integration with third party products, such as VMware or Mircrosoft HyperV, from which VM endpoint information is extracted and automatically converted into usable policies for use in the ExtremeControl module, which acts as a RADIUS server for authorizing Endpoint Tracking MACs.

The following diagram illustrates an example of Extreme Management Center or ExtremeCloud IQ - Site Engine interaction with a switch for Endpoint Tracking:

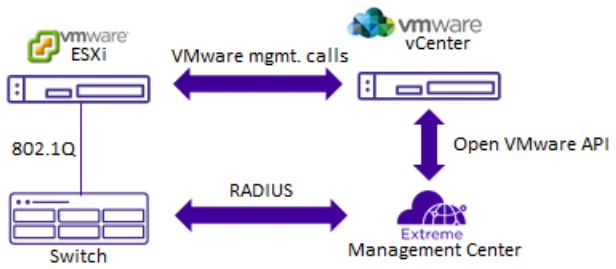

Figure 75: Extreme Management Center or ExtremeCloud IQ - Site Engine Endpoint Tracking Interaction Example

RADIUS Server Attributes

The RADIUS attributes to configure in either standard or custom Extreme Management Center or ExtremeCloud IQ - Site Engine RADIUS profiles for Endpoint Tracking depend on your deployment and traffic type:

- For tagged traffic, if the RADIUS server provides both the VLAN ID and I-SID value, use only the **FA-VLAN-ISID** attribute.
- For tagged traffic, if the RADIUS server provides only the VLAN ID (and you are therefore using an I-SID offset value), use only the **Tunnel-Private-Group-ID** attribute.
- For untagged traffic, if the RADIUS server provides both the VLAN ID and I-SID value, use the **FA-VLAN-ISID** and **Egress-VLANID** or **Egress-VLAN-name** attributes.
- For untagged traffic, if the RADIUS server provides only the VLAN ID (and you are therefore using an I-SID offset value), use the **Tunnel-Private-Group-ID** and **Egress-VLANID** or **Egress-VLAN-name** attributes.
- Use the **Session-Timeout** attribute to override the default timeout period of 24 hours, which is amount of time, in seconds, between a MAC address authentication and the deletion of that MAC address from the Endpoint Tracking binding table.

All other RADIUS attributes are ignored.

Managing Binding Updates using RADIUS Change-of-Authorization

Endpoint Tracking uses RADIUS RFC 5176 Change-of-Authorization (CoA) functionality to enable forced VLAN:ISID binding updates.

For example, when a VLAN segment is changed on a VM that resides on a previously authenticated switch, that VM requires a new VLAN:ISID binding to reflect the new VLAN segment. Because the switch has previously been authenticated, you must force a new authentication request to update the binding information.

Using ExtremeControl, you can manually push a reauthentication request for the VM MAC. This action sends a disconnect-request from the RADIUS server to the switch, which deletes the old binding. When the switch detects the VM again, a new RADIUS authentication request is sent from the switch to the RADIUS server, resulting in updated binding information upon sucessful authentication.

For more information about RADIUS Dynamic Session Change Support (RFC 5176), see RFC 5176 — Dynamic Session Change on page 2433.

Deployment Examples

Endpoint Tracking deployment scenarios include Distributed Virtual Routing (DvR) deployments, or regular SPBM deployments.

The following example illustrates a DvR depoyment:

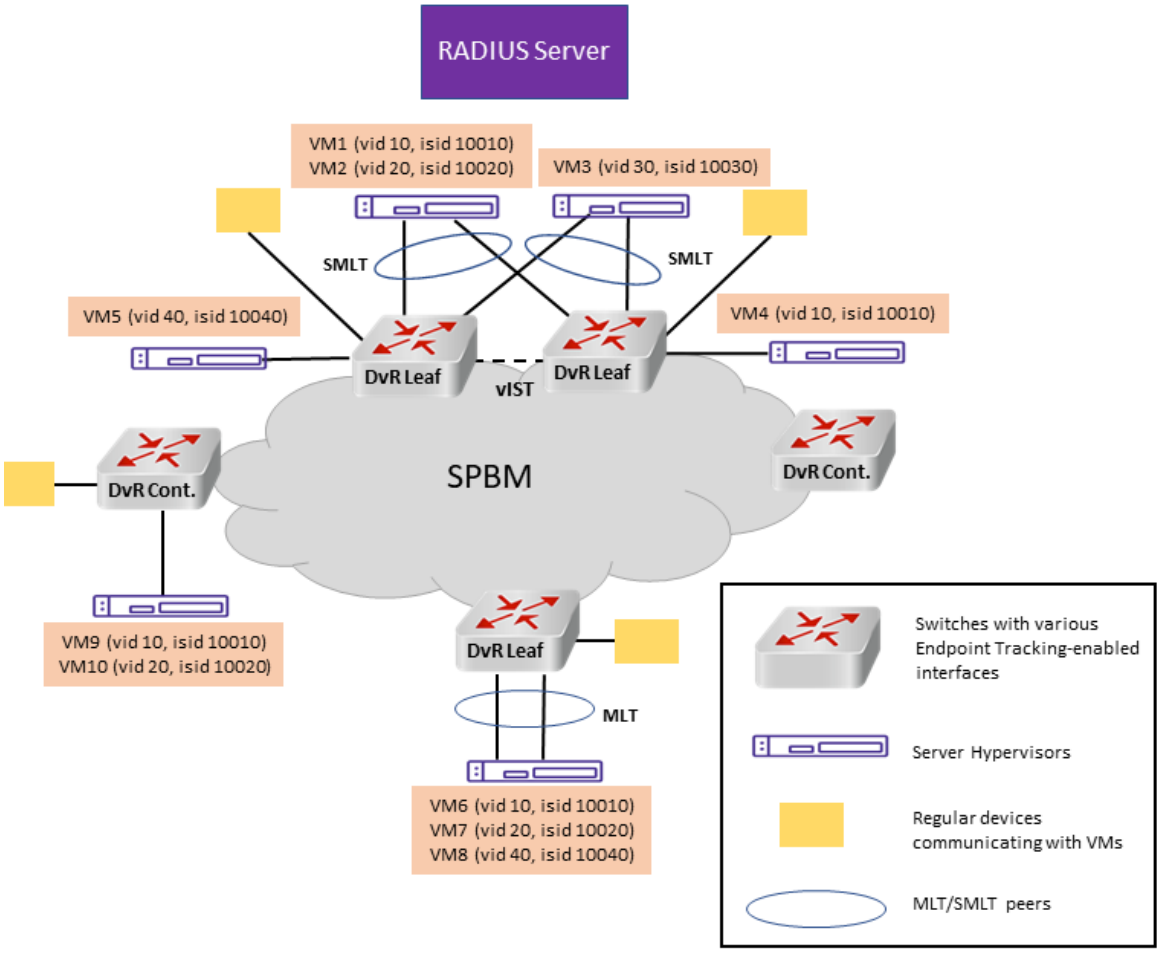

Figure 76: DvR Topology Example

The following example illustrates a regular SPBM depoyment:

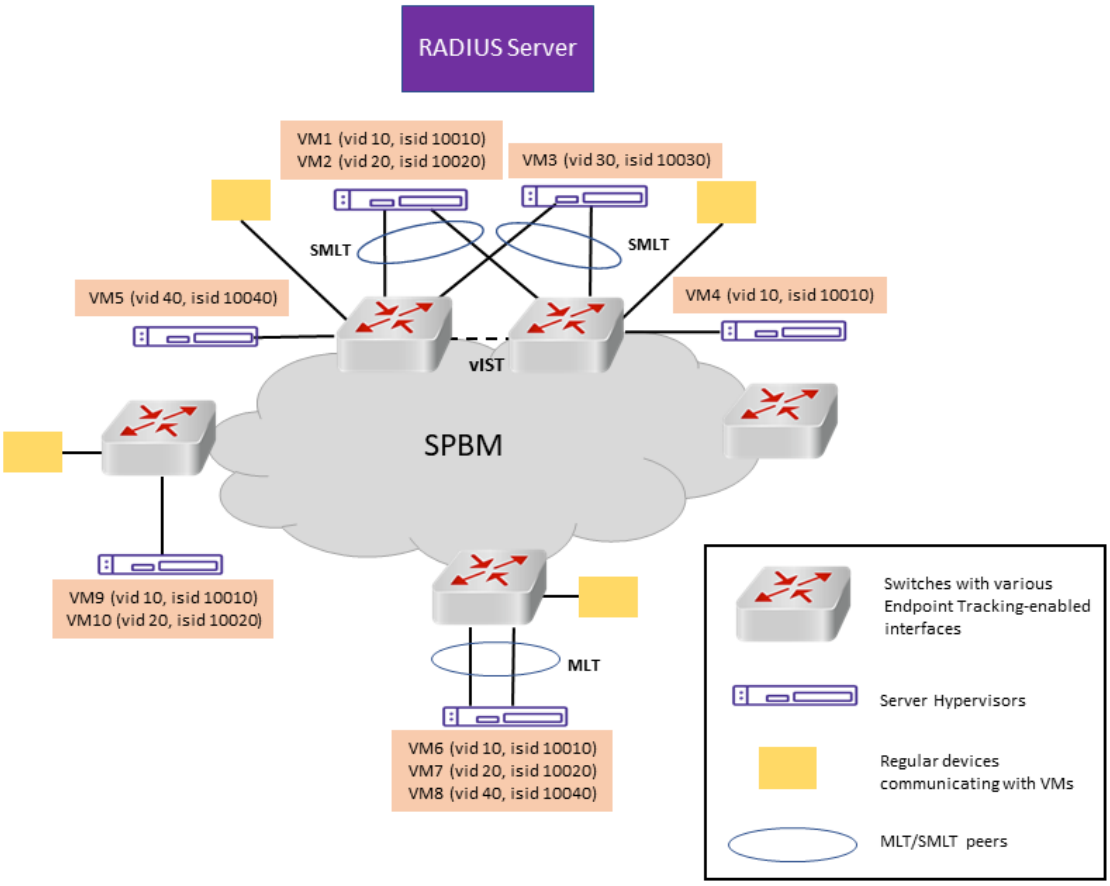

Figure 77: SPBM Cloud Example

Configuration Fundamentals

Extreme Management Center or ExtremeCloud IQ - Site Engine Configuration

To configure Endpoint Tracking, you must perform the following:

- Using the ExtremeConnect component, configure and manage your third-party virtualization platform.
- Using the ExtremeControl component, configure and manage the RADIUS server used for Endpoint Tracking authentication.

For information about configuring Extreme Management Center or ExtremeCloud IQ - Site Engine, see the Extreme Management Center or ExtremeCloud IQ - Site Engine documentation at https://www.extremenetworks.com/support/documentation/.

Switch Configuration

To configure Endpoint Tracking, you must perform the following:

- Add, configure, and enable the RADIUS server host as configured in the Extreme Management Center or ExtremeCloud IQ - Site Engine to function as the switch authentication server for Endpoint Tracking. Ensure that you select **`endpoint-tracking`** for the **`used-by`** variable. Add, configure

and enable the RADIUS dynamic-server client. For information about adding a RADIUS server host and a RADIUS dynamic-server client to the switch, see RADIUS on page 2426.

- Optionally configure a global I-SID offset value.

  When you provision the Endpoint Tracking RADIUS server in Extreme Management Center or ExtremeCloud IQ - Site Engine, you choose which outbound attributes the RADIUS server includes in each authentication response. If you always include an I-SID value in those outbound attributes, you do not need to configure an I-SID offset value on the switch.

  For MACs that do not receive an I-SID attribute from the RADIUS server, use Auto-ISID-Offset functionality. The configured I-SID offset value is used to calculate an I-SID value for a switched UNI when no I-SID value is provided by the RADIUS server in the outbound attributes. In that case, the I-SID value is calculated as follows:

  I-SID = VLAN ID + configured I-SID offset value.
- After optionally configuring a global I-SID offset value, enable Endpoint Tracking globally on the switch.
- Create and enable Endpoint Tracking on each interface. Ensure that you have deleted any existing VLAN bindings on the interfaces, as the Endpoint Tracking bindings are dynamic.

  CLI commands provide the functionality to separate the creation, deletion, enabling, and disabling of Endpoint Tracking on interfaces. For example, if you want to flush all VLAN:ISID bindings on a port, you can disable (but not delete) Endpoint Tracking on that port, keeping the port distinct from other ports where Endpoint Tracking is not yet created.

SPBM and IS-IS infrastructure configuration using CLI

This section provides procedures to configure SPBM and IS-IS using Command Line Interface (CLI).

Important

The **spbm-config-mode** boot flag must be enabled (default) before you can configure SPBM or IS-IS. To verify the setting, enter **show boot config flags** in Privileged EXEC mode.

Running the SPBM script

Use the following procedure to run the SPBM script to automate the minimum required SPBM and IS-IS parameters to allow Fabric Connect to operate on the switch.

Before You Begin

- Enable SPBM before running the SPBM script.
- Delete existing IS-IS interfaces before running this script. See Removing specific IS-IS and MLT interfaces on page 907 for information on removing IS-IS interfaces.

About This Task

You can use this procedure to quickly configure the minimum SPBM and IS-IS parameters. However, a manual procedure is available instead of using this script. The default values are given in square

brackets. You may input your values at the prompt or if you wish to accept the default values, press `Enter`. This command first accepts all values and then removes existing SPBM configurations before configuring the entered values.

Note

This process causes the SPBM traffic to flap temporarily.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Run the SPBM script:

   ```
   run spbm
   ```

   Note

   If the script causes a configuration conflict or cannot execute a command, an error message displays and the script stops.

Example

Run the SPBM script:

```
Switch:1(config)# run spbm
*****************************************************************
*** This script will guide you through configuring the        ***
*** switch for optimal operation SPB.                         ***
*** ------------------------------------------------------     ***
*** The values in [] are the default values, you can          ***
*** input alternative values at any of the prompts.           ***
*** If you wish to terminate or exit this script              ***
*** enter ^C <control-C> at any prompt.                       ***
*** NOTE: THE COMMAND WILL TEMPORARILY FLAP IS-IS,SPBM        ***
*****************************************************************
SPB Ethertype <0x8100,0x88a8> [0x8100]:
SPB primary BVLAN 2-4059 [4051]:300
SPB secondary BVLAN 2-4059 [4052]:400
ISIS system id <xxxx.xxxx.xxxx> [a051.c6eb.7c65]:0200.0000.0100

Enable CFM SPBM (y/n) [n]:y
Enter CFM SPBM MEPID <1-8191> [1]:2
Enter CFM SPBM level <0-7> [4]:4

****CONFIGURATION IN PROGRESS****
*SPBM enabled globally*
```

```
*SPBM instance 1 configured*
*SPBM BVLANS configured*
*SPBM SMLT configured*
*SPBM multicast enabled globally*
*IP shortcuts configured*
*SPBM SMLT configured*
*IS-IS enabled*
*IS-IS on port 1/5 configured*
*IS-IS on port 1/6 configured*
*IS-IS on MLT 1 configured*
*CFM SPBM configured*
****SCRIPT EXECUTION COMPLETE****
```

Remove Existing SPBM Configuration

Use the following procedure to remove existing SPBM configurations, disable CFM, and return the CFM MEP-ID and level configurations to default values.

Before You Begin

- Enable SPBM before running this script.
- If the switch uses Zero Touch Fabric Configuration, you must run the following commands before you perform this procedure:
  - **no auto-sense onboarding i-sid**
  - **no vlan i-sid <1-4059>**

Procedure

1. Enter Global Configuration mode:
   ```
   enable

   configure terminal
   ```
2. Run the script:
   ```
   run spbm clean
   ```

   

   Note

   If the script causes a configuration conflict or cannot run a command, an error message displays and the script stops.

3. To ensure proper cleanup of MAC tables, save the configuration, and then reboot the switch.

Example

Run the script:

```
Switch:1(config)#no auto-sense onboarding i-sid
Switch:1(config)#no vlan i-sid
Switch:1(config)#run spbm clean
The following will delete all SPBM and interfaces and default the CFM configurations. Do
you want to continue? <y/n>[n]:y

Switch:1(config)#no router isis enable
Switch:1(config)#interface gigabitethernet 1/10
Switch:1(config-if)#no isis
Switch:1(config-if)#interface gigabitethernet 1/11
Switch:1(config-if)#no isis
Switch:1(config-if)#configure terminal
```

```
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#no vlan 4051
Switch:1(config)#no vlan 4052
Switch:1(config)#router isis
Switch:1(config-isis)#no spbm 1
Switch:1(config-isis)#router isis

Configuring the IS-IS port interfaces using SPBM script

Use the following procedure to run the SPBM script to configure the IS-IS port interfaces. As this command does not flap IS-IS or SPBM, it is particularly effective to use this command when SPBM is already configured and you require to configure additional ports or MLTs. Running the run spbm interface command does not alter existing IS-IS or SPBM configurations.

About This Task

You can use this procedure to quickly configure the minimum SPBM and IS-IS parameters. However, a manual procedure is available instead of using this script.

Note

You must enable SPBM before running the SPBM script.

Procedure

1. Enter Global Configuration mode:
   ```
   enable

   configure terminal
   ```
2. Run the SPBM script:
   ```
   run spbm interface
   ```

   Note

   If the script causes a configuration conflict or cannot execute a command, an error message displays and the script stops.

Example

Run the SPBM script:

```
Switch:1(config)# run spbm interface
```

```
*************************************************************
*** This script will guide you through configuring the        ***
*** switch for optimal operation SPB.                         ***
*** ---------------------------------------------------       ***
```

```
*** The values in [] are the default values, you can          ***
*** input alternative values at any of the prompts.           ***
*** If you wish to terminate or exit this script              ***
*** enter ^C <control-C> at any prompt.                       ***
*****************************************************************
ISIS port interfaces <a/b,c/d> []:1/2,1/4,1/8
ISIS MLT interface <MLT ID LIST> []:1
*IS-IS on port 1/2 configured*
*IS-IS on port 1/4 configured*
*IS-IS on port 1/8 configured*
*IS-IS on MLT-1 configured*
```

Removing specific IS-IS and MLT interfaces

Use the following procedure to remove specific IS-IS ports and MLT interfaces when you get the error `IS-IS SPBM interfaces have been configured. Please delete these interfaces`.

About This Task

This procedure removes existing IS-IS ports and MLT interfaces. You can choose which port and MLT interfaces need to be removed. This command does not alter the other SPBM or IS-IS configurations.

Note

You must enable SPBM before running the SPBM script.

Procedure

1. Enter Global Configuration mode:
   ```
   enable

   configure terminal
   ```
2. Run the script:
   ```
   run spbm interface clean
   ```

Note

If the script causes a configuration conflict or cannot execute a command, an error message displays and the script stops.

Example

Run the spbm interface clean script:

```
Switch:1(config)# run spbm interface clean
*****************************************************************
*** This script will guide you through deleting the           ***
*** IS-IS SPBM interfaces.                                        ***
*** ---------------------------------------------------       ***
*** The values in [] are the default values.                  ***
*** If you wish to terminate or exit this script              ***
*** enter ^C <control-C> at any prompt.                       ***
*****************************************************************
ISIS port interfaces to be deleted <a/b,c/d>[]:1/2,1/4,1/8
ISIS MLT interface <MLT ID LIST> []:1
IS-IS port 1/2 deleted
```

```
IS-IS port 1/4 deleted
IS-IS port 1/8 deleted
** 3 IS-IS port interfaces deleted **
MLT 1 deleted
** 1 IS-IS MLTs deleted **
```

Configure Minimum SPBM and IS-IS Parameters

Use the following procedure to configure the minimum required SPBM and IS-IS parameters to enable SPBM operation on the switch.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable SPBM globally:

   ```
   spbm
   ```

3. Enter IS-IS Router Configuration mode:

   ```
   router isis
   ```

4. Create the SPBM instance (only one SPBM instance is supported):

   ```
   spbm <1–100>
   ```

5. Add the SPBM B-VLAN to the SPBM instance:

   ```
   spbm <1–100> b-vid {<vlan-id [-vlan-id][,...]} [primary <1-4059>]
   ```

6. Configure the system nickname (2.5 bytes in the format <x.xx.xx>):

   ```
   spbm <1–100> nick-name <x.xx.xx>
   ```

   Note

   Although it is not strictly required for SPBM operation, you should change the IS-IS system ID from the default B-MAC value to a recognizable address to easily identify a switch (Log on to IS-IS Router configuration mode and use the `system-id <xxxx.xxxx.xxxx>` command). This helps to recognize source and destination addresses for troubleshooting purposes.

7. Configure an IS-IS manual area (1-13 bytes in the format <xx.xxxx.xxxx...xxxx>, only one manual area is supported.):

   ```
   manual-area <xx.xxxx.xxxx...xxxx>
   ```

8. Exit IS-IS Router Configuration mode to Global Configuration mode:

   ```
   exit
   ```

9. Create the SPBM backbone VLAN (B-VLAN):

   ```
   vlan create <2-4059> type spbm-bvlan
   ```

10. Enter Interface Configuration mode, by specifying the ports or MLTs that are going to link to the SPBM network:

    ```
    interface {GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]}| mlt <1–512> }
    ```

11. Configure an IS-IS interface on the selected ports or MLTs:

    a. Create an IS-IS circuit and interface on the selected ports or MLTs:

       ```
       isis
       ```

    b. Enable the SPBM instance on the IS-IS interfaces:

       ```
       isis spbm <1–100>
       ```

    c. Enable the IS-IS circuit/interface on the selected ports or MLTs:

       ```
       isis enable
       ```

12. Enable interface.
13. Exit Interface Configuration mode:

    ```
    exit
    ```

14. Enable IS-IS globally:

    ```
    router isis enable
    ```

15. Display the SPBM configurations:

    ```
    show isis spbm
    ```

16. Display the global IS-IS configuration:

    ```
    show isis
    ```

17. Display the interface IS-IS configuration:

    ```
    show isis interface
    ```

Examples

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#spbm
Switch:1(config)#router isis
Switch:1(config-isis)#spbm 1
Switch:1(config-isis)#spbm 1 b-vid 4051,4052 primary 10
Switch:1(config-isis)#spbm 1 nick-name 1.11.16
Switch:1(config-isis)#manual-area c0.2000.000.00
Switch:1(config-isis)#exit
Switch:1(config)#interface GigabitEthernet 1/21
Switch:1(config-if)#isis
Switch:1(config-if)#isis spbm 1
Switch:1(config-if)#isis enable
Switch:1(config-if)#exit
Switch:1(config)#vlan create 4051 type spbm-vlan
Switch:1(config)#vlan create 4052 type spbm-vlan
Switch:1(config)#router isis enable
```

```
Switch:1(config)#show isis spbm

Variable definitions

The following table defines parameters for the **isis** command.

Variable	Value
enable	Enables or disables the IS-IS circuit/interface on the specified port or MLT. The default is disabled. Use the no option to disable IS-IS on the specified interface.
spbm <1–100>	Enable the SPBM instance on the IS-IS interfaces.

The following table defines parameters for the **manual-area** command.

Variable	Value
<xx.xxx.xxx...xxx>	Specifies the IS-IS manual-area (1–13 bytes in the format <xx.xxx.xxx...xxx>). Only one manual area is supported. For IS-IS to operate, you must configure at least one area. Use the no option to delete the manual area.

The following table defines parameters for the **spbm** command.

Variable	Value
<1–100>	Creates the SPBM instance. Only one SPBM instance is supported.
b-vid {<vlan-id [-vlan-id] [,...]}	Sets the IS-IS SPBM instance data VLANs. Use the no option to remove the specified B-VLAN from the SPBM instance.
nick-name <x.xx.xx>	Specifies a nickname for the SPBM instance globally. The value is 2.5 bytes in the format <x.xx.xx>. Use the no or default options to delete the configured nickname.
primary <1-4059>	Sets the IS-IS instance primary data B-VLAN.

The following table defines parameters for the **vlan create** command.

Variable	Value
<2-4059>	Specifies the VLAN ID. Creates an SPBM Backbone VLAN (B-VLAN). You can optionally specify a name for the SPBM B-VLAN.
type {port-mstprstp|protocol-mstprstp|spbm-bvlan}	Specifies the type of VLAN created. • port-mstprstp — Create a VLAN by port. • protocol-mstprstp — Create a VLAN by protocol. • spbm-bvlan — Create an SPBM B-VLAN.

Job aid

Important

After you have configured the SPBM nickname and enabled IS-IS. To maintain the same nickname with a different system ID, perform the following steps:

1. Disable IS-IS.
2. Change the system ID.
3. Change the nickname to a temporary one.
4. Enable IS-IS.
5. Wait up to 20 minutes for the LSPs with the original system ID to age out.

   Note

   To check the age out time, use the **show isis lsdb sysid <original-sys-id>** command on any of the other SPB nodes in the network. When there is no output from this command, proceed to the next step. The time left (in seconds) for the LSPs to age out is shown under the column **LIFETIME**.
6. Disable IS-IS.
7. Change the nickname to the original nickname.
8. Enable IS-IS.

Configure Minimum SPBM and IS-IS Parameters using auto-nni Command

Use the following procedure to configure the minimum required SPBM and IS-IS parameters using the **auto-nni** command to have the node create an IS-IS interface, attach the interface to an SPBM instance, and then enable IS-IS on the port interface.

This procedure is only for the port interface. The **auto-nni** command is not supported on the MLT interface and the Fabric Extend Logical Interface.

About This Task

The **auto-nni** command provides a quick and simple way to configure the IS-IS interface. You can use the **auto-nni** command instead of the following existing IS-IS commands on the physical (port) interface:

- **isis**
- **isis spbm instance**
- **isis enable**

The existing commands are still available and you have the option to use the new command or the three existing commands. If you need to modify any of the default parameters under **isis** or **isis spbm instance** , use **isis** and **isis spbm instance** constructs even if you created the interface with the **auto-nni** command.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable SPBM globally:

   ```
   spbm
   ```

3. Enter IS-IS Router Configuration mode:

   ```
   router isis
   ```

4. Create the SPBM instance (only one SPBM instance is supported):

   ```
   spbm <1–100>
   ```

5. Add the SPBM B-VLAN to the SPBM instance:

   ```
   spbm <1–100> b-vid {<vlan-id [-vlan-id][,...]} [primary <1–4059>]
   ```

6. Configure the system nickname (2.5 bytes in the format <x.xx.xx>):

   ```
   spbm <1–100> nick-name <x.xx.xx>
   ```

   Note

   Although it is not strictly required for SPBM operation, you should change the IS-IS system ID from the default B-MAC value to a recognizable address to easily identify a switch (Log on to IS-IS Router configuration mode and use the `system-id <xxxx.xxxx.xxxx>` command). This helps to recognize source and destination addresses for troubleshooting purposes.

7. Configure an IS-IS manual area (1-13 bytes in the format <xx.xxxx.xxxx...xxxx>. Only one manual area is supported.):

   ```
   manual-area <xx.xxxx.xxxx...xxxx>
   ```

8. Exit IS-IS Router Configuration mode to Global Configuration mode:

   ```
   exit
   ```

9. Create the SPBM backbone VLAN (B-VLAN):

   ```
   vlan create <2–4059> type spbm-bvlan
   ```

10. Enter Interface Configuration mode, by specifying the ports or MLTs that are going to link to the SPBM network:

    ```
    interface {GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]}| mlt <1–512> }
    ```

11. Configure an IS-IS interface on the selected ports.

    ```
    auto-nni
    ```

12. Enable interface.
13. Exit Interface Configuration mode:

    ```
    exit
    ```

14. Enable IS-IS globally:

    ```
    router isis enable
    ```

15. Display the SPBM configurations:

    ```
    show isis spbm
    ```

16. Display the global IS-IS configuration:
    ```
    show isis
    ```
17. Display the interface IS-IS configuration:
    ```
    show isis interface
    ```

```

Configure I-SIDs for Private VLANs

Before You Begin

- A private VLAN must be created. For more information about creating private VLANs, see Create a Private VLAN on page 3425.

About This Task

Assign one I-SID for each private VLAN.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Assign the I-SID to the primary and secondary VLAN.

   ```
   vlan i—sid <1-4059> <0-16777215> [force]
   ```

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#vlan i-sid 5 75
Switch:1(config)#show vlan private-vlan
================================================================================
        PRIVATE VLAN
================================================================================
Primary              Primary              Secondary            Secondary
VLAN                 ISID                 VLAN                 ISID
--------------------------------------------------------------------------------
5                    75                    6                    75
```

Variable Definitions

The following table defines parameters for the **vlan i-sid** command.

Variable	Value
<1-4059>	Specifies the VLAN ID. Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
<0-16777215>	Specifies the service instance identifier (I-SID). You cannot use I-SID 0x00ffffff. The system reserves this I-SID to advertise the virtual BMAC in an SMLT dual-homing environment. This value is the same for the primary and secondary VLANs.
force	Specifies the software must replace the existing VLAN-to-I-SID mapping, if one exists.

Displaying global SPBM parameters

Use the following procedure to verify the proper global SPBM configuration.

Procedure

1. Display the SPBM configuration:

   `show isis spbm`

2. You can also use the following command to identify SPBM VLANs. For spbm-bvlan, the attribute `TYPE` displays `spbm-bvlan` instead of `byport`. For private VLANs,. the attribute `TYPE` displays `private` instead of `byport`.

   `show vlan basic`

Example

```
Switch# show isis spbm

================================================================================================================

Display Global IS-IS Parameters

Use the following procedure to display the global IS-IS parameters.

Procedure

1. Display IS-IS configuration information:

   ```
   show isis
   ```

2. Display the IS-IS system-id:

   ```
   show isis system-id
   ```

3. Display IS-IS net info:

   ```
   show isis net
   ```

Example

```
Switch:1>show isis
================================================================================
                              ISIS General Info

--------------------------------------------------------------------------------
c0.2000.0000.00          HOME
```

Configuring SMLT parameters for SPBM

Use the following procedure to configure the required Split MultiLink Trunking (SMLT) parameters to allow SPBM to interoperate with SMLT on the switch.

Note

- The assignment of primary and secondary roles to the vIST peers is automatic. The switch with the lower system ID (between the two vIST peers) is primary, and the switch with the higher system ID is secondary when default system-id values are being used.
- SMLT peer system ID is part of the required configuration. You must configure the SMLT peer system ID as the nodal MAC of the peer device. In the IS-IS network, the nodal MAC of devices should be eight apart from each other.
- When using the default hardware assigned system-id value, the SMLT Virtual BMAC is automatically derived by comparing the system-id values of the two vIST peers. A value of 0x01 plus the lower of the two system-id values is used as the SMLT Virtual BMAC.

  When using a manually configured system-id value, the SMLT Virtual BMAC must also be manually configured.
- An I-SID must be assigned to every VLAN that is a member of a Layer 2 VSN. Also, if a Layer 2 VSN is created on one vIST Peer, it must also be created on the other vIST peer.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```
2. Disable IS-IS on the switch:

   ```
   no router isis enable
   ```
3. Enter IS-IS Router Configuration mode:

   ```
   enable

   configure terminal

   router isis
   ```
4. Specify the system ID of the vIST peer, so that if it goes down, the local peer can take over forwarding for the failed peer:

   ```
   spbm <1–100> smlt-peer–system–id <xxxx.xxxx.xxxx>
   ```
5. Configure the virtual B-MAC, which is shared and advertised by both peers:

   ```
   spbm <1–100> smlt-virtual-bmac <0x00:0x00:0x00:0x00:0x00:0x00>
   ```
6. Exit to Global Configuration mode:

   ```
   exit
   ```
7. Enable IS-IS on the switch:

   ```
   router isis enable
   ```
8. Display the SPBM SMLT configuration:

   ```
   show isis spbm
   ```

Example

```
Switch:1>enable
Switch:1#configure terminal
```

Disable IS-IS on the switch:

```
Switch:1(config)#no router isis enable
```

Enter the IS-IS Router Configuration mode:

```
Switch:1(config)#router isis
Switch:1(config-isis)#spbm 1 smlt-peer-system-id 0018.b0bb.b3df
Switch:1(config-isis)#spbm 1 smlt-virtual-bmac 00:14:c7:e1:33:e0
Switch:1(config-isis)#router isis enable
Switch:1(config-isis)#show isis spbm
================================================================================================================

Total Num of SPBM instances: 1
--------------------------------------------------------------------------------
```

Variable definitions

The following table defines parameters for the **spbm** command.

Variable	Value
smlt-peer-system-id <xxxx.xxxx.xxxx>	Specifies the IS-IS SPBM peer system ID. SMLT peer system ID is part of the required configuration. You must configure the SMLT peer system ID as the nodal MAC of the peer device. In the IS-IS network, the nodal MAC of devices should be eight apart from each other.
smlt-virtual-bmac <0x00:0x00:0x00:0x00:0x00:0x00>	Specifies a virtual MAC address that can be used by both peers. SMLT virtual B-MAC is an optional configuration. Note: • If SMLT virtual B-MAC is not configured, the system derives SMLT virtual B-MAC from the configured SMLT peer system ID and the nodal MAC of the device (IS-IS system ID). The system compares the nodal MAC of the device with the SMLT peer system ID configured and takes the small one, plus 0x01, as the SMLT virtual B-MAC. • The system also derives SMLT split BEB from the SMLT peer system ID and nodal MAC of the device. The device with the lower system ID is primary, the device with the higher system ID is secondary.

Configuring optional SPBM parameters

Use the following procedure to configure optional SPBM parameters.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the SPBM ethertype:

   ```
   spbm ethertype {0x8100 | 0x88a8}
   ```

3. Configure the optional link-state database (LSDB) trap global parameter. To configure this parameter, you must globally disable IS-IS on the switch:

   a. Disable IS-IS on the switch:

      ```
      no router isis enable
      ```

   b. Enter IS-IS Router Configuration mode:

      ```
      router isis
      ```

   c. Enable a trap when the SPBM LSDB changes:

      ```
      spbm <1-100> lsdb-trap enable
      ```

   d. Enable IS-IS on the switch:

      ```
      router isis enable
      ```

   e. Exit IS-IS Router Configuration mode:

      ```
      exit
      ```

4. Configure the optional SPBM interface parameters. To configure these parameters, you must disable IS-IS on the interface:
   a. Specify an SPBM interface to configure:
      ```
      interface {GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]} | mlt <mltid> }
      ```
   b. Disable IS-IS on the interface:
      ```
      no isis enable
      ```
   c. Configure SPBM instance interface-type on IS-IS interface. SPBM supports only pt-pt:
      ```
      isis spbm <1–100> interface-type {broadcast|pt-pt}
      ```
   d. Configure the IS-IS Interface level 1 metric:
      ```
      isis spbm <1–100> l1-metric <1–16777215>
      ```
   e. Enable IS-IS on the switch:
      ```
      isis enable
      ```

Example

```
Switch> enable

Switch# configure terminal

Switch(config)# spbm ethertype 0x8100

Switch(config-isis)# no router isis enable

Switch(config)# router isis

Switch(config-isis)# spbm 1 lsdb-trap enable

Switch(config-isis)# router isis enable

Switch(config-isis)# exit

Switch(config)# interface gigabitethernet 1/7

Switch(config-if)# no isis enable

Switch(config-if)# isis spbm 1 interface-type pt-pt

Switch(config-if)# isis spbm 1 l1–metric 500

Switch(config-if)# isis enable
```

Variable definitions

The following table defines parameters for the **spbm** command.

Variable	Value
ethertype {0x8100 | 0x88a8}	Configures the SPBM ethertype. The default value is 0x8100.
<1–100> lsdb-trap enable	Configures whether to enable or disable a trap when the SPBM LSDB changes. The default is disabled. Use the **no** or **default** options to disable LSDB traps.

The following table defines parameters for the **isis spbm** command.

Variable	Value
<1–100> interface-type {broadcast|pt-pt}	Configures the SPBM instance interface-type on the IS-IS interface located on the specified port or MLT. SPBM only supports the point-to-point (pt-pt) interface type. The default is pt-pt. Use the **no** or **default** options to set this parameter to the default value of pt-pt.
<1–100> l1-metric <1–16777215>	Configures the IS-IS interface level 1 metric on the specified port or MLT. The default value is 10. Use the **no** or **default** options to set this parameter to the default.

Configuring optional IS-IS global parameters

Use the following procedure to configure optional IS-IS global parameters.

Procedure

1. Enter IS-IS Router Configuration mode:

   ```
   enable

   configure terminal

   router isis
   ```

2. Configure optional IS-IS global parameters:
   a. Specify the Complete Sequence Number Packet (CSNP) interval in seconds:

      ```
      csnp-interval <1–600>
      ```

   b. Configure the router type globally:

      ```
      is-type {l1|l12}
      ```

   c. Configure the maximum level, in seconds, between generated LSPs by this Intermediate System:

      ```
      max-lsp-gen-interval <30–900>
      ```

   d. Configure the IS-IS metric type:

      ```
      metric {narrow|wide}
      ```

   e. Set or clear the overload condition:

      ```
      overload
      ```

   f. Configure the overload-on-startup value in seconds:

      ```
      overload-on-startup <15–3600>
      ```

g. Configure the Partial Sequence Number Packet (PSNP) in seconds:
   `psnp-interval <1–120>`
h. Configure the minimum time between retransmission of an LSP:
   `retransmit-lsp-interval <1–300>`
i. Configure the SPF delay in milliseconds:
   `spf-delay <0–5000>`
j. Configure the name for the system:
   `sys-name WORD<0–255>`
k. Configure the IS-IS system ID for the switch:
   `system-id <xxxx.xxxx.xxxx>`

Example

```
Switch> enable

Switch# configure terminal

Switch(config)# router isis

Switch(config-isis)# csnp-interval 10

Switch(config-isis)# is-type l1

Switch(config-isis)# max-lsp-gen-interval 800

Switch(config-isis)# metric wide

Switch(config-isis)# overload

Switch(config-isis)# overload-on-startup 30

Switch(config-isis)# psnp-interval 10

Switch(config-isis)# retransmit-lsp-interval 10

Switch(config-isis)# default sys-name

Switch(config-isis)# spf-delay 200

Switch(config-isis)# default system-id
```

Variable definitions

The following table defines parameters for the **csnp-interval** command.

Variable	Value
<1–600>	Specifies the CSNP interval in seconds. This is a system level parameter that applies for level 1 CSNP generation on all interfaces. A longer interval reduces overhead, while a shorter interval speeds up convergence. The default value is 10. Use the **no** or **default** options to set this parameter to the default value of 10.

The following table defines parameters for the **is-type** command.

Variable	Value
{l1|l12}	Sets the router type globally: • l1: Level-1 router type • l12: Not valid. The default value is l1. Use the **no** or **default** options to set this parameter to the default value of l1.

The following table defines parameters for the **max-lsp-gen-interval** command.

Variable	Value
<30–900>	Specifies the maximum interval, in seconds, between generated LSPs by this Intermediate System. The default value is 900 seconds. Use the **no** or **default** options to set this parameter to the default value of 900.

The following table defines parameters for the **metric** command.

Variable	Value
{narrow|wide}	Specifies the IS-IS metric type. Only wide is supported. The default value is wide. Use the **no** or **default** options to set this parameter to the default value of wide.

The following table defines parameters for the **overload** command.

Variable	Value
overload	Sets or clears the overload condition. The default value is disabled. Use the **no** or **default** options to set this parameter to the default value of disabled.

The following table defines parameters for the **overload-on-startup** command.

Variable	Value
<15–3600>	Specifies the IS-IS overload-on-startup value in seconds. The overload-on-startup value is used as a timer to control when to send out LSPs with the overload bit cleared after IS-IS startup. The default value is 20. Use the **no** or **default** options to set this parameter to the default value of 20.

The following table defines parameters for the **psnp-interval** command.

Variable	Value
<1–120>	Specifies the PSNP interval in seconds. This is a system level parameter that applies for level 1 PSNP generation on all interfaces. A longer interval reduces overhead, while a shorter interval speeds up convergence. The default value is 2. Use the **no** or **default** options to set this parameter to the default value of 2.

The following table defines parameters for the **retransmit-lsp-interval** command.

Variable	Value
<1–300>	Specifies the minimum time between retransmission of an LSP. This defines how fast the switch resends the same LSP. This is a system level parameter that applies for Level1 retransmission of LSPs. The default value is 5 seconds. Use the **no** or **default** options to set this parameter to the default value of 5.

The following table defines parameters for the **spf-delay** command.

Variable	Value
<0–5000>	Configures the delay, in milliseconds, to pace successive Shortest Path First (SPF) runs. The timer prevents more than two SPF runs from being scheduled back-to-back. The mechanism for pacing SPF allows two back-to-back SPF runs. The default value is 100 milliseconds. Use the **no** or **default** options to set this parameter to the default value of 100 milliseconds.

The following table defines parameters for the **sys-name** command.

Variable	Value
WORD<0–255>	Specifies a name for the system. This may be used as the host name for dynamic host name exchange in accordance with RFC 2763. By default, the system name comes from the host name configured at the system level. Use the **no** or **default** options to set this parameter to the default value (host name). Note: The system does not display any consistency checks when you edit sys-name.

The following table defines parameters for the **system-id** command.

Variable	Value
<xxxx.xxxx.xxxx>	Specifies the IS-IS system ID for the switch. Use the **no** or **default** options to set this parameter to the default value (node BMAC).

Job aid

Important

After you have configured the SPBM nickname and enabled IS-IS. To maintain the same nickname with a different system ID, perform the following steps:

1. Disable IS-IS.
2. Change the system ID.
3. Change the nickname to a temporary one.
4. Enable IS-IS.
5. Wait up to 20 minutes for the LSPs with the original system ID to age out.

Note

To check the age out time, use the **show isis lsdb sysid <original-sys-id>** command on any of the other SPB nodes in the network. When there is no output from this command, proceed to the next step. The time left (in seconds) for the LSPs to age out is shown under the column **LIFETIME**.

6. Disable IS-IS.
7. Change the nickname to the original nickname.
8. Enable IS-IS.

Configuring Optional IS-IS Interface Level 1 Parameters

Use the following procedure to configure optional IS-IS interface level 1 parameters.

Important

Save your configuration using **save config** for the updates to be available after reboot. Saving the configuration also ensures that any authentication keys (passwords) specified during the configuration are properly encrypted.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]} or interface mlt <1-512>
   ```

   Note
   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure optional IS-IS interface level 1 parameters:
   a. Specify the authentication type used for IS-IS hello packets on the interface:

      ```
      isis hello-auth type {none|simple|hmac-md5|hmac-sha-256}
      ```

   b. If you select `simple` as the `hello-auth type`, you must also specify a key value but the key-id is optional:

      ```
      isis hello-auth type simple key WORD<1-16> [key-id <1-255>]
      ```

   c. If you select `hmac-md5` or `hmac-sha-256`, you must also specify a key value. The key-id is optional:

      ```
      isis hello-auth type hmac-md5 key WORD<1-16> [key-id <1-255>]]

      isis hello-auth type hmac-sha-256 key WORD<1-16> [key-id <1-255>]]
      ```

   d. Configure the IS-IS Interface level 1 designated router priority:

      ```
      isis [l1-dr-priority <0-127>]
      ```

      Note
      This parameter is not used for SPBM because SPBM only runs on point-to-point interfaces. This parameter is for designated router election on a broadcast LAN segment, which is not supported.

   e. Configure the IS-IS Interface level 1 hello interval:

      ```
      isis [l1-hello-interval <1-600>]
      ```

   f. Configure the IS-IS Interface level 1 hello multiplier:

      ```
      isis [l1-hello-multiplier <1-600>]
      ```

Example

```
Switch:1> enable

Switch:1# configure terminal

Switch(config):1# interface gigabitethernet 1/1

Switch(config-if):1# isis

Switch(config-if):1# isis hello-auth type hmac-md5 key test
```

```
Switch(config-if):1# isis l1-dr-priority 100

Switch(config-if):1# isis l1-hello-interval 20

Switch(config-if):1# isis l1-hello-multiplier 10

Switch(config):1# save config
```

Variable Definitions

The following table defines parameters for the **isis** command.

Variable	Value
hello-auth type {none| simple|hmac-md5|hmac-sha-256}][key [key WORD<1-16>] [key-id <1-255>]	Specifies the authentication type used for IS-IS hello packets on the interface. **type** can be one of the following: • none • simple: If selected, you must also specify a key value but the key id is optional. Simple password authentication uses a text password in the transmitted packet. The receiving router uses an authentication key (password) to verify the packet. • hmac-md5: If selected, you must also specify a key value but the key-id is optional. MD5 authentication creates an encoded checksum in the transmitted packet. The receiving router uses an authentication key (password) to verify the MD5 checksum of the packet. There is an optional key ID. • hmac-sha–256: If selected, you must also specify a key value but the key-id is optional. With SHA-256 authentication, the switch adds an hmac-sha–256 digest to each Hello packet. The switch that receives the Hello packet computes the digest of the packet and compares it with the received digest. If the digests match, the packet is accepted. If the digests do not match, the receiving switch discards the packet. There is an optional key ID. Note: Secure Hashing Algorithm 256 bits (SHA-256) is a cipher and a cryptographic hash function of SHA2 authentication. You can use SHA-256 to authenticate IS-IS Hello messages. This authentication method uses the SHA-256 hash function and a secret key to establish a secure connection between switches that share the same key. This feature is in full compliance with RFC 5310. The default is none. Use the **no** or **default** options to set the hello-auth type to none.
l1-dr-priority <0-127>	Configures the IS-IS Interface level 1 designated router priority to the specified value. The default value is 64. Use the **no** or **default** options to set this parameter to the default value of 64. Note: This parameter is not used for SPBM because SPBM only runs on point-to-point interfaces. This parameter is for designated router election on a broadcast LAN segment, which is not supported.

Variable	Value
l1-hello-interval <1-600>	Configures the IS-IS interface level 1 hello interval. The default value is 9 seconds. Use the **no** or **default** options to set this parameter to the default value of 9 seconds.
l1-hello-multiplier <1-600>	Configures the IS-IS interface level 1 hello multiplier. The default value is 3 seconds. Use the **no** or **default** options to set this parameter to the default value of 3 seconds.

Display IS-IS Interface Parameters

Use the following procedure to display the IS-IS interface parameters.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Display IS-IS interface configuration and status parameters (including adjacencies):

   ```
   show isis interface [l1|l2|l12] [home|remote]
   ```

3. Display IS-IS interface authentication configuration:

   ```
   show isis int-auth [home|remote]
   ```

4. Display IS-IS interface timers:

   ```
   show isis int-timers [home|remote]
   ```

5. Display IS-IS circuit level parameters:

   ```
   show isis int-ckt-level [home|remote]
   ```

Example

```
Switch:1# show isis interface

Variable Definitions

The following table defines parameters for the **show isis interface** command.

Variable	Value
home	Displays the IS-IS interface information that the system configures in the home area.
l1	Displays the interface information for Level 1.
l2	Displays the interface information for Level 2.
l12	Displays the interface information for Level 1 and Level 2.
remote	Displays the IS-IS interface information that the system configures in the remote area.

The following table defines parameters for the **show isis ini-auth** command.

Variable	Value
home	Displays the IS-IS interface authentication information that the system configures in the home area.
remote	Displays the IS-IS interface authentication information that the system configures in the remote area.

The following table defines parameters for the **show isis ini-timer** command.

Variable	Value
home	Displays the IS-IS interface timer information that the system configures in the home area.
remote	Displays the IS-IS interface timer information that the system configures in the remote area.

The following table defines parameters for the **show isis ini-ckt-level** command.

Variable	Value
home	Displays the IS-IS interface circuit level parameters that the system configures in the home area.
remote	Displays the IS-IS interface circuit level parameters that the system configures in the remote area.

Display the IP Unicast FIB, Unicast FIB, and Unicast Tree

About This Task

In SPBM, Backbone MAC (B-MAC) addresses are carried within the IS-IS link-state database. To do this, SPBM supports an IS-IS Type-Length-Value (TLV) that advertises the Service Instance Identifier (I-SID) and B-MAC information across the network. Each node has a System ID, which also serves as B-MAC of the switch. These B-MAC addresses are populated into the SPBM Forwarding Information Base (FIB).

When the network topology is discovered and stored in the IS-IS link-state database, each node calculates shortest path trees for each source node, so that a unicast path now exists from every node to every other node. With this information, each node populates unicast information received from SPBM into the FIB for forwarding purposes.

I-SIDs are only used for virtual services (Layer 2 VSNs and Layer 3 VSNs). If you only enable IP Shortcuts on the Backbone Edge Bridges, I-SIDs are never exchanged in the network as IP Shortcuts allow Global Routing Table (GRT) IP networks to be transported across IS-IS.

The **show isis spbm ip-unicast-fib** or **show isis spbm ipv6-unicast-fib** command displays all of the IS-IS routes in the IS-IS LSDB. The IP ROUTE PREFERENCE column in the show output displays the IP route preference.

Routes within the same VSN are added to the LSDB with a default preference of 7. Inter-VSN routes are added to the LSDB with a route preference of 200. IS-IS accept policies enable you to change the route preference for incoming routes. If the same route is learned from multiple sources with different route preferences, then the routes are not considered equal cost multipath (ECMP) routes. The route with the lowest route preference is the preferred route. In Layer 2, in the event of a tie-break between routes from multiple sources, the tie-breaking is based on cost and hop count.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Display the SPBM IP unicast FIB:

   - For IPv4:

     ```
     show isis spbm ip-unicast-fib [all] [id <1-16777215] [spbm-nh-as-
     mac] [home|remote]
     ```

   - For IPv6:

     ```
     show isis spbm ipv6-unicast-fib [all] [id <1-16777215] [spbm-nh-as-
     mac] [home|remote]
     ```

3. Display the SPBM unicast FIB:

   ```
   show isis spbm unicast-fib [b-mac <0x00:0x00:0x00:0x00:0x00:0x00>]
   [vlan <1-4059>] [summary] [home|remote]
   ```

4. Display the SPBM unicast tree:

   ```
   show isis spbm unicast-tree <1-4059> [destination <xxxx.xxxx.xxxx>]
   ```

Examples

```
Switch# show isis spbm ip-unicast-fib

Variable Definitions

The following table defines parameters for the **show isis spbm ip-unicast-fib** command.

Variable	Value
all	Displays entries for the Global Routing Table (GRT) and all Virtual Routing and Forwarding (VRF) instances. Note: If you use the command **show isis spbm ip-unicast-fib** the device displays only GRT entries. The command shows IP routes from remote Backbone Edge Bridges (BEBs).
home	Displays the IS-IS SPBM IP unicast Forwarding Information Base (FIB) information that the system configures in the home area.
id <1-16777215>	Displays IS-IS SPBM IP unicast FIB information by Service Instance Identifier (I-SID) ID.

Variable	Value
remote	Displays the IS-IS SPBM IP unicast FIB information that the system configures in the remote area.
spbm-nh-as-mac	Displays the next hop B-MAC of the IP unicast FIB entry.

The following table defines parameters for the **show isis spbm ipv6-unicast-fib** command.

Variable	Value
all	Displays entries for the Global Routing Table (GRT) and all Virtual Routing and Forwarding (VRF) instances. Note: If you use the command **show isis spbm ipv6-unicast-fib** the device displays only GRT entries. The command shows IPv6 routes from remote Backbone Edge Bridges (BEBs).
home	Displays the IS-IS SPBM IPv6 unicast Forwarding Information Base (FIB) information that the system configures in the home area.
id <1-16777215>	Displays IS-IS SPBM IPv6 unicast FIB information by Service Instance Identifier (I-SID) ID.
remote	Displays the IS-IS SPBM IPv6 unicast FIB information that the system configures in the remote area.
spbm-nh-as-mac	Displays the next hop as MAC of the IPv6 unicast FIB entry.

The following table defines parameters for the **show isis spbm unicast-fib** command.

Variable	Value
b-mac <0x00:0x00:0x00:0x00:0x00:0x00>	Displays the FIB for the specified BMAC.
home	Displays the IS-IS SPBM unicast Forwarding Information Base (FIB) information that the system configures in the home area.
remote	Displays the IS-IS SPBM unicast FIB information that the system configures in the remote area.
vlan <1-4059>	Displays the FIB for the specified SPBM VLAN.
summary	Displays a summary of the FIB.

The following table defines parameters for the **show isis spbm unicast-tree** command.

Variable	Value
<1-4059>	Specifies the SPBM B-VLAN ID.
destination <xxxx.xxxx.xxxx>	Displays the unicast tree for the specified destination.

Display IS-IS LSDB and Adjacencies

Use the following procedure to display the IS-IS LSDB and adjacencies.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the IS-IS LSDB:
   `show isis lsdb [level {l1|l2|l12}] [sysid <xxxx.xxxx.xxxx>] [lspid <xxxx.xxxx.xxxx.xx-xx>] [tlv <1-236>] [detail] [home|remote]`
3. Display IS-IS adjacencies:
   `show isis adjacencies [home|remote]`
4. Clear IS-IS LSDB:
   `clear isis lsdb`

Example

```
Switch:1# show isis lsdb
================================================================================
                                  ISIS LSDB

Variable Definitions

The following table defines parameters for the **show isis lsdb** command.

Variable	Value
detail	Displays detailed information.
home	Displays the IS-IS LSDB information that the system configures in the home area.
level {l1|l2|l12}]	Displays the LSDB for the specified level: l1, l2, or l12.
local	Displays IS-IS local LSDB information.
remote	Displays the IS-IS LSDB information that the system configures in the remote area.
sysid <xxxx.xxxx.xxxx>	Displays the LSDB for the specified system ID.
lspid <xxxx.xxxx.xxxx.xx-xx>	Displays the LSDB for the specified LSP ID.
tlv <1-236>	Displays the LSDB by TLV type.

The following table defines parameters for the **show isis adjacencies** command.

Variable	Value
home	Displays the IS-IS adjacencies that the system configures in the home area.
remote	Displays the IS-IS adjacencies that the system configures in the remote area.

The following table defines parameters for the **clear isis** command.

Variable	Value
lsdb	Clears the IS-IS Link State Database (LSDB). The command clears learned LSPs only. The command does not clear local generated LSPs. As soon as the platform clears the LSDB the LSP synchronization process starts immediately and the LSDB synchronizes with its neighbors.

Display IS-IS Statistics and Counters

Use the following procedure to display the IS-IS statistics and counters.

Procedure

1. Display IS-IS system statistics:
   ```
   show isis statistics
   ```
2. Display IS-IS interface counters:
   ```
   show isis int-counters [home|remote]
   ```
3. Display IS-IS level 1 control packet counters:
   ```
   show isis int-l1-cntl-pkts [home|remote]
   ```

   Note
   The switch uses level 1 IS-IS. The switch does not support level 2 IS-IS. The command **show isis int-l2-contl-pkts** is not supported because the IEEE 802.1aq standard currently only defines the use of one hierarchy, Level 1.

4. Clear IS-IS statistics:
   ```
   clear isis stats [error-counters] [packet-counters]
   ```

Example

```
Switch:1# show isis statistics

```

Variable Definitions

The following table defines parameters for the **show isis int-counters** command.

Variable	Value
home	Displays the IS-IS interface counters that the system configures in the home area.
remote	Displays the IS-IS interface counters that the system configures in the remote area.

The following table defines parameters for the **show isis int-l1-cntl-pkts** command.

Variable	Value
home	Displays the IS-IS L1 control packet counters that the system configures in the home area.
remote	Displays the IS-IS L1 control packet counters that the system configures in the remote area.

The following table defines parameters for the **clear isis stats** command.

Variable	Value
error-counters	Clears IS-IS stats error-counters.
packet-counters	Clears IS-IS stats packet-counters.

Suspend Duplicate System ID Detection When Replacing a Switch

When a switch is replaced and the original system ID and nickname is used, you must wait up to 20 minutes for the LSPs with the original system to age out. This is due to duplicate system ID and nickname detection. However, you can suspend duplicate detection on the replacement switch so that you can bring the switch into the network immediately.

About This Task

To temporarily disable duplicate detection on the replacement switch, perform the following steps:

Procedure

1. Copy the configuration file of the original switch to the replacement switch.
2. Power up the replacement switch while it is not connected to the SPB network, that is, network-to-network interface (NNI) ports are not connected.
3. Disable IS-IS on the original switch, or remove the switch from the network.
4. On the replacement switch, enter the following Global Configuration command to suspend duplicate detection for up to 21 minutes:

   ```
   isis dup-detection-temp-disable
   ```

5. To check the remaining time, use the `show isis dup-detection-temp-disable remaining time` command.
6. Remove the original switch from the network.
7. Connect the replacement switch to the network.

Configure Dynamic Nickname Assignment

About This Task

Use this procedure to specify a nickname prefix for Dynamic Nickname Assignment.

Note

You must disable Dynamic Nickname Assignment before you can change the nickname prefix.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the Dynamic Nickname Assignment nickname allocation:

   ```
   spbm nick-name server prefix x.xx.xx
   ```

3. Enable Dynamic Nickname Assignment:

   ```
   spbm nick-name server
   ```

4. Verify the configuration:

   ```
   show spbm
   ```

Examples

Configure a nickname allocation prefix and enable Dynamic Nickname Assignment:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#spbm nick-name server prefix C.30.00
Switch:1(config)#spbm nick-name server
```

Dynamic Nickname Assignment configuration values and their associated behavior are shown in the following output from the **`show spbm`** command:

```
Switch:1>show spbm
                                  spbm : enable
                             ethertype : 0x8100
                       nick-name server : enable
                    nick-name allocation : static
                  nick-name server range : C.30.00-C.3F.FF
```

Variable Definitions

The following table defines parameters for the **spbm nick-name server** command.

Variable	Value
prefix x.xx.xx	Specifies the nickname server allocation prefix. x.xx.xx uses the form X.X0.00 from 0.00.00 to F.F0.00. A group, X.X0.00 to X.XF.FF, can provide up to 4,096 nicknames. The default nickname allocation range is A.00.00-A.0F.FF.

Display Dynamic Nickname Assignment

About This Task

Use this procedure to display the current status and values for Dynamic Nickname Assignment.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display Dynamic Nickname Assignment configuration values:

   ```
   show spbm
   ```

Example

```
Switch:1>show spbm
                                  spbm : enable
                             ethertype : 0x8100
                        nick-name server : disable
                    nick-name allocation : static
                  nick-name server range : A.00.00-A.0F.FF
```

Enable MSTP-Fabric Connect Multi Homing

Before You Begin

You must configure a nickname for the specific SPBM instance on which you enable MSTP-Fabric Connect Multi Homing.

About This Task

Perform this procedure to enable MSTP-Fabric Connect Multi Homing for a specific SPBM instance.

Procedure

1. Enter IS-IS Router Configuration mode:

   ```
   enable

   configure terminal

   router isis
   ```

2. Enable MSTP-Fabric Connect Multi Homing on a specified SPBM instance:

   ```
   spbm <1-100> stp-multi-homing enable
   ```

Example

```
Switch:1>enable
Switch:1#configure terminal
```

```
Switch:1(config)#router isis
Switch:1(config-isis)#spbm 1 stp-multi-homing enable
```

Variable definitions

The following table defines parameters for the **spbm** command.

Variable	Value
<1–100>	Specifies the IS-IS SPBM instance ID to create an SPBM instance.
stp-multi-homing enable	Enables MSTP-Fabric Connect Multi Homing on the specific SPBM instance. The default is disabled.

Determine the Root Bridge in an MSTP-Fabric Connect Multi Homing Configuration

Identify the root bridge by determining where the Common and Internal Spanning Tree (CIST) regional root MAC address is learned for the STP-reserved I-SID. Check which MAC address has the same first five octets as the CIST regional root MAC address.

About This Task

When you enable MSTP-Fabric Connect Multi Homing, you can use the following two commands to determine which BEB is the root bridge:

- **show spanning-tree mstp status**
- **show i-sid mac-address-entry 16777003**

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Determine the CIST regional root:
   ```
   show spanning-tree mstp status
   ```
3. Determine which MAC address has the same first five octets as seen in the CIST regional root MAC address:
   ```
   show i-sid mac-address-entry 16777003
   ```

Example

In the following example, bold text identifies the relevant information in the command output. In the output of the second command, the DEST-MAC shows 10:cd:ae:6e:d8:84, which is the system ID of the CIST regional root BEB, and the system name is BEB-1000.

```
Switch:1>show spanning-tree mstp status

================================================================================
                                MSTP Status

```

Increase the Number of SPB Nodes per Area

Note

This procedure only applies to 5320 Series and 5420 Series.

Perform this procedure to increase the number of SPB nodes per area that the switch supports. For more information about maximum scaling numbers, see *Fabric Engine Release Notes*.

About This Task

If you enable this boot config flag, it decreases the scaling limits for the following features:

- Switched UNI (S-UNI) endpoints
- Layer 2 and Layer 3 I-SIDs
- IP Multicast over Fabric Connect local streams

The scaling numbers for the following items are limited by the use of a shared hardware resource, and thus they affect one another:

- the number of SPB nodes per area
- the number of SPB nodes that send IP Multicast streams that the local BEB receives
- local SPB services:
  - Layer 2 I-SIDs
  - Layer 3 I-SIDs
  - IP Multicast over Fabric Connect remote IP Multicast stream data I-SIDs
  - I-SID mirroring instances

If you enable this boot config flag:

1. The switch supports up to 500 nodes per area.
2. The switch supports up to 200 nodes per area, when all of them are concurrently sending IP Multicast over Fabric Connect streams while local BEB receives.
3. The switch supports a maximum of 500 Switched UNI (S-UNI) endpoints.

If you disable this boot config flag (default configuration):

1. The switch supports up to 350 nodes per area.
2. The switch supports up to 150 nodes per area, when all of them are concurrently sending IP Multicast over Fabric Connect streams while local BEB receives.
3. The switch supports a maximum of 1,000 Switched UNI (S-UNI) endpoints.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Increase the number of supported SPB nodes per area:

   ```
   boot config flags spbm-node-scaling
   ```

3. Verify the configuration:

   ```
   show boot config flags
   ```

4. Save the configuration:

   ```
   save config
   ```

5. Restart the switch for the change to take effect:

   ```
   reset
   ```

Example

Enable the boot config flag to increase the number of SPB nodes per area that switch supports.

```
Switch:1>en
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#boot config flags spbm-node-scaling
Switch:1(config)#save config
Switch:1(config)#reset

Warning: Please save the configuration and reboot the switch
         for this configuration to take effect.
```

Note

Flag support can vary across hardware models.

```
Switch:1#show boot config flags
flags advanced-feature-bandwidth-reservation low

flags verify-config true
flags vrf-scaling true
```

Fabric Extend configuration using the CLI

The following sections provide procedural information you can use to configure Fabric Extend (FE) using the Command Line Interface (CLI).

Configure Fabric Extend

Before You Begin

The tunnel source IP address can be a brouter port IP, a CLIP IP, or a VLAN IP.

For information about product support, see Fabric Extend Considerations on page 877.

Important

Switches that support a single active VRF have feature interactions with Fabric Extend. For more information, see VRF Lite Configuration Rules on page 3484. To assist with the single-active VRF restrictions, an *overlay* parameter exists for the *ip-tunnel-source-address* command.

If using the tunnel originating address on the GRT, Fabric Extend has the following requirements:

- The tunnel source IP address must be on the GRT, not on a VRF.

  

  Note

  A best practice is to use separate IP addresses for the SPBM IP Shortcuts **ip-source-address** command and the Fabric Extend **ip-tunnel-source-address** command. However, if you want these IP addresses to be the same, you MUST exclude the **ip-source-address** address with an IS-IS accept policy. You cannot use the redistribute command with a route map exclusion.

  Specify a CLIP interface to use as the source address for SPBM IP shortcuts.

- If IP Shortcuts is enabled, you must configure an IS-IS accept policy or exclude route-map to ensure that tunnel destination IP addresses are not learned through IS-IS.

If you are using the tunnel originating address on a VRF, configure a CLIP and tunnel source IP address on the VRF.

About This Task

Configuring Fabric Extend consists of two primary tasks: configuring the tunnel source address and configuring the logical interface. These tasks must be completed on both ends of the tunnel.

Note

VRF is an optional parameter. If a VRF is not configured, then FE uses the GRT.

Procedure

1. Enter IS-IS Router Configuration mode:

   ```
   enable

   configure terminal

   router isis
   ```

2. Configure the IP tunnel source address:

   ```
   ip-tunnel-source-address <A.B.C.D> [vrf WORD<1-16>] [overlay]
   ```

3. Enter Global Configuration mode:

   ```
   exit
   ```

4. Use one of the following commands to create a logical IS-IS interface:

   - In a network with a Layer 3 Core, enter `logical-intf isis <1-255> dest-ip <A.B.C.D> [name WORD<1-64>]`
   - In a network with a Layer 2 Core, enter `logical-intf isis <1-255> vid <list of vids> primary-vid <2-4059> port <slot/port> mlt <mltId> [name WORD<1-64>]`

   Note

   The primary VLAN ID (**primary-vid** must be one of the VIDs in the **vid <list of vids>**.

Variable Definitions

The following table defines parameters for the **ip-tunnel-source-address** command.

Variable	Value
<A.B.C.D>	Specifies the IS-IS IPv4 tunnel source address, which can be a brouter interface IP, a CLIP IP, or a VLAN IP.
overlay	Permits the configuration of the tunnel source address even though it belongs to a VRF with an attached I-SID.
vrf *WORD<1-16>*	Specifies the VRF name associated with the IP tunnel.

The following tables define parameters for the **logical-intf isis** command, depending on whether you have a Layer 2 or Layer 3 core.

Table 86: Layer 2 core

Variable	Value
<1-255>	Specifies the index number that uniquely identifies this logical interface.
port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Specifies the physical port that the logical interface is connected to in a Layer 2 network.
vid <list of vids>	Specifies the list of VLANs that are associated with this logical interface.

Table 86: Layer 2 core (continued)

Variable	Value
primary-vid <2-4059>	Specifies the primary tunnel VLAN ID associated with this Layer 2 IS-IS logical interface.
mlt <mltId>	Specifies the MLT ID that the logical interface is connected to in a Layer 2 network.
name WORD<1-64>	Specifies the administratively-assigned name of this logical interface, which can be up to 64 characters.

Table 87: Layer 3 core

Variable	Value
<1-255>	Specifies the index number that uniquely identifies this logical interface.
dest-ip <A.B.C.D>	Specifies the tunnel destination IP address of the remote BEB.
name WORD<1-64>	Specifies the administratively-assigned name of this logical interface, which can be up to 64 characters.

Configure IS-IS Hello Padding

Perform this procedure to dynamically configure IS-IS hello padding on all IS-IS network-to-network interface (NNI) links. IS-IS hello padding is enabled by default.

About This Task

Disable hello padding if the WAN-line MTU is less than 1596 bytes and fragmentation and reassembly functionality is enabled.

Procedure

1. Enter IS-IS Router Configuration mode:
   ```
   enable

   configure terminal

   router isis
   ```
2. Perform one of the following actions:
   - Disable hello padding: `no hello-padding`
   - Enable hello padding, if previously disabled: `hello-padding`
3. Verify the configuration:
   ```
   show isis
   ```

Example

Verify IS-IS hello padding status:

```
Switch:1>show isis
================================================================================
                                ISIS General Info
================================================================================
                             AdminState : enabled
```

```
                          RouterType : Level 1
                           System ID : 0014.c7e1.33df

```

Adjust the TCP Maximum Segment Size

Adjust the TCP maximum segment size (MSS) to improve the throughput for the TCP session over a Fabric Extend (FE) adjacency.

About This Task

Note

If you downgrade to an earlier release that does not support this feature, you must disable the feature and save the configuration. Downgrading to an earlier release requires a compatible configuration file.

The default value, when enabled, is 1300.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Use one of the following commands to configure the MSS adjustment functionality as required:
   a. Configure an explicit MSS adjust value:

      ```
      ip tcp adjust-mss <500–1900> [enable]
      ```

   b. Disable MSS adjustment explicitly:

      ```
      no ip tcp adjust-mss enable
      ```

3. Verify the configuration:

   ```
   show ip tcp adjust-mss
   ```

Examples

Configure an MSS value of 1100 and verify the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#ip tcp adjust-mss 1200
Switch:1>show ip tcp adjust-mss
================================================================================
                              IP TCP Adjust MSS
================================================================================
ENABLE            STATUS            TCP MSS                   TCP MSS
                                    TYPE                      VALUE
--------------------------------------------------------------------------------
TRUE              ACTIVE            MANUAL-CONFIG             1200
```

.

Configure BFD on a Fabric Extend Tunnel

About This Task

Use the following procedure to configure BFD on a Fabric Extend Tunnel.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable BFD:

   ```
   router bfd enable
   ```

3. In the VLAN Interface Configuration mode, you can enable BFD:

   ```
   ip bfd enable
   ```

4. In the Loopback Interface Configuration mode, you can enable BFD:

   ```
   ip bfd enable
   ```

5. Enable BFD on an IS-IS Logical Interface:

   ```
   logical-intf isis <1-255> bfd enable
   ```

Example

Enable BFD on a Fabric Extend tunnel:

```
Switch:1>enable
Switch:1#config terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#router bfd enable
Switch:1(config)#interface loopback 1
Switch:1(config-if)#ip bfd enable
Switch:1(config-if)#logical-intf isis 1
Switch:1(config-isis-1-1.2.3.5)#bfd enable
```

Display IS-IS Logical Interfaces

Use the following procedure to display the Intermediate-System-to-Intermediate-System (IS-IS) logical interfaces configured on the switch.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the IS-IS logical interfaces:

   ```
   show isis logical-interface [name]
   ```

Examples

Example of a Layer 2 Core

```
Switch:1> show isis logical-interface
================================================================================================
                          ISIS Logical Interfaces
================================================================================================
IFIDX  NAME   ENCAP         L2_INFO                  TUNNEL     L3_TUNNEL_NEXT_HOP_INFO
              TYPE          PORT/MLT  VIDS(PRIMARY)  DEST-IP     PORT/MLT    VLAN   VRF
------------------------------------------------------------------------------------------------
1      --     L2-P2P-VID    Port2/40  101,201(101)    --           --        --     --
2      --     L2-P2P-VID    Port1/3   102,202(102)    --           --        --     --
------------------------------------------------------------------------------------------------
 2 out of 2 Total Num of Logical ISIS interfaces
------------------------------------------------------------------------------------------------
```

Example of a Layer 3 Core

```
Switch:1> show isis logical-interface
================================================================================================
                          ISIS Logical Interfaces
================================================================================================
IFIDX  NAME   ENCAP         L2_INFO                  TUNNEL     L3_TUNNEL_NEXT_HOP_INFO
              TYPE          PORT/MLT  VIDS(PRIMARY)  DEST-IP     PORT/MLT    VLAN  VRF
------------------------------------------------------------------------------------------------
1      SPBoIP_T1    IP       --         --      41.41.41.41       MLT10     2     vrf24
2      SPBoIP_T2    IP       --         --      42.42.42.42       MLT10     2     vrf24
3      SPBoIP_4K5   IP       --         --      187.187.187.187   MLT10     2     vrf24
------------------------------------------------------------------------------------------------
 3 out of 3 Total Num of Logical ISIS interfaces
------------------------------------------------------------------------------------------------
```

Example showing the status of BFD configurations on the IS-IS Logical interface

```
Switch:1> show isis logical-interface
================================================================================================
                    ISIS Logical Interfaces
================================================================================================
IFIDX  NAME       ENCAP   L2_INFO                 TUNNEL     L3_TUNNEL_NEXT_HOP_INFO  BFD
                  TYPE    PORT/MLT  VIDS(PRIMARY) DEST-IP     PORT/MLT   VLAN  VRF   STATUS
------------------------------------------------------------------------------------------------
1      tunnel01   IP      --        --            198.51.100.1  Port1/2  123   vrf30 disabled
2      tunnel102  IP      --        --            198.51.100.2  Port1/3  345   vrf20 disabled
------------------------------------------------------------------------------------------------
 2 out of 2 Total Num of Logical ISIS interfaces
------------------------------------------------------------------------------------------------
```

Example showing the full IS-IS logical interface name

The command **show isis logical-interface** truncates the IS-IS logical interface name to the first 16 characters. To view the entire name (up to a maximum of 64 characters), use the command **show isis logical-interface name**.

```
Switch:1> show isis logical-interface name
================================================================================================
                          ISIS Logical Interface name
================================================================================================
ID      NAME

------------------------------------------------------------------------------------------------
1       SPBoIP_T1
2       SPBoIP_T2
3       SPBoIP_4K5
6       This_Is_A_50_Character_ISIS_Logical_Interface_Name
------------------------------------------------------------------------------------------------
 4 out of 4 Total Num of Logical ISIS interfaces
------------------------------------------------------------------------------------------------
```

Variable Definitions

The following table defines parameters for the **show isis logical-interface** command.

Variable	Value
name	Displays the full name of the IS-IS logical interface (up to a maximum of 64 characters).

Display BFD Fabric Extend Neighbor Information

About This Task

Use this procedure to display BFD Fabric Extend neighbors.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the BFD configurations:

   ```
   show ip bfd neighbors vrf WORD<1-16>
   ```

Example

```
Switch:1>show ip bfd neighbors vrf vrf30
================================================================================================================================
                                      BFD Session - VRF vrf30
================================================================================================================================

MY_DISC    YOUR_DISC  NEXT_HOP        STATE     MULTI MIN_TX MIN_RX ACT_TX DETECT_TIME REMOTE_STATE APP    RUN

--------------------------------------------------------------------------------------------------------------------------------
  1 out of 1 BFD session displayed
--------------------------------------------------------------------------------------------------------------------------------
```

Fabric Attach Configuration using the CLI

The following sections provide procedural information you can use to configure Fabric Attach (FA) and Logical Link Discovery Protocol (LLDP) using the Command Line Interface (CLI). For information about LLDP related to FA, see Link Layer Discovery Protocol configuration using CLI on page 1945.

Configure Fabric Attach Globally

For proper operation, FA must be enabled at both the global level and at the interface level on the FA Server. By default, FA is globally enabled. However, FA is disabled by default at the interface level and must be explicitly enabled on each interface.

Use this procedure to enable Fabric Attach globally on a switch.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable FA:

   ```
   fa enable
   ```

3. (Optional) Disable FA:

   ```
   no fa enable
   ```

   Caution
   Disabling FA flushes all FA element discovery and mappings.

4. View the FA configuration status. Use one of the following commands:
   - `show fa`
   - `show fa agent`

Example

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#fa enable

Switch:1>show fa

================================================================================
                        Fabric Attach Configuration
================================================================================
                           FA Service : enabled
                      FA Element Type : server
                 FA Assignment Timeout : 240
                  FA Discovery Timeout : 240
                     FA Provision Mode : spbm
Switch:1>show fa agent

================================================================================
                        Fabric Attach Configuration
================================================================================
                           FA Service : enabled
                      FA Element Type : server
                 FA Assignment Timeout : 240
                  FA Discovery Timeout : 240
                     FA Provision Mode : spbm
```

Configuring Fabric Attach discovery timeout

Use this procedure to configure the Fabric Attach discovery time-out.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the FA discovery time-out in seconds:

   ```
   fa discovery-timeout <45–480>
   ```

   Note
   The discovery time-out must be greater than or equal to the assignment time-out.

3. (Optional) Configure the default FA discovery time-out:

   ```
   default fa discovery-timeout
   ```

Example

Configure the FA discovery time-out.

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#fa discovery-timeout 50
```

Verify the configuration.

```
Switch:1(config)#show fa

================================================================================
                           Fabric Attach Configuration
================================================================================
                             FA Service : enabled
                        FA Element Type : server
                    FA Assignment Timeout : 45
                     FA Discovery Timeout : 50
                        FA Provision Mode : spbm
```

Variable definitions

The following table defines parameters for the **`fa discovery-timeout`** command.

Variable	Value
<45–480>	Specifies the Fabric Attach discovery time-out in seconds. The default value is 240 seconds.

Configuring Fabric Attach assignment timeout

Use this procedure to configure the Fabric Attach assignment time-out.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the FA assignment time-out in seconds:

   ```
   fa assignment-timeout <45–480>
   ```

   Note

   The assignment time-out must be less than or equal to the discovery time-out.

3. (Optional) Configure the default FA assignment time-out value:

   ```
   default fa assignment-timeout
   ```

Example

Configure the FA assignment time-out:

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#fa assignment-timeout 50
```

Verify the configuration:

```
Switch:1(config)#show fa

================================================================================
                           Fabric Attach Configuration
================================================================================
                              FA Service : enabled
                         FA Element Type : server
                    FA Assignment Timeout : 50
                     FA Discovery Timeout : 240
                        FA Provision Mode : spbm
```

Variable definitions

The following table defines parameters for the **`fa assignment-timeout`** command.

Variable	Value
<45–480>	Specifies the Fabric Attach assignment time-out in seconds. The default value is 240 seconds.

Enabling Fabric Attach on an interface

Use this procedure to enable Fabric Attach on an interface (port, static MLT or LACP MLT). Enabling FA on an MLT enables FA on all ports of the MLT. If your platform supports channelization, FA can also be enabled on channelized ports.

Before You Begin

Verify that FA is enabled globally on the switch.

About This Task

Enabling FA on a port or MLT is necessary for element discovery.

On the FA Server, FA is enabled globally by default. However, you must explicitly enable FA on the desired port or MLT interface. FA is successfully enabled on an MLT only if all ports of the MLT have FA successfully enabled. Enabling FA automatically configures LLDP on all ports. Tagging is configured and spanning tree is disabled.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]}
   ```
   or `interface mlt <1-512>`

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable FA on the interface:

   ```
   fa enable
   ```

3. (Optional) Disable FA on the interface:

   ```
   no fa enable
   ```

   Caution

   Disabling FA flushes all FA element discovery and I-SID-to-VLAN mappings associated with the interface.

4. View the FA configuration status:

   ```
   show fa interface [disabled-auth] [enabled-auth] [mlt <1-512>] [port <{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}>]
   ```

Example

Enable FA on a port:

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#interface gigabitethernet 1/2
Switch:1(config-if)#fa enable
Switch:1(config-if)#exit
Switch:1(config)#
```

Enable FA on an MLT:

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#interface mlt 10
Switch:1(config-mlt)#fa enable
```

```
Switch:1(config-mlt)#exit
Switch:1(config)#
```

Verify that FA is enabled on the interfaces.

Note

When FA is enabled, message authentication is enabled by default. The authentication key is set to the default value and displays encrypted on the output.

```
Switch:1>show fa interface

==========================================================================
                           Fabric Attach Interfaces
==========================================================================
INTERFACE    SERVER   MGMT     MGMT     MSG AUTH MSG AUTH    ORIGIN
             STATUS   ISID     CVID     STATUS   KEY

```

Variable definitions

The following table defines parameters for the **show fa interface** command.

Variable	Value
disabled-auth	Displays the FA interfaces (port or MLT) that have authentication disabled.
enabled-auth	Displays the FA interfaces (port or MLT) that have authentication enabled.
<1-512>	The valid range for MLT ID. Displays FA configuration on the specified MLT interface.
port *{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}*	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. Displays FA configuration on the specified port.

Configuring FA message authentication on an interface

Use this procedure to configure FA message authentication on an interface (port or MLT).

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]}
   ```
   or `interface mlt <1-512>`

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure FA message authentication on a port or MLT:

   ```
   [default] [no] fa message-authentication
   ```

   Note

   When FA is enabled, message authentication is enabled by default. The authentication key is set to the default value and displays encrypted on the output.

Example

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#
```

Enable message authentication on a port.

```
Switch:1(config)#interface gigabitEthernet 1/2

Switch:1(config-if)#fa message-authentication
Switch:1(config-if)#show fa interface port 1/2

================================================================
                          Fabric Attach Interfaces

```

Configuring the FA authentication key on an interface

On the FA Server, you can configure an authentication key on an interface (port, static MLT or LACP MLT), to authenticate a client or proxy device on that interface. The authentication key is stored in encrypted form when you save configuration on the FA Server.

Before You Begin

Ensure that:

- On the FA Server, FA is enabled globally and also on the interface.
- FA message authentication is enabled on the interface.

Note

By default, enabling FA enables message authentication. The authentication key is set to the default value and the system displays the encrypted authentication key on the output.

About This Task

Use this procedure to configure an FA authentication key on a specified port or on all ports of an MLT, on the switch. If you do not configure an authentication key, the default value is used. If you specify a key, the default value is overridden and is stored in encrypted format in a separate file other than the configuration file, when you execute the `save config` command.

Caution

For an FA Client or an FA Proxy device to successfully authenticate and attach to the FA Server, the authentication key must match on both the client and the server. If the authentication key is changed on the FA Server switch, it must correspondingly be changed on the FA Client or Proxy attached to it, for FA to operate properly.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]} or interface mlt <1-512>
   ```

   

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the FA authentication key:

   ```
   fa authentication-key WORD<0-32>
   ```

3. (Optional) Configure the default FA authentication key:

   ```
   default fa authentication-key
   ```

Example

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line.  End with CNTL/Z.
```

Enable FA and message authentication on a port. Configure the authentication key `phone-network` on the port.

```
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#fa enable
Switch:1(config-if)#fa message-authentication
Switch:1(config-mlt)#fa authentication-key phone-network
Switch:1(config-if)#exit
Switch:1(config)#
```

Enable FA and message authentication on an MLT. Configure the authentication key `client-network` on the MLT.

```
Switch:1(config)#interface mlt 10
Switch:1(config-mlt)#fa enable
Switch:1(config-mlt)#fa message-authentication
Switch:1(config-mlt)#fa authentication-key client-network
```

Verify configuration of the FA authentication key. The system displays the encrypted authentication key on the output.

```
Switch:1(config-if)#show fa interface

==========================================================================

--------------------------------------------------------------------------
 2 out of 2 Total Num of fabric attach interfaces displayed
--------------------------------------------------------------------------
```

Variable Definitions

The following table defines parameters for the **`fa authentication-key`** command.

Variable	Value
WORD*<0–32>*	Specifies the authentication key on the port or MLT.

Configure FA Management on a Port or MLT

Use this procedure to configure a management I-SID on a Fabric Attach (FA)-enabled port or MLT.

To configure an FA management I-SID for Auto-sense-enabled ports, see Configure a Management I-SID for Auto-sense Fabric Attach Proxy Switches on page 29.

Before You Begin

Ensure that the port or MLT is enabled for FA.

About This Task

This command applies to all traffic sent or received on a port or MLT, carrying the VLAN ID specified using the `c-vid` parameter. This parameter is optional.

Depending on whether the `c-vid` parameter is specified or not, the behavior is as follows:

- If you specify the `c-vid` parameter, the FA Server transmits this VLAN ID as the management VLAN in the FA Element TLV. A client or proxy receiving this TLV uses this VLAN-ID for management traffic on the FA Server uplink.
- If you do not specify the `c-vid` parameter, the FA Server transmits a management VLAN with a VLAN ID value of 4095 in the FA Element TLV. A client or proxy receiving this TLV uses untagged traffic for network management on the FA Server uplink.

An FA management I-SID can have a platform VLAN associated with it. For Layer 3 support on the management I-SID, you must create a platform VLAN by port and associate the platform VLAN with the management I-SID. The C-VID can be of the same value or of a different value than that of the platform VLAN.

If the management I-SID matches one of the FA Switched UNI (ELAN) I-SIDs (as displayed by the command `show i-sid elan`), then the platform VLAN is automatically associated with the FA-enabled interface (port or MLT).

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]} or interface mlt <1-512>
   ```

   

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the FA management I-SID:

   ```
   fa management i-sid <i-sid><c-vid>
   ```

   

   Important

   If you do not specify a C-VID value, the port or MLT is untagged.

3. Verify configuration of FA management on the port or MLT, using the following commands:

   - `show i—sid <i-sid>`
   - `show interfaces gigabitEthernet i-sid [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]`
   - `show mlt i-sid [<1-512>]`

Examples

Configure FA management on port 1/2:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#interface gigabitethernet 1/2
Switch:1(config-if)#fa management i-sid 101 c-vid 101
Switch:1(config-if)#show i-sid 101
================================================================================================

```

Variable Definitions

The following table defines parameters for the **fa management** command.

Variable	Value
i-sid <i-sid>	Specifies the management I-SID. Different hardware platforms support different customer I-SID ranges. To see the available range for the switch, use the CLI Help.
<c-vid>	Specifies the customer VLAN ID. Different hardware platforms support different customer VLAN ID ranges. Use the CLI Help to see the available range for the switch. Important: If you do not specify a C-VID value, the port or MLT is **untagged**.

View Fabric Attach Global Configuration Status

Use this procedure to display the Fabric Attach global configuration status on a switch.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the FA configuration status using one of the following commands:
   - `show fa`
   - `show fa agent`

Example

Sample output for the **show fa** command:

```
Switch:1>show fa

================================================================================
                          Fabric Attach Configuration
================================================================================
                             FA Service : enabled
                         FA Element Type : server
                    FA Assignment Timeout : 240
                     FA Discovery Timeout : 240
                        FA Provision Mode : spbm
```

Sample output for the **show fa agent** command:

```
Switch:1>show fa agent

================================================================================
                          Fabric Attach Configuration
================================================================================
                             FA Service : enabled
                         FA Element Type : server
                    FA Assignment Timeout : 240
                     FA Discovery Timeout : 240
                        FA Provision Mode : spbm
```

Viewing Fabric Attach interface configuration

Use this procedure to view FA interface configuration.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View all FA interfaces (ports and MLTs):

   ```
   show fa interface
   ```
3. To view FA interface configuration on ports, use one of the following commands:
   - View FA configuration on all ports:

     ```
     show fa interface port
     ```
   - View FA configuration on a specific port, enter:

     ```
     show fa interface port [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]
     ```
4. To view FA interface configuration on MLTs, use one of the following commands:
   - View FA configuration on all MLTs:

     ```
     show fa interface mlt
     ```
   - View FA configuration on a specific MLT:

     ```
     show fa interface mlt [<1-512>]
     ```

Example

The following example displays sample outputs for the **show fa interface** command.

```
Switch:1>show fa interface

=============================================================================

```

Variable definitions

The following table defines parameters for the `show fa interface port` command.

Variable	Value
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

The following table defines parameters for the `show fa interface mlt` command.

Variable	Value
<1–512>	The valid range for MLT ID.

Viewing Fabric Attach Discovered Elements

Use this procedure to view Fabric Attach discovered elements.

About This Task

When FA is enabled on an FA Server switch, LLDP PDUs are exchanged between the FA Server and FA Clients or FA Proxies. Standard LLDPs allow neighbors to be learned. With the help of organizational-specific element discovery TLVs, the client or proxy recognizes that it has attached to the FA Server. Only after the discovery handshake is complete, an FA Client or FA Proxy can transmit I-SID-to-VLAN assignments to join the SPB Fabric network through the FA Server.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Display FA discovered elements:

   `show fa elements`

3. Display FA discovered elements on a specific port:

   `show fa elements [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]`

Example

The following example displays the sample output for the `show fa elements` command.

```
Switch:1#show fa elements

================================================================================

```

Variable definitions

The following table defines parameters for the **`show fa elements`** command.

Variable	Value
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Viewing Fabric Attach I-SID-to-VLAN Assignments

Use this procedure to display the I-SID-to-VLAN assignments advertised by an FA Client or an FA Proxy, to be supported on the FA Server. These assignments can be accepted or rejected by the FA Server. An

assignment that is successfully accepted by the FA Server results in the creation of a Switched UNI I-SID on the interface.

Before You Begin

Verify that IS-IS and SPBM are properly configured on the FA Server switch.

- Verify SPBM configuration using the command **show running-config module spbm**.
- Verify IS-IS configuration using one of the following commands:
  - **show isis**
  - **show isis interface**
  - **show isis adjacency**
  - **show isis lsdb**

Procedure

1. Enter Privileged EXEC mode:

   `enable`
2. Display FA I-SID-to-VLAN assignments:

   `show fa assignment`
3. Display FA I-SID-to-VLAN assignments on specific ports:

   `show fa assignment [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]`

Example

The following example displays a sample output for the `show fa assignment` command.

Note

The state of I-SID-to-VLAN assignments on a client or proxy device is `pending` until it is changed by the FA Server to `active` or `reject`.

```
Switch:>en
Switch:1#show fa assignment
================================================================================
                           Fabric Attach Assignment Map
================================================================================
Interface  I-SID      Vlan       State      Origin
--------------------------------------------------------------------------------
1/1        2          2          active     proxy
1/2        3          3          active     proxy
1/2        4          4          active     proxy
1/3        5          5          reject     proxy
--------------------------------------------------------------------------------

 4 out of 4 Total Num of fabric attach assignment mappings displayed

--------------------------------------------------------------------------------
```

Variable definitions

The following table defines parameters for the **show fa assignment** command.

Variable	Value
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Viewing Fabric Attach Statistics

If FA discovery fails, use this procedure to display FA statistics to determine if FA discovery TLVs were processed. You can also view the FA assignment statistics to determine the number of FA assignments that were accepted or rejected by the FA Server.

You can view the statistics at either the global level or at the port (interface) level.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. View global level FA statistics:

   ```
   show fa statistics [summary]
   ```

3. View FA statistics at the slot/port level:

   ```
   show fa statistics [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]
   ```

   Note

   If a slot is removed from the switch chassis, the FA statistics are not displayed on the slot ports. When the slot is inserted back again, the statistics counters are reset.

4. (Optional) Clear FA statistics:

   ```
   clear fa statistics [summary] [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]
   ```

Examples

Viewing FA discovery and assignment statistics:

```
Switch:1>en
Switch:1#show fa statistics

================================================================================
                          Fabric Attach STATISTICS

================================================================================
                      Fabric Attach ASSIGNMENTS STATISTICS SUMMARY
================================================================================
Port      Asgn       Asgn       Asgn       Asgn       Asgn       AsgnAuth
          Received   Accepted   Rejected   Expired    Deleted    Failed
--------------------------------------------------------------------------------
1/1       3149       3          1          3          0          0
1/2       1500       0          1          2          0          0
```

Viewing FA statistics on a specific port (port `1/1`):

```
Switch:1>en
Switch:1#show fa statistics 1/1

================================================================================
                            Fabric Attach STATISTICS
================================================================================
Port      DiscElem   DiscElem   DiscElem   DiscAuth
          Received   Expired    Deleted    Failed
--------------------------------------------------------------------------------
1/1       3057       0          1          0

================================================================================
                      Fabric Attach ASSIGNMENTS STATISTICS
================================================================================
Port      Asgn       Asgn       Asgn       Asgn       Asgn       AsgnAuth
          Received   Accepted   Rejected   Expired    Deleted    Failed
--------------------------------------------------------------------------------
1/1       3149       3          1          3          0          0
```

Optionally, clear FA statistics and verify that the statistics are cleared.

```
Switch:1#clear fa statistics
Switch:1#show fa statistics

================================================================================
                            Fabric Attach STATISTICS
================================================================================

1/1       0          0          0          0          0          0
1/2       0          0          0          0          0          0
```

Variable Definitions

The following table defines parameters for the **show fa statistics** command.

Variable	Value
summary	Displays a summary of Fabric Attach element discovery and assignment statistics at the global level.
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Display Learned LLDP Neighbors

Use this procedure to verify details of the LLDP neighbors learned.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```
2. Verify details of LLDP neighbors learned:
   ```
   show lldp neighbor
   ```
3. Verify details of LLDP neighbors learned on a specific port:
   ```
   show lldp neighbor port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
   ```

Example

The following example shows how two switches—an FA Server and an FA Proxy discover each other as LLDP neighbors.

Switch A, which is the FA Server is a 5320 Series switch (model 5320-48T-8XE) and switch B which is the proxy device is an ERS 4826GTS switch.

The following examples show neighbor discovery on non-channelized ports.

On the non-channelized port 1/1 on the FA Server, verify neighbor discovery of the proxy switch.

```
Switch:1>enable
Switch:1#show lldp neighbor
```

```
================================================================================================

Total neighbors: 1
```

Variable Definitions

The following table defines parameters for the **`show lldp neighbor`** command.

Variable	Value
port *{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}*	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. Displays LLDP neighbor information on the specified port.

Display Switched UNI (ELAN) I-SID Information

Use this procedure to display information on FA-created Switched UNI (ELAN) I-SIDs.

Procedure

1. Enter Privileged EXEC mode:
   `enable`
2. Display all Switched UNI (ELAN) I-SIDs:
   `show i-sid elan`
3. Display ELAN I-SID information on an MLT:
   `show mlt i-sid [<1-512>]`

   Note
   Viewing ELAN I-SID information on an MLT is useful to understand the origin of the I-SID when multiple client or proxy devices connecting to the FA Server using SMLT MLT advertise the same I-SID-to-VLAN mappings. In the event of a link failure on an MLT, the origin of the I-SID helps determine on which MLT, and thereby from which proxy or client device, the mappings were successfully learnt.

4. Display ELAN I-SID information on ports:
   `show interfaces gigabitEthernet i-sid [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]`

Examples

Display information on all Switched UNI (ELAN) I-SIDs.

The following sample output displays, for example, the I-SID information on one of the peer switches of the FA Server, in a dual-homed SMLT configuration.

```
Switch:1>enable
Switch:1#show i-sid elan

================================================================================================
                                              Isid Info
================================================================================================
ISID        ISID                PORT           MLT            ORIGIN              ISID

All 6 out of 6 Total Num of Elan i-sids displayed

ORIGIN Legend:
C: manually configured; D: discovered by FA or EPT
M: FA management; E: discovered by EAP; A: auto-sense
l: discover by local switch  r: discover by remote VIST switch
```

Note
The `I-SID TYPE` field displays once for each I-SID. The `I-SID TYPE` of an I-SID that is either learned through FA mapping assignments or configured as an FA management I-SID, is always ELAN. If a platform VLAN has the same I-SID value as that of the I-SID in an FA mapping assignment or in an FA management I-SID configuration, then the platform VLAN is associated with the I-SID endpoint and displays in the `VLANID` column.

Display MLT I-SID information for MLT `1`.

In this sample output, the ORIGIN field indicates the origin of the I-SID endpoint.

```
Switch:1>show mlt i-sid

```

Variable Definitions

The following table defines parameters for the **show i-sid** command.

Variable	Value
elan	Displays all ELAN I-SIDs.

The following table defines parameters for the **show mlt i-sid** command.

Variable	Value
<1–512>	The valid range for MLT ID.

The following table defines parameters for the **show interfaces gigabitEthernet i-sid** command.

Variable	Value
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Enabling or disabling FA Zero Touch Client Attachment

Use this procedure to enable or disable the global FA Zero Touch Client Attachment feature on an FA Proxy or Server. By default, FA Zero Touch Client Attachment support is enabled.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable an FA Zero Touch client:

   ```
   fa zero-touch-client standard <camera|ona-sdn|ona-spb-over-ip|phone|
   router|security-device|srvr-endpt|switch|video|virtual-switch|wap-
   type1|wap-type2> i-sid <1–15999999>
   ```

3. Disable an FA Zero Touch client:

   ```
   no fa zero-touch-client standard <camera|ona-sdn|ona-spb-over-ip|
   phone|router|security-device|srvr-endpt|switch|video|virtual-switch|
   wap-type1|wap-type2>
   ```

Example

```
Switch:1(config)# fa zero-touch-client standard camera i-sid 1003
Switch:1(config)# no fa zero-touch-client standard camera
```

Variable definitions

The following table defines parameters for the **fa zero-touch-client standard** command.

Variable	Value
camera	Specify element type to match camera.
ona-sdn	Specify element type to match ona-sdn.
ona-spb-over-ip	Specify element type to match ona-spb-over-ip.
phone	Specify element type to match phone.

Variable	Value
router	Specify element type to match router.
security-device	Specify element type to match security-device.
srvr-endpt	Specify element type to match srvr-endpt.
switch	Specify element type to match switch.
video	Specify element type to match video.
virtual-switch	Specify element type to match virtual-switch.
wap-type1	Specify element type to match wap-type1.
wap-type2	Specify element type to match wap-type2.

Displaying FA Zero Touch Client Attachment

Use this procedure to display the Zero Touch Client Attachment data you have configured on an FA Server.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Display Zero Touch Client Attachment data:

   ```
   show fa zero-touch-client
   ```

Example

The following example displays sample output for the **`show fa zero-touch-client`** command.

```
Switch:1#show fa zero-touch-client

================================================================================

                            Fabric Attach Zero Touch Client

Configure Endpoint Tracking Using CLI

The following sections provide procedural information to configure Endpoint Tracking using CLI.

Configure Endpoint Tracking Interfaces

Create and enable Endpoint Tracking on ports and MLT/SMLT interfaces. Creating, deleting, enabling, and disabling Endpoint Tracking on interfaces can be accomplished as separate steps using this procedure.

Before You Begin

- In ExtremeCloud IQ - Site Engine, configure your third-party virtualization platform, and the RADIUS server used for Endpoint Tracking authentication. For information about configuring ExtremeCloud IQ - Site Engine, see the ExtremeCloud IQ - Site Engine documentation at https://www.extremenetworks.com/support/documentation/.
- On the switch, add and configure the RADIUS server as configured in ExtremeCloud IQ - Site Engine.

About This Task

Configure ports and MLT/SMLT interfaces to function as Switched UNI interfaces, and then create and enable Endpoint Tracking on those interfaces.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]}
   ```
   or `interface mlt <1-512>`

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable Flex UNI on the interface:

   ```
   flex-uni enable
   ```
3. Create and enable Endpoint Tracking:
   - Create Endpoint Tracking on the interface:

     ```
     endpoint-tracking
     ```
   - Create and enable Endpoint Tracking on the interface:

     ```
     endpoint-tracking enable
     ```

What to Do Next

Configure Endpoint Tracking globally on the switch.

Configure Endpoint Tracking Globally

Configure Endpoint Tracking globally on the switch.

Before You Begin

- In ExtremeCloud IQ - Site Engine, configure your third-party virtualization platform, and the RADIUS server used for Endpoint Tracking authentication. For information about configuring ExtremeCloud IQ - Site Engine, see the ExtremeCloud IQ - Site Engine documentation at https://www.extremenetworks.com/support/documentation/.
- On the switch, add and configure the RADIUS server as configured in ExtremeCloud IQ - Site Engine.
- Create and enable Endpoint Tracking on interfaces.

About This Task

Optionally, if the RADIUS outbound attributes do not include an I-SID value, configure an I-SID offset value, and globally enable I-SID offset for Endpoint Tracking. The I-SID offset value is used to calculate an I-SID value for a switched UNI if no I-SID value is provided by the RADIUS server. In that case, the I-SID value is calculated as follows: I-SID = VLAN ID + configured I-SID offset value.

After optionally configuring an I-SID offset value, enable Endpoint Tracking globally on the switch.

Note

If you have previously enabled Endpoint Tracking globally and want to change the currently configured I-SID offset value, you must disable Endpoint Tracking globally, change the I-SID value, and then re-enable Endpoint Tracking globally.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. (Optional) Configure an I-SID offset value, and enable I-SID offset globally on the switch:

   ```
   endpoint-tracking auto-isid-offset <0-15995903>
   endpoint-tracking auto-isid-offset enable
   ```

3. Enable Endpoint Tracking globally on the switch:

   ```
   endpoint-tracking enable
   ```

Variable Definitions

The following table defines parameters for the **`endpoint-tracking auto-isid-offset`** command.

Variable	Value
<0-15995903>	The I-SID offset value. The default is 15990000.
enable	Enables or disables I-SID offset value globally on the switch. The default is disabled.

Configure Endpoint Tracking Visibility Mode

Configure Endpoint Tracking visibility mode on the switch.

Before You Begin

- In ExtremeCloud IQ - Site Engine, configure your third-party virtualization platform, and the RADIUS server used for Endpoint Tracking authentication. For information about configuring ExtremeCloud IQ - Site Engine, see the ExtremeCloud IQ - Site Engine documentation at https://www.extremenetworks.com/support/documentation/.
- On the switch, add and configure the RADIUS server as configured in ExtremeCloud IQ - Site Engine.
- Create and enable Endpoint Tracking on interfaces.
- Enable Endpoint Tracking globally on the switch.

About This Task

Enable visibility mode to allow MAC learning on static S-UNIs for Endpoint Tracking.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable Endpoint Tracking visibility mode on the switch:

   ```
   endpoint-tracking visibility-mode
   ```

Display Endpoint Tracking Configuration Information

Perform this procedure to display configuration information for Endpoint Tracking.

About This Task

Perform this procedure to display global, interface and binding information for Endpoint Tracking.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the global status of Endpoint Tracking on the switch, and the configured I-SID offset value, if applicable:

   show endpoint-tracking

3. Display the status of all interfaces that have Endpoint Tracking created:

   show endpoint-tracking interfaces [gigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]}] | [mlt <1-512>]]

4. Display a summary of the VLAN:ISID binding information for all ports, or MLT/SMLT interfaces:

   show endpoint-tracking bindings summary

5. Display the VLAN:ISID binding information for the switch, for ports, or for MLT/SMLT interfaces:

   show endpoint-tracking bindings [gigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]}] | [mlt <1-512>]]

Example

The following example displays all of the Endpoint Tracking configuration information for a switch.

```
Switch:1>show endpoint-tracking
================================================================================================
                          Endpoint Tracking Configuration
================================================================================================

                             endpoint tracking status : ENABLED
                               auto-isid-offset value : 15990000
                             auto-isid-offset enabled : ENABLED
                               visibility-mode status : ENABLED

Switch:1>show endpoint-tracking interfaces
================================================================================================

                                  Endpoint Tracking Interfaces
================================================================================================

Switch:1>show endpoint-tracking bindings
================================================================================================================================
                                        Endpoint Tracking Bindings
================================================================================================================================
PORT/MLT  INDEX  MAC                STATUS   VLAN ID  ISID     SOURCE       TIMEOUT             TIME REMAINING
--------------------------------------------------------------------------------------------------------------------------------
1/10      201    00:00:00:00:1b:01  accept   27       15990027 autoconfig   0 day(s), 00:01:40  0 day(s), 00:00:00
1/10      201    00:00:00:00:1b:02  accept   27       15990027 autoconfig   0 day(s), 00:01:40  0 day(s), 00:00:00
1/10      201    00:00:00:00:1b:03  accept   27       15990027 autoconfig   0 day(s), 00:01:40  0 day(s), 00:00:00
1/10      201    00:00:00:00:1b:04  accept   27       15990027 autoconfig   0 day(s), 00:01:40  0 day(s), 00:00:00
1/10      201    00:00:00:00:1b:05  accept   27       15990027 autoconfig   0 day(s), 00:01:40  0 day(s), 00:00:00

5 out of 5 Total Num of Endpoint Tracking bindings displayed.
```

Variable Definitions

The following table defines parameters for the **show endpoint-tracking bindings** command.

Variable	Value
gigabitEthernet *{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}*	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
MLT <1-512>	Specifies the MLT ID.
summary	Provides a summary of the total number and status of bindings for all interfaces.

IS-IS external metric configuration using the CLI

This section provides procedures for IS-IS external metric configuration.

Matching metric type for IS-IS routes

About This Task

Use this procedure to match the external metric-type by using a route-map for any of the following cases:

- accepting a remote IS-IS route with the help of IS-IS accept policies.
- redistributing IS-IS routes into other protocols.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure.
- You must log on to the route-map configuration mode in the CLI.

Procedure

1. Enter Route-Map Configuration mode:

   ```
   enable

   configure terminal

   route-map WORD<1-64> <1-65535>
   ```

2. Match IS-IS metric type:

   ```
   match metric-type-isis {any|internal|external}
   ```

3. Permit the route policy action:

   ```
   permit
   ```

4. Enable the route policy

   ```
   enable
   ```

Example

Match metric type for IS-IS routes:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# route-map ro1 10
Switch:1(route-map)# match metric-type-isis internal
Switch:1(route-map)# permit
Switch:1(route-map)# enable
```

Match metric type for IS-IS routes in accept policies:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# route-map ro1 10
Switch:1(route-map)# match metric-type-isis internal
Switch:1(route-map)# permit
Switch:1(route-map)# enable
Switch:1(route-map)# exit
Switch:1(config)# router isis
Switch:1(config-isis)# accept route-map ro1
Switch:1(config-isis)# exit
Switch:1(config)# isis apply accept
```

Match metric type to redistribute IS-IS routes into some other protocol (OSPF,RIP,BGP)

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# route-map ro1 10
Switch:1(route-map)# match metric-type-isis internal
Switch:1(route-map)# permit
Switch:1(route-map)# enable
Switch:1(route-map)# exit
Switch:1(config)# router bgp
Switch:1(router-bgp)# redistribute isis route-map ro1
Switch:1(router-bgp)# exit
Switch:1(config)# ip bgp apply redistribute
```

Variable Definitions

The following table defines parameters for the **`match metric-type-isis`** command.

Variable	Value
metric-type-isis {any|internal|external}	Specifies the IS-IS metric type: • internal – permits or denies routes that are internal to the IS-IS domain. • external – permits or denies routes that originate from an external routing protocol domain. • any – permits or denies both internal routes as well as external routes.

Setting metric type for IS-IS routes

About This Task

Use this procedure to set the IS-IS external metric-type by using a route-map for any of the following cases:

- accepting a remote IS-IS route with the help of IS-IS accept policies.

- redistributing routes from other protocols into IS-IS.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure.
- You must log on to the route-map configuration mode in the CLI.

Procedure

1. Enter Route-Map Configuration mode:

   ```
   enable

   configure terminal

   route-map WORD<1-64> <1-65535>
   ```

2. Set IS-IS metric type:

   ```
   set metric-type-isis {any|internal|external}
   ```

3. Permit the route policy action:

   ```
   permit
   ```

4. Enable the route policy

   ```
   enable
   ```

Example

Set metric type for IS-IS routes:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# route-map ro1 10
Switch:1(route-map)# set metric-type-isis internal
Switch:1(route-map)# permit
Switch:1(route-map)# enable
```

Set metric type for IS-IS routes in accept policies:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# route-map ro1 10
Switch:1(route-map)# set metric-type-isis internal
Switch:1(route-map)# permit
Switch:1(route-map)# enable
Switch:1(route-map)# exit
Switch:1(config)# router isis
Switch:1(config-isis)# accept route-map ro1
Switch:1(config-isis)# exit
Switch:1(config)# isis apply accept
```

Set metric type to redistribute routes from other protocols into IS-IS:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# route-map ro1 10
Switch:1(route-map)# match metric-type-isis internal
Switch:1(route-map)# permit
Switch:1(route-map)# enable
Switch:1(route-map)# exit
Switch:1(config)# router isis
Switch:1(config-isis)# redistribute bgp route-map ro1
Switch:1(config-isis)# exit
Switch:1(config)# isis apply redistribute
```

Variable Definitions

The following table defines parameters for the **set metric-type-isis** command.

Variable	Value
metric-type-isis {any|internal|external}	Specifies the IS-IS metric type: • internal – permits or denies routes that are internal to the IS-IS domain. • external – permits or denies routes that originate from an external routing protocol domain. • any – permits or denies both internal routes as well as external routes.

Setting metric type for IS-IS routes using global redistribute command

About This Task

Use this procedure to set the IS-IS external metric-type using the global redistribute command for the following cases redistributing routes from other protocols into IS-IS.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure.
- You must log on to the IS-IS router configuration mode in the CLI.

Procedure

1. Enter IS-IS Router Configuration mode:

   ```
   enable

   configure terminal

   router isis
   ```

2. Set IS-IS metric type using global redistribute command:

   ```
   redistribute direct metric-type {internal|external}
   ```

3. Enable the route policy

   ```
   redistribute direct enable
   ```

Example

Set metric type for IS-IS routes using global redistribute command:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# router isis
Switch:1(config-isis)# redistribute direct metric-type internal
Switch:1(config-isis)# redistribute direct enable
```

Variable Definitions

The following table defines parameters for the **redistribute direct metric-type** command.

Variable	Value
metric-type {internal|external}	Specifies the IS-IS metric type: • internal – permits or denies routes that are internal to the IS-IS domain. • external – permits or denies routes that originate from an external routing protocol domain.

SPBM and IS-IS infrastructure configuration using EDM

This section provides procedures to configure basic SPBM and IS-IS infrastructure using Enterprise Device Manager (EDM).

Important

The **EnableSpbmConfigMode** boot flag must be enabled (default) before you can configure SPBM or IS-IS. To verify the setting, navigate to **Configuration** > **Edit** > **Chassis** and click on the Boot Config tab.

Configure Required SPBM and IS-IS Parameters

About This Task

Use the following procedure to configure the minimum required SPBM and IS-IS parameters to enable SPBM to operate on the switch. SPBM uses the Intermediate-System-to-Intermediate-System (IS-IS) link state routing protocol to provide a loop free Ethernet topology that creates a shortest path topology from every node to every other node in the network based on node MAC addresses.

Procedure

1. Configure SBPM B-VLANs:

   Note

   Always configure two B-VLANs in the core to enable load distribution over both B-VLANs.

   a. In the navigation pane, expand **Configuration** > **VLAN**.
   b. Select **VLANs**.
   c. Select the **Basic** tab.
   d. Select **Insert**.
   e. In the **type** field, select **spbm-bvlan**.
   f. Select **Insert**.
2. Enable SPBM globally:
   a. In the navigation pane, expand **Configuration** > **Fabric**.
   b. Select **SPBM**.
   c. Select the **Globals** tab.

d. In the **GlobalEnable** field, select **enable** to enable SPBM globally.
e. Select **Apply**.

3. Create an SPBM instance:

Note
Only one SBPM instance is supported.

a. In the navigation pane, expand **Configuration** > **Fabric**.
b. Select **SPBM**.
c. Select the **SPBM** tab.
d. Select **Insert** to create an SPBM instance.
e. In the **Id** field, specify the SPBM instance ID.
f. In the **NodeNickName** field, specify the node nickname (valid value is 2.5 bytes in the format <x.xx.xx>).
g. In the **Vlans** field, specify the IDs of the SPBM B-VLANs to add to the SPBM instance.
h. In the **PrimaryVlan** field, specify which of the SPBM B-VLANs specified in the previous step is the primary B-VLAN.
i. Select **Insert**.

4. Create a manual area:

Note
Only one manual area is supported.

a. In the navigation pane, expand **Configuration** > **Fabric**.
b. Select **IS-IS**.
c. Select the **Manual Area** tab.
d. Select **Insert**.
e. Specify the Manual Area address (a valid value is 1–13 bytes in the format <xx.xxxx.xxxx...xxxx>).
f. Select **Insert**.

5. Update the default IS-IS system ID to a recognizable address:

a. In the navigation pane, expand **Configuration** > **Fabric**.
b. Select **IS-IS**.
c. Select the **Globals** tab.
d. In the **SystemId** field, update the default B-MAC value to a recognizable address.

Note
Although it is not strictly required for SPBM operation, you must change the IS-IS system ID from the default B-MAC value to a recognizable address to easily identify a switch. This helps to recognize the source and destination addresses for troubleshooting purposes.

e. In the **AdminState** field, select **on**.
f. Select **Apply**.

6. Create an IS-IS circuit and enable SPBM on the circuit:
   a. In the navigation pane, expand **Configuration** > **Fabric**.
   b. Select **IS-IS**.
   c. Select the **Interfaces** tab.
   d. Select **Insert** to create an IS-IS circuit.
   e. In the **IfIndex** field, specify the port or MLT on which to create the IS-IS circuit.
   f. Select **Insert**.
   g. Select the newly created IS-IS circuit entry, and select **SPBM**.
   h. In the **Interfaces SPBM** tab, select **Insert**.
   i. In the **State** field, select **enable**.
   j. Select **Insert**. This enables the SPBM instance on the IS-IS circuit.
   k. Navigate back to the **Interfaces** tab.
   l. In the **AdminState** field for the IS-IS circuit entry, select **on** to enable the IS-IS circuit.
   m. Select **Apply**.

SPBM Field Descriptions

Note

The following tables list the minimum required SPBM and IS-IS parameters to allow SPBM to operate on the switch. For more detailed information on all of the parameters see the procedures that follow. For more information on how to configure VLANs, see VLAN Configuration using EDM on page 3454.

Use the data in the following table to use the **VLANs Basic** tab.

Name	Description
Type	Specifies the type of VLAN: • byPort • byProtocolId • spbm-bvlan • private

Use the data in the following table to use the **SPBM Globals** tab.

Name	Description
GlobalEnable	Enables or disables SPBM globally. The default is disabled. To ensure proper cleanup of MAC tables after you disable SPBM, save the configuration, and then reboot the switch.
GlobalEtherType	Specifies the global ethertype value as 0x8100 or 0x88a8. The default value is 0x8100.
NicknameServerEnable	Enables or disables the nickname server. The default is disabled.

Name	Description
NicknameDynamicAllocationStatus	Displays the Dynamic Nickname Allocation service operational status.
NicknameServerPrefix	Specifies the nickname server allocation prefix. x.xx.xx uses the form X.X0.00 from 0.00.00 to F.F0.00. A group, X.X0.00 to X.XF.FF, can provide up to 4,096 nicknames. The default is A.00.00.

Use the data in the following table to use the **SPBM** tab.

Name	Description
Id	Specifies the SPBM instance ID. Only one SPBM instance is supported.
NodeNickName	Specifies a nickname for the SPBM instance globally. Valid value is 2.5 bytes in the format <x.xx.xx>.
PrimaryVlan	Specifies the primary SPBM B-VLANs to add to the SPBM instance.
Vlans	Specifies the SPBM B-VLANs to add to the SPBM instance.
LsdbTrap	Configures whether to enable or disable a trap when the SPBM LSDB changes. The default is disable.
IpShortcut	Enables or disables SPBM IP shortcut state. The default is disable.
SmltSplitBEB	Specifies whether the switch is the primary or secondary vIST peer. The default is primary.
SmltVirtualBmac	Specifies a virtual MAC address that can be used by both peers.
SmltPeerSysId	Specifies the system ID of the SPBM SMLT for this SPBM instance.
Mcast	Specifies if IP multicast over SPBM is enabled. The default is disabled.
McastFwdCacheTimeout	Specifies the global forward cache timeout in seconds. The default is 210 seconds.
Ipv6Shortcut	Enables or disables SPBM IPv6 shortcut state. The default is disable.
McastSpbPimGwControllerEnable	Enables or disables ISIS PLSB Multicast SPB PIM Gateway controller. Disabled by default.
McastSpbPimGwGatewayEnable	Enables or disables ISIS PLSB Multicast SPB PIM Gateway. Disabled by default.

Name	Description
StpMultiHoming	Enables or disables MSTP-Fabric Connect Multi Homing. The default is disabled (false).
BVlanOrigin	Shows how the B-VLAN was created. The values can be config for manual configuration using CLI or SNMP, or dynamic through Zero Touch Fabric Configuration and Auto-sense. The default is dynamic.

Use the data in the following table to use the **IS-IS Manual Area** tab.

Name	Description
AreaAddr	Specifies the IS-IS manual area. Valid value is 1-13 bytes in the format <xx.xxxx.xxxx...xxxx>. Only one manual area is supported. Use the same manual area across the entire SPBM cloud. For IS-IS to operate, you must configure at least one manual area.

Use the data in the following table to use the **IS-IS Globals** tab.

Name	Description

Use the data in the following table to use the **IS-IS Interfaces** tab.

Name	Description
Index	The identifier of this circuit, unique within the Intermediate System. This value is for SNMP Indexing purposes only and need not have any relation to any protocol value.
AdminState	Specifies the administrative state of the circuit: on or off.

Use the data in the following table to use the **IS-IS Interfaces SPBM** tab.

Name	Description
State	Specifies whether the SPBM interface is enabled or disabled.

Job aid

Important

After you have configured the SPBM nickname and enabled IS-IS. To maintain the same nickname with a different system ID, perform the following steps:

1. Disable IS-IS.
2. Change the system ID.
3. Change the nickname to a temporary one.
4. Enable IS-IS.
5. Wait up to 20 minutes for the LSPs with the original system ID to age out.

   Note

   To check the age out time, use the **`show isis lsdb sysid <original-sys-id>`** command on any of the other SPB nodes in the network. When there is no output from this command, proceed to the next step. The time left (in seconds) for the LSPs to age out is shown under the column **LIFETIME**.
6. Disable IS-IS.
7. Change the nickname to the original nickname.
8. Enable IS-IS.

Displaying SPBM and IS-IS summary information

Use the following procedure to view a summary of SPBM and IS-IS protocol information.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **IS-IS**.
3. Select the **Protocol Summary** tab.

Protocol Summary field descriptions

Use the data in the following table to use the **Protocol Summary** tab.

Name	Description
Globals ISIS	
AdminState	Indicates the global status of IS-IS on the switch.
SystemId	Indicates the IS-IS system ID for the switch. Valid value is a 6–byte value in the format <xxxx.xxxx.xxxx>
HostName	Indicates a name for the system. This may be used as the host name for dynamic host name exchange in accordance with RFC 2763. By default, the system name comes from the host name configured at the system level.
Globals SPBM	
GlobalEnable	Indicates whether SPBM is enabled or disabled at the global level.

Name	Description
NodeNickName	Indicates the nickname for the SPBM instance globally. Valid value is 2.5 bytes in the format <x.xx.xx>.
PrimaryVlan	Indicates the primary VLAN ID for this SPBM instance.
SmltSplitBEB	Indicates whether the switch is the primary or secondary IST peer.
ISIS Interfaces	
Circuit Index	Displays the identifier of this IS-IS circuit, unique within the Intermediate System. This is for SNMP Indexing purposes only and need not have any relation to any protocol value.
IfIndex	Indicates the interface to which this circuit corresponds.
AdminState	Indicates the administrative state of the circuit: on or off.
OperState	Indicates the operational state of the circuit: up or down.
ISIS Adjacency View	
Circuit Index	Displays the identifier of this IS-IS circuit, unique within the Intermediate System. This value is for SNMP Indexing purposes only and need not have any relation to any protocol value.
AdjIndex	Displays a unique value identifying the IS adjacency from all other such adjacencies on this circuit. This value is automatically assigned by the system when the adjacency is created
AdjIfIndex	Indicates the interface to which this circuit corresponds.
AdjState	Indicates the state of the adjacency: • down • initializing • up • failed
AdjNeighSysID	Indicates the system ID of the neighboring Intermediate System.
AdjHostName	Indicates the host name listed in the LSP, or the system name if the host name is not configured.

View the SPBM I-SID Information

Use the following procedure to display the SPBM Service Instance Identifier (I-SID) information. The SPBM B-MAC header includes an I-SID with a length of 24 bits. This I-SID can be used to identify and transmit any virtualized traffic in an encapsulated SPBM frame.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **SPBM**.
3. Select the **I-SID** tab.

I-SID field descriptions

Use the data in the following table to use the **I-SID** tab.

Name	Description
SysId	Indicates the system identifier.
Vlan	Indicates the B-VLAN where this I-SID was configured or discovered.
Isid	Indicates the IS-IS SPBM I-SID identifier.
NickName	Indicates the nickname of the node where this I-SID was configured or discovered.
HostName	Indicates the host name listed in the LSP, or the system name if the host name is not configured.
Type	Indicates the SPBM I-SID type; either configured or discovered.

View Level 1 Area Information

Use the following procedure to display Level 1 area information. IS-IS provides support for hierarchical routing, which enables you to partition large routing domains into smaller areas. IS-IS uses a two-level hierarchy, dividing the domain into multiple Level 1 areas and one Level 2 area. The Level 2 area serves as backbone of the domain, connecting to all the Level 1 areas.

Important

The IEEE 802.1aq standard currently only defines the use of one hierarchy, Level 1. Level 2 function is disabled.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **IS-IS**.
3. Select the **L1 Area** tab.

L1 Area field descriptions

Use the data in the following table to use the **L1 Area** tab.

Table 88:

Name	Description
AreaAddr	Specifies an area address reported in a Level 1 link-state packets (LSP) generated or received by this Intermediate System.

Configure SMLT Parameters for SPBM

Use the following procedure to configure the required Split MultiLink Trunking (SMLT) parameters to enable SPBM to interoperate with SMLT on the switch.

Note

- The assignment of primary and secondary roles to the vIST peers is automatic. The switch with the lower system ID (between the two vIST peers) is primary, and the switch with the higher system ID is secondary when default system-id values are being used.
- SMLT peer system ID is part of the required configuration. You must configure the SMLT peer system ID as the nodal MAC of the peer device. In the IS-IS network, the nodal MAC of devices should be eight apart from each other.
- When using the default hardware assigned system-id value, the SMLT Virtual BMAC is automatically derived by comparing the system-id values of the two vIST peers. A value of 0x01 plus the lower of the two system-id values is used as the SMLT Virtual BMAC.

  When using a manually configured system-id value, the SMLT Virtual BMAC must also be manually configured.
- An I-SID must be assigned to every VLAN that is a member of an Layer 2 VSN. Also if an Layer 2 VSN is created on one vIST Peer, it must also be created on the other vIST peer.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **SPBM**.
3. Select the **SPBM** tab.
4. Use the **SmltSplitBEB** field to see whether the switch is the primary or secondary vIST peer. This field cannot be modified.
5. Use the **SmltVirtualBmac** field to specify a virtual MAC address that can be used by both peers.
6. Use the **SmltPeerSysId** field to specify the vIST peer B-MAC address.
7. Select **Apply**.

Enable or Disable SPBM at the Global Level

Use the following procedure to enable or disable SPBM at the global level. SPBM uses the Intermediate-System-to-Intermediate-System (IS-IS) link state routing protocol to provide a loop free Ethernet topology that creates a shortest path topology from every node to every other node in the network based on node MAC addresses.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **SPBM**.
3. Select the **Globals** tab.
4. To enable or disable SPBM, select **enable** or **disable** in the **GlobalEnable** field.
5. To configure the global ethertype value, select the desired option in the **GlobalEtherType** field.
6. Select **Apply**.

Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
GlobalEnable	Enables or disables SPBM globally. The default is disabled. To ensure proper cleanup of MAC tables after you disable SPBM, save the configuration, and then reboot the switch.
GlobalEtherType	Specifies the global ethertype value as 0x8100 or 0x88a8. The default value is 0x8100.
NicknameServerEnable	Enables or disables the nickname server. The default is disabled.
NicknameDynamicAllocationStatus	Displays the Dynamic Nickname Allocation service operational status.
NicknameServerPrefix	Specifies the nickname server allocation prefix. x.xx.xx uses the form X.X0.00 from 0.00.00 to F.F0.00. A group, X.X0.00 to X.XF.FF, can provide up to 4,096 nicknames. The default is A.00.00.

Configuring SPBM parameters

Use the following procedure to configure SPBM global parameters. SPBM uses the Intermediate-System-to-Intermediate-System (IS-IS) link state routing protocol to provide a loop free Ethernet topology that creates a shortest path topology from every node to every other node in the network based on node MAC addresses.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **SPBM**.
3. Select the **SPBM** tab.
4. To create an SPBM instance, click **Insert**.
5. Configure the SPBM parameters.
6. Select **Apply**.

SPBM Field Descriptions

Use the data in the following table to use the **SPBM** tab.

Name	Description
Id	Specifies the SPBM instance ID. Only one SPBM instance is supported.
NodeNickName	Specifies a nickname for the SPBM instance globally. Valid value is 2.5 bytes in the format <x.xx.xx>.
PrimaryVlan	Specifies the primary SPBM B-VLANs to add to the SPBM instance.

Name	Description
Vlans	Specifies the SPBM B-VLANs to add to the SPBM instance.
LsdbTrap	Configures whether to enable or disable a trap when the SPBM LSDB changes. The default is disable.
IpShortcut	Enables or disables SPBM IP shortcut state. The default is disable.
SmltSplitBEB	Specifies whether the switch is the primary or secondary vIST peer. The default is primary.
SmltVirtualBmac	Specifies a virtual MAC address that can be used by both peers.
SmltPeerSysId	Specifies the system ID of the SPBM SMLT for this SPBM instance.
Mcast	Specifies if IP multicast over SPBM is enabled. The default is disabled.
McastFwdCacheTimeout	Specifies the global forward cache timeout in seconds. The default is 210 seconds.
Ipv6Shortcut	Enables or disables SPBM IPv6 shortcut state. The default is disable.
McastSpbPimGwControllerEnable	Enables or disables ISIS PLSB Multicast SPB PIM Gateway controller. Disabled by default.
McastSpbPimGwGatewayEnable	Enables or disables ISIS PLSB Multicast SPB PIM Gateway. Disabled by default.
StpMultiHoming	Enables or disables MSTP-Fabric Connect Multi Homing. The default is disabled (false).
BVlanOrigin	Shows how the B-VLAN was created. The values can be config for manual configuration using CLI or SNMP, or dynamic through Zero Touch Fabric Configuration and Auto-sense. The default is dynamic.

Displaying SPBM nicknames

Use the following procedure to display SPBM nicknames.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **SPBM**.
3. Select the **Nick Names** tab.

Nickname field descriptions

Use the data in the following table to use the **NickName** tab.

Name	Description
Level	Indicates the level at which the system displays this LSP.
ID	Indicates the 8 byte LSP ID, consisting of the SystemID, Circuit ID, and Fragment Number.
LifetimeRemain	Indicates the remaining lifetime in seconds for the LSP.
NickName	Indicates the nickname for the SPBM node.
HostName	Indicates the hostname listed in the LSP, or the system name if the host name is not configured.

Configure Interface SPBM Parameters

Use the following procedure to configure the SPBM interface parameters.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **SPBM**.
3. Select the **Interfaces SPBM** tab.
4. Configure the SPBM interface parameters.
5. Select **Apply**.

Interfaces SPBM Field Descriptions

Use the data in the following table to use the **Interfaces SPBM** tab.

Name	Description
Index	Specifies an Index value for the SPBM interface.
SpbmId	Specifies the SPBM ID.
State	Specifies whether the SPBM interface is enabled or disabled.
Type	Configures the SPBM instance interface-type on the IS-IS interface located on the specified port or MLT: ptpt or bcast. Only the point-to-point (ptpt) interface type is supported.
L1Metric	Configures the IS-IS Interface level 1 metric on the specified port or MLT. The default value is 10.
Origin	Specifies the source of the SPBM instance configuration, either manually configured through CLI or EDM, or dynamically configured through Auto-sense.

Configuring SPBM on an interface

Use the following procedure to configure SPBM on an interface.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **IS-IS**.

3. Select the **Interfaces** tab.
4. Select the **SPBM** button.
5. In the **Interfaces SPBM** tab, select **Insert**.
6. Select **Insert**.

SPBM field descriptions

Use the data in the following table to use the **Interfaces SPBM** tab.

Name	Description
Index	Specifies an Index value for the SPBM interface.
SpbmId	Specifies the SPBM ID.
State	Specifies whether the SPBM interface is enabled or disabled.
Type	Configures the SPBM instance interface-type on the IS-IS interface located on the specified port or MLT: ptpt or bcast. Only the point-to-point (ptpt) interface type is supported.
L1Metric	Configures the IS-IS Interface level 1 metric on the specified port or MLT. The default value is 10.
Origin	Specifies the source of the SPBM instance configuration, either manually configured through CLI or EDM, or dynamically configured through Auto-sense.

View the IP Unicast FIB

Use the following procedure to display the IP unicast Forwarding Information Base (FIB). The tab shows IP routes from remote Backbone Edge Bridges (BEBs)

In SPBM, each node has a System ID, which also serves as Backbone MAC address (B-MAC) of the switch. These Backbone MAC addresses are populated into the SPBM VLAN Forwarding Information Base (FIB). When the network topology is discovered and stored in the IS-IS link-state database, each node calculates shortest path trees for each source node, so that a unicast path now exists from every node to every other node. With this information, each node populates unicast information received from SPBM into the FIB for forwarding purposes.

I-SIDs are only used for virtual services (Layer 2 VSNs and Layer 3 VSNs). If you only enable IP Shortcuts on the Backbone Edge Bridges, I-SIDs are never exchanged in the network as IP Shortcuts allows for Global Routing Table (GRT) IP networks to be transported across IS-IS.

The **IP Unicast FIB** tab displays all of the IS-IS routes in the IS-IS LSDB. The Preference column in the **IP Unicast FIB** tab displays the IP route preference.

Routes within the same VSN are added to the LSDB with a default preference of 7. Inter-VSN routes are added to the LSDB with a route preference of 200. IS-IS accept policies allow you to change the route preference for incoming routes. If the same route is learned from multiple sources with different route preferences, then the routes are not considered equal cost multipath (ECMP) routes. The route with the lowest route preference is the preferred route. In Layer 2, in the event of a tie-break between routes from multiple sources, the tie-breaking is based on cost and hop count.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **SPBM**.
3. Select the **IP Unicast FIB** tab.

IP Unicast FIB field descriptions

Use the data in the following table to use the **IP Unicast FIB** tab.

Name	Description
VrfId	Specifies the VRF ID of the IP unicast FIB entry, 0 indicates NRE.
DestinationIpAddrType	Specifies the address type of the destination IP address.
DestinationIpAddr	Specifies the destination IP Address of the IP unicast FIB entry.
DestinationMask	Specifies the destination IP mask of the IP unicast FIB entry
NextHopBmac	Specifies the nexthop B-MAC of the IP unicast FIB entry.
DestId	Specifies the destination I-SID of the IP unicast FIB entry.
Vlan	Specifies the VLAN of the IP unicast FIB entry.
Isid	Specifies the I-SID of the IP unicast FIB entry.
NextHopName	Specifies the nexthop hostname of the IP unicast FIB entry.
OutgoingPort	Specifies the outgoing port of the IP unicast FIB entry.
PrefixCost	Specifies the prefix cost of the IP unicast FIB entry.
SpbmCost	Specifies the B-MAC cost of the IP unicast FIB entry.
Preference	Specifies the IP Route preference of the IP unicast FIB entry
MetricType	Specifies the IP Metric Type of the IP unicast FIB entry.

View the IPv6 Unicast FIB

Use the following procedure to display the IPv6 unicast Forwarding Information Base (FIB). The tab shows IPv6 routes from remote Backbone Edge Bridges (BEBs)

In SPBM, each node has a System ID, which also serves as Backbone MAC address (B-MAC) of the switch. These Backbone MAC addresses are populated into the SPBM VLAN Forwarding Information Base (FIB). When the network topology is discovered and stored in the IS-IS link-state database, each node calculates shortest path trees for each source node, so that a unicast path now exists from every node to every other node. With this information, each node populates unicast information received from SPBM into the FIB for forwarding purposes.

I-SIDs are only used for virtual services (Layer 2 VSNs and Layer 3 VSNs). If you only enable IP Shortcuts on the Backbone Edge Bridges, I-SIDs are never exchanged in the network as IP Shortcuts allows for Global Routing Table (GRT) IP networks to be transported across IS-IS.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.

2. Select **SPBM**.
3. Select the **IPv6 Unicast FIB** tab.

IPv6 Unicast FIB Field Descriptions

Use the data in the following table to use the **IPv6 Unicast FIB** tab.

Name	Description
VrfId	Specifies the VRF ID of the IPv6 unicast FIB entry, 0 indicates NRE.
DestinationIpAddrType	Specifies the address type of the destination IPv6 address.
DestinationIpAddr	Specifies the destination IPv6 Address of the IPv6 unicast FIB entry.
DestinationMask	Specifies the destination IPv6 mask of the IPv6 unicast FIB entry
NextHopBmac	Specifies the nexthop B-MAC of the IPv6 unicast FIB entry.
DestIsid	Specifies the destination I-SID of the IPv6 unicast FIB entry.
Vlan	Specifies the VLAN of the IPv6 unicast FIB entry.
Isid	Specifies the I-SID of the IPv6 unicast FIB entry.
NextHopName	Specifies the nexthop hostname of the IPv6 unicast FIB entry.
OutgoingPort	Specifies the outgoing port of the IPv6 unicast FIB entry.
PrefixCost	Specifies the prefix cost of the IPv6 unicast FIB entry.
SpbmCost	Specifies the B-MAC cost of the IPv6 unicast FIB entry.
MetricType	Specifies the Metric Type of the IPv6 unicast FIB entry.

View the Unicast FIB

Use the following procedure to display the unicast FIB.

In SPBM, B-MAC addresses are carried within the IS-IS link-state database. To do this, SPBM supports an IS-IS TLV that advertises the I-SID and B-MAC information across the network. Each node has a System ID, which also serves as Backbone MAC address (B-MAC) of the switch. These Backbone MAC addresses are populated into the SPBM VLAN Forwarding Information Base (FIB).

When the network topology is discovered and stored in the IS-IS link-state database, each node calculates shortest path trees for each source node, so that a unicast path now exists from every node to every other node. With this information, each node populates unicast information received from SPBM into the FIB for forwarding purposes.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **SPBM**.
3. Select the **Unicast FIB** tab.

Unicast FIB field descriptions

Use the data in the following table to use the **Unicast FIB** tab.

Name	Description
SysId	Specifies the system ID of the node where the unicast FIB entry originated.
Vlan	Specifies the VLAN of the unicast FIB entry.
DestinationMacAddr	Specifies the destination MAC Address of the unicast FIB entry.
OutgoingPort	Specifies the outgoing port of the unicast FIB entry.
HostName	Specifies the host name of the node where unicast FIB entry originated.
Cost	Specifies the cost of the unicast FIB entry.

View LSP Summary Information

Use the following procedure to display link-state packet (LSP) summary information. Link State Packets (LSP) contain information about the state of adjacencies or defined and distributed static routes. Intermediate System to Intermediate System (IS-IS) exchanges this information with neighboring IS-IS routers at periodic intervals.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **IS-IS**.
3. Select the **LSP Summary** tab.

LSP Summary field descriptions

Use the data in the following table to use the **LSP Summary** tab.

Table 89:

Level	Specifies the level at which the system displays this LSP.
ID	Specifies the 8 byte LSP ID, consisting of the SystemID, Circuit ID, and Fragment Number.
Seq	Specifies the sequence number for this LSP.
Checksum	Specifies the 16 bit Fletcher Checksum for this LSP.
LifetimeRemain	The remaining lifetime in seconds for this LSP.
HostName	The hostname listed in LSP, or the system name if host name is not configured.

View IS-IS Adjacencies

Use the following procedure to display IS-IS adjacency information. The platform sends IS-IS Hello (IIH) packets to discover IS-IS neighbors and establish and maintain IS-IS adjacencies. The platform continues to send IIH packets to maintain the established adjacencies. For two nodes to form an adjacency the B-VLAN pairs for the primary B-VLAN and secondary B-VLAN must match.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **IS-IS**.
3. Select the **Adjacency** tab.

Adjacency field descriptions

Use the data in the following table to use the **Adjacency** tab.

Name	Description
Interface	Specifies the IS-IS interface on which the adjacency is found.
Level	Indicates the level of the IS-IS interface (Level 1 [default] or Level 2).
State	Specifies the state of the adjacency: • down • initializing • up • failed
LastUpTime	Indicates when the adjacency most recently entered the state **up**, measured in hundredths of a second since the last re-initialization of the network management subsystem. Displays 0 if the adjacency has never been in state **up**.
NeighPriority	Specifies the priority of the neighboring Intermediate System for becoming the Designated Intermediate System.
HoldTimer	Specifies the holding time in seconds for this adjacency. This value is based on received IS-IS Hello (IIH) PDUs and the elapsed time since receipt.
NeighSysID	Specifies the system ID of the neighboring Intermediate System.
AdjHostName	Specifies the host name listed in the LSP, or the system name if host name is not configured.
ParallelActive	Specifies if the current adjacency among all the parallel adjacencies between two nodes is active. • true • false

Configure IS-IS Global Parameters

Use the following procedure to configure IS-IS global parameters. SPBM uses IS-IS to discover network topology, build shortest path trees between network nodes, and communicate network information in the control plane.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.

2. Select **IS-IS**.
3. Select the **Globals** tab.
4. Configure the global IS-IS parameters.
5. Select **Apply**.

Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
AdminState	Specifies the global status of IS-IS on the switch: on or off. The default is off.
LevelType	Sets the router type globally: • level1: Level-1 router type • level1and2: Level–1/2 router type is not supported. The default value is level1.
SystemId	Specifies the IS-IS system ID for the switch. Valid value is a 6–byte value in the format <xxxx.xxxx.xxxx>. Important: After you have configured the SPBM nickname and enabled IS-IS, if you require a change of the system ID, you must also change the nickname. However, for naming convention purposes or configuration purposes, you may not want to change the nickname. To maintain the same nickname with a different system ID, see Job aid on page 912.
MaxLspGenInt	Specifies the maximum interval, in seconds, between generated LSPs by this Intermediate system. The value must be greater than any value configured for RxmtLspInt. The default value is 900 seconds.
CsnpInt	Specifies the Complete Sequence Number Packet (CSNP) interval in seconds. This is a system level parameter that applies for L1 CSNP generation on all interfaces. The default value is 10.
RxmtLspInt	Specifies the minimum time between retransmission of an LSP. This defines how fast the switch resends the same LSP. This is a system level parameter that applies for L1 retransmission of LSPs. The default value is 5 seconds.

Name	Description
PSNPInterval	Specifies the Partial Sequence Number Packet (PSNP) interval in seconds. This is a system level parameter that applies for L1 PSNP generation on all interfaces. The default value is 2.
SpfDelay	Specifies the SPF delay in milliseconds. This value is used to pace successive SPF runs. The timer prevents two SPF runs from being scheduled very closely. The default value is 100 milliseconds.
HostName	Specifies a name for the system. This can be used as the host name for dynamic host name exchange in accordance with RFC 2763. By default, the system name comes from the host name configured at the system level.
IpSourceAddress	Specifies IP source address for SPBM IP shortcuts.
Ipv6SourceAddress	Specifies IPv6 source address for SPBM IP shortcuts.
IpTunnelSourceAddress	Specifies the IS-IS IPv4 tunnel source address.
IpTunnelVrf	Specifies the VRF name associated with the IP tunnel.
IpTunnelOverlay	Permits the configuration of the tunnel source address even though it belongs to a VRF with an attached I-SID. The default is disabled.
MgmtClipIpAddr	Specifies the DvR management IP address for this node, in the DvR domain.
BackboneEnable	Select to enable this node to join the DvR backbone so that it can receive redistributed DvR host routes from all DvR Controllers in the network.
FanMember	Specifies whether the node is a member of the Fabric Area Network (FAN) .
DynamicallyLearnedArea	For FAN members, specifies the IS-IS area that is dynamically learned from the neighbor's Hello PDU if the node does not have the IS-IS manual area configured.
HelloPadding	Configures IS-IS hello padding on all IS-IS network-to-network interface (NNI) links. IS-IS hello padding is enabled by default.

Configuring system-level IS-IS parameters

Use the following procedure to configure system-level IS-IS parameters.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric** > **IS-IS**.
2. Select the **System Level** tab.

3. Configure the IS-IS system level parameters.
4. Select **Apply**.

System Level field descriptions

Use the data in the following table to use the **System Level** tab.

Name	Description
Index	Specifies the level: l1 or l2. Only l1 is supported.
State	Specifies the state of the database at this level. The value 'off' indicates that IS-IS is not active at this level. The value 'on' indicates that IS-IS is active at this level, and not overloaded. The value 'waiting' indicates a database that is low on an essential resources, such as memory. The administrator may force the state to 'overloaded' by setting the object **SetOverload**. If the state is 'waiting' or 'overloaded', you originate LSPs with the Overload bit set.
SetOverload	Sets or clears the overload condition. The possible values are true or false. The default value is false.
SetOverloadUntil	Sets the IS-IS overload-on-startup value in seconds. The overload-on-startup value is used as a timer to control when to send out LSPs with the overload bit cleared after IS-IS startup. Note: If you configure **SetOverloadUntil** to a number other than zero, then the overload bit is set at this level when the **AdminState** variable goes to the state 'on' for this Intermediate System. After the **SetOverloadUntil** seconds elapse, the overload flag remains set if the implementation runs out of memory or if you configured it manually using **SetOverload** to true. If **SetOverload** is false, the system clears the overload bit after **SetOverloadUntil** seconds elapse, if the system has not run out of memory. The default value is 20.
MetricStyle	Specifies the IS-IS metric type. Available values are narrow, wide or both. Only wide is supported.

View IS-IS System Statistics

Use the following procedure to view the Intermediate-System-to-Intermediate-System (IS-IS) system statistics.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **Stats**.
3. Select the **System Stats** tab.

System Stats field descriptions

Use the data in the following table to use the **System Stats** tab.

Name	Description
CorrLSPs	Indicates the number of corrupted in-memory link-state packets (LSPs) detected. LSPs received from the wire with a bad checksum are silently dropped and not counted.
AuthFails	Indicates the number of authentication key failures recognized by this Intermediate System.
LSPDbaseOloads	Indicates the number of times the LSP database has become overloaded.
ManAddrDropFromAreas	Indicates the number of times a manual address has been dropped from the area.
AttmptToExMaxSeqNums	Indicates the number of times the IS has attempted to exceed the maximum sequence number.
SeqNumSkips	Indicates the number of times a sequence number skip has occurred.
OwnLSPPurges	Indicates the number of times a zero-aged copy of the system's own LSP is received from some other node.
IDFieldLenMismatches	Indicates the number of times a PDU is received with a different value for ID field length to that of the receiving system.
PartChanges	Indicates partition changes.
AbsoluteValue	Displays the counter value.
Cumulative	Displays the total value since you opened the Stats tab.
Average/sec	Displays the average value for each second.
Minimum/sec	Displays the minimum value for each second.
Maximum/sec	Displays the maximum value for each second.
LastVal/sec	Displays the last value for each second.

Configure IS-IS Interfaces

Use the following procedure to configure the IS-IS interfaces. SPBM uses IS-IS to discover network topology, build shortest path trees between network nodes, and communicate network information in the control plane.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **IS-IS**.
3. Select the **Interfaces** tab.
4. Configure the IS-IS interface parameters.
5. Select **Apply**.

Interfaces Field Descriptions

Use the data in the following table to use the **Interfaces** tab.

Name	Description
Index	The identifier of this circuit, unique within the Intermediate System. This value is for SNMP Indexing purposes only and need not have any relation to any protocol value.
IfIndex	Specifies the interface on which the circuit is configured (port or MLT).
Type	Specifies the IS-IS circuit type. Only the point-to-point (PtToPt) interface type is supported.
AdminState	Specifies the administrative state of the circuit: on or off.
OperState	Specifies the operational state of the circuit.
AuthType	Specifies the authentication type: • none • simple: If selected, you must also specify a key value but the key id is optional. Simple password authentication uses a text password in the transmitted packet. The receiving router uses an authentication key (password) to verify the packet. • hmac-md5: If selected, you must also specify a key value, but the key-id is optional. MD5 authentication creates an encoded checksum in the transmitted packet. The receiving router uses an authentication key (password) to verify the MD5 checksum of the packet. There is an optional key ID. • hmac-sha–256: If selected, you must also specify a key value, but the key-id is optional. With SHA-256 authentication, the switch adds an hmac-sha–256 digest to each Hello packet. The switch that receives the Hello packet computes the digest of the packet and compares it with the received digest. If the digests match, the packet is accepted. If the digests do not match, the receiving switch discards the packet. There is an optional key ID. Note: Secure Hashing Algorithm 256 bits (SHA-256) is a cipher and a cryptographic hash function of SHA2 authentication. You can use SHA-256 to authenticate IS-IS Hello messages. This authentication method uses the SHA-256 hash function and a secret key to establish a secure connection between switches that share the same key. This feature is in full compliance with RFC 5310. The default is none.
AuthKey	Specifies the authentication key.

Name	Description
KeyId	Specifies the authentication key ID.
LevelType	Specifies the router type globally: • level1: Level-1 router type • level 1and2: Level–1/2 router type. This type is not supported. The default value is level1.
NumAdj	Specifies the number of adjacencies on this circuit.
NumUpAdj	Specifies the number of adjacencies that are up.
AutoNniEnable	Enable to have the node create an IS-IS interface, attach the interface to an SPBM instance, and then enable IS-IS on the port interface. This field displays on the Insert Interfaces dialog box and applies to port interfaces only.
Origin	Specifies the origin of the IS-IS circuit configuration on the port, either manually configured through CLI or EDM or dynamically configured through Auto-sense.

Configure IS-IS Interface Level Parameters

Use the following procedure to configure IS-IS interface level parameters. SPBM uses IS-IS to discover network topology, build shortest path trees between network nodes, and communicate network information in the control plane.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **IS-IS**.
3. Select the **Interfaces Level** tab.
4. Configure the IS-IS interface level parameters.
5. Select **Apply**.

Interfaces Level Field Descriptions

Use the data in the following table to use the **Interfaces Level** tab.

Name	Description
Index	The identifier of this circuit, unique within the Intermediate System. This value is for SNMP Indexing purposes only and need not have any relation to any protocol value.
Level	Specifies the router type globally: • l1: Level1 router type • l12: Level1/Level2 router type. This type is not supported. The default value is l1.
ISPriority	Specifies an integer sub-range for IS-IS priority. The default is 64.

Name	Description
HelloTimer	Configures the level 1 hello interval. Specifies the maximum period, in milliseconds, between IS-IS Hello Packets (IIH) PDUs on multiaccess networks at this level for LANs. The value at Level1 is used as the period between Hellos on Level1/Level2 point to point circuits. Setting this value at Level 2 on an Level1/Level2 point-to-point circuit results in an error of InconsistentValue. The default value is 9000 milliseconds or 9 seconds.
HelloMultiplier	Configures the level 1 hello multiplier. The default value is 3 seconds.
DRHelloTimer	Indicates the period, in milliseconds, between Hello PDUs on multiaccess networks when this Intermediate System is the Designated Intermediate System. The default is 3.

View IS-IS Interface Counters

Use the following procedure to view the Intermediate-System-Intermediate-System (IS-IS) interface counters.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **Stats**.
3. Select the **Interface Counters** tab.

Interface Counters Field Descriptions

Use the data in the following table to use the **Interface Counters** tab.

Name	Description
Index	Shows a unique value identifying the IS-IS interface.
Level	Shows the type of circuit that discovered the interface counters. The point to point Hello PDU includes both Layer 1 and Layer 2, and IS from a single adjacency on point to point links, therefore combining counts on point to point links into one group.
AdjChanges	Shows the number of times an adjacency state change has occurred on this circuit.
InitFails	Shows the number of times initialization of this circuit has failed. This counts events such as PPP NCP failures. Failures to form an adjacency are counted by isisCircRejAdjs.
RejAdjs	Shows the number of times an adjacency has been rejected on this circuit.
IDFieldLenMismatches	Shows the number of times an IS-IS control PDU with an ID field length different to that for this system has been received.
MaxAreaAddrMismatches	Shows the number of times an IS-IS control PDU with a max area address field different to that for this system has been received.

Name	Description
AuthFails	Shows the number of times an IS-IS control PDU with the correct auth type has failed to pass authentication validation.
LANDesISChanges	Shows the number of times the Designated IS has changed on this circuit at this level. If the circuit is point to point, this count is zero.

View IS-IS interface control packets

Use the following procedure to view the Intermediate-System-to-Intermediate-System (IS-IS) interface control packets.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **Stats**.
3. Select the **Interface Control Packets** tab.

Interface Control Packets Field Descriptions

Use the data in the following table to use the **Interface Control Packets** tab.

Name	Description
Index	Shows a unique value identifying the Intermediate-System-to-Intermediate-System (IS-IS) interface.
Direction	Indicates whether the switch is sending or receiving the PDUs.
Hello	Indicates the number of IS-IS Hello frames seen in this direction at this level.
LSP	Indicates the number of IS-IS LSP frames seen in this direction at this level.
CSNP	Indicates the number of IS-IS Complete Sequence Number Packets (CSNP) frames seen in this direction at this level.
PSNP	Indicates the number of IS-IS Partial Sequence Number Packets (PSNP) frames seen in this direction at this level.

View Statistical Graph of IS-IS Interface Counters

Use the following procedure to view statistical graph of the IS-IS interface counters.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **IS-IS**.
3. Select the **Interfaces** tab.
4. Select an interface.
5. Select the **Graph** button.

Interface Counters field descriptions

The following table describes the fields in the **Interface Counters** tab.

Name	Description
InitFails	Indicates the number of times initialization of this circuit has failed. This counts events such as PPP NCP failures.
RejAdjs	Indicates the number of times an adjacency has been rejected on this circuit.
IDFieldLenMismatches	Indicates the number of times an Intermediate-System-to-Intermediate-System (IS-IS) control PDU with an ID field length different from that for this system has been received.
MaxAreaAddrMismatches	Indicates the number of times an IS-IS control PDU with a max area address field different from that for this system has been received.
AuthFails	Indicates the number of times an IS-IS control PDU with the correct auth type has failed to pass authentication validation.
LANDesISChanges	Indicates the number of times the Designated IS has changed on this circuit at this level. If the circuit is point to point, this count is zero.
AbsoluteValue	Displays the counter value.
Cumulative	Displays the total value since you opened the Stats tab.
Average/Sec	Displays the average value for each second.
Minimum/Sec	Displays the minimum value for each second.
Maximum/Sec	Displays the maximum value for each second.
Last Val/Sec	Displays the last value for each second.

View Statistical Graph of IS-IS Interface Sending Control Packet

Use the following procedure to view the statistical graph of the IS-IS interface sending control packet.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **IS-IS**.
3. Select the **Interfaces** tab.
4. Select an interface.
5. Select the **Graph** button.
6. Select the **Interface Sending Control Packets** tab.

Interface Sending Control Packets field descriptions

The following table describes the fields in the **Interface Sending Control Packets** tab.

Name	Description
Hello	Indicates the number of IS-IS Hello (IIH) PDUs seen in this direction at this level. Point-to-Point IIH PDUs are counted at the lowest enabled level: at L1 on Layer 1 or L1L2 circuits, and at Layer 2 otherwise.
LSP	Indicates the number of IS-IS LSP frames seen in this direction at this level.
CSNP	Indicates the number of IS-IS Complete Sequence Number Packet (CSNP) frames seen in this direction at this level.
PSNP	Indicates the number of IS-IS Partial Sequence Number Packets (PSNPs) seen in this direction at this level.
AbsoluteValue	Displays the counter value.
Cumulative	Displays the total value since you opened the Stats tab.
Average/Sec	Displays the average value for each second.
Minimum/Sec	Displays the minimum value for each second.
Maximum/Sec	Displays the maximum value for each second.
Last Val/Sec	Displays the last value for each second.

View Statistical Graph of IS-IS Interface Receiving Control Packets

Use the following procedure to view statistical graph of the IS-IS interface receiving control packets.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **IS-IS**.
3. Select the **Interfaces** tab.
4. Select an interface.
5. Select the **Graph** button.
6. Select the **Interface Receiving Control Packets** tab.

Interface Receiving Control Packets field descriptions

The following table describes the fields in the **Interface Receiving Control Packets** tab.

Name	Description
Hello	Indicates the number of IS-IS Hello PDUs seen in this direction at this level. Point-to-Point IIH PDUs are counted at the lowest enabled level: at L1 on Layer 1 or L1L2 circuits, and at Layer 2 otherwise.
LSP	Indicates the number of IS-IS link-state packet (LSP) frames seen in this direction at this level.
CSNP	Indicates the number of IS-IS Complete Sequence Number Packet (CSNP) frames seen in this direction at this level.
PSNP	Indicates the number of IS-IS Partial Sequence Number Packets (PSNPs) seen in this direction at this level.

Name	Description
AbsoluteValue	Displays the counter value.
Cumulative	Displays the total value since you opened the Stats tab.
Average/Sec	Displays the average value for each second.
Minimum/Sec	Displays the minimum value for each second.
Maximum/Sec	Displays the maximum value for each second.
Last Val/Sec	Displays the last value for each second.

Configure an IS-IS Manual Area

Use the following procedure to configure an IS-IS manual area.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **IS-IS**.
3. Select the **Manual Area** tab.
4. Select **Insert**.
5. In the **AreaAddr** field, type the Area Address.
6. Select **Insert**.

Manual Area or Manual Area Remote Field Descriptions

Use the data in the following table to use the **Manual Area** or **Manual Area Remote** tab.

Name	Description
AreaAddr	Specifies the IS-IS manual area. Valid value is 1-13 bytes in the format <xx.xxxx.xxxx...xxxx>. Only one manual area is supported. Use the same manual area across the entire SPBM cloud. For IS-IS to operate, you must configure at least one manual area.

Configure Dynamic Nickname Assignment

About This Task

Use this procedure to enable Dynamic Nickname Assignment and specify a nickname allocation range.

Note
You must disable Dynamic Nickname Assignment before you can change the nickname allocation range.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **SPBM**.
3. Select the **Globals** tab.
4. To enable the Nick-name server, select **enable** for **NicknameServerEnable**.

5. In **NicknameServerPrefix**, type a prefix.
6. Select **Apply**.

Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
GlobalEnable	Enables or disables SPBM globally. The default is disabled. To ensure proper cleanup of MAC tables after you disable SPBM, save the configuration, and then reboot the switch.
GlobalEtherType	Specifies the global ethertype value as 0x8100 or 0x88a8. The default value is 0x8100.
NicknameServerEnable	Enables or disables the nickname server. The default is disabled.
NicknameDynamicAllocationStatus	Displays the Dynamic Nickname Allocation service operational status.
NicknameServerPrefix	Specifies the nickname server allocation prefix. x.xx.xx uses the form X.X0.00 from 0.00.00 to F.F0.00. A group, X.X0.00 to X.XF.FF, can provide up to 4,096 nicknames. The default is A.00.00.

Fabric Extend Configuration using EDM

The following sections provide procedural information you can use to configure Fabric Extend (FE) using Enterprise Device Manager (EDM).

Configure Fabric Extend Tunnels

Before You Begin

The tunnel source IP address can be either a brouter port IP, a CLIP IP, or a VLAN IP.

Important

Switches that support a single active VRF have feature interactions with Fabric Extend. For more information, see the Configuration Rules in the VRF feature content. To assist with the single-active VRF restrictions, an overlay parameter is available for the IP tunnel source address configuration.

If using the tunnel originating address on the GRT, Fabric Extend has the following requirements:

- The tunnel source IP address must be on the GRT, not on a VRF.

  Note

  A best practice is to use separate IP addresses for the SPBM IP Shortcuts **ip-source-address** command and the Fabric Extend **ip-tunnel-source-address** command. However, if you want these IP addresses to be the same, you MUST exclude the **ip-source-address** address with an IS-IS accept policy. You cannot use the redistribute command with a route map exclusion.

  Specify a CLIP interface to use as the source address for SPBM IP shortcuts.

- If IP Shortcuts is enabled, you must configure an IS-IS accept policy or exclude route-map to ensure that tunnel destination IP addresses are not learned through IS-IS.

If you are using the tunnel originating address on a VRF, configure a CLIP and tunnel source IP address on the VRF.

About This Task

Configuring Fabric Extend consists of two primary tasks: configuring the tunnel source address and configuring the logical interface. These tasks must be completed on both ends of the tunnel.

Note

VRF is an optional parameter. If a VRF is not configured, then FE uses the GRT.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **IS-IS**.
3. Select the **Globals** tab.
4. In the **IpTunnelSourceAddress** field, enter the IP tunnel source address.
5. If you are using a VRF, select **IpTunnelVrf** field.
6. Select **Apply**.

Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
AdminState	Specifies the global status of IS-IS on the switch: on or off. The default is off.
LevelType	Sets the router type globally: • level1: Level-1 router type • level1and2: Level–1/2 router type is not supported. The default value is level1.

Name	Description
SystemId	Specifies the IS-IS system ID for the switch. Valid value is a 6–byte value in the format <xxxx.xxxx.xxxx>. Important: After you have configured the SPBM nickname and enabled IS-IS, if you require a change of the system ID, you must also change the nickname. However, for naming convention purposes or configuration purposes, you may not want to change the nickname. To maintain the same nickname with a different system ID, see Job aid on page 912.
MaxLspGenInt	Specifies the maximum interval, in seconds, between generated LSPs by this Intermediate system. The value must be greater than any value configured for RxmtLspInt. The default value is 900 seconds.
CsnpInt	Specifies the Complete Sequence Number Packet (CSNP) interval in seconds. This is a system level parameter that applies for L1 CSNP generation on all interfaces. The default value is 10.
RxmtLspInt	Specifies the minimum time between retransmission of an LSP. This defines how fast the switch resends the same LSP. This is a system level parameter that applies for L1 retransmission of LSPs. The default value is 5 seconds.
PSNPInterval	Specifies the Partial Sequence Number Packet (PSNP) interval in seconds. This is a system level parameter that applies for L1 PSNP generation on all interfaces. The default value is 2.
SpfDelay	Specifies the SPF delay in milliseconds. This value is used to pace successive SPF runs. The timer prevents two SPF runs from being scheduled very closely. The default value is 100 milliseconds.
HostName	Specifies a name for the system. This can be used as the host name for dynamic host name exchange in accordance with RFC 2763. By default, the system name comes from the host name configured at the system level.
IpSourceAddress	Specifies IP source address for SPBM IP shortcuts.
Ipv6SourceAddress	Specifies IPv6 source address for SPBM IP shortcuts.
IpTunnelSourceAddress	Specifies the IS-IS IPv4 tunnel source address.

Name	Description
IpTunnelVrf	Specifies the VRF name associated with the IP tunnel.
IpTunnelOverlay	Permits the configuration of the tunnel source address even though it belongs to a VRF with an attached I-SID. The default is disabled.
MgmtClipIpAddr	Specifies the DvR management IP address for this node, in the DvR domain.
BackboneEnable	Select to enable this node to join the DvR backbone so that it can receive redistributed DvR host routes from all DvR Controllers in the network.
FanMember	Specifies whether the node is a member of the Fabric Area Network (FAN) .
DynamicallyLearnedArea	For FAN members, specifies the IS-IS area that is dynamically learned from the neighbor's Hello PDU if the node does not have the IS-IS manual area configured.
HelloPadding	Configures IS-IS hello padding on all IS-IS network-to-network interface (NNI) links. IS-IS hello padding is enabled by default.

Configure Fabric Extend Logical Interfaces

Use the following procedure to configure Fabric Extend (FE) on switches with native FE support.

Configure Fabric Extend Logical Interfaces for Native Support

About This Task

Configuring Fabric Extend consists of two primary tasks: configuring the tunnel source address and configuring the logical interface. These tasks must be completed on both ends of the tunnel.

VRF is an optional parameter. If a VRF is not configured, then FE uses the GRT.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **IS-IS**.
3. Select the **Logical Interfaces** tab.
4. Select **Insert**.
5. In **Id**, type the index number that uniquely identifies this logical interface.
6. For **Type**, select the type of core network that the tunnel will traverse:

   Note

   Different fields will be available depending on the type of core network you select.

   - If it is a Layer 2 Core, select **layer2**.
   - If it is a Layer 3 Core, select **ip**.

7. For **Name**, type the name of this logical interface.
8. To enable BFD, select **enable** for **BFDEnable**.
9. For a Layer 2 Core, configure the following fields:
   a. For **DestIfIndex**, select the physical port that the logical interface connects to or enter the name of the MLT.
   b. In **Vids**, type the list of VLANs for this logical interface.
   c. In **PrimaryVid**, type the primary tunnel VLAN ID.

   Note
   The primary VLAN ID must be one of the VIDs listed in the **Vids** field.

10. For a Layer 3 Core, complete the following field:
    a. In **DestIPAddr**, type the destination IP address for the logical interface.
11. Select **Insert**.

Logical Interfaces Field Descriptions

Use the data in the following table to use the **Logical Interfaces** tab and the **Insert Logical Interfaces** dialog. The available fields in the dialog differ depending on the type of core you select: **layer 2** or **ip**.

Name	Description
Id	Specifies the index number that uniquely identifies this logical interface. This field displays on the **Insert Logical Interfaces** dialog only.
IfIndex	Specifies the index number that uniquely identifies this logical interface. This field is read-only. This field displays on the **Logical Interfaces** tab only.
Name	Specifies the administratively assigned name of this logical interface, which can be up to 64 characters.
Type	Specifies the type of logical interface to create: • Specify **layer 2** for a Layer 2 core network that the tunnel will traverse. • Specify **ip** for a Layer 3 core network that the tunnel will traverse.
DestIPAddr	Specifies the destination IP address for the IP-type logical interface.
DestIfIndex	Specifies the physical port or MultiLink Trunking (MLT) that the Layer 2 logical interface is connected to.
Vids	Specifies the list of VLANs that are associated with this logical interface.
PrimaryVid	Specifies the primary tunnel VLAN ID associated with this Layer 2 Intermediate-System-to-Intermediate-System (IS-IS) logical interface.
CircIndex	Identifies the IS-IS circuit created under the logical interface. This field displays on the **Logical Interfaces** tab only.
NextHopVrf	Identifies the next-hop VRF name to reach the logical tunnel destination IP. This field displays on the **Logical Interfaces** tab only.
BfdEnable	Enables or disables BFD on an IS-IS Logical Interface.

Adjust the TCP Maximum Segment Size

Adjust the TCP maximum segment size (MSS) to improve the throughput for the TCP session over a Fabric Extend (FE) adjacency.

About This Task

Note

If you downgrade to an earlier release that does not support this feature, you must disable the feature and save the configuration. Downgrading to an earlier release requires a compatible configuration file.

By default, this functionality is disabled. The default value, when enabled, is 1300.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Select **IP**.
3. Select the **Globals** tab.
4. Select **TcpAdjustMssEnable** to enable this functionality.
5. (Optional) Enter a value in **TcpAdjustMssValue**.
6. Select **Apply**.

Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
Forwarding	Configures the system for forwarding (routing) or for dropping. The default value is forwarding.
DefaultTTL	Configures the default time-to-live (TTL) value for a routed packet. TTL indicates the maximum number of seconds elapsed before a packet is discarded. Enter an integer from 1 to 255. The default value of 255 is used if a value is not supplied in the datagram header.
ReasmTimeout	Specifies the maximum number of seconds that received fragments are held while they wait for reassembly. The default value is 30 seconds.

Name	Description
ICMPUnreachableMsgEnable	Enables the generation of Internet Control Message Protocol (ICMP) network unreachable messages if the destination network is not reachable from this system. These messages help determine if the system is reachable over the network. The default is disabled. Important: As a best pactice, enable icmp-unreach-msg only if it is absolutely required. If icmp-unreach-msg is enabled and a packet is received for which there is no route in the routing table, CPU utilization can dramatically increase.
ICMPRedirectMsgEnable	Enables or disables the system sending ICMP destination redirect messages.
IcmpEchoBroadcastRequestEnable	Enables or disables IP ICMP echo broadcast request feature. The default is enabled.
IcmpDropFragmentsEnable	Enables or disables IPv4 Fragmented ICMP packet filtering globally. The default is disabled.
AlternativeEnable	Globally enables or disables the Alternative Route feature. If the alternative-route parameter is disabled, all existing alternative routes are removed. After the parameter is enabled, all alternative routes are re-added. The default is enabled.
RouteDiscoveryEnable	Enables the ICMP Router Discovery feature. The default is disabled (not selected). Use ICMP Router Discovery to enable hosts attached to multicast or broadcast networks to discover the IP addresses of neighboring routers.
AllowMoreSpecificNonLocalRouteEnable	Enables or disables a more-specific nonlocal route. If enabled, the system can enter a more-specific nonlocal route into the routing table. The default is disabled.
SuperNetEnable	Enables or disables supernetting. If supernetting is globally enabled, the system can learn routes with a route mask less than 8 bits. Routes with a mask length less than 8 bits cannot have ECMP paths, even if you globally enable the ECMP feature. The default is disabled.
UdpCheckSumEnable	Enables or disables the UDP checksum calculation. The default is enable.
SourceRouteEnable	Enables or disables IP Source Routing globally. It is disabled by default.

Name	Description
ARPLifeTime	Specifies the lifetime of an ARP entry within the system, global to the switch. The default value is 360 minutes.
EcmpEnable	Globally enables or disables the Equal Cost Multipath (ECMP) feature. The default is disabled. After ECMP is disabled, the EcmpMaxPath is reset to the default value of 1.
EcmpMaxPath	Globally configures the maximum number of ECMP paths. You cannot configure this feature unless ECMP is enabled globally. Different hardware platforms can support a different number of ECMP paths. For more information, see *Fabric Engine Release Notes*.
Ecmp1PathList	Selects a preconfigured ECMP path.
Ecmp2PathList	Selects a preconfigured ECMP path.
Ecmp3PathList	Selects a preconfigured ECMP path.
Ecmp4PathList	Selects a preconfigured ECMP path.
Ecmp5PathList	Selects a preconfigured ECMP path.
Ecmp6PathList	Selects a preconfigured ECMP path.
Ecmp7PathList	Selects a preconfigured ECMP path.
Ecmp8PathList	Selects a preconfigured ECMP path.
EcmpPathListApply	Applies changes in the ECMP pathlist configuration, or in the prefix lists configured as the pathlists.
TcpAdjustMssEnable	Adjusts the TCP maximum segment size (MSS) to improve the throughput for the TCP session over a Fabric Extend (FE) adjacency. The default is disabled.
TcpAdjustMssStatus	Displays the activation status of the MSS adjustment functionality.
TcpAdjustMssType	Displays if the MSS adjustment value is manually configured or auto-derived. The software does not support auto-derived values for this feature.
TcpAdjustMssValue	Configures the MSS adjustment value. • The default value is 1300.

Display the Logical Interface Next Hop

Use the following procedure to display the next hop for the logical interface.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric** > **IS-IS**.
2. Select the **Logical Interfaces NextHop** tab.

Logical Interfaces NextHop field descriptions

Use the data in the following table to use the **Logical Interfaces NextHop** tab.

Name	Description
Id	Shows a unique value that identifies the logical interface tunnel.
Ip	Shows a unique value that identifies the next hop IP address of the logical interface tunnel.
DestIfIndex	Shows the next hop destination interface index to reach the next hop IP of the logical interface tunnel.
DestVid	Shows the next hop destination VLAN ID to reach the next hop IP of the logical interface tunnel.

Fabric Attach configuration using the EDM

The following sections provide procedural information you can use to configure Fabric Attach (FA) and Logical Link Discovery Protocol (LLDP) using Enterprise Device Manager (EDM). For information about LLDP related to FA, see Link Layer Discovery Protocol configuration using EDM on page 1968.

Configure Fabric Attach Globally

Use this procedure to configure FA globally or view existing FA global configuration.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Click **Fabric Attach**.
3. Click the **Globals** tab.
4. To enable or disable the Fabric Attach service, click **enabled** or **disabled** in the **Service** field.

   Caution
   Disabling FA flushes all FA element discovery and mappings.

5. View the element type in the **ElementType** field.

   Note
   The only supported element type is **faServer** (FA Server).

6. To specify the assignment time-out, enter a time-out value in seconds in the **AsgnTimeout** field.

7. View the provision mode in the **ProvisionMode** field.

   Note
   The supported provision mode is **spbm**.

8. To specify the discovery time-out, enter a time-out value in seconds in the **DiscTimeout** field.
9. To clear the FA statistics, select the **Clear FA Statistics** checkbox.
10. To clear the error counters, select the check boxes **ClearErrorCounters** and/or **ClearGlobalErrorCounters**.
11. Click **Apply**.

Fabric Attach Globals Field Descriptions

Use the data in the following table to use the **Fabric Attach Globals** tab.

Name	Description
Service	Enables or disables Fabric Attach service globally. The default is enable.
ElementType	Specifies the Fabric Attach element type. The supported element type is Fabric Attach Server.
AsgnTimeout	Specifies the Fabric Attach assignment time-out in seconds. The range is 45 to 480 seconds. The default is 240 seconds.
ProvisionMode	Specifies the Fabric Attach provision mode. The supported provision mode is SPB.
DiscTimeout	Specifies the Fabric Attach discovery time-out in seconds. The range is 45 to 480 seconds. The default is 240 seconds.
Clear FA Statistics	Clears Fabric Attach statistics.
ClearGlobalErrorCounters	Clears Fabric Attach global error counters. Disabled by default.

Configure Fabric Attach I-SID-to-VLAN Assignments

Use this procedure to view or configure FA I-SID-to-VLAN assignment information.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Click **Fabric Attach**.
3. Click the **Assignment** tab.
4. If you make configuration changes, click **Apply** to save changes.

Assignments Field Descriptions

Use the data in the following table to use the **Assignments** tab.

Name	Description
IfIndex	Specifies the interface identifier of the I-SID-to-VLAN assignment.
Isid	Specifies the I-SID value of the I-SID-to-VLAN assignment.
Vlan	Specifies the VLAN ID component of the I-SID-to-VLAN assignment.

Name	Description
State	Specifies the current state of the I-SID-to-VLAN assignment. It can be one of the following values: • Other • Pending • Active • Rejected
Origin	Specifies the origin information of the I-SID-to-VLAN assignment.
Isid name	Specifies the I-SID name.

Configure Fabric Attach Interface-level Settings

Use this procedure to configure FA interface-level settings or view existing interface-level settings.

You can enable Fabric Attach on a port, static MLT or an LACP MLT. Enabling FA on a port not only enables tagging but also disables spanning tree on that port. Enabling FA on an MLT enables FA on all ports of the MLT. When FA is enabled on ports in an MLT or LACP MLT, tagging is enabled and spanning tree is disabled on all those ports.

Before You Begin

Ensure that FA is enabled globally on the switch.

About This Task

Enabling FA on a port or MLT is necessary for element discovery. On the FA Server, FA is enabled globally by default. However, you must explicitly enable FA on a desired port or MLT interface, following which the FA Server can begin transmitting LLDP PDUs that contain the element discovery TLVs. This information is received by FA Client and FA Proxy devices which in turn also transmit their FA capabilities and settings. After the element handshake completes, the FA Server receives I-SID-to-VLAN assignment mappings from the connected client or proxy devices, on that port or MLT.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Click **Fabric Attach**.
3. Click the **Ports** tab.

   The FA interface-level settings are displayed.
4. To modify existing settings, double-click on the fields on this window. After making the required changes, click **Apply** to save your changes.
5. To configure FA on a new port or MLT interface:
   a. Click **Insert**.

      The **Insert Ports** dialog box opens.
   b. To configure FA on a port, enter a port number in the format slot/port[/sub-port], or click **Port** to select from a list of available ports.

c. To configure FA on an MLT, enter an MLT ID or click **Mlt** to select from a list of configured MLTs.

Note

FA is successfully enabled on the MLT, only if all ports of the MLT have FA successfully enabled. Enabling FA enables LLDP on all ports. Tagging is enabled and spanning tree is disabled.

d. Click **Insert** to save your changes.

6. To remove (delete) FA on a port or MLT:

a. In the content pane, select a port or MLT from the list.

b. Click **Delete**.

Caution

Removing FA on an interface flushes all FA element discovery and I-SID-to-VLAN mappings associated with that interface.

Ports Field Descriptions

Use the data in the following table to use the **Ports** tab.

Name	Description
IfIndex	Specifies the interface (port or MLT) on which Fabric Attach is configured.
State	Specifies the current state of the Fabric Attach port. It is either enabled or disabled. This field indicates whether LLDP PDUs (that include FA TLVs) are generated on the port (enabled) or not (disabled).
MsgAuthStatus	Specifies the Fabric Attach message authentication status on the port. It is either enabled or disabled.
MsgAuthKey	Specifies the Fabric Attach message authentication key for the associated port. The maximum length of this key is 32 characters.
MgmtIsid	Specifies the Fabric Attach management I-SID for the associated port. The range is 0 to 16777215. A zero value indicates that the management I-SID is not specified for the interface.
MgmtCvid	Specifies the Fabric Attach management customer VLAN ID (C-VID) for the interface. A zero value indicates that no C-VID is specified for the interface. Using the maximum configuration value for your switch indicates the port is untagged. Platform support determines the C-VID range.
Origin	Specifies the origin of Fabric Attach port, either manually configured through CLI or EDM, or dynamically configured through Auto-sense.

Viewing Fabric Attach discovered elements

Use this procedure to view discovered Fabric Attach elements.

About This Task

When FA is enabled on an FA Server switch, LLDP PDUs are exchanged between the FA Server and FA Clients or Proxies. Standard LLDPs allow neighbors to be learned. In addition, organizational specific element discovery TLVs allow the Client or Proxy to recognize that it has attached to an FA Server. Only after the discovery handshake is complete, an FA Client or Proxy can transmit I-SID-to-VLAN assignments to join the SPB Fabric through the FA Server.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Click **Fabric Attach**.
3. In the content pane, click the **Elements** tab.

Elements field descriptions

Use the data in the following table to use the **Elements** tab.

Name	Description
IfIndex	Specifies the interface (port or MLT) at which the Fabric Attach element was discovered.
ElementType	Specifies the element type of the discovered Fabric Attach element, as advertised using LLDP. The supported element type is the Fabric Attach Server.
ElementVlan	Specifies the VLAN ID of the discovered Fabric Attach element, as advertised using LLDP.
ElementId	Specifies the system ID of the discovered Fabric Attach element, as advertised using LLDP.
ElementState	Specifies the state flag data associated with the discovered Fabric Attach element, as advertised using LLDP.
ElementOperAuthStatus	Specifies the authentication status of the discovered Fabric Attach element.
ElementAsgnsOperAuthStatus	Specifies the authentication status of remote assignments.
ElementAuth	Specifies the discovered element authentication status.
AsgnsAuth	Specifies the assignment authentication status.

Viewing FA statistics

Use this procedure to view FA statistics.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Click **Fabric Attach**.
3. In the content pane, click the **Stats** tab.

Stats field descriptions

Use the data in the following table to use the **Stats** tab.

Name	Description
PortIndex	Specifies the port for which the FA statistics are displayed.
DiscElemReceived	Specifies the number of element discoveries received on the port.
AsgnReceived	Specifies the number of remote assignments received on the port.
AsgnAccepted	Specifies the number of remote assignments accepted on the port.
AsgnRejected	Specifies the number of remote assignments rejected on the port.
AsgnExpired	Specifies the number of remote assignments that have expired, on the port.
AuthFailed	Specifies the number of authentications that have failed on the port.
DiscElemExpired	Specifies the number of discovery elements that have expired on the port.
DiscElemDeleted	Specifies the number of discovery elements that are deleted on the port.
AsgnDeleted	Specifies the number of remote assignments deleted on the port.
AsgnAuthFailed	Specifies the number of remote assignment authentications that failed on the port.

View Global FA Statistics Graphically

Use this procedure to view the global FA statistics graphically.

Procedure

1. In the navigation pane, expand **Configuration** > **Graph**.
2. Click **Chassis**.
3. Click the **Fabric Attach** tab.
4. To view a graphical representation of the statistics, select a row and click the appropriate icon on the top left-hand-side of the menu bar to draw a line chart, area chart, bar chart or a pie chart.
5. Click **Clear Counters** to clear the existing counters, and fix a reference point in time to restart the counters.
6. Click **Export**, to export the statistical data to a file.
7. To fix a poll interval, select an appropriate value from the **Poll Interval** drop-down list.

Fabric Attach field descriptions

Use the data in the following table to use the **Fabric Attach** tab.

Name	Description
DiscElemReceived	Specifies the number of discovery elements received globally.
AsgnReceived	Specifies the number of remote I-SID-to-VLAN assignments received globally.

Name	Description
AsgnAccepted	Specifies the number of remote I-SID-to-VLAN assignments accepted globally.
AsgnRejected	Specifies the number of remote I-SID-to-VLAN assignments rejected globally.
AsgnExpired	Specifies the number of remote I-SID-to-VLAN assignments that expired globally.
AuthFailed	Specifies the number of authentications that failed globally.
DiscAuthFailed	Specifies the number of discovery authentications that failed globally.
DiscElemExpired	Specifies the number of discovery elements that expired globally.
DiscElemDeleted	Specifies the number of discovery elements that were deleted globally.
AsgnDeleted	Specifies the number of remote assignments that were deleted globally.

View FA Port Statistics Graphically

Use this procedure to view the FA port statistics graphically.

Before You Begin

Ensure that a switch port is selected in the **Device Physical View** tab.

Procedure

1. In the navigation pane, expand **Graph** > **Port**.
2. Click the **Fabric Attach** tab.

   The FA port statistics are displayed.
3. To view a graphical representation of the port statistics, select a row and click the appropriate icon on the top left-hand-side of the menu bar to draw a line chart, area chart, bar chart or a pie chart.
4. Click **Clear Counters** to clear the existing counters, and fix a reference point in time to restart the counters.
5. Click **Export**, to export the statistical data to a file.
6. To fix a poll interval, select an appropriate value from the **Poll Interval** drop-down list.

Fabric Attach Field Descriptions

Use the data in the following table to use the **Fabric Attach** tab.

Name	Description
DiscElemReceived	Specifies the number of discovery elements received on a given port.
AsgnReceived	Specifies the number of remote I-SID-to-VLAN assignments received on a given port.

Name	Description
AsgnAccepted	Specifies the number of remote I-SID-to-VLAN assignments accepted on a given port.
AsgnRejected	Specifies the number of remote I-SID-to-VLAN assignments rejected on a given port.
AsgnExpired	Specifies the number of remote I-SID-to-VLAN assignments that expired on a given port.
AuthFailed	Indicates the number of received TLVs for which authentication was attempted and failed on the identified port.
DiscElemExpired	Specifies the number of discovery elements that expired on a given port.
DiscElemDeleted	Specifies the number of discovery elements that were deleted on a given port.
AsgnDeleted	Specifies the number of remote assignments that were deleted on a given port.
AsgnAuthFailed	Specifies the number of remote assignment authentications that failed on a given port.

Inserting a Zero Touch Client

Use this procedure to insert a FA Zero Touch Client.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Click **Fabric Attach**.
3. Click the **Zero Touch Client Auto Attach** tab.
4. Click **Insert**.

   The **Insert Zero Touch Client** dialog box opens.
5. In the **Type** field click the ellipsis and select a client. Click **Ok** to select the client or **Refresh** to update the list.
6. In the **Isid** field enter the I-SID value.

   The I-SID value is between 0 and 16777214.
7. Click **Insert**.

Configure FA Zero Touch Client Auto Attach

Use this procedure to configure FA Zero Touch Client auto attach.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **Fabric Attach**
3. Select the **Zero Touch Client Auto Attach** tab.

   From the Zero Touch Client Auto Attach tab you can configure a number of auto attach settings.
4. Select **Insert**.
5. In the **Type** field, select the ellipsis and select a client.

6. Select **Ok** to select the client or **Refresh** to update the list.
7. In the **Isid** field enter the I-SID value.
8. Select **Insert**.
9. (Optional) To **Delete** a FA Zero Touch client select it from the auto attach table and select **Delete**.

Zero Touch Client Auto Attach Field Descriptions

Use the data in the following table to use the **Zero Touch Client Auto Attach** tab

Field	Description
Type	This column describes the type of client assigned to auto attach. Available FA client types are: • Wireless AP (Type 1) • Wireless AP (Type 2) • Switch • Router • IP Phone • IP Camera • IP Video • Security Device • Virtual Switch • Server Endpoint
Vlan	Specifies the VLAN ID component of the I-SID-to-VLAN assignment.
Isid	Specifies the I-SID value of the I-SID-to-VLAN assignment.

Configure Endpoint Tracking Using EDM

The following sections provide procedural information to configure Endpoint Tracking using Enterprise Device Manager (EDM).

Configure Endpoint Tracking Interfaces

Configure ports and MLT/SMLT interfaces for Endpoint Tracking.

Before You Begin

- In Extreme Management Center or ExtremeCloud IQ - Site Engine, configure your third-party virtualization platform, and the RADIUS server used for Endpoint Tracking authentication. For information about configuring Extreme Management Center, see theExtreme Management Center or ExtremeCloud IQ - Site Engine documentation at https://www.extremenetworks.com/support/documentation/.
- On the switch, add and configure the RADIUS server as configured in Extreme Management Center or ExtremeCloud IQ - Site Engine.

About This Task

Enable Endpoint Tracking on ports or MLT/SMLT interfaces.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.

2. Select **Endpoint Tracking**.
3. Select the **Interface** tab.
4. Select **Insert**.
5. Select **Port** or **Mlt**, select the slot and port number or MLT ID, and select **OK**.
6. Select **InterfaceEnable**.
7. Select **Insert**.
8. Select **Apply**.

What to Do Next

Configure Endpoint Tracking globally on the switch.

Interface Field Descriptions

Use the data in the following table to use the **Interfaces** tab.

Name	Description
InterfaceIndex	Specifies the interface index of the selected port or MLT.
InterfaceEnable	Enables Endpoint Tracking on the selected port or MLT.

Configure Endpoint Tracking Globally

Configure Endpoint Tracking globally on the switch.

Before You Begin

- In Extreme Management Center or ExtremeCloud IQ - Site Engine, configure your third-party virtualization platform, and the RADIUS server used for Endpoint Tracking authentication. For information about configuring Extreme Management Center or ExtremeCloud IQ - Site Engine, see the Extreme Management Center or ExtremeCloud IQ - Site Engine documentation at https://www.extremenetworks.com/support/documentation/.
- On the switch, add and configure the RADIUS server as configured in Extreme Management Center or ExtremeCloud IQ - Site Engine.
- Create and enable Endpoint Tracking on interfaces.

About This Task

Optionally, if the RADIUS outbound attributes do not include an I-SID value, configure an I-SID offset value, and globally enable I-SID offset for Endpoint Tracking. The I-SID offset value is used to calculate an I-SID value for a switched UNI if no I-SID value is provided by the RADIUS server. In that case, the I-SID value is calculated as follows: I-SID = VLAN ID + configured I-SID offset value.

After optionally configuring an I-SID offset value, enable Endpoint Tracking globally on the switch.

Note

If you have previously enabled Endpoint Tracking globally and want to change the currently configured I-SID offset value, you must disable Endpoint Tracking globally, change the I-SID value, and then re-enable Endpoint Tracking globally.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Endpoint Tracking**.
3. Select the **Globals** tab.
4. (Optional) Configure an I-SID offset value, and enable I-SID offset globally on the switch:

   Enter a value into the **AutoIsidOffset** field and select **AutoIsidOffsetEnable**.
5. Select **GlobalEnable**.
6. Select **Apply**.

Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
AutoIsidOffset	The I-SID offset value. The default is 15990000.
AutoIsidOffsetEnable	Enables or disables I-SID offset value globally on the switch. The default is disabled.
GlobalEnable	Enables or disables Endpoint Tracking globally on the switch. The default is disabled.
VisibilityEnable	Enables or disables visibility mode for Endpoint Tracking. The default is disabled.

Display Binding Information

Display Endpoint Tracking binding information.

About This Task

Display all VLAN:ISID binding information on the switch for Endpoint Tracking.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Endpoint Tracking**.
3. Select the **Binding** tab.

Binding Field Descriptions

Use the data in the following table to use the **Binding** tab.

Name	Description
IfIndex	Specifies the interface index of the selected port or MLT.
MacAddress	Specifies the MAC address that corresponds to the VLAN:ISID binding.

Name	Description
Status	Specifies the Endpoint Tracking data binding status as follows: • pending: indicates that a request has been sent to the RADIUS server • accept: indicates that the RADIUS server has successfully returned the request • reject: indicates that the RADIUS server has rejected the request • timeout: indicates that the RADIUS server request has timed out. The entry is deleted if it remains in this state for 15 minutes. • serverNotConfigured: indicates that the RADIUS server is not configured for Endpoint Tracking. The entry is deleted if it remains in this state for 15 minutes.
VlanId	Specifies the VLAN ID.
Isid	Specifies the I-SID value, either provided by the RADIUS server, or calculated using the VLAN ID plus the configured I-SID offset value.
IsidSource	Specifies whether the I-SID value is provided by the RADIUS server (radius), or calculated using the VLAN ID plus the configured endpoint-tracking offset value (autoconfig).
Timeout	Specifies the timeout period that is applied to the MAC in the bindings table when the MAC is aged out. If the MAC is in timeout state (there is no response from the RADIUS server), the timeout triggers immediately with a 15 minute period. Otherwise, the default timeout is one day, and triggers the moment the MAC ages out from the VLAN/I-SID bridge forwarding database (FDB) table. The default timeout of one day can be overridden by the RADIUS server if the Session-Timeout attribute is configured and returned.
TimeRemaining	Specifies the time remaining until the Endpoint Tracking data binding entry expires.

SPBM configuration examples

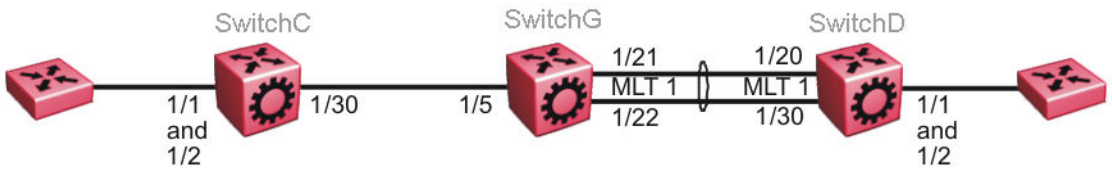
This section provides configuration examples to configure basic SPBM and IS-IS infrastructure.

Examples and network illustrations in this document may illustrate only one of the supported platforms. Unless otherwise noted, the concept illustrated applies to all supported platforms.

Basic SPBM configuration example

The following figure shows a sample greenfield deployment for SPBM.

Figure 78: Greenfield SPBM deployment



Note

For migration purposes, SPBM can coexist with existing SMLT configurations.

Ethernet and MLT configuration

The following sections show the steps required to configure the Ethernet and MLT interfaces in this example.

SwitchC

```
PORT CONFIGURATION - PHASE 1

interface GigabitEthernet 1/30
encapsulation dot1q
exit
```

SwitchG

```
PORT CONFIGURATION - PHASE 1

interface GigabitEthernet 1/5
encapsulation dot1q
exit

MLT CONFIGURATION

mlt 1 enable
mlt 1 member 1/21-1/22
mlt 1 encapsulation dot1q
```

SwitchD

```
MLT CONFIGURATION

mlt 1 enable
mlt 1 member 1/20,1/30
mlt 1 encapsulation dot1q
```

IS-IS SPBM global configuration

The following figure shows the IS-IS area information added to the network.

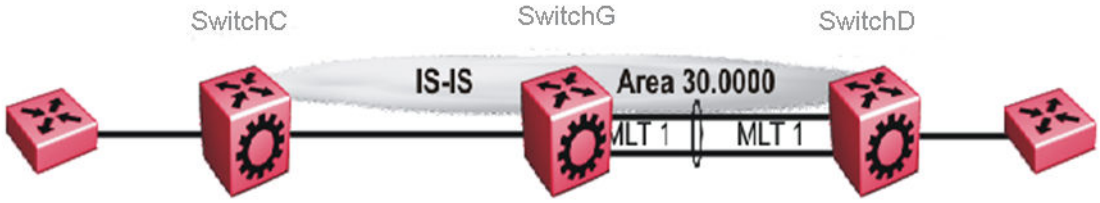


Figure 79: IS-IS SPBM global

The following sections show the steps required to configure the global IS-IS SPBM parameters in this example.

SwitchC

```
enable
configure terminal
prompt SwitchC

BOOT CONFIGURATION

spbm
spbm ethertype 0x8100

ISIS SPBM CONFIGURATION

router isis
spbm 1

Fabric Extend Configuration Examples

This section provides a Fabric Extend configuration example.

For more configuration examples, see *Shortest Path Bridging (802.1aq) Technical Configuration Guide*.

Fabric Extend over Layer 2 Pseudowire

This example shows a Fabric Extend deployment using service provider VLAN tunnels over MPLS Pseudowire. In this scenario, you map two dedicated VLAN IDs (VIDs) from the Hub to the Spoke sites. Then the logical IS-IS interfaces translate the BVIDs to map them to the per branch provider VIDs.

Because the tunnels are point-to-point VLAN connections, not VXLAN, there is no need to encapsulate a VXLAN header to SPB packets.

Important

10/40/100 Gbps switch — — — — — — Core — — — — — — 1 Gbps switch

- You cannot have IS-IS in the Core.
- Do not create the two VLANs represented in the logical interface connection on the BEBs. If you do, you will not be able add any Fabric Extend ports to be members of those VLANs. One links the port that is facing the core and those VLANs in the logical interface connection.

The following figure shows a sample Fabric Extend deployment over Pseudowire.

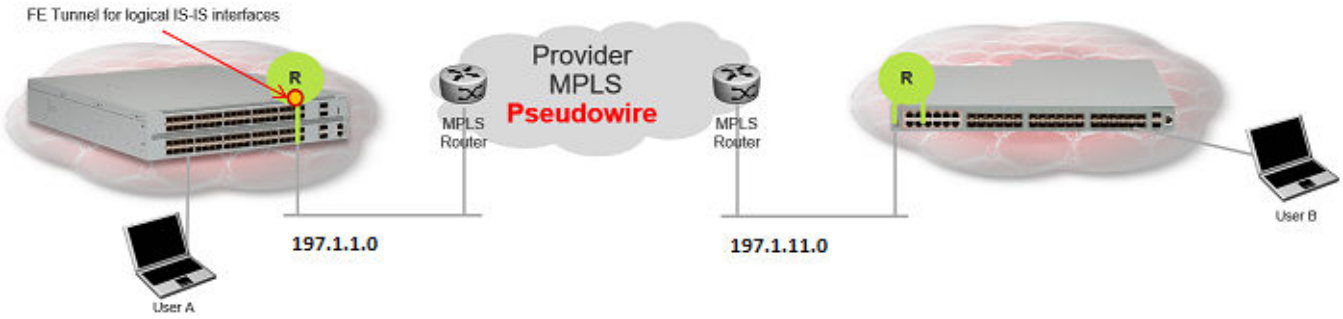

Figure 81: FE over Pseudowire traffic flow

Figure 82: FE over Pseudowire traffic flow component view

For 10/40/100 Gbps Switches

Note

Logical interface VLANs cannot be the same as the SPBM B-VLANs and you cannot create these VLANs locally. Use these VLANs for configuring the logical interface only. Once a port is being used for a logical interface it cannot be added to any platform VLAN and spanning tree is automatically disabled on the port.

```
Switch(config)# logical-intf isis 255 vid 200,300 primary-vid 200 port 2/14 name
fe_to_Switch
Switch(config-isis-255)# isis
Switch(config-isis-255)# isis spbm 1
Switch(config-isis-255)# isis enable
Switch(config-isis-255)# exit
```

For 1 Gbps Switches

Note

Logical interface VLANs cannot be the same as the SPBM B-VLANs and you cannot create these VLANs locally. Use these VLANs for configuring the logical interface only. Once a port is being used for a logical interface it cannot be added to any platform VLAN and spanning tree is automatically disabled on the port.

```
Switch(config)# mlt 11
Switch(config)# mlt 11 encapsulation dot1q
Switch(config)# mlt 11 mem 1/49-1/50
Switch(config)# router isis enable

Switch(config)# logical-intf isis 255 vid 200,300 primary-vid 200 mlt 11 name fe_to_Switch
Switch(config-isis-255)# isis
Switch(config-isis-255)# isis spbm 1
Switch(config-isis-255)# isis enable
Switch(config-isis-255)# exit
```

For Intermediate Router 1

Intermediate routers are typically configured by an Internet service provider (ISP). The following configurations are for reference only.

```
Switch(config)# vlan create 200 type port-mstprstp 1
Switch(config)# vlan create 300 type port-mstprstp 1
Switch(config)# vlan member add 200 8/1,8/19
Switch(config)# vlan member add 300 8/1,8/19
```

For Intermediate Router 2

```
Switch(config)# mlt 11

Switch(config)# vlan mlt 300 11
```

Fabric Attach configuration examples

This section provides configuration examples to configure Fabric Attach.

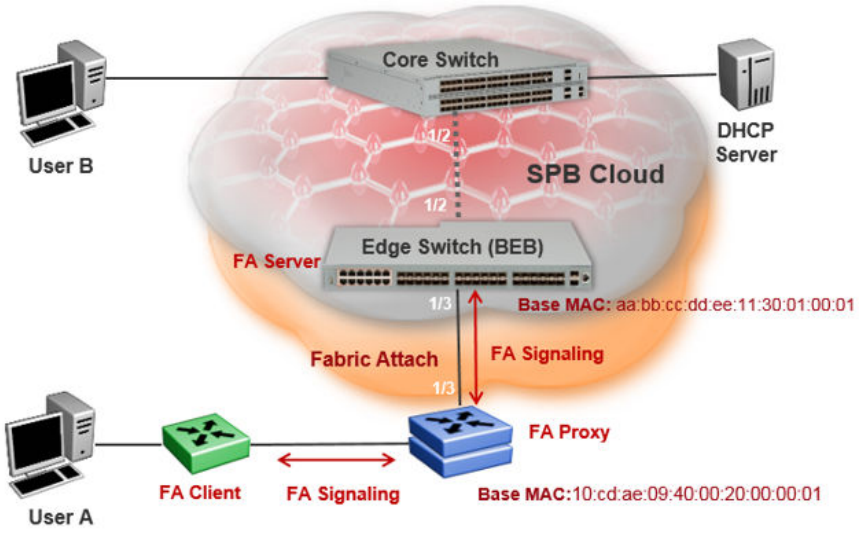
Configure a Fabric Attach Solution

The following section describes a simple configuration example to configure Fabric Attach (FA) at the edge of a Fabric Connect network. This is a typical deployment at its simplest level and is powerful because of its use in conjunction with a Fabric Connect core.

About This Task

Configuring FA primarily consists of configuring the FA Server. The FA Server in turn discovers neighboring FA component devices (like the FA Proxies and FA Clients) using FA TLVs within the LLDP PDUs.

In the following deployment, the switch at the edge of the Fabric Connect cloud is configured as the FA Server. On this switch, FA is enabled globally and at the interface (port) level. Another switch, functioning as the FA Proxy connects to the FA enabled port (1/3) on the FA Server. User A is an end user device that needs to send and receive data traffic from User B (another end user device) across the network.



Before You Begin

Configure SPBM and IS-IS on the edge and core switches. For more information, see Configure Minimum SPBM and IS-IS Parameters on page 908.

Procedure

Configure the edge switch (BEB) as the FA Server:

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable FA globally:

   ```
   fa enable
   ```

3. Enter port interface configuration mode:

   ```
   interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
   ```

4. Enable FA on the port:

   ```
   fa enable
   ```

   Note

   Enabling FA automatically enables message authentication. Also, the authentication key is set to the default value and the system displays the encrypted authentication key on the output.

   Note

   Enabling FA on a port not only enables tagging but also disables spanning tree on that port.

Verify global and interface level FA configuration:

5. Verify global configuration of FA using one of the following commands:
   - `show fa`
   - `show fa agent`
6. Verify interface level configuration of FA:

   ```
   show fa interface
   ```
7. Verify the discovery of clients attaching to the FA Server:

   ```
   show fa elements
   ```
8. Display the FA I-SID-to-VLAN assignments:

   ```
   show fa assignment
   ```

   To verify I-SID-to-VLAN assignments on a specific port, enter:

   ```
   show fa assignment {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
   ```
9. Verify creation of Switched UNI (ELAN) I-SIDs:

   ```
   show i-sid elan
   ```

Example

SPBM and IS-IS configuration on the core and edge switches:

SPBM configuration:

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#spbm
Switch:1(config)#spbm ethertype 0x8100
```

IS-IS SPBM configuration:

```
Switch:1(config)#router isis
Switch:1(config)#spbm 1
Switch:1(config-isis)#spbm 1 nick-name 1.00.01
Switch:1(config-isis)#spbm 1 b-vid 41-42 primary 41
Switch:1(config-isis)#spbm 1 ip enable
```

IS-IS router configuration:

```
Switch:1(config-isis)#router isis
Switch:1(config-isis)#sys-name BEB-Switch
Switch:1(config-isis)#ip-source-address 3.3.3.3
Switch:1(config-isis)#is-type l1
Switch:1(config-isis)#system-id 0001.0001.0001
Switch:1(config-isis)#manual-area c0.2000.000.00
Switch:1(config-isis)#exit
```

Interface (port-level) configuration

```
Switch:1(config)#interface GigabitEthernet 1/2
Switch:1(config-if)#no shutdown
Switch:1(config-if)#isis
Switch:1(config-if)#isis spbm 1
Switch:1(config-if)#isis enable
Switch:1(config-isis)#exit
Switch(config)#vlan create 41 type spbm-vlan
Switch(config)#vlan create 42 type spbm-vlan
Switch(config)#router isis enable
Switch(config)#show isis spbm
```

Configuration of the edge switch as the FA Server.

Enable FA globally.

```
Switch:1(config)#fa enable
Switch:1(config)#show fa

============================================================
                          Fabric Attach Configuration
============================================================
                            FA Service : enabled
                         FA Element Type : server
                  FA Assignment Timeout : 240
                   FA Discovery Timeout : 240
                      FA Provision Mode : spbm
```

Enable FA on the port.

Enabling FA automatically enables message authentication. The authentication key is configured with the default value, which the system displays in encrypted format in the output.

```
Switch:1(config)#int gigabitEthernet 1/3
Switch:1(config-if)#fa enable
Switch:1(config-if)#show fa interface port 1/3

Configure Fabric Attach in an SMLT

The following example describes FA configuration and behavior in a dual-homed SMLT deployment.

The following figure shows a simple FA solution in a dual-homed SMLT deployment. In this deployment, a pair of BEB switches (BEB A and BEB B) operating as IST peers are configured as the FA Server. An access switch or a wiring closet switch configured as an FA Proxy connects to the FA Server. The FA Proxy advertises I-SID-to-VLAN assignment mappings to the FA Server. Both BEB switches receive the mapping information using LLDP PDUs containing assignment TLVs. The switch that learns the mapping first considers the I-SID to be discovered locally and creates the I-SID on its device. The mapping information is then shared with its IST peer switch. When the peer switch receives the mapping across IST in a new SMLT message, it too creates the I-SID on its device. This I-SID however, is considered to be discovered remotely because it is learnt from synchronization with the peer switch. The mappings can also be learned on the FA Server from both LLDP PDUs and from IST synchronization.

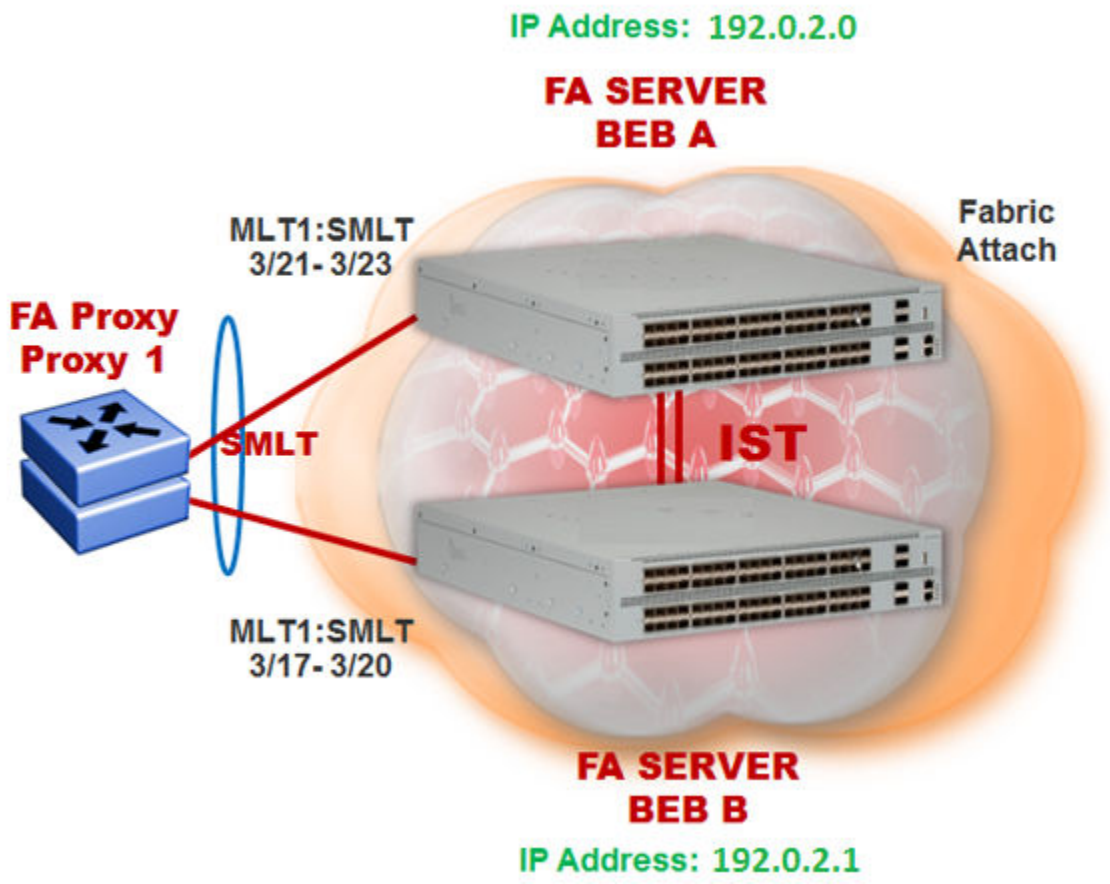

Figure 83: FA configuration in dual-homed SMLT

Before You Begin

Ensure that the proxy device (for example, an access switch) is properly configured for FA. See the corresponding product documentation for information on how to configure FA on the switch.

Procedure

1. Configure SMLT and vIST on switches BEB A and BEB B.

   Caution
   For the IST peer switches acting as the FA Server to transmit the same FA System ID (based on the virtual MAC), SMLT configuration on both the switches must be the same.

   For detailed information on configuring SMLT and vIST, see MultiLink Trunking and Split MultiLink Trunking on page 2090.

Configure BEB A and BEB B as the FA Server

Perform the following configuration on each switch.

2. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

3. Enable FA globally:

   ```
   fa enable
   ```

4. Enter MLT interface configuration mode:

   ```
   interface mlt <1-512>
   ```

5. Enable FA on the MLT:

   ```
   fa enable
   ```

   Note

   Enabling FA automatically enables message authentication. Also, the authentication key is set to the default value and the system displays the encrypted authentication key on the output.

6. (Optional) Configure an FA authentication key with a value different from that of the default value:

   ```
   fa authentication-key [WORD<0-32>]
   ```

   Caution

   When you configure the FA authentication key, you must configure the same value on both BEB switches in the SMLT.

Verify global and MLT-level FA configuration on BEB A and BEB B:

7. Verify global configuration of FA using one of the following commands:
   - `show fa`
   - `show fa agent`
8. Verify MLT-level (interface-level) configuration of FA:

   ```
   show fa interface
   ```

Verify FA discovery on BEB A and BEB B:

9. Verify discovery of the FA Proxy.

   ```
   show fa elements
   ```

View FA I-SID-to-VLAN assignments on BEB A and BEB B:

10. View the FA I-SID-to-VLAN assignments:

    ```
    show fa assignment
    ```

    To view FA I-SID-to-VLAN assignments on specific ports, enter:

    ```
    show fa assignment {slot/port[/sub-port] [-slot/port[/sub-port]]
    [,...]}
    ```

Verify creation of Switched UNI I-SIDs on BEB A and BEB B:

11. Verify creation of Switched UNI (ELAN) I-SIDs:
    - View ELAN I-SID information using `show i-sid elan`.
    - View ELAN I-SID information on a specific MLT using `show mlt i-sid [<1–512>]`.

    Note

    Viewing ELAN I-SID information on an MLT is very useful to understand the origin of the I-SID, when multiple client or proxy devices connecting to the FA Server using SMLT MLT advertise the same I-SID-to-VLAN mappings. In the event of a link failure on an MLT, the origin of the I-SID helps determine on which MLT, and thereby from which proxy or client device, the mappings were successfully learnt.

Examples

SMLT configuration on BEB A and BEB B:

On BEB A:

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface mlt 1
Switch:1(config)#smlt
```

On BEB B:

```
Switch:2>en
Switch:2#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:2(config)#interface mlt 1
Switch:2(config)#smlt
```

vIST configuration on BEB A and BEB B:

On BEB A:

```
Switch:1(config)#vlan create 2261 type port-mstprstp 0
Switch:1(config)#vlan i-sid 2261 1502261
Switch:1(config)#interface vlan 2261
Switch:1(config)#ip address 192.0.2.0 255.255.255.0 2
```

Configure BEB B (IP address `192.0.2.1`) as the IST peer.

```
Switch:1(config)#virtual-ist peer-ip 192.0.2.1 vlan 2261
Switch:1(config)#show virtual-ist
Switch:1(config)#exit
```

On BEB B:

```
Switch:2(config)#vlan create 2261 type port-mstprstp 0
Switch:2(config)#vlan i-sid 2261 1502261
Switch:2(config)#interface vlan 2261
Switch:2(config)#ip address 192.0.2.1 255.255.255.0 2
```

Configure BEB A (IP address `192.0.2.1`) as the IST peer.

```
Switch:2(config)#virtual-ist peer-ip 192.0.2.1 vlan 2261
Switch:2(config)#show virtual-ist
Switch:2(config)#exit
```

FA configuration on BEB A:

Enable FA globally and on the MLT:

```
Switch:1(config)#fa enable
Switch:1>show fa

================================================================================
                          Fabric Attach Configuration
================================================================================
                             FA Service : enabled
                         FA Element Type : server
                   FA Assignment Timeout : 240
                    FA Discovery Timeout : 240
                       FA Provision Mode : spbm
```

Optionally, configure an FA authentication key with the value `dual-homed-smlt`. Ensure that you configure the **same** value on both switches BEB A and BEB B.

```
Switch:1(config)#interface mlt 1
Switch:1(config-mlt)#fa authentication-key dual-homed-smlt
```

Enable FA on the MLT:

```
Switch:1(config-mlt)#fa enable
Switch:1(config-mlt)#exit
Switch:1(config)#show fa interface

3/22       3          3          active     proxy
3/22       4          4          active     proxy
3/23       2          2          active     proxy
3/23       3          3          active     proxy
3/23       4          4          active     proxy
```

FA configuration on BEB B:

Enable FA globally and on the MLT:

```
Switch:2(config)#fa enable
Switch:2(config)#show fa
==========================================================================
                          Fabric Attach Configuration
==========================================================================
                             FA Service : enabled
                        FA Element Type : server
                   FA Assignment Timeout : 240
                    FA Discovery Timeout : 240
                       FA Provision Mode : spbm
```

Configure the FA authentication key `dual-homed-smlt`. Ensure that you configure the **same** value as on BEB A.

```
Switch:2(config)#interface mlt 1
Switch:2(config-mlt)#fa authentication-key dual-homed-smlt
```

Enable FA on the MLT:

```
Switch:2(config-mlt)#fa enable
Switch:2(config-mlt)#exit
```

```
Switch:2(config)#show fa interface

Layer 2 VSN configuration fundamentals

This section provides fundamentals concepts for Layer 2 VSN.

SPBM Layer 2 VSN

SPBM supports Layer 2 VSN functionality where customer VLANs (C-VLANs) are bridged over the SPBM core infrastructure.

At the Backbone Edge Bridges (BEBs), customer VLANs (C-VLAN) are mapped to I-SIDs based on the local service provisioning. Outgoing frames are encapsulated in a MAC-in-MAC header, and then forwarded across the core to the far-end BEB, which strips off the encapsulation and forwards the frame to the destination network based on the I-SID-to-C-VLAN provisioning.

In the backbone VLAN (B-VLAN), Backbone Core Bridges (BCBs) forward the encapsulated traffic based on the BMAC-DA, using the shortest path topology learned using IS-IS.

The following figure shows a sample campus SPBM Layer 2 VSN network.

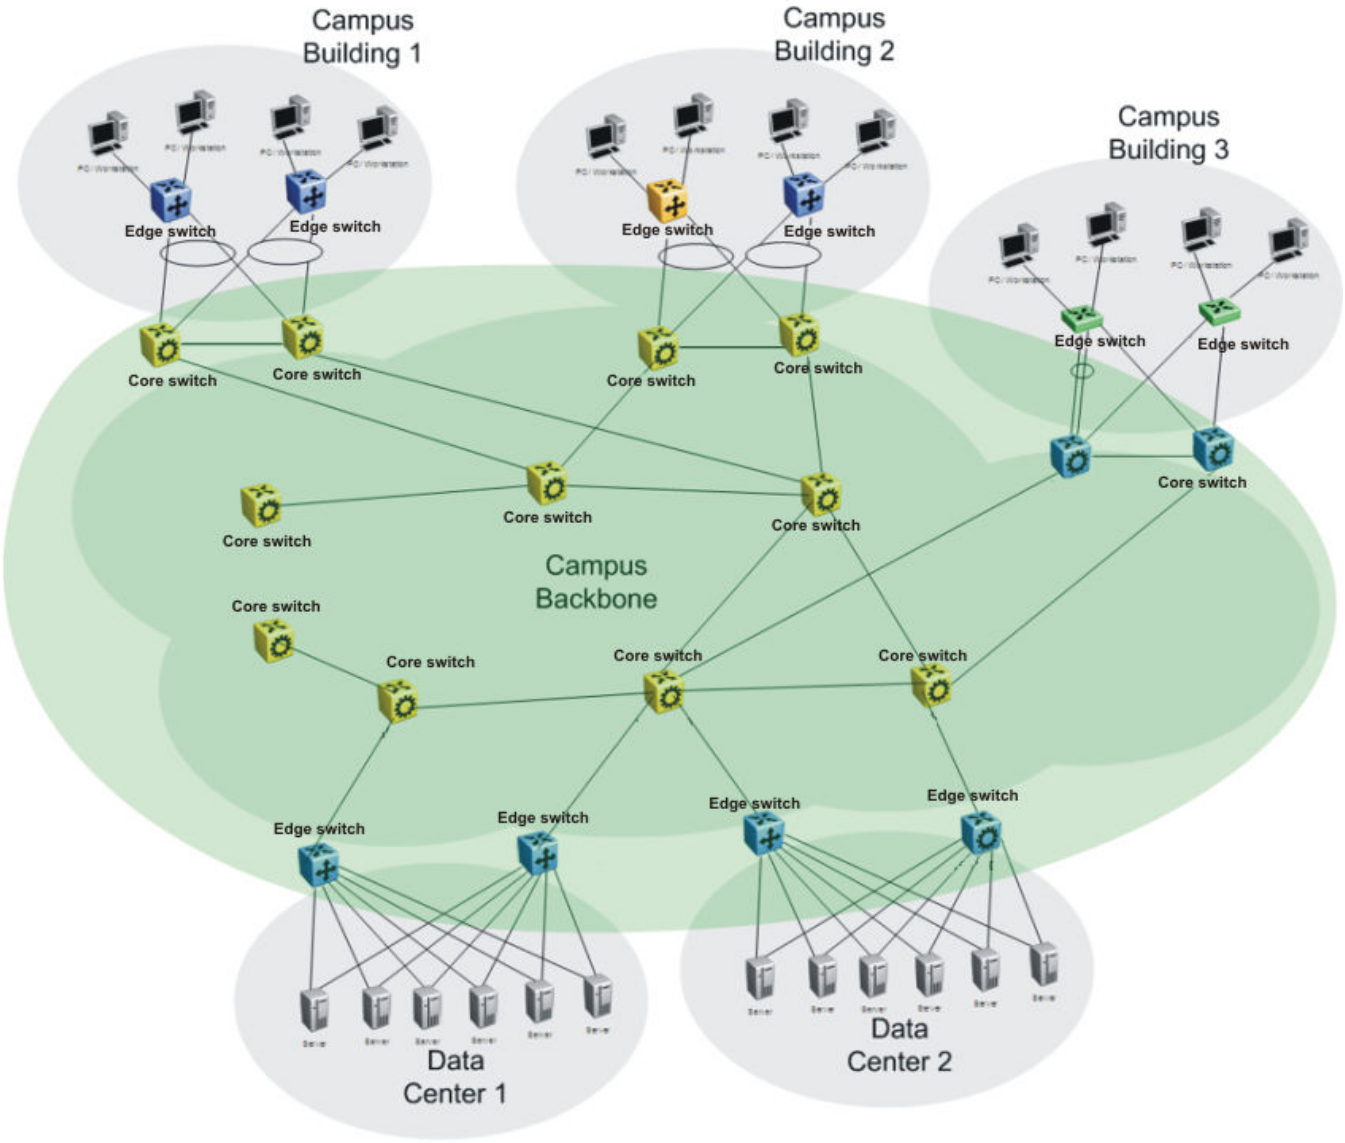

Figure 85: SPBM L2 VSN in a campus

One of the key advantages of the SPBM Layer 2 VSN is that network virtualization provisioning is achieved by configuring only the edge of the network (BEBs). As a result, the intrusive core provisioning that other Layer 2 virtualization technologies require is not needed when new connectivity services are added to the SPBM network. For example, when new virtual server instances are created and need their own VLAN instances, they are provisioned at the network edge only and do not need to be configured throughout the rest of the network infrastructure.

Based on its I-SID scalability, this solution can scale much higher than any 802.1Q tagging based solution. Also, due to the fact that there is no need for Spanning Tree in the core, this solution does not need any core link provisioning for normal operation.

Redundant connectivity between the C-VLAN domain and the SPBM infrastructure can be achieved by operating two SPBM switches in switch clustering (SMLT) mode. This allows the dual homing of any traditional link aggregation capable device into an SPBM network.

Configuration difference from ERS 8800

One major difference between this switch and the ERS 8800 is how they connect to two SMLT devices.

The ERS 8800 uses an interswitch trunk (IST). The IST connects directly to two SMLT devices with a dedicated MLT and runs IS-IS over it. The dedicated MLT carries the IST control traffic and data traffic during an SMLT failover. This feature dramatically improves resiliency over other methods. However, if the dedicated MLT breaks, then there is no way to communicate between the IST peers, which causes traffic loss.

This switch uses a virtual IST (vIST) that eliminates this single point of failure. The vIST feature creates a virtualized IST channel in the SPBM cloud. With vIST, the IST tunnel is always up as long as there is SPBM connectivity between the vIST peers. vIST also interoperates between any two devices that support vIST, and the devices do not have to be the same type of device.

Before you can create a vIST, you must do the following:

- Enable SPBM and IS-IS globally.
- Configure SPBM and IS-IS.
- Create a VLAN (that is not used anywhere else) for each peer.
- Create an I-SID that is not used anywhere else.
- Configure an IP address for the vIST VLAN.
- Configure an Layer 2 VSN by assigning an I-SID to the C-VLAN, which is used by the vIST.

Important

- An I-SID must be assigned to every VLAN that is a member of an Layer 2 VSN.
- For proper traffic flow, if an Layer 2 VSN is created on one vIST peer, it must also be created on the other vIST peer.
- For Simplified vIST deployment, if a VLAN is part of an SMLT it must be configured on both the IST peers.

For information about vIST, see MultiLink Trunking and Split MultiLink Trunking on page 2090.

Fabric Connect Service Types

The Fabric Connect technology delivers Layer 2 and Layer 3 virtualization. These virtualized Layer 2 and Layer 3 instances are referred to as Virtual Service Networks (VSNs). A Service Identifier (I-SID) is used to uniquely distinguish these service instances network-wide, and a User Network Interface (UNI) is the boundary or demarcation point between the “service layer” of traditional networks, that is VLANs and VRFs, and the Fabric Connect “service layer”, that is Layer 2 & Layer 3 VSNs.

- Layer 2 VSNs are virtual broadcast domains interconnecting UNI members that share the same Layer 2 VSN I-SID. MAC learning/aging is applied to all Layer 2 VSNs.
- Layer 3 VSNs are virtual routed Layer 3 networks (Layer 3 VPN) leveraging IS-IS as the routing protocol between VRFs that share the same Layer 3 VSN I-SID.

Fabric Connect uses the User-Network-Interface (UNI) to denote the capabilities and attributes of the service interfaces. Fabric connect devices support the following UNI types:

- VLAN UNI (C-VLAN) — a device-specific VLAN-ID maps to a Layer 2 VSN I-SID – all device physical ports that are associated with the VLAN are therefore associated with the UNI.

- Flex UNI — it has the following sub-types:
  - Switched UNI — a VLAN-ID and a given port (VID, port) maps to a Layer 2 VSN I-SID. With this UNI type, VLAN-IDs can be reused on other ports and therefore mapped to different I-SIDs.
